UNIVERSAL CYCLOPÆDIA AND ATLAS

A NEW EDITION UNDER DIRECTION OF

CHARLES KENDALL ADAMS, LL.D.

PRESIDENT OF THE UNIVERSITY OF WISCONSIN

EDITOR-IN-CHIEF

ASSISTED BY A CORPS OF ASSOCIATE EDITORS
COMPOSED OF THE ABLEST AND MOST DISTINGUISHED SCHOLARS
IN THE UNITED STATES AND CANADA, AND OF EMINENT
SPECIALISTS IN BOTH EUROPE AND AMERICA

A NEWLY REVISED AND ENLARGED EDITION

ROSSITER JOHNSON, PH.D., LL.D.

EDITOR OF REVISION

ILLUSTRATED WITH COLORED PLANS, PLATES, AND ENGRAVINGS

COMPLETE IN TWELVE ROYAL OCTAVO VOLUMES

VOLUME IX

THE LIBRARY OF CONGRESS

NEW YORK
D. APPLETON AND COMPANY
PUBLISHERS
1901

MAPS IN VOL. IX.

POLITICAL.

CITIES.

PLATES.

PECULIAR PHONETIC SYMBOLS

USED IN THE WRITING OR TRANSLITERATION OF THE DIFFERENT LANGUAGES.

ā, ē, etc.: long vowels; in the Scandinavian languages the accent (*á*, *é*, etc.) is used to denote length.

ą: a nasalized *a*; so used in the transliteration of the Iranian languages.

å: labialized guttural *a* in Swedish.

æ: open *a* of Eng. *hat*, used chiefly in O. Eng.

aí: used in Gothic to denote *e* (open), in distinction from *ái*, the true diphthong.

aú: used in Gothic to denote *o* (open), in distinction from *áu*, the true diphthong.

bh: in Sanskrit a voiced labial aspirate (cf. *ch*).

ƀ: voiced bilabial (or labio-dental?) spirant, used in discussions of Teutonic dialects.

ç: voiceless palatal sibilant, similar to Eng. *sh*, used especially in transliteration of Sanskrit.

č: frequently used, e. g. in Slavonic languages, to denote the sound of Eng. *ch* in *cheek*.

c: voiceless palatal explosive, commonly used in transliteration of Sanskrit and the Iranian languages.

ch: as used in the transliteration of Sanskrit, a voiceless palatal aspirate, an aspirate being an explosive with excess of breath; as used in German grammar, the symbol for a voiceless palatal or guttural spirant.

dh: voiced dental aspirate (cf. *ch*) in Sanskrit.

ḍ: voiced cerebral explosive, so used in transliteration of Sanskrit.

ḍh: voiced cerebral aspirate (cf. *ch*) in Sanskrit.

đ: voiced dental (interdental) spirant, equivalent to Eng. *th* in *then*; so used in the Teutonic and Iranian languages and in phonetic writing.

ë: a short open *e*, used in Teutonic grammar, particularly in writing O. H. G.

e: the short indefinite or "obscure" vowel of Eng. *gardener*; used in the reconstruction of Indo-Eur. forms, and in transliterating the Iranian languages.

gh: in Sanskrit a voiced guttural aspirate (cf. *ch*).

ǵ: voiced velar (back-guttural) explosive, used most frequently in Indo-Eur. reconstructions.

ɜ: voiced guttural (or palatal) spirant, equivalent to Mod. Greek *γ*, and used in transliteration of Iranian languages and O. Eng.

ḥ: a voiceless breathing, the Sanskrit *visarga*.

hw: a labialized *h*, similar to *wh* in Eng. *what*; used in transliteration of Gothic and the Iranian languages.

ḫ: voiceless guttural (or palatal) spirant, equivalent to German *ch*, and used in transliteration of the Iranian languages.

i̯: the semi-vowel *y*, or consonant form of *i*; used in phonetic writing and reconstructions of Indo-Eur. forms.

j: in the transliteration of Sanskrit and the Iranian languages a voiced palatal explosive; in the Teutonic languages a semi-vowel (= *y*), for which in Indo-Eur. reconstructions *i* is generally used.

jh: in Sanskrit a voiced palatal aspirate (cf. *ch*).

kh: in Sanskrit a voiceless guttural aspirate (cf. *ch*).

ɬ: the guttural ("thick" or "deep") of the Slavonic and some of the Scandinavian languages.

ḷ: vowel *l*; used in transliterating Sanskrit, in reconstructing Indo-Eur. forms, and in other phonetic writing.

n̥: nasal vowel; used in reconstruction of Indo-Eur. forms and in phonetic writing.

ṇ: in Sanskrit the cerebral nasal.

ñ: in Sanskrit the guttural nasal (see following).

ŋ: the guttural nasal, equivalent to Eng. *n* in *longer*; used in transliteration of Iranian languages.

ñ: palatal nasal, similar to *gn* in Fr. *regner*; used in transliterating Sanskrit and in phonetic writing.

ö: palatalized *o*; used in German and in phonetic writing.

ǫ: short open *o* in Scandinavian.

ø: short palatalized *o* (ö) in Scandinavian.

ph: in Sanskrit, voiceless labial aspirate (cf. *ch*).

q̡: voiceless velar (back-guttural) explosive; used in reconstructions of Indo-Eur. forms and in other phonetic writing.

ṛ: vowel *r*: used in transliterating Sanskrit, in reconstructions of Indo-Eur. forms, and in other phonetic writing.

š: voiceless cerebral sibilant, equivalent to Eng. *sh*; used in transliterating the Iranian languages and in phonetic writing.

ṣ: voiceless cerebral spirant; used in transliterating Sanskrit.

th: in Sanskrit a voiceless dental aspirate (cf. *ch*).

ṭh: in Sanskrit a voiceless cerebral aspirate (cf. *ch*).

ṭ: in Sanskrit a voiceless cerebral explosive.

ţ: a form of dental spirant used in transliterating the Iranian languages (represented in Justi's transliteration by ṭ).

þ: voiceless dental (interdental) spirant, equivalent to Eng. *th* in *thin*; used in Teutonic dialects and in phonetic writing.

u̯: consonant form of *u*; used in phonetic writing.

ž: voiced cerebral sibilant, equivalent to *s* in Eng. *pleasure*, and to *j* in Fr. *jardin*; used in Iranian, Slavonic, and in phonetic writing.

ʒ: a symbol frequently used in the writing of O. H. G. to indicate a voiced dental sibilant (Eng. *z*), in distinction from *z* as sign of the affricata (*ts*).

EXPLANATION OF THE SIGNS AND ABBREVIATIONS USED IN THE ETYMOLOGIES.

>, yielding by descent, i. e. under the operation of phonetic law.
<, descended from.
=, borrowed without change from.
: , cognate with.
+, a sign joining the constituent elements of a compound.
*, a sign appended to a word the existence of which is *inferred*.

ablat.	ablative
accus.	accusative
adjec.	adjective
adv.	adverb
cf.	compare
conjunc.	conjunction
deriv. of	derivative of
dimin.	diminutive
fem.	feminine
genit.	genitive
imper.	imperative
impf.	imperfect
indic.	indicative
infin.	infinitive
masc.	masculine
nomin.	nominative
partic.	participle
perf.	perfect
plur.	plural
prep.	preposition
pres.	present
pron.	pronoun
sc.	scilicet, supply
sing.	singular
subst.	substantive
vocat.	vocative

Anglo-Fr.	Anglo-French
Arab.	Arabic
Avest.	Avestan
Dan.	Danish
Eng.	English
Fr.	French
Germ.	German
Goth.	Gothic
Gr.	Greek
Heb.	Hebrew
Icel.	Icelandic
Ital.	Italian
Lat.	Latin
Lith.	Lithuanian
Mediæv. Lat.	Mediæval Latin
Mod. Lat.	Modern Latin
M. Eng.	Middle English
M. H. Germ.	Middle High German
O. Bulg.	Old Bulgarian (= Church Slavonic)
O. Eng.	Old English (= Anglo-Saxon)
O. Fr.	Old French
O. Fris.	Old Frisian
O. H. Germ.	Old High German
O. N.	Old Norse
O. Sax.	Old Saxon
Pers.	Persian
Portug.	Portuguese
Prov.	Provençal
Sanskr.	Sanskrit
Sc.	Scotch
Span.	Spanish
Swed.	Swedish
Teuton.	Teutonic

KEY TO THE PRONUNCIATION.

aa..... as *a* in *father*, and in the second syllable of *armada*.

ăa..... same, but less prolonged, as in the initial syllable of *armada*, *Arditi*, etc.

a..... as final *a* in *armada*, *peninsula*, etc.

ă..... as *a* in *fat*, and *i* in French *fin*.

ay or ā.. as *ay* in *nay*, or as *a* in *fate*.

ăy or *ā*.. same, but less prolonged.

ā..... as *a* in *welfare*.

aw..... as *a* in *fall*, *all*.

ee..... as in *meet*, or as *i* in *machine*.

ĕe..... same, but less prolonged, as final *i* in *Arditi*.

e..... as in *men*, *pet*.

e..... obscure *e*, as in *Bigelow*, and final *e* in *Heine*.

ė..... as in *her*, and *eu* in French *-eur*.

i..... as in *it*, *sin*.

ī..... as in *five*, *swine*.

ī..... same, but less prolonged.

ō..... as in *mole*, *sober*.

ō..... same, but less prolonged, as in *sobriety*.

o..... as in *on*, *not*, *pot*.

oo..... as in *fool*, or as *u* in *rule*.

o͝o..... as in *book*, or as *u* in *put*, *pull*.

oi..... as in *noise*, and *oy* in *boy*, or as *eu* in German *Beust*.

ow..... as in *now*, and as *au* in German *haus*.

ö..... as in *Göthe*, and as *eu* in French *neuf*, *Chintreuil*.

ŭ..... as in *but*, *hub*.

ŭ..... obscure *o*, as final *o* in *Compton*.

ü..... as in German *süd*, and as *u* in French *Buzançais*, *vu*.

y or *l*.... see *l* or y.

yu..... as *u* in *mule*.

yŭ..... same, but less prolonged, as in *singular*.

ch..... as in German *ich*.

g..... as in *get*, *give* (never as in gist, congest).

hw..... as *wh* in *which*.

kh..... as *ch* in German *nacht*, *g* in German *tag*, *ch* in Scotch *loch*, and *j* in Spanish *Badajos*, etc.

ṅ..... nasal *n*, as in French *fin*, *Bourbon*, and nasal *m*, as in French *nom*, Portuguese *Sam*.

ñ or n-y.. Spanish *ñ*, as in *cañon*, *piñon*, French and Italian *gn*, etc., as in *Boulogne*.

l or y.... French *l*, liquid or mouillé, as (-i)ll- in French *Baudrillart*, and (*-i*)*l* in *Chintreuil*.

th..... as in *thin*.

th..... as in *though*, *them*, *mother*.

v..... as *w* in German *zwei*, and *b* in Spanish *Cordoba*.

sh..... as in *shine*.

zh..... as *s* in pleasure, and *j* in French *jour*.

All other letters are used with their ordinary English values.

NOTE.

The values of most of the signs used in the above Key are plainly shown by the examples given. But those of ö, ü, *ch*, *kh*, ñ, and *v*, which have no equivalents in English, can not be sufficiently indicated without a brief explanation, which is here given.

ö. The sound represented by this symbol is approximately that of -u- in *hurt* or -e- in *her*, but is materially different from either. It is properly pronounced with the tongue in the position it has when ā is uttered and with the lips in the position assumed in uttering ō.

ü. This vowel is produced with the lips rounded as in uttering oo and with the tongue in the position required in uttering ee, into which sound it is most naturally corrupted.

ch and *kh*. These are both rough breathings or spirants made with considerable force, *ch* being made between the flat of the tongue and the hard palate, and *kh* between the tongue and the soft palate. *ch* approaches in sound to English sh, but is less sibilant and is made further back in the mouth; *kh* is a guttural and has a hawking sound.

l or y. These are both used to represent the sound of French l mouillé, in (-i)ll- and (-i)l, which resembles English -y- in *lawyer*. Final *l*, that is, (-i)l, may be approximated by starting to pronounce lawyer and stopping abruptly with the -y-.

ñ or n-y. The consonants represented by ñ (Spanish ñ, French and Italian gn, etc.) are practically equivalent to English -ni- or -ny- in bunion, bunyon, onion, etc., and, except when final, are represented by n-y. Final ñ, as French -gn(e), may be produced by omitting the sound of -on in the pronunciation of *onion*.

v. This may be pronounced by attempting to utter English v with the use of the lips alone.

See PREFACE (vol. i., p. xli.) and the article PRONUNCIATION OF FOREIGN NAMES.

THE
UNIVERSAL CYCLOPÆDIA.

ptics [from Gr. *τὰ ὀπτικά*, neut. plur. of *ὀπτικός*, optic, pertaining to sight. Cf. *ὄψις*, sight, and *ὄπωπα*, I have seen]: the science which treats of the phenomena of light. The subject is usually treated from two points of view. 1. The laws and properties of light, as ascertained by observation, may, by applying the principles of pure geometry, be employed to explain the phenomena. 2. A definite theory having been adopted in regard to the nature of the luminiferous medium, the phenomena may be expounded as the necessary consequences of their assumed physical cause. The present article will be confined to a brief history of optical discovery.

A notion was for a very long time prevalent among the ancients that vision is effected by means of rays proceeding from the eye to the object. This idea is not found in Aristotle, but it was introduced into the school of Plato, and continued to be received for many centuries. The elementary phenomena of reflection and refraction suggest a natural division of the science of optics into two principal branches; and this distinction is made by the earliest systematic writer on the subject whose works have descended to us. This was Euclid, supposed to have been the geometrician of that name, who lived about 300 years before our era. The general laws which govern the reflection of light, being comparatively easy of detection, were stated by him with tolerable correctness; but what he has written on refraction is of little value. Ptolemy, the astronomer of Alexandria, who was born about the year 70 of our era, attempted to discover the law of refraction by experiment. His apparatus was ingenious, and was not different in principle from that which has been employed by Silbermann, Soleil, and others, in our own time, for the same purpose. He measured the angles of refraction corresponding to various angles of incidence, between 0° and 90°, for both water and glass, and left his measurements recorded in his *System of Optics*. We may judge of the degree of accuracy attained by him by comparing the indices of refraction deducible from his determinations with those of the same bodies fixed with severe exactness by modern observers. The ascertained index of refraction for water is 1·33582. If we make a computation of its value from the measured angles of Ptolemy, we find a mean of 1·30147; but if we take his measurements at the incidence of 50°, where the relative variations of the angles of incidence and refraction are most marked and most easily measured, we obtain 1·33555, which is exceedingly near the truth. As an astronomer, Ptolemy noticed the effect of atmospheric refraction upon the apparent positions of the heavenly bodies; and he recognized the fact, which others after him disputed, that the displacement is always in a vertical plane, and also that it attains its maximum in the horizon and is zero in the zenith. About the beginning of the seventeenth century Galileo, Jansen, and Metius invented the telescope independently, and Galileo by its means made important astronomical discoveries. Shortly afterward Kepler explained how to find the focal lengths of lenses, and gave the true theory of the telescope; he also made experiments on the nature of colors, and showed that the images formed on the retina of the eye are inverted.

It was impossible, however, that optical science should make any important progress so long as the law which determines the path of a ray in passing from one medium to another remained unknown. Willebrord Snellius, Professor of Mathematics at Leyden, who died in 1626, left behind him manuscripts, among which was contained a statement of the law in question. It was first published by Descartes, eleven years after the death of Snellius. It is therefore frequently referred to as the law of Descartes. See Refraction.

The next important step in the progress of optical discovery, after the detection of the general law of refraction, was made by Newton, who in 1672 communicated to the Royal Society the experimental researches by which he established the compound nature of light and the unequal refrangibility of its component rays. This phenomenon of the separation of the component colors of light by refraction has been called Dispersion (*q. v.*).

The dispersion of light by refraction furnishes an easy explanation of the interesting natural phenomenon of the rainbow. This beautiful meteor had before Newton's time been the subject of many unsatisfactory speculations; and though De Dominis, as early as 1611, had conceived a true theory of the manner of formation of the inner bow, he had not been able to account for its colors. Newton's discovery furnished the necessary supplement to the theory. See Rainbow.

In 1665 there was published at Bologna a posthumous work by Francis Maria Grimaldi, an Italian Jesuit, in which were for the first time described certain phenomena now familiar under the name of Diffraction (*q. v.*). They were carefully studied by Newton and others, and have occupied a prominent place in all the discussions which have since arisen in regard to the nature of light.

In 1669 the attention of the scientific world was called to a case of new and extraordinary refraction observed to take place in crystals of carbonate of calcium—a species of refraction which, from the circumstance of its dividing an incident beam into two beams entirely distinct, or of presenting two images of any object seen through the crystal, has been called double refraction. (See Refraction, Double.) The first publication on this subject was made by Erasmus Bartholinus, a physician of Copenhagen, who gave to the mineral the name of Iceland spar, from the circumstance that his specimens had been obtained from that island. The phenomenon was more fully explained by Huyghens, who also originated the undulatory theory of Light (*q. v.*). Soon after his announcement of the compound nature of light, Sir Isaac Newton made public the results of his investigations in regard to the colors exhibited by *thin plates* of transparent substances. (See Thin Plates, Colors of.) These investigations, together with many improvements of the teleseope and his corpuscular theory of the propagation of light, completed Newton's contributions to the science.

The next important step in the progress of optical science was the discovery of the progressive propagation of light and the determination of its velocity. Dominic Cassini suggested that certain irregularities in the observations of the first satellite of Jupiter could be accounted for by supposing that light took an appreciable time to travel from Jupiter to the earth. He seems, however, to have abandoned the

idea, but Römer followed it up with perseverance and conclusively established its truth. See Light.

The next discovery of importance was made near the close of the eighteenth century by Dr. Wollaston in his observations upon the prismatic spectrum. He discovered that by employing a pencil of light very narrow in the direction of the plane of refraction, but broad parallel to the axis of the prism, several well-defined dark straight lines could be distinguished crossing the spectrum at right angles, and maintaining invariably the same positions relatively to the colors. See Spectrum.

In the year 1808 the French Academy of Sciences proposed the problem of the double refraction of light as the subject for a prize to be awarded two years thereafter. The successful competitor for this prize was Malus. To him is also due the polarization of light by reflection.

In the year 1811 Arago communicated to the Academy of Sciences of Paris one of the most remarkable and beautiful discoveries that have ever been made in the history of optics. Upon examining thin plates of certain transparent crystals, such as mica, selenite, or quartz, by means of transmitted polarized light, he found that when the light was received upon the eye through a prism formed of Iceland spar the richest conceivable colors made their appearance, which were complementary to each other in the two images, and which varied in intensity with the azimuth of the laminæ or of the prism. (See Polarization of Light.) When a bi-refringent prism was employed as an analyzer, the two images seen were constantly complementary in color, and as the analyzer was turned they ascended in tint, in the order of Newton's scale, from red to violet. Biot in subsequent experiments discovered that in some crystals the ascent of the tints in the scale is produced by a right-hand rotation (the ordinary direction of a screw), and in others by a left-hand rotation. These classes of crystals have been distinguished by the names right-handed and left-handed crystals, or *dextrogyre* and *lævogyre*. The peculiar kind of polarization produced by quartz has on this account been called *rotatory* polarization.

In the year 1815 Biot discovered that many liquids possess the power of rotatory polarization—a discovery which was independently made by Seebeck. Arago early made the discovery that the light which comes to us from the atmosphere is polarized. Brewster also made investigations concerning the double refraction of crystals. He discovered that the great majority of non-isotropic substances are doubly refracting, and are in general biaxial—that is, have two axes. (See Crystallography and Mineralogy.) The determination of the undulations in such bodies, or the form of their "wave surface," was, approximately at least, effected by Fresnel, one of the latter's most brilliant discoveries. It led to Sir William Hamilton's prediction of the two species of conical refraction, which was experimentally verified by Lloyd and others, viz.: in one case a single ray passing through a plate of a biaxial crystal comes out as a hollow cone; in the other case a single ray which falls upon the plate is transformed into a cone inside the crystal, and comes out as a hollow cylinder. Fresnel also discovered that glass and other simply refracting bodies are rendered doubly refracting when in a state of strain: and Clerk Maxwell showed that shearing stress applied to viscous liquids renders them temporarily doubly refracting.

For an account of the present state of the science, see Preston's *Theory of Light* (1890); also Tait's *Light*, Glazebrook's *Physical Optics* (1883), and Basset's *Physical Optics* (1892). Revised by R. A. Roberts.

Optimism [from Lat. *op'timus*, best]: the doctrine that the world is the best possible, or that evil is only relative and contingent, being incident to the evolution of good—that good is substantial, evil only temporary. It is the philosophical counterpart to the religious doctrine of an overruling Providence that educes good out of evil. The divine purpose in creation is held to be the bringing of good into existence where nothing existed before, and the replacing of the imperfect by the more perfect; in general, it is to change chaos to a cosmos, and make it reflect the attributes of God. Creation, evolution, or change of any sort involves contrast and the manifestation of two principles. Hence the passive principle (chaos), which is eliminated by the activity of the good, is manifested or made apparent by the same activity that annuls it. Without the activity of creation the passive or negative principle (chaos or mere potentiality) would remain a pure zero, and be neither good nor evil. In all the stages of the realization of good, from the lowest to the highest, there is contrast, and hence the phenomenon of evil: but evil or the relatively imperfect exists only as the battle-field upon which it receives defeat from the victorious higher good. This is the view *sub specie æternitatis*, as Spinoza called it. Of course, any partial view, taking its point of observation from some one imperfect being, would see in the destruction of that being the triumph of evil rather than of good, and evil might seem predominant in the world. The optimistic theory is consistent only with theism, perhaps only with Christian theism. It finds place in the theory that God creates the world from nothing (chaos or pure space) and makes it in some sort his manifestation or self-revelation. Opposed to this is the emanation-theory characteristic of Oriental thinking, in which the Absolute is an abstract unity devoid of attributes, impersonal, and above multiplicity, and all creating is removal from unity toward multiplicity, and hence evil; it is a lapse from the Absolute, and finite existence is therefore altogether a mistake, or perhaps even a punishment for sin in a former state. This is called "pessimism." The return of all finite to the infinite through absorption or annihilation is regarded as the desirable end: Nature is not a conflict of good and evil, but altogether evil. Still, even in this theory, the good is the only true being; for all creation is held to be *maya* or illusion of the senses and intellect. The religion of the emanation-theory lays chief stress on ascetic renunciation with a view to reabsorption into the Absolute. Even the destruction of consciousness and individuality is regarded as blessedness. "The conclusive, incontrovertible, one only knowledge, is that neither I am, nor is aught mine, nor do I exist," says the *Sankhya Karika*.

In contrast with this, European thought generally embraces optimism. From the doctrine of Plato, that God is the absolute good, and "the Good possesses not envy, and on this account has made the world most similar to itself," down to the doctrine of Hegel, that all nature and history are the celebration of God's personality, optimism accompanies the doctrine which makes man a free, progressive, immortal spirit transcending nature, and nature to be the theater best fitted for his development. The Christian philosophers have variously expanded this doctrine. St. Augustine explains that evil is only contingent, or incident to finitude in its different degrees of imperfection, and that it exists only as an adjunct of the good; "as a painting with dark colors is beautiful when seen as a whole, so the sum of things when seen with one glance is good." St. Anselm adopted the same view, and asserted that the fall of man rendered him capable of attaining higher good. We should say that the fall renders possible the development of free individuality, hence makes possible independent reflection of the divine. St. Thomas Aquinas likewise: "The infinite manifoldness in the objects of nature is requisite in order to display God's infinite perfection; evil is only the privation of perfect actuality incident to the mere participation in the divine." Malebranche says that God has used everywhere the simplest means to realize his purposes, and accordingly has admitted the fewest evils possible into the world. Leibnitz, who is the best-known defender of optimism, distinguished three kinds of evil: (*a*) metaphysical, owing to the finiteness of things: this is unavoidable; (*b*) physical evil or pain, which is conditional good, being a monitor to warn us against error; (*c*) moral evil or wickedness, for which man alone is responsible, being incident to freedom, which is his highest gift. "God, therefore, out of the infinite number of possible worlds which he saw, chose the one which is actually the best." William T. Harris.

Opzoomer, Cornelis Willem: See the Appendix.

Oracle [viâ O. Fr. from Lat. *ora'culum*, oracle, deriv. of *ora're*, pray]: a term applied to answers given by the ancient Egyptian and Greek deities when solemnly consulted by their votaries, and also to the places where they spoke. Oracles spoke in different ways—in some cases through a human being, who uttered words of inspiration (e. g. at the oracle of Apollo at Delphi); in others by signs, which the priests watched and interpreted (e. g. at the oracle of Zeus at Dodona); then by dreams, as in the temples of Asclepius; and lastly by calling up the shades of the dead, as when Odysseus consulted the shade of Teiresias (*Od.*, xi.). The ancients consulted oracles on all important affairs, whether public or private. If, as often happened, an enterprise failed even though the gods had seemed to favor it, the oracles still

lost no credit, for their answers were so ambiguous that it was no easy matter to interpret them clearly.

O'ran: department of Algeria; bounded N. by the Mediterranean, E. by the department of Algiers, S. by the desert, and W. by Moroeco. Area, 44,616 sq. miles. Large tracts of this province are cultivated with the utmost care, and wheat, maize, cotton, and wine are grown with great success. The climate is hot, but healthful. Pop. (1891) 942,066. Its capital is Oran, a Mediterranean seaport.

Orange [= Fr., from Arab. *nāranj*, orange]: the fruit of many varieties of the genus *Citrus*. The botany of the genus is much confused, but it is now held that the oranges of the U. S. represent but two species, the common type, *Citrus aurantium*, and the mandarin or kid-glove type, *C. nobilis*. The bitter or Seville orange is a form of *C. aurantium*. *Citrus* is a genus formerly placed in the family *Aurantiaceæ*, but now included in *Rutaceæ*. It embraces trees and shrubs, all exotic and unable to endure the climate of the Northern States. In the extreme southern parts of the U. S. the orange is productive. The foliage is fragrant, and the flowers are pure-white, odorous, and beautiful. Wherever known throughout the world they are regarded as the appropriate ornaments of a bride. These flowers have from twenty to sixty or more stamens, sometimes in sets, and have one style. There are from four to eight, usually five, petals. The filaments of the stamens are more or less united, and the ovary many-celled, with a prominent disk at the base. The fruit is a juicy and luscious berry with a leathery rind. This rind contains little cysts or cells filled with a fragrant and volatile oil which is easily inflammable. The branches of the trees are spiny and the leaves in reality compound; that is, they consist of a single leaflet, as is shown by the articulation between the blade and the petiole. This is also shown by the trifoliolate leaf of the related *Citrus trifoliata* (properly *Ægle sepiaria*).

The original of the orange came from the East Indies or from China. The orange has now spread over all the warmer regions of the earth. It has an astonishing productiveness. The trees we meet with in conservatories usually bear a bitter, unpalatable fruit, and are chiefly grown for ornament. Oranges are evergreen, and bear simultaneously fruit and blossoms. The leaves are fragrant and have a limited use in medicine in cases of hysteria, where they are employed instead of tea. Oil of neroli is prepared from orange-flowers, and is the basis of the popular perfume known as eau de cologne. The fruit contains citric acid, but not in so large proportion as the lemon. The rind enters into various articles of confectionery, and is used for flavoring. The numerous seeds often contain more than one embryo. Sicily, Malta, Spain, the Azores, Portugal, and Cuba have furnished most of the oranges of commerce, but Florida and California are now strong competitors. The Riverside district, California, had in 1900 19,200 acres in oranges, with 1,536,000 trees, mostly of the seedless variety. The crop is valued at $6,000,000 annually.

Consult Wickson's *California Fruits*, Manville's *Orange Culture*, Moore's *Orange Culture*, and the volumes of Bailey's *Annals of Horticulture*. Revised by L. H. Bailey.

Orange: town of France, in the department of Vaucluse; on the left bank of the Aigue; 18 miles N. of Avignon (see map of France, ref. 8–H). It is old, ill-built, and dirty, but it has several well-preserved and interesting remains from the Roman time (a triumphal arch and a theater), some manufactures of linen and cotton fabrics, and a large trade in honey, wine, spirits, essences, oil, truffles, saffron, and madder. Pop. (1896) 9,980. The *Arausio* of the Romans, it became after Cæsar an important Roman colony. It was an independent countship from the eleventh century until 1530, when it fell by marriage to René of Nassau Dillenburg, stadtholder of the Netherlands, who, being childless, chose as his successor his cousin William, father of William the Silent. As William III., King of Great Britain, who was Prince of Orange, died childless, there began a controversy as to the succession between Frederick I. of Prussia, of the older branch of the house of Nassau, and the head of the younger branch. At the Peace of Utrecht in 1713 the King of Prussia made over Orange to Louis XIV., still calling himself, however, Prince of Orange; but the title was also assumed, and has been retained since, by the stadtholders and Kings of the Netherlands of the younger line.

Orange: city (first settled as a part of Newark about 1666, created a township in 1806, divided by separation of East Orange and Fairmount 1862–63, incorporated as a city in 1870); Essex co., N. J. (for location, see map of New Jersey, ref. 2–E); on the Del., Lack. and W. and the Erie railways; 4 miles N. W. of Newark, 12 miles W. of New York city. The city is connected with Newark, Bloomfield, East Orange, and South Orange by electric street-railways; it is lighted by electricity, and owns a water-works system with a reservoir between the First and Second Mountains, completed in 1884, and a sewerage system, completed in 1894. There are 6 public-school buildings, including a high school, a manual-training school, public-school property valued at more than $165,000, several high-grade private schools, public library, 2 national banks with combined capital of $250,000, 2 savings-banks with aggregate deposits of $1,750,000, and a monthly and 5 weekly periodicals. Llewellyn Park, extending from the base to the summit of the First Mountain, comprising 750 acres, and containing many fine residences; Eagle Rock, 650 feet above tide-water, in West Orange, from which New York city and harbor may be seen; and Hemlock Falls, the wildest mountain part of South Orange, are among the attractions of the city and its immediate vicinity. Pop. (1890) 18,844; (1900) 24,141.

Orange: city; capital of Orange co., Tex. (for location, see map of Texas, ref. 5–K); on the Sabine river, at the head of navigation, and on the S. Pacific Railroad; 103 miles E. of Houston. It is in a rice, cotton, orange, sugar, and stock-raising region, and contains lumber and shingle mills. Pop. (1890) 3,173; (1900) 3,835.

Orange, or **Gariep**: the largest river in South Africa, S. of 20° S. lat. It is about 1,150 miles long, rises on the western slope of Mont aux Sources in the Drakenbergs (29° S. lat.), runs through Basutoland, in a narrow valley and with swift currents and many waterfalls, and receives in the upper two-fifths of its course all its important tributaries, the Caledon and Vaal being most important. Then flowing W. through a wide semi-arid region the river loses much of its volume through evaporation, and in its lower course it is often fordable. C. C. Adams.

Orangeburg: city. See the Appendix.

Orange City: town. See the Appendix.

Orange Free State: formerly an independent Boer republic in Southeast Africa, with the Transvaal Colony on the N. and separated from the Indian Ocean by Natal, Basutoland, and Cape Colony. Now the Orange River Colony of Great Britain. It was founded by Boers who withdrew from Cape Colony in 1836. Area, 48,326 sq. miles. Pop. (1890) 77,716 white and 120,787 black. The undulating and healthful plains are well adapted for stock-raising, which is the leading industry. It joined with the South African Republic in the Boer war of 1899–1900. After the capture of Bloemfontein (Meh. 13) Lord Roberts proclaimed it a colony of Great Britain, May 28, 1900. See Africa. The capital is Bloemfontein (*q. v.*). C. C. Adams.

Orangemen: members of a political association whose official name is **The Loyal Orange Institution**, formed, in opposition to the Roman Catholic association of the Ribbonmen, for the purpose of defending the Protestant religion in Ireland, maintaining the legislative union between Great Britain and Ireland, and the Protestant succession to the throne. The term Orangemen, which came into use after the Revolution of 1688, meant originally the supporters of William III., Prince of Orange, against the deposed Stuarts and their Roman Catholic adherents; but the association was not formed till 1795, when the first Orange lodge was founded in the north of Ireland. The society grew rapidly, and the hostility between its members and Roman Catholics soon gave rise to bloody conflicts, which it required considerable military force to suppress. At last, in 1836, the association was dissolved, but in 1845 it was revived as a secret society. In 1829 the institution was transferred to British America with great success, but there, too, as well as in New York, its processions have sometimes occasioned riots.

Orange, Prince of: See William of Nassau.

Orange Sands: See Lafayette Formation.

O'rang U'tan, or (vulgarly) **Orang'-outang'** [from Malayan *ōrang ūtan*, man of the woods; *ōrang*, man + *ūtan*, wood, forest]: a large anthropoid ape (*Simia satyrus*) inhabiting many of the low districts of Borneo, and more rarely found in the eastern portion of Sumatra. In bulk the adult male orang comes next to the gorilla, but, owing to the shortness of the legs, the animal rarely attains a height of 4 ft. 6 in., the maximum size recorded being 4 ft. 8 in. The arms

are very long, the digits of the hands and feet much curved, the thumb very small. In the old males the face, which is black, or nearly so, is almost round, owing to the presence of cheek callosities. The collar-bones are so long that the shoulders are nearly on a level with the ears. The canines are large and the jaws powerful, but, although the

Female orang utan.

males fight with one another, the orang is a timid animal and harmless unless brought to bay. The females, which are much smaller than the males, have no facial callosities. The orang is sparsely clad in coarse red hair, which is subject to considerable variation in tint. It is strictly arboreal, never descending to the ground unless compelled to do so, for it walks poorly, owing to the curvature of the toes and the oblique manner in which the foot is set on the leg. The orang prefers low-lying or swampy forests, feeds on fruits and vegetables, and builds a rude nest in which to sleep.

F. A. Lucas.

Oraon: See Dravidian Languages.

Orato'rio [= Ital. < Late Lat. *orato'rium*, chapel, neut. of *orato'rius*, pertaining to praying; cf. *ora're*, speak, pray]: an elevated form of musical composition in which voices and instruments combine to represent scenes, passages, or themes from biblical or sacred history, the text consisting of verses from the Scriptures arranged with a view to moral and spiritual effect; the music comprising chorus, recitative, aria, quartette, trio, solo—in short, all the recognized combinations of harmony and melody, with organ and orchestral accompaniment, as in opera. It differs from opera principally in being sacred instead of secular, and in being unsuited to stage or scenic representation. When it becomes operatic in the sense of scenic and passionate, as in the case of Rossini's *Moses in Egypt*, it ceases to be oratorio. The movement is subjective, the development ideal, the characterization intellectual, the spirit epical. The oratorio was never intended to do service in the offices of worship, was never written in the direct interest of Sabbath or cathedral observances. It was, in fact, an effort to associate the charm of musical composition with the solemnity of sacred themes. Hence, in large measure, its popularity in England with the "evangelical" Protestants, who are forbidden by their religious feeling to attend operatic and theatrical entertainments, and with a similar class in the U. S. In Paris it has, in fact, no abiding-place, nor is it held in favor in Italy, where it originated. In Germany, also, oratorio is seldom heard, except at occasional festivals where many voices can be grouped together. The germs of oratorio existed in the Middle Ages in the shape of *mysteries* and *moralities*—scenes from Scripture rudely dramatized, with some primitive sort of music, the design being to entertain the coarse and vacant-minded peasantry and entice them from idleness and vicious pleasure. The steps of development in conception and form can not be traced. In the middle of the sixteenth century St. Philip Neri, a man of deep humor and genuine sympathy with the people, attempted to mingle instruction and entertainment by engaging the music director of St. Peter's church to aid him in his popular interpretations of sacred story. The musician introduced songs in passages of dialogue and soliloquy. That the attempt was successful appears from the fact that it was made in other places and with more art. In the year 1600 one of these musical dramas was exhibited on a stage erected in the Church Sta. Maria in Valicella. It was called *Soul and Body*, was composed by Emilio dei Cavalieri, and may be regarded as the first systematic production of oratorio, with chorus, recitative, and song. To these the dance was added. From this point to the time of Handel the history of oratorio is uncertain. In the seventeenth century Giacomo Carissimi composed *Jephthah* and the *Judgment of Solomon*; in the latter part of the same century Francis Federici composed two pieces, *Santa Cristina* and *Santa Catarina di Siena*, which were called oratorios. Among composers of oratorio may be mentioned Alessandro Scarlatti, Alessandro Stradella (*John the Baptist*), Giacomo Perti (*Abraham*), Benedetto Marcello (*Judith*), Heinrich Schütz (*Resurrection* and *Seven Words*), all of about the same period (1645–1710) Among oratorios the *Passion Music according to St. Mat thew*, composed by John Sebastian Bach, must be regarded as the greatest, most monumental work of its kind. Equally imbued with the religious spirit of its day as in case of Handel's *Messiah*, its technical value is far greater. From the standpoint of popularity, using the word in its best and broadest sense, the *Messiah* seems to enjoy a perennial life wherever the English tongue is spoken. Both by the number and caliber of his works, and by their enduring influence down to this day, Handel may well be considered the great master of oratorio. His best-known works were *Saul* (1740); *Messiah* (1741); *Samson*, *Judas Maccabeus* (1747); *Jephthah* (1751). All have English words. The greatest, *Messiah*, is considered the masterpiece of its kind. *The Creation*, by Haydn (1798), ranks next to it in popular repute. They have but one peer, Mendelssohn, whose *St. Paul* (1836) and *Elijah* (1846) are brilliant and beautiful examples of the capacity of this species of composition. With lovers of music *Elijah* is greeted with more enthusiasm than even the *Messiah*, its spirit being more modern, its musical form more flexible, its conceptions more intellectual. While the tone is purely and throughout religious, the ideas, less confined to dogma, are addressed to the imagination rather than to the heart—to the æsthetic rather than to the "spiritual" sense. Revised by Dudley Buck.

Oratory, Congregation of the: a monastic order in the Roman Catholic Church, founded in 1560 by St. Philip Neri; established in France in 1611. Its first rule was oral, but was afterward written out, and received papal approval in 1612. The fathers are mostly devoted to the spread of learning; they assume no vows but those of the secular priesthood. One of the most eminent of their number in modern times was Dr., afterward Cardinal, J. H. Newman. Baronius, Bosio, Bérulle, Malebranche, Gallandi, and Massillon are among those who belonged to the order in times past. The French Oratory, called the Oratory of Jesus, was always a distinct though kindred organization. It is now nearly extinct. Revised by J. J. Keane.

Orbego'so, Luis José: politician; b. near Huamachueo, Peru, Aug. 25, 1795. He was a rich proprietor, took an active part in politics, and on Dec. 20, 1833, was elected president of Peru by the constitutional convention which was then sitting. Strictly speaking, the convention had no right to elect a president, but Orbegoso was popular, and for a year his rule was generally accepted. In Jan., 1834, Gamarra declared against him, proclaiming Bermudez as supreme chief. The civil war which followed was ended in April by mutual agreement, but new rebellions, headed by Gamarra, Salaverry, and others, broke out early in 1835, and Orbegoso, after repeated defeats, accepted the intervention of President Santa Cruz of Bolivia. The result was the invasion of Peru by Santa Cruz, who formed the Peru-Bolivian confederation in 1836 (see Santa Cruz), Orbegoso being nominated president of North Peru, one of the confederated states. In 1837 he was defeated by Gamarra and the Chilians. After passing several years in exile, he was allowed to return to Truxillo, where he died in 1847. H. H. S.

Orbigny, ōr'bēn'yee', Alcide Dessalines, d': zoölogist and ethnologist; b. at Coueron, Loire-Inférieure, France, Sept. 6, 1802. From 1826 to 1833 he explored Southern Brazil, the Platine States, Patagonia, Bolivia, and Peru. The results of this journey were published at the expense of the French Government, with the general title *Voyage dans l'Amérique Méridionale* (1834–47); the work includes, be-

sides the narrative, several volumes on zoölogy, and *l'Homme Américain* (2 vols.), an important treatise on South American ethnology. D'Orbigny also published various monographs on Foraminifera, etc.; he contributed the volumes on Foraminifera, Mollusca, and birds to Ramon de la Sagra's *Historia de Cuba*, and collaborated with his brother, Charles Dessalines d'Orbigny, in the *Dictionnaire d'histoire naturelle*. His most important work was the *Paléontologie française* (14 vols., 1840–54; unfinished). From 1852 he was Professor of Palæontology in the Museum of Natural History at Paris. D. near Paris, June 30, 1857. H. H. S.

Orbil'ius Pupil'lus, Lucius: a grammarian and teacher at Rome in Horace's boyhood; b. at Beneventum. He served at first, as stated by Suetonius, who mentions him in his list of distinguished grammarians, as an attendant on the magistrates of his native place, then in the army in Macedonia. In his fiftieth year he removed to Rome, in the consulship of Cicero, where he taught school for many years, and had among his pupils the poets Domitius Marsus and Horace, who recalls in his *Epistles* the severity of his master. His teaching brought him more fame than profit, for he died poor at the age of nearly a hundred. His fellow townsmen erected a marble statue to his honor in Beneventum. Suetonius cites a work of his with the title *Perialogos*, but this name is evidently corrupt. See Teuffel, *Lat. Lit.*, § 200; Estré, *Prosopogr. Horat*, p. 437.

Orbit [from Lat. *or'bita*, wheel-track, course, circuit, deriv. of *or'bis*, circle, wheel]: the path in which a heavenly body moves. When there are but two bodies the revolution occurs in consequence of their mutual gravitation, combined with the original relative motion of the bodies. The orbit is then described in accordance with Keppler's laws, which, when modified in accordance with modern mechanics, are as follows:

1. Each body describes an ellipse in space, having the center of gravity of the two bodies as the center of motion, in one of its foci. If the motion of the lesser body is referred to the greater, taken as a point at rest, as is usual in astronomy, the lesser still describes an ellipse having the greater in one of its foci.

2. The velocity of each body in its orbit varies in such a way that the radius vector, or line drawn from one body to the other, sweeps over equal areas in equal times. The velocity is therefore greater the nearer the two bodies come together.

3. The cube of the semimajor axis of the ellipse, divided by the square of the time of revolution, is proportional to the combined masses of the two bodies.

These laws of Kepler were shown by Sir Isaac Newton to result directly from the theory of gravitation. From them it follows that, in order to determine and define the motion of a body around an attracting center, such as a planet around the sun, certain quantities, called *elements*, are necessary. In the case of an elliptic orbit these elements are as follows, the symbol which follows each being the letter commonly used to represent the elements:

1. The mean distance, or half the major axis of the ellipse in which the planet moves around the sun. It is equal to half the sum of the greatest and least distances of the planet. Symbol a.

2. The eccentricity of the ellipse, symbol e. Instead of e an angle ϕ is often used, of which e is the sine.

3. The longitude of the ascending node, or the angle which the vernal equinox makes with the line in which the plane of the orbit intersects the plane of the ecliptic. Symbol Ω.

4. The inclination of the plane of the orbit to that of the ecliptic. Symbol i.

5. The longitude of the perihelion, by which is commonly meant the longitude of the node, plus the angular distance from the node to the perihelion as seen from the sun. Symbol π.

6. The mean longitude of the planet at some given epoch. By mean longitude is here meant the longitude of a fictitious or imagined planet which moves around the sun with uniform velocity, in the same time as the actual planet, and in such a way that, in a general average, it is as much behind the actual planet as in advance of it. Symbol L.

7. The mean daily motion, or the daily angular motion of a planet which would revolve around the sun in the same time as the actual planet. When the masses of the two bodies are known this element can be determined from the mean distance. Symbol μ or n.

Various combinations of these elements are sometimes introduced, among them the distance from the node to the perihelion, symbol ω, and the mean anomaly, symbol M. The relations of these quantities to the other elements are:

$$\omega = \pi - \Omega$$
$$M = L - \pi$$

If but a single planet moved around the sun its motion would take place in strict accordance with Kepler's laws, and the elements of the orbit, as above described, would remain invariable; but, owing to the attraction of the other planets, each planet deviates from such an elliptic orbit. Moreover, this elliptic or mean orbit is slowly changing from century to century. These changes are called secular variations, and the problem of their computation is one of the most remarkable of modern astronomy. Their laws can not be derived from all the observations hitherto made on the planets; but from mathematical investigation, founded on the theory of gravitation, the changes in the orbits can be computed for hundreds of thousands of years past and to come. S. Newcomb.

Orcagna, ōr-kaan'yăă, Andrea (also called Andrea di Cione, after his father): painter, sculptor, and architect; b. at Florence about 1316. He learned sculpture as a child from Andrea Pisano. After a few years he studied painting, which he preferred, with the Gaddis, and architecture by studying the works of Giotto and Arnolfo di Lasso. The principal chapel in Sta. Maria Novella was painted by Andrea and his brother Bernardo. Andrea executed *A Last Judgment* and *Christ and the Virgin enthroned in Heaven*. From 1358 to 1360 he was chief architect of the cathedral at Orvieto. His architectural skill is shown in the Loggia dei Lanzi and in the tabernacle of Or San Michele, one of the wonders of the age for its richness of ornamentation. It was completed in 1569. Few of his paintings remain. One, a retable painted for the Church of St. Pietro Maggiore, in Florence, is now in the National Gallery in London. Orcagna was also a poet. D. about 1376. W. J. Stillman.

Or'cein (*lichen-red*, *Flechtenroth*): $C_7H_7NO_3$, the chief ingredient of the red and purple dyestuffs known under the name of Archil (*q. v.*). It is formed by the action of ammonia and oxygen on orein, $C_7H_8O_2$, and consists of two substances, one having the composition $C_{14}H_{13}NO_4$, the other $C_{14}H_{12}N_2O_3$. When ammonia is added to a solution of orcin, and the whole is exposed to the air, the liquid assumes a dark-red or purple tint by the absorption of oxygen. On acidulating with acetic acid, a dark-red precipitate of orcein is obtained. Orcein is slightly soluble in water and freely soluble in ammonia and fixed alkalies, with a purple or violet color; it is very soluble in alcohol.

Revised by Ira Remsen.

Orchardson, William Quiller: genre and portrait painter; b. in Edinburgh, Scotland, in 1835. Studied in the Trustees' Academy, Edinburgh; painted portraits in Edinburgh until 1863, when he went to London; was elected Royal Academician 1878 and a D. C. L. of Oxford in 1890; was awarded third-class medals at the Paris Expositions of 1867 and 1878; first-class at Paris Exposition of 1889. His works are distinguished by fine quality of color and have a marked personality. Studio in London. W. A. C.

Orchestra, ōr'kes-tra [from Lat. *orches'tra* = Gr. ὀρχήστρα, the space in a theater between the stage and the audience, liter., dancing-place, deriv. of ὀρχεῖσθαι, dance]: the place or structure occupied by performers on instruments in a theater, music-hall, or other building fitted for concerts, oratorios, etc. In oratorios, cantatas, and other pieces with vocal parts a portion of the orchestra is also allotted to the choir. The term "orchestra," in modern use, often means the body of instrumental performers themselves, especially as distinguished from the choir or vocal department, in the execution of such works as are for voices and instruments.

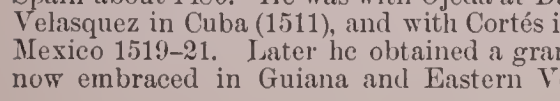
Orchids, or **Orchida'ceæ** [Mod. Lat. *Orchidaceæ*, from *Or'chis*, the typical genus = Lat. *or'chis* = Gr. ὄρχις, orchid, testicle, so called from the shape of its tubers]: a family of perennial endogenous herbs, found all over the world except in very cold and very dry climates. In the cooler regions they are terrestrial, while in hot countries they are often air-plants, growing upon stones and trees, but epiphytic rather than parasitic. They have irregular and often extremely beautiful, but sometimes very grotesque, flowers, perfect, with a hexamerous adnate perianth, a one-celled ovary, numerous ovules, and three parietal placentæ. The stamens are one, two, or three; the pollen generally coheres in masses.

Fertilization is almost always effected by the aid of insects. Many of the species have flowers singularly resembling insects in form. Many have very fragrant blossoms. This vast order affords a few useful plants, among which are vanilla, faham, salep, also several medicinal products. Florists successfully cultivate many superb tropical epiphytes of this order. The U. S. has comparatively few species of orchids, although some, like the lady-slippers, are curious and beautiful. See CATTLEYA, CYPRIPEDIUM, EPIDENDRUM, HOLY GHOST FLOWER, etc. Revised by L. H. BAILEY.

Orchil: See ARCHIL.

Orchom'enus (in Gr. 'Ορχομενός): an old city of Greece, situated in Bœotia, at the entrance of the river Cephissus into the Lake Copais; the capital of the prehistoric empire of the Minyæ. It is reported by Homer to have sent thirty ships to the siege of Troy, and to have contained riches which might be compared to those of Thebes in Egypt. In the Persian wars it abandoned the national cause, and in the wars between the various Greek races it always sided with the aristocratic party; but in 367 B. C. it was taken and destroyed by the Thebans. The buildings were burnt, the men put to the sword, the women and children sold as slaves. Rebuilt by the Phocians, it was again destroyed by the Thebans in 346, and although Philip of Macedon once more rebuilt it, it never again acquired any importance. The site was excavated by Schliemann in 1880, 1881, and 1886. See his *Orchomenos*, but better Schuchhardt, *Schliemann's Excavations* (London, 1891), pp. 299–303. J. R. S. STERRETT.

Or'cin: a compound belonging to the class of PHENOLS (*q. v.*), being closely related to ordinary phenol or CARBOLIC ACID (*q. v.*). It is derived from TOLUENE (*q. v.*) by the substitution of two hydroxyl groups for two hydrogen atoms:



Toluene. Orcin.

It is obtained from certain lichens which yield ARCHIL (*q. v.*), though in most of these it is not contained ready formed. It is produced by transformations of other constituents of the lichens, especially erythrin, $C_{20}H_{22}O_{10}$; lecanoric acid, $C_{16}H_{14}O_7$; evernic acid, $C_{16}H_{14}O_7$; and orsellinic acid, $C_8H_8O_4$. It can be made artificially by a number of methods, and is so prepared on the large scale. Ammonia converts it into ORCEIN (*q. v.*). IRA REMSEN.

Ord, EDWARD OTHO CRESAP: soldier; b. in Cumberland, Md., Oct. 19, 1818; graduated from the U. S. Military Academy, and was appointed second lieutenant of artillery July, 1839; served in Florida and on frontier duty, and at the outbreak of war in 1861 was stationed in California. Appointed brigadier-general of volunteers, he fought the battle of Dranesville Dec. 20, 1861; and as major-general of volunteers commanded the left wing of Gen. Grant's army in Mississippi Aug.-Sept., 1862, participating in the battle of Iuka, Sept. 19–20, and while in command at the action on the Hatchie, Oct. 5, 1862, was severely wounded. He commanded the Thirteenth Army-corps during the siege and capture of Vicksburg and capture of Jackson: the Eighth Corps and middle department July 11–21, 1864; and the Eighteenth Corps before Richmond, July 21–Sept. 29, when again wounded in the assault and capture of Fort Harrison. On Jan. 18, 1865, he relieved Gen. Butler in command of the department of Virginia and North Carolina and of the Army of the James, with which army he remained throughout the siege of Petersburg and subsequent pursuit of the Confederate army of Northern Virginia, ending in the surrender at Appomattox Court-house. At the close of the war he had received brevets from lieutenant-colonel to major-general, U. S. army, had attained the rank of lieutenant-colonel of artillery, but continued to hold his volunteer rank of major-general, and commanded various districts and departments until Sept., 1866, when mustered out of the volunteer service, having, however, been appointed a brigadier-general (July, 1866) in the regular army. He was in command of various military departments 1866–80; and on Dec. 6, 1880, was by special act of Congress placed on the retired list with rank of major-general Jan. 28, 1881. D. in Havana, Cuba, July 22, 1883. Revised by JAMES MERCUR.

Ordaz, or **Ordás**, DIEGO, de: soldier and explorer; b. in Spain about 1480. He was with Ojeda at Darien (1509), with Velasquez in Cuba (1511), and with Cortés in the conquest of Mexico 1519–21. Later he obtained a grant of the country now embraced in Guiana and Eastern Venezuela, and in 1531–32 he made the first exploration of the Orinoco, ascending, it would appear, to the mouth of the Meta. During this journey one of his officers, Martinez, wandered far inland, and claimed to have seen a magnificent city whose king was gilded with gold-dust; this account or invention was the origin of the myth of El Dorado. On his return to the coast charges were made against Ordaz, and he was arrested and sent to Santo Domingo; there he was released, and started for Spain, but died at sea 1533. H. H. SMITH.

Ordeal [O. Eng. *ordāl*, *ordēl*, judgment: Germ. *urtheil*, judgment. The original meaning is something dealt out; cf. Goth. *us-*, out, and Eng. *deal*]: a form of trial of guilt or innocence, consisting in an appeal to the immediate judgment or intervention of God by subjecting a person to a certain test in the belief that if he be innocent God will so shape the result as to indicate it.

Evidence of the existence in one form or another of the trial by ordeal is found in the earliest records of all the races of mankind; and the institution formed a prominent part of the jurisprudence of the Christianized barbarian races of mediæval Europe, from which the nations of modern Europe are descended, being the survival of customs which obtained among them when pagans. Its legal existence has survived in some countries into the nineteenth century, as in England, where trial by BATTEL (*q. v.*) was only finally abolished in the year 1819 (59 George III., c. 46). There are traces of the institution in the literature of all the civilized nations of antiquity, as among the Greeks in Sophocles's *Antigone* (ver. 264–267), and among the Jews in the Bible (Num. v. 11–31; Joshua vii. 16–18; 1 Samuel xiv. 41–42).

The tests which have been resorted to for the purpose of trial by ordeal are very numerous, such as fire, wager of battle, boiling water, the drinking of poisoned water, etc., the last mentioned being a very general practice among savage races.

Trial by *wager of battle* was a very common form among the Germanic nations, and was resorted to in both criminal and civil cases. The accused challenged the accuser, and they fought, either in person or later by champions, in the presence of judges, the victor being deemed innocent or just in his cause. (See BATTEL.) The trial by battle continued in practice until the seventeenth century, and survives today in the modern duel. See DUEL.

Trial by *fire* was one of the forms of ordeal most thoroughly established in mediæval Europe, and was sanctioned by the Christian clergy, and administered under their superintendence. At first it was used only on very solemn occasions, but later became quite common as a more aristocratic mode of trial than that by water, which later came to be considered plebeian. It had various forms, such as the putting on of a red-hot iron glove, walking barefooted and blindfolded over red-hot plowshares, and passing through a fire with nothing but a thin shirt for a covering; but the most common method was for the accused to carry a piece of red-hot iron in his hand for a given distance. If unhurt, he was declared innocent; if burned, guilty. Cases in which persons were injured or killed by this ordeal were very rare, for the trial was seldom granted, except when the accused by some means could be given a victory. It was granted to noble ladies as a means of proving their chastity, and tradition records a number of instances in which the ordeal was successfully submitted to. In 1498 Savonarola appealed to the trial by fire, but at the last moment the ordeal was given up, his enemies alleging that he refused to submit to it. Another form of trial by fire or heat was that in which the accused thrust his hand, or hand and arm, into a vessel filled with boiling water to take up some small object placed in the water. Sometimes boiling oil was used instead of water. If the accused escaped uninjured, he was deemed innocent; if burned, guilty; but in some cases it was the custom to bind and seal up the arm for three days, when it was examined, and innocence or guilt determined by the result. This ordeal survived as late as the middle of the fifteenth century.

In the *cold water* ordeal the accused was thrown, with the arms and legs tied, into a pond or river, and was adjudged guilty if he floated, innocent if he sank. If he was drowned before he was removed by the rope which was attached to his body, the innocent dead person became a saint. After this form of ordeal ceased to be in general use, it was much used in cases of women accused of witchcraft, and these witch ordeals did not disappear until the middle of the eighteenth century.

The ordeal of *bread or cheese* consisted in giving the accused a bit of bread or cheese over which prayers and adjurations had been performed, and if the accused were able to swallow it, he was adjudged innocent; if not, guilty. A special form of this was the ordeal of the *Eucharist*, used mostly among the clergy, which consisted in taking the holy sacrament under solemn imprecations of the vengeance of God if it were taken to cover a lie. It was believed that the guilty could not swallow the morsel without being choked; and it is possible that the consciousness of guilt might produce involuntary inability to swallow.

The ordeal of the *cross* was one of simple endurance between the accused and the accuser, the test being which could uphold his arms the longer before the cross. This ordeal became obsolete at an early day.

The ordeal of the *bier* was based upon the superstition that the body of a murdered person would bleed or move upon the approach or touch of the murderer. This ordeal survived until a comparatively late date as a superstition, although it early lost its authority as an ordeal.

Trial by *lot* was an early form of ordeal which was chiefly used as a means of discovering a thief or a murderer. Its insufficiency for this purpose was soon understood, however, but it continues as a superstitious means of decision in doubtful circumstances.

In the early periods many of the forms of ordeal were sanctioned by the councils of the Church, and administered by ecclesiastics; yet from the sixth century down they were generally condemned by the popes, but with little effect on the clergy, who continued to sanction and administer them. The papal authority, however, and the revival of the Roman law in the twelfth and thirteenth centuries, and the general growth of intelligence among the people, finally resulted in the overthrow of the institution of trial by ordeal. See Henry C. Lea's *Superstition and Force* (2d ed. Philadelphia, 1870). F. Sturges Allen.

Order [from Lat. *or'do*, *or'dinis*, row, series, order]: a name used by zoölogists and botanists for combinations of animals and plants. In zoölogy it is now always used for a group comprising one or more families and intervening between the Family (*q. v.*) and the class. In botany the term has generally been used much as family is used in zoölogy—that is, to denote a group above the rank of a genus; but in the botanical articles in this cyclopædia the usage agrees with that in zoölogy. F. A. L.

Orders: originally, organized bodies of men vowed to monastic rule as well as military life, especially for war against the Saracens and Moors; secondly, select bodies of knights and nobles having a peculiar title conferred upon each of them, and a badge of some sort to testify to it; thirdly, modern organizations, sometimes supposed to be confined to men (or in rare cases to women) who have shown especial courage or merit, and more often consisting partly of these and partly of men occupying high official positions; also the decorations or badges indicating membership in such organizations. Perhaps 300 orders have existed in Europe since the tenth century, and there are imitations of these established by Oriental sovereigns.

1. *Mediæval Fighting Orders.*—The Order of St. John of Jerusalem is thought to have been founded in the eleventh century, and was certainly organized as a great military and religious body about 1120. When the Christians were finally expelled from Palestine this order settled at Rhodes, and afterward at Malta, and they were called Knights of Rhodes and Knights of Malta accordingly. They are often called *Knights Hospitallers*, because their first organization was connected with a hospital in Jerusalem. The order still exists, and a grand-master was elected in 1879, but it is now *honorary*. The Templars, or Knights of the Temple, were a similar order, equally famous and powerful, but the order was entirely destroyed and the leaders put to death with torture during the pontificate of Clement V. and largely by the efforts of King Philip the Fair of France. The rich possessions of the order, which could easily be confiscated, probably had much to do with this act of authority, which may be compared with the dissolution of the monasteries under Henry VIII. of England. The Teutonic Order was another body of religious knights; this still exists in a much modified condition.

2. *Honorary Orders of the Middle Ages and of the Renaissance.*—The Order of the Garter was founded by Edward III. of England after his victories in France and against the Scots, and dates from 1349. It has existed ever since. The number of Knights of the Garter is limited to twenty-five besides the sovereign as its patron. As it is very small in numbers, and limited to nobles of very high rank and to members of foreign royal houses, it is one of the two or three most envied and admired orders of Europe. The Order of the Elephant of Denmark is another such; it dates from the fifteenth century and consists of thirty members, each of whom must be already a member of the Order of the Danebrog. The most famous of all these orders is that of the Golden Fleece, founded by the Duke of Burgundy, Philippe le Bon, in 1429. It was established with great splendor, and even more magnificently treated by Philippe's successor, Charles le Téméraire. After his death and the ruin of the duchy of Burgundy as an independent state, the order was claimed at once by Spain and by the house of Austria, and to this day there are two branches of it. No person but a Catholic of very high birth and dignity can become a member. The Order of the Thistle, founded by James II. of England and VIII. of Scotland, consists of sixteen knights only. The Teutonic Order, named above, is now an Austrian aristocratic and limited body having strong Catholic tendencies. The Black Eagle of Prussia, though not founded until 1701, ought to be named here as being purely aristocratic and limited to thirty persons besides foreign princes. These five orders, together with a Prussian branch of the great Order of St. John of Jerusalem and two orders for women, one of Prussia and one of Bavaria, are the only ones which the *Almanach de Gotha* mentions in connection with the names of princes and princesses who belong to them. This serves to show the peculiar importance ascribed to these eight among all the other orders of Europe, an importance depending entirely upon their honors being shared by so few persons.

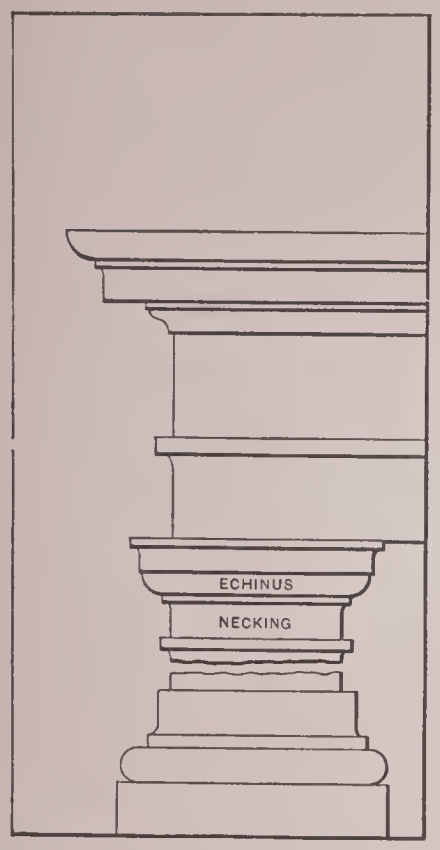
3. *Modern Orders.*—Of these much the most celebrated is the Legion of Honor, founded by the First Consul Bonaparte. It was maintained by the Restoration, but with Henry IV. substituted for Napoleon on the badges, and other similar changes, all of which were done away with when the second republic brought Louis Napoleon to the front. Under the Second Empire it consisted of 80 Knights Grand Cross, 200 grand officers, 1,000 commanders, 4,000 officers, and any number of knights, the chief of the state being the grand-master. The present organization is nearly the same. The rank of knight (*chevalier*) is given theoretically for merit in military or civil life, and for merit only, but some men receive the honor as a necessary consequence of some public office which they have discharged, apart from special merit, and of course there are sometimes complaints and charges of favoritism. The knights receive a very small annual stipend, the members of higher grade a little more, but the pay even of the *Grand Croix* is only 3,000 francs a year. All have, however, certain privileges much esteemed in France. Although there are perhaps 30,000 men entitled to wear the red ribbon or rosette, it is a most honorable and enviable distinction. The English Order of the Bath is somewhat similar, though much more rarely given; it consists of 75 Knights Grand Cross, who may put G. C. B. after their names, 200 or 300 knights commanders (K. C. B.), and about 700 "Companions of the Bath" (C. B.). The Order of the Star of India and that of St. Michael and St. George are British orders provided for distinction in the colonial service and in India. Every nation of Europe has such distinctions for military merit in the first place, and then for success as artist, author, engineer, or the like.

4. *Badges and Visible Distinctions.*—All the orders have their "crosses" or "jewels," and their ribbons of special colors; and for the higher grades *plaques* or stars, which are worn on the breast. The cross of the Legion of Honor is a five-pointed flat jewel of gold and enamel, worn at the buttonhole, or hanging from a ribbon at the neck according to grade, but it is worn only by soldiers or navy men in uniform, or by citizens when in evening dress. Citizens in their ordinary dress wear a small bow of ribbon of a peculiar red in the buttonhole for the grade of chevalier, and a rosette of the same silk for the higher grades; a broad ribbon is worn over the shoulder by the *Grand Croix*. A silver star is borne on the right breast by the grand officers and on the left breast by the *Grands Croix*. Similar laws govern the decorations of all the honorary orders. Russell Sturgis.

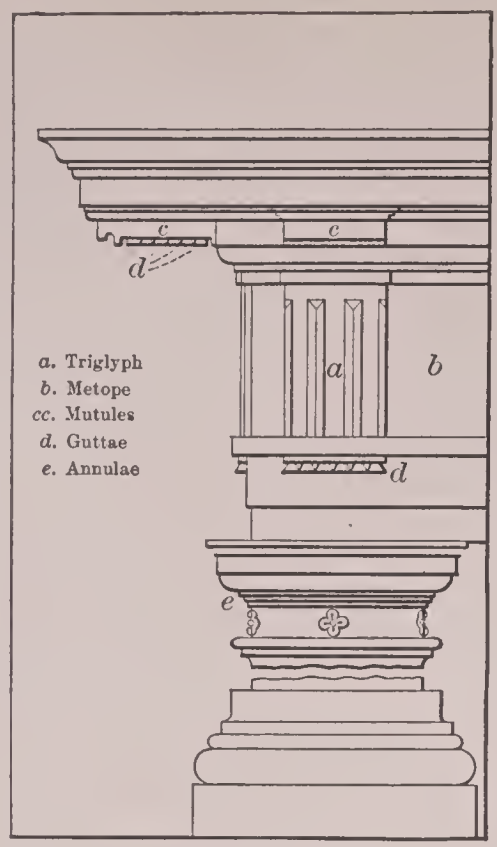
Orders in Council: See Privy Council.

Orders of Architecture: While the word *order* may be used in architecture to mean any systematic combination of

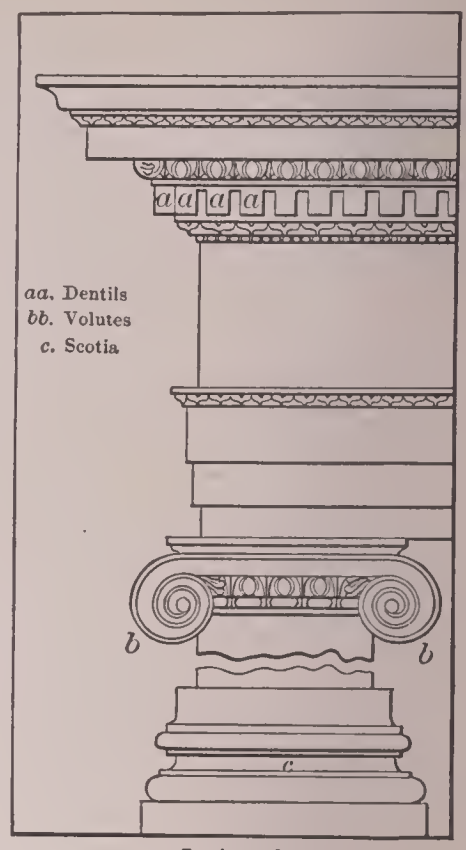
supporting and supported members, it is customarily understood, in the absence of qualifying context, to refer to the combination of a column or a pilaster with an entablature consisting of architrave, frieze, and cornice, according to an established system or canon of design. The five orders commonly referred to in architectural treatises, and known respectively as the Tuscan, Doric, Ionic, Corinthian, and Composite, formed the basis of Roman decorative architecture, and were copied by the architects of the Italian Renaissance of the fifteenth century, and their successors in Italy and elsewhere. At first the imitation was free and more or less fanciful. As the result of minuter study and comparison, their proportions and details were systematically formulated by various architects, who sought to establish, in spite of endless variations of detail, a canon of proportions for each order. Among these various efforts the *Treatise on the Orders*, by Giacomo Barozzi da Vignola (1507–73), has found the widest acceptance, and has survived down to our own day as the best text-book on the subject.



Tuscan order.



Doric order.



Ionic order.

The Egyptians had no orders in the accepted sense of the term; they employed an unvarying type of entablature over a great variety of columns of diverse proportions. The Greeks employed mainly two orders. The *Doric* was at first the only one known to them, but the *Ionic* was in the early fifth century imported, so to speak, from Asia Minor, and made use of in buildings calling for more elegant and slender forms than those of the sturdier Doric order. (See ARCHITECTURE.) In the fourth century a variant of the Ionic was devised, with a much enriched capital, and called Corinthian, though hardly forming a distinct order, except as to its capital.

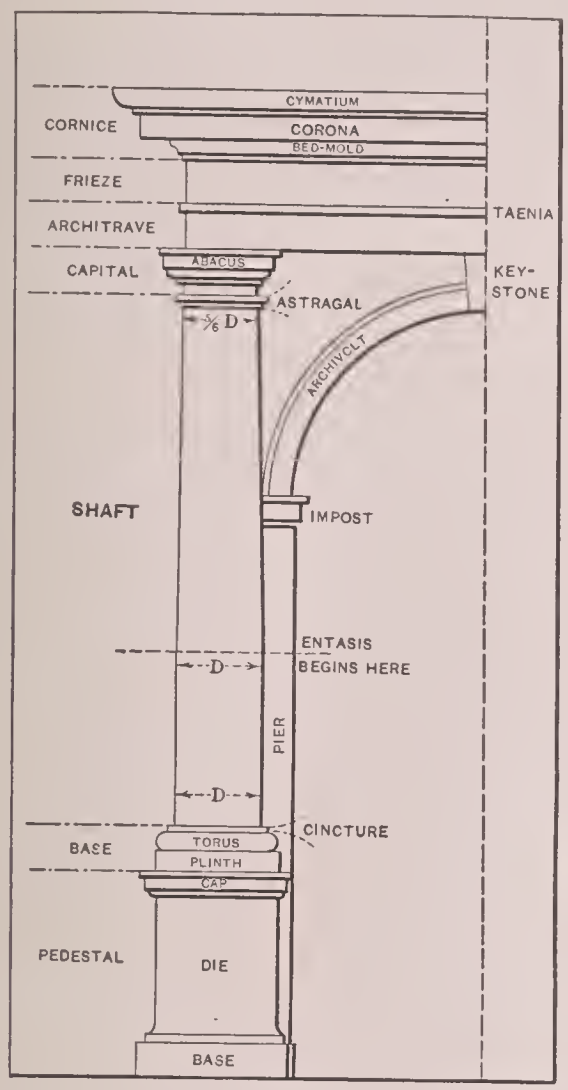
These orders, as used by the Greeks, varied widely both in proportions and details. The practical and systematic Romans, having conquered the Greeks and adopted the forms of their architecture, modified them radically in the direction of greater uniformity and of increased splendor of detail, perfecting and enriching all parts of the Corinthian, and retaining in addition their own uncouth Etruscan or Tuscan column and entablature as a fourth order. They also added a fifth, the Composite, a sort of hybrid combination of the Ionic and Corinthian. See COMPOSITE ORDER.

An order is composed of the *column*, having a *base* (except in the Greek Doric), *shaft*, and *capital*; and the *entablature*, resting upon the columns and comprising an *architrave*, *frieze*, and *cornice*. The base consists of circular mouldings (*tori* and *scotiæ*), resting on a square *plinth*. The shaft, flaring into a *cincture* at the bottom and an *astragal* at the top, has a slight taper, called *entasis*, for the upper two-thirds of its length. It may be smooth or fluted; the edges of the flutings are called *arrises*. The capital is composed of various parts (*necking*, *echinus*, *volutes*, *abacus*), according to the order, as shown in the diagrams. The architrave is moulded in two or three horizontal bands, and crowned by a *tænia* or upper moulding. The frieze has no special characteristic in any order except the Doric, where it is decorated with repeated vertical-grooved members called *triglyphs*, alternating with square spaces called *metopes*. The cornice always has a *bed-mould* (which may comprise a group of mouldings), an overhanging shelf-like *corona*, and a crowning moulding, the *cymatium*. In the Doric there are also *mutules*, the under surfaces of which are ornamented with *guttæ* resembling trenail-heads; in the Ionic there are *dentils* in the bed-mouldings; and the Corinthian and Composite cornices have in addition under the corona more or less rich brackets or *modillions*. When arches are used in conjunction with columns or pilasters, the arch springs from an *impost* which serves as cap to the *pier*, and is adorned with an *archivolt* (somewhat like a curved architrave) and *keystone*. The column is sometimes elevated on a *pedestal* composed of *base*, *die*, and *cap*.

Corinthian order.

Vignola's system involves an elaborate kind of measurement of the relative proportions of all the orders by means of modules, each module being divided into twelve or eighteen parts according to the order; but it is equally useful and more simple to express all measurements in terms of the lower diameter of the shaft (D and fractions of D).

The same orders, as given by Palladio, Scammozzi, and Sir William Chambers, vary slightly from Vignola's in minor details, but not in essentials. It may be stated that in all cases the base is $\frac{1}{2}$ D in height, as also the capital in the first three orders; that the shaft diminishes in each order exactly $\frac{1}{6}$ D in its upper as compared with its lower diameter; that the entablature always measures in height precisely one-quarter the total height of the column, or one-fifth the height of the whole order; and that the cornice always



One-half of an arcaded order, showing names of principal parts.

measures $\frac{1}{4}$ D more than the architrave. Taking the columns of the Dorie, Ionic, and Corinthian in that order, each is seen to exceed the one preceding it in the diagram by one diameter in height.

This formal canon of proportions, though generally accepted as the most perfect standard, was never strictly adhered to even by Vignola himself and his contemporaries. The apparent uniformity of the antique Roman orders was approximate, not absolute, and the value of Vignola's formulation of an exact canon is disciplinary and suggestive, rather than authoritative and binding. For further details, consult the editions of Vignola's treatise published in Paris, New York, and Boston. See ARCHITECTURE, COLUMN, MODULE, RENAISSANCE ARCHITECTURE, and the brief articles on the several orders; also *Treatise on Civil Architecture*, by Sir William Chambers (London). A. D. F. HAMLIN.

Orders, Religious: See MONACHISM.

Ordinance of 1787: The confederation of the U. S. was delayed and put in jeopardy more by a dispute as to what should be the fate of the unoccupied lands at the West than by anything else. The large States, which by their charters extended to the "South Sea," claimed to have the entire disposal of and jurisdiction over the territory within their boundaries as described in charters proceeding from the crown of England. Some of the States not thus richly provided with unsettled lands, as Maryland and New Jersey, claimed that the States which were proprietors of them ought to yield them up as common property for the benefit of all, since the efforts of all the States had secured the acknowledgment of independence from Great Britain. In 1780 New York gave authority to its delegates in Congress to fix a limit for its western boundaries, and to cede a part of its lands for such States as should become members of the Confederation. It was not until the next year that Maryland, last of all the States, joined the new league. Soon afterward the State of Virginia gave up her lands N. W. of the Ohio for the general benefit; but it was not until 1784 that an ordinance for the temporary government of the Northwest Territory, which emanated from a committee of which Jefferson was chairman, was passed by the Congress of the Confederation. Jefferson's act provided for the formation on this soil of States which might be organized whenever there should be 20,000 inhabitants on the territory to be formed into a State, and which might be admitted into the Confederation on certain terms whenever their inhabitants should be equal in number to those of the smallest of the original thirteen States. It also contained this provision in its original form as presented to Congress; "that after the year 1800 there should be neither slavery nor involuntary servitude in any of the said States, otherwise than for the punishment of crimes, etc." This anti-slavery clause was lost, and the ordinance without it was passed Apr. 23, 1784, but no settlements were made within the territory in question for some years.

Two other attempts at legislating for the Northwestern Territory were made in 1785 and 1786, and the committee appointed in the latter year to consider this subject made a report which was ordered to a third reading in 1787. Very fortunately the bill reported was laid aside, and a new committee, appointed July 9 of the same year, reported two days later the ordinance of 1787, which became a law in two days after it was submitted to Congress. It related to the whole of the Northwest Territory, and included what afterward constituted the States of Ohio, Indiana, Illinois, Michigan, and Wisconsin. This ordinance, besides defining the rights of the citizen, contained provisions of great importance. The fourth article prohibited slavery and involuntary servitude except in punishment of crimes. Another article provided that the navigable waters leading into the Mississippi and St. Lawrence, and the carrying-places between the same, should be common highways, free to the citizens of the U. S. The importance of this ordinance in shaping the destinies of the U. S. is beyond calculation. It can scarcely be doubted that if slavery, even a small percentage of it, had been able to creep into the territory where the great free States of the West, E. of the Mississippi and N. of the Ohio now lie, the U. S. would have become a slave republic. Another declaration of great importance was that in regard to education, in which it was declared that "religion and morality being necessary to the welfare of the State, therefore schools and the means of education shall for ever be encouraged." On the basis of this declaration the Constitutional Conventions, as well as the Legislatures of the several States formed of the Northwest Territory, have felt bound to make liberal provisions for all grades of educations. It has been generally supposed that Nathan Dane, of Massachusetts, then in the Congress of the Confederation and a member of the committee which reported the ordinance, was its principal author; but it has been shown by Dr. W. F. Poole and others, from documents which had not been used before, that the authorship of it belongs mainly to the Rev. Manasseh Cutler, who appeared in New York, where the last Congress of the Confederation was then sitting, and who was ready to purchase 1,500,000 acres in Ohio for a company composed of officers in the then recent war living in Eastern Massachusetts, and 4,000,000 acres for other parties in case the ordinance should be adopted. The history of Cutler's connection with the ordinance may be found in *The North American Review* for Apr., 1876, and in W. P. Cutler's *Life, Journals, and Correspondence of Manasseh Cutler* (1888).

T. D. WOOLSEY. Revised by C. K. ADAMS.

Ordinances: See BY-LAWS.

Ordinary [from Lat. *ordina'rius*, orderly, regular, deriv. of *or'do*, order]: In the later Roman empire the official who heard and decided in first instance the more important civil and criminal cases (the president of the province) was commonly described as the ordinary judge (*judex ordinarius*). In the mediæval Church judicial powers were vested, in first instance, in the bishop of each diocese; and the ecclesiastical law, which was largely based upon the Roman, transferred to the bishop, as a judicial officer, the Roman title of judge ordinary. The judicial powers of the bishop, however, were commonly delegated to and exercised by a deputy or surrogate (*subrogatus*).

The jurisdiction claimed and exercised by the mediæval

Church extended over marriage and family law in general, and over cases of testamentary and interstate succession, as far at least as the personal estate was concerned. In modern states this entire jurisdiction has been transferred to the civil courts, but in England, even after the Reformation, it was exercised by special tribunals (ecclesiastical courts), and in the U. S. probate business at least is still regularly assigned to special judicial officers, who in many of the States retain the designation of "ordinary" or "surrogate." MUNROE SMITH.

Ordinate [from Lat. *ordina'tus*, perf. partic. of *ordina're*, appoint, order, arrange, deriv. of *or'do*, *or'dinis*, series, order]: in co-ordinate geometry, one of the elements of reference used to determine the position of a point with respect to the co-ordinate axis. It is the distance of the point from the axis of abscissas, measured on a line parallel to the axis of ordinates. Every function of a single variable may be regarded as the ordinate of a point of a curve of which the variable is the corresponding abscissa. This curve is called the curve of the function.

Ordination [from Lat. *ordina'tio*, appointment, ordering, deriv. of *ordina're*, appoint, order, ordain]: the ceremony by which ministers of the Christian Church are dedicated to their office. It is performed in a somewhat different manner, and somewhat different ideas are attached to it, in the different Christian Churches, but the ceremony itself and its principal feature, the imposition of hands, are as old as the Church, and are mentioned in the New Testament (Acts vi. 1–7; xiii. 1–4; xiv. 23; 1 Tim. iv. 14; 2 Tim. i. 6). In the Greek and Roman Churches ordination is considered a sacrament; that is, a special divine gift, a new spirit, a fitness for the office, is believed to be conferred by the ceremony upon the candidate, and he is thus, at once and for ever, set apart from the laity and entered among the clergy, *ordo*. In order to be valid ordination must be performed by a bishop of the Church, and if once duly performed it can never be forfeited or made invalid by any act of the ordained in his after life, and it is not repeated when the candidate ascends from one rank in the Church to another. An ordination is not lawful, however, because it is valid: the Roman Catholic Church has enacted very strict and very minute laws concerning this point. A candidate can be lawfully ordained only by his own bishop—that is, the bishop to whom he belongs by birth, by domicile, by benefice, or by connection of personal service—and any irregularities render both the ordaining bishop and the ordained candidate liable to heavy ecclesiastical penalties. In the Protestant or Evangelical Churches ordination is not considered as sacramental or indelible, though it has been questioned in the Church of England whether a bishop could be lawfully deprived of his orders as bishop. The Church of England has generally retained the regulations of the ancient canon law, according to which no one could be ordained who was not provided with some appointment in the Church capable of maintaining him, or who was disqualified by bodily infirmity, immorality, etc., nor could the ordination take place until after an examination of the fitness of the candidate. The ordinal, as drawn up under Edward VI., then modified in the reign of Elizabeth, and finally fixed by the convocation of 1661, also resembles the ancient service, though it is simpler, and lays a particular stress on the examination. A clergyman may be suspended or deprived of his ecclesiastical benefices by his bishop without forfeiting his ordination. He is deprived of his status of priest or deacon only when he is deposed or degraded on account of his being convicted of treason, murder, or felony. In the Presbyterian Church when a minister is deposed he forfeits not only his office but his clerical status. Those who accept the idea of a universal priesthood of believers view the ministry as a calling rather than an office, and consider ordination simply as a solemn ceremony, conferring no special gift and establishing no special status, but beautiful by itself on account of its pious remembrance of the time of the apostles.

Revised by S. M. JACKSON.

Ordnance [an old form of *ordinance*, ordaining, arrangement, decree, preparation, provision, from Lat. *ordina're*, appoint]: guns, howitzers, and mortars. The term *ordnance* is synonymous with *artillery*, but less comprehensive in its meaning. It signifies cannon, and these simply as material and nothing more. Its application as a military term had its origin from an *ordinance* promulgated in the reign of Henry VIII. of England, regulating the caliber, figure, and dimensions of cannon. Under this a board—which subsequently took the name of the ordinance or ordnance board—was established, charged with the care of crown fortifications and their armaments. Prior to this, artillery, as well as arms of all kinds, had been fashioned according to the fancy of each manufacturer, and the object and effect of the ordinance was to establish uniformity. Arms made in conformity to the specifications of the board were termed *ordinance* or *ordnance*, in contradistinction to those of irregular pattern; and from this sprang the custom of designating all artillery as ordnance. In addition to cannon, strictly speaking, the U. S., following the English custom, has extended the term ordnance to include all firearms of every description, whether cannon or small-arms. The term *ordnance stores* comprehends every description of ammunition, all carriages used for artillery purposes and their equipments, and all other apparatus and machines required for the service and manœuvers of artillery, together with the materials for their construction, preservation, and repair; also all side-arms and accoutrements for artillery, cavalry, and infantry, together with utensils and stores for laboratories. For the various steps of development leading up to modern ordnance, see ARTILLERY.

Since 1860 the entire system of gun-construction throughout the world has been revolutionized. The chief, if not the primary, impulse to this was imparted by the battle between the U. S. ironclad Monitor and the Confederate ironclad Merrimac in Mar., 1862. Up to this period the art of constructing armor-clad vessels had not progressed beyond the experimental stage, and the battle referred to was the first practical test of armor *versus* guns. The maritime nations of Europe, taking alarm at this successful application of the armor principle, at once began remodeling their navies, and clad their vessels with a thickness of plating before unknown. To meet these new conditions guns were devised capable of piercing the heaviest armor then in existence. Then more powerful armor of steel was adopted, and still more powerful guns constructed. The contest yet continues. In its progress it has evoked much scientific study and mechanical ingenuity, leading through various stages to the present system of "built-up" guns. Pieces of this nature are constructed of an inner tube, forming the bore, and certain bands and hoops surrounding and strengthening it. This method of construction admits of the principle of initial tension, a chief factor in the strength of modern artillery. This principle is based upon the phenomena of elasticity, and in gun-construction is utilized by shrinking successive layers of metal one over the other, each being given an initial strain to assist it in supporting the layer underneath. (See under GUNNERY, *Interior Ballistics*.) The cost of guns constructed on the built-up principle is enormously great as compared with cast-iron pieces of equivalent calibers.

In 1883 the U. S. Government sent to Europe a mixed commission of army and navy officers to examine and report upon the most advanced methods there in use. Special inquiry was made as to the systems pursued by the leading European nations for supplying themselves with artillery. The board found the system in vogue in France (since the Franco-German war) the most promising of good results, and accordingly recommended it. In this system the Government depends upon the private industries of the country for foundry-work—i. e. for the rough forgings of the various parts of the guns; but for assembling and finishing work the Government has its own factories.

Acting upon these recommendations, the Government established two gun-factories—that for the army at the Watervliet arsenal, Watervliet, N. Y., and that for the navy at the Washington navy-yard. The board, in its recommendations, emphasized the necessity of proper encouragement to the private steel-manufacturers of the U. S. by such liberal appropriations for gun-forgings as would induce them to expand their plants and means of production. Liberal appropriations of money by Congress soon followed, and under this stimulus several steel-foundries expanded their plants to a capacity equal to any requirements. Chief among these works is that at Midvale, Pa., and that at Bethlehem, Pa., both of which are capable of fabricating forgings for guns up to and even beyond 12 inches caliber.

Description of Heavy Ordnance.—All guns, howitzers, and mortars of the built-up system consist essentially of a tube, surrounding bands, and the breech mechanism. They differ but little except in dimensions of parts and the number of bands. For a general description of the U. S. system the

8-inch rifle may be taken as a fair type. This piece (see Fig. 1) is composed of a tube, a jacket, 8 C, 3 D, and 7 A hoops, a breech-block receiver, and the various parts of the breech mechanism. The tube is 266 inches (22 ft. 2 in.)

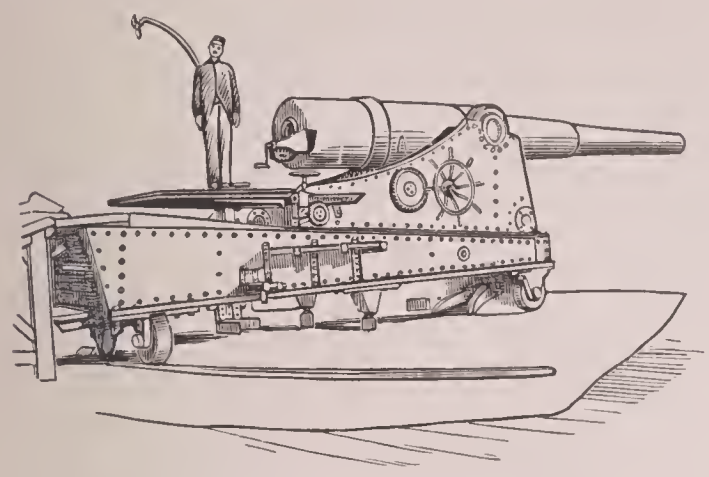


Fig. 1.—8-inch breech-loading rifle.

long, and has an exterior diameter of 15 inches at the breech and 11·5 inches at the muzzle. This tapering is by nine shallow steps or shoulders against which the jacket and certain of the hoops abut. The jacket is an elongated hoop embracing the rear part of the tube for a distance of 96·6 inches, and extending beyond the rear of the tube 12·5 inches. The front end of the jacket rests about 19 inches in front of the axis of the trunnions; from this point to the muzzle the tube is enveloped and strengthened by eight hoops, technically known as C-hoops. These have varying widths, the average being 21·2 inches; the rear one—that next the jacket—has an exterior diameter of 18·25 inches, while that at the muzzle has but 14 inches, this being the diameter of the finished piece at this part.

The jacket and C-hoops constitute the first layer over the tube. Then comes the layer of D-hoops, three in number, having an average width of 22·5 inches. The rear D-hoop overlaps an offset on the front end of the jacket; the other two break joints with the underlying C-hoops. The rear D-hoop—partly covered by the front A-hoop—has an exterior diameter of 24·5 inches; from here forward the D-hoops have a uniform taper to a diameter of 17·6 inches, when the end of the front one is rounded off, forming the first projection, or offset, on the finished piece.

Next come the A-hoops, seven in number, covering the entire length of the jacket and part of the rear D-hoop. They have varying widths, the total being 112·75 inches. The second from the front constitutes the trunnion band; the one in front of it tapers and is rounded in front, forming the second offset or shoulder on the exterior of the finished piece. The exterior of those in rear of the trunnion hoop have no taper.

The 10 and 12 inch guns have another layer of hoops covering the A-hoops from the breech to the front of the trunnions; the last, or front one, is the trunnion band, and

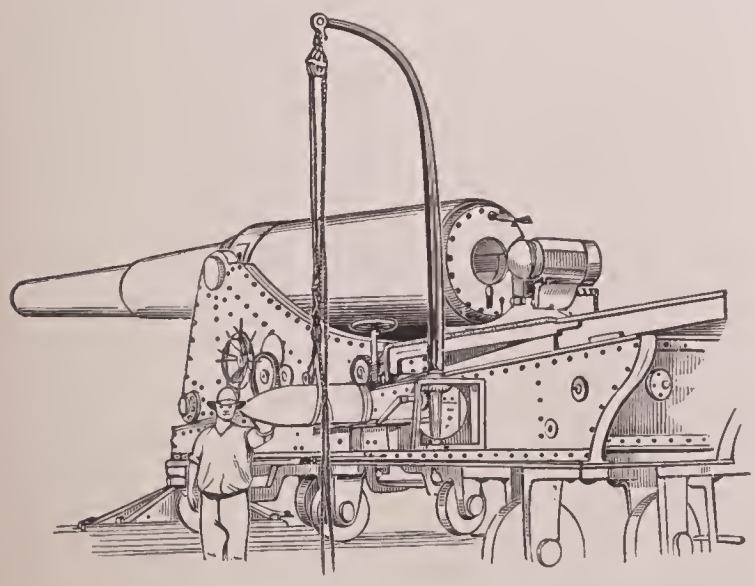

Fig. 2.—12-inch breech-loading rifle.

being rounded off in front forms a shoulder on the exterior of the piece. Fig. 2 represents a 12-inch rifle ready for loading.

The exterior of the muzzle of the tube is made slightly conical, with the base of the cone to the front; the interior of the front C-hoop being also conical—but in the opposite direction—prevents, when the latter is shrunk on, all possibility of slipping forward. The jacket sustaining the breech mechanism is prevented from slipping to the rear by a projection on its front end engaging a shoulder on the tube. The entire system—tube, jacket, and hoops—is thus united into one compact body.

The rifling occupies 200·76 inches of the bore, the remaining 60·74 inches being taken up by the seat for the shot, the powder-chamber, and the seat for the gas-check. The shot-seat and the powder-chamber are connected by a sloping surface, 10 inches in length, to give facility in shoving the shot home to its seat. The rear ends of the lands are sloped for the same purpose. The powder-chamber of modern guns is made larger than the bore, in order that the enormous charges now used may not take up so much of the length of the bore. This increase of diameter possesses also other advantages of a ballistic nature. (See Gunnery.) The powder-chamber of the 8-inch rifle has a capacity of 3,609 cubic inches, or of 130 lb. of powder.

The gas-check seat, 2·5 inches long, is a slightly tapering enlargement of the rear end of the powder-chamber, and is intended for the reception of the gas-check, hereafter described. The shot when in position for firing rests directly between the trunnions; its base, with the copper rings to take the grooves, rests in the shot-chamber.

The breech mechanism, although originally invented in the U. S., is a modification of what is known as the French system. The principal parts are the receiving-ring, the breech-block, the obturator, the console or loading-tray, and the breech-plate. The extension of the jacket beyond the rear end of the tube forms a recess for the reception of an inner hoop called the receiving-ring, which has the same thickness, viz., 2·75 inches, as the end of the tube against which it abuts. A screw-thread is cut on its exterior, which works in a thread on the interior of the jacket, the ring is then set home by powerful leverage, the junction between the ring and end of the tube being hermetically sealed by a thin ring of copper. The interior of the receiving-ring contains slotted screw-threads into which similarly slotted threads on the breech-block engage. There are three of these slots, each occupying one-sixth of the circumference of the interior of the receiving-ring, and running longitudinally. The breech-block is turned on its axis to engage or disengage the slotted screw-threads by means of a pinion and circular rack, for which recesses are cut in the upper part of the breech-plate. When disengaged, the slots of the receiver being opposite the threaded portions of the breech-block and *vice versa*, the breech-block may be moved back and forth with freedom; when engaged, the bore is closed ready for firing the same as though the threads were continuous.

The obturator consists of a steel head of mushroom shape, of the diameter of the powder-chamber, the rear part of which it occupies; this head is attached to a spindle which works with freedom through the axis of the breech-block, to the rear end of which it is secured by a screw and nut. In rear of the mushroom head are two annular cups of elastic steel surrounding the spindle. These cups inclose between them a canvas pad containing a mixture of tallow and asbestos. The spindle is fitted to allow a certain amount of longitudinal motion within the block, so that when the piece is fired the gas pressure on the mushroom head forces it back upon the annular cups, compressing the canvas pad until it swells out against the walls of the bore, thus making a tight packing, effectually preventing the escape of gas to the rear. After the explosion a spring at the rear end of the spindle forces it forward to its former position, thus releasing the cups and packing from pressure, and allowing the breech-block to be withdrawn without difficulty. One packing-pad will stand many rounds, and when no longer serviceable is readily replaced by a fresh one. The vent is bored longitudinally through the spindle and mushroom head. An automatic safety-cover keeps it closed except when the breech-block is in position ready for firing.

The console, or tray, is an irregularly shaped bronze casting attached to a hinge fastened to the breech of the piece, and is intended to receive the breech-block when withdrawn from the bore and swing it around on a hinge to one side. As the breech-block is heavy, it is moved back and forth on the tray by means of a translating roller, on which is cut a

screw-thread, of considerable pitch, into which engages a stud on the bottom of the block. On the under side of the tray is a latch securing it to the breech of the piece, when the block is being withdrawn from or inserted into the bore.

The breech-plate is a 4·5-inch thick steel disk attached by screw-bolts to the breech of the piece, covering and protecting the breech mechanism, and giving support to some of its parts. An opening is cut in the central portion of the plate, through which the breech-block enters to close the bore.

To operate the breech mechanism, suppose the breech closed as though ready for firing; to open it, turn the rotating crank in the direction marked "open"; this rotates the breech-block to the proper position to be withdrawn. While the block is making this one-sixth of a revolution it is moved slightly to the rear by the action of the screw-threads, and this loosens the gas-check from its seat. As soon as the motion begins the vent-cover slides into position, thus preventing the insertion of a primer until the block is again in position for firing. The translating stud of the block at the same time enters the thread of the translating roller, the crank of which is now turned to the left, causing the breech-block to slide back upon the tray. When the block is withdrawn to the proper point the tray-latch is disengaged automatically from its catch, allowing the tray and block to be swung around by hand to the right, until the securing latch catches and holds it in that position. The piece is now ready for loading.

The operation of closing the breech is almost the reverse of the foregoing.

Forging.—All of the parts of a gun, forged and fashioned in the rough, are furnished by the steel contractor. The metal is steel of a low percentage of carbon, commonly called low steel. This is melted and brought to a proper physical and chemical condition in an open-hearth furnace —the Siemens furnace. (See FURNACE.) From the furnace the liquid metal is drawn off into cylindrical moulds of great strength and peculiar construction. These are placed under a powerful hydraulic press, which expels all gas from the fluid mass and compresses it into a dense ingot. Some of the ingots thus treated weigh upward of 40 tons. After cooling the ingot is transferred from the mould to the lathe, where it is bored and cut to proper lengths for the parts to be forged from it.

To forge one of these sections to a required figure it is placed in a furnace heated by coal-gas—all the heating is done by gas—where it is brought to a glowing heat, and then transferred to the hydraulic forging-press, where it is fashioned into the desired shape, the soft metal being moulded into shape as putty is moulded in the fingers. Owing to the great weight of the ingots and forgings, the most powerful cranes and other machinery, set in motion by compressed air, are employed for handling them. Metallic templetes are used by the workmen in fashioning the forgings as the pressing progresses.

The forgings are now rough-bored, turned, and machined to the required dimensions, which is just sufficient to admit of proper tooling in the assembling and finishing process at the gun-factory. After this the parts are oil-tempered and then annealed. These two processes impart to the metal toughness with the required degree of hardness. In oil-tempering the tubes and jackets are heated vertically and as evenly as possible; they are then immersed in rapeseed oil, in the direction of their axes, in such manner that a current of the fluid flows through the bore. This operation must always be performed on the whole of each piece at one time.

For annealing, which removes any strains that may have been produced in tempering, the tubes and jackets are heated as evenly as possible; this operation also is performed on the whole piece at one time. The degree of heat, which is generally that producing a salmon color, is maintained uniformly for several days.

After the tempering and annealing treatment, should a part be found to have warped or bent to such a degree as to require straightening, it is returned to the forging furnace and press and tempered and annealed again. All the hoops and the forgings for the various parts of the breech mechanism are treated in like manner.

The forgings, stamped and numbered, are delivered to the Government on board of cars at the foundry, whence they are transported to the Government gun-factory. The present cost of a set of forgings for an 8-inch gun is $10,938, or 27½ cents per pound. For the 10-inch gun the cost is $24,865, or 30¼ cents per pound. For the 12-inch gun it is $42,218, or 30½ cents per pound.

During all of the foregoing operations each process is subject to the inspection of expert officers of the ordnance department, who are stationed at the foundries for that purpose, and for this it is stipulated in the contracts that they and their employees shall be allowed free access at all times to every part of the manufacturers' works; but the details of operations carried on are considered confidential so far as the manufacturers may desire. Each establishment has its own chemist, laboratory, and testing-machine. The latter is compared with and adjusted to the Government machine at Watertown arsenal, thus assuring uniformity of results among all establishments supplying forgings. The test specimens have a stem length of 3 inches, with a diameter of 0·564 inch, and the specifications are very precise as to their number and the part of the forging from which taken. They must show an elastic limit of not less than 42,000 lb. per square inch for tubes and 46,000 lb. for jackets, and a tensile strength of not less than 78,000 lb. for tubes and 86,000 for jackets. A tabulated record is kept of all these tests, so that the Government has a complete history of the fabrication of each piece and the strength and composition of each fiber of its body.

Assembling the Piece.—The first operation in assembling the forgings received from the founder is to place the tube in a lathe, where it is bored and reamed to within about a tenth of an inch of the exact diameter of bore; at the same time the exterior is turned to the proper dimensions for the hoops. It is then faced at the rear end, from which all measurements are made. The powder-chamber is next bored and reamed, as also the conical junction between the chamber and bore.

The jacket is then bored and reamed to fit the shoulder left on that part of the tube over which it is to fit. The interior diameter of the jacket is about 0·02 inch less than the exterior diameter of the tube. This is for the purpose of bringing an initial strain on the jacket after it has been shrunk to the tube. The shrinkage allowance for each part is taken from tables carefully prepared from a long course of experiments, conducted for the purpose of determining the most suitable strains.

The next operation is to shrink the jacket on the tube. The assembling-pit, about 30 feet deep and 8 feet in diameter, is so arranged as to receive and sustain the tube in a vertical position. The tube is adjusted muzzle upward in the pit; the jacket is brought to the proper temperature (about 600° F.) in the furnace, swung over the tube by means of a crane, and then let down over the tube a short distance, after which the tube is pulled up through it, by means of the crane, until the shoulders come together. A water-collar and water-rings are then adjusted to perform the function of jetting water upon the precise parts to be first cooled. The whole is then allowed to cool, after which the now united tube and jacket are removed from the pit to rest in a horizontal position. The first C-hoop is now heated for expansion, slipped over the tube, and tightly clamped up against the jacket by means of a powerful clamping device, when it is allowed to cool. After this the piece is returned to the lathe, and the shrinkage surface of the tube turned for the next two C-hoops, which are now shrunk on, following which the piece is again returned to the lathe, and the shrinkage surface of the tube is prepared for the remaining C-hoops, and also that portion of the jacket and of the C-hoops to be covered by the D-hoops, all of which are now shrunk on in succession. The exterior of the jacket is next turned and the A-hoops shrunk into position. While the exterior is being turned and finished, the bore (now diminished by the heavy pressure brought upon the tube by the shrinkage of jacket and hoops) is reamed out to the precise caliber of 8 inches. At the same time the powder-chamber, the seat for the shot and for the gas-check, are bored to the proper dimensions, the whole interior being given a well-polished surface. The threads for the breech-block receiver are now cut, and the latter is screwed home against the thin copper ring fitting between the receiver and the rear end of the tube, and intended to prevent all escape of gas in this direction. The next operation is to slot the receiver and cut the threads for the breech-block. The piece is now rifled. For the number and dimensions of grooves and lands, see table at end of article. The twist of the rifling is increasing, being one turn in 50 calibers at the breech, and 25 calibers at 16 inches from the muzzle, from which point

it is uniform. The various parts of the breech mechanism are now fitted on, and the gun is complete.

The Appropriation Act passed by the U. S. Congress in 1890, supplemented by that of the following year, directed the purchase of 100 completed guns, viz., 25 8-inch, 50 10-inch, and 25 12-inch, the total expenditure for which shall not exceed $4,250,000. The length of time required for the production of these guns, including the time required for the erection of a gun-factory plant, is estimated to be about ten years.

Mortars, as well as guns, are now constructed on the built-up principle, and are also breech-loading. A mortar thus constructed is, in general features, but a gun of the same caliber shortened. A mortar of the 12-inch type is made up of an interior tube, a jacket, and one layer of hoops. The breech mechanism is the same as for guns. For weight, dimensions, etc., see table at end of article.

Carriages.—The great weight and power of the new guns require proportional strength and mechanical appliances in the carriage. A thoroughly equipped carriage for a modern piece is a machine almost as complicated in construction as a locomotive. Owing to the very great accuracy of modern fire and the rapidity of discharge of machine-guns, it becomes an essential condition that the pieces and their carriages, as well as the cannoneers, should be protected. The tendency is therefore to resort to armor-shields and to disappearing carriages. In the latter case the gun is exposed to the fire of the enemy only for a brief period—at the time when it is hoisted above the parapet to its firing position. After discharge the piece disappears behind the parapet, where it is again loaded in security. One form of such an arrangement is a gun-lift, by means of which gun and carriage are hoisted and lowered on a platform by means of hydraulic power. The most general form, however, is some application of the counterpoise principle. Still another form, and one promising good results, is a pneumatic disappearing carriage.

Another difficult problem is a suitable carriage for the modern high-power, breech-loading mortar, the conditions for which embrace enormous strength to resist the great strain of vertical fire, together with the freedom and precision of motion demanded by this class of artillery. A mortar mounted on one form of such carriages—the hydro-pneumatic carriage—is illustrated by Fig. 3.

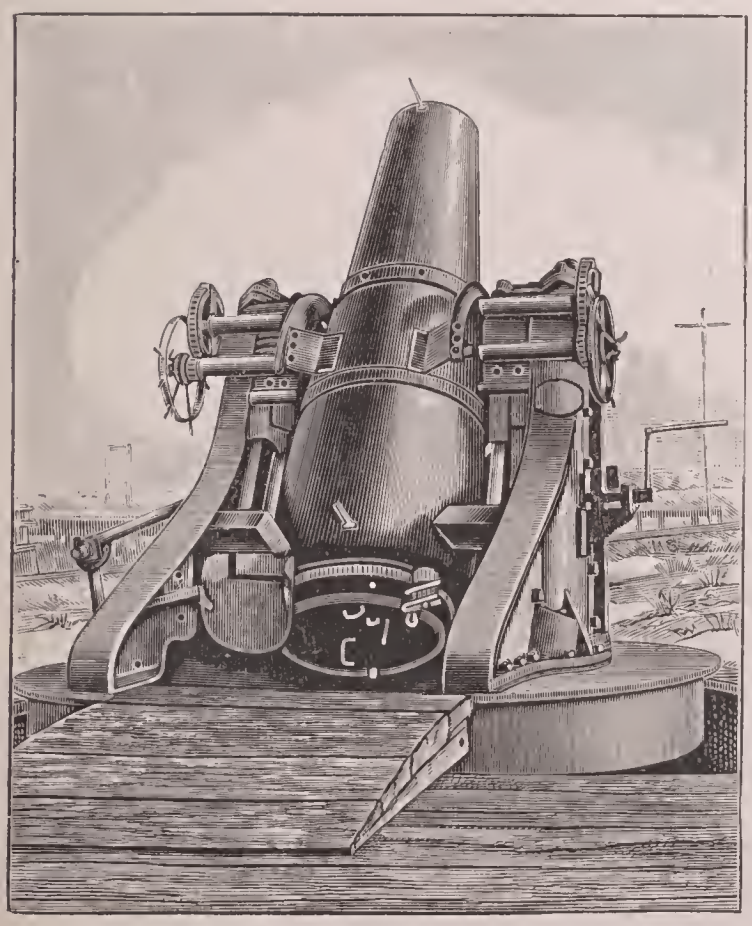

Fig. 3.—Modern breech-loading mortar.

Field Ordnance.—A new type of field-gun has been introduced by the U. S. Government. In this piece there are no hoops proper. The trunnion band and jacket are forged in one piece. The breech-block, being comparatively light, dispenses with the tray, and is supported by a ring hinged to the breech of the piece, which swings readily to one side. For dimensions, etc., of this piece, see table at end of article. The carriage and caisson for this piece are of steel so far as practicable; the only parts of wood being the felloes, spokes, pole, and the ammunition-chests. A swinging bar takes the place of the old-fashioned pole-yoke. The rigid splinter-bar of the old carriages is replaced by a movable double-tree, similar to that of ordinary carriages. The ammunition-chests, dispensing with trays, are much lower than formerly. Each one carries 42 rounds, making 168 per gun. For each battery of six pieces three extra caissons are allowed, making in all 33 chests carrying an aggregate of 1,386 rounds. The battery-wagon and forge of the old system have been united into one carriage, resembling in appearance a caisson.

The U. S. system of field artillery embraces a 3·6-inch breech-loading mortar—a short light piece (Fig. 4) intend-

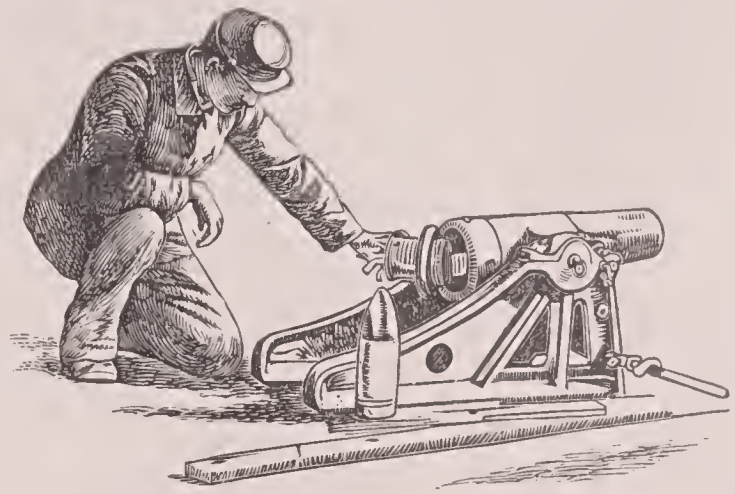

Fig. 4.—Breech-loading mortar for field use.

ed for vertical fire, chiefly against the *personnel* of an enemy protected by field intrenchments or inequalities of the ground against the direct fire of field-guns. It takes the place of the old Coehorn, but is much more powerful, accurate, and far-reaching. The body of the piece is made of a single ingot of forged steel, having the trunnions forged solid with the piece. The breech mechanism is similar to that of field-guns. The carriage is of bronze, cast chiefly in one piece, and when in position for firing rests directly on the ground; in transportation it, with the piece, is carried on a wagon especially devised for it—three on one wagon.

A 5-inch gun has been devised for light siege or heavy field service. In general construction it is similar to the 3·2-inch field-piece. For dimensions, etc., see table at end of article. The carriage supporting the piece is of steel, to be attached to a limber for traveling. The most noticeable feature about the carriage is the great height of the trunnions (72 inches) as compared with ordinary field-carriages. This is to admit of high elevation in firing. In the ordinary field-carriage the lowness of the trunnions is noticeable. Owing to the heavy charges used the recoil is excessive; to check this an hydraulic buffer, consisting of a cylinder and piston, is attached to the carriage and to a pintle firmly secured to the front of the platform on which the carriage stands. The piston-rod is attached to the under side of the stock, and the front end of the cylinder to the pintle.

The 7-inch siege-howitzer, the dimensions of which are given in the table at the end of this article, has about the same construction as the siege-gun just mentioned, except that it is very much shorter; the carriage for it is almost identical.

A 3-inch Hotchkiss rapid-firing gun has been adopted as a mountain-piece, to take the place of the small bronze mountain-howitzer of the old artillery.

Pneumatic Dynamite Gun.—Much ingenuity has been expended to devise some means of safely firing shells loaded with high explosives from ordinary powder-using guns. Although some experiments in this direction have been successful to a limited degree, the problem, as a whole, is as yet quite unsolved.

About 1885 a pneumatic gun capable of throwing heavy charges of high explosives was produced in the U. S. This machine, often called the Zalinski gun, consists essentially of a long steel tube, made as light as admissible, an air-reservoir, and a system of valves and other mechanism at

the breech for the control of compressed air, the propelling force of the projectile. The piece is provided with trunnions, supporting it on a carriage. one form of which resembles in general appearance the top carriage of an ordinary barbette gun. (See Fig. 5).

limited to about 5,000 yards. The piece is fired at a high elevation, giving the trajectory the character of that of the ordinary mortar shell.

The success attending the firing of an 8-inch piece of this character induced Congress to authorize the procurement of

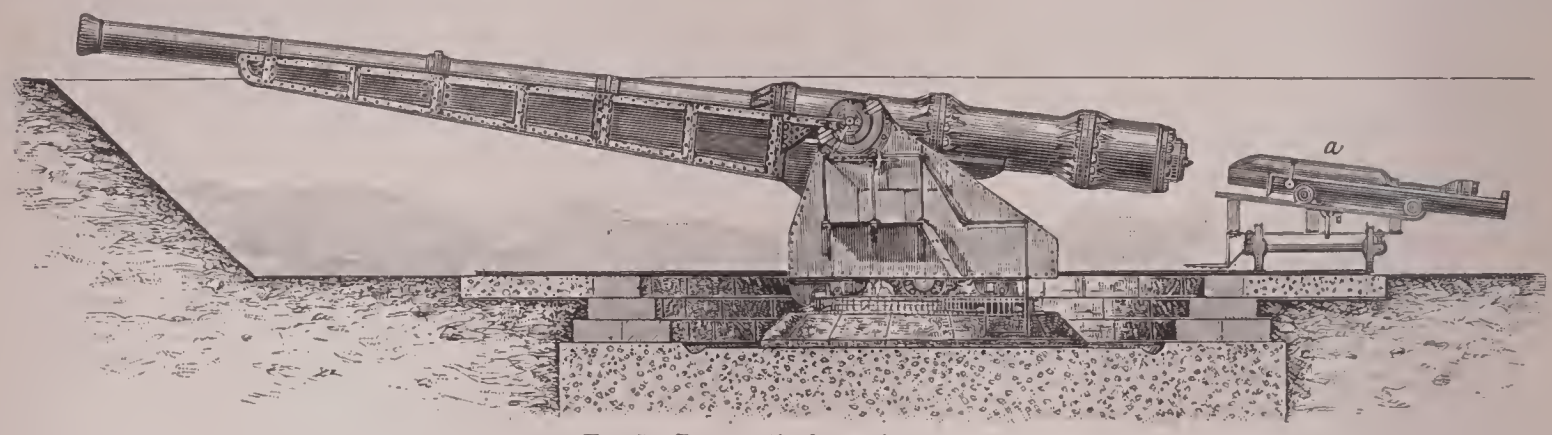

Fig. 5.—Pneumatic dynamite gun.

The tube is supported underneath by a cantilever steel truss, extending forward almost to the muzzle. The piece, as its name implies, is simply an air-gun. The air-compressor is a complicated system of cylinders, pistons, chambers, coolers, pipes, and valves. This apparatus is disposed of under and within the carriage, and is operated by a steam-engine, which may be at any convenient distance from the piece. The working capacity of the apparatus admits of about ten shots per hour, and the valve arrangements are so nicely adjusted as to admit the required amount of air with as much precision as gunpowder is weighed for ordinary guns. The projectile is simply a vessel to convey the explosive agent against or near the object to be destroyed, and consists of an elongated metallic cylinder to which is attached an ogival head containing the fuse mechanism. To the rear end of the cylinder is attached some form of oblique flanges, which, acting against the air, gives rotation to the projectile during its flight. Such a projectile is seen at *a* in Fig. 5. Dynamite and nitrogelatin are the usual explosives. As it is all-important that the explosion should take place with certainty, and at the proper moment, the fuses are an important feature of the projectile, each of which is usually provided with three—one to act by impact against the object, one to act by immersion when the water is struck, and the other to act in case of failure of the other two. The impact fuse is similar to the ordinary percussion fuse, but the other two act by means of a complicated electrical device.

ten others, nine of which are of 15-inch caliber. Three of these are to be mounted at San Francisco, and the remainder are to be mounted at important harbors on the Atlantic coast.

Wire-wound Guns.—In the U. S. considerable success has attended efforts to produce guns by this process. Pieces of this nature consist essentially of a steel tube for the bore, and of a series of layers of wire coiled around it. During the winding process a strong tension is given the wire, decreasing gradually from the interior to the exterior. The wire—which is tinned—has a rectangular cross-section. A jacket sustaining the trunnions covers the rear part of the piece, as likewise the breech mechanism. When the wire-winding process is complete, the piece is subjected to a low furnace-heat, to effect a soldering together of the wire strands through the agency of thin sheets of soldering foil inserted between the layers of wire during the winding process.

It is claimed that serviceable guns can be constructed by this method with but moderate plant as compared with built-up pieces—a feature of great importance to a nation of defensive unreadiness.

The following table shows the principal dimensions, weights, etc., of the system of rifled and breech-loading field, siege, and seacoast artillery, adopted for the U. S. land service, and now constructed at the Watervliet gun-factory:

DIMENSIONS, WEIGHTS, ETC.	FIELD ARTILLERY.			SIEGE ARTILLERY.		SEACOAST ARTILLERY.			
	3·2-inch steel breech-loading rifle.	3·6-inch steel breech-loading rifle.	3·6-inch steel breech-loading mortar.	5-inch steel breech-loading rifle.	7-inch steel breech-loading howitzer.	8-inch steel breech-loading rifle.	10-inch steel breech-loading rifle.	12-inch steel breech-loading rifle.	12-inch steel breech-loading mortar.

The ordinary projectile for the 15-inch gun has a total length of about 10 feet, exclusive of the directing apparatus attached to its rear end. Its weight when loaded with 500 lb. of nitrogelatin is approximately 1,000 lb. The muzzle-velocity is only about 500 feet per second, and the range is

John C. Tidball.

Ordnance Department: that branch of the U. S. army which supplies arms, ammunition, and equipments to the military force of the nation. In instituting this as a separate branch the U. S. has followed the traditions of Great

Britain. The European continental states do not have such distinct organizations for the supply of ordnance and ordnance material. These duties devolve upon the artillery, and are performed by officers detailed therefrom. Attached to its department of war, each government has a bureau of artillery, which regulates all matters connected with national armament. In Germany the fabrication of arms is directed by officers detailed from the foot-regiments of artillery; the labor is performed by civilian employees. Besides Government establishments, there are private armories supplying small-arms to the Government the manufacture of which is superintended by officers of infantry.

In the U. S. the department was created a distinct branch of the military establishment in 1812, a short period before the outbreak of the war with Great Britain. Prior to this ordnance and ordnance stores had been obtained from private establishments, and were received and inspected by civil or military agents without regard to any strict system.

The duties of the ordnance department were specifically set forth in the law creating it to be the inspection and proving of all pieces of ordnance, cannon-balls, shells, and shot procured for the army, and to direct the construction of all carriages and every apparatus of ordnance for garrison and field service, and all ammunition-wagons, pontoons, and traveling forges, and also the direction of the laboratories, the inspection and proving the public powder, and the preparing of all kinds of ammunition for garrison and field service. In 1815, at the close of the war with Great Britain, the department was reorganized and its duties and powers enlarged. The officers, with a colonel at the head, were given direct military rank, and it was made the duty of the chief to make estimates, and, under the Secretary of War, to make contracts and purchases for procuring the necessary supplies of arms, equipments, ordnance, and ordnance stores. The national armories were placed under control of the department, and authority was given to establish dépôts of arms, ammunition, and ordnance in such parts of the U. S. as might be deemed necessary. These are substantially the duties of the ordnance department at the present time, except that all that relates to pontoons has been transferred to the Engineer Corps of the army. In the following year an act was passed assigning ordnance officers to their duties with the staff of the army, in the same manner as for the Corps of Engineers. Ever since then they have continued to belong to the staff.

By the act of Congress of 1821, reducing the military peace establishment, the ordnance department, as an independent bureau, was abolished. It was merged into the artillery, and the President was authorized to select from the regiments of artillery such officers as might be necessary to perform ordnance duties. One supernumerary captain was provided for each of the four regiments of artillery to perform ordnance duty. In 1832 the department was reorganized and placed on an independent footing by an act of Congress which provided for one colonel, one lieutenant-colonel, two majors, ten captains, and as many enlisted men, not exceeding 250, as the public service might require.

From time to time, but especially during the civil war, the department has been enlarged until now it consists of 1 brigadier-general, chief of ordnance, 3 colonels, 4 lieutenant-colonels, 10 majors, 24 captains, 12 first lieutenants, 4 ordnance storekeepers, and 543 enlisted men of various grades, from sergeants to privates. The enlisted men serve in detachments as guards at the various arsenals and dépôts. All operations of construction and repair at these establishments are performed by the hired labor of civilians.

Since 1874 all officers entering the ordnance have come from the line of the army, entering as first lieutenants at the foot of the list, and by competitive examination. Previous to this vacancies at the foot of the list were filled by appointments direct from the military academy, the ordnance having second grade, the engineers the first.

In supplying the *fighting* material of war the ordnance department has recourse to both manufacturing and purchasing by contract. The chief establishments for the former are the national armory at Springfield, Mass., for the manufacture of small-arms of all kinds; the Watervliet arsenal at Watervliet, N. Y., at which is the gun-factory referred to in the article on Ordnance; the Watertown arsenal, near Boston, Mass., at which gun-carriages are constructed; the Frankford arsenal, Philadelphia, Pa., for the manufacture of small-arm ammunition; and Rock Island arsenal, Illinois, at which are manufactured saddlery and other horse equipments, targets and accessories for rifle-ranges, knapsacks, haversacks, and canteens, together with other stores required for current use.

In addition to the fourteen arsenals, most of which are mere depositories of obsolete material, the ordnance department has charge of the powder dépôt near Dover, N. J., and the one near St. Louis, Mo.

The Fortification Act of 1888, resuming measures for the national defenses, established a board of ordnance and fortifications, consisting of the commanding general of the army, an officer of the Corps of Engineers, an officer of ordnance, and an officer of artillery, and by subsequent legislation a civilian. This board is empowered to provide suitable regulations for the inspection of guns and materials at all stages of manufacture to the extent necessary to protect fully the interests of the U. S., and generally to provide such regulations concerning matters within its scope as shall be necessary to carry out to the best advantage all duties committed to its charge. It will be observed that this board is constituted to subserve the best interests of the Government—the engineer to plan and construct fortifications, the ordnance to plan and construct cannon, and the artillery to use the latter and defend the works. The board meets once a month, and, besides directing how appropriations shall be carried out, passes upon inventions and improvements proposed for guns, mortars, ammunition, implements, and other kindred matters. Liberal allotments are made for inventions that bid fair to be useful. All contracts and expenditure of money are made, as before, by the ordnance department, the officers of which conduct the work and make all tests and experiments under general instructions from the board.

A permanent board of ordnance officers has existed since 1882, and carries out the details of the operations prescribed by the ordnance and fortification board. Tests and experiments are made at the proving-ground at Sandy Hook, N. J.

Beginning with the year 1882, the department has published from time to time a series of papers bearing the title *Notes on the Construction of Ordnance*, containing the results of its own investigations and experiments in the development of heavy guns, carriages, powders, etc.; also such translations of papers published in Europe as are considered important in their bearing on the manufacture or treatment of steel or the construction of cannon, carriages, etc. See Ordnance.

John C. Tidball.

Ordnance Survey: the name given to the aggregate of persons employed by the British Government, or the operations undertaken by them, for the surveying and preparation of maps of the British islands; so called from having been originally under the control of the board of ordnance. It may be said to have had its beginning in the operations conducted by Gen. Roy in 1784 for the determination of the difference of longitude of the observatories of Greenwich and Paris, though it was only in 1791 that the systematic survey of the country with the view of producing a military map of the whole kingdom on the scale of an inch to a mile ($\frac{1}{63360}$) was begun. The first sheet of this map was published Jan. 1, 1801, and in 1824 the work was so far advanced as to include the whole of the south of England, with part of Wales and a small part of Scotland, when it was in a great measure suspended in order that the survey of Ireland on the scale of 6 inches to a mile might be proceeded with. In 1840, this survey of Ireland being completed, and the military map of England finished up to the southern boundaries of Lancashire and Yorkshire, the Government decided on adopting the scale of 6 inches to a mile for the survey of the remaining counties of England and the whole of Scotland. Lancashire and Yorkshire and six of the southern counties of Scotland were accordingly surveyed on the 6-inch scale. In 1855 the scale was again changed, and that of $\frac{1}{2500}$ (25·344 inches to a mile) ordered for the cultivated districts of the four northern counties of England and of the whole of Scotland. The uncultivated districts were at the same time to be drawn on the scale of 6 inches to a mile ($\frac{1}{10560}$), and the $\frac{1}{2500}$th plan to be reduced to the 6-inch scale, so as to make the plans of every county perfect on that scale. In 1862 the four northern counties were finished, and in 1863 the extension of the large scale to those portions of the country which had been previously surveyed on the scale of an inch only was ordered. In 1893 the state of the survey was as follows:

1. Scale $\frac{1}{500}$, or 10·56 feet to a mile, and $\frac{1}{1056}$, or 5 feet to a mile. On one or other of these two scales every town of the United Kingdom which has a population of 4,000 in-

habitants or upward has been surveyed. Most of the plans are on the $\frac{1}{500}$ scale.

2. Scale $\frac{1}{2500}$, or 25·344 inches to a mile. This is the scale for the agricultural or cultivated districts. The whole of the cultivated area of Great Britain was completed in 1893, except parts of Lancashire and Yorkshire and of six counties of Scotland, which were originally surveyed, as stated above, on the 6-inch scale; it was expected that these would be completed about 1896. The survey of Ireland on this scale was only begun.

3. Scale $\frac{1}{10560}$, or 6 inches to a mile. The plans of the whole of the United Kingdom have been published on this scale. Those of Ireland were completed in 1840, those of Great Britain in 1890. Most of the latter have been produced by reduction from the $\frac{1}{2500}$ scale.

4. Scale $\frac{1}{63360}$, or 1 inch to a mile. Maps of England and Wales, most of them drawn from a special survey on a scale of 2 inches to a mile, were completed on the scale of 1 inch to a mile about 1868. In 1872 it was decided to make a "new series" map on this scale, based on the large-scale surveys. In 1893 this was still in progress, both in outline and with hills; the outline edition was to be completed about 1896, the "hills" edition about 1900. The 1-inch map of Scotland, reduced from the large-scale plans, was completed in outline in 1886, and that of Ireland reduced from the 6-inch plans was completed in outline in 1861.

The $\frac{1}{500}$ and $\frac{1}{2500}$ plans are either zincographed, or, more recently, photozincographed. The 1-inch maps are engraved on copper. The 6-inch plans were also up to about 1880 engraved on copper, but this method was then found to be too slow to keep up with the progress of the survey, and they are now photozincographed by direct reduction from the $\frac{1}{2500}$ plans. The relation between the maps on these two scales is that a 6-inch plan contains $4 \times 4 = 16$ similar rectangles, and each of these rectangles corresponds to a plan on the $\frac{1}{2500}$ scale. The plans on the $\frac{1}{500}$ or town scale are formed by dividing a $\frac{1}{2500}$ plan into $5 \times 5 = 25$ similar rectangles, and each of the latter forms a plan on the $\frac{1}{500}$ scale.

The principal triangulation of Great Britain and Ireland consists of some 250 stations, the triangle sides being in some cases upward of 100 miles in length. The angles were measured with theodolites of 36, 24, and 18 inches diameter. The latitudes of 32 stations were determined by observation, and the direction of the meridian observed in 60 stations. The triangulation was reduced by the method of least squares. Six base-lines were measured in the course of the work, but the final results are made to depend on the two lines—one in the north of Ireland (8 miles long) and the other in the south of England (7 miles long)—which were measured with Colby's "compensation-bars."

Special surveys have been and are made from time to time for the War Department and other services, not only in the United Kingdom, but, for instance, in Canada and in Gibraltar, and trained parties from the Ordnance Survey have been employed at the Cape of Good Hope and in British Columbia and elsewhere, as well as on the delimitation of various colonial boundaries. The Ordnance Survey is under the control of the Board of Agriculture. The essential feature of the organization is the combination of military and civil elements. There are employed on the survey 24 officers of the Royal Engineers, including 1 director, 4 field officers, 18 captains, and a quartermaster. There are four companies of Royal Engineers, which, including non-commissioned officers, number 361 men, and are about to be increased to 454 men. The number of civil assistants and laborers is about 2,000. At Southampton there are from 60 to 70 non-commissioned officers and men of the Royal Engineers, with 9 officers and about 700 civil assistants and laborers. In this staff are included about 70 engravers on copper, 130 zincographic tracers and printers, 50 colorists, 170 draughtsmen and examiners of plans, 6 trigonometrical computers, from 20 to 30 artificers, including 2 opticians, and about 40 photographers and engravers on glass negatives. The sum voted annually by Parliament for the prosecution of the survey varies; in 1893 it was £218,000.

A. R. Clarke. Revised by John Farquharson.

Ordovician Period: See Silurian Period.

Ore [O. Eng. *ār*, brass: Goth. *ais* < Teuton. *ais*: Lat. *aes*, *ae'ris*, bronze (for older **aies*-): Sanskr. *ayas*, metal, bronze]: a metal chemically combined, or in a native state, mechanically mixed with other substances, which render treatment necessary to separate it. In a strictly technical sense, only those substances are ores which contain the metal in sufficient quantity and of sufficient purity to make the treatment profitable. Arsenopyrite, a combination of arsenic, sulphur, and iron, contains 34·4 per cent. of iron, but is not an ore of iron, because the metal made from it is not of sufficient commercial value to pay the expenses of treating it.

Thomas Egleston.

Ore Deposits: any natural occurrences of metalliferous minerals from which one or more of the heavy metals can be profitably extracted. The ore may be a single native metal, or a chemical or mechanical mixture of metals, or a single mineral consisting of a metallic oxide or a metallic salt, or it may be a mechanical mixture of several of these minerals. Generally, the ore is associated more or less intimately with other minerals, which are called the gangue. The ore and the gangue together form the deposit.

Texture.—Metalliferous deposits sometimes consist solely of one ore, as in some occurrences of magnetite, hæmatite, spathic iron ore, galena, more often of two or more ores, with one or more minerals forming the gangue. The different ores may be intimately associated with each other and with the minerals forming the gangue, or they may exist separately and with a greater or less regularity of distribution. The more common varieties of texture, chiefly as given by von Cotta, are—

Compact, when the texture is so fine that the separate particles are not visible to the naked eye: compact hæmatite.

Granular, when the particles are visibly in the form of grains: fine-grained, medium-grained, coarse-grained, are terms used to indicate the size of the individual particles: granular magnetite, granular pyrites, etc.

Micaceous or finely laminated, when the particles are in thin laminæ or scales: micaceous specular iron ore.

Disseminated, when the ore is distributed through the gangue in grains or laminæ.

Porphyritic, when the ore is distributed as integral crystals through the gangue.

Banded or combed, when the constituents—ores or gangue or both—are arranged in parallel layers. This variety, which is very common in certain kinds of deposits, is of signal interest from both scientific and economic standpoints. Deposits having this structure were formed in cavities, fissures, caves, chimneys, and the layers indicate gradual growth under more or less varying conditions. The oldest members or layers (*a a*) formed on the opposite walls (Fig. 1), then *b b* *c c*, till finally the two youngest members, *d d*, filled the narrowed space. Frequently two contemporaneous layers, which may alone fill the vein or may form the two youngest members, consist of crystals set perpendicularly to the walls of the vein, and with their terminal faces bristling toward each other from opposite sites or interlacing (*d d* in the sketch). This symmetrical repetition is sometimes interfered with by the interposition of other layers when the vein has reopened and formed a new vein between the walls of an older one. Fig. 2 represents three distinct veins, A B C, between the same walls.

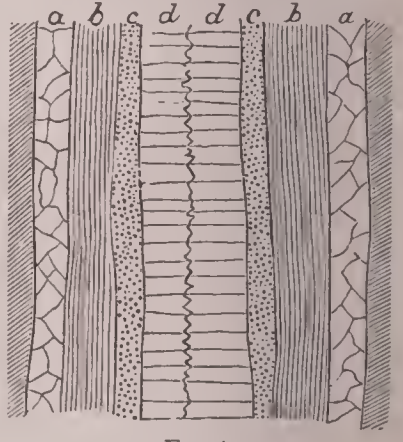

Fig. 1.

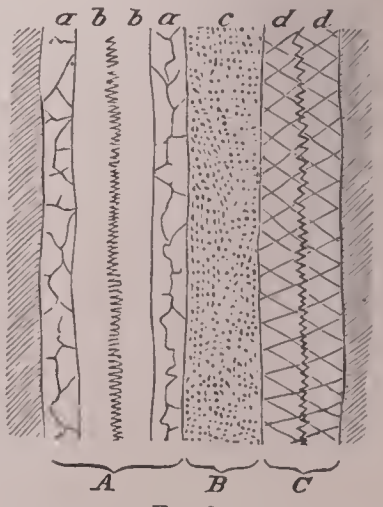

Fig. 2.

Concentric-banded, *Cocardenerze*, or *Ringerze*, when the bands are arranged symmetrically around a nucleus, which is often a fragment, as in Fig. 3.

Brecciated.—The deposits very often contain fragments of the inclosing rock or "country," or, also, pieces of still older ore-formations. When these are very numerous the texture is brecciated. Sometimes these fragments form nuclei, around which the

minerals of the ore and gangue have crystallized, forming a massive or banded or drusy cement. Very often, especially in veins, the highly altered fragments of the wall-rock form nearly the entire filling, in which the minerals of the ore and gangue are distributed in thin threads and seams. (See Fig. 4.) The texture is then generally earthy-granular or flaky and lenticular.

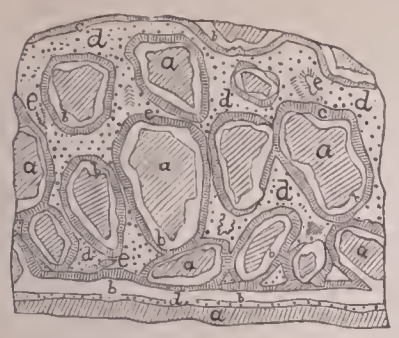

FIG. 3.—Concentric vein structure, Adalbert vein, Przibram (*Grimm*): *a*, greenstone; *b*, brown blende; *c*, galena; *d*, siderite; *e*, drusy cavities.

Drusy, when the deposit contains many cavities lined with crystals.

The boundaries of a deposit are called walls; when these are well defined, the plane between the deposit and the wall-rock is called the selvage (*Salband*); this is sometimes very smooth and highly polished (*Slickenside*).

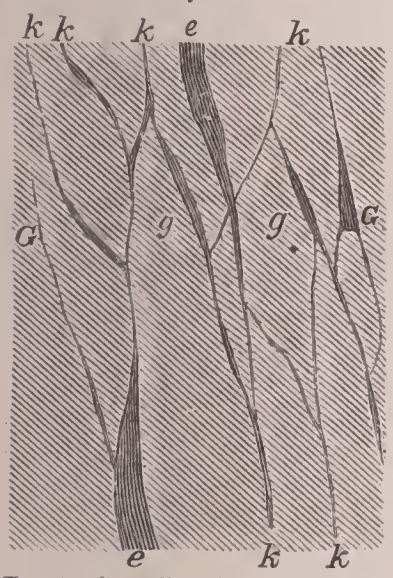

FIG. 4.—G, wall-rock; *k*, clefts; *g*, wall-rock in the lode; *e*, ore.

Succession of Minerals.—The formation of any deposit was due to slowly acting causes working during long periods of time, and often under more or less varying conditions. The progress of growth is often marked by the banded structure when present, the varying conditions by the alternating constitution of the bands, and the relative ages of the constituents by their relative positions in the separate bands or by the superposition of one upon another, forming what is called a paragenetic series, as in Fig. 5. Frequently the constituents of one of the minerals have been removed in part or wholly, and other substances have taken their place, forming a new mineral, which, however, retains the external crystalline form of its predecessor; this process, called pseudomorphism, has sometimes gone so far that a new series of minerals has taken the place of the older deposit. Limonite, pseudomorphous after spathic iron ore, is one of the more frequent instances of deposits changed as regards mineral composition.

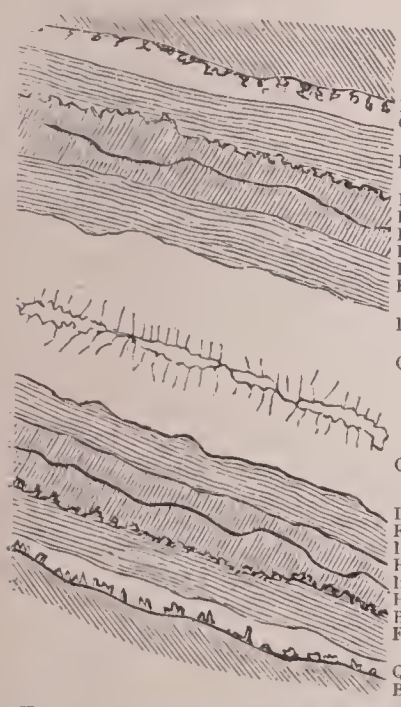

FIG. 5.—Paragenetic series (*von Weissenbach*).

Grouping of Minerals.—Certain metalliferous substances have a tendency to occur together, either chemically combined or associated as separate minerals; for instance, ores of lead and zinc, of copper and iron, of cobalt and nickel, of iron and manganese, of tin and wolfram. A similar tendency to association exists with regard to certain gangue minerals, among themselves and with certain ore groups.

Classification.—Numerous attempts have been made to arrive at a classification of ore deposits which would at the same time meet strictly scientific requirements and serve a useful technical purpose. A. Werner, von Cotta, and later, in the U. S., J. D. Whitney, R. Pumpelly, R. W. Raymond, J. S. Newberry, and W. O. Crosby, and in Europe, von Groddeck, J. A. Phillips, de Launay, and F. Posepny brought forward suggestions. The last-named proposes two principal groups—deposits contemporaneous with the country rock (*idiogenous*) and those subsequently formed in it (*xenogenous*). He adds a third class, in harmony with the older systems, which includes deposits of *débris*, calling it *hysterogenous*. With reference to the country rock he distinguishes between deposits caused by filling spaces of diseission (fissures, etc.), by filling of spaces of dissolution in soluble rocks, and metamorphic deposits in soluble rocks.

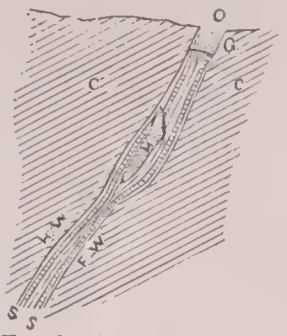

FIG. 6.—C, country rock; O, outcrop; G, gossan; H, horse; H W, hanging wall; F W, footwall; S S, selvage.

The ore deposits in spaces of diseission include those generally known as "fissure veins." The country rock has been torn asunder, the movement often being complex. Veins so formed often send out minor cracks, usually at an acute angle, into the wall-rock, which are called feeders or branches. Very often the vein incloses large masses of the wall-rock or "country," which are called "horses." (Fig. 6.) The extension of a vein horizontally is called its strike, direction, course, or bearing, and is expressed in points of the compass as N. E. by N., or in degrees of the quadrant, as N. 33° 45′ E. The vertical angle which it makes with the horizon is called the dip; thus the dip varies from 0° in a horizontal vein to 90° in a vertical one. The thickness of veins varies from a mere crack to hundreds of feet. Veins often divide into several smaller ones, which keep proximately the original strike; they are then said to split up. (Fig. 7.) In districts which contain ore-bearing veins there are almost always a number of them, and they are then often grouped in a zone of nearly parallel veins, which sometimes run together or are united by leaders. Some districts have several zones, each roughly parallel to a different direction, and the different zones are then generally of different ages and more or less different in character. It is a common occurrence to find that a vein has been subjected to an upward or downward movement of the country on one of its sides, leaving the opposite walls in different relative positions to those existing before the movement. This motion has had more or less crushing, especially of the projecting portions of the wall, for a result, and has often left highly polished wall-surfaces. Where the fissure lay in a warped plane, the tendency of a movement was to produce a vein of irregular thickness by bringing the alternating convex portions of the two walls into opposition. An important result of this is the permanent enlargement of the fissure as a whole. (Fig. 8.) The evidence of movement having taken place in a given vein is found in the relative displacement of the opposite sides. This is marked by interruption of the continuation of individual strata if the country rock is stratified (Fig. 8), or, if the vein intersects dikes or other veins which are older, by the displacement of these.

FIG. 7.

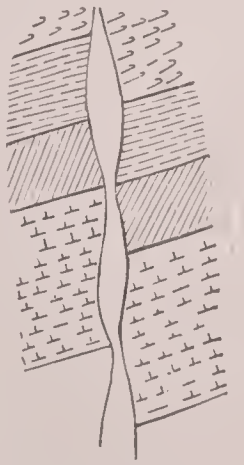

FIG. 8.

The second group, that of deposits which are fillings of spaces of dissolution, includes, according to Posepny, the majority of the deposits in limestone. Conspicuous among them are those of Leadville and of Eureka, Nev. An ideal section of the latter, after J. S. Curtis, is shown in Fig. 9, in which *a* represents the quartzite, *b* crushed limestone, *c* limestone, *d* shale, *f* stratified limestone, *x y* the ore body, and *m* the Richmond shaft. Posepny includes in this group also the lead and zinc deposits of Missouri and Wisconsin.

Among the "metasomatic" deposits which made room for themselves by the expulsion of an earlier mineral, Posepny includes the copper shales of Mansfeld, the lead-carrying sandstones of Mechernich, Germany, the silver deposits of Silver Reef, Utah, and the copper deposits of Arizona.

Through the dislocation of the strata, or the country rock, by *faults*, and through the intrusion of eruptive rocks, great complexities are often brought about. As an exam-

ple, Fig. 10 shows a vertical cast and west section, after A. A. Blow, through the McKean shaft, Iron Hill, Leadville, W P being white porphyry, B L blue limestone, G P gray porphyry, W L white limestone, L Q lower quartzite, and

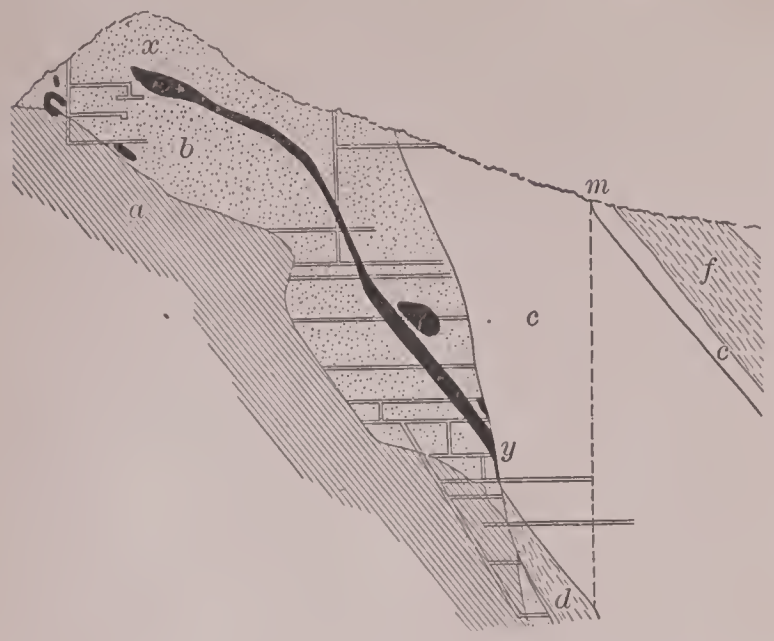

Fig. 9.

G granite, the ore deposit being indicated by heavy black. Elaborate rules have been worked out to aid the miner in the search for the displaced ore body, which it would lead too far to follow up.

The contents of a vein are the ore and the gangue. Some veins have a very simple character as regards the filling, containing one ore, or this and one kind of gangue. Others, again, are exceedingly complex, containing in the same part of the vein or in different parts a great variety of metallic compounds, associated with numerous gangue minerals. Veins are generally filled compactly with their contents, though druses sometimes exist. As has been already mentioned, the constituents—ore and gangue minerals—are often distributed in symmetrical layers parallel to the walls; they are often also heterogeneously mixed. The distribution of ore and gangue minerals is generally more or

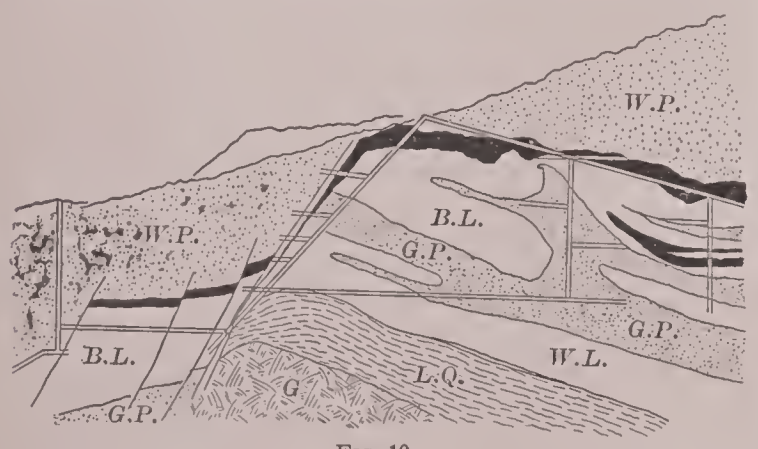

Fig. 10.

less irregular within the same vein. Sometimes the ore is concentrated at different points into bodies called bonanzas, nests, chimneys, pockets, masses, etc., while the rest of the vein is barren or contains only disseminated ores of the same kind or of different kinds to that of the bonanzas. This inequality of distribution is sometimes traceable to a cause. Thus in some veins changes in the character of the wall-rock are accompanied by change in the character of the vein-filling—changes which may in one place be due to certain portions of the country rock contributing metallic solutions, in another place to parts of the country contributing a reagent capable of precipitating metals from solutions in the vein. Again, in veins of varying thickness, if the ore is one of the younger members, the older filling of the narrower parts by poor or barren material would leave room only in the wide parts for the richer member. The intersection of veins is often accompanied by enrichment. Besides changes due to local influences, there is observed in some districts a difference of character in depth. Thus the veins of Oruro in Bolivia, which were rich in silver in their upper levels, contained ores barren of silver in depth. Veins containing both tin and copper have often the tin ores above and copper ores below. Sometimes a dike of eruptive rock has been altered to a considerable depth in such manner as to roughly simulate a fissure-vein.

Surface-deposits, or, as Posepny calls them, "hysterogenous" deposits, have formed the source of enormous quantities of gold, platinum, and tin ore. When, by disintegration and erosion or by being dissolved, a rock-mass containing ore deposits of any form is removed, and the removing cause is not competent to carry away the ore, this remains in a more concentrated form and is a residuary deposit. The often important masses of magnetic iron sand which are concentrated by the wave-action on beaches from the disintegrated *débris* of rock-masses are of this form. Iron Mountain, in Missouri, was wholly mantled to a depth of from 2 to 20 feet with a loose mass consisting entirely of fragments of iron ore of all sizes. These representatives of the broken-up reticulated veins are all that remain of a large amount of porphyry, which has disappeared, leaving only the insoluble iron ore.

Stream-deposits consist of loosely aggregated material in modern or ancient water-courses. They are generally the lowest member of a river-deposit, and owe their existence to the specific gravity and insolubility of the metals or ores. The annexed sketch (Fig. 11) from Whitney (*Geological Sur-*

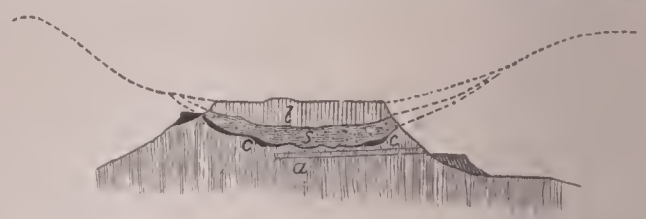

Fig. 11.—Table Mountain: *l*, lava; *s*, sandstone; *c c*, auriferous channels; *a*, slate.

vey of California) represents an auriferous stream-deposit formed in a valley which, after being filled with a lava stream, became a mountain-crest by the erosion of the softer hills on either side.

In many localities iron ore is deposited in marshes and on the bottoms of lakes. The ore is a variety of limonite called bog ore, and owes its origin to the action of decaying organic matter on ferric oxide, producing soluble ferrous carbonate, which, on entering the aërated waters of a lake, is oxidized and sinks. Such a deposit is worked in a lake near Radnor Forges, Canada.

Concerning the genesis of ore-deposits, renewed interest has been aroused through the researches made by Fridolin Sandberger, of Würzburg, who advanced what is known as the lateral secretion theory. He found by painstaking chemical analyses that the mica, olivine, augite, and hornblende of country rock contain minute quantities of the useful metals, and claimed that the filling of ore deposits is derived through chemical solution from the surrounding country rock. Other economic geologists, notably Posepny, hold that the chief agency for the accumulation of useful minerals is the underground circulation of water. He makes a sharp distinction between what he calls vadose, or shallow underground circulation, and deep underground circulation, relying upon the solvent power of water, with increasing temperature and pressure.

Relative Values of Deposits.—Fissure-veins, as a rule, are more trustworthy, because of the continuity of the fissures and the consequent facility offered the miner for underground prospecting. The same may be said of certain beds, while the other forms are of the most uncertain character; any given one may be an isolated occurrence or one of many, but from their nature they rarely offer clews by which the miner can work from one to another. The most productive mines of iron ore are beds and irregular masses. The most productive copper mine is at present the Calumet and Hecla on Lake Superior, which is a bed of conglomerate impregnated with native copper. The largest production of lead has probably been from the quickly exhausted but innumerable deposits in limestones and dolomites. The greater proportion of tin and native gold is derived from surface deposits. On the other hand, a great part of the silver of the world is wrought from true fissure-veins; and, if we except deposits of iron and some isolated deposits of other metals, the instances of permanent ore-mining industries are found to be established on fissure-veins.

Geological Survey, and of the Geological Surveys of Pennsylvania, New Jersey, Ohio, Michigan, Missouri, Wisconsin, and Minnesota.

R. Pumpelly. Revised by C. Kirchhoff.

Oregon: one of the U. S. of North America (Western group); the twentieth State admitted to the Union; capital, Salem.

Location and Area.—It lies between lat. 42° and 46° 18′ N. and lon. 116° 33′ and 124° 25′ W.; is bounded N. by Washington, E. by Idaho, S. by California, and W. by the Pacific Ocean; length E. to W. about 360 miles, breadth N. to S. 290 miles; coast-line about 300 miles; area, 96,030 sq. miles, of which 1,470 are water.

Seal of Oregon.

Physical Features.—Three ranges of mountains divide the State from N. to S., the Coast Range, from 10 to 30 miles from the ocean; the Cascade Mountains, from 110 to 150 miles inland; and the Blue Mountains, near the eastern boundary. The Cascades and Coast Range are united by four lateral ranges—the Callapooia, Umpqua, Rogue River, and Siskiyou Mountains. The Coast Range has an extreme altitude of 4,000 feet, and is covered to its summit with dense forests. The Cascade Mountains are a continuation of the Sierra Nevada Mountains; the extreme height is 7,000 feet, with a number of peaks rising from 2,000 to 5,000 feet higher. The most noted of these are Mt. Hood, 11,500 feet; McLoughlin or Pitt, 11,000; Jefferson, 10,500; and Three Sisters, 9,500. The Cascades are densely timbered to the snow line. The Blue Mountains have an extreme height of about 3,000 feet, with no high peaks, and are well covered with timber, especially at the north end of the range. Toward the S. the mountains recede and shoot off in lateral spurs W. to the interior table-land. Along the river courses and between the various mountain ranges and spurs are numerous fertile valleys. The largest is the Willamette, lying between the Coast Range and Cascade Mountains and the Columbia river and the Callapooia spur. It is 150 miles long and from 90 to 70 wide, is extremely fertile, and contains the densest population of the State. S. of it, between the lateral ranges, are the Umpqua and Rogue River valleys. The region E. of the Cascade Mountains, embracing two-thirds of the State's area, is known as Eastern Oregon. That portion of it between the Cascade and Blue Mountains is in the main a high table-land, with little rainfall, and is sparsely populated. There are fertile valleys along the water-courses and in the vicinity of the numerous lakes in the southern part, the largest being Harney and Goose Lakes, while at the northern extremity, near the base of the Blue Mountains, the land is rolling and extremely fertile. In the Blue Mountains and between it and Snake river, the eastern boundary, are numerous fertile valleys, the largest being Grand Ronde and Wallowa on the N., Powder and Burnt rivers in the middle, and Malheur and Owyhee on the S. The mountains are well covered with soil, especially the Coast Range, and large areas are being brought under cultivation by removal of the timber.

The rivers flowing into the ocean are the Nehalem, Nestucca, Yaquina, Alsea, Siuslaw, Umpqua, Coquille, Rogue, and Chetco; those flowing into the Columbia are the Lewis and Clarke, Young's, Clatskanie, Willamette, Sandy, Hood, Deschutes, John Day, and Umatilla; and those flowing into Snake river, itself a branch of the Columbia, are Grand Ronde, Powder, Burnt, Malheur, and Owyhee. The chief tributaries of the Willamette are the Clackamas, Tualatin, Yamhill, Santiam, Molalla, Luckiamute, Mary, Long Tom, the river itself dividing into the Mackenzie and Middle and Coast Forks. The large lakes are all in the southern portion of the central division, some of them being saline. They are the Klamath, upper and lower, Goose, Warner, Salt, Christmas, Abert, Summer, Silver, Harney, and Malheur. Crater Lake lies in the Cascades, 8,000 feet above sea-level, in the crater of a huge extinct volcano 10 miles in circumference and surrounded by bluffs 2,000 feet high. It is the deepest fresh water in America. The chief harbor is the Columbia river, improved by the U. S. Government so that its entrance has 28 feet at extreme low tide. Minor harbors are Tillamook Bay, Yaquina Bay, Alsea river, Siuslaw river, Coos Bay, Coquille river, Rogue river, and Port Orford. The principal capes and headlands are Point Adams, at the mouth of the Columbia, Tillamook Head, Cape Foulweather, Cape Lookout, Cape Perpetua, Cape Blanco, and Umpqua Head. The coast-line is very abrupt and rocky, and but slightly indented.

The fauna embraces the huge grizzly, black, and cinnamon bears, cougar (mountain-lion or panther), catamount (wild-cat), polecat, raccoon, porcupine, beaver, otter, muskrat, several varieties of wood and ground squirrels, silver and red foxes, martens, hares or "jack rabbits," rabbits, deer, elk, antelope, mountain-sheep, and mountain-goat. Seals and sea-lions enter the Columbia, and the latter have rookeries off the coast. Salmon enter all the streams in great quantities, and millions are caught annually. The chinook, or quinnat, is the leading variety. Sturgeon are caught in great numbers in the Columbia and Willamette. The streams teem with salmon-trout and mountain-trout. In the spring swarms of smelt and herring enter the rivers. Many less valuable fish, including transplanted carp, are found in the rivers and lakes. Transplanted shad are becoming plentiful. Oysters of a small but finely flavored variety are found in Yaquina Bay, and crabs and lobsters along the coast. The birds include the golden and baldheaded eagle, several varieties of hawks, cormorant, sea-gull, pelican, albatross, vulture, buzzard, pigeon, mountain-quail, grouse, imported Chinese pheasants of five varieties, American and trumpeter swans, brant, Canada goose, many varieties of ducks, including canvasback, the robin, field-lark, skylark, jay, woodpecker, yellowhammer, blackbird, grosbeak, bullfinch, greenfinch, chaffinch, nightingale, goldfinch, song-thrush, starling, and several other varieties of song-birds.

Mineral Productions.—Oregon has a great variety of minerals. Gold, both placer and quartz, is mined in Jackson, Josephine, Douglas, Linn, Grant, Baker, and Union Counties. Placer-mining began in Jackson and Josephine Counties in 1851, and in Baker and Grant Counties in 1861–62. Hydraulic mining is carried on extensively in both Southern and extreme Eastern Oregon. The most recent quartz discoveries are in the Cascade Mountains near the Santiam river, and in the Pine Creek Mountains, between the Blue Mountains and Snake river. Gold is found also in the sands of the ocean beach at various places. Silver ore is found almost coextensive with the gold, though predominating in Eastern Oregon; copper and lead occur frequently with the silver; and cinnabar is found and worked in Josephine County. Douglas County has the most extensive deposit of nickel ore yet discovered in America. Iron ore of a superior quality is mined near Portland, yielding upward of 50 per cent. of magnetic iron. It is reduced at a blast furnace at Oswego. Unworked deposits of iron ore exist in other counties. Coal is found in various places in Western Oregon, and is extensively mined on Coos Bay. Outcroppings have also been discovered on the western slope of the Blue Mountains. Other minerals are chalcedony, agate, carnelian, and jasper. Salt is extracted for local use in Jackson and Douglas Counties.

Soil and Productions.—The soil of Oregon is volcanic in origin and the valleys are alluvial. It is extremely fertile. The entire region W. of the Cascades and the northern portion E. of them have ample rainfall for crops. Large areas

of the central and southeastern portion of the State depend largely upon irrigation in farming. The chief product is wheat. The Oregon prunes are acknowledged to be the largest and finest in the world. Vineyards produce abundantly. The wool-growing industry is very large.

The following summary from the U. S. census reports of 1880 and 1890 shows the extent of farming operations:

FARMS, ETC.	1880.	1890.	Per cent.*
Total number of farms	16,217	25,530	57·4
Total acreage of farms	4,214,712	6,909,888	63·9
Value of farms, with buildings and fences	$56,908,575	$115,819,200	103·5

* Increase.

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	13,789	317,147 bu.	$180,774
Wheat	1,173,769	16,198,012 "	8,908,907
Oats	177,447	3,282,770 "	1,345,936
Rye	5,841	94,040 "	57,364
Barley	31,347	905,928 "	380,490
Potatoes	15,382	1,692,020 "	761,409
Hay	713,653	1,677,085 tons	11,404,178
Totals	2,131,248	....	$23,039,058

The farm animals on Jan. 1, 1900, comprised 183,986 horses, value $5,516,923; 5,441 mules, value $210,241; 115,415 milch cows, value $3,583,636; 522,018 oxen and other cattle, value $12,192,775; and 2,446,695 sheep, value $6,532,676—total head, 3,446,695; total value, $28,036,251.

Climate.—Each of the three natural divisions of the State has a climate peculiar to itself, and throughout the State the seasons are distinguished as the wet and dry. The dry season usually extends from May 1 to Oct. 15, and during the wet season about 75 per cent. of the precipitation occurs. In Eastern Oregon the temperature ranges from 90° in summer to 10° in winter, with an occasional summer rise to 100° and a winter fall to 0°. The summer is drier and the winter colder than in Western Oregon. The rainfall averages about 20 inches. In Western Oregon the average spring temperature is 52°, summer 67°, autumn 53°, and winter 39°. The rainfall averages 44 inches in the Willamette valley, and is sufficient to prevent drought in the other valleys. In Southern Oregon the mean average temperature of July is 68°, of January 45°, and the temperature seldom exceeds 95° in summer and 16° in winter. The average rainfall is 22 inches.

Divisions.—There are 33 counties, as follows:

COUNTIES AND COUNTY-TOWNS, WITH POPULATION.

COUNTIES.	* Ref.	Pop. 1890.	Pop. 1900.	COUNTY-TOWNS.	Pop. 1900.

* Reference for location of counties, see map of Oregon.
† Formed since 1890.

Principal Cities and Towns, with Population for 1900.—Portland, 90,426; Astoria, 8,381; Baker, 6,663; Pendleton, 4,406; Salem, 4,258; The Dalles, 3,542; Oregon, 3,494; Eugene, 3,236; Albany, 3,149; La Grande, 2,991; Ashland, 2,634; Grant's Pass, 2,290; Corvallis, 1,819; Medford, 1,791; Roseburg, 1,690; McMinnville, 1,420; Marshfield, 1,391.

Population and Races.—In 1860, 52,465; 1870, 90,923; 1880, 174,768; 1890, 313,767 (native, 256,450; foreign, 57,317; male, 181,840; female, 131,927; white, 301,758; colored, 12,009, including 1,186 persons of African descent, 9,540 Chinese, 25 Japanese, and 1,258 civilized Indians).

Industries and Business Interests.—The census returns of 1890 showed that 1,523 manufacturing establishments reported. These had a combined capital of $32,122,051, employed 18,798 persons, paid $11,535,229 for wages and $21,793,578 for materials, and had products valued at $41,432,174. The State is exceptionally favored in the provision of water-power for manufacturing purposes, there being hardly a section in which it does not exist in almost unlimited amounts. The census reports on the fisheries of the State showed: Capital invested, $2,396,632; persons employed, 4,682; vessels and boats employed, 1,558; value of apparatus used, $437,943; and value of products, $1,033,574. The salmon-canning industry had 34 canneries, employed 1,584 persons, and had an output of 21,390,648 lb. of canning valued at $889,772, and 320,822 cases of prepared canned salmon valued at $1,901,617.

Commerce.—Besides a large internal traffic, the State has a considerable direct foreign trade through the ports of Oregon and Willamette. In the fiscal year ending June 30, 1899, the imports of merchandise amounted in value to $1,522,097 and the exports to $9,116,973, and in 1900 the imports to $1,810,987 and the exports $8,344,144.

Finance.—The constitution prohibits the State from becoming interested in the stock of any corporation, and the Legislature from loaning the credit of the State or creating a debt which singly or in the aggregate with previous debts shall exceed $50,000, excepting in case of war, to repel invasion, or to suppress insurrection. Counties, towns, and other municipal corporations are under similar prohibition, excepting that the maximum of county indebtedness is fixed at $5,000, with the above exceptions. As a result of these restrictions Oregon has practically no public debt. The assessed valuation in 1900 as equalized by the State board was $125,738,761.13, and the amount to be raised by taxation in 1901 was $671,487.78.

Banking.—Owing to the panic in 1893 sixteen banks suspended in the first eight months. Sept. 5, 1900, there were 27 national banks with combined capital of $2,370,000, surplus and profits of $1,464,847.84, and deposits of $11,782,009.39. The State banks on June 30 numbered 19, with capital of $614,450, surplus and profits of $180,232, and deposits of $3,301,580. There were also 2 private banks with a capital of $87,000 and deposits of $87,061.

Post-offices and Periodicals.—On Jan. 1, 1901, there were 892 post-offices, of which 34 were presidential (1 first-class, 7 second-class, 26 third-class) and 858 fourth-class, with 337 money-order offices, and 3 money-order stations. Of newspapers and periodicals there were 17 daily, 7 semi-weekly, 144 weekly, 1 bi-weekly, 2 semi-monthly, and 22 monthly publications—total, 193.

Means of Communication.—The transportation system consists of railways and navigable rivers. Steamers ply on the Columbia and Willamette and for short distances on some of their tributaries. Navigation on the Columbia is broken at the Cascades, 140 miles from the ocean, and again at The Dalles, 50 miles farther. Around the Cascades the State has built a portage railway, and the U. S. Government has nearly completed a canal and locks there, upon which it has been working since 1876 and has expended about $2,000,000. No plan for overcoming the obstructions at The Dalles has yet been adopted. The Willamette is obstructed at Oregon City by falls 41 feet high, around which a canal and locks have been constructed by the State. The railway system consists of the lines of the Southern Pacific from Portland S. to California, there being four distinct lines running up the Willamette valley: the Oregon Railway and Navigation Company's line, leased by the Union Pacific, running up the Columbia from Portland to the boundary-lines of Washington and Idaho; the Northern Pacific, running down the Willamette and Columbia from Portland 39 miles and crossing into Washington, and a leased line of the same road from the Washington boundary S. to Pendleton; the Oregon Pacific, running E. from Yaquina Bay to the Cas-

cade Mountains; and a railway under construction from Coos Bay to Roseburg. The mileage of the railways in the State in 1894 was as follows: Southern Pacific, 698·87; Oregon Railway and Navigation, 533·53; Northern Pacific, 38·82; Oregon Pacific, 141·36; Astoria and South Coast, 15·78; Rogue River Valley, 5·50; and Independence and Monmouth, 2·50—total, 1,481·04. Total in 1899, 1,612·89 miles.

Churches.—The census of 1890 gave the following statistics of the religious bodies having a membership of 800 and upward in the State:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Roman Catholic	95	95	30,231	$290,090
Methodist Episcopal	203	201	9,436	614,625
Baptist	108	108	5,306	317,325
Disciples of Christ	74	42	4,067	76,700
Presb. in the U. S. of America	73	70	3,935	416,500
Congregational	35	38	2,037	160,200
Methodist Episcopal South	70	62	1,936	50,850
Protestant Episcopal	31	26	1,849	361,930
United Brethren, Old Constitution	49	46	1,203	24,700
Evangelical Association	25	24	1,199	63,900
Cumberland Presbyterian	23	21	897.	22,200
Unitarian	5	5	890	139,500

Schools.—The number of children of school age in the State in 1899 was 132,408; the number enrolled in the public schools, 88,485; average daily attendance, 61,234. The number of teachers employed was 3,693—1,250 men and 2,443 women; average monthly salaries—men $42.96, women $34.81; number of schoolhouses, 2,060; value of school property, $2,871,718; revenue for school purposes, $1,270,568; expenditure, $1,159,125. Normal schools were maintained by the State at Ashland, Drain, Monmouth, The Dalles, and Weston. There were seventeen endowed academies and private secondary schools. The institutions for higher education comprised Blue Mountain University at La Grande (non-sectarian, opened 1876); Christian College, at Monmouth (Christian, chartered 1865); Corvallis College, at Corvallis (Methodist Episcopal South, opened 1865); McMinnville College, at McMinnville (Baptist, chartered 1859); University of Oregon, at Eugene City (non-sectarian, chartered 1872); Pacific University, at Forest Grove (Congregational, opened 1848); Philomath College, at Philomath (United Brethren, chartered 1865); Willamette University, at Salem (Methodist Episcopal, opened 1844); and Portland University, at Portland. The State Agricultural College is a part of Corvallis College.

Libraries.—According to a U. S. Government report on public libraries of 1,000 volumes and upward each in 1891, Oregon had 17 libraries, containing 68,544 bound volumes and 18,519 pamphlets. The libraries were classified as follows: General, 3; school, 5; college, 5; college society, 2; scientific, 1; and Masonic, 1.

Charitable, Reformatory, and Penal Institutions.—These include the Oregon School for Deaf Mutes, Oregon Institute for the Blind, Oregon State Prison, Oregon State Reform School, Oregon State Insane Asylum, county and city jails, and county almshouses. According to a provision of the State constitution all public institutions provided for by the Legislature must be at the seat of government. In 1893 the Legislature provided for the establishment of a State Soldier's Home and for a branch asylum for the insane in Eastern Oregon.

Political Organization.—Oregon was admitted into the Union in 1859, and its constitution, adopted in 1857, remains unchanged. State officers are elected for terms of four years and county officers for two, the election occurring in June. The Legislature consists of thirty senators, holding office for four years, one-half elected every two years, and sixty representatives, holding office two years. They draw pay only for forty days for each biennial session. Suffrage is enjoyed by every citizen or person who has declared his intention to become such, who has resided in the State six months. The secretary of State acts as auditor. All State institutions are governed by boards of three State officers, selected from the Governor, secretary, treasurer, and superintendent of public instruction, except the deaf and dumb school, agricultural society, State university, normal schools and soldier's home, which have special boards of trustees or regents. The penitentiary, insane asylum, blind school, and reform school have superintendents appointed by the State boards.

History.—The first recorded exploring voyages along the coast of Oregon were those of the Spaniard Ferrelo, in 1543; Sir Francis Drake, the English freebooter, in 1578; the probably mythical De Fuca, in 1592; Aguilar, the Spaniard, in 1603; the certainly mythical Fonte, in 1640; the Spaniard Perez, in 1774; the Spaniard Heceta, in 1775, when the mouth of the Columbia was first observed; Capt. Cook, an Englishman, in 1777; and numerous other Spanish, English, and American explorers and traders in the ensuing fifteen years. Yet none set foot on land or knew much about even the coast-line, until Capt. Robert Gray, a trader from Boston, in the ship Columbia, entered the mouth of the Columbia May 11, 1792, and laid the foundation of the American title to Oregon. The U. S. purchased Louisiana in 1803, and acquired all the French title W. of the Missouri river, and in 1819 secured the entire Spanish title N. of lat. 42° by the Florida purchase. In 1804–05 Lewis and Clarke explored the country from St. Louis to the mouth of the Columbia for the U. S. Government. Nathan Winship, from New England, entered the Columbia in the Albatross May 10, 1810, and built a trading-post at Oak Point, 40 miles inland, the first settlement in Oregon, but abandoned it in a few weeks. Astoria was founded by the Pacific Fur Company Mar. 22, 1811, and named after John Jacob Astor, president of the company. It was captured by the British and named Fort George Dec. 12, 1813, and was restored to U. S. jurisdiction in Oct., 1818. In 1818 the U. S. and Great Britain made a treaty of joint occupation of Oregon, which was terminated in 1846 by a treaty confirming the title of the U. S. The Hudson Bay Company was in practical possession after 1813 until enough citizens of the U. S. arrived to create a provisional government in 1843. A Methodist mission was founded by Jason Lee in 1834, and a Presbyterian mission by Dr. Marcus Whitman in 1836. The first large immigration was in 1843, overland from the Mississippi valley. Oregon was made a Territory Aug. 12, 1848, and the territorial government superseded the provisional government Mar. 3, 1849, Gen. Joseph Lane being the first territorial Governor, the provisional Governor having been George Abernethy. A State constitution was framed in 1857, and the State admitted to the Union Feb. 14, 1859. There were Indian wars in 1849, 1851, 1852, 1853–56, 1866–67, 1872–73, 1877, and 1878. There are now but few Indians in the State, and these are peacefully settled on reservations.

GOVERNORS OF OREGON.

Provisional.	
George Abernethy	1845–49
Territorial.	
Joseph Lane	1849–50
John P. Gaines	1850–52
Joseph Lane	1853

H. W. SCOTT.

Oregon: city; capital of Ogle co., Ill. (for location, see map of Illinois, ref. 2-E); on the Rock river, and the Chi., Burl. and Quincy Railroad; 100 miles W. of Chicago. It is a summer resort, is principally engaged in agriculture and manufacturing, and has a national bank with capital of $50,000, a private bank, and three weekly newspapers. Pop. (1880) 1,088; (1890) 1,566; (1900) 1,577.

Oregon City: city; capital of Clackamas co., Ore. (for location, see map of Oregon, ref. 2-C); on the Willamette river and the S. Pacific Railroad; 12 miles S. of Portland, with which it is connected by steamboats and by an electric railway. The city is the center of a rich agricultural region, with a prolific fruit country tributary to it. The river here falls 40 feet, affording unlimited water-power, and boats pass from one level to the other by means of locks constructed in 1874. Among the large manufacturing establishments are woolen, flour, paper, pulp, and sawmills, sash and door factories, and ice-works. There are the U. S. land-office for the northern district of Oregon, a State bank,

with capital of $100,000, a private bank, and three weekly newspapers. Pop. (1880) 1,263; (1890) 3,062; (1900) 3,494.

EDITOR OF "ENTERPRISE."

Oregon River: See COLUMBIA.

O'Reilly, JOHN BOYLE: journalist and poet; b. at Dowth Castle, County Meath, Ireland, June 28, 1844. At the age of eighteen he went to England and enlisted in the British army, where he acted as a secret agent of the Fenian Society. He was convicted of high treason in 1866, and sent to Australia under a twenty years' sentence, but escaped after a year's imprisonment, and went to the U. S. in 1869. In 1870 he became editor of the Boston *Pilot*, with which he was connected till his death. D. at Hull, Mass., Aug. 10, 1890. His published writings include *Songs of the Southern Seas* (1873); *Songs, Legends, and Ballads* (1878); *Moondyne* (1879); *Statues in the Block* (1881); *In Bohemia* (1886); *Stories and Sketches* (1888). H. A. BEERS.

Orel': government of Russia, between lat. 51° 50′ and 54° N., and lon. 33° and 39° E. Area, 18,042 sq. miles. The surface is mostly level. The soil is fertile and well watered by the Desna, an affluent of the Dnieper, the Oka, an affluent of the Volga, and the Sosna, an affluent of the Don, all of which are navigable. The climate is mild. Agriculture is the chief industry. Large quantities of wheat are exported, in grain and flour, to Riga and St. Petersburg. About one-third of the surface is covered with forests. Hemp is extensively cultivated, and oil of hempseed, sailcloth, rope, and yarn are manufactured. Some iron mines are worked and many horses and cattle are reared. Pop. (1897) 2,054,609.

Orel: town of Russia; capital of the government of the same name; on the Oka; 222 miles S. S. W. of Moscow (see map of Russia, ref. 8–D). It is mostly built of wood, and was almost destroyed by fire in 1848 and again in 1858. It has many educational institutions, breweries, distilleries, ropewalks, tallow-houses, and other manufactories, and an important trade in grain with St. Petersburg and Riga. It formerly formed a stronghold against Tartar invasions. Pop. (1897) 68,557.

O'Rell, MAX: See BLOUET, PAUL.

Orellana, ō-rāl-yaa′naă, FRANCISCO, de: first explorer of the Amazon; b. at Truxillo, Spain, about 1490. He was intimate from boyhood with the Pizarros, and joined them in Peru about 1535; in 1537 he founded Guayaquil. Later he was the lieutenant of GONZALO PIZARRO (*q. v.*) in his expedition to the "Land of Cinnamon," about the head-waters of the Coca and Napo. The expedition left Quito (according to lately discovered documents) in Feb. or Mar., 1541, and crossed the Andes to the Coca; here a small vessel was built to descend the river, while the army followed along the shore to the junction of the Napo. Thence Orellana and fifty men were sent ahead in the boat, with orders to bring back provisions from the villages farther down. Floating on the swift current they reached the junction of the Napo with the Amazon in a few days, but Orellana could find no provisions and, unable or unwilling to return, he resolved to go on down the Amazon. This scheme was carried out after a new and better vessel had been built. In the course of their voyage the Spaniards had many skirmishes with the Indians. They heard of a tribe of female warriors, or Amazons, and claimed to have fought with them near the mouth of the Trombetas. Probably the story of these women was an aboriginal myth or wonder-tale, traces of which are still found in South America. The account of the Amazon tribe was readily believed in Europe, however, and eventually gave its name to the river. Orellana reached the sea after a voyage of eight months, made his way to the Spanish settlements of Venezuela, and thence went on to Spain. In 1544 he received a grant to conquer and govern the regions he had passed through. He sailed for the Amazon in 1545 (or in 1549, according to Acuña) with 500 men; but many soldiers perished during the voyage; the enterprise was abandoned after they had ascended the river for a short distance, and Orellana died soon after, probably on the island of Margarita. HERBERT H. SMITH.

Orel'li, JOHANN KASPAR: classical scholar; b. at Zurich, Switzerland, Feb. 13, 1787; studied theology, but especially ancient and modern languages and literature, and was appointed *professor eloquentiæ* in 1819, and Professor of Classical Philology in the newly founded University of Zurich in 1833. Author of a celebrated edition of *Cicero* in 8 vols., including the *Scholia* and an *Onomasticon Tullianum* (3 vols., 2d ed. by Halm and Baiter, 1861); a justly esteemed commentary of *Horace* (4th ed. 1892, with *Lexicon Horatianum*), and of *Tacitus* (new edition by various scholars, 1879–94). His *Inscriptionum Latinarum Selectarum Collectio* (3 vols., 1856; 2d ed. by W. Henzen, with copious indexes) is still a valuable aid for the study of Roman history, antiquities, and language. See Adert, *Essai sur la vie et les travaux de J. G. Orelli* (Geneva, 1849); Bursian, *Gesch. der class. Philol. in Deutschland*, pp. 850–857. D. at Zurich, Jan. 6, 1849. Revised by A. GUDEMAN.

O'renburg: government of European Russia; bounded N. and N. W. by Perm, Ufa, and Samara. Area, 73,816 sq. miles. The central part of the government is mountainous, covered with branches of the Ural Mountains which are very rich in iron, copper, and gold; the crown mines yield over 1,000 lb. of gold annually, and the private double as much. On both sides of the mountains are extensive steppes, in many places barren and dotted with salt lakes, but in others presenting good pasture-grounds, where immense herds of cattle, sheep, horses, and camels are reared. Besides the breeding of cattle, in which the Ural Cossacks are engaged, and mining, fishing and preparation of caviare form an important branch of industry. Pop. (1897) 1,608,388.

Orenburg: town of European Russia, capital of the government of Orenburg; on the Ural; 727 miles E. S. E. by rail from Moscow (see map of Russia, ref. 8–H). It was founded as a frontier fortress in 1743, but is now of importance for its trade only. Tea from China, shawls and silks from Persia, skins, tallow, and cattle from the Khirgheez and Cossacks, and metals from the Ural Mountains are brought here and exchanged. Pop. (1897) 72,740.

Oren'se: town of Spain, capital of the province of Orense; on the left bank of the Minho, which is crossed here by a magnificent bridge, 1,400 feet long, 145 feet high, built in 1230, spanning the river with seven arches (see map of Spain, ref. 13–B). At the foot of the hill on which the city is built are the famous hot sulphur springs, Las Burgas. The town is the seat of a bishopric and is celebrated for its chocolate, hams, and wine. Pop. (1887) 14,168.

Oreodon'tidæ [Mod. Lat., named from *Ore'odon*, the typical genus; Gr. *ὄρος*, *ὄρεος*, mountain + *ὀδούς*, *ὀδόντος*, tooth]: a family of extinct mammals belonging to the order *Ungulates* and sub-order *Artiodactyles*, intermediate between the typical ruminants and hogs.

Ores'tes (in Gr. *Ὀρέστης*): in Grecian mythology, a son of Agamemnon and Clytemnestra; avenged the murder of his father by killing his mother and her paramour, Ægisthus, but was immediately attacked by the Erinyes, who drove him mad, pursuing him from place to place. He sought refuge with Apollo in Delphi, but the manner in which the Erinyes were finally appeased is variously related by the Attic tragedians, who frequently treated this myth and developed it differently. According to one version, Orestes went to Athens, where the court of the Areopagus declared him innocent through the influence of Athene. According to another, Apollo sent him to Tauri, whence he succeeded, by the aid of his sister, Iphigenia, who was a priestess there, in carrying away the image of Artemis. Of the tragedies which treated the myth, the trilogy *Orestea* by Æschylus, *Electra* by Sophocles, and *Electra*, *Orestes*, and *Iphigenia in Tauris* by Euripides, are extant.

Revised by J. R. S. STERRETT.

Oreus: See HISTIÆA.

Orfa, Orfah, or **Urfah** (Gr. *Edessa*; Arab. *Rouha*): city in Asiatic Turkey; in the vilayet of Aleppo; lat. 37° 8′ N.; about 40 miles E. of the Euphrates (see map of Turkey, ref. 6–H). Improbable tradition makes Nimrod its founder. The Jews identify it with Ur of the Chaldees; this was apparently the opinion of St. Stephen, who located Ur in Mesopotamia (Acts vii. 2). The Arabs also associate it with Abraham, calling their chief sanctuary in the city the Mosque of Abraham, while the pond containing the sacred fish is the Pool of Abraham. As EDESSA (*q. v.*), it was important in the crusades. The town, surrounded by a wall, is partly built on the side of a hill, 1,650 feet high, overlooking an extensive plain. Its gardens are large and luxuriant and its narrow streets unusually clean. The river Kara Kuzu, spanned by three bridges, flows through it. As the central station on the great route between Aleppo and Diarbekir, its transit trade is extensive. Pop. about 30,000, nearly a quarter of whom are Christians and Jews.

Organ [O. Eng. *organ*, from Lat. *or'ganum* = Gr. ὄργανον, implement, tool, organ of the body, a musical instrument; cf. ἔργον, work, Eng. *work*]: a musical instrument in which sounds are produced by the passage of wind through pipes. Its capabilities are due to three principal properties. First of all, it includes a large number of distinct pipes, each of which is, in a sense, an independent instrument. Second, it contains peculiar arrangements, of which the chief is the keyboard (clavier), by which numbers of these pipes very remote from one another may be simultaneously operated on. Third, it substitutes for the natural production of the moving force (namely, air-currents) by the human lungs an artificial production of the same by means of a bellows, which substitution not only relieves the performer of the most fatiguing part of his work, but also increases in a vast measure the power of the instrument. By means of this large bellows, of a structure similar to that which is seen in an accordion, and worked by a lever-handle, water motor, or electric motor, air is forced into a closed chest or reservoir, where it can be stored up in a compressed state. In the modern bellows, the horizontal as distinguished from the old-fashioned diagonal, there are two divisions—a feeder and a temporary air-chest. The air is unable to return by the way it came, and can only find vent above through its upper floor, called the sounding-board. This sounding-board separates the air-chest from the organ-pipes, which are arranged above it. The air is admitted to the pipes by the action of certain slides and valves which are set in motion by drawing out the registers and by pressing down the keys or pedals. The drawing out of a slide partly opens up to the air a whole set of pipes of one peculiar quality or tone, so that when any of the keys is pressed down the air finds its way into the appropriate pipe of this particular series. Of course, when more than one stop is drawn out the air is admitted simultaneously into several distinct groups of pipes. The larger organs consist of three or more distinct partial organs, each of which has its peculiar keyboard, and a separate air-chest and sounding-board for its pipes.

The sound of an organ is produced by the vibrations of the column of air within the pipe. The compressed air of the air-chest, as soon as obstacles are removed by the action of the stop and of the key, rushes upward into the pipe, and so produces the tone. The shape of a metal organ-pipe is very much the same as that of a common tin whistle. The stem or "body" of the pipe is cylindrical. The lower part or "foot" is an inverted cone with its apex cut off. At the juncture of the body and the foot there is an opening in the side of the pipe called its "mouth." There is also a horizontal plate termed the "languid" or "language," which partially divides the foot from the body, and leaves a narrow egress for the air coming from below close to the mouth of the pipe. The wooden pipes are of a slightly different structure, being commonly square instead of round, but their mode of action is not materially different. When the air rushes up into the pipe it is driven against the upper edge or "lip" of the mouth-hole. Breaking against the sharpened edge, it produces a peculiar hissing or rushing noise, which is all we hear when the pipe does not "speak." The agitation thus set up at the mouth communicates itself to the column of air within the body of the pipe, which is thus made to vibrate with a rapidity determined by its length. The shorter the pipe the more rapid the series of vibrations, and the higher consequently the pitch of the note produced. Organ-pipes are of a great many varieties, according to the material used and the shape of their several parts. Metal pipes are made of tin, "metal" (a mixture of tin and lead), zinc, etc., while wooden pipes are generally constructed of cedar, deal, or pine. The shape of pipes also varies considerably. Thus among metal pipes we have the forms of cylinder, cone, and inverted cone, while among wooden pipes we have the forms of quadrilateral, trilateral, cylinder, pyramid, and inverted pyramid. Further, there is a distinction between pipes which are open and those which are stopped or plugged at their upper extremity. An open pipe produces a tone with a wave of air twice as long as the body of the pipe, and a stopped pipe produces a tone with a wave four times the length of its body. Thus a stopped pipe is always an octave deeper than an open pipe of the same length.

The peculiar quality of sound belonging to an organ-stop is due to the structure of the pipes belonging to the stop. According to the researches of Prof. Helmholtz, the *timbre* of a musical instrument is determined solely by the number and strength of the upper partial tones which enter into the tones of the instrument. Thus he found that wide-stopped organ-pipes have scarcely any upper partial tones at all, and that all stopped pipes are wanting in the even members of the series of upper tones. Hence stopped pipes give a soft hollow sound, while open pipes produce a sharp brilliant style of tone. The number of partial tones, and so the timbre of a pipe, vary with the shape and size of the pipe, and also with the material of which it is made. Certain stops called "reeds" owe their peculiar character to the addition of a vibrating tongue, like those of a harmonium, to the pipe. This tongue is a thin, oblong brass plate fitted into the aperture of a cylindrical tube called a reed. The tongue in its oscillations alternately opens and closes the aperture of the tube through which the air seeks to pass. The consequence is that the stream of air is separated into a series of individual pulses. The sound of a reed pipe is the result of these interrupted pulses of air, together with the vibrations of the metal tongue itself. Other stops having a peculiar quality of tone are in reality compound stops; that is, they bring into simultaneous action a plurality of pipes of different pitch. The twelfth, fifteenth, sesquialtera, and mixture are among the best-known compound stops. The notes of these combined pipes have the same relation to one another as the partial tones of a single musical tone. Thus it is usual to connect the upper octave with the prime tone, and after that the twelfth. Some of these compounds give as many as the first six partial tones. The number and strength of the combining tones in the note of one of these compound stops give to it a peculiarly bright, and in some cases a dazzling and overpowering character.

The names of the several organ-stops point partly to the quality of the sound produced, partly to the range or compass of the pipes belonging to it, and to other circumstances. Thus the trumpet and the oboe, which are both reed-stops, are so named from the resemblance of their tones to those of these instruments. The diapason-stops again are so called because their pipes extend through the whole compass of the organ. The stop "principal," which is an octave higher than the open diapason, is so named from the fact that it is the first stop tuned, and the standard, therefore, for the pitch of the remaining stops.

Many mechanical aids to registration have been furnished, whereby the organist may radically change his stop-combinations to a degree never before attainable by simply touching a knob or pedal. The application of electricity is also beginning to do away with much cumbersome machinery connecting key with pipe. The principle of the swell is being largely developed and applied to extensive portions of the organ formerly lacking in this respect—this to the great gain of the instrument from the standpoint of *expression*.

History.—The history of the organ forms an important branch of the history of music as a whole. We are able to trace back the pedigree of this instrument to an humble ancestry: the pipes of Pan and the bagpipe. It is difficult to fix the date of the first organs referred to in ancient writers, owing to the ambiguity of the word *organ* (ὄργανον), which was properly fitted to denote any musical instrument. The organ, properly so called, originated among the Greeks of Alexandria in the second century B. C. The first species of organ of which we have a description is the water-organ, ὕδραυλος (literally, water-flute). It is described by Vitruvius and Athenæus as sweet, though not powerful. This instrument was designed for domestic amusement. On a Roman monument we have a bas-relief representation of a domestic organ. It contains sixteen pipes, and the performer, a lady, plays with both hands on the keyboard. It is placed on a table, and looks easily portable.

The organ is said to have been introduced into the Church by Pope Vitalian in the seventh century, but its employment in church services probably dates from a much earlier period. Organs were certainly used in churches very commonly in the time of the Carlovingians. We read of organs being sent to King Pepin and Charlemagne as presents by the Byzantine emperors. The first of these is described as a wonderful structure of the form of a tree, in the branches of which were birds of various species, each bird giving forth the note peculiar to its species. At a much later period than this we find the structure of the organ to be exceedingly rude. The keys were often from 4 to 6 inches broad, and

were struck with the closed fist or in some cases with the elbow, so that only two tones could be produced simultaneously. The compass was sometimes as great as twenty-one notes, the series being that of our diatonic scale (the white notes of a piano). In addition to these more common instruments, we read of gigantic organs, such as that built for Winchester in the year 951, which is said to have contained 400 pipes and 26 bellows, requiring 70 strong men, and to have been played by two performers or four fists. From the twelfth century on we read of a light portable organ named "portative," which was distinguished from the fixed organ or "positive." The performer, who carries the instrument by means of a belt, plays with one hand, and manages the bellows with the other. Italian painters of the fourteenth and fifteenth centuries were fond of representing the instrument in the hands of saints and angels. In the fourteenth century the structure of the organ underwent certain improvements. A step had been taken before this toward enabling the organist to produce a larger number of simultaneous tones. By the invention of mixture or compound stops —which seem to have been arrived at at a very early date— two or three notes could be sounded by means of one key, the combinations being selected according to the strange ideas respecting sequence of accords prevalent at this age (as illustrated in the *Organon* or mode of harmony of Hucbald and his successors). In the fourteenth century this capability of uttering simultaneous tones was much further increased by the reduction of the size of the keys, so as to make them workable by means of the fingers. This change also involved a large extension of the compass of the keyboard. We read of organs of this period having three octaves, including semitone intervals.

The period of the supremacy of the polyphonic music of the Netherlands (1450–1550) was marked by considerable improvements both in the structure and in the art of performance of the organ. The development of the contrapuntal or fugue style of music, which was diffused from the Netherlands through Germany, Italy, England, etc., gave a great impetus to the art of organ-playing. There are still preserved volumes of organ compositions used by the German performers of this time, from which we see that organ pieces were now growing into independent productions. In Germany the art of organ-playing was diligently cultivated by a series of musicians, of whom the family of the Bachs were among the most distinguished. Thus were laid the foundations of the art which Sebastian Bach was afterward to carry to so high a degree of perfection. In Italy, during the sixteenth century and at the beginning of the seventeenth, organ compositions very ornamental in design and containing the germs of our modern harmony became common. The seventeenth century, too, was marked by great progress in organ-building and in organ-playing. Germany and Holland trained builders of great eminence, whose works may be found in other countries besides, including England. Some of the finest old organs of England, including those of Westminster Abbey, the Temple church, and Durham Cathedral, were erected by a German named Schmidt. The style of organ composition was greatly elevated in that century by the addition of harmony in the modern sense, of which Palestrina had laid the foundations in Italy.

From the beginning of the eighteenth century the organ has undergone a vast though gradual improvement of structure, which has served to increase its scope and variety by lessening the mechanical difficulties of performance. In this way it became possible to execute such rich and elaborate works as later composers have produced. The principal mechanical additions to the instrument have been directed to a more varied combination of pipes by compound stops, to a diminution of the labor of the manual performance by means of arrangements which facilitate the drawing of stops and the depression of keys. Among the methods used to lessen this last ingredient in the labor of the organist are pneumatic action which is commonly adopted in the best modern organs.

Among the largest European organs still to be seen, the following may be mentioned: The Weingarten organ (66 stops and 6,666 pipes). the Haarlem organ (60 stops), the organ of the Church of the Cavalieri di San Stefano at Pisa (over 100 stops), that of the Church of S. Alessandro in Colonna (100 stops, circa), the Crystal Palace organ. London (65 stops), and the transept organ of St. Paul's, London (60 stops). In Paris, the organs of St. Eustache, St. Sulpice, the Madeleine, the Trocadéro, etc. In the U. S. there are now a number of large and fine organs well worthy of comparison with anything of European construction. The concert-organ in the Chicago Auditorium is one of the largest in the world.

The reader is referred to the following works on the structure and history of the organ: *The Organ, its History and Construction*, by Edward J. Hopkins, with a new history of the organ by Edward F. Rimbault (London). This is by far the most complete treatise on the subject. The nature of the sounds of organ-pipes is elucidated by Prof. Helmholtz in his great work on *The Sensation of Tones* (*Die Tonempfindungen*), translated by A. J. Ellis (London). Many curious chapters in the history of the organ and of organists may be found in the histories of music of Dr. Burney and Sir John Hawkins, and of the German historian Kiesewetter, Forkel, and especially A. W. Ambros.

Revised by Dudley Buck.

Organic Chemistry: a term that came into use formerly to express that branch of chemistry which dealt with the substances that occur in living things. A distinction was then made between these constituents of animate things and the mineral substances, the constituents of the inanimate portions of the earth. That branch of chemistry which had to do with the latter was called inorganic chemistry. As investigation advanced it was found that there is no essential difference between the compounds treated of in the two branches. They are all chemical compounds; and many of the substances found in plants and animals can be made artificially in the laboratory without the intervention of the life-process. (See Chemistry.) That which chiefly characterizes organic compounds is the fact that they all contain carbon, and therefore the term chemistry of the compounds of carbon has been generally adopted in place of organic chemistry. This name is not strictly correct, for the reason that the carbonates, such as limestone, marble, dolomite, etc., would be included, and it is not usual to treat of them under the head of compounds of carbon. Another name that has been proposed is chemistry of the hydrocarbons and their derivatives. This is based upon the conception that the great majority of so-called organic compounds are either hydrocarbons or are derived from these hydrocarbons. The truth is, the separate treatment of the compounds of carbon is merely a matter of convenience. The large number of these compounds and their great variety make special treatment necessary. It would, perhaps, be best to include *all* compounds of carbon, no matter what their origin, and keep the name chemistry of the compounds of carbon. In the same way there is a chemistry of silicon and of oxygen, and of every other element, but thus far there has been no occasion for making other subdivisions of the subject of chemistry.

Ira Remsen.

Organic Radicals: See Radicals.

Organism: See Biology.

Organ Mountains (Port. *Serra dos Orgãos*): a group of mountains facing the northern end of the bay of Rio de Janeiro, Brazil. They are the culminating portion of the Serra do Mar, attaining an altitude of 7,322 feet. In clear weather they are plainly visible from the city of Rio de Janeiro, and their grandeur and singularity are noted by every traveler. One of the numerous sharp pinnacles is called the Dedo de Deos (finger of God); it resembles a gigantic finger, pointing upward. Petropolis, Theresopolis, and other favorite summer resorts are in or near these mountains, and are easily accessible for tourists. H. H. S.

Organ of Bojanus: a name formerly applied, from its discoverer, to the excretory organ of Molluscs and Tunicates. These organs are now known to be homologous with those of most other animals, and the term Nephridium (*q. v.*) should be used for them.

Organ of Corti: See Histology (*Organs of Special Sense*).

Organ-point [cf. Fr. *point d'orgue*]: in music, a series of harmonious combinations having for its bass one long, sustained, and unvarying note. As the organ is the only instrument on which these passages can be performed with full effect, the origin of the name and of its substitute, "pedal" or "pedale," is readily explained. This holding or pedal note is usually either the dominant or the keynote of the piece, and the upper parts consist partly of harmonies related to the bass, and partly of accidental or passing chords, serving as links in the general course of the harmony. Organ-points are of great variety in structure and duration, occupying sometimes as many as twelve or sixteen bars, and seldom less than three. They generally

terminate with the perfect or imperfect cadence, or with a chord of the seventh and a pause, and may be classified as follows: (1) Those consisting of a train of simple chords, chiefly derived from the bass; (2) those formed of plain harmonies with suspensions; (3) those which consist of a number of deceptive or interrupted cadences; (4) those formed of sequences variously elaborated; and (5) those of a more abstruse character, in which harmonies of a foreign, and even discordant, nature are introduced. An organ-point is sometimes *double*, the former part having the dominant for its bass, and the latter part the tonic or keynote. Instances are occasionally found of *inverted* organ-points, or those in which the holding-note is not in the bass, but in one or more of the upper parts.

Organum: See NOVUM ORGANUM.

Orgetorix: a Helvetian of noble birth, who instigated the migration of the Helvetii, described by Cæsar in the first book of his *Gallic War*.

Oriani, ō-reĕ-aa'nĕĕ, BARNABA: astronomer, count, and senator of Italy; b. at Garegnano, near Milan, July 17, 1752. His teacher in mathematics was Lagrange, to whom he succeeded as astronomer, and he continued the *Effemeridi Astronomiche*, which had been begun by his great master. He prepared a map of the kingdom of Italy, and the observatory of Milan is largely indebted to him. Oriani was a man of very noble character, was honored with various decorations and the membership of many learned societies, and was especially noticed by Napoleon. His principal publications are *Lettera ad un Amico Astronomo*, etc.; *Lettere Astronomiche*, etc.; *Risposta alle Note che l'Abate Frisi fece*, etc.; *Obliquità dell' Eclittica dedotta dalle Osservazione solstiziali*, etc.; *Distanza dallo Zenito del Sole e delle Stelle fisse presso il Meridiano*; *Rifrazione osservata*, etc.; *Elementi di Trigonometria Sferoidica*. D. in Milan, Nov. 12, 1832. Revised by S. NEWCOMB.

Oriba'sius (in Gr. 'Ορειβάσιος) **of Pergamus**: physician to Julian the Apostate, whom he accompanied on his fatal expedition against the Persians (363). He was banished by the successors of Julian, but afterward recalled with honor, and lived to the end of the century. Of his medical encyclopædia (in seventy books), 'Ιατρικῶν συναγωγῶν ἑβδομηκοντάβιβλος, considerable portions remain. His two abridgments have been published only in Latin translations. There is an edition by Boussemaker and Daremberg, with a French translation (6 vols., Paris, 1851–76).
Revised by B. L. GILDERSLEEVE.

Oribe, ō-ree'bā, MANUEL: soldier and politician; b. in Uruguay about 1802. He was a leader of the *gauchos*, attained high military rank under Frutos Rivera, was his Minister of War and Marine 1833–35, and succeeded him as president Mar. 1, 1835. About this time the parties called *Colorado* and *Blanco* were formed, Oribe being chief of the latter, while Rivera led the former. Rivera and the Colorados revolted in 1837, and, though at first unsuccessful, eventually defeated Oribe and forced him to leave Montevideo (Oct. 25, 1838) four months before the end of his term. Oribe took refuge with the dictator Rosas, at Buenos Ayres, and soon after agreed to support a scheme for redueing Uruguay to his rule. Rosas furnished him with troops and arms; he invaded Uruguay and besieged Montevideo intermittently from 1842 to 1851, holding a large part of the interior of the country. This is known as the nine years' siege. For a time France supported the legal or Montevidean government, and in 1851 Brazil and Entre Rios interfered in its favor. Oribe finally capitulated Oct. 10, 1851, and Rosas was defeated and deposed soon after. In Sept., 1855, Oribe led the revolt which drove Flores from Montevideo, but he was prevented from seizing the presidency by the interference of foreign powers. D. at Montevideo, Nov., 1857. HERBERT H. SMITH.

O'riel Window; called also **Bow** (or **Bay**) **Window** [*oriel* is from O. Fr. *oriol*, gallery, corridor < Late Lat. *ori'olum*, portico, hall; cf. Lat. *aure'olus*, golden, gilded]: a window which projects from the side of the house, has three glazed sides, and is often divided by mullions. It is one of the most picturesque features in the domestic architecture of the Middle Ages and the age of Elizabeth. Some writers discriminate between the oriel window, carried on corbels and projecting from an upper story, and the bay window resting on the ground. Revised by RUSSELL STURGIS.

Orien'te: a province of Ecuador, embracing all the territory E. of the Andes. As claimed by Ecuador, it has an extent of 96,000 sq. miles; but the greater part of this is also claimed by Colombia and Peru, and the southern portion, along the upper Amazon, is actually held by the latter. The province includes the lower slopes of the Andes, and vast, forest-covered plains bordering the Napo and other branches of the Amazon; the only roads are almost impassable mule-tracks and footpaths, and the inhabitants, nearly all Indians, do not exceed 80,000. The streams are said to be rich in gold, and a little is obtained by primitive methods. Capital, Archidona. H. H. S.

Orien'tius: a Christian Latin poet from Gaul, of the fifth century; perhaps to be identified with the Bishop of Auch, who about the year 439 acted as ambassador of Theodoric I. to the Roman generals Aëtius and Litorius. His poem, in two books, containing 1,036 elegiacs, is entitled *Commonitorium*, an earnest admonition to the Christian to avoid besetting sins, which are enumerated. Of twenty-four prayers only two, in Senarii, are preserved. The authenticity of other poems attributed to Orientius is doubtful. There is an edition by Robinson Ellis (Vienna, 1888). See Manitius, *Geschichte der Christlich-Lateinischen Poesie* (pp. 192–201). M. WARREN.

Or'iflamme [= Fr. < O. Fr. *oriflambe* < Late Lat. *auriflamma*; *au'rum*, gold + *flam'ma*, flame]: the ancient battle-standard of France, once a banner belonging to the abbey of St. Denis. After 1124, when it was adopted as a royal standard by Louis VI., it was often borne in battle, but seems never to have been employed after the battle of Agincourt in 1415. The accounts of its form and color differ considerably, but it was of flame-colored silk beautifully adorned.

Or'igen, surnamed ADAMANTIOS, from his untiring energy: one of the most learned and spirited of the Christian Fathers; b. at Alexandria in 185 A. D.; was early initiated both in Christianity by Clemens Alexandrinus and in Greek wisdom by his father, Leonides, who was a teacher of rhetoric. During the persecutions which took place in the reign of Severus, Leonides suffered martyrdom, and the son undertook to maintain the family by opening a school, in which at first he simply taught the Greek language and literature, but soon also began to expound the doctrines of Christianity with great success. Bishop Demetrius appointed him master of the famous catechetical school of Alexandria, and in order to maintain himself in this position he sold his library and subjected himself to the severest asceticism, at the same time pursuing his mental development with unflagging vigor. He made an exhaustive study of Greek philosophy, and became a pupil of Ammonius Saccas, and during a visit to Rome he acquired a mastery of the Hebrew language. His school, which he still continued, prospered in spite of occasional disturbances by the pagans, and his fame increased. In 228 he was called to Greece to dispute some heresy which had lately arisen there. On his way he visited Palestine, was everywhere received with great attention and invited to preach, and at Cæsarea he was ordained a presbyter. This ordination Bishop Demetrius of Alexandria refused to recognize as valid, partly because it was not given by himself as Origen's proper diocesan bishop, and perhaps partly because he knew that Origen, misunderstanding the passage in Matt. xix. 12, had mutilated himself. Two synods held in Alexandria supported the bishop; and as the broad and liberal views which Origen held on many points, and the critical examination and allegorical explanation to which he subjected the Scriptures, had made him many enemies, the second synod even condemned several of his ideas as heretical, and excommunicated him (231). In the West, where his writings were very little known, the case attracted no attention, but the bishops of the East—of Palestine, Phœnicia, Achaia, and Arabia—declared for him, and he found refuge in Cæsarea, where he reopened his school with still greater success. During the persecutions under Maximinus he fled to Cappadocia, where he lived for two years. Under Gordianus he returned and continued his beneficial activity, but the sufferings and torture to which he was subjected during the Decian persecution broke his strength, and he died at Tyre in 254. Origen is considered unsound in his eschatology, and his teaching of restorationism, even of demons, is the chief count against him, but he ranks with the best of the Fathers and the holiest men of the Church. Of his many writings (6,000, it is said) only a few have come down to us. Of his *De Principiis* (Of the Principles) there exists only a free and even interpolated translation into Latin by Rufinus, edited by E. R. Redepenning (Leipzig,

1836) and by K. F. Schnitzer (Stuttgart, 1836). Of his HEXAPLA (*q. v.*), an edition of the Old Testament in six parallel columns in Hebrew, Hebrew text in Greek letters, and in the four versions by Aquila, Symmachus, the Septuagint, and Theodotion, and in parts other versions in parallel columns, we have only fragments, edited by B. de Montfaucon (2 vols. fol., Paris, 1713), but best by F. Field (Oxford, 1875). The beautiful treatise on martyrdom and the celebrated eight books against Celsus, which are an apology for Christianity, are entire. His works were among the earliest printed; his homilies appeared in 1475, and editions of his complete works appeared at Paris (2 vols. fol., 1512–19, and another in 1522–30); later and better editions in Basel, edited by Erasmus (2 vols. fol., 1545); in Paris (1572–74, 2 vols. fol.); by C. and V. de la Rue (4 vols. fol., Paris, 1733–59; also in Migne's series, vols. xi.–xvii.); by C. H. E. Lommatzsch (25 vols., Berlin, 1831–48); and an English translation of his treatises *On the Principles* and *Against Celsus*, with a few other writings, in Clark's Ante-Nicene Christian Library. See E. R. Redepenning, *Origenes, eine Darstellung seines Lebens und seiner Lehre* (Bonn, 1841–46).

Revised by SAMUEL MACAULEY JACKSON.

Original Burgher Synod: a Scottish Presbyterian body. See PRESBYTERIAN CHURCH.

Original Sin (Lat. *pecca'tum origina'le*): in theology, that act or state of sin from which all other sins originate. It is distinguished into *original sin imputed*—e. g. the guilt of Adam's apostasy charged to his descendants (see IMPUTATION)—and *original sin inherent*—that innate subjective moral corruption which is inherited by all men at birth, and which is the immanent cause of all actual transgression. The term is taken in the latter sense in this article, the *peccatum habituale* as distinguished from the *peccatum actuale*. It is proposed to state in historical order the principal opinions which have been entertained, first, as to its *nature* and *extent*, and, second, as to the manner of its propagation.

I. *Its Nature and Extent.*—(A) *Opinions prevalent before the Controversies of Augustine with Pelagius.*—There prevailed no definite and generally accepted views as to the nature and extent of the moral ruin wrought in human nature in consequence of Adam's sin. All agreed in the fact of a sinful taint, and of the need of redemption. The Eastern portion of the Church generally, and more particularly the Alexandrian school founded by Origen, in extreme reaction alike from Gnostic and from Neo-Platonic dualism, emphasized the self-determining power of the human will and man's responsibility, and consequently his ability to co-operate with any divine assistance vouchsafed for his recovery. On the other hand, the Latin Fathers, especially Tertullian, Hilary, and Ambrose, the immediate teacher of Augustine, emphasized hereditary sin and guilt, and the absolute dependence of the soul upon grace.

(B) *The Opinions entertained by the several Parties to the Anthropological Controversies of the Fifth Century.*—(1) Pelagius and his party held that Adam's sin injured only himself; that men are now born in the same moral state in which they were created; that *liberum arbitrium*, the power to choose indifferently good or evil, is essential to moral responsibility in every stage of action, and an inalienable prerogative of human nature. Hence man is morally well. (2) The *Semi-Pelagians* held that human nature is seriously injured by Adam's sin, and that hereditary corruption is a fault or disease, rather than a sin properly so called, since it involves no guilt (either *reatus pœnæ* or *culpæ*) previous to actual transgression. Man can choose and attempt the good, but through weakness is unable to effect it. Hence they denied *gratia preveniens*, predisposing grace, but admitted the necessity of *gratia co-operans*, which is rendered efficient by the spontaneous co-operation of the human will. (3) Augustine taught that the apostasy of Adam, in whom all men sinned, is the common guilt of all his natural descendants, who, while retaining freedom in the sense of rational spontaneity, come into being spiritually dead, unable either to begin or to effect any really good act before God—free only to sin, and dependent for salvation upon unmerited, sovereign, omnipotent grace. Before regeneration the soul can only resist grace; afterward, by the assistance of grace, it may co-operate with grace. Hence the necessity of *gratia preveniens*, disposing grace, *gratia operans*, regenerating grace, and *gratia co-operans*, grace assisting the regenerated to every holy act. See G. F. Wiggers, *Hist. of Augustinianism and Pelagianism*, part i. and part ii. For the history of the condemnation of Pelagianism and the adoption of Augustinianism in the Roman Catholic Church see ARMINIUS and CALVINISM.

(C) *The Tridentine doctrine*, or the later Catholic doctrine formulated by the Council of Trent (1545–63). It is admitted that human nature bears the guilt of Adam's sin, is morally corrupted, and without grace helpless. It distinguishes, however, between the *dona naturalia*, the soul with its constitutional faculties, and the *dona supernaturalia*, the superadded gift of supernatural righteousness. In the original creation all Adam's faculties, physical, intellectual, and moral, were in perfect equilibrium, the lower held in due subordination to the higher. To confirm this equilibrium, God added the gift of original righteousness. This supplementary gift Adam lost for himself and his descendants, and this loss (1) involves guilt; (2) leaves the natural powers in a state of instable equilibrium, so that the free will certainly falls into actual transgression as soon as moral agency begins. Yet man may seek the grace offered in baptism, which effects justification *ex opere operato* in all non-resistants (*non ponentibus obicem*). "Original sin" in the Roman Church consists, therefore, in the loss of "original righteousness," which nevertheless involves "obliquity of will from God"; and yet free will must co-operate with grace. See *Counc. of Trent*, sess. 6, 1, 3, 5, 7; Bellarmine, *Amiss.*, gr. iv. 3 and v. 17.

(D) *All the original Protestant Churches, Lutheran and Reformed*, agree, as to "original sin," that it includes (1) moral corruption of the whole man as well as the loss of "original righteousness." (2) This implies no physical change in the substance of the soul, but a depraved moral habit. (3) All the faculties, intellectual as well as emotional or volitional, as far as they relate to moral objects, are depraved. (4) This depravity, although admitting many civil virtues, is called total, because (1st) the whole man is involved; (2d) the breach with God is complete, and, without supernatural aid, irremediable; (3d) the tendency is ultimately to all sin. (5) This condition involves guilt (both of blame and punishment). Some say, because all sin is inherently blameworthy; others say, because it originated in Adam's abuse of free will, for which we are all responsible. (6) Man is morally impotent to change his own general disposition to evil. Hence he can not co-operate with grace before regeneration, but afterward by the continued operation of grace the free will acts graciously. See *Form of Concord* (Hase), pp. 639, 640, 645, 662, 681; *Gal. Conf.*, art. ii.; *Heidel. Cat.*, ques. 7–10; *West. Conf. Faith.* chs. vi., ix.; *Thirty-nine Articles*, art. 9.

(E) *The Arminian doctrine*, as held by the Dutch Remonstrants, regarded "original sin" rather as a fault or defect of nature than a sin. As held by the Wesleyans, it admits that man's nature is corrupted, indisposed, and disabled from all spiritual good; but both parties differ from the Lutheran and Reformed Churches in holding (1) that it involves no guilt, since it is not brought upon us by our own agency; and (2) that every soul retains power to co-operate with the grace with which God for Christ's sake endows every soul. *Conf. Remonstr.*, pp. 84 and 162, and Dr. D. D. Whedon in *Bib. Sacr.*, Apr., 1862.

(F) *The Socinian and Rationalistic doctrine* is nearly the same with that of Pelagius, above stated. There is no innate corruption. Sin is propagated by example. Man always retains plenary power to do all God requires of him. There is no grace beyond providential advantages and objective instruction. *Racov. Cat.*, pp. 294 and ques. 428–430.

II. *The Mode of its Propagation.*—(1) Origen taught the doctrine of the pre-existence of human souls, and their personal sin and *self*-corruption in a previous state of probation. This view, which denies the propagation of inherent corruption from Adam altogether, was revived by Dr. Edward Beecher in his *Conflict of Ages* (1853). (2) Tertullian taught the doctrine that souls as well as bodies are derived by generation from parents, and that sin, like every essential quality and many acquired accidents of nature, is propagated *ex traduce*. Augustine hesitated to decide between this origin of souls and their immediate creation. Many of the Greeks were creationists, and many of the Latins traducianists. Since the Reformation most of the Lutherans have been traducianists, and most of the Reformed creationists. (3) Jerome held that each soul was immediately created by God. Creationists account for inherent moral corruption either (*a*) *per corpus*—that is, from the union of the soul with a body in which sin is propagated by generation (*Lampe* (Utrecht, 1683–1729), vol. i., p. 572)—or (*b*) *per culpam* —from the judicial withholding from the new-created soul

of the life-supporting influence of the Holy Ghost, as the punishment of Adam's first sin. See Dr. R. Ridgeley (London, 1667–1734); Turretine (L. ix., ques. 12).

Revised by F. H. Foster.

Orihuela, ō-rē̆e-wā'lăă: town of Spain; in the province of Alicante; on the Segura; 36 miles S. W. of the city of Alicante, in the middle of a most fertile plain (see map of Spain, ref. 18–H). It has a cathedral, a college, and manufactures of hats, linen and silk fabrics, and paper, and many flour and oil mills. Pop. (1887) 24,364.

Oril'lia: post-village of Simcoe co., Ontario, Canada; on Lake Couchiching, and on the Grand Trunk Railway; 90 miles from Toronto (see map of Ontario, ref. 3–D). It is the seat of a provincial asylum for lunatics. The town is connected by steamboat with Lake Simcoe and the Muskoka country. It has a good trade, important manufactures, and two monthly and three weekly papers. Pop. (1891) 4,752.

Orino'co: one of the largest rivers of South America; lying entirely in Venezuela, but with branches in Colombia. In the article America, South (*q. v.*), it was shown that three great river-depressions extend from the Atlantic far into the interior of the continent, becoming confluent toward the W. The Orinoco depression is the northernmost and smallest of the three; separating the highlands of Guiana from the Venezuelan coast mountains, it runs into the Amazonian depression southwestward, thus leaving Guiana like an island, cut off from the rest of South America by comparatively low lands. (See Guiana.) The southwestern part of the Orinoco depression is about 1,000 feet higher than the eastern part, forming an interior basin largely covered with forest, and quite different in character from the broad open plains near the Atlantic. On leaving this upper basin the river flows down in a series of rapids, which occupy a comparatively small space, and separate the navigable upper part from the wide lower channels. The Orinoco rises on the southeastern side of the highlands of Venezuelan Guiana, and follows their edges around in a broad curve northward, finally turning E., still near the edges of the highlands, until it reaches the Atlantic. Hence the right bank of the river is generally high, or the lowlands on that side are of small extent, and the tributaries are navigable for comparatively short distances; the great plains and the most important navigable branches are on the left side. Near and above the rapids there are isolated hills or mountains in the upper basin, on the left side of the river. We know almost nothing of the vast tract to the S. W., about the Meta and Guaviare branches; and it is quite possible that the upper basin in this direction is broadly continuous with the Amazonian depression. That the two river-basins are confluent, at least for a small space, is shown by their actual water connection through the Cassiquiare and Rio Negro; but this connection is 920 feet above sea-level. The sources of the Orinoco (discovered by Chaffanjon in Dec., 1886) are in the Sierra de Parima, close to the frontier of Brazil. Descending rapidly to the W. N. W. the river enters the upper basin, where it becomes navigable for small vessels. In this region is the remarkable and unique channel which connects it with the Rio Negro and Amazon. The Orinoco bifurcates; about one-sixth of its water takes the left-hand channel, which is here about 50 yards wide, and after a course of 190 miles enters the upper Rio Negro. Below the Cassiquiare the Orinoco receives the Ventuario on the right and the Guaviare on the left. It then turns N., and enters the region of the *raudales* or rapids. The most important of these are the Raudales de Maypures, 4 miles long, and the Raudales de Aturés, 6 miles long. The river, straitened by opposing hills, rushes foaming through numerous small channels between rocky islets, forming a scene of almost unsurpassed grandeur. The Indians drag their canoes through these rapids with great difficulty and danger, but they are impassible for large vessels. From the Raudales de Atures downward the river is freely navigable, though its shifting sandbanks and bewildering channels require an experienced pilot. It receives the Meta and Apure, its two most important tributaries, from the W., then turns directly E., flowing between the highlands of Guiana and the broad open plains of the Llanos (*q. v.*). The river here is so near sea-level that its waters rise and fall regularly with the tide as far up as Ciudad Bolivar, 270 miles from the mouth. On approaching the sea it forms an immense swampy and forest-covered delta, dividing into more than fifty channels, which spread out over 180 miles of coast. The islands are haunted by fevers, and swarm with mosquitoes. The few Indian inhabitants often build their houses on platforms to escape the river floods. Only one of the channels is used by large vessels. The whole length of the Orinoco is about 1,550 miles; it is navigable for 870 miles to the rapids, and above them to within 150 miles of its source. It receives eight large tributaries and an immense number of smaller ones; the Meta and Apure are navigable to the base of the Andes. The area drained by it is roughly estimated at nearly 400,000 sq. miles of very thinly inhabited country. Steamers from Trinidad ascend the main river regularly, and some attempts have been made to open up the tributaries. Diego de Ordaz navigated the Orinoco to the junction of the Apure in 1531–32, and subsequently the region was traversed by many adventurers in search of El Dorado. Humboldt (1800) was the first to describe the Cassiquiare channel, though it had long been known to missionaries. The latest and best survey is that of Chaffanjon (1885–87). See Orinoco River in the Appendix; Humboldt's *Travels*; Michelena y Rojas, *Exploración Oficial* (1867); Schomburgk, *Reisen en Guiana und am Orinoko* (1841); Chaffanjon, *Découverte des sources de l'Orénoque* (in *Comptes rendus de la Société de Géographie de Paris*, Dec., 1887).

H. H. Smith.

O'riole [from O. Fr. *oriol* > Fr. *loriot* (for *l'oriol*, the oriole) < Lat. *aure'olus*, dimin. of *au'reus*, golden, deriv. of *au'rum*, gold]: a name properly belonging to bright-colored Old World birds of the genus *Oriolus* and the family *Oriolidæ*; but in the U. S. the name is given to birds of the family *Icteridæ*. The name was probably transferred to these birds of the New World on account of their color, which is usually black and yellow, like that of the true orioles. (See Baltimore Oriole.) The only European oriole is the *O. galbula*, or golden oriole. Its name it derives from its color, which in the adult male is bright yellow over the whole of the head, neck, and body, with the exception of the wings, the two central tail-feathers, and the basal portions of the remaining feathers, which are jetty black, the two colors contrasting finely with each other. Across the eye runs a dark stripe, and the eyes themselves are reddish. The bird has a very peculiar note, loud, flutelike, and so singularly articulate that the Italian peasantry believe it speaks their language. Its nest is a very elegantly formed and well-constructed edifice of a shallow cup-like shape, and is usually placed in a horizontal fork of a convenient branch. The materials of which it is made are mostly delicate grass-stems so firmly interwoven with wool that the whole structure is strong and warm. The eggs are generally four or five in number, and their color is purplish white, sparely marked with blotches of a deep-red and ashen gray. Its food consists chiefly of insects; and, as the bird is rather a voracious creature, it is very serviceable in clearing away caterpillars and other fruit-devouring insects. It is an exceedingly shy and timorous bird, and, as it always takes the trouble to set sentries on guard, it can not be approached without the greatest patience and wariness on the part of the sportsman or the observer. It is quite common in Italy, and it is also found in the other countries of Southern Europe. It is gregarious in its habits, generally associating in little flocks and frequenting lofty trees and orchards, where it finds plenty of food.

Revised by F. A. Lucas.

Ori'on [= Lat. = Gr. Ὠρίων, Orion, fabled to have been a hunter transferred to the sky]: one of the constellations. It is mentioned (Job ix. 9; xxxviii. 31) by the Hebrew word *cesil*, which signifies a "fool," and also an "impious, godless man," called by the Arabs "the giant." The giant of ancient astronomy was Nimrod, who was fabled to have been bound to the sky for his impiety. The Greek mythology in various ways represent him as a giant who was slain by Diana, who in remorse placed him among the stars. The constellation is represented by the figure of a man with a sword by his side. Though a southern constellation with regard to the ecliptic, the plane of the equator passes through its middle. Its contains seven conspicuous stars; the three forming the belt are also called "Jacob's staff" and the "yard wand." One of the most remarkable nebulæ of the heavens is situated in the sword-handle of Orion.

Orissa [Sanskr. *Odra*, northern]: formerly the northern part of the old province of Kalinga, now the southeast portion of the province of Bengal, India. Its coast region is an extremely fertile, alluvial delta formed by the numerous branches of the Mahánadi, Bráhmani, and Baitarani rivers. Behind this densely populated coast region is the hill country, rather sparsely peopled and comprising two-thirds of

the total area of the district, which is 24,140 sq. miles. Rice is the chief product, agriculture is almost the only pursuit, and nearly all the inhabitants are Hindus. Pop. (1891) 3,865,020. C. C. Adams.

Orizaba, ō-rē̆e-thaa'bă̆a (called *Citlaltepetl*, or Mountain of the Star, by the Aztecs): a mountain of Mexico, on the confines of the states of Vera Cruz and Puebla, near the eastern edge of the plateau. The summit is covered with snow, and the ascent is difficult and dangerous. According to the careful measurements (partly by triangulation) made by Scovell and Bunsen in 1891–92, the highest point is 18,314 feet above sea-level; it is therefore the highest mountain in Mexico, and possibly the highest in North America. Orizaba is a quiescent volcano. In clear weather it is visible from the Gulf of Mexico, near Vera Cruz, presenting a magnificent sight. The railway from Vera Cruz to Mexico passes by its base. Herbert H. Smith.

Orizaba [corrupted from the Nahuatl *Ahauializapan*, liter., pleasant waters]: a town of the state of Vera Cruz, Mexico; on the railway from Vera Cruz to the capital; 17 miles S. E. of the mountain to which it has given its name (see map of Mexico, ref. 7–I). It is beautifully situated in a broad valley, 4,025 feet above sea-level; its delightful climate and magnificent scenery make it a favorite resort both for Mexicans and for foreigners. Maize, tobacco, and sugar-cane are extensively cultivated in the vicinity, and the town has several cotton-mills and other manufactories, the motive-power being derived from the Rio Blanco. Orizaba was an ancient Indian town. It was the headquarters of the French in 1862. Pop. (1894) about 25,000.

Herbert H. Smith.

Orkhan, Ghazi, the Victorious: first Ottoman sultan (1326–60); b. 1290; captured Broussa (1326) shortly before his father's death, and as his elder brother Alaeddin refused the throne, he succeeded to it. The brothers were devotedly attached to each other, and Alaeddin, who was a statesman and scholar, aided him as his grand vizier. Orkhan was an able soldier, and captured Nice, Nicomedia, and Pergamus, and by these and other conquests more than trebled his states, which Alaeddin organized. By the conquest of Tzympe and Gallipoli (1357) the Ottomans gained their first foothold in Europe. Orkhan married (1347) Theodora, daughter of John VI. Cantacuzenos, Byzantine emperor, but did not force her to adopt his creed. He died (1360) of grief at the death of his brother and his son Suleïman.

E. A. Grosvenor.

Ork'ney Islands: a group of sixty-seven islands, of which twenty-nine are inhabited, lying off the northern coast of the mainland of Scotland, from which they are separated by the Pentland Firth. They comprise an area of 375 sq. miles, with a population in 1901 of 27,723. The largest is Pomona or the Mainland; the most remarkable among the others are South Ronaldshay, Hoy, Flotta, Rousay, and Sanda. With the exception of the Hoy, which is rocky and mountainous, its western coast reaching a height of 1,600 feet, the Orkney islands are low, presenting an irregular coast-line—in some places rocky, in others sandy. The climate is mild, considering the northern latitude, frosts are very rare, but the summers are often chilly, and always moist. The soil is remarkably fertile. The chief agricultural products are barley, oats, potatoes, and turnips, and sheep and cattle are extensively reared. Fishing, hunting for wild birds and eggs, rearing of poultry, and distilling are important occupations. There is regular steam communication between Kirkwall, the chief town, and Wick, Aberdeen, and Leith, and between Stromness (the next most important town) and Thurso on the mainland, and a small steamer connects Kirkwall with the North isles. Communication with the other islands is by "packet." The tides rush with great rapidity through the numerous sounds and channels formed by the islands, and navigation is dangerous. In 1889 the Orkney islands were separated from the Shetlands and erected into a separate county. Orkney and Shetland together send one member to Parliament. The Orkney islands are mentioned by the ancient geographers Pliny and Ptolemy, and by other classical writers, under the name Orcades, whence the modern adjective "Orcadian." Little, however, is known of the inhabitants till the dawn of the Middle Ages. They were probably of the same stock as the British Celts. The islands, together with the Hebrides, were conquered by the Norwegians in 876, and formally annexed to the Norwegian crown in 1098. In 1397 they were united to Denmark, and in 1468 the Danish king, Christian I., gave them to the Scottish king, James III., who married his daughter, as a security for her dowry. The dowry was never paid, and in 1590 the islands were formally turned over to Scotland. During their long connection, however, with Norway and Denmark all traces of the primitive Celtic population disappeared, and the present inhabitants are of pure Norwegian stock.

Revised by R. Lilley.

Orlando: city; capital of Orange co., Fla. (for location, see map of Florida, ref. 5–J); on the Fla. Cent. and Peninsular and the Savannah, Fla. and West. railways; 90 miles S. of Palatka. It is in the heart of the orange, pineapple, and grape region; has 6 churches, street-railways, gas and water-works, large foundry and machine-works, 2 State banks, and a daily and 2 weekly newspapers; and is a noted winter resort. Pop. (1890) 2,856; (1900) 2,481.

Editor of "Reporter."

Orléanais, ōr'lā'ă̆a'nā': an ancient province of France; situated nearly in the center of the country, bounded by the provinces of Île de France, Champagne, Burgundy, Berry, Touraine, Maine, Perche, and Normandy. It consisted of Orléanais proper, with the capital of Orleans; Beauce, comprising Pays Chartrain, Dunois, and Vendômois, with the capital of Chartres; Blaisois, with the capital of Blois; and Gatinais-Orléanais, with the capital of Montargis. Its territory constitutes the three departments of Loire-et-Cher, Eure-et-Loire, and Loiret, and parts of Indre, Indre-et-Loire, Nièvre, and Yonne.

Or'leans: city of France; capital of the department of Loiret; 75 miles by rail S. S. W. of Paris, on the right bank of the Loire, which is crossed here by a magnificent bridge of nine arches (see map of France, ref. 4–E). It has many fine promenades, handsome public squares, and elegant buildings, among which the cathedral is one of the most magnificent Gothic edifices of France; but generally the town is ill-built. Its educational institutions, especially its medical schools, and its museums are excellent, and its sugar-refineries and manufactories of vinegar and woolen fabrics are very extensive. The University of Orleans, founded in 1312, was suppressed in 1789. The city contains three beautiful statues of Joan of Arc, the Maid of Orleans, and its museums have numerous antiquities and monuments relating to her. During the Franco-German war Orleans was the center of the preparations made by the government of defense for the purpose of raising the siege of Paris, and for some time in 1870 the city was occupied by the Germans, though without suffering any harm. Pop. (1891) 63,705; (1896) 66,699.

Orleans, Duchy of: an old division of France, consisting of Orléanais proper, with the capital, Orleans. It formed a countship under the Carlovingian and Capetian dynasties, but was erected into a duchy in 1344 by Philip VI. of the house of Valois, and given to his son as an appanage. Subsequently it was held in the same way by different younger branches of the reigning families of Valois and Bourbon. Thus Louis, the second son of Charles V. of Valois, and for a time lieutenant-general of France during the insanity of his brother the king, Charles VII., received the duchy of Orleans in 1392 as a fief, and after his death, in 1407, his son Charles held it to 1465; but when, in 1498, his grandson, Louis, ascended the throne of France as Louis XII., it returned to the French crown. In 1626 it was bestowed on Jean Baptiste Gaston, brother of Louis XIII., the youngest son of Henry IV. of the house of Bourbon, famous in history for the unflagging steadfastness with which he formed one conspiracy after the other against Richelieu, and the cynical treachery with which he every time sacrificed his accomplices; he died in 1660, leaving no male heirs. The most remarkable of the several families which have held the title and possessions of the duchy is that descending from the younger brother of Louis XIV., Philip, a son of Louis XIII., b. in 1640, married in 1661 to Henrietta of England, and after her death, in 1671, to Charlotte Elizabeth of Bavaria; d. in 1701. This branch of the family, by virtue of its descent from Louis XIII., played a very prominent part in subsequent French history. In the Treaty of Utrecht (1713) the Duke of Orleans waived all rights to the throne of Spain, and the Duke of Anjou (Philip V.) all hereditary rights to the French succession. These provisions determined the rights of the Count de Chambord and the Count of Paris in the nineteenth century. During the administration of Richelieu as well as during the reigns of Louis XIV. and Louis XV. the family occupied a position of special prominence. Revised by C. K. Adams.

Orleans, Prince Louis Philippe, Duke of: eldest son of the Count of Paris; b. Feb. 6, 1869. On attaining his majority (Feb. 6, 1890) he entered Paris, and expressed his desire as a Frenchman to perform his military service; was arrested in accordance with the Expulsion Act of 1886, which forbids the soil of France to the direct heirs. He was liberated after a few months' imprisonment.

Orleans, Louis Philippe Joseph, Duke of, better known as Philippe Égalité: revolutionist; b. at St.-Cloud, Apr. 13, 1747; married in 1769 Adelaide of Bourbon-Penthièvre, who brought him immense wealth; entered with zeal into the revolutionary agitation, and became on account of his rank and influence the center of the opposition to the court. He renounced his rank and titles, assuming the name of Citizen Égalité, and aspired to be the leader of the republican movement, but lacked the ability and force of character to command respect. Influenced by fear he voted for the death of the king, but neither this nor his subserviency as the tool of the Jacobins saved him from the suspicion of complicity with his kinsmen, and he was tried and guillotined on Nov. 6, 1793.

Orleans, Philippe, Duke of: regent of France during the minority of Louis XV.; b. Aug. 4, 1674; distinguished himself as a soldier, especially while in command of the French army in Spain, where in 1707 and 1708 he conducted brilliant and successful campaigns; became sole regent on the death of Louis XIV., and showed himself in some respects an able ruler. The Stuarts left France, and an alliance was formed with Great Brit'n. On the other hand, his Government countenanced the nancial folly of the Mississippi scheme. In his private .'e he was grossly licentious, and his excesses hastened his death, which occurred Dec. 2, 1723.

Orleans, Maid of: See Joan of Arc.

Orley, Bernard van: painter; b. in Brussels in 1490. Having studied art with his father and cousin, he went to Rome, where he became a pupil of Raphael, who employed him in his great compositions. After Raphael's death he returned to Brussels, where Charles V. commissioned him to paint several pictures of hunting scenes. He made cartoons for tapestries for the palaces of the emperor and of the princes of the house of Austria and of the Duchess of Parma. He painted a fine picture of the *Last Judgment* for the chapel of the Almoners in Antwerp, and a *St. Luke painting the Virgin* for the society of painters of Mechlin. He also made designs for the tapestries of the Castle of Breda for William of Nassau. D. in 1560. W. J. S.

Or'loff: name of a Russian family, prominent since the seventeenth century, remarkable rather for courage and physical characteristics than for intellectual and moral qualities. (1) Ivan: one of the rebellious strelitzi, pardoned on the scaffold (1689) by Peter the Great, who was pleased by his undaunted bearing. He assumed the name Orloff.—(2) Orloff, Gregory: soldier; son of (1), father of five sons and one daughter, the latter commonly revered as St. Catherine.—(3) Orloff, Ivan: author; son of (2); b. 1733; d. 1791.—(4) Orloff, Gregory: general; son of (2); b. 1734; chief of the conspirators who deposed Peter III. (July 9, 1762) and made Catherine II. sole ruler. In consequence, he and his four brothers were made counts. By him Catherine had a son, Count Bobrinski. His brutality and arrogance finally alienated the empress; he was banished, then recalled, and on account of his courage during the pest at Moscow, partially restored to favor. Failing in a diplomatic mission and again disgraced, he became insane and died (1783) at Moscow.—(5) Orloff Tcheshmenski, Alexis: general; son of (2): b. 1736; d. 1808; a man of gigantic stature but little intellect. Joining his brother's conspiracy, he is said to have strangled Peter III. with his own hands. He commanded the Russian squadron which won the great naval battle of Tcheshme (1770), whence he received the title of *Tcheshmenski*. That victory was due, however, to his British officers, Elphinstone, Gregg, and Dugdale. The Princess Tarakanoff, daughter of the dead Empress Elizabeth, was then residing in Italy, and caused anxiety to Catherine II. Professing himself the lover of the princess, he won her hand, enticed her on board his fleet, and carried her to Russia, where she was put to death. He was banished soon after the accession of the Emperor Paul.—(6) Orloff, Vladimir: scientist; son of (2); president of the Academy of Sciences of St. Petersburg.—(7) Orloff, Gregory Vladimir: author; son of (6); b. 1777; d. 1826; wrote numerous works on history and art.—(8) Orloff, Feodor: general; son of (2); b. 1741; d. 1796; notable only through his four illegitimate sons, from whom the present members of the family descend.—(9) Orloff, Alexis: general; son of (8); b. 1786; d. 1861; saved the life of Emperor Nicholas in 1825; skillfully negotiated Treaty of Adrianople (1829), and Treaty of Hounkiar Iskelessi (1833), but was afterward generally unsuccessful in the many high offices he held; represented Russia at the Congress of Paris (1856), and was made a prince.—(10) Orloff, Nicolas: diplomat; son of (9); b. 1827; d. 1885; Russian ambassador to Paris in 1872; wrote on campaign of 1806 in Prussia.—The Orloff-Denissoff family, unconnected with the persons above mentioned, are prominent on the Don, and have hereditary right to furnish the hetman of the Cossacks.

E. A. Grosvenor.

Ormazd, or **Ormuzd** [Pers. < O. Pers. *auramazdā*: Avest. *ahura mazdāh*; cf. Sanskr. *asura*, spirit, divinity, (later) demon, and *médhas-*, wisdom]: the supreme god in Zoroastrianism, or the religion of ancient Persia. The meaning of the name *Ahura Mazdāh* in Avestan (*q. v.*) is the Lord Wisdom, and he is the omniscient, omnipresent source of all that is good in the world; his opponent, Ahriman (Avest. *Anra Mainyu*, the Enemy Spirit), affords a parallel to Satan. Zoroastrian dualism recognizes the two principles of Ormazd and Ahriman as primeval and coeval, but not coeternal: Ormazd in the end shall triumph and destroy Ahriman. A later Persian sect, the Zervanists, regarded both these principles as sprung from *Zarvan Akarana* (Time Eternal); one Iranian sect, called Gayomarthians, conceived Ahriman to be an evil spirit sprung from Ormazd. The exalted and spiritual conception of Ahura Mazda with his ministering angels that is found in the Zoroastrian scriptures is the nearest approach to Jehovah that can be found in ancient religions. See Zoroaster.

A. V. Williams Jackson.

Ormiston, William, D.D., LL.D.: clergyman; b. at Symington, Lanarkshire, Scotland, Apr. 21, 1821; removed to Canada in 1834; was educated at Victoria College, Cobourg, Ontario, afterward Victoria University, Toronto, where he completed his theological course, was classical tutor four years and Professor of Moral Philosophy one year; was pastor at Newtonville, Ontario, 1849–53; superintendent of the township schools 1849–63; mathematical master and lecturer in science in the Normal School, Toronto, 1853–57; examiner at Toronto University 1854–57; pastor of the Central Presbyterian church, Hamilton, Ontario, 1857–70; of the Collegiate Reformed church, New York, 1870–88; stated supply at Pasadena, Cal., 1889–90; since 1890 was an evangelist in Southern California. He wrote copiously for periodicals; prepared series of textbooks; edited with notes *The Acts of the Apostles* (New York, 1883); was author of *An Exposition on a Part of the Epistle of James* in *The Homiletical Monthly*; and long prepared the Sunday-school lessons for *The Sunday-school Times*. D. in Aruza, near Los Angeles, Cal., Mar. 21, 1899.

Ormolu, or **Mosaic Gold** [*ormolu* is from Fr. *or moulu*, liter., ground or milled gold; *or*, gold (< Lat. *aurum*) + *moulu*, perf. partic. of *moudre*, mill, grind (< Lat. *molere*)]: an alloy of zinc and copper, containing from 25 to 75 parts of zinc in 100 of the alloy, a considerable proportion of the zinc being volatilized, unless the lowest possible temperature be employed in fusing the metals. The fused mass is kept until it takes on a white color, when it is cast at once, for if remelted it becomes a comparatively worthless kind of brass. It is largely employed in making household ornaments, which are colored by pickling in dilute oil of vitriol and then washed and varnished. In France the name is applied to gold-leaf prepared for gilding surfaces such as bronze or brass.

Ormond, James Butler, First Duke of: soldier and statesman; b. in London, England, Oct. 19, 1610; educated by Archbishop Abbot as a ward of the king; succeeded to the earldom of Ormond on the death of his grandfather 1632; was commander of the royal troops in Ireland as lieutenant-general during the insurrection of 1641; was created marquis 1642; was forced to make a disadvantageous armistice with the rebels 1643; became lord-lieutenant 1644; resigned his office to the Parliamentary commissioners, and retired to France 1647; proclaimed Charles II. in Ireland, and made an unsuccessful attempt to capture Dublin 1649; was driven from Ireland by Cromwell Dec., 1650; was created duke by Charles II. 1660; was Viceroy of Ireland 1661–69;

chancellor of the University of Oxford 1669; narrowly escaped assassination by Col. Blood 1670; again Viceroy of Ireland 1677–85; was made a duke in the English peerage 1682. D. at Kingston Hall, Dorsetshire, July 21, 1688.

Ormus: an island, 12 miles in circumference, in the Strait of Ormus, at the entrance to the Persian Gulf; now important only for its salt-works. At its northeastern extremity a miserable village of a hundred huts occupies the site of the once splendid city. This was captured by Albuquerque (1507), who made it the entrepôt of European-Indian commerce, but was utterly destroyed (1622) by Shah Abbas and the British East India Company. It is held by the Imam of Muscat, who pays tribute for it to Persia. E. A. G.

Ormuzd: See Ormazd.

Orne, ōrn: department of France; part of the old province of Normandy; area, 2,354 sq. miles. It is traversed by a range of wooded hills rising 1,370 feet above the sea, and rich in iron, copper, marble, and granite. To the N. and S. of these hills large pasture-grounds extend, where numerous cattle and horses are reared. Hemp is extensively cultivated, and there are large apple and pear orchards. About 22,000,000 gal. of cider are made annually. Manufactures, especially of metal-ware, are carried on. Pop. (1896) 339,162. Capital, Alençon.

Ornithology [from Gr. *ὄρνις*, *ὄρνιθος*, bird + *λόγος*, discourse]: that branch of zoölogy which treats of birds and the literature respecting them. Although it includes all that relates to birds, their external appearance, pterylosis, anatomy, and habits, it is very largely concerned with their classification, or their division into groups, and the arrangement of these groups with respect to each other. In fact, a history of the attempts at the classification of birds is practically a history of the progress of ornithological science, and it is the purpose of this article to note some of the more important systems which have been brought forward and the characters on which they were based.

We look in vain in the ancient authors for any clear idea of the relations of the various groups of this class; birds are chiefly considered (e. g. by Aristotle) with relation to their food and the means by which they obtain it, or (e. g. by Belon and Aldrovandi) with respect to their adaptation for progression and their habitat. Willoughby,* and his commentator Ray,† first gave a reasonable arrangement of the constituents of the class dividing it, primarily, into land and water birds; the former were then differentiated into those organized as birds of prey and those adapted for a less carnivorous or for a frugivorous diet; the latter were divided into waders and swimmers.

Linnæus‡ is celebrated as a systematist, and is looked up to as the father, to a great extent, of the modern methods; it is necessary, therefore, that his system should be alluded to. In the final edition of the *Systema Naturæ* (ed. 12, 1766) he divided the class into six orders—viz.: (1) *Accipitres*, in which the bill is hooked and decurved; the upper mandible projecting beyond the lower, and on each side dilated or armed with teeth; and the feet provided with acute arched claws. (2) *Picæ*, in which the bill is cultriform and with the dorsal outline convex, and the feet short and quite strong. (3) *Anseres*, in which the bill is smooth, covered with an epidermis, and enlarged at the tip; the feet webbed, and with the tibiæ compressed and short. (4) *Grallæ*, in which the bill is subcylindrical, the feet elongated and adapted for wading, and the femora partially naked. (5) *Gallinæ*, whose species have the bill convex, the upper mandible arched above the lower, and the nostrils overarched by a cartilaginous membrane, the feet adapted for walking, and the toes rough beneath; and (6) *Passeres*, in which the bill is conical and pointed, and the feet slender, with the toes separated and adapted for hopping. It will be thus seen that these groups were based entirely on the consideration of the structure of the bill and feet, the other characters enumerated by Linnæus, but not here reproduced, relating to the body, food, and nesting habits, being quite subsidiary; but this classification was generally accepted, and the views involved therein prevailed with naturalists generally until very recent times. Cuvier§ in 1797 slightly modified the classification of Linnæus in its details, but the orders were essentially the same as those of his predecessor. Lacépède in 1799 divided the birds into two classes—differentiated because in the one case the leg is furnished with feathers, and in the other destitute of them. Fourteen orders were recognized. Meyer and Wolff* in 1810 primarily divided the birds into terrestrial and aquatic species: (*a*) the former into the orders (1) *Accipitres*; (2) *Coraces*; (3) *Picæ*; (4) *Oscines*, or singing birds; (5) *Chelidones*, including the swallows, swifts, and goatsuckers; (6) *Columbæ*, or the pigeons; and (7) *Gallinæ*; (*b*) the latter into the orders (8) *Grallæ*, or waders, and (9) *Natantes*, or swimming birds.

Illiger,† who attempted to reform the classification as well as nomenclature of the mammals and birds, presented an arrangement of the latter in which he grouped the various genera of birds into 41 families combined under 7 orders. The orders were distinguished, as by his predecessors, chiefly on account of the feet; the families by various characters, but more especially by the form of the bill and minor details of structure of the feet and wings. As the families were for the first time systematically introduced into this work, a synopsis of the system is worthy of reproduction:

Order I. Scansores, with families—1, Psittacini (parrots); 2, Serrati (toucans, plantain-eaters, etc.); 3, Amphiboli (cuckoos, etc.); 4, Sagittilingues (woodpeckers); 5, Syndactyli (jacamars).

Order II. Ambulatores, with families—6, Angulirostres (kingfishers, bee-eaters); 7, Suspensi (humming-birds); 8, Tenuirostres (sunbirds, hoopoes, etc.); 9, Pygarrhichi (creepers, Dendrocolaptes); 10, Gregarii (orioles, starlings, etc.); 11, Canori (song-birds); 12, Passerini (sparrows); 13. Dentirostres (motmots, hornbills); 14, Coraces (Corvidæ, birds of paradise, grakles, etc.); 15, Sericati (Ampelis, Procnias); 16, Hiantes (swallows, swifts, goatsuckers).

Order III. Raptatores, with families—17, Nocturni (owls); 18, Accipitrini (Falconidæ); 19, Vulturini (vultures).

Order IV. Rasores, with families—20, Gallinacei (fowls, etc.); 21, Epollicati (Ortygis, Syrrhaptes); 22, Columbini (pigeons); 23, Crypturi (tinamous); 24, Inepti (dodos).

Order V. Cursores, with families—25, Proceri (ostriches); 26, Campestres (bustards); 27, Littorales (shore-birds).

Order VI. Grallatores, with families—28, Vaginati (Chionis); 29, Alectorides (mixture); 30, Herodii (cranes, etc.); 31, Falcati (Tantalidæ); 32, Limicolæ (Scolopacidæ, etc.); 33, Macrodactyli (jacanas, rails); 34, Lobipedes (lobe-footed birds); 35, Hygrobatæ (incongruous mixture).

Order VII. Natatores, with families—36, Longipennes (Laridæ); 37, Tubinares (Procellariidæ; 38, Lamellosodentati (Anatidæ); 39, Steganopodes (swimmers with four anterior toes); 40, Pygopodes (swimmers with legs far back); 41, Impennes (penguins).

In 1812 a German zoölogist, Blasius Merrem,‡ proposed a new arrangement, which was destined to be ignored by his contemporaries, but, in its primary features at least, after being almost dormant for half a century, to be revived and quite generally accepted. Instead of differentiating the class into orders distinguished by differences of bill, wings, and feet, he took the sternum as the essential feature, and divided the class primarily into two groups—(1) *Aves carinatæ*, in which the sternum was produced at the median line and provided with a keel; and (2) *Aves ratitæ*, in which the sternum was flat toward the middle and entirely destitute of a keel. The former (1) included all the ordinary birds, which were further differentiated into aërial birds (*Aves aëreæ*), including the *Raptores*, *Pici*, and *Passeres*; terrestrial birds (*Aves terrestriæ*), embracing the gallinaceous forms; water-birds (*Aves aquaticæ*), represented by the swimming types; and marsh-birds (*Aves palustres*), corresponding with the waders of other authors. The latter division (2) was limited to the ostriches, nandus, cassowaries, emus, and kiwis. The only really important modification introduced into the classification was the distinction of the two primary groups.

N. A. Vigors in 1823 read a memoir before the Linnean Society of London§ on the classification of the class,

* *Ornithologiæ libri tres* (London, 1676)—a posthumous work edited by Ray.

† *Synopsis Methodica Avium et Piscium* (London, 1713).

‡ *Systema Naturæ*.

§ *Tableau élémentaire de l'Histoire naturelle des Animaux* (Paris, 1797).

* *Taschenbuch der deutschen Vogelkunde* (Frankfort-on-the-Main, 1810).

† *Caroli Illigeri Prodromus Systematis Mammalium et Avium* (Berlin, 1811).

‡ *Tentamen Systematis Naturalis Avium* (in *Abhandl. K. Pr. Akad. Wissensch.*, 1812).

§ *Observations on the Natural Affinities that connect the Orders and Families of Birds*, in *Trans. Linn. Soc. London* (vol. xiv., pp. 395–517, 1825).

which deserves special mention, less because of any improvements in classification than because in it was for the first time given a uniform nomenclature of families ending in *-idæ*. Vigors applied the fanciful quinarian system introduced by MacLeay to the arrangement of the birds, and divided the class into five orders—two (*Raptores* and *Insessores*), "endowed with feet formed for grasping," and three (*Rasores, Grallatores*, and *Natatores*), "endowed with feet incapable of grasping." These were subdivided into families, and in one case (*Passeres*) into five tribes. The leading groups are as follows:

ORDER I. Raptores, with the families—(1) Vulturidæ, (2) Falconidæ, (3) Strigidæ, (4) unknown, and (5) Gypogeranidæ.

ORDER II. Insessores, with 5 tribes (1–2 of normal group; 3–5 of aberrant group) and 25 families—viz.:

(1) Dentirostres, with the families of normal group Laniadæ, Merulidæ; of aberrant group Sylviadæ, Pipridæ, Muscicapidæ.

(2) Conirostres, with the families of normal group Sturnidæ, Corvidæ; of aberrant group Buceridæ, Loxiadæ, Fringillidæ.

(3) Scansores, with the families of normal group Psittacidæ, Picidæ; of aberrant group Certhiadæ, Cuculidæ, Rhamphastidæ.

(4) Tenuirostres, with the families of normal group Cinnyridæ, Trochilidæ; of aberrant group Promeropidæ? Meliphagidæ? Nectariniadæ?

(5) Fissirostres, with the families of normal group Hirundinidæ, Caprimulgidæ; of "typical group" Todidæ, Halcyonidæ, and Meropidæ.

ORDER III. Rasores, with the families of normal group Phasianidæ, Tetraonidæ; of aberrant group Struthionidæ, Cracidæ, Columbidæ.

ORDER IV. Grallatores, with families of normal group Ardeidæ, Scolopacidæ; of aberrant group Rallidæ, Charadriadæ, Gruidæ.

ORDER V. Natatores, with families of normal group Colymbidæ, Alcadæ; of aberrant group Pelecanidæ, Laridæ, Anatidæ.

Vigors thus groups the families into normal and aberrant, in pursuance of the views of M. S. MacLeay; for it is, says he, "certainly a more scientific mode of exhibiting the series of affinities" (*op. cit.* p. 426); but he preferred "to view it with more perfect or typical form in the center," "and with its less perfect forms on each side." In this way the last of the "scientific" mode became always the first of the "convenient" mode, the sequence being otherwise the same, save that it was unbroken in the latter. The arrangement, it will be seen, practically starts with the assumption that all the types, down to families at least, were known, and consequently no provision or room was made for the extinct types that were to be afterward discovered. In other respects, too, whatever may be the "philosophical" value of the scheme, it is a most inapt expression of the morphological facts of avine structure, the only true basis for scientific classification.

In 1826 Sundevall,* an eminent Swedish naturalist, introduced an entirely new idea in his proposed arrangement of the class and introduced a physiological consideration. Recalling that some species when hatched were almost featherless, blind, and incapable of taking care of themselves, while others were covered with down or feathers, fully endowed with sight, and able to run about at once, he proposed to consider these characteristics as of primary importance in the determination of the relations of species, and therefore divided the class into two legions: (1) *Altrices*, including those whose young were callow and incapable of taking care of themselves; and (2) *Præcoces*, comprising those competent of caring for themselves.

This division into *Altrices* and *Præcoces*, based on the physiology of the newly hatched young, was quickly adopted by several authors. Bonaparte especially, in one of his numerous new classifications (that published in 1853 †), adopted the divisions in question, and ranked the several orders of birds in parallel columns under the heads *Altrices* and *Præcoces*, considering that the orders of the one group or sub-class were, to a certain extent, represented by those of the other. Inasmuch as this is the most perfected form of the arrangement, and will give a very good idea of the relations of altricism and præcocism to structure, the classification is reproduced in the following:

AVES.

ALTRICES.	PRÆCOCES.
1, Psittaci.	
1. Americani; 2, Orbis antiqui.	
2, Accipitres.	
3, Passeres.	
1, Oscines; 2, Volucres.	
1, Zygodactyli; 2, Anisodactyli.	
4, Columbæ.	
1, Inepti.	7, Struthiones.
2, Gyrantes.	8, Gallinæ.
	1, Passeripedes; 2, Grallipedes.
5, Herodiones.	9, Grallæ.
	1, Cursores; 2, Alectorides.
6, Gaviæ.	10, Anseres.
1, Totipalmi; 2, Longipennes.	1, Lamellirostres; 2, Urinatores; 3, Ptilopteri.

The bearing of the pterylosis, or arrangement of the feathers, on classification, was recognized by Christian Ludwig Nitzsch in 1833, although the results of his labors were not published until 1840, or three years after his death. Nitzsch showed that very few birds are evenly clad with feathers, and that in most birds the feathers are grouped in certain well-defined tracts, interspersed with bare spaces, or apteria, these tracts and apteria being arranged differently in different groups of birds. Nitzsch, too, was the predecessor of Garrod in the study of the carotid artery and its relation to classification, for he published a paper on the subject as early as 1829, and he was one of the first to see the value of the character of the vocal apparatus, or syrinx, among passerine birds.

As early as 1838 Macgillivray recognized that there were essential differences between the vocal organs of those birds to which the terms clamatores and oscines were given later on, but it was Johannes Müller who, in 1845–47, described at length the structure of the syrinx and arrangement of the tracheal muscles, and founded the groups *Oscines* and *Tracheophones*. Prof. Newton says of Müller that his work "forms the groundwork of all the later or recent researches in the comparative anatomy and consequent arrangement of the *Passeres*."

In 1867* Prof. Thomas Henry Huxley, in a course of lectures afterward printed in the *Proceedings* of the Zoölogical Society, made known a new system of classification of birds, which excited great interest, and has had a very decided influence on the recent progress of ornithology, as much by the spirit infused into the mode of investigation as by the innovations that were proposed. The author, like Merrem and Blanchard, recognized as the primary divisions of the class the *Carinatæ* and *Ratitæ*, and these, like Blanchard, he dignified as the only existing orders, degrading the subordinate groups, equivalent in rank at least to many of those which had been called orders by others, to inferior rank. Four secondary groups were distinguished among the *Carinatæ*, more especially by the condition of the vomer and its relation to the neighboring bones. Tertiary groups were combinations of families or peculiar isolated families, characterized by osteological and other characters of moment. This classification had the merit of being the first expression, in a rigorous systematic form, of combinations of anatomical facts, and first gave due weight to aggregates of osteological and other anatomical features characteristic of the several groups of birds. The following synopsis, modified from Prof. Huxley's *Manual of the Anatomy of Vertebrated Animals*, is an exhibit of the chief features of this classification:

I. ORDER SAURURÆ. The metacarpals not ankylosed together. The tail longer than the body.

1, Archæopterygidæ (extinct).

II. ORDER RATITÆ. The metacarpals ankylosed together. The tail considerably shorter than the body. The sternum devoid of a keel.

a. The wing with a rudimentary, or very short, humerus, and with not more than one ungual phalanx.

2, Apterygidæ (the kiwis).
3, Dinornithidæ (the moas).
4, Casuaridæ (the cassowaries).

* *Ornithologiskt System af C. J. Sundevall* (in *K. Vetenskaft Academiens Handlingar för ar 1835, 1836*).

† *Comptes Rendus.*

* *On the Classification of Birds; and on the Taxonomic Value of the Modifications of certain of the Cranial Bones observable in that Class* (in *Proc. Zoöl. Soc. London* for 1867, pp. 415–472).

b. The wing with a long humerus and with two ungual phalanges.

5, Rheidæ (the nandus).
6, Struthionidæ (the ostriches).

III. Order Carinatæ. The metacarpals ankylosed together. The tail considerably shorter than the body. The sternum provided with a keel.

a. The vomer broad behind, and interposing between the pterygoids, the palatines, and the basisphenoidal rostrum.

[I. Sub-order] Dromæognathæ.

7, Tinamomorphæ (the tinamous).

b. The vomer narrow behind; the pterygoids and palatines articulating largely with the basisphenoidal rostrum.

a. The maxillo-palatines free.

i. The vomer pointed in front.

[II. Sub-order] Schizognathæ.

8, Charadriomorphæ (plovers, etc.).
9, Cecomorphæ (gulls, petrels, divers, and auks).
10, Spheniscomorphæ (penguins).
11, Geranomorphæ (cranes).
12, Turnicimorphæ (hemipods).
13, Alectoromorphæ (fowls).
14, Pteroclomorphæ (sand-grouse).
15, Peristeromorphæ (pigeons).
16, Heteromorphæ (hoazin).

ii. The vomer truncated in front.

[III. Sub-order] Ægithognathæ.

17, Coracomorphæ (passerines).
18, Cypselomorphæ (humming-birds, swifts, and goatsuckers).
19, Celeomorphæ (woodpeckers).

β. The maxillo-palatines united.

[IV. Sub-order] Desmognathæ.

20, Ætomorphæ (birds of prey).
21, Psittacomorphæ (parrots).
22, Coccygomorphæ (colies, plantain-eaters, cuckoos, barbets, toucans, capitonidæ, galbulidæ, kingfishers, hornbills, hoopoes, bee-eaters, motmots, coraciidæ, and trogons).
23, Chenomorphæ (anatidæ, palamedeidæ).
24, Amphimorphæ (flamingoes).
25, Pelargomorphæ (storks, ardeidæ, plataleidæ, etc.).
26, Dysporomorphæ (cormorants, pelicans, tropic-birds, darters).

In 1873 and 1874 A. H. Garrod * based a classification of birds upon the consideration of the muscles of the thigh. He also made known those differences in the characters of the narial openings and nasal bones to which he applied the terms holorhinal and schizorhinal, and showed the importance of certain peculiarities in the arrangement of the deep plantar tendons. He also extended the researches on the trachea and tracheal muscles on the lines laid down by Müller. In his classification as based on the muscles of the thigh, the more important characters from a taxonomic point of view were considered to be the femoro-caudal muscle, the accessory femoro-caudal, the semitendinosus, and the accessory semitendinosus; but most important of all is the ambiens muscle; this arises from the tip of the short anteriorly directed spine, which is situated just above the anterior border of the acetabulum, and runs along the inner side of the thigh to the inner side of the knee, where it is covered by the sartorius, which is above it in the former part of its course. Its thin tendon then crosses the knee, running in the substance of the fascial extensor tendon, just in front of the patella, to the outer side, where it joins the fibers of the origin of the flexor perforatus digitorum. The presence or absence of this muscle determined Garrod to differentiate the class into two sub-classes. Those forms in which it is present were designated *Homologonatæ*, or typical kneed; while those in which it is absent were combined as *Anomalogonatæ*, or abnormally kneed. "There are," said Garrod, "peculiarities in the arrangement of the cæca of the intestine and of the tuft of feathers on the oil-gland which are correlatable with this presence or absence of the ambiens muscle." The secondary and tertiary groups of these sub-classes were distinguished by the combinations of the muscles already alluded to, and the presence or absence of cæca to the intestine, the development of a tufted or nude oil-gland, and the combinations in which those characters occur; and further, in the homologonatous birds, by the development of either a left or right carotid, or of both.

* *On Certain Muscles of Birds and their Value in Classification*, part ii. (in *Proc. Zoöl. Soc. London*, 1874, pp. 111–123).

The chief and apparently only merit of this arrangement is the generalized information respecting the muscles in question therein conveyed. The exceptions suggest the inadequacy of the combinations in question to serve as the expressions of the natural affinities of the various forms. Combined with other information, it will be of use in the construction of a more perfect system.

Other important characters used in classification are the number of the primaries, the arrangement of the wing coverts, the convolutions of the intestine and general character of the alimentary canal, the arrangement of the muscles of the upper arm, and resemblances or differences between the plumage of the young and adult. The importance of this last point seems to have been first recognized by Seebohm.

Numerous classifications of birds have been brought forward since 1880, but these have of necessity been based on the better use of known facts rather than founded on new discoveries. Among the most important are the systems of Dr. Leonhard Stejneger, Dr. Max Fürbringer, Dr. R. Bowdler Sharpe, Henry Seebohm, and Dr. H. Gadow. The first two are noteworthy for the fact that the primary divisions *Ratitæ* and *Carinatæ* are discarded, a step which seems a decided advance in classification, as the characters ascribed to the *Ratitæ* are very largely those due to a loss of the power of flight, and are not based on morphological facts. Dr. Stejneger employs Dr. Gill's convenient terms super-order and super-family to express degrees of group division. His system is based mainly on anatomical characters, although external characters are used as well. Omitting the families, Dr. Stejneger's scheme is as follows:

Sub-class I. Saururæ.
  Order I. Ornithopappi. (*Archæopteryx.*)
Sub-class II. Odontotormæ.
  Order I. Pteropappi. (*Ichthyornis*, etc.)
Sub-class III. Odontolcæ.
  Order I. Dromæopappi. (*Hesperornis.*)
Sub-class IV. Eurhipiduræ.
  Super-order I. Dromæognathæ.
    Order I. Struthiones.
      Super-family I. Struthioideæ.
      " II. Rheoideæ.
      " III. Casuaroideæ.
      " IV. Dinornithoideæ.
    Order II. Æpyornithes.
    Order III. Apteryges.
    Order IV. Crypturi.
  Super-order II. Impennes.
    Order V. Ptilopteri.
  Super-order III. Euornithes.
    Order VI. Cecomorphæ.
      Super-family I. Colymboideæ.
      " II. Heliornithoideæ.
      " III. Alcoideæ.
      " IV. Laroideæ.
      " V. Procellaroideæ.
    Order VII. Grallæ.
      Super-family VI. Chionoideæ.
      " VII. Scolopacoideæ.
      " VIII. Eurypygoideæ.
      " IX. Cariamoideæ.
      " X. Gruioideæ.
    Order VIII. Chenomorphæ.
      Super-family XI. Anhimoideæ.*
      " XII. Anatoideæ.
      " XIII. Phœnicopteroideæ.
    Order IX. Herodii.
      Super-family XIV. Ibidoideæ.
      " XV. Ardeoideæ.
    Order X. Steganopodes.
      Super-family XVI. Pelecanoideæ.
      " XVII. Fregatoideæ.
      " XVIII. Phaetontoideæ.
    Order XI. Opisthocomi.
    Order XII. Gallinæ.
      Sub-order I. Gallinæ Alectoropodes.
      " II. Gallinæ Peristeropodes.
    Order XIII. Pterocletes.
    Order XIV. Columbæ.
    Order XV. Accipitres.
    Order XVI. Psittaci.
    Order XVII. Picariæ.
      Super-family, Cuculoideæ.

* Equivalent to Palamedeæ of other authors.

Super-family, Coracoideæ.
" Colioideæ.
" Alcedinoideæ.
" Upupoideæ.
" Picoideæ
" Trogonoideæ.
" Micropodoideæ.
Order XVIII. Passeres.
Super-family, Menuroideæ.
" Eurylaimoideæ.
" Tyrannoideæ.
" Formicaroideæ.
" Passeroideæ.

Dr. Fürbringer's system is founded on anatomical characters, and he employs the term GENS in much the sense that Dr. Stejneger uses super-family, while his sub-orders have about the same value as Dr. Stejneger's orders. The arrangement is as follows:

Sub-classis I. SAURURÆ.
Order Archornithes.
Sub-order Archæopterygiformes.
Gens Archæopteryges.
Sub-classis II. ORNITHURÆ.
Order Struthiornithes.
Sub-order Struthioniformes.
Gens Struthiones.
Order Rheornithes.
Sub-order Rheiformes.
Gens Rheæ.
Order Hippalectryornithes.
Sub-order Casuariiformes.
Gens Casuarii.
Intermediate sub-order Æpyornithiformes.
Gens Æpyornithes.

Realizing the fact that no correct idea of the relationships of animals can be given by arranging them in a continuous line, Dr. Fürbringer has carefully elaborated the idea of a genealogical tree. He gives views of this ideal tree from two sides, and also gives cross-sections which illustrate very clearly his ideas regarding the line of descent and affinities of various groups. While the *Passeres* do not stand first in Dr. Fürbringer's tables, they form the topmost twig of his genealogical tree.

In reviewing the various classifications of birds, the two facts which stand out most prominently are the gradual abandonment of external for anatomical characters, and the advancement of the perching birds from a subordinate to the leading position. The earlier systems are based wholly on external, the more recent almost as entirely on internal characters, and while the idea held by Linnæus, that the *Accipitres*, or birds of prey, stood at the head of the class Aves, prevailed for a long time, it is now generally agreed that the *Oscines*, or singing birds, stand first, and among these the place of honor is variously assigned to the thrushes, crows, or sparrows. Incidentally it may be said that while the old plan in tabulating groups was to begin at the top and work downward, the modern method is to begin at the bottom and go upward, and that Lillejeborg, in the year 1866, was almost the first to publish a system arranged in this manner.

From what has been said in this article, it will be observed that the classification of birds is an extremely difficult problem, and, furthermore, that it is one whose satisfactory solution is still far from reached. It is, however, very evident that it is the resultant of many characters, rather than the use of any one or two, no matter how salient these may be, which must be relied upon for determining relationships and differences, and it will require the patient accumulation of detailed information on many points to set matters straight.

BIBLIOGRAPHY.—The best general works are *Standard Natural History*, vol. *Birds* (Boston, 1884); * *Riverside Natural History*, vol. *Birds* (Boston, 1888); * article *Birds*, *Encyclopædia Britannica* (9th ed.); * *A Dictionary of Birds*, by Alfred Newton (London, 1893–94). Anatomical works are Owen's *Anatomy and Physiology of Vertebrates* (London, 1866–68); Huxley's *Anatomy of Vertebrated Animals* (London, 1871; New York, 1878); * *Morphologie und Systematik der Vögel*, by Fürbringer (Amsterdam, 1888). On classification, see *The Genera of Birds*, by G. R. Gray (London, 1844–49); * *Hand List of Birds*, by G. R. Gray (London, 1869–71); * article *Birds*, *Encyclopædia Britannica* (9th ed.); * *A Review of Recent Attempts to Classify Birds*, by R. B. Sharpe (Budapest, 1891). The following is a list of the more important or more accessible publications relating to the birds of certain regions: 1. Europe.—*A History of the Birds of Europe*, by H. E. Dresser and R. B. Sharpe (London, 1871–81); *A History of British Birds*, by W. Yarrell (4th ed., revised and enlarged, by Howard Saunders, London, 1884–85). 2. Asia.—*The Birds of Asia*, by John Gould, completed by R. B. Sharpe (London, 1850–84); *The Birds of India*, by T. C. Jerdon (Calcutta, 1877); *Birds of Palestine*, by Canon Tristram; *Les Oiseaux de la Chine*, by David and Oustalet (Paris, 1877); *The Fauna of British India, including Ceylon and Burma*, by Eugene W. Oates (London, 1889); *The Birds of the Japanese Empire*, by Seebohm (London, 1890). 3. Af-

* Titles preceded by an asterisk contain many bibliographical references.

rica.—*The Birds of South Africa*, by E. L. Layard (edited by R. B. Sharpe, London, 1875–84); *Die Vögel Ost Afrikas*, by Finsch and Hartlaub (Leipzig and Heidelberg, 1870); *Ornithologie d'Angola*, by du Bocage (Lisbon, 1877); Shelley's *Handbook to the Birds of Egypt* (London, 1872). 4. Australasia.—Gould's *Handbook to the Birds of Australia* (London, 1865); Buller's *History of the Birds of New Zealand* (London, 1887–88), and *Manual of the Birds of New Zealand* (Wellington, New Zealand, 1882); *Ornithologia della Papuasia e delle Molluche*, by Salvadori (Turin, 1880–81). 5. South America.—*Systematische Uebersicht der Thiere Brasiliens*, by C. H. Burmeister (Berlin, 1855–56); *Ornithologie du Perou*, by Ladislaus Tacanowski (Rennes, 1884–86); *Argentine Ornithology*, by Hudson (London, 1888–89). 6. North America.—*The Birds of America*, by Audubon (New York, 1828–30); *The Birds of North America*, by Baird, Cassin, and Lawrence (Philadelphia, 1860; reprint with additions from Pacific R. R. Report, Salem, 1870); *A History of North American Birds*, by Baird, Brewer, and Ridgeway (Boston, 1874–84); *Biologia Centrali Americana*, by Salvin and Godman (London, 1879–87); Ridgeway's *Manual of North American Birds* (Philadelphia, 1887); Coues's *Key to North American Birds* (4th ed. Boston, 1892).

A very complete bibliography of literature relating to American ornithology up to 1879 is given by Dr. Coues in *Birds of the Colorado Valley* (Washington, 1878), and *Bull.* U. S. Geol. Survey, vol. v., Nos. 2 and 4 (Washington, 1879–80). For large and not generally accessible monographs, consult library catalogues under D. G. Elliott, John Gould, C. H. T. and G. F. L. Marshall, Alfred Malherbe, R. B. Sharpe.

THEODORE GILL.
Revised by F. A. LUCAS.

Ornithorhyn'chidæ [Mod Lat., named from *Ornithorhyn'chus*, the typical genus; ὄρνις, ὄρνιθος, bird + ῥύγχος, snout, beak]: one of the two families representing the order *Monotremata* and sub-class *Ornithodelphia*, and including the DUCKBILL (*q. v.*) or "water-mole" of Australia. The general form of the body is somewhat beaver-like; the covering is a dense and soft fur; the jaws are produced into a depressed bill-like snout resembling somewhat (but only superficially) the bill of a duck; the nostrils are above and near the end of the bill; no external ears are developed; there are eight horny teeth—i. e. each jaw is provided on each side behind with a broad and nearly oval tooth with a flattened crown adapted for grinding, and toward the front it has a long and narrow one; the tongue is short, and covered, to some extent, with horny papillæ; the legs are short; the feet well adapted for swimming, and each provided with five toes; the anterior ones have a web extending considerably beyond the toes, and the claws are depressed; the posterior feet have webs only between the toes, and the claws are curved; in the male a spur is developed on the hinder surface of each hind leg, which has no representative in the female; the tail is rather short, depressed, and quite broad. These are the characters which at once superficially distinguish the *Ornithorhynchidæ* from the *Tachyglossidæ*, but in addition to these are numerous anatomical characters. The family is peculiar to Australia, and is represented by but a single genus containing but one certainly known species, which, however, exhibits differences which have caused a distinction, by some authors, of two species. The species was first made known in 1799 by Shaw, under the name of *Platypus anatinus*, and in the following year by Blumenbach under that of *Ornithorhynchus paradoxus*; the name *Platypus* having been previously used in ornithology, that of *Ornithorhynchus* has been almost universally retained. The specimen which first served for description was supposed by some to be a made-up specimen composed of the bill of some unknown duck-like bird and the body of a mammal. The fact that the animal is oviparous was not established until 1884.

Ornithorhynchus: See ORNITHORHYNCHIDÆ and DUCKBILL.

O'ro: a southwestern province of Ecuador; on the Gulf of Guayaquil, adjoining Peru; area, 2,340 sq. miles. It lies entirely in the lowlands adjoining the coast, and the climate is hot and in parts unhealthful. Cacao-raising is the principal industry. The capital and largest town is Machala, on the river Santa Rosa, near its mouth. Pop. of Oro (1885) estimated, 32,600.

H. H. S.

Or'odus [Mod. Lat.; Gr. ὄρος, mountain + ὀδούς, tooth]: a genus of cestraciont sharks of which the remains are found in the Carboniferous rocks. The teeth have their crowns set with a series of blunt but frequently highly ornamented cones. The spines called *Ctenacanthus* probably belonged to the same fish. Some of the species of *Orodus* must have been of immense size, as the teeth, of which the number was large, are occasionally found 4 to 5 inches broad and very massive.

Orono: town (settled in 1774, incorporated in 1806); Penobscot co., Me. (for location, see map of Maine, ref. 6–E); on the Penobscot river, and the Maine Cent. Railroad; 8 miles N. of Bangor. It is the seat of the MAINE STATE COLLEGE (*q. v.*), and has paper, pulp, and lumber mills, iron-foundries, machine-shops, a savings-bank, and a monthly college paper. Pop. (1890) 2,790; (1900) 3,257.

EDITOR OF "CADET."

Oron'tes (in Gr. Ὀρόντης and Ὀρόντας): 1. A Persian general, put to death by Cyrus for treason (Xen., *Anabasis*, i., 6). 2. A Persian general, satrap of Armenia and son-in-law of Artaxerxes II. Mnemon. His immediate family reigned as satraps of Armenia and kings of Commagène from the times of Darius Hystaspis to those of Trajan, or for about seven centuries. See Humann and Puchstein, *Reisen in Klein-Asien und Nord-Syrien* (Berlin, 1890, pp. 283–286), and *American Journal of Archæology* (1890, p. 534). J. R. S. S.

Orontes [= Lat. = Gr. Ὀρόντης], or **Nahr-el-Asi** (the rebellious river): the principal river of Syria. 240 miles long, but not navigable. It rises in the Anti-Lebanon, proceeds northerly 200 miles, then turning abruptly S. W. flows close to Antioch (Antakia) through a picturesque country, and enters the Mediterranean 29 miles S. of Iscanderoon. It was originally called Typhon from a mythical dragon who was said to have traced its course with his tail, but received its later name from Orontes, who built a bridge over it. The neighboring country was often called by the same name. Not far from its source is a peculiar square monument terminating in a pyramid about 65 feet high. Grotesque hunting scenes are carved in relief on the four sides. This monument is connected with the garden or hunting-park mentioned by Strabo as being near the source.

E. A. GROSVENOR.

Oroomiah: See URUMIA.

Oro'sius, PAULUS: historian; b. in Spain, probably at Tarragona, toward the end of the fourth century A. D.: took orders, and engaged with zeal in the controversies of his time. Having by direction of his bishop visited Africa to confer with St. Augustine, he was sent by the latter to Palestine, where Pelagius was spreading his heresies. In Bethlehem he made the friendship of Jerome. At a synod held at Jerusalem he opposed Pelagius, and in so doing provoked the hostility of John, the Bishop of Jerusalem. Orosius wrote in justification of himself in 415 a work entitled *Liber Apologeticus* (*contra Pelagium*) *de Arbitrii Libertate*. He returned to Africa, and probably to Spain, and after his return composed, at the request of his friend Augustine, or completed, his *Historiæ* (*adversus Paganos*), a history of the world, in seven books, from the beginning of the world to A. D. 417, designed to meet the assertions of pagan writers that the calamities of Rome, especially the capture of the city (A. D., 410), were chargeable to Christianity for having abolished the worship of the old heathen gods. The date of Orosius's death is not known. The best edition is by C. Zangemeister (Vienna, 1882; ed. minor, Leipzig, 1889). King Alfred translated the history of Orosius into Anglo-Saxon, which has been edited with an English translation by Dr. Bosworth (London, 1856), and by H. Sweet (1883) with the Latin text. Another work of Orosius, entitled *Commonitorium ad Augustinum de Priscillianistis et de Origenis errore*, is printed in Schepss's edition of Priscillian (Vienna, 1889). See Teuffel's *Hist. Rom. Lit.*, § 455; Mörner, *De Orosii Vita eiusque Historiarum Libris Septem* (Berlin, 1844).

Revised by M. WARREN.

Oroz'co y Ber'ra, MANUEL: author and publicist; b. at Mexico city, June 8, 1816. He studied topographical engineering and subsequently law, and was admitted to the bar in 1847. In 1852 he was appointed director of the national archives; he was twice secretary of public works under the liberal governments; and in 1863 he became associate judge of the Supreme Court. Having accepted office under Maximilian, he was imprisoned on the return of Juarez in 1867, but was soon pardoned. His works on Mexican history and ethnology are widely and favorably known; they include *Geografía de las lenguas y carta etnográfica de*

México (1864); *Historia de México* (1880–81), etc. He edited the Mexican supplement of the *Diccionario universal de historia y geografía*. D. at Mexico, Jan. 27, 1881.

HERBERT H. SMITH.

Or'pheus, ōr'fyus, or ōr'fĕĕ-ŭs (in Gr. 'Ορφεύς): a mythical singer of Thrace, son of Oeagrus by the muse Calliope, and husband of the nymph EURYDICE (*q. v.*). The charm of his song and lyre-playing was so great that even wild animals, trees, and rocks followed him. When Eurydice died of a snake's bite he descended to Hades to bring her back, and moved even Persephone to grant his request, conditionally. He was a member of the Argonautic expedition, and wrought various wonders in behalf of his comrades. He was torn to pieces by Thracian bacchantes, either because he was opposed to their orgies or because, after the death of Eurydice, he hated all women. His dismembered body was buried by the Muses of Pieria on Mt. Olympus, but his head and lyre floated across the sea to Methymna in Lesbos, the island of song. Aristotle (Cicero, *De natura deorum*, i., 38) denied the very existence of Orpheus, but ancient critics had early disputed the genuineness of the *poems* ascribed to Orpheus. The poems that have been preserved to us under his name are Αργοναυτικά (1,394 hexameters), being a glorification of the deeds of Orpheus on the Argo; Λιθικά (768 verses), in which the magical powers of certain precious stones are described; eighty-eight *Hymns* in honor of various gods. These poems were written by members of the ORPHIC BROTHERHOOD (*q. v.*), which was powerful even in the time of Pisistratus and continued to exist for some time after the Christian era. A number of other poems belonging to different periods, such as the Θεογονία, Ἱεροὶ λόγοι, Κατάβασις ἐς Ἄιδου, etc. (for a list of them, see Christ, *Griechische Litteraturgeschichte*, pp. 658–659), were ascribed to Orpheus, but some of them, for varying reasons, must be assigned even to the second century after Christ. See Hermann, *Orphica* (Leipzig, 1805); Tyrwhitt, *Lithica* (London, 1781); Abel, *Orphica* (1885); Abel, *Orphei Lithica* (Berlin, 1881); Buresch, *Klaros* (Leipzig, 1890); Lobeck, *Aglaophamus* (1829); Schuster, *De veteris Orphicæ theogoniæ indole* (Leipzig, 1869); Kern, *De Orphei Epimenidis Pherecydis theogoniis* (Berlin, 1888). For a discussion of Orpheus in works of art, see the article *Orpheus* in Baumeister's *Denkmäler*, and for a discussion of the Orphic cult, see Gruppe, *Die Griechischen Culte und Mythen* (Leipzig, 1887, i., 612–674. J. R. S. STERRETT.

Orphic Brotherhood (in Gr. *οἱ 'Ορφικοί*): in ancient Greece, a society of ascetic persons who devoted themselves to a mystical worship of the Thracian Bacchus (Dionysus-Zagreus) and the elaboration of a system of theology, under the professed guidance of the spirit of ORPHEUS (*q. v.*). They dressed in white, ate no animal food, avoided all excesses, and professed to aim at purity of life, an exalted religious experience, and an immortal existence after death. See Gruppe, *Die Griechischen Culte und Mythen* (Leipzig, 1887, i., 612–674), where the literature on the subject will be found cited. J. R. S. STERRETT.

Orpiment, or **King's Yellow** [*or'piment* is viâ O. Fr. from Lat. *auripigmen'tum*, liter., pigment of gold; *au'ri*, genit. of *au'rum*, gold + *pigmentum*, coloring, pigment, deriv. of *pin'gere*, draw, paint, color]: a sulphide of arsenic of the composition As_2S_3. It may be prepared artificially by precipitating a solution of arsenic with sulphuretted hydrogen gas, and by fusing together equal parts of white arsenious acid and sulphur. It is stated on good authority that, when entirely *free from arsenious acid*, orpiment is not poisonous when swallowed, owing to its insolubility even in acids. As, however, it is easily soluble in alkalies, it is a dangerous material, and should be banished from common use as a pigment by those unfamiliar with its nature. It was formerly employed, in admixture with lime, as a depilatory, and in another dangerous way is used as an ingredient in fireworks. Revised by IRA REMSEN.

Orr, JAMES, D. D.: clergyman and professor; b. at Glasgow, Scotland, Apr. 11, 1844; was educated at the University of Glasgow; minister at East Bank United Presbyterian church of Hawick 1873–91; first lecturer on the Kerr foundation, United Presbyterian Hall, Edinburgh, 1891; delegate to the Pan-Presbyterian Council at Toronto 1892; since 1891 has been Professor of Church History in the United Presbyterian College of Edinburgh. He has written numerous articles for periodicals, such as *Assyrian and Hebrew Chronology* in *The Presbyterian Review* (1888), and the homiletical sections in the volumes of the *Pulpit Commentary* on Exodus, Deuteronomy, 2 Kings, and Hosea. He has published the Kerr Lectures for 1891; *The Christian View of God and the World as Centering in the Incarnation* (Edinburgh, 1893); and with Principal Rainy and Prof. Dods, *The Supernatural in Christianity* (Edinburgh, 1894).

C. K. HOYT.

Orr, JAMES LAWRENCE: jurist and Congressman; b. at Craytonville, S. C., May, 12, 1822; graduated at the University of Virginia 1842; was admitted to the bar and practiced in Anderson, S. C.; member of the Legislature 1844–45; member of Congress 1848–59, and Speaker of the Thirty-fifth Congress; in 1860 was one of the convention that inaugurated secession, and was a State commissioner to Washington to treat with the U. S. Government for partition of property in South Carolina; Confederate State Senator 1862–65. He was provisional Governor of South Carolina 1865–69; was appointed judge of the circuit court of South Carolina 1870, and in 1873 U. S. minister to Russia. D. in St. Petersburg, May 5, 1873.

Or'rery [named in honor of the Earl of Orrery]: a machine constructed to exhibit the motions of the planets round the sun, or of satellites round their primary. Planetary machines (that is, machines exhibiting the motions of the planets) constructed in accordance with the idea that the earth was the center of motion were very early in use. Such were the Chinese spheres, said to have been made some 2,000 years before the Christian era, and later the spheres of Archimedes and Posidonius. It is thought that the earliest machine representing the Ptolemaic system was that of Chromatus. This system continued to be represented in all planetary machines until about fifty years after the death of Copernicus, when the last of the kind of any note was erected in the library of the Pantheon at Paris by Orone Finnée. Machines intended to represent the Copernican system were invented in the latter part of the seventeenth century by Huyghens and Römer, Huyghens introducing a method of calculating the wheelwork with precision. Then Römer invented a planetarium, and also a satellite-machine. The orrery made by Rowley in 1715 at the expense of Charles Boyle, Earl of Orrery, was a combination of the planetarium of the sixteenth century with other machines which showed the motions of the earth, moon, and planetary satellites.

Perhaps the most perfect of orreries were two invented and constructed by David Rittenhouse, LL. D., one of which is in possession of the College of New Jersey. The date on the face of the instrument is 1768. It is fitted for exhibiting continually the motions of the moon, as well as those of the earth and other principal planets to Saturn inclusive, then the outermost known. It is furnished with dial-plate arrangements for the current month and the day of the month, as well as the passing year, and the successive positions, at the dates thus recorded, of the bodies already specified, and the years of cycles; the whole kept in motion by a clockwork attachment. The orbits of the moon and of the planets are all elliptical, and the surrounding graduated circular ring, representing the arrangement of the twelve signs, has a rackwork and a screw of slow motion attached, by which even the precession of the equinoxes is allowed for.

Though it is impossible to construct a machine which will represent the motions of planets and satellites accurately, an orrery is useful in giving a general notion of the way in which they take place. Revised by R. A. ROBERTS.

Orris Root: See IRIS.

Orrville: village; Wayne co., O. (for location, see map of Ohio, ref. 3–G); on the Cleve., Akron and Col., the Penn., the Pitts. and W., and the Wheeling and Lake Erie railways; 14 miles W. N. W. of Massillon, 54 miles S. of Cleveland. It is in an agricultural and stock-raising region, is an important shipping-point, and has a private bank and a weekly newspaper. Pop. (1880) 1,441; (1890) 1,765; (1900) 1,901.

Or'say, ALFRED GUILLAUME GABRIEL, Count d': society leader; b. in Paris, France, Sept. 4, 1801; served in the French army; married in 1827 a daughter of the Earl of Blessington by his first wife; was separated from her 1829; lived thenceforth chiefly in London, where he was regarded as a model of elegance and courtliness; was the most conspicuous member of the social circle at Gore House; was for many years a constant companion of Lady Blessington; was distinguished for his handsome person, fascinating powers of conversation, and artistic skill; became director of fine arts at Paris under Louis Napoleon. D. in Paris, Aug. 4, 1852.

Orsi'ni; a wealthy Roman family of princely rank; belonged to the party of the Guelphs, and became very conspicuous in the history of Rome during the Middle Ages by its perpetual feuds with the family of the Colonnas, which belonged to the Ghibelline party. It spread very widely, acquired immense possessions, and its power culminated in the latter part of the thirteenth century, when one of its members became pope under the name of Nicholas III. (1277–81). Another member of the family became pope under the name of Benedict XIII. (1724–30). The family-seat is still at Rome, where the Orsini palace stands on the spot where formerly stood the theater of Marcellus.

Orsini, Felice: conspirator; b. in 1819 at Meldola, in the province of Forlì, Italy, at that time a part of the papal states; joined Mazzini's Young Italy Society in 1838; was imprisoned and condemned to the galleys for life, but restored to liberty in 1846 by the amnesty of Pius IX.; acted as a deputy for Bologna in the constituent assembly at Rome in 1849, and after the fall of the Roman republic was an agitator in Genoa and Modena; fled in 1853 to England, but reappeared in 1854 in Italy, agitating in Parma, Milan, Trieste; was captured at Vienna and put in the fortress of Mantua, but escaped to England in 1856. He repaired in 1857 to Paris, having formed a conspiracy with three others, Pieri, Rudio, and Gomez, for the assassination of Napoleon III., on whom vengeance was to be taken for his desertion of the principles of the Carbonari, into whose organization Napoleon had been admitted in 1831. On Jan. 14, 1858, Orsini, with his accomplices, threw three explosive bombs under the carriage of the emperor in the Rue Lepelletier, killing eight persons and wounding over a hundred. He was tried and sentenced to the guillotine. While in prison he wrote two letters to the emperor calling upon him to free Italy from her oppressors. These, which were published in the French papers, served to direct popular attention to Italian affairs, and Napoleon's policy in 1859 was along the lines advised by Orsini. The latter was guillotined Mar. 13, 1858. His autobiography was translated into English by G. Carbonel (Edinburgh, 1857).

Orsova, ōr'shō-vaă: Hungarian frontier town on the Danube; consisting of Alt (Old) Orsova and Neu (New) Orsova; the latter, a strongly fortified island which commands the Roumanian and Servian frontier, was ceded by Turkey in 1878 (see map of Austria-Hungary, ref. 9–J). Equidistant between the Iron Gates, it is the center of the grandest Danubian scenery. Pop. (1891) 3,381. E. A. G.

Orte'lius, Abraham: geographer; b. at Antwerp, Apr. 4, 1527. He was wealthy, traveled in England, France, Germany, and Italy, and had a wide acquaintance with the geographers of his time. In 1570 he published his *Theatrum orbis terrarum*, a collection of maps with short descriptions of the various countries in Latin. This was long a standard geographical authority in Europe, and there are various editions in Latin, French, and German. Several of the maps are of great interest for the early cartography of America. Ortelius published other geographical works, and he amassed a museum of coins, antiquities, etc. He was appointed royal geographer by Philip II. in 1575. D. at Antwerp, Jan., 1598. Herbert H. Smith.

Orth, Johannes, M. D.: pathologist; b. at Wallmerod, Nassau, Germany, Jan. 14, 1847; studied medicine at the Universities of Bonn, under Rindfleisch, and Berlin, under Virchow, graduating M. D. from the former in 1870; in 1878 was elected Professor of Pathology and Pathological Anatomy in the University of Göttingen. His most important works are *Compendium der pathologisch-anatomischen Diagnostik* (Berlin, 1876; 5th ed. 1893); *Cursus der normalen Histologie* (1878; 5th ed. 1888); *Lehrbuch der speciellen pathologischen Anatomie* (1887). S. T. Armstrong.

Orthacan'thus [Mod. Lat.; Gr. *ὀρθός*, straight, erect + *ἄκανθα*, spine]: a name given to certain defensive spines of sharks found in the coal-measures. They are slender and acute, but not always straight, though the name indicates this, and are ornamented with two rows of sharp, depressed hooks on the posterior face. They probably belong to the shark of which the teeth have been named *Diplodus*.

Orthagoris'cidæ [Mod. Lat., named from *Orthagoris'cus*, the typical genus, from Gr. *ὀρθαγορίσκος*, sucking pig]: a family of plectognath fishes, distinguished from all other fishes by the peculiar truncation of the posterior region of the body. The form varies, being either oblong or higher than long, but in all ends abruptly behind, and is entirely destitute of anything like a tail or caudal peduncle; the abdomen is never distensible by air, as in the swell-fishes; the skin is rough or covered with hexagonal plates; the head externally inseparable from the body, and with all the bones covered by the integument; mouth terminal, small; the jaws, both upper and lower, developed into cutting ridges, and each destitute of a median suture; branchial apertures very small, slits in front of the pectoral fins; dorsal and anal fins far back, opposite each other, and developed alike, higher than long, and united with the caudal fin when present; pectorals well developed; ventrals entirely wanting. The skeleton is peculiar for the small number of caudal vertebræ, there being less than twenty, and in the adult of *Mola* there are ten abdominal and about eight caudal; no pelvic bones are developed; the air-bladder is absent; many other peculiarities are observable in the anatomy. The family is represented by two genera: *Mola* and *Orthagoriscus*. The species attain a large size, *Mola* sometimes weighing as much as 800 lb. Revised by D. S. Jordan.

Or'thidæ [Mod. Lat., named from *Or'this*, the typical genus, from Gr. *ὀρθός*, straight]: a family of extinct brachiopods abundantly represented in Palæozoic rocks. An elaborate analysis and description of the various genera of this group of fossils is contained in the eighth volume of the *Palæontology of New York State*.

Orthocerat'idæ [Mod. Lat., named from *Ortho'ceras*, the typical genus; Gr. *ὀρθός*, straight + *κέρας*, *κέρατος*, horn]: a family name under which are combined a varying number of genera belonging to the class of Cephalopods, order of Tetrabranchiates, and sub-order *Nautiloidea*. All have a shell furnished with numerous chambers, which extend across the axis of the shell; the septal margins are simple and the funnel-like throat more or less sub-central and directed backward; they differ, however, in other respects. In the typical forms (*Orthoceras*, etc.) the shell is straight and the aperture simple: to this, by some authors, the family is restricted; others (*Cyrtoceras*) have the shell curved, but the aperture simple; others, again (*Gomphoceras*), have the shell straight, but a heterogeneous aperture; others still (*Phragmoceras*) have the shell curved, and the aperture is heterogeneous. The species are numerous, and lived from the Lower Silurian up to the Liassic epoch. They sometimes attained a large size. A species of Endoceras, 15 feet long, has been described from the Trenton limestone. Revised by H. S. Williams.

Orthoëpy: See Pronunciation.

Orthognathous: See Face.

Orthog'raphy [viâ O. Fr. from Lat. *orthogra'phia* = Gr. *ὀρθογραφία*, correct writing, deriv. of *ὀρθόγραφος*, writing correctly; *ὀρθός*, straight, correct + *γράφειν*, write]: the art of conventionally correct spelling, or of writing words according to a conventional standard of usage. The necessity for such an art commonly arises only in languages which have developed a standard literary type, compromising or repressing dialectal diversities of the same period, and to some extent also absorbing historical varieties of successive periods. When a language is first reduced to writing its spelling is approximately phonetic, at least so far as the available alphabet will permit. In the early Greek inscriptions, for example, each of a score or more of local communities speaking diverse dialects has recorded its language in a rude phonetic spelling. They simply used the alphabetic symbols in their received value, making with them as well as they might a record of words as they sounded when spoken. In the fourth century B. C. the Bœotians adopted from Athens the Ionic alphabet, but not an orthography, for they simply proceeded to apply the symbols in the value they had at Athens to the respelling of their *spoken* language. Only four or five of the Greek dialects became the receptacles of literary records. These began therewith to show some tendency toward the establishment of a standard form of spelling, but not until the Attic dialect in the form of the *koinè* began to assert its pre-eminence as a universal Greek literary medium did a sense for a standard Greek orthography manifest itself. This standard, which, following the manuscripts, we now use for all the monuments of Attic Greek literature, and which has even extended itself in large measure to the Modern Greek, represents essentially the pronunciation of the fourth century B. C.

The experience of Greece illustrates the general principle. The necessity for an orthography is dictated (1) by the existence of dialects within the domain covered by a litera-

ture, and (2) by the accumulation of books which give an historical continuity to a literature even over periods in which the spoken language has suffered change.

The English orthography presents the most extreme illustration of divorcement of the written from the spoken form of language. The spelling forms no certain guide to the sound of a word. The word and not the letter is the unit. The appeal is to the eye, not the ear. In acquiring the written language, one must practically learn each word by itself. How inconsistently the alphabetic symbols are used may be judged from a few illustrations. The voiceless lingual sibilant *š* is variously denoted by *sh* in *shine*, *si* in *pension*, *s* in *sugar*, *sensual*, *ss* in *issue*, *sci* in *conscious*, *ti* in *nation*, *ci* in *social*, *ce* in *ocean*, *ch* in *charade*, *chivalry*, *machine*. The combination *si* denotes the voiced sibilant *ž* in *vision*, *occasion*, etc., as does also *s* in *usual*, *pleasure*, etc. The voiced dental sibilant *z* is denoted by *z* in *zeal*, *zz* in *buzz*, *s* in *easy*, *lands*, *ss* in *scissors*, *sc* in *discern*, *c* in *sacrifice* (verb), *x* in *Xerxes*. The voiceless guttural explosive *k* is variously denoted by *k* in *book*, *ck* in *duck*, *c* in *music*, *cc* in *accuse*, *ch* in *chord*, *q* in *queen*, *qu* in *liquor*. The high-front vowel *ī* (*ii*) is represented by *e* in *me*, *ee* in *see*, *ea* in *sea*, *ie* in *piece*, *ei* in *conceit*, *ey* in *key*, *eo* in *people*, *ay* in *quay*, *i* in *marine*, *æ* in *Cæsar*. The combination *ough* denotes *ŏf* in *cough*, *trough*, *ou* in *though*, *dough*, *ŭf* in *enough*, *au* in *plough*. Words of like sound are often widely apart in spelling; as *cite*, *site*, *sight*; *draft*, *draught*; *bored*, *board*; *air*, *heir*; *base*, *bass*. Words of different sound are sometimes spelled alike; as *read* (pres.), *read* (pret.); *abuse* (noun), *abuse* (verb.); *close* (adjec.), *close* (verb); *record* (noun), *record* (verb), etc.

Prior to the sixteenth century the spelling of English, though not self-consistent, owing in general to the diversity in the sources of the language, and especially to the perverting influence of French methods of spelling, was still quasi-phonetic; i. e. though it did not always represent the same sound by the same symbol, it undertook to represent the spoken word. The appearance, however, in this (sixteenth) century of an abundant literature, coincident with the development of printing, tended to fix the spelling and remove it from subservience to sound. Since this time English spelling has remained in its essential features unchanged, though the pronunciation has meantime, especially in the vowel system, suffered radical change. Our present orthography may therefore be roughly said to represent nineteenth century words by means of symbols which, though by no means used with the simplicity or self-consistency of phonetic spelling, really stand for sixteenth century sounds. At that time the vowel-symbols were used essentially in their "continental" values. We now write the phonetic word *naym* (*name*) with *a*, because it was pronounced *naam* in the sixteenth century, and write *mile* with *i*, because it was then pronounced *meel*. We write the word *see*, on the one hand, as *sea*, commemorating its former pronunciation with the open *ay*-sound (indicated phonetically as *æ*), and on the other as *see*, as a record of the older close *ay*-sound (indicated phonetically as *ē*). The two words were distinct in Shakspeare's time.

In the latter part of the sixteenth century appeared the first treatises on orthography: Sir Thomas Smith, *De recta et emendata linguæ anglicæ scriptione dialogus* (Paris, 1568); John Hart, *An Orthographie, conteyning the due order and reason howe to write or printe thimage of mannes voice, most like to the life or nature* (London, 1569); William Bullokars, *Booke at large for the Amendment of Orthographie* (1580); Richard Mulcaster, *The First Part of the Elementarie which entreateth chefelie of the right writing of the English tung* (London, 1582).

The influence of printing tended to the gradual development of an orthographical uniformity which was practically established in its present existing form by the beginning of the eighteenth century. The appearance of dictionaries (Bailey's, 1721; Johnson's, 1755) and the use of spelling-books in the schools further developed this sense for uniformity into the present extraordinary orthographical prudery, which often treats false spelling as a mark of vulgarity, if not of mental inferiority. The following examples of diverse spellings current between 1600 and 1800 may serve to illustrate how late an achievement our present orthodoxy is: *arithmetic*, *arithmetike*, *arithmetique*, *arithmatick*, *arithmaticke*, *arithmetick*; *beauty*, *beawtye*, *bewtie*, *bewtye*, *beautie*, *beuty*; *engineer*, *engenier*, *ingenier*, *ingenicr*, *engenir*, *ingeneer*, *inginier*, *ingineer*; *bailiff*, *bailliff*, *bailiffe*, *baliffe*, *balyfe*, *balyve*, *baylyff*, *bailiefe*, *baylife*, *bayliffe*, *bailive*, *bayllive*, *bayliff*; *curb*, *courbe*, *kurbc*, *kerbe*, *kirb*, *kerb*. There still remains a slight residue of words for which an authoritative spelling has not been established; thus notably in the case of loan-words from languages not using the Roman alphabet, as *Brahmin*, *Brahman*; *attar*, *ottar*; *baksheesh*, *bakhshish*; also in the case of dialectal words which have but recently appeared in literature, as *bletherskate*, *blatherskite*; and in certain derivatives, as *abridg(e)ment*, *judg(e)ment*, *blam(e)able*, *civilize* (*-ise*), *inflection* (*-xion*), *worship(p)er*, *travel(l)er*, *mileage* (*milage*), *mov(e)able*, *sal(e)able*, *wool(l)en*, etc.; also individual cases like *ambassador* (*em-*), *briar* (*brier*), *brazier* (*brasier*), *offence* (*offense*), *dispatch* (*des-*), *inquire* (*en-*), *centre* (*-er*), *theatre* (*-er*), etc. See list in Webster's *International Dictionary*, pp. xciii. ff., and the rules for spelling, pp. xc. ff.

English spelling is neither phonetic nor etymological, but merely conventional. Attempts to reform it in the interest of etymology, and especially in conformity to Greek and Latin etyma, have been frequent since the revival of learning, but they have helped little and hindered much. Thus the addition of a *b* in *debt* and *doubt* (M. Eng. *dette*, *doute*) serves to suggest Lat. *debita* and *dubitare*, but is perfectly gratuitous and unhistorical, for both words came into English without either the sound or the letter. In a case like *fault* for *faute* or *arctic* for *artic* (O. Fr. *artique*), the introduction of the letter in spelling has resulted in perverting the pronunciation. Often the etymology suggested by the revised spelling is entirely false. Thus the *g* in *sovereign* (older *soverayne*, M. Eng. *soverain*, representing a Latin *supera'nus*) falsely suggests *reign*; as the *sc* of scissors (M. Eng. *sisoures*) does Lat. *scissus*, cut. The *s* of *island* (M. Eng. *iland*) is a deception, as *island* and *isle* are not related etymologically; so the *u* of *guest*, which is a Teutonic, not a French word, the *w* of *whole* (earlier *hole*), *whoop* (M. Eng. *houpen*), which is not etymological, and the *gh* of *delight* (M. Eng. *delit*), which imitates cases like *night*, *right*, where *gh* has etymological value. The *ue* of *tongue* (older *tung*; cf. Germ. *zunge*) sadly disfigures a genuine English word in a possible deference to *langue*, and the plain Eng. *rime* (O. Eng. *rīm*) is even ludicrous masquerading in Greek toggery as *rhyme*. Much of this pseudo-etymological spelling is merely a decorative rococo.

Various attempts have also been made to reform the spelling upon a purely phonetic basis. See F. A. March, *The Spelling Reform*, Circular of Information of U. S. Bureau of Education (1880), No. 7; Skeat, *Principles of English Etymology*, i., ch. xvii. While radical changes in our present system are scarcely to be expected, especially such changes as involve a restoration of the "continental" values of the vowel-signs, or in other ways involve a violent break with the older recorded form of the language, it is not unlikely that a consideration for the spoken form of words will gradually tend to the simplification of our spelling and the elimination of some of its grosser inconsistencies.

Orthometric Systems: See CRYSTALLOGRAPHY.

Orthopædic Surgery [*orthopædic* is from Gr. *ὀρθός*, straight + *παίς*, *παιδός*, child]: that branch of general surgery which relates to the prevention and treatment, both by surgical and mechanical measures, of the various deformities and malformations of the human body, particularly such deformities as pertain to the osseous and muscular structures. In some countries deformities and malformations of the soft parts, as harelip, cleft palate, hypospadias, etc., are classified under this heading; but in the U. S. these are ordinarily grouped under plastic surgery.

There is no sharply drawn line between general and orthopædic surgery; nor is the division between orthopædic and nervous diseases with paralysis a distinct one, since there is an overlapping in both directions. The term orthopraxy (from Gr. *ὀρθός*, straight + *πράσσειν*, to do, act), is also occasionally employed. By the term deformity is meant any marked deviation from the normal symmetrical proportions of the human frame. The following classifications are generally recognized:

- DEFORMITIES.
  - Congenital.
    - Malformations.
    - Distortions.
  - Acquired.
    - From traumatism.
    - " paralysis.
    - " inflammatory conditions.
    - " rickets.
    - " joint diseases.
    - " other diseases.

Hippocrates in his book on *Articulations* discusses both the nature and the character of the treatment of clubfoot,

spinal curvature, and other diseases now included under orthopædic surgery. His practical ideas were not equaled by other surgeons for centuries afterward. He describes accurately a very effective apparatus for straightening club-foot, which was not improved upon from that time (B. C. 500) until the sixteenth century, when Ambrose Paré published a work in which he reëapitulated Hippocrates's teachings and ideas, and added many suggestions of his own. Paré's method of treating hunchback, or disease of the spine, was to have the patient lie on a bed while two strong persons pulled in opposite directions, the surgeon meanwhile moulding and forcing the bones into position by a wooden bar. About the middle of the eighteenth century Andry published a book with the specific title *Orthopædic Surgery*, in which he described a large number of mechanical appliances which, though rude, were efficient and ingenious. Scarpa, at the close of the eighteenth century, devised a shoe for clubfoot which has since been designated by his name. About this time the treatment of lateral curvature by suspension and splints received further impetus. To Delpech, of Montpellier, was largely due the great advance in this branch, yet none of Delpech's countrymen was wise enough to see the advantages to be gained from his work. It remained for Stromeyer, of Hanover, in 1834, to introduce the practice of subcutaneous tenotomy, although this operation had been foreshadowed by Mincius in the fifteenth century. Tenotomy proved to be almost revolutionary, and the subcutaneous division of tendons soon became a recognized procedure. Orthopædic surgery has since then steadily advanced. The tenth international congress at Berlin in 1890 was the first to give a special section to this subject, and the U. S. of America contains the only distinct national association of orthopædic surgeons.

Rickets, a disease essentially due to filth, close confinement, and poor air, and hence commonly found in crowded cities, is one of the most common causes of deformities. Knock-knee, bow-legs, curve of the arms, and sometimes lateral curvature of the spine, etc., are notable instances. The treatment consists in supplying good air, good food, and proper hygienic surroundings, with the internal administration of tonics, lime-salts, cod-liver oil, etc. The weight of the body should not be put upon the bones during their soft stage unless the limbs are properly supported by apparatus. After hardening occurs straightening is more difficult, but it may be accomplished, first, by the use of mechanical appliances; secondly, by division of the bone, or osteotomy; and, thirdly, by fracture of the bone, or osteoclasis.

Lateral curvature of the spine is a very common cause of deformity. It occurs with the greatest frequency in young girls about the age of puberty, especially if in poor health. Among the numerous causes are faulty positions in sitting or standing, difference in the length of the limbs, unequal weight bearing upon the shoulders, feeble muscular development, etc. As the deformity advances not only are the spinous processes twisted laterally, but rotation of the vertebral bodies also takes place, with consequent projection of the ribs and shoulder-blade on one side, and flattening of the chest on the opposite side. The condition is due to feeble muscular development, and indicates disproportionate power of the two sides of the body; hence gymnastics and general attention to the health are of primary importance, and if these are properly employed the use of apparatus is seldom necessary. When used it should be of the lightest kind. Strong supports are only necessary when the deformity is rapidly increasing. Spinal curvature should be distinctly separated from caries of the spine; the latter is an entirely different process—an osteitis—that involves the vertebral bodies; while lateral curvature of the spine is dependent not upon disease of the vertebræ, but upon unequal muscular development.

Clubfoot, or talipes, is a deformity of the foot usually occurring congenitally; but it may be found as an acquired condition, following the various paralyses of infancy. When one set of muscles becomes stronger than its opposing group, deviation occurs. When the anterior part of the foot turns inward, the variety known as talipes *varus* is produced. When the anterior part of the foot drops, with elevation of the heel, the condition known as *equinus* results, so called from its resemblance to the position of the bones of the foot in the horse. When the toes turn outwardly, the deformity is known as *valgus*; when upward, with elongation of the heel, it is *calcaneus*; other varieties are known as *cavus*, *plantaris*, etc., when the instep is highly elevated. In congenital cases the bones are sometimes distorted at birth, and the distortion rapidly increases as soon as the weight of the body is placed upon them. In congenital cases the treatment should begin at birth with systematic measures designed to straighten the foot and mould it into proper position by manipulation and forcible stretching of the contracted tissues.

Some form of mechanical appliance should also be employed at once in order to bring the bones of the foot into the proper shape, particularly during the rapid growth of the first weeks of life. Various forms of apparatus are useful, and operative measures are required whenever the child begins to walk, provided the foot has not been already straightened by the previous use of apparatus. In older cases removal of the bones, or tarsectomy, is sometimes necessary, when other operative measures, such as tenotomy, fasciotomy, etc., have failed.

Hammer-toe is a condition of flexion in which the ligaments of one or more toes are contracted. It can be relieved by apparatus or by division of the fascial bands and tendons.

Dupuytren's contraction of the fingers is due to shortening of the fascia, and is usually found in rheumatic patients. It can be relieved by multiple and subcutaneous divisions of the shortened tissues. The tendons are rarely involved.

Joint diseases are among the most common causes of deformity. They are usually inflammatory in character, and in the majority of cases are tubercular in their origin. The inflammation is usually awakened by some slight injury, but is largely dependent upon a tubercular predisposition in the individual. The course of the osteitis is ordinarily slow and tends to destruction first of the bones in the neighborhood of the joint, the process then extending to the articulation. Absolute rest in the recumbent posture is the first indication, to be followed by thorough mechanical fixation of the joint involved. Ambulatory apparatus, with axillary or perineal crutches, is permissible after the acute or painful stage has passed. Extension, both in bed and after the upright position has been assumed, is beneficial. Operative measures are usually necessary after suppuration has occurred. Hip, knee, and ankle joint disease are the most common varieties, the articulations of the upper extremities being but seldom affected.

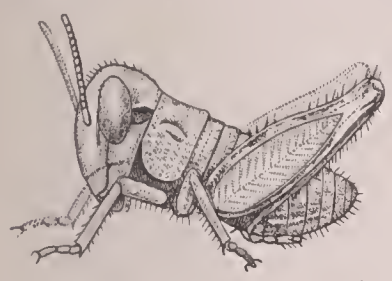
DE FOREST WILLARD.

Orthopnœa: See DYSPNŒA.

Orthoptera [from Gr. *ὀρθός*, straight + *πτερόν*, wing]: an order of insects (see ENTOMOLOGY), characterized by having the jaws fitted for biting, an incomplete metamorphosis, and four wings, the anterior or outer pair narrow and coriaceous and serving as wing covers, the posterior pair membranous, broad, and folded like a fan when at rest. Examples are familiar to all in the grasshoppers, locusts, walking-sticks, cockroaches, and the like. A few (the mantis insects) are beneficial to man, but with these exceptions all are injurious from the fact that they feed on vegetation, and some forms, coming in vast swarms, are the most terrible scourges of the agriculturist. In all the jaws are strong. The head bears, besides the large compound eyes, three pairs of ocelli. The three joints of the thorax are distinct, and the abdomen in the female is frequently provided with an enormous ovipositor. The eggs are laid either in plants or in the ground, and the young when hatched resemble the parent, except in the absence of wings. With successive casting of the skin the adult condition is gradually attained. There are many forms in which wings are lacking even in the adult. Among the interesting features are the presence of sound-producing structures. These occur only in the males of certain forms, and consist of rasping organs upon the wings, or wings and legs. Corresponding to these, organs usually interpreted as ears occur, in the grasshoppers on the basal joint of the abdomen, in the crickets upon the tibial joint of the first pair of legs.

Six families are recognized. The *Blattidæ*, or cockroaches, are among the oldest of insects, numerous fossils occurring in the Carboniferous. In these the legs are all fitted for walking, the body is flattened, and no sound-producing apparatus occurs. The eggs are laid in a pod-like case, which the female carries about with her. The best-known example is the imported "Croton bug" (*Blatta germanica*), which forms a pest in most parts of the U. S. Persian insect-powder is the best means of ridding a house of them. The mantis insects (*Mantidæ*) are tropical and subtropical. From the strange attitudes they take they are known as rear-horses, praying-mantes, camel-crickets, and the like. They feed upon other insects, for which they lie in wait. In

the walking-sticks and leaf insects (*Phasmidæ*) are some of the strangest examples of mimicry. In the U. S. the forms are long and wingless, and resemble closely a dried twig, but in the tropics occur winged forms in which the whole body is strikingly leaf-like, sometimes bright green, sometimes of the color of a dried leaf. The two families *Acrididæ* and *Locustariæ* exhibit a strange confusion of scientific and popular names, for the Acridians are locusts and the Locustarians are grasshoppers. In both the hind legs are large and stout, serving as organs for leaping; sound-producing organs are present. The *Acrididæ* have short antennæ and short ovipositors. Among the most prominent forms is the Rocky Mountain locust (*Melanoplus spretus*) which in 1872–75 created much destruction in the region W. of the Missouri river. In the *Locustariæ* the antennæ are long and thread-like, while the ovipositor is enormous. The katydids, named from their note, are the best-known forms. The last family is that of the crickets (*Gryllidæ*). The males make a chirping sound by rubbing together the anterior wings. With these are to be grouped the large mole-crickets which live subterranean lives, feeding upon the roots of the grass, etc. In these the anterior legs are fashioned into digging organs.



Locust just hatched, enlarged.

See Reports of U. S. Entomological Commission (1878–83); Thomas, *Synopsis of Acrididæ*, U. S. Geological Survey (vol. v., 1872); Ayers, *Embryology of Œcanthus*; *Memoirs* Boston Society Natural History (iii., 1884); and numerous papers by Scudder, Brnner, and Walker. J. S. Kingsley.

Or'tolan [= Fr. from Ital. *ortolano*, ortolan, liter., gardener < Lat. *hortula'nus*, gardener, deriv. of *hor'tulus*, dimin. of *hor'tus*, garden]: any one of several species of song-birds. In Enrope the name was primarily employed for the garden-bunting, *Emberiza hortulana*, common on the continent of Europe and in the Levant. It is a handsome little bird without song, and is chiefly noteworthy for its extensive nse as food. Immense numbers are captured in nets and are placed in dark rooms, where they are gorged with millet and other grain mixed with spices, until they undergo a kind of fatty degeneration. In fact when killed the ortolan is a mere lump of fat, of a flavor highly prized by gourmands. It is some 6 inches in total length, and attains a weight of nearly 3 oz. In some parts of the U. S. the name is applied to the Bobolink (*q. v.*), and to the Sora rail (*Porzana carolina*). Revised by F. A. Lucas.

Or'ton, Edward, Ph. D., LL. D.: geologist; b. at Deposit, N. Y., Mar. 9, 1829; graduated at Hamilton College in 1848; studied science at Lawrence School; was Professor of Natural Sciences, New York State Normal School, 1856–59, and at Antioch College 1866–73; was president of Antioch College 1872–73; president State University of Ohio 1873–81; Professor of Geology, State University of Ohio, from 1873; Assistant Geologist, Geological Survey of Ohio, 1869–83; State geologist of Ohio from 1883; vice-president (geological section) American Association for the Advancement of Science 1885. In geology Prof. Orton has given chief attention to economic problems, especially problems conneeted with the distribution of petroleum, natural gas, and coal. His principal writings are contained in the official reports of the Ohio Geologieal Survey from 1869 to 1890. He has also contributed papers on the geology of petroleum, gas, and asphalt to the Kentucky Geological Reports, 1891, to the *Annual Report* of the U. S. Geological Survey for 1887, to the *Bulletin of the Geological Society of America*, and to various journals. G. K. Gilbert.

Orton, James: naturalist and traveler; b. at Seneca Falls, N. Y., Apr. 21, 1830. He graduated at Williams College 1855, and at Andover Theological Seminary 1858; traveled in Europe and Asia Minor; became a Congregational minister 1860; was appointed instructor in Natural Science in Rochester University 1866; was at the head of the Williams College expedition which crossed the Andes of Ecuador and descended the Napo and Amazon 1867–68; became Professor of Natural History in Vassar College 1869; and in 1873 made another journey to South America, ascending the Amazon and visiting Peru. He published *The Andes and the Amazon* (1870; enlarged edition 1876); *Underground Treasures: how and where to find them* (1872); *The Liberal Education of Women* (1873); *Comparative Zoölogy* (1875). In 1877 he attempted to explore the river Beni, from Bolivia, but was forced to return after being deserted by his Indian canoemen, and died on Lake Titicaca, Sept. 25, 1877. Revised by Herbert H. Smith.

Ortygia: See Delos.

Oru'ro: a western department of Bolivia, S. of La Paz and bordering on Chili; area, 21,333 sq. miles; population (1888) 111,372. It lies in the southern part of the great inclosed plateau called the Titicaca basin, and includes Lake Aullagas and part of the Desaguadero river; hardly any portion of the surface is below 12,000 feet, and the Andes on the W. and the Cordillera Real on the E. rise far above the limits of perpetual snow. Much of the land is arid, with extensive marshes and salty plains, and it is so cold that few crops will grow. The department is rich in silver, copper, and tin, and mining is the only important industry. A large proportion of the rural population is of Indian blood. Oruro, the capital, is near the left bank of the Desaguadero river, 118 miles S. S. E. of La Paz (see map of South America, ref. 6–C). It was founded in 1590, was an important mining town, and during the latter part of the seventeenth century is said to have had over 75,000 inhabitants: but later the mines were abandoned, and the place was nearly depopulated. It has lately become important again, owing to the railway which connects it with the port of Antofagasta in Chili. Valuable tin mines are worked in the vicinity, and tin, copper, and silver are largely exported. In 1891 Oruro was temporarily the capital of Bolivia. Pop. (1894) about 9,000. Herbert H. Smith.

Orvie'to (anc. *Orbitum*, *Urbs Vetus*): city; in the province of Perugia, Italy; 78 miles N. N. W. of Rome (see map of Italy, ref. 5–D). It crowns an abrupt volcanic hill near the confluence of the Chiana and the Paglia, about 8 miles from Lake Bolsena. The Pozzo di San Patrizio (a circular well with 250 steps, exeavated by Clement VII. in 1527 after the famous sack of Rome) is worthy of notice; but the great boast of Orvieto is its beautiful cathedral, founded in 1290 in honor of the famous miracle of Bolsena. (See Charles E. Norton's *Notes of Travel and Study in Italy*.) Orvieto is of Etruscan origin, was not conspicuous nnder the Romans, but on the breaking up of the empire declared itself independent, and being Guelph in its policy was long a safe refuge for fugitive popes. It manufactures white wine, and has considerable trade in silk, grain, and cattle. Pop. 7,304.

Orzeszkowa, or'zesh-kov'a, Eliza: novelist; b. at Milkowszczyzna, Poland, the hereditary estate of an uncle, in 1842; was edueated at Warsaw; married when hardly sixteen. Her first published work, a prose idyl, *Obrazek z lat glodowych* (A Sketch of the Lean Years), appeared in 1866 in the *Tygodnik Ilustrowany*. Her novels, the first of which, *W Klatce* (In Prison), was published in 1867, include *Na dnie sumienia* (At the Bottom of Conscience, 1871); *Rodzina Brochwiczów* (1876); and *Bene Nati* (1890). She has also written a number of essays on literary and social matters. In her stories woman is generally represented as a victim of social injustice and a slave to her lord, the man, and the author appears as a champion of woman's rights. Her collected works appeared in 1885. J. J. Král.

Osage: city; capital of Mitchell co., Ia. (for location, see map of Iowa, ref. 2–H); on the Red Cedar river, and the Ill. Cent. and the Winona and S. W. Railways; 17 miles N. N. W. of Charles City. It is the seat of Cedar Valley Seminary (Baptist, opened in 1863), is the trade center of a large agrieultural region, has a number of manufactories, and contains 2 national banks with combined capital of $100,000, a private bank, and 2 weekly newspapers. Pop. (1880) 2,012; (1890) 1,913; (1900) 2,734.

Osage City: city (founded in 1869); Osage co., Kan. (for location, see map of Kansas, ref. 6–I); on the Atch., Top. and S. Fé and the Mo. Pac. railways; 35 miles S. W. of Topeka. It is in the great Kansas coal basin and is principally engaged in coal-mining and flag-stone quarrying. The city and vicinity have extensive beds of pure yellow ocher, from which an excellent quality of brick is manufactured. There are 12 churches, a national bank, a State bank, and 2 weekly newspapers. Pop. (1880) 2,098; (1890) 3,469; (1900) 2,792. Editor of "Free Press."

Osage Indians: See Siouan Indians.

Osage Orange, or **Bois d'Arc**: a North American tree, *Maclura aurantiaca*, of the family *Urticaceæ*, native to the Arkansas region. It has a handsome, tough, and durable

yellow wood, which has been proposed as a substitute for fustic. The fruit is large, yellow, and somewhat like an orange, whence the name. It is not edible. The principal use of the tree is as a hedge-plant.

Osage River: a stream which rises in Kansas, where it is often called MARAIS DES CYGNES (*q. v.*). It traverses Missouri, and falls into the Missouri river 10 miles below Jefferson City. Its lower course is navigable.

Osaka (liter., hill of the large estuary): an important seaport, the second city of Japan in population and general importance, and in early times its capital; situated on the bay of the same name at the mouth of the river Yodogawa, which carries off the overflow of Lake Biwa (see map of Japan, ref. 6-C). For purposes of foreign trade Osaka is united with Hiogo, one hour distant by rail. Until the fifteenth century it bore the name of Naniwa; it dates its modern greatness from the time of HIDEYOSHI (*q. v.*), who resolved to make it the seat of his government, and founded the magnificent castle, still used as barracks. The interior palace, possibly in its time the handsomest building in the empire, was destroyed by fire in 1868; the gateways of the castle, with the huge stones of which they are constructed, attest the grand scale on which the whole structure was planned. The city, the streets of which are narrow, is the commercial center of the empire, and the great rice emporium. The most important Government building is the mint, opened in 1871 for the coining of bullion. Originally officered by Englishmen from the Hongkong mint, it has turned out a coinage of the finest quality. Close to Osaka is Sakai, where are made the cotton rugs which are largely exported. The trade in straw-matting has also its center in this neighborhood. On an island in the Yodogawa is situated the small foreign settlement, now deserted by traders and left entirely to missionaries. Osaka and its environs form one of the three city prefectures or *fu*, the other two being Tokio and Kioto. Population of the city, 483,600; of the *fu*, 1,216,670.

J. M. DIXON.

Osar: See DRIFT.

Osawatomie: city; Miami co., Kan. (for location, see map of Kansas, ref. 6-K); on the Mo. Pacific Railway; 8 miles S. W. of Paola, the county seat. It is in an agricultural region, and contains the Kansas State Insane Asylum, 2 State banks with combined capital of $37,740, and 2 weekly newspapers. Pop. (1880) 681; (1890) 2,662; (1900) 4,191.

Osborn, SHERARD: admiral; b. in Madras, India, Apr. 25, 1822; entered the British navy 1837; served in one of the expeditions in search of Sir John Franklin, in the Crimean war, and in the seas of China and Japan; accepted from the Chinese Government the command of a squadron for the suppression of piracy 1862; returned to England 1864 to take command of the turreted monitor Royal Sovereign; was for several years manager at Bombay of the Great Indian Peninsular Railway; became rear admiral 1873, and was a member of the commission for fitting out the Aretic expedition of 1875. Author of *Stray Leaves from an Arctic Journal* (1852); *A Cruise in Japanese Waters* (1859); *The Past and Future of British Relations in China* (1860); and other works. D. in England, May 6, 1875.

Oscan: See ITALIC LANGUAGES.

Oscar I.: King of Norway and Sweden; b. in Paris, France, July 4, 1799; the only child of Bernadotte, who, on Aug. 21, 1810, was elected heir to the throne of Sweden. On June 19, 1823, Oscar married Josephine, a daughter of Eugène Beauharnais, formerly Viceroy of Italy. He ascended the throne Mar. 8, 1844, and died July 8, 1859. He was a successful composer of music; in 1840 he published a work on prisons and the punishment of crime. His eldest son, Charles XV., succeeded him on the throne. R. B. A.

Oscar II., FREDRIK, of the house of Bernadotte: King of Norway and Sweden; poet and writer; b. Jan. 21, 1829, succeeded to the throne at the death of his brother, Charles XV., Sept. 18, 1872. His literary and artistic talents are of a very high order. In 1858 he gained the second prize of the Swedish Academy for a collection of poems, *Ur Svenska Flottans Minnen* (2d ed. 1862); since that time he has published miscellaneous writings under the title *Nytt och Gammalt af O***** (5 small volumes, 1859–72); *Några bidrag till Sveriges krigshistoria åren 1711, 1712, och 1713* (1859–65); translations of Herder's *Cid*, Goethe's *Torquato Tasso*, and others. His complete writings (*Samlade Skrifter*) have appeared in four volumes (1875–91). King Oscar is a very felicitous speaker, and most of his addresses and speeches on different occasions in the Swedish, Norwegian, and other languages have been published in the periodical press. His speeches in the Musical Academy (*Tal i Musikaliska Akademien*) were published in 1885, with notes by Fr. Cronhamn. A fifth volume of his complete writings, containing all his speeches made since his accession to the throne, appeared in 1894. P. GROTH.

Osceola: city (founded in 1850); capital of Clarke co., Ia. (for location, see map of Iowa, ref. 7-G); on the Chi., Burl. and Quincy and the Des M. and Kan. City railways; 50 miles S. by W. of Des Moines. It is in an agricultural and stock-raising region; contains 7 churches, 3 public-school buildings, new court-house, a sanitarium, 2 State banks, a private bank, electric-light plant, and 2 weekly newspapers; and has marble-works, agricultural-implement works, and railway machine-shops. Pop. (1880) 1,769; (1890) 2,120; (1900) 2,505. EDITOR OF "SENTINEL."

Osceola: a Seminole chief, son of William Powell, an Englishman, by an Indian mother, born about 1804, near the river Chattahoochee. Osceola was early distinguished for ability, courage, and hatred of the whites; attained great influence among the Seminoles, and strongly opposed the cession of the tribal lands in Florida. In 1835 his wife, the daughter of a fugitive slave, was stolen as a slave, and Osceola, demanding her release of Col. Thompson, U. S. agent at Fort King, used language which the latter resented, and the chief was put in irons. Six months later Thompson was murdered; the battle on the Withlacoochie, the massacre of Dade, the assaults on Forts Micanopy and Drane, and other spirited actions followed, in which the Indians more than held their own against very great odds; but during a conference with Gen. Jessup, under a flag of truce, Osceola was treacherously seized (Oct. 22, 1837), and imprisoned at Fort Moultrie, S. C., where he died Jan. 20, 1838.

Os'cines: a term applied by Johannes Müller to a group of *Passeres* containing those with a highly developed singing apparatus, having five or six pairs of tracheal muscles attached to the ends of the upper bronchial half rings—an arrangement termed acromyodian. The name was used by Merrem, but not in the same manner as it was by Müller, and not with his exactness of definition. The group, or sub-order, contains over nine-tenths of the passerine birds, and is contrasted with the CLAMATORES (*q. v.*) or Mesomyodian birds. F. A. LUCAS.

Osco'da: village; Iosco co., Mich. (for location, see map of Michigan, ref. 5-J); on Lake Huron, at the mouth of Au Sable river, and the Au Sable and N. W. and the Detroit, Bay City and Alpena railways; 100 miles N. E. of Bay City, 200 miles N. of Detroit. It is in an agricultural, lumber, and salt-manufacturing region; has a large trade in lumber; and contains three churches, public and Roman Catholic schools, a savings-bank, and a weekly newspaper. Pop. (1880) 1,951; (1890) 3,593; (1900) 1,109.

EDITOR OF "SATURDAY NIGHT."

Oscula'trix and **Osculatory Circle** [*osculatrix* is Mod. Lat., liter., femin. of **oscula'tor*, a kisser, deriv. of *osculum*, a kiss, liter., dimin. of *os*, mouth]: an osculatrix is a curve of a given kind which, at an assigned point of another curve, has the closest possible contact with the latter. If two plane curves have two consecutive points in common, the straight line passing through these points is tangent to both curves at the first point, and the two curves are said to have a contact of the first order. In general, if two plane curves have $n + 1$ consecutive points in common, they will have n consecutive rectilinear tangents in common, and the two curves are then said to have a contact of the nth order. If two curves have a contact of the nth order, they must have $n + 1$ consecutive ordinates in common, counting from the first point, and consequently they must have n successive differential coefficients of their ordinates at that point equal to each other. Conversely, if two curves have a common point, and if n successive differential coefficients of their ordinates at that point are equal, they will have a contact of the nth order.

It is a property of osculatrices that no osculatrix whose contact is of an odd order can cut the curve to which it is osculatory at the point of osculation, and that every osculatrix whose contact is of an even order must cut the curve to which it is osculatory at the point of osculation.

The *osculatory circle* is a circle that, at a given point of a curve, has the closest possible contact with the curve. Thus it passes through three consecutive points of the curve, as a

circle is determined by the three conditions; consequently the first and second differential coefficients of the ordinates of the curve and circle are equal at the point of contact. The radius of the circle is called the radius of curvature, and its reciprocal may be considered as a measure of the curvature of the curve. The center of the circle is called the center of curvature; and the locus of this point is the evolute of the curve. (See EVOLUTE.) It is to be remarked that we can not assign to a circle a higher order of contact than the second, but it may happen that it has a higher order of contact at particular points. This is the case at those points where three consecutive normals (see NORMAL) pass through a point, as, for instance, at the vertices of the conic sections. Revised by R. A. ROBERTS.

Osgood, SAMUEL: soldier and official; b. at Andover, Mass., Feb. 14, 1748; graduated at Harvard 1770; studied divinity, but became a merchant; was much in public life; attained the rank of colonel and assistant commissary in the Revolutionary army; served in the Massachusetts Legislature; was in Congress 1780–84; was first commissioner of the U. S. Treasury 1785–89; Postmaster-General 1789–91; became Speaker of the New York House of Assembly; supervisor in New York 1801–03; naval officer of the port of New York 1803–13. He wrote various works, chiefly on religious questions. D. in New York, Aug. 12, 1813.

Osgood, SAMUEL, D. D., LL. D.: clergyman and man of letters; b. in Charlestown, Mass., Aug. 30, 1812; graduated at Harvard College 1832, and at Cambridge Theological School 1835; was pastor in Nashua, N. H., 1837, in Providence 1841, and in New York 1849; in 1870 left Unitarianism for the Episcopal Church, but assumed no pastoral charge. His numerous writings include *Studies in Christian Biography* (1851); *The Hearth-stone* (1854); *God with Men* (1854); *Mile-stones in our Life Journey* (1855); *Student Life* (1860); he translated from the German de Wette's *Human Life* (1842) and Olshausen's *History of the Passion* (1839). He edited *The Western Messenger* two years and *The Christian Inquirer* four; was for many years home corresponding secretary of the New York Historical Society. D. in New York, Apr. 14, 1880.

O'Shaughnessy, ō-shaw'ne-sē̆, ARTHUR WILLIAM EDGAR: poet; b. 1846; d. 1881. In 1864 he entered the British Museum. In 1873 he married Eleanor, sister of Philip Bourke Marston. He belonged to the neo-romantic group of poets, followers of Morris and Swinburne and of the French romantic school; published *An Epic of Women* (1870); *Lays of France* (1871), a free paraphrase of the *lais* of Marie de France; *Music and Moonlight* (1874); and *Songs of a Worker* (1881). H. A. B.

Osh'awa: town and warehousing port of Whitby township, Ontario County, Ontario, Canada; on the Grand Trunk railway, 33 miles N. E. of Toronto and near Lake Ontario (see map of Ontario, ref. 4–E). It has manufactures of flour, furniture, farm implements, machinery, etc., and two weekly newspapers. Pop. (1891) 4,066.

O'Shea, M. VINCENT: See the Appendix.

Osheba: See FANS.

Osh'kosh: city; capital of Winnebago co., Wis. (for location, see map of Wisconsin, ref. 5–E); on Lake Winnebago at the mouth of Fox river, and on the Chi. and N. W., the Chi., Mil. and St. P., Mil., L. S. and W., and the Wis. Cent. railways; 35 miles N. W. of Milwaukee, 49 miles S. S. W. of Green Bay. It is in a lumber region; has an excellent location for communication with distant points by water; and is the third city in the State in population, wealth, and commercial importance. The census returns of 1890 showed that 423 manufacturing establishments (representing 71 industries) reported. These combined had a capital of $6,531,213, employed 5,397 persons, paid $2,017,267 for wages and $4,663,510 for materials, and had products valued at $8,619,219. The principal manufactures were connected with the lumber and sash and door industry, and comprised 15 establishments, which had a combined capital of $3,354,598, used materials valued at $2,700,816, and had products valued at $4,208,400. Other important industries, in the order of capital investment, were the manufacture of furniture, $556,464; carriages and wagons, $378,702; foundry and machine-shop products, $313,960; malt liquors, $151,838; flour and grist mill products, $116,655; tobacco, $107,771; printing and publishing, $97,951; and slaughtering and meat-packing, $38,300. The city is the seat of a State normal school and of the Northern Wisconsin Insane Asylum; contains a U. S. Government building, 2 libraries (State Normal School and Public) with over 7,000 volumes, large city-hall building, 10 public-school buildings, public-school property valued at over $233,000, gas and electric-light works, and Holly water-works; and has 4 national banks with combined capital of $600,000, 3 State banks with capital of $350,000, and 2 daily, 7 weekly, and 2 monthly periodicals. The assessed valuation in 1894 was $8,580,497, and the bonded debt on Feb. 15, 1894, was $236,800. Pop. (1880) 15,748; (1890) 22,836; (1900) 28,284.
EDITOR OF "NORTHWESTERN."

Osian'der (or **Hosemann**, his true name), ANDREAS [*Osiander* is a Grecized form of *Hosemann*: cf. Gr. ἀνήρ, ἀνδρός, man, and Germ. *mann*, man]: theologian; b. at Gunzenhausen, near Nuremberg, Dec. 19, 1498; studied theology at Ingoldstadt and Wittenberg; became preacher at Nuremberg in 1520, and being an ardent adherent of Luther he labored with great energy for the Reformation. In 1548, however, he was deprived of his office, as he would not subscribe to the Augsburg Interim, but he was shortly after (1549) made preacher and Professor in Theology at Königsberg. Here he entered into a hot controversy concerning justification. He held very peculiar views on that point. Fundamentally he agreed with Luther and was as antagonistic to Calvinism as to Romanism, but he was a mystic, and maintained the righteousness of Christ is not imputed to us but infused into us. His views may be best learned from his two pamphlets *An filius dei fuerit incarnandus*, etc. (1550), and *Von dem einigen Mittler, Jesu Christo*, etc. (1551). He died suddenly in Königsberg, Oct. 17, 1552. His principal works were *Harmonia Evangetica* (1537); *De Lege et Evangelio* (1549); and *De Justificatione* (1550). See his *Life*, by W. Möller (Elberfeld, 1870). See also the article GERMAN THEOLOGY. Revised by S. M. JACKSON.

Osi'ris [= Lat. = Gr. Ὄσιρις, Egypt. Ausâr Âsiri, Hesiri]: the Egyptian god of the dead and ruler of the nether regions. He is conceived as the son of Nut, brother and husband of Isis; brother also of Nephthys and Set-Typhon. The story of Osiris is told at length by Plutarch (*Isis and Osiris*), and is the only Egyptian myth of which we have the outlines in any degree of completeness. The native texts are full of allusions to this as to a multitude of other myths, but they are fragmentary in character and extent. *Osiris* appears first as a divine ruler of Egypt, elevating the mode of life, improving the condition of the land, dividing it and organizing its administration. After a happy and prosperous reign he was murdered by his brother Set. He afterward rose again in the region of the departed and became the ruler of the dead, in which character he henceforth appears. His death was avenged by Horus, son of Isis, who succeeded in overcoming Set. According to the myth, Set had divided the body of Osiris into fourteen parts. Thirteen of these were found by Isis, who erected a temple to Osiris over each. The place which was specially sacred to him was Abydos, where his heart was believed to be buried. Before him, as god of the dead, the judgment scene occurs, with its weighing of the soul of the individual over against the symbol of truth. (See RITUAL OF THE DEAD.) Like Osiris, every man must die, be judged, and rise again in order to partake in the future happiness that awaited the pious Egyptian. The dead themselves were called by his name. He was the special hero of the *Book of the Dead*, and the prayers of funeral steles were addressed to him. The belief in him and in the immortality which he symbolized was the deepest in Egyptian religious thought.
CHARLES R. GILLETT.

Oskaloosa: city; capital of Mahaska co., Ia. (for location, see map of Iowa, ref. 6–I); on the divide between the Des Moines and the South Skunk rivers, and the Burlington Route, the Ia. Cent., and the Chi., Rock Is. and Pac. railways; 24 miles N. N. W. of Ottumwa, 62 miles E. S. E. of Des Moines. It is in a coal, agricultural, and stock-raising region, which also has valuable deposits of iron ore and fire-clay. It is the seat of Oskaloosa College (Christian, chartered in 1855), and of Penn College (Friends, chartered in 1873); has gas and electric light plants, water-works, street-railways, 4 libraries (public, high school, and Oskaloosa and Penn Colleges) containing over 11,000 volumes; a national bank, 2 State banks, a private bank, and a daily, 5 weekly, and 3 monthly periodicals; and manufactures flour, woolen goods, iron and brass goods, paving-brick, and furnaces, and packs pork. Pop. (1880) 4,598; (1890) 6,558; (1900) 9,212.
EDITOR OF "HERALD."

Osler, William, M. D., F. R. C. P.: clinician; b. at Tecumseth, Ontario, Canada, July 12, 1849; graduated at Trinity College, Toronto: studied medicine at McGill University, Montreal, and in London, Berlin, and Vienna; was Professor of the Institutes of Medicine, McGill University, 1874–84: Professor of Clinical Medicine, University of Pennsylvania, 1884–89; became professor in Johns Hopkins University, and physician-in-chief Johns Hopkins Hospital, Baltimore, in 1889; was Galstonian lecturer at the Royal College of Physicians, London, in 1885, and Cartwright lecturer at the College of Physicians and Surgeons, New York, in 1886. He is the author of *Clinical Notes on Smallpox* (Montreal, 1877); *Histology Notes for Students* (1881); *The Cerebral Palsies of Children* (London and Philadelphia, 1889); *The Principles and Practice of Medicine* (New York, 1892); and edited *Montreal General Hospital Reports* (1878).

S. T. Armstrong.

Osman: See Othman.

Osman Pasha: soldier; b. at Tokat, Asia Minor, 1832; was educated at the military schools of Constantinople; fought in the Crimean war, the Cretan campaign, and the Serbo-Turkish war; at the outbreak of the Russo-Turkish war was commander of the Fifth Army-corps. Defeated at Scalevitze, he intrenched himself at Plevna, which he held from Aug. 31 to Dec. 10, 1877, when he surrendered with 43,000 men. Since the conclusion of peace he has been several times Minister of War, and is now (1894) grand marshal of the palace. In personal appearance, character, and mode of warfare, he is a typical Ottoman soldier, fanatical, frugal, brave, and when behind earthworks almost invincible.

E. A. Grosvenor.

Os'mazome [from Gr. *ὀσμή*, smell + *ζωμός*, broth]: a name given by Thénard to that portion of meat extract which is soluble in alcohol and contains those constituents of the flesh which determine its taste and smell.

Os'mium [from Gr. *ὀσμή*, smell, odor, deriv. of *ὄζειν*, smell]: an element of matter, one of the "platinum metals"; that is, found in association in nature with platinum. Its only ore is a native compound with another metal of the same natural group, Iridium (*q. v.*), forming the mineral metallic alloy called iridosmine or osmiridium, which is exceedingly hard, and therefore used for tipping gold pens. This native alloy contains also Ruthenium (*q. v.*). The methods of procuring metallic osmium and its compounds from the ore are complex and difficult. At the most intense heats it volatilizes without fusion. In fine division it is very combustible, burning to osmic acid. Osmium is believed to be, in some of its combinations, the most poisonous also of known substances. Revised by Ira Remsen.

Osmundaceæ: See Fernworts.

Os'nabrück: town; in the province of Hanover, Prussia; on the Hase; 70 miles W. S. W. of Hanover (see map of German Empire, ref. 3–D). It contains a large cathedral, built in the thirteenth century, a town-hall, in which the Treaty of Westphalia was signed in 1648, and numerous manufactories of steel and iron, tobacco, chicory, soap, paper-hangings, leather, and linen and woolen fabrics. It dates from 772; suffered much during the Thirty Years' war, but recovered in the eighteenth century, owing to the development of its linen industry. Pop. (1890) 39,929.

Oso'rio, Manoel Luiz: soldier; b. near Pelotas, Rio Grande do Sul, Brazil, May 10, 1808. He early entered the army; first attained distinction in the civil war in Rio Grande do Sul 1839–45; was prominent in the campaign in Uruguay and against Rosas 1851–52: and on the breaking out of the Paraguayan war was made commander-in-chief of the Brazilian forces in operation Mar. 1, 1865. He was superseded by Caxias July 15, 1866, but continued to serve until Dec., 1869, when he was severely wounded. As a cavalry leader he was unsurpassed: the soldiers called him *O legendario*, or The Fabulous, on account of his bravery. He became lieutenant-general in June, 1867, and was created successively baron, viscount, and Marquis of Herval. After the war he took an active part in politics; was senator from Jan. 11, 1877, and Minister of War from Jan. 5, 1878. D. at Rio de Janeiro, Oct. 4, 1879. Herbert H. Smith.

Osorkon: the name of three Egyptian kings; the second and fourth of the twenty-second (Bubastite) dynasty, and the second of the twenty-third (Tanite) dynasty. Of Osorkon I. and II. little of importance is known, except that the former apparently founded a city at the entrance to the Fayum near the site of the modern Illahun. It has also been conjectured, on the ground of chronology, that he was the Zaræus of Josephus (*Antiq. Jud.*, viii., 12, 1–2) and the Zerah of 2 Chron. xiv. 9–13; but this is very doubtful. The third Osorkon is named among the twenty kings of Egypt at the time of Pianchi the Ethiopian conqueror, as King of Bubastis in the Delta. The divided condition of the land made it an easy prey to the power of the growing Ethiopian kingdom whose capital was at Napata (*q. v.*).

Charles R. Gillett.

Osorno, Marquis of: See O'Higgins, Ambrosio.

Ospi'na Rodriguez, Mariano: politician; b. at Guasca, New Granada, 1803. He was a lawyer, early took part in politics, and joined the party which opposed Bolivar in 1830. Subsequently he was a leader of the conservative party; was a member of congress, Secretary of the Interior 1841, and governor of Bogotá. From 1857 to 1861 he was president of the Grenadine Confederation. A revolt which broke out in 1859 was partially suppressed, but was successful soon after Ospina's term came to an end, and resulted in a change of constitution. Ospina was imprisoned for a short time, and subsequently exiled until 1872. D. at Medellin, 1885. Herbert H. Smith.

Osprey: See Fish-hawk.

Os'sein [from Lat. *os*, *ossis*, bone]: the modification of Gelatin (*q. v.*) that occurs in bones, forming substantially the whole of the organic part of the bone, apart from the tricalcic phosphate, which makes up the mass of the earthy part. Ossein may be isolated in its natural state by dissolving out the earthy part of the bone with muriatic acid and long and repeated washing with cold water. It then forms, before drying, a soft elastic mass, which is insoluble in cold water, but quickly dissolves in boiling water to a solution of ordinary gelatin. Revised by Ira Remsen.

Osse'tish: an Iranian language; the speech of the Caucasus folk Ossetians. The Ossetians are the most northwestern people of the Iranians, and they are somewhat separated by other tribes from the main body of the race, but their speech is none the less Iranic. Three dialects of the language may be recognized: First, the northeastern or eastern, called Tagaurian; second, the northwestern or western, termed Digorian (but styled Ironian by the Ossetians themselves); third, the southern or Tualian. In its inflectional system the Ossetish shows ten cases, including a so-called sociative and elative, in the declension; the verb conjugation and the syntax show a comparative fullness in accordance. A striking phonetic feature of the speech is the absence of *h*, a letter otherwise common in Iranian tongues. Ossetish can make but slight literary claims.

The names of the principal authorities on this language are Sjögren, G. von Rosen, W. Miller, Fr. Müller, Lerch, Tsorajew, Salemann, B. Joseph, Stackelberg, and Hübschmann. A. V. Williams Jackson.

Ossian (Oisin or Ossin): bard and hero of Irish legend, son of Fingal (Finn or Find), father of Oscar. The legend puts these heroes in the latter half of the third century, and in the earliest poems and tales they have the air of historical characters. References to them in the oldest sources are scanty. Between the twelfth and fifteenth centuries they were the center of a vigorous growth of stories that developed in the east of Ireland, and are known as the cycle of Leinster, or the Ossianic cycle. This cycle long kept its vitality, developing new branches as late as the eighteenth century. It was carried across to the Scotch Highlands, and first came to general notice through the Gaelic forms of the tradition. James MacPherson, a young Highland schoolmaster, had collected from oral tradition a few fragments of Gaelic poetry, and brought them to the notice of the Rev. John Home, who showed them to Dr. Hugh Blair, then a power in the world of Scotch letters. Blair urged MacPherson to publish his English versions of them, and these accordingly appeared in 1760, in a small volume, entitled, *Fragments of Ancient Poetry, collected in the Highlands of Scotland, and translated from the Gaelic or Erse*, with a preface by Dr. Blair. The volume provoked considerable enthusiasm among Scotch literary men and antiquarians, who subscribed money in aid of further search for similar remains. MacPherson undertook the task, and traveled extensively through the remoter Highlands, and upon his return published in London two additional volumes: *Fingal, an Ancient Epic Poem, in six books, with other lesser poems* (1762); *Temora, an Epic Poem, in eight books, with other poems* (1763). All were then collected in

a single volume as *The Poems of Ossian* (1765). Immediately upon their appearance a fierce controversy arose. Dr. Johnson declared that no ancient poetry could be discovered among the Highlanders; that MacPherson had had no originals and was tricking the public; and that his poems were worthless bombast. W. Shaw's *Inquiry into the Authenticity of the Poems of Ossian* (London, 1781) and Malcolm Laing's *Notes and Illustrations to Ossian* (Edinburgh, 1805) were important works in support of that contention. On the other hand, Dr. Blair and others collected evidence of the existence of poetry in the Highlands and its collection by MacPherson, and pointed out beauties in the poems equal to those of Homer. In 1805 the Highland Society of Edinburgh published a report of its elaborate inquiry into the question of the existence of ancient Gaelic originals. The report found that a great legend of Finn and Ossian and popular poetry concerning them had existed; that fragments were collected having in the main the same substance as the poems published by MacPherson, but none which were exact originals; and that MacPherson had edited his materials freely, and added of his own invention. Those who attacked the authenticity of the poems had challenged MacPherson to publish the Gaelic manuscripts, and £1,000 had been subscribed among his Scotch supporters for that purpose. MacPherson died (1796) without publishing them, but left among his papers materials which were published in 1807. This Gaelic text seems to be a curious mosaic of old and new materials, made by one unproficient in the Gaelic language; it was contended that MacPherson had made his Gaelic text by translating his poems from the English, and the dispute continued. It has not yet been entirely abandoned, though the advances in Celtic scholarship and the publication of authentic remains of old Gaelic tradition (cf. notably J. F. Campbell, *Popular Tales of the West Highlands, orally collected, with a Translation*, 4 vols., Edinburgh, 1860–62; *The Dean of Lismore's Book*, edited by T. MacLauchlan, London, 1862) have confirmed the general conclusions of the Highland Society's report of 1805, and made it clear that MacPherson had originals to work upon, found in the living oral tradition; that these originals were very old, or made up of very old materials, developed and elaborated in the popular imagination, and were not indeed poems of Ossian, but Ossianic poems; that MacPherson used his materials with great freedom, and mixed with the heroes of the Ossianic cycle those of the cycle of Ulster; and that the style, tone and manner of MacPherson's versions are very different from the older forms of the traditions, and are the work of the translator himself.

Wholly aside from the question of authenticity, MacPherson's publications produced an impression upon literary Europe that was phenomenal in its breadth and intensity for nearly two generations. Numerous translations of MacPherson's volumes, or parts of them, appeared in Germany, France, Italy, Spain, and other countries. In Italy Cesarotti wrote a considerable essay, ranking Ossian with Homer. Goethe, Schiller, Herder, Schubert, Chateaubriand, Byron, and Coleridge all passed under the spell. Napoleon carried Ossian about with him incased in a costly box. Lamartine owns him as among the most powerful formative influences of his youth. Traces of the general enthusiasm are universal in the works of the years about 1800. At that time a Parisian publisher, planning to issue the masterpieces of the world's literature, made Ossian the first and Homer the second of the series. Now the poems of Ossian have passed almost completely out of notice. The ecstatic, declamatory style, the indistinct actors and nebulous landscape, saturated with a vague and monotonous melancholy, have ceased to be pleasing. They have been reprinted in almost innumerable editions. For the Ossianic cycle in Celtic literature, cf. d'Arbois de Jubainville, *Cours de littérature celtique*, vols. i., ii., and v. (Paris, 1884–93). A. E. Canfield.

Os'soli, Sarah Margaret Fuller, Marchioness: author; b. in Cambridgeport, Mass., May 23, 1810: daughter of Hon. Timothy Fuller, a representative in Congress 1817–25; was in early childhood a proficient in the classical languages and modern literature, but noted for eccentricities and the violence of her passions; taught languages in Boston to private classes, and in Bronson Alcott's school after the death of her father in 1835; was a conspicuous figure in the literary set comprising also Emerson, Hawthorne, and Channing, and became widely known for brilliant powers of conversation; became principal of a school at Providence, R. I., in 1837; was in 1840 editor of *The Dial*, a quarterly magazine: published in 1839 a translation of Eckermann's *Conversations with Goethe*, and in 1841 the *Letters of Günderode and Bettina*; made in 1843 a journey to Lake Superior, and wrote *A Summer on the Lakes*; removed to New York in Dec., 1844; became a writer for the *Tribune*, to which she contributed most of the *Papers on Art and Literature* issued in a volume in 1846; expanded an early essay in *The Dial* into a volume entitled *Woman in the Nineteenth Century* (1845; new ed. 1855); went to Europe early in 1846; married in Rome in Dec., 1847, a nobleman, Giovanni Angelo Ossoli; was a witness of the Roman revolution of 1848, and of the siege of Rome by the French in 1849, at which time she was appointed by Mazzini directress of one of the hospitals; embarked at Leghorn for the U. S. in the ship Elizabeth May 17, 1850, accompanied by her husband and infant son, and with them perished by shipwreck at Fire island, near New York, July 19, 1850. An unpublished history of the Roman revolution was lost with her. A monument to her memory is in Mt. Auburn cemetery. Her collected newspaper correspondence, edited by her brother, Rev. Arthur B. Fuller, was published in 1856, under the title *At Home and Abroad*. See the memoirs by Emerson, Channing, and James Freeman Clarke (2 vols., 1852), by Julia Ward Howe (Boston, 1883), and by Thomas W. Higginson (Boston, 1884). A new edition of her complete works appeared at Boston in 1874. Revised by H. A. Beers.

Ostade, ōs'tăă-de, Adrian, van: painter and etcher; b. at Lubeck in 1610. He studied under Franz Hals, and soon became famous as a genre-painter. His pictures were in great demand in his own time, and are to be seen in Flanders, Germany, France, and England. He worked in Haarlem, in Lubeck, and in Amsterdam, where he died in 1685. A series of fifty-four of his etched plates have been published. His brother Isaac, who was his pupil, acquired the manner of his brother so thoroughly that his pictures are often mistaken for those of Adrian. W. J. Stillman.

Ostend': town; in the province of West Flanders, Belgium; on the German Ocean, 77 miles by rail W. N. W. of Brussels (see map of Holland and Belgium, ref. 9–A). It has a good harbor, is fortified and neatly built, and communicates daily by steamers with London and Dover. Besides manufactures of linen, sail-cloth, and ropes, it has important fisheries of oysters, cod, and herrings and an active traffic in the transport of butter, rabbits, etc. In the summer season it is the resort of 20,000 visitors. There is a handsome kursaal, and a sea-wall 3 miles long and 35 yards broad forms a favorite promenade. Pop. (1896) 30,730.

Ostend Manifesto: See the Appendix.

Osteoblasts and **Osteoclasts**: See Histology (*Bone*).

Osteoglos'sidæ [Mod. Lat., named from *Osteoglos'sum*, the typical genus; Gr. ὀστέον, bone + γλῶσσα, tongue]: a family of fresh-water fishes of the sub-order *Isospondyli*, characterized by the peculiar form and bony head. The body is more or less elongated, compressed, and covered with large hard scales composed of mosaic-like pieces; the lateral line high, little incurved from the back, and with widened mucous ducts; the head oblong, with the integument very thin, and cheeks protected, with large suborbital and postorbital plates; mouth with a lateral cleft; its upper margin formed by the intermaxillaries at the middle and the supramaxillaries at the sides; teeth acute, on the jaws as well as palate; gill apertures large; branchiostegal rays numerous (8–16); dorsal and anal posterior elongated, the anal originating farther forward than the dorsal; caudal separately developed; pectorals inserted low down on each side of the throat; ventrals perfect, not very far from the head. The skeleton has numerous vertebræ (60–80). The family is noted for the peculiar distribution of its species. It is divisible into two sub-families (1) *Osteoglossinæ*, in which the abdomen is trenchant, having two genera, *Osteoglossum*, represented in South America, and *Scleropages*, with one species in several of the Philippine islands, and another in Queensland, Australia; and (2) *Heterotinæ*, also with two genera: *Hetrotis*, peculiar to West Africa and the Nile, and *Arapaima*, confined to South America. One species (*Arapaima gigas*) reaches a gigantic size, sometimes exceeding 15 feet in length and weighing upward of 400 lb. It is taken sometimes with a hook baited with small fishes, and sometimes with a harpoon. In Brazil it sells for a high price. Revised by F. A. Lucas.

Osteol'ogy [Gr. ὀστέον, bone + λόγος, discourse, reason]: the science of the skeleton of vertebrated animals. This

skeleton is composed of bone, or its cartilaginous or membranous basis, the intimate structures of which are pointed out in the article Histology (*q. v.*). The skeleton consists either of a cartilaginous or membranous continuum, or of cartilaginous or osseous segments arranged in continuous succession, so as to form two tubes, one superior and one inferior, attached by a solid axis between them, the whole furnished with various appendages. Each axial segment is in turn composed of sub-segments, each of which arises from a separate (sometimes more than one) center of ossification in the primal cartilage or membrane. Each primary segment of the skeleton is called a vertebra, and each vertebra is composed of the same elementary segments, some of which may be omitted, subdivided, etc., and also greatly modified in their form for the accommodation of the viscera they inclose. The superior arches or tubes protect the nervous axis of the animal, while the inferior surround the nutritive organs, or the digestive, circulatory, respiratory, and reproductive systems. The elementary segments and their modifications are exhibited in the accompanying sections from the cranial, thoracic, and caudal regions respectively, in order to display the excessive developments of the *neural* or upper arch (Fig. 1), the *hæmal* or lower arch (Fig. 2), and of the centrum (Fig. 3), by reduction of the arches. The

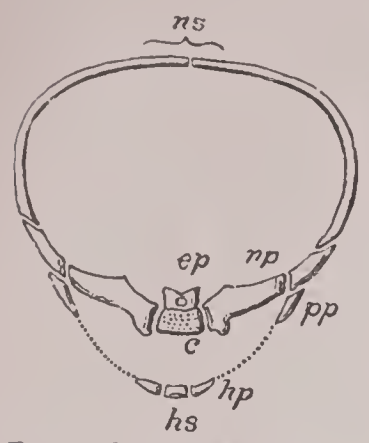


Fig. 1.—Cranial segment : *c*, centrum ; *np*, neurapophysis ; *ns*, neural spine ; *ep*, epapophysis ; *pp*, pleurapophysis ; *hp*, hæmapophysis ; *hs*, hæmal spine.

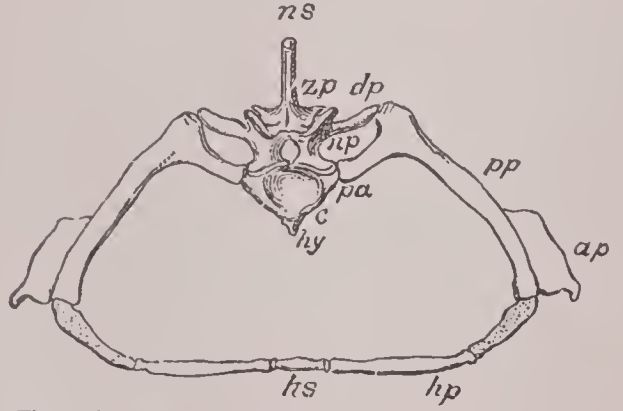

Fig. 2.—Thoracic segment from a crocodile. Letters as in Fig. 1: *zp*, zygapophysis ; *dp*, diapophysis ; *pa*, parapophysis ; *hy*, hypapophysis ; *ap*, appendage.

elements are named as follows : *ns*, neural spine : *zp*, zygapophysis ; *dp*, diapophysis ; *pp*, pleurapophysis : *hp*, hæmapophysis ; *hs*, hæmal spine. In addition to these, there are other processes less universally present—namely, on the middle line of the centrum above, *ep*, epapophysis (Fig. 1), on the middle line below, *hy*, hypapophysis (Fig. 2), and on the side of the centrum below the diapophysis, *pa*, parapophysis (Fig. 2, represented by capitular articulation for rib). In the thoracic vertebra the segments correspond to the following special names of the bones : neural spine, *spinous process* ; zygapophysis, *articular process* : diapophysis, *transverse process* ; neurapophysis, *superior arch* ; pleurapophysis, *rib* ; hæmapophysis, *thoracic rib* or *cartilage* ; hæmal spine, *sternal segment* ; centrum, *body*.

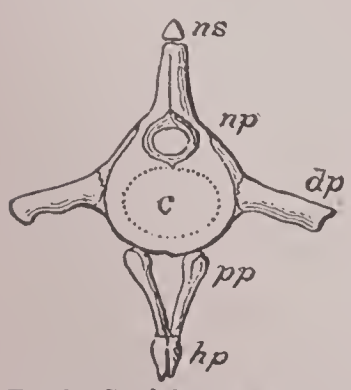

Fig. 3.—Caudal segment from dugong. Letters as before.

There are many peculiarities in the segments which compose the skull of the Vertebrata, on which account the name of vertebræ has been denied them. Since they also present some likenesses to the vertebræ of the body in their growth-history as well as composition, they may be regarded as representing a special class of vertebræ. The limbs of Vertebrata also have received a variety of interpretations. These, when fully represented by a front pair and a hinder pair, are attached to corresponding arches, which depend from the vertebral axis, and are therefore hæmal. The pelvic arch, which bears the hinder limbs, is attached to the sacral vertebræ, and includes one superior (*ilium*) and two inferior elements (viz., *ischium* and *pubis*). That which supports the fore limbs, or the scapular arch, is not attached to an axial body in any class excepting that of the fishes, and then it is to the occipital or posterior segment of the skull and by dermal bones only. It also includes one superior element (*scapula*) and two inferior (*epicoracoid* and *coracoid*). The limbs are lateral appendages of these arches, like the uncinate processes of the ribs (Fig. 2, *ap*), opercula of the suspensor of the lower jaw in fishes, etc.

Development of the Skeleton.—The spinal column will first claim attention. The germinal layer of the yolk of the egg, or blastoderm, is early marked by a linear impression, the "primitive groove." The blastoderm is divided into three layers, of which the lower ultimately forms the interior lining of the alimentary canal, and the upper forms the cerebro-spinal nervous axis and the epidermis of the body. It is the upward longitudinal folding of the upper and middle layers (ectoderm and mesoderm) on each side

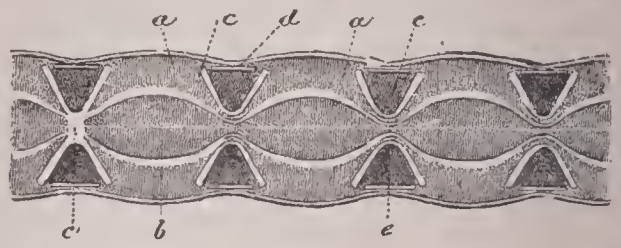

Fig. 4.—Longitudinal section of the posterior part of the vertebral column of *Heptanchus* (from Kölliker) : *a*, fibro-cartilaginous part of sheath of chorda dorsalis ; *b*, gelatinous chorda ; *c*, osseous double cone perforated for the contracted chorda ; *c'*, section of a vertebra to one side of the perforation ; *d*, the external lateral osseous plates of the vertebræ ; *e*, the cartilage filling the interspace of a double cone.

into the "dorsal laminæ" that forms the "primitive groove." The laminæ grow toward each other and unite along the median line, forming the neural canal. The two layers are at the same time folded downward as parallel folds, or ventral laminæ. The middle layer divides, the inner laminæ, with the entoderm, forming the alimentary canal, while the outer, with the mesoderm, form the outer walls of the abdominal cavity, or the somatopleure. In the meantime there appears in the layers below the primitive groove a cylindrical body of large cells filled with transparent protoplasm or sarcode, around which are differentiated from two to four layers, forming a sheath. This cylinder is the *chorda dorsalis*, which extends forward to within a short distance of the end of the primitive groove. The portion of the

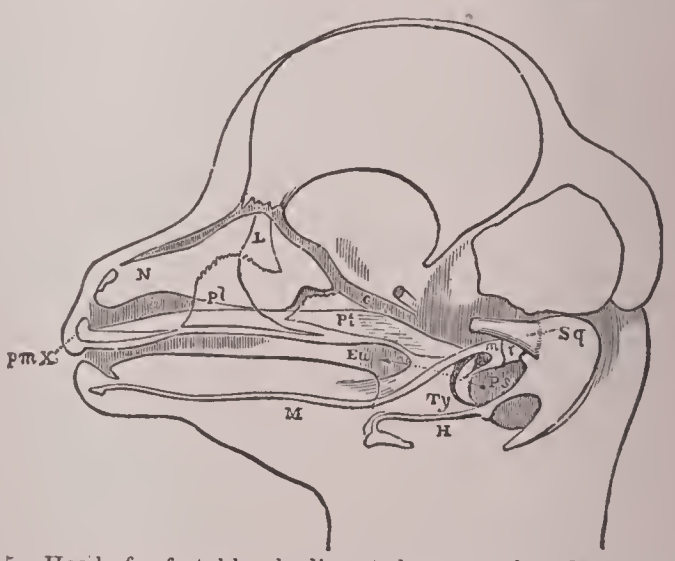

Fig. 5.—Head of a fœtal lamb, dissected so as to show Meckel's cartilage, M (from Huxley) : *m*, the malleus ; *i*, the incus ; *Ty*, the tympanic ; *H*, the hyoid ; *Sq*, the squamosal ; *Pt*, the pterygoid ; *pl*, the palatine ; *L*, the lachrymal ; *pmx*, premaxillary ; *N*, nasal sac ; *Eu*, Eustachian tube.

groove above it is enlarged, and then bent downward in front of the chorda. There is a constriction in the last-named portion of the now inclosed groove, or neural canal, so that three vesicles are formed, which are the concavities of the three axial segments of the future brain. The walls of this neural canal are continuous from the one end of the animal to the other. In the bodily portion of the axis, that part of the blastoderm which surrounds the chorda dorsalis

early presents the appearance of sub-quadrate segments or bodies, which, extending, gradually inclose the chorda as rings. At the same time corresponding segments appear in the dorsal laminæ. These are the bases of the future vertebræ, representing centrum and neurapophysis. The diapophysis and ribs appear in the form of cartilage in the somatopleure. The elements are completed by the deposit of phosphate of lime round the nutritive vessels, or the process of ossification; and they may remain distinct from each other or become co-ossified, according to the type of vertebrate. The manner of ossification of the body of the vertebra varies as follows:

I. Spinal column represented by the membranous sheath of the chorda dorsalis: class *Leptocardii* (lancelet).

II. Spinal column represented by the membranous sheath of the chorda, and cartilaginous neurapophyses and pleurapophyses; class *Marsipobranchii* (lamprey) and the *Chondrostei* (sturgeon, etc.).

III. Column represented by imperfect ossifications of the sheath of the chorda alone, with similar neurapophyses and pleurapophyses: certain sharks; e. g. *Hexanchus* and the merospondylous *Teleostomi*.

IV. Bodies of column ossifications of the chorda, together with the investing sheath: class *Selachii*, most sharks and rays.

V. Centra of vertebræ composed of ossifications of the external or blastodermic investment of the chorda: classes *Teleostomi*, bony fishes, *Batrachia*, *Reptilia*, *Aves*, and *Mammalia*.

The ossification of the bodies, beginning in the circumference of the sheath, first completes a ring, which then grows inward, constricting the chorda. The latter may be nearly or quite divided by the osseous body, and portions of it and the sheath remain between the biconcave centra as doubly conical or globular bodies, as in the osseous fishes and many salamanders.

When cartilage appears round the chorda dorsalis, in what becomes the base of the skull, it is unsegmented. It is plate-like, and sends a bar on each side round that part of the brain cavity (hypophysis) which is decurved in front of the end of the chorda. The bars (trabeculæ) reunite in front of it, forming another smaller plate. The borders of the plates then curve upward, forming the sides of the primordial cartilaginous skull, and, meeting above, close it in, leaving a vacuity in the middle line, or a fontanelle. In the cranial as in the spinal parts of the axis, cartilaginous rods appear in the inferior folds of the blastoderm or somatopleure, forming the visceral arches, the upper pieces of which become the ribs. Two of these appear beneath the posterior part of the skull, which become the *hyoid arch*, and the mandibular arch or lower jaw; a third (the palatopterygoid arch) appears as nearly horizontal, extending from the base of the second to near the end of the cartilaginous skull in front. When ossification sets in, the segmentation of the skull appears. This, however, takes place under two forms: the ossific deposit may be made in the cartilage or in the membrane investing that cartilage, forming the membrane bones of anatomists. It appears that the membrane bone represents a primary condition, and one that prevailed among the early Vertebrata, while the penetration of ossification to the cartilage was the mode of origin of the first cartilage bones. Hence, though corresponding ones of the cranial bones may have different origins to-day, their correspondence is not thereby destroyed. The base of the brain-case ossifies into three bones, the posterior the *basioccipital*, the next the *basisphenoid*, the anterior the *presphenoid*. The sides of the case ossify three plate-like bones, which correspond to and rest on these; namely, the *exoccipital*, the *alisphenoid*, and the *orbitosphenoid*. Closing the cranial cavity above are the three corresponding bones, the *supraoccipital*, *parietal*, and *frontal*. Thus three distinct cranial segments are presented, the occipital, the parietal, and the frontal. A section of the parietal arch is seen at Fig. 1 (*ns*, parietal; *np*, alisphenoid; *c*, basisphenoid). Of these elements the parietal and frontal bones are membrane bones, the remainder cartilage bones. An extended membrane

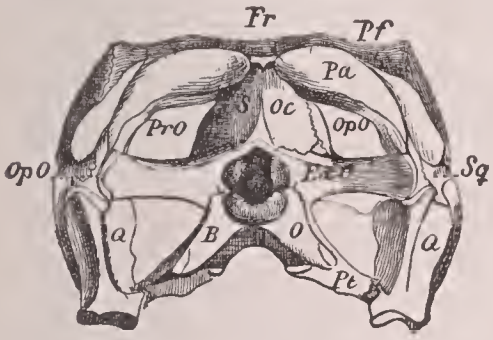

FIG. 6.—Cranium of *Iguana tuberculata*, from behind.

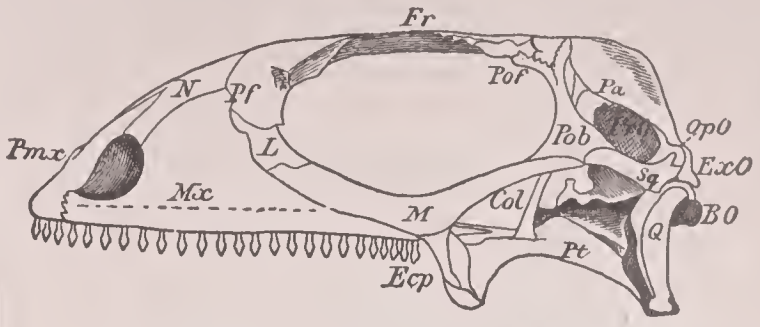

FIG. 7.—Cranium of *Iguana tuberculata*, profile.

bone, the *parasphenoid*, takes the place more or less completely of the cartilage bones, forming the axis or base of the brain-case in the fishes and batrachians. In front of it is another membrane bone, which is always present, the *vomer*, which forms the axis of that part of the skull which lies in front of the brain-case. This consists, first, of the ethmoid bone, which is a flattened cylinder formed by the union of the upturned borders of the primitive cartilaginous basal plate of that part of the skull. After uniting at the top, they turn downward in the middle line, forming a vertical septum. Laminæ project into the cavities so formed, from the outer wall, on which the branches of the olfactory nerve are spread; these are the *turbinal* bones. Above or on the ethmoid two membrane bones are developed, the *nasals*; at their sides behind and in front of the orbit, two other membrane bones may be present—viz., the *prefontal* (the upper) and the *lachrymal* (the lower). We have then a fourth or *ethmoid* segment. It remains to consider another series of bones situated between the parietal and occipital segments. These do not extend to the middle line of the superior or neural arch, but are developed in the cartilage in which the semicircular canals of the labyrinth of the auditory organs are imbedded. The upper lateral bone, which is usually only present in fishes, is the *pterotic*. Below this is the *petrous* bone, which is separated posteriorly from the exoccipital in some fishes by the *intercalary*. This bone is wanting in higher Vertebrata. In the Rhipidopterygian and Crossopterygian fishes, in Stegocephalous Batrachia, and in Cotylosaurian Reptilia the temporal fossa in which the temporal muscle is inclosed is covered by a roof which consists of some or all of the following bones: Immediately posterior to the orbit, above, the postfrontal; below, the postorbital. Posterior to these, above, the supramastoid; below, the supratemporal. Below these, in front, the jugal; behind, and joining the quadrate, the zygomatic. Between the supramastoid, supraoccipital, and exoccipital, the tabulars. In higher Vertebrata this roof is perforated by large foramina, so that bars or arches only remain. These may be either of three, or any two of them together. These are, according to their posterior attachments, the supramastoid, the supratemporal, or the zygomatic arches.

If we turn to the inferior or hæmal arches, we find three almost constantly and several others occasionally present. The former are, beginning at the front of the skull, the maxillary, the pterygopalatine, the mandibular, and the hyoid arches; the latter are the branchial arches, most of which are present only in fishes and some batrachians. The maxillary rods of opposite sides do not meet on the middle line, but the apex of the ethmoid arch is produced and its membrane ossifies on each side, forming the premaxillary bones, which in all vertebrates occupy the space between the maxillaries. The latter result from the ossification of the membrane covering the cartilage of the first visceral rods. Their inner margins sometimes grow together, forming the roof of the mouth and removing the posterior opening or the nostrils to the back part of it. The mandibular arch in its cartilaginous state is known as *Meckel's cartilage*. The part next the skull becomes separated from the rest, and is the support of the palatopterygoid cartilage. The remaining portion may be wanting, as in the lampreys (*Marsipobranchi*), or may remain as a movable articulated lower jaw. If these portions remain mostly cartilaginous, we have the permanent condition seen in the sharks and rays. In bony fishes three ossifications appear in it, namely (beginning next the skull), the *metapterygoid*, the *inferior quadrate*, and the *articular*. In the membrane

surrounding the cartilage the *angular* and *coronoid* bones appear in some; round the remainder of it the *dentary* is developed in all Vertebrata above Marsipobranchii. In reptiles and birds the metapterygoid and the inferior quadrate are represented by a single bone, the *quadrate*, which is the true support of the under jaw. In mammals the articular disappears, while the quadrate is drawn into the ear-chamber

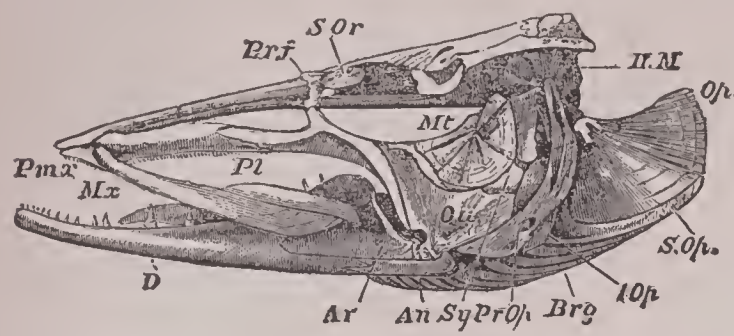

FIG. 8.—Skull of pike (*Esox*), from Huxley: *Pmx*, premaxillary; *Mx*, maxillary; *Pl*, palatine; *Prf*, prefrontal; *SOr*, supraorbital; *HM*, hyomandibular; *Mt*, metapterygoid; *Op*, operculum; *SOp*, suboperculum; *IOp*, interoperculum; *PrOp*, preoperculum; *Brg*, branchiostegal rays; *Sy*, symplectic; *Qu*, quadrate; *An*, angular; *Ar*, articular; *D*, dentary.

as the *malleus* or hammer, leaving the dentary to articulate directly with the skull. The hyoid arch also develops several osseous segments. In fishes these are called (beginning at the cranium) the *hyomandibular*, the *stylohyal*, *ceratohyal*, and as the middle piece below, the *basihyal*. The first named is a large bone, and supports in part the articulation of the lower jaw through the intervention of the inferior quadrate. The *stylohyal* segment is united by suture with the ceratohyal in fishes; in reptiles and mammals it is cartilaginous or ligamentous, and the portion next the skull in the latter when ossified is called the *styloid process*.

It remains to notice some membrane bones which protect the sides of the cranium, and the muscles attached to them. The maxillary carries on its posterior end a more or less flat rod, the *malar* bone, which protects the orbit below in mammals and many reptiles. On its posterior end it is joined to another piece, the *zygomatic*. In mammals this piece is fused to a plate on the side of the temple (the *squamosal*), and unites with the petrosal bone to form the *temporal*. In reptiles, where the quadrate carries the articulation of the lower jaw away from the skull, the zygomatic accompanies them and stands above the end of the quadrate, supported on the projecting rod formed of the paroccipital, exoccipital, etc., which is now known as the *suspensorium*. In *Batrachia salientia* the supratemporal lies over the length of the quadrate, and in fishes occupies a similar position on the outer face of the inferior quadrate and hyomandibular, and is known as the *preoperculum*. In fishes other membrane bones are added; namely, the operculum and suboperculum behind it, and the interoperculum below it. Another bone is formed in some reptiles which develops in the cartilage between the position of the interealary in fishes and the exoccipital, viz., the paroccipital. In tortoises and pythonomorphs it forms part of the suspensorium, and is very much elongated in serpents. In lizards it sends a process upward with the supramastoid, which forms, with a descending projection of the posterior angle of the parietal, the parieto-quadrate arch. The zygomatic arch is the only one found among the mammals. The ethmoid segment surrounds the olfactory lobes of the brain; the frontal is in front of the optic foramen; the parietal passes before the foramen of exit of the trigeminus (fifth) nerve. The otic bones extend posteriorly to the vagal (tenth) foramen, and the occipital to the foramen magnum.

In the fishes no bones are expressly related to the function of hearing. In the Batrachia and forms above them a portion of the otic capsule is separated as a lid, and is known as the *stapes*. In the tailless Batrachia (Salientia) a short bone originates at its anterior border (the interstapedial) and extends forward. To its distal end is appended a cartilaginous rod (the mesostapedial), and this is followed by a cartilaginous disk, the epistapedial, over which is stretched the integument forming the tympanum or ear-drum. In reptiles the interstapedial and mesostapedial are represented by a single bony rod, which is confluent with the stapes, the whole being termed the columella auris. In Mammalia the stapes is distinct, the interstapedial is represented by a small bone, the orbiculare, and the mesostapedial by the incus or anvil. The epistapedial has disappeared, and in its place the proximal end of the Meckel's cartilage is ossified as the malleus, which impinges on the tympanic membrane.

Special Osteology.—There are very numerous peculiarities characteristic of natural divisions of the Vertebrata to which only brief allusion can be made here. The vertebral bodies consist originally of three elements, two superior, each supporting a neurapophysis, and one below, or an intercentrum. All unite to form the body in fishes generally, but both form complete bodies in the tail of the Amia, etc. In Batrachia the body consists chiefly of intercentrum, while in the remaining Vertebrata the intercentrum is gradually extinguished, remaining principally in the caudal region as the basis of the chevron-bones. The centrum may be concave at both ends (*amphicœlous*), as in selachians, fishes, and Ichthyosauri, and many tailed batrachians; with ball-and-socket joint, the concavity being in the front of the body (*procœlous*), as in most tailless Batrachia and a majority of reptiles; with the cup behind (*opisthocœlous*), in the bony garfishes, some salamanders and frogs, a few Reptilia, and in the neck of many ungulate mammals. Finally, the centra are plane at both ends in Mammalia in general, and numerous reptiles, especially the extinct types Rhynchocephalia, Sauropterygia, Dinosauria, and some Crocodilia, where the ends are sometimes somewhat excavated. In Mammalia, and to a lesser degree in other Vertebrata, the vertebræ are distinguished into cervical, dorsal, lumbar, sacral, and caudal. The first are generally seven in number, and are readily distinguished by the perforation of their transverse processes (= diapophysis + parapophysis) for the conduct of the vertebral artery. The dorsals are distinguished as furnishing the points of attachment for the ribs. These vary in structure as follows: I. A single rib-basis; *a*, exclusively on the vertebral centrum: fishes, batrachians, and some reptiles, viz., tortoises, lizards, Pythonomorpha, and serpents; *aa*, partially standing on the neural arch: Sauropterygia. II. Two separate points of rib attachment; *a*, on the centrum only: Reptilia, Ichthyopterygia; *aa*, the lower (capitular) articulation on the centrum, the upper (tubercular) on the diapophysis, which springs from the neural arch: reptiles (Crocodilia, Dinosauria, most Theromora, Pterosauria), birds and mammals. The lumbar vertebræ succeed the dorsals, and are distinguished by the absence of rib articulations; but the ribs extend to the sacrum in some Crocodilia (Belodon), Dinosauria, Theromora, and birds. The sacral vertebræ are usually co-ossified into a single mass, the sacrum, with very massive diapophyses for sutural attachment to the iliac bones or pelvis. They are numerous in the birds, less so in the Dinosauria (Agathaumas has eight), four to six among mammals with well-developed hind limbs. There are three or two in reptiles with hind limbs, while in any of the orders where these members are small or rudimental a single vertebra serves the same purpose. The caudal vertebræ are distinguished among Vertebrata below the mammals by the presence of the chevron-bones (see Fig. 3, *pp*, *hp*) on the inferior surface. They are present in Cetacea (whales), Edentata, some Insectivora, etc., among Mammalia.

The ribs present a general similarity except in their proximal attachments, as already pointed out. They articulate in the thorax with the median bones of the breast or sternum in all above the fishes, and usually remain separate for the remainder of their length. An exception, however, occurs in the tortoises, where they are so widened as to unite by their borders into a more or less complete shield, which protects the entire visceral cavity, and into which, in many species, the head, tail, and limbs may be withdrawn. In birds and some crocodiles and Rhynchocephalia there are recurved processes on the ribs pointing backward, the "uncinate processes." The thoracic ribs are united by segments on the middle line below, which, taken together, constitute the sternum. The hæmal element of the ribs is wanting in fishes, serpents, Ichthyopterygia, Sauropterygia, and tortoises; the sternum is absent in the same groups, so far as known. The first appearance of the sternum is in the Batrachia, where a cartilaginous plate behind the shoulder-girdle represents it in the tailed and many of the tailless forms. In many of the latter it becomes an osseous segment, and in some extinct Stegocephali is a bony, shield-like body. In Lacertilia and Pterosauria it is a broad plate behind the coracoid bones. In Dinosauria it is small and often divided. In birds it is of similar form in the most reptile-like forms, as the apteryx, ostriches, etc., but is peculiar in the possession of a produced process on each side in front (costal process). This is frequently ossified from a separate cen-

ter (protosteon), while the main shield originates from a center on each side, the pleurosteon, and sometimes from two others behind these, the metostea. In most existing birds besides the ostriches there is a middle center of ossification, the lophosteon, which when ossified is a prominent keel extending along the length of the sternum. The metostea are frequently produced as separate lateral rods, and in nearly all birds the hinder margin of the sternum is variously incised. In Crocodilia the sternum exists as a small shield in front, and a prolongation from it backward on the median line. This brings us to the form seen in the Mammalia, where it defends the middle line of the thorax as a series of segments which may number from two (Echidna) to thirteen (two-toed sloth). In the whales it is represented by an oval or cruciform bone, and its posterior segment in other mammals is a spatulate cartilage or bone known as the xiphisternum.

There are various *dermal* ossifications found posterior to the sternum and hæmapophyses in different Vertebrata. These consist, in many Stegocephali, of osseous rods arranged *en chevron*, with the angle anteriorly directed. Similar pieces, with the addition of lateral ones, exist in ichthyopterygian, sauropterygian, crocodilian, and rhynchocephalian reptiles. In tortoises these extend below the shoulder-girdle in front and the pelvic arch behind, and unite together into the solid inferior plate or plastron. This is connected with the ribs by a series of membrane bones, the marginals, which also extend all round the free margin of the upper shell or carapace. The dermal pieces of the plastron are the two clavicles, the interclavicle between them, the two hyosternals, the two hyposternals, and the two postabdominals.

The scapular arch in vertebrates is composed of both cartilage and membrane bones. Like the pelvic arch, it appears as a cartilaginous rod in the somatopleure of the fœtus, often extending in its fold to near the point of contact above the vertebræ on the median line. If development proceeds, the upper part of this cartilage becomes segmented off, forming the scapula, while the lower portion becomes bifurcated into the coracoid and epicoracoid bones. In mammals, fishes, and some others, a membrane bone is developed in front of the epicoracoid, the clavicle. From the junction of the three, the cartilaginous basis of the fore limb appears. Above the scapula another segment is usually present, the suprascapula.

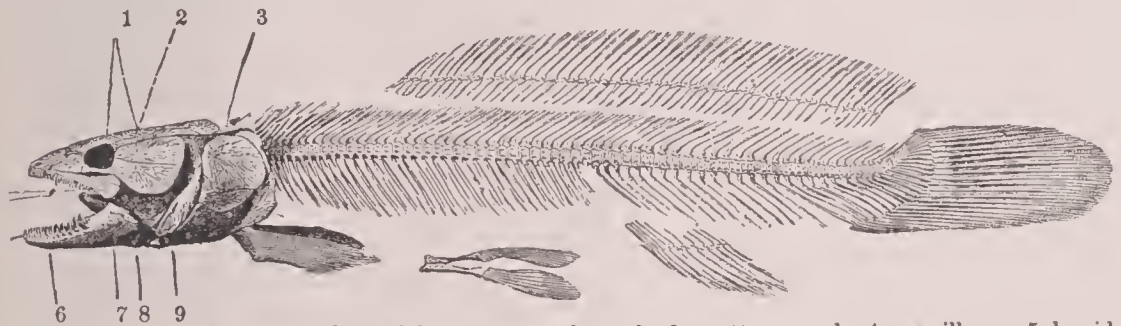

FIG. 9.—*Amia calva*, L.: 1, frontal bone; 2, postfrontal; 3, posttemporal; 4, maxillary; 5, hyoid; 6, dentary: 7, angular; 8, interoperculum; 9, branchiostegal rays.

The fishes differ from other vertebrates in having another membrane bone, the posttemporal, connecting the epiclavicle with the cranium at the tabular bone. This is wanting in sharks, where the arch is cartilaginous and without laminiform membrane bones. In many fishes there are membrane bones which extend in a bar backward and downward from the clavicle; namely, the first, second, and third postclavicles. There may also be a cartilage bone behind the coracoid, the postcoracoid. The following scheme will express the leading characters of the classes and orders in the structure of the scapular arch:

A. Arch suspended to cranium by posttemporal.

1. Scapula, coracoid; epiclavicle and clavicle, and sometimes interclavicle, present: *Pisces.*

AA. Arch not suspended to the cranium; no laminiform dermal bones.

1. Arch cartilaginous: *Selachii.*

2. Coracoid and scapula osseous; suprascapula and epicoracoid cartilaginous: *Batrachia urodela.*

3. Coracoid and scapula, suprascapula and clavicle osseous; epicoracoid cartilaginous: *Batrachia anura.*

AAA. Arch not suspended; laminiform dermal bones present (except Chamæleo).

1. Scapula and coracoid only ossified; no clavicle or interclavicle: *Lacertilia rhiptoglossa.*

2. Interclavicle only ossified membrane bone: *Crocodilia.*

3. Clavicle and single interclavicle of membrane, and scapula, procoracoid and coracoid of cartilage, all osseous.

a. Clavicle and interclavicle united with plastron: *Testudinata.*

aa. Clavicle and interclavicle free; epicoracoid cartilaginous: *Ichthyopterygia, Lacertilia.*

aaa. Clavicle and interclavicle united with a short procoracoid, forming furcula; epicoracoid not osseous; suprascapula co-ossified with scapula: *Aves.*

aaaa. Clavicle and interclavicle distinct; epicoracoid large, osseous; procoracoid wanting: *Mammalia prototheria.*

AAAA. Arch not suspended; both membrane and cartilage bones; coracoid rudimental or wanting.

a. Clavicle united with mesoscapula and procoracoid into one bar; epicoracoid and suprascapula rudimental or wanting: *Mammalia eutheria.*

The Limbs.—The cartilage forming the limb-bones appears early in a fold of the outer skin, and in the Vertebrata above the fishes is soon divided by transverse interruptions into three segments. In the Lepidosirenidæ this cartilage may be broken up into many successive joints. In Ceratodus a branch segment is given off at the end of each of these primary joints, but in sharks and fishes most of the segments diverge from one side only. The basal and the first and second of the one side are especially enlarged in the sharks, forming the *metapterygium*, *mesopterygium*, and *propterygium*, from which numerous cartilaginous radii arise, forming a triangular fin. The extremital parts of the fins are dermal, and embrace the ends of the cartilaginous rods. In true fishes the propterygium and mesopterygium are wanting, and the radii of the first cross-row, either cartilaginous or osseous, reach the scapular arch. The upper radial unites with the metapterygium to form the first ray of the fin, often a strong spine; the remainder usually number four, but may be more numerous in the lower groups. They are subquadrate in the higher fishes, but much elongate in the Pediculati, where the number is reduced to three and two.

In Vertebrata, from the Batrachia up, the limbs, both fore and hind, are early divided into three principal segments. In the anterior, the first presents a single bone, the humerus; the second, two parallel bones, the ulna and radius; and third the foot. This consists of two transverse rows of small bones, the carpals, and from three to five rows of longer bones, the phalanges, arranged in typically five ray-like lines or digits, the basal segments of which are called the metacarpals. Typically, there are three bones in the first transverse row of carpals and five in the second, with a median bone inclosed between the rows, a condition seen in various batrachians and reptiles. In higher classes these bones are variously combined or omitted. The bone next the radius is the scaphoid, the next the lunar, the next the cuneiform; in the second row the first is the trapezium, the second trapezoides, third magnum, while in many forms the fourth and fifth are combined and called the unciform, and the centrale is united with the scaphoid. In Ichthyopterygia the bones of the fore and hind limb beyond the humerus and femur are of similar shape, but, though undistinguishable as to form, are proximally of the usual position and number. In birds there are never more than three digits of the fore foot, in the Apteryx and Casuarius only one. These answer to the second, third, and fourth of the ordinary foot. The metacarpals are co-ossified in all birds excepting the extinct Archæopteryx. In Mammalia of the order *Cetacea* the ulna and radius are immovably fixed in a single plane with the carpus and manus, and not flexibly articulated with the humerus, thus resembling the aquatic reptiles (Sauropterygia). In higher orders the radius possesses greater or less power of rotation on the ulna, which is especially developed in apes and man. In proboscidians the proximal end of the radius is moved outward above the ulna, so as to cross it obliquely. In Perissodactyla (odd-toed) and Artiodactyla the ulnar attachment to the carpus is more and more reduced, until the radius, appropriating the larger part, extends almost entirely in front of the ulna. The latter becomes in the horse and

ruminants very slender and co-ossified with the radius. In the carpus a bone develops below the tendon of one of the flexors of the foot, which articulates with the cuneiform, called the *pisiform*. In five-toed orders the carpals are usually distinct, excepting in the Carnivora, where the scaphoid and lunar are generally co-ossified. In the Artiodactyla the number of toes is regularly reduced from four to

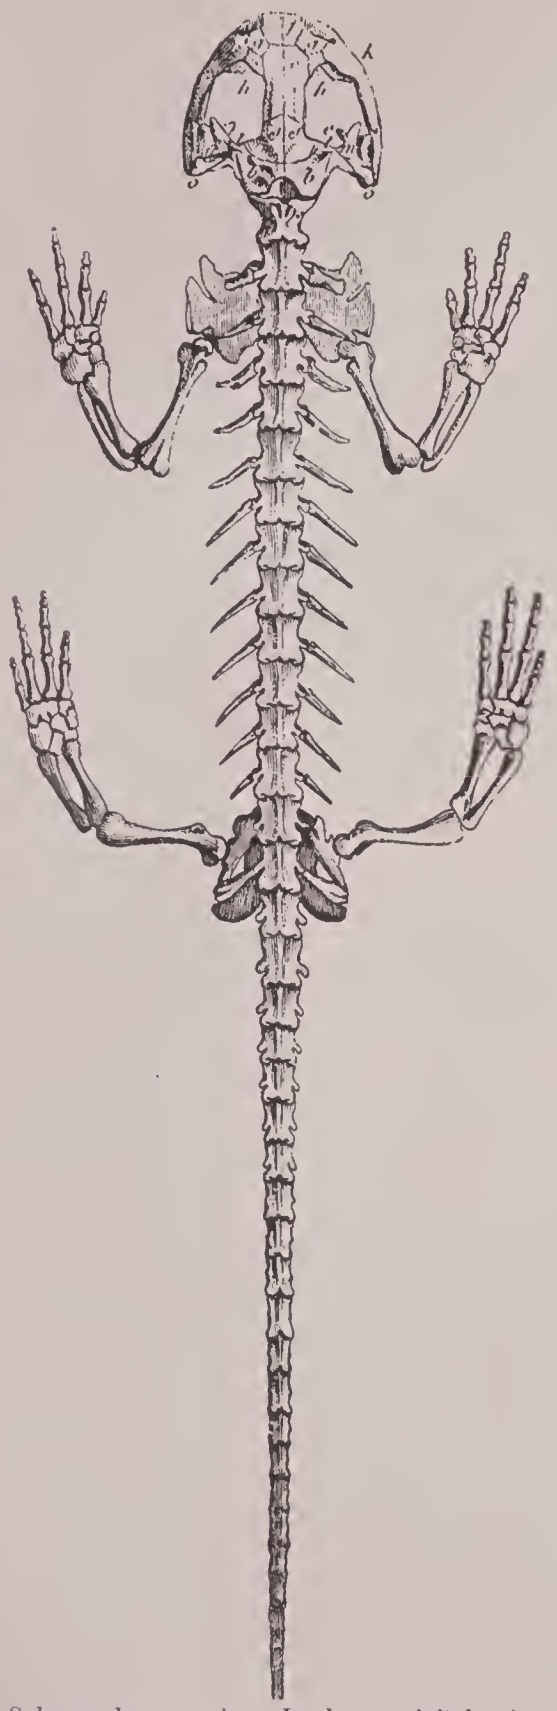

FIG. 10.—*Salamandra maculosa*, L.: *b*, exoccipital; *c'*, parietal; *c*, frontal; *e*, pterygoid; *f*, premaxillary; *g*, nasal; *h*, prefrontal; *k*, maxillary; *l*, proötic; *m*, squamosal; *o*, quadrate.

two, and the number of carpals is reduced correspondingly in the second row, those of the first being narrowed. In the most specialized Ruminantia the trapezium is wanting, and the trapezoides and magnum are confluent. The outer digits become smaller and disappear, while the two middle metacarpals, representing the third and fourth, co-ossify into the single "cannon-bone." In the living types the third metacarpal supports the whole width of the trapezoides and magnum, while in the extinct family of the *Anoplotheriidæ* it articulated with the magnum only. The last phalange in Carnivora, Insectivora, bats, rodents, etc., is compressed, and with its complete horny sheath forms a claw; in ungulates it is broad, the posterior faces becoming inferior when in use; the horny covering partly incloses it behind, and forms a hoof. In apes and men the last phalange is flat, and supports a flat horny nail.

The *pelvic* arch is composed of the single superior element, the *ilium*, and the two inferior ones arranged as limbs of a fork, the anterior, the *pubis*, the posterior, the *ischium*. The ilium corresponds with the scapula, the pubis with the epicoracoid, and the ischium with the coracoid. The ilium generally presents a crest forward, from which a strong ligament descends to the end of the pubis, which represents the clavicle. It is the Poupart's ligament of human anatomy. Fishes, however, do not possess a pelvis, with two exceptions, those of the Lepidosirenidæ and of the Holocephali. In the

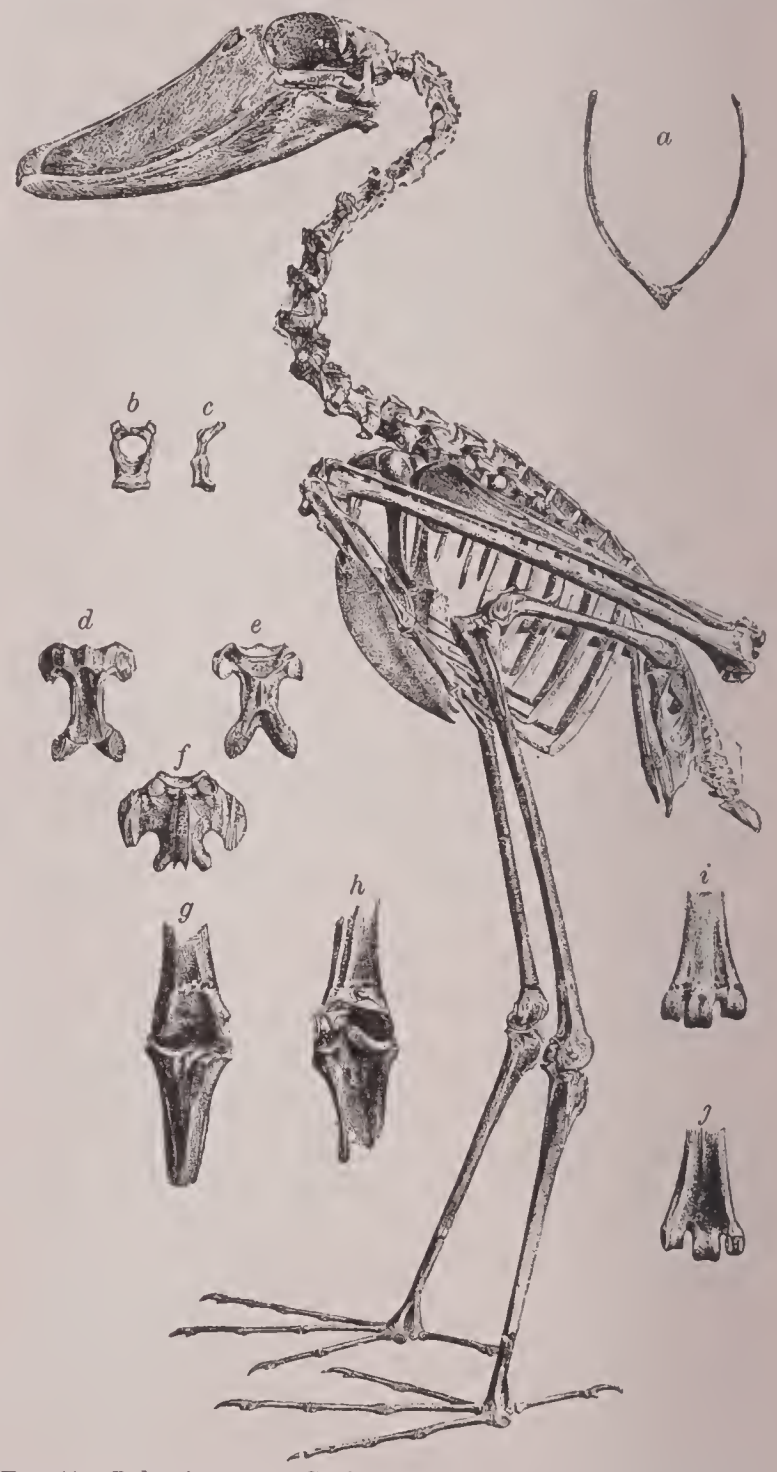

FIG. 11.—*Balæniceps rex*, Gould: *a*, hyoid arch; *b*, atlas from behind; *c*, atlas, profile; *d*, ninth cervical vertebra from below; *e*, same from above; *f*, middle dorsal vertebra from above; *g*, posterior view of tibio-tarsal joint; *h*, anterior view of the same; *i*, distal end of tarso-metatarsus, front view; *j*, same from behind.

former there is a single median diamond-shaped cartilage, to which the limbs are attached, whose homology is unknown. In the latter there is a flat curved cartilage extending forward from the basis of each fin on each side, which occupies the position of the pubis. Another and serrate cartilage is attached to its anterior margin in the male, which projects into an open pouch, from which it can be protruded. A cartilaginous rod succeeds the pubic bone as the basal element of the posterior limb. In the Dipnoi this is followed by others, forming the segmented ray representing the ventral fin. In Ceratodus each segment is furnished with a short divergent sub-segment on each side; but in the sharks and rays the sub-segments or radii are all on one side. In

these animals the axis is much shortened, so that the radii are packed closely together on the basal piece or metapterygium; the first radius also is enlarged, forming an opposite border of the fin. In the rays the latter is much enlarged, and supports radii indistinguishable from the others. In Polypterus the basal element is deprived of rays, except at its extremity, and they, as in the sharks, support the dermal fin-rays proper. In sturgeons the radial bones are present in the ventral fins only, but in Lepidosteus and Amia one or two very small rudiments remain, and the dermal fin-rays are attached immediately to the femur, as is the case with all the true fishes. In sharks the axis is developed into some peculiar and complex organs, the elaspers, which function as intromittent reproductive organs.

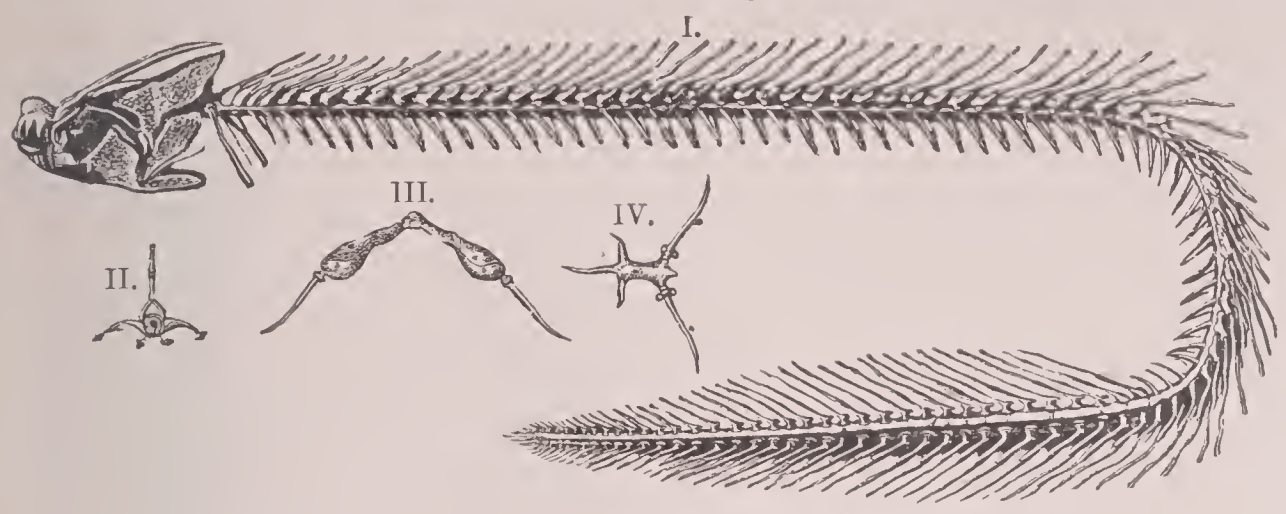

FIG. 12.—*Lepidosiren paradoxa* (I.); II., a vertebra: III., pelvis; IV., pectoral arch.

The three pelvic elements are remarkably constant in all the land vertebrates, the most marked variations being seen in the *Batrachia anura* and the Dinosauria and Aves. In the former the ilia are much elongate and extended backward to the acetabula, round which the ischia and pubes are compacted in a solid mass. In Dinosauria Goniopoda the ischia are slender and unite into a dense osseous rod, which served as a support when in a sitting position (e. g. Megadactylus). In the Dinosauria Orthopoda the pubes are turned backward beneath the ischia, are slender, and not united distally. They are similar in position in the birds, but are united distally in the ostriches. The ischia in birds are slender and not distally united, but often co-ossified with the ilia. The ilium is directed backward and upward in reptiles, both backward and forward in birds and Dinosauria, and forward in Mammalia. In the earliest Batrachia and Reptilia (of the Palæozoic realm) it is directed upward. The acetabulum is perforated and not completed at the fundus in Dinosauria and the birds. In Crocodilia the pubes are not united on the middle line below, but are directed forward. In the marsupial mammals the pubes support a pair of bones directed outward and forward, the marsupial bones, which are ossifications of the produced symphysial cartilage. In Mammalia the pubes and ischia are in contact on the middle line below, and are sometimes extended posteriorly, joining the peduncles of the ilia (American Edentata, Notoryctes).

FIG. 13. — Posterior foot of *Rhinoceros*: *a*, calcaneum; *b*, astragalus; *c*, cuboid; *d*, navicular; *e*, mesocuneiform; *f*, ectocuneiform; *g*, fourth; *h*, third; *i*, second toe.

The *hinder limbs* are wanting in Leptocardii, Dermopteri, and several orders of true osseous fishes collectively called Apodes or eels. In most other fishes they occupy the usual position on the abdomen, but in the Physoclysti they are placed beneath the pectoral limbs, or nearly so, the pubic bones being more or less united and suspended from the symphysis of the coracoids. In Plectognathi they form a simple rod, which is generally deprived of fins. In Batrachia the hind limbs are constituted like the fore limbs, and therefore embrace one bone in the first segment, *femur*; two in the second, *tibia* and *fibula*; three in the third, *tibiale*, *mediale*, and *fibulare*; five in the fourth, from which are continued the five metatarsals and series of phalanges. These correspond with the elements of the fore leg as follows: femur to humerus; tibia to radius in front, and fibula to ulna behind. These relations are maintained so long as the limbs extend horizontally without twist, either in paddles, as in Ichthyopterygia, or terrestrial animals, as salamanders. In most vertebrates the first bones are twisted in opposite directions, that is, toward each other, the knee pointing forward, the elbow backward, which causes an apparent reversal of the homologies of the two bones of the second segment. In the hind foot of the higher Vertebrata, especially the mammals, the tibiale and intermedium form the single astragalus, while the fibulare is produced backward, forming the heel-bone or calcaneum. The centrale becomes the navicular, while the fourth and fifth of the second row unite to form the cuboid. In the reptiles these bones are less distinctly constituted, and various modes of combination present themselves. In the Dinosauria the astragalus and calcaneum are often co-ossified, and may be united, by suture or co-ossification, with the tibia. In the birds the latter case always prevails, and the fibula, being much reduced, does not generally extend to the articulation. In reptiles and birds, then, the ankle-joint is between the two rows of tarsals, while in Mammalia it is between the tibia and astragalus. The number of toes is usually four and five in the Batrachia and reptiles; among birds it is usually four, the inner being turned backward and reduced in size, and sometimes wanting. The metatarsals of the three remaining toes are co-ossified with each other and with the second row of tarsal bones. In Mammalia the normal number of digits is five, but is often reduced to four. Among ungulates the hippopotamus displays four; the lateral ones are reduced in the hog and the *Tragulus*, till in the *Poëbrotherium* they are reduced to rudiments, two only remaining. These are united into a solid "cannon-bone" in the *Boöidea*, which supports two distinct toes. In the rhinoceros there are but three toes, of which the central is the largest; the laterals are successively reduced in the horse series, composed of such genera as *Anchitherium* and *Prothippus*. In ruminants the navicular and cuboid bones are united, and often the second and third of the second row or cuneiforms with each other and the naviculo-cuboid.

FIG. 14.—*Diplopus*, hind foot (from Kowalevsky): *Cal*, calcaneum; *As*, astragalus; *nav C*, navicular; *Cb*, cuboid; C^3, ectocuneiform.

It remains to notice the peripheral ossifications of fishes and a few appendages of other Vertebrata. In the archetypal fin each neural spine and each hæmal behind the abdominal cavity supports an additional bone called an interneural, and the latter another bone, the basilar. This is the case in a large portion of the unpaired fins of the sharks and the Dipnoi. These basilar bones support the fin-rays, which are developed in the dermal fold that represents the fins in the early stages. The vertebræ in the Dipnoi and a number of other fishes gradually diminish in size to the end of the tail, forming a type called the protocereal. In other fishes the hæmal spines of the last vertebræ are largely developed, forming the principal part of the basis of the caudal fin. In these the vertebral axis turns upward to the end, forming the type called heterocercal, which is seen in sharks, sturgeons, and some bony fishes. In the majority of osseous fishes the terminal vertebræ are wanting, and the greatly expanded hæmal spines extend round its end, forming a fan. This is the homo-

cercal tail. In the dorsal and anal fins of the Teleostomi the basilar bones are usually wanting, but in some cases rudimentary; they are long in the anal fin of Amia. In Polypterus certain median fin rays are very elongate, and each supports a number of cartilaginous rays, the posterior from the end, but the more anterior from the posterior side, forming the horizontal dorsal pinnules of that genus. In higher fishes the interneurals, which support the dorsal, and the interhæmals, that support the anal fin, are more numerous than the vertebræ they are opposite to. In many fishes there are interneurals between the cranium and dorsal fin which support no fin.

Horn cores are developed on the crania of various species of Mammalia, especially the *Eobasiliidæ* among Amblypoda, *Menodus* among Perissodactyla, and the *Boöidea* among Artiodactyla. They are permanent except in the *Cervidæ* among ruminants, where they grow and are shed annually, leaving a basal portion, the burr, attached to the frontal bones. They are often of large size, and grow with incredible rapidity.

Osteopathy [from ὀστέον, bone, and πάθος, suffering]: a method of treating diseases of the human body without the use of drugs, by means of manipulations applied to various nerve centers, chiefly those along the spine, with a view to inducing free circulation of the blood and lymph, and an equal distribution of the nerve forces. Special attention is given to the readjustment of any bones, muscles, or ligaments not in the normal position.

The system was formulated in 1874 by Dr. A. T. Still, a physician of Baldwin, Kan., who, having become dissatisfied with the results attained through the practice of medicine, determined, if possible, to discover a more natural and efficacious method of healing. He reasoned that a body so perfectly constructed mechanically should be able to protect itself against the inroads of disease without the artificial aid of external substances, except those employed as food. His next conclusion was that "a natural flow of blood is health, and disease is the effect of local or general disturbance of blood." With this as a working hypothesis, he made a series of experiments, the results of which convinced him that the various organs of the body were controlled by nerve centers located chiefly along the spine, and that these could be operated upon and controlled by pressure or stimulation of the fingers. He holds also that if the bones, muscles, arteries, veins, lymphatics, glands, organs, and tissues of the body are in their correct anatomical positions, disease can not exist. Displacement may arise from a variety of causes, such as a fall, a blow, a strain, or atmospheric changes. Pressure upon the blood vessels or nerves in the immediate vicinity of the part so affected will follow, and a consequent shutting off of the nerve or blood supply to some organ, which will then become diseased. With a readjustment of the displaced part will come "perfect freedom of motion of all the fluids, forces, and substances pertaining to life, thus re-establishing a condition known as health."

Osteopathy does not confine itself to a treatment of maladies of the bones, nor does it find in diseased bones the origin of all pathological conditions. The name was considered by Dr. Still as applicable to his system because of the relative importance which his theory gives to anatomy, and because of his belief that "the bones could be used as levers to relieve pressure on nerves, arteries, and veins." Treatments, which do not as a rule occupy more than twenty minutes, are given through thin garments, and not, as in massage, upon the bare flesh. No machines or appliances are used. Among the complaints said to have been treated successfully are heart and lung diseases, nervous prostration, sciatica, lumbago, all forms of neuralgia and paralysis, asthma, catarrh, incipient consumption, spinal curvature, eye and ear affections, and all dislocations, liver, kidney, stomach, and intestinal affections.

The first institution for the training of practitioners in osteopathy was opened about 1894 in Kirksville, Mo., under the name of the American School of Osteopathy. Since then others have been established in different parts of the U. S.

Osthoff, Hermann: comparative philologist; b. at Billmerich, Westphalia, Apr. 18, 1847; educated at the gymnasium in Unna and at the Universities of Bonn, Tübingen, and Berlin; teacher at the gymnasium in Cassel 1871–74, privat docent in Leipzig 1875–77; Professor of Comparative Philology in the University of Heidelberg since 1877. His chief works are *Forschungen im Gebiete der indogerm. nominalen Stammbildung* (2 vols., 1875–76); *Das Verbum in der Nominalcomposition* (1878); *Morphotogische Untersuchungen* (in collaboration with Karl Brugmann, 5 vols., 1878–90); *Zur Geschichte des Perfects im Indogermanischen* (1884); also many important articles in various scientific journals.

Benj. Ide Wheeler.

Os'tia: an old Roman town; on the left side of the mouth of the Tiber; about 14 miles S. W. of Rome. Ancient writers agree in stating that it was founded by Ancus Martius as a maritime station for his capital, but it was not until the wars with Carthage that it became important as a port for the introduction of foreign grain. From that time it grew rapidly, and was soon the principal commercial and naval station of the Romans. The harbor, however, was never a really good one, and in the reign of Claudius it was already so shoaled up by deposits from the Tiber as to necessitate the construction of an artificial basin about 2 miles to the N. This was called *Portus Augusti*, afterward *Portus Trajani*; but the new town which grew up around it (*Portus* or *Portus Urbis*) never equaled the old one in size and opulence. Ostia began to decline with the declining empire, and early in the ninth century was a heap of ruins. Gregory IV. then tried to rebuild it, but without success; and later popes have made similar fruitless attempts. Fine statues and other works of art are often disinterred here, and excavations, which have been systematically carried on since 1855, have disclosed extensive warehouses and other commercial and public structures, whose foundations and lower stories remain to witness to the former greatness of this ancient city. Ostia was an episcopal see at the beginning of the fifth century, and the title bishop of Ostia and Velletri is now given only to the dean of the Sacred College, resident in Rome.

Os'tracism [from Gr. ὀστρακισμός, ostracism, deriv. of ὀστρακίζειν, banish by vote, ostracize, deriv. of ὄστρακον, shell, tile (used in voting)]: a form of temporary banishment that prevailed in ancient Athens and some other Greek cities (Argos, Megara, Miletus). The Athenian senate and ecclesia having decided that ostracism was necessary in the case of any citizen, the ten tribes voted upon the question in the agora. Each voter in favor of the ostracism presented a tablet or shard of burnt clay, on which was written the name of the person to be banished. If there were 6,000 votes for it, the person ostracized was obliged to leave the state within ten days and not return for ten years unless recalled. Ostracism was not a penalty for crime, but was employed against persons supposed to possess dangerous power. The exile retained his property and social position. In Syracuse the olive-leaf was used instead of the clay tablet, and the act of exile was called *petalism*.

Ostrac'oda [from Gr. ὄστρακον, shell + εἶδος, form]: an order of Crustacea, sub-class Entomostraca (*q. v.*), embracing a few small aquatic forms, some living in the sea, others in fresh water. The most striking features in their structure are the presence of seven pairs of appendages, a short unjointed abdomen, the whole inclosed in a horny or even calcareous bivalve shell. These forms feed upon decaying animal matter and are abundant in stagnant water. Fossil forms occur in all formations since the Palæozoic. For an illustration, see article Cypris. The two principal genera are *Cypris* and *Cypridina*, the former of which has the power of reproducing parthenogenetically. See Brady, *Transactions of Linnean Society* of London (xxvi.), and papers by Claus and Sars. J. S. Kingsley.

Ostre'idæ [Mod. Lat. from *Ostre'a*, the typical genus, from Lat. *os'trea*, from Gr. ὄστρεον, oyster]: the family of Lamellibranch molluscs which includes the Oysters (*q. v.*). Among the characters separating it from the Lamellibranchiata (*q. v.*) are the following: The mantle lobes are not united to each other, no siphon is formed, there is but a single adductor muscle for closing the shell, while the foot has disappeared. The shell is irregular, the two valves being more or less unequal, and the hinge is without projections or teeth. Only one living genus, *Ostrea*, is recog-

nized, while this and two others (*Gryphæa* and *Exogyra*) exist as fossils. The pearl oysters belong to a different family.

J. S. Kingsley.

Ostrich [from O. Fr. *ostruche* > Fr. *autruche*: Span. *avestruz*: < Lat. *a'vis stru'thio*; *a'vis*, bird + *stru'thio* = Gr. στρουθίων, ostrich, deriv. of στρουθός, sparrow, bird]: the largest of living birds, belonging to the family *Struthionidæ* and order *Struthiones*, distinguished by its great size and by having only two toes on each foot. Its scientific name is *Struthio camelus*. The adult male ostrich stands nearly 8 feet high and weighs upward of 200 lb. The head is flattened, eyes large, neck and thighs praetically bare, the wings small and useless. The plumage, including the wing and tail feathers, which furnish the large plumes of commerce, is loose and wavy. The males are glossy black with white wings and tail, the females and young are dirty gray; the chicks are striped. The ostrich inhabits the sandy plains of Africa from the Barbary States to Cape Colony, but in many places has been exterminated, or nearly so, for its feathers. In former days it was found over a considerable portion of Southwestern Asia, but is now practically restricted to Central Arabia. The ostrich is sometimes found in small troops, but more often, especially during the breeding season, a male and from three to five females will be found together. The females lay their eggs to the number of about thirty in one nest, a shallow pit scooped in the sand, and during the day they are mostly left to the heat of the sun. At night the male sits on the eggs and they are rarely left unguarded in the daytime. A number of loose eggs are always found in the vicinity of the nest, it is said for the nourishment of the newly hatched young. The food of the ostrich consists of grass, roots, and seeds, but lizards, insects, and other animal food are also eaten. The ostrich trusts to flight for protection, but can inflict a dangerous blow with its foot. Two or three species of ostriches have been described, but it is not yet clear whether these are good species or only geographical races. The egg of the northern bird is rough; that of the southern smooth.

Ostrich-farming is extensively carried on in South Africa, and to a far less extent in Northern Africa, South America, and Southern California. London is the chief market for ostrich feathers, and the annual sales amount to from 120,000 to 175,000 lb. The prices vary greatly; from $200 per lb. for the best white plumes to $7 for the young feathers. The name ostrich is frequently applied to the South American rhea. See Rheidæ. F. A. Lucas.

Ostrog': town; in the government of Volhynia, European Russia; 176 miles W. of Kieff (see map of Russia, ref. 8–C). Here the first Slavonic Bible was printed. Ostrog has a military school, a school for teachers, five churches, and a trade in wool, wood, leather, wheat, and flour. Pop. about 16,900, mostly Jews.

Ostrogoths: See Goths.

Ostrolen'ka (in Polish, *Ostroleka*): town; in the government of Lomza, Russian Poland; on the Narew. An encounter took place here Feb. 16, 1807, between the French under Savary and the Russians under Essen, in which the former were victorious. The place became still more famous by the battle which was fought here May 26, 1831, between the Poles under Skrzynecki and the Russians under Diebitsch. After a long and bloody contest the Poles were forced to retreat, but the Russians were unable to follow them on account of their own losses. Pop. 5,120.

Ostrov'skiĭ. Aleksandr Nikolaevich: dramatist; b. in Moscow, Russia, Mar. 30, 1824; d. June 2, 1886. Having begun to write while still a schoolboy, he first became known to the public by a couple of scenes which appeared in Moscow newspapers in 1847. Two years later he established his reputation with *Svoĭ Liudi sochtemsia* (We Get on with Our Own Kind), one of his best comedies. His pieces followed each other in rapid succession. After 1862, while still continuing with his comedies, he also composed dramatic chronicles in verse, which, however, do not rise to the height of real historical tragedy, and achieved only moderate success. Perhaps the best known of them are *Dmitriĭ Samozvanets i Vasiliĭ Shuiskiĭ* (1867) and *Vasilisa Melentĭevna* (1868). Ostrovskiĭ is very popular in Russia. He chose as the field of his descriptions the life and ways of the middle classes in Moscow, a part of society hardly above the peasants in intelligence, with customs and ideas still those of the Middle Ages, almost unaffected by Western European thought and culture. Among the best of his plays are *Bednaĭa Nevesta* (The Poor Bride, 1852); *Bednost ne Porok* (Poverty is not a Fault, 1853); *Dokhodnoe Mesto* (A Profitable Place, 1857); *Groza* (The Storm, 1859); and *Goriachee Serdtso* (A Warm Heart, 1869). He also was the author of many excellent single scenes and of several translations, especially a remarkable one of *The Taming of the Shrew*. His complete works were published at St. Petersburg (1887, 10 vols.). Three of his plays have been translated into French by Durand Greville. A. C. Coolidge.

Ostrow'ski: the name of a celebrated family of Polish nobility, originally descending from the palatinate of Lublin. Among its most remarkable members was Tomasz Adam Rawicz, Count Ostrowski, b. at Ostrow, Dec. 21, 1739. He took a very active part in the establishment of the constitution of May 3, 1791, and was appointed Minister of Finance, but resigned when the king shortly after joined the confederacy of Targowicza, and lived after the third division of Poland (1795) in retirement on his estates in the Ukraine. On the establishment of the duchy of Warsaw he was made grand marshal of the diet in 1809, and president of the senate Dec. 6, 1811. The Emperor Alexander I. also showed great confidence in him, and the Poles received their new constitution of 1815 from his hands. D. Feb. 5, 1817.—His son, Antoni Joannes, Count Ostrowski, b. at Warsaw, May 27, 1782, studied at the University of Leipzig; entered in 1806 the French body-guard; was made a member of the provisional government of the duchy of Warsaw; followed Napoleon to Dresden in 1813, and fought in the battle of Leipzig; entered the Polish senate after the death of his father, and opposed the arbitrary measures of the Grand Duke Constantine; was one of the leaders in the Polish revolution of 1830, fighting at last in the ranks on the walls of Warsaw, and wrote the manifesto which the last remnant of the Polish army issued (Oct. 4, 1831) to the kings and nations of Europe after crossing the Prussian frontier and laying down their arms. He afterward lived in France, and published *Le Panslavisme moscovite* (1842). D. in Paris in 1847.

Osu'na: an old, substantially but irregularly built town, in the province of Seville, Spain; 48 miles E. S. E. of the city of Seville; on a hill in a very fertile plain rich in wine, almonds, figs, and olives (see map of Spain, ref. 19–D). The castle of the Duke of Osuna is a large and magnificent building. There are manufactures of silk, linen, and leather. Pop. (1887) 19,376.

Osuna, Pedro Tellez Giron, Duke of: statesman; b. at Valladolid, Spain, in 1579; spent his childhood at Naples, where his grandfather was viceroy; was educated at Salamanca, and assumed the title of Duke of Osuna on his marriage with a daughter of the Duke of Alcala. He was at first unpopular at the courts both of Philip II. and Philip III., and was twice exiled, but having gained military distinction in Flanders, where the twelve years' truce of 1609 was advised by him, he was restored to favor at the Spanish court. He became Viceroy of Sicily 1611, but was transferred to Naples 1616. In the latter office he won great popularity by his defense of the people against the oppressions of the nobility and clergy. He was subsequently suspected of conspiring with foreign princes to make himself independent in Southern Italy; was recalled 1620, and subjected to a long and secret trial for high treason. Though not convicted, he was retained a prisoner in the Castle of Almeidas, where he died in 1624, either by suicide or poisoned by his wife.

Oswald, Saint: King of Northumbria; b. about 604; son of Ethelfrid, who was killed in 617 by Redwald, King of East Anglia; resided some years thereafter an exile in Scotland (or Ireland), where he was converted to Christianity; came to the throne 634; made war upon Cadwalla, King of Wales, whom he killed in battle; introduced Christianity into Wales; married Cyneburg, daughter of the West Saxon king Cynegil, on condition of her embraeing Christianity, and was killed at Maserfield Aug. 5, 642, by the heathen king Penda of Mercia. The events of his life as given by Bede and Alcuin are overgrown with miraculous legends, which were long popular, especially in Germany. He was canonized by the Roman Church.

Oswego: city; capital of Labette co., Kan. (for location, see map of Kansas, ref. 8–J); on the Neosho river, and the Mo., Kan. and Tex. and the St. L. and S. Fé railways; 13 miles S. by E. of Parsons. It derives good power from the river for manufacturing, and has several mills, a national bank with capital of

$50,000, a private bank, and three weekly newspapers. Pop. (1880) 2,351; (1890) 2,574; (1900) 2,208.

Oswego: city; capital of Oswego co., N. Y.: on Lake Ontario, at the mouth of the Oswego river; at the northern terminus of the Oswego Canal; on the Del., Lack. and West., the N. Y., Ont. and West., and the Rome, Watertown and Ogdensburg railways; 35 miles N. N. W. of Syracuse, and 328 miles N. W. of New York city (for location, see map of New York, ref. 3–G). It is beautifully laid out on three large, low hills, thus, having unsurpassed natural drainage, and is a noted summer resort. The streets have a uniform width of 100 feet and cross at right angles; the building blocks are 400 feet long by 200 feet wide; the paving is asphalt and brick. The city has five large public parks, delightfully shaded, with an average area of 5 acres. It has fine national, State, municipal, and other buildings, including the U. S. custom-house, which contains the post-office and the U. S. court-room, a spacious city hall, State armory, handsome new county jail, new county clerk's office, one of the most commodious court-houses in the State, and a U. S. life-saving station supplied with modern apparatus. Fort Ontario, on the east side of the river, commanding the entrance to the harbor, is a casemated structure, with moat and bastions, and is garrisoned by a company of U. S. infantry. It is one of the three fortifications that originally defended the city while a British possession. There are 20 churches. Oswego is noted for her educational facilities, having a State Normal and Training School, six large brick public schools, and many smaller ones, all graded, besides several parochial and private schools and business colleges. The number of pupils enrolled in the public schools in 1900 was 4,000; in the parochial schools, 1,425. The city contains a public library (founded by Gerrit Smith in 1855) with over 20,000 volumes, and a city-school and a normal-school library. It has a hospital and asylums for homeless old ladies and orphans. In 1900 the total receipts of the city were $378,207.10, and expenditures $371,682.06, and the assessed valuations were, real estate, $8,541,688; personal, $1,686,443—total, $10,429,791. There are 2 national banks, with a total capital of $300,000, and 2 savings-banks with total deposits of about $2,000,000, besides several aid and loan associations. The city has abundant water-power, supplied by the Oswego river, which divides it E. and W. and forms the outlet of a beautiful group of eleven lakes in Central New York. It has many manufacturing concerns, several of which are the largest of their kind in the U. S., such as starch-works, knitting factories, boiler-works, the Standard Oil Company's box-shops, malt-house, shade-cloth works, and a match factory. Other large local industries are a book-bindery, car-building and repair shops, sash and blind factory, and extensive lumber yards. During the past ten years Oswego has been transformed from a commercial to a manufacturing city. The lake shipping has been diverted because of the increased tariff rates on Canadian goods, but the industrial conditions have continued to be very prosperous. Here are located the famous Deep Rock Mineral Springs. The paid fire department is one of the best equipped and most efficient in the State. Oswego is one of the chief ports of entry in the U. S. A vast outer harbor is formed by a breakwater with parapet, over a mile long, and contains the D., L. and W. Railroad Company's immense coal-trestles. The old or inner harbor is formed by two piers at the river's mouth, and contains two large coal trestles. These harbors protect several miles of wharfage and accommodate the largest vessels. Coal is the main article of export, and 510,000 net tons were shipped during the year ending December 31, 1900. There were received during the same period 190,000 bushels of grain and 40,000,000 feet of lumber. The total revenue collected for the year was $117,386.69. A steamer runs three times a week from the city to the Thousand Islands during the pleasure season. Oswego has various outing clubs and a yachting club with a fine fleet and is a noted fishing resort. There are 2 daily and 3 weekly newspapers. The city is one of the oldest settlements in the State, and was incorporated as a city in 1848. It was the last point to be surrendered by Great Britain to the U. S. Government. Pop. (1880) 21,116; (1890) 21,842; (1900) 22,200.

JOHN M. HURLEY.

Otaheite, ō-tăă-hĕĕ'te: See TAHITI.

Ota'go [from Maori *Otakou*, red earth]: the most southern provincial district of the Middle island of New Zealand. Area, 25,487 sq. miles. The first settlement was made here in 1847, and in 1851 the number of settlers had increased to 1,740; but in 1861 gold was discovered in several districts, and in two years the population swelled to 48,907, of whom only 500 were natives. The gold-fields now comprise an area of 2,500,000 acres, and in other directions the province has made great progress; it is being extensively cultivated, and its natural riches are rapidly developing. Pop. (1891) 153,097. Capital, Dunedin.

Otari'idæ [Mod. Lat., named from *Ota'ria*, the typical genus, from Gr. *ὠταρός*, large-eared, deriv. of *οὖς*, *ὠτός*, ear]: a family of mammals of the order *Pinnipedia*, containing the sea-lions and fur-seals. The form is more like that of ordinary quadrupeds than in any other members of the order; the fore limbs are flippers, the hind limbs flexible forward; the head is bear-like; small linear ears are developed; the 34 or 36 teeth are present (M. $\frac{5-6}{5-5}$, C. $\frac{1}{1}$, I. $\frac{3}{2} \times 2$), and the incisors of the upper jaw are notched; the anterior limbs are about as large as the posterior; their digits decrease in a curved line and are destitute of claws; the posterior feet have all their digits nearly coterminal, and are furnished with long flaps extending beyond the tips; the three middle toes are alone provided with claws. The family has been variously subdivided, but by naturalists in the U. S. is regarded as being represented by five genera, viz.: (1) *Zalophus*, (2) *Eumetopias*, (3) *Otaria*, (4) *Arctocephalus*, and (5) *Callotaria*. The first is represented on the coast of California as well as Japan and Australia; the second is restricted to the North Pacific, *E. stelleri* descending, however, as far as California; the third and fourth belong to the southern seas; and the fifth to the North Pacific. The first three are "hair-seals" and the last two "fur-seals." *Arctocephalus* is hunted for its fur at widely distant places; *Callotaria*, however, is only sought for to any extent on the Pribyloff islands, Alaska, and Commander islands, Kamchatka. Revised by F. A. LUCAS.

Otfried: poet; a Frank by birth; studied at Fulda under Hrabanus Maurus (822–847), and also under Salomon I., Bishop of Constance (839–871); went to St.-Gall, and was afterward monk in the Benedictine monastery at Weissenburg, Alsace. Here he wrote, with the avowed purpose of displacing the worldly songs of the people, his famous *Evangelienbuch*, a paraphrase in verse of the Gospels. The first part of his poem he sent to Hartmuat and Werinbracht, monks of St.-Gall, another part to Bishop Salomon, and the complete work he finally dedicated about 865 to King Louis, the German, and to Archbishop Liutbert of Mentz. In an extremely interesting letter, written in Latin to Liutbert, he speaks of the aim of his poem and of the difficulties he encountered with the German language while composing it. The poetical merit of Otfried's work is very small. As one of the most extensive documents of the Old High German period, which, moreover, was composed in rhymes, Otfried's *Evangelienbuch* is, however, of the greatest value for the study of the German language and of German metrics. For the didactic parts of his poem, which are very frequent, Otfried used the works of Hrabanus, Beda, and Alcuin. See the editions of Otfried by J. Kelle, P. Piper, and O. Erdmann; K. Lachmann, *Kl. Schriften*, i., 449. J. GOEBEL.

Othman or **Osman I.**, GHAZI, the Victorious: founder of the empire and people, called from his name Ottoman or Osmanli; b. in 1259. After a romantic and adventurous youth, he succeeded his father, Ertogrul Shah, a Turkish chieftain, as principal commander of Alaeddin III., Seldjuk Sultan of Roum (1288). The Seldjuk empire falling to pieces (1299), Othman at Kara Hissar was proclaimed *Padishahi ali Osman*, Emperor of the Ottomans (1300). His kingdom comprised parts of Bithynia and Phrygia. Though his name was mentioned in the Friday prayer (one of the two distinctive attributes of sovereignty among the Mussulmans), he did not coin money or assume the title of sultan. His life was passed in petty but advantageous wars with the Byzantine empire, and in the organization of his conquests. Broussa was captured (1326) just before his death. He was brave, patient, sagacious, generous and frugal, and possessed the peculiar virtues and talents essential to the founders of empires.—OTHMAN II.: Ottoman sultan (1617–22): b. in 1604; succeeded Mustapha I. Though he was a warlike and intelligent prince, his reign was unfortunate, being convulsed by frequent rebellions of the janissaries and by a disastrous war with Poland. At the unsuccessful siege of Choczim 50,000 Ottomans perished. Imprudently threatening to suppress the janissaries, he was dethroned by them, and

strangled in the Seven Towers by the hands of the grand vizier, the first Ottoman sultan put to death by his subjects. —Othman III.: Ottoman sultan (1754–57); b. in 1700; succeeded Mahmoud I. He was effeminate and soured by his long seclusion in the seraglio, but his reign was uneventful.
E. A. Grosvenor.

Othman or **Osman-Ibn-Affan**: third caliph of the Mussulmans; b. about 574; an early convert to Islam, a relative and secretary of the prophet Mohammed, whose daughters Rubiya and Um-Sul-sum he married. On the assassination of Omar (644) he was chosen caliph, mainly through the influence of the Korëish. During his caliphate the first authentic copy of the Koran was compiled (652), Armenia and Asia Minor were partially subdued (646), and Cyprus, Crete, Rhodes, and Cos conquered by the first naval expedition ever sent out by the Arabs (649); but his reign was distracted by numerous insurrections, which he could not put down. He was a feeble and incapable ruler, indulgent and despotic by turns, and often unjust. When he ordered Mohammed, the son of Abubekir, to be put to death, the latter marched upon Medina without opposition, and stabbed the caliph on the pulpit steps (655). E. A. Grosvenor.

Otho: King of Greece; second son of Louis I., King of Bavaria; b. at Munich, July 1, 1815. Nominally chosen king by the Greeks (May 7, 1832) he was really appointed by France, Great Britain, and Russia, with scant regard to Greek aspirations. He married the beautiful Princess Amelia of Oldenburg, Sept. 22, 1836. Surrounding himself with Bavarians, insisting on German as the official language, despotic and reactionary in policy, he was soon detested by his subjects. The peaceful revolution of Sept. 14, 1843, forced the king to dismiss the foreigners and to grant a constitution, promulgated Mar., 1844. Its provisions he soon sought to evade or nullify. He gained a temporary popularity during the Crimean war by wishing to attack the Ottoman empire, but the Anglo-French fleet occupied the Piræus and prevented action. The popular hatred of his government soon returned, and showed itself in several attempts at insurrection, which were, however, easily crushed. The national outburst of Oct. 21, 1862, was successful. Boulgaris, Canaris and Kouffos formed a provisional government, and pronounced the deposition of the king, who returned to Bavaria, and died in obscurity at Bamberg, July 26, 1867. In Otho's behalf it may be said that British, French, and Russian intrigues at Athens complicated and increased his difficulties, and that the newly enfranchised Greeks were impatient of control. E. A. Grosvenor.

Otho, Marcus Salvius: Roman emperor from Jan. to Apr., 69 A. D. As a young man he was conspicuous as a companion of Nero, and a sharer in his revels: but the emperor's passion for the wife of Otho, Poppæa Sabina, was the cause of alienation, and finally of practical exile, Otho being sent to take charge of the remote province of Lusitania (Portugal). Here, on the revolt of the provinces against Nero, Otho joined the forces of Galba, hoping to be adopted by him, and thus designated as his successor. When, however, Galba adopted L. Calpurnius Piso, Otho by a daring stroke won over the prætorian guard, already somewhat disaffected, and was saluted by them as emperor. Galba and Piso were thereupon murdered by the guard, and on the same day the senate clothed Otho with the imperial dignities. Soon after his succession news was brought that Vitellius, commander of the legions on the lower Rhine, had been proclaimed emperor by his army, and that his forces were advancing on Rome to make good his claim. Otho with great promptness collected his forces, and met the advance of the enemy in the region of the Po. Here for a time his operations were successful, but, a portion of his army suffering defeat near Cremona, he lost heart, and put an end to his life. His brief reign gave promise of a liberal and vigorous administration.
George L. Hendrickson.

O'thoes (Egypt. *Tetà*): the name given by Manetho to the first king of the sixth Egyptian dynasty. According to Manetho (Africanus) Othoes-Teta ruled thirty years. He was the first king to assume the royal title, which was ever afterward customary, "Son of Ra." Particularly noteworthy is the fact that his pyramid at Saqqarah, opened in 1881, was one of those containing funereal texts, which have been published by Maspero (*Recueil de travaux relatifs à la philologie et à l'archéologie égyptiennes et assyriennes*, vol. v.). The name *Tetà* also belonged to the second king of the first dynasty, reported to have been a writer on medicine and anatomy, and later to the sixth king of the third dynasty, who is called Tosertasis by Manetho.
Charles R. Gillett.

Otho of Freising: historian; b. about 1114; a grandson of Henry IV., and the uncle of Friedrich I.; was educated for the Church, studied in Paris, entered the Cistercian monastery of Morimund in 1130, and was in 1137 appointed Bishop of Freising. D. Sept. 21, 1158. He took an active part in the various theological and political movements of his age, but he is principally known as a historian. Between 1143 and 1146 he wrote a work (*De duabus civitatibus*), an imitation of the work of Orosius, and, like that, based on Augustine. Especially the last book of the work is of great interest. His *Gesta Frederici*, a work of still greater interest, he left unfinished. His works have been edited by Wilman (Hanover, 1884) and in *Mon. Hist. Germ.*

Otid'idæ [Mod. Lat., from *O'tis*, name of a genus, from Lat. *o'tis* = Gr. *ὠτίς*, a kind of bustard with long ear-feathers, deriv. of *οὖς, ὠτός*, ear]: a family of birds containing the bustards, confined to the Old World. There are about twenty-five species, two of which occur in Europe, one in Australia, and the others in India and Africa. See Bustard.

Otis, Elwell S.: See the Appendix.

Otis, Fessenden Nott, A. M., M. D.: surgeon; b. at Ballston Spa, N. Y., May 6, 1825; graduated at the New York Medical College 1852; was resident assistant physician at Blackwell's Island Hospital 1852–53; surgeon to the U. S. M. Steamship Company 1853–60; surgeon of the New York police department 1861; lecturer on genito-urinary diseases at the New York College of Physicians and Surgeons 1862–71; superintending surgeon to Pacific Mail Steamship Company 1869–73; president of New York board of police surgeons 1870–72; surgeon to the Strangers' Hospital and president of its medical board 1871–73; Clinical Professor at the College of Physicians and Surgeons 1871; advisory physician to the Artists' Fund Society, and member of the medical board of the New York Charity Hospital 1873. He wrote *Landscape Perspective and Animal Drawing* (1849), *History of the Panama Railroad and the Pacific Mail S. S. Co.* (1861), and numerous monographs on urethral and syphilitic diseases, and invented a number of surgical instruments. D. May 24, 1900. Revised by S. T. Armstrong.

Otis, George Alexander, M. D.: surgeon; b. in Boston, Mass., Nov. 12, 1830; graduated at Princeton 1849, and at the medical department of the University of Pennsylvania 1851; studied surgery two years in London and Paris; established *The Virginia Medical Journal* 1853; entered the U. S. army in 1861 as surgeon; was assigned to duty July, 1864, in the office of the surgeon-general at Washington; published monographs on *Amputation of the Hip Joint* (1867) and *Excisions of the Head of the Femur for Injury* (1869); prepared in 1871 a *Report of Surgical Cases treated in the Army of the United States from 1867 to 1871*, forming a quarto volume; and in 1872 edited the surgical volume of the first part of the *Medical and Surgical History of the War*. He was curator of the Army Medical Museum at Washington. D. in Washington, D. C., Feb. 23, 1881.

Otis, James: political leader; b. in West Barnstable, Mass., Feb. 5, 1725; graduated at Harvard College 1743; studied law with Jeremiah Gridley, and began practice at Plymouth 1746; removed to Boston 1750; published in 1760 *Rudiments of Latin Prosody*; in 1761, when advocate-general of the admiralty, refused to argue in favor of the writs of assistance, and resigned his office to plead the people's cause; in 1762 was elected to the State legislature, and in 1765, on his motion, the Stamp Act congress met in New York, to which he was a delegate. His speeches and pamphlets placed him at the head of the patriotic party in Massachusetts; in 1769 he denounced in print the commissioners of customs, and on Sept. 9, meeting one of the commissioners in a coffee-house, he was attacked, and received a cut on his head which led to derangement; took part, however, in the battle of Bunker Hill; retired to Andover, where he was killed by lightning May 23, 1783. His published works include *Vindication of the Conduct of the House of Representatives* (1762); *Rights of the British Colonies asserted* (1765); and *Consideration on Behalf of the Colonists* (1765).

Otomis, or **Othomis**: a tribe of Indians inhabiting the mountain regions of the states of Querétaro, Hidalgo, and Guanajuato, with scattered bands in several other states of Mexico. They have been established in their present seats

from time immemorial, and occupied the valley of Mexico before the Toltecs and Aztecs. At present they maintain no tribal organization, are Mexican citizens, and usually speak Spanish in addition to their own language, which is one of the harshest and most guttural of all Indian dialects. It consists in a great measure of words of one or two syllables only, whence it has erroneously been supposed to belong to a different linguistic family from the neighboring tribes, and unsuccessful efforts have been made to connect it with the Chinese. Several catechisms and devotional works have been printed in Otomi, the best-known grammar being that of Neve y Molina (Mexico, 1767).

Otranto, Duke of: See Fouché.

Otranto, Terra di: See Lecce.

Otsego Lake: a body of water in Otsego co., N. Y.; 7½ miles long, 1½ broad, 1,193 feet above tide; the source of the main fork of the Susquehanna river. Its waters are clear and abound in fish. Cooperstown stands at its outlet.

Otsu: a town and garrison-station of Japan; at the southern end of Lake Biwa; about 7 miles from Kioto; the seat of government of the Shiga prefecture (see map of Japan, ref. 7–C). In a monastery on the hill is a famous bell, said to have been stolen by Benkei, the Japanese Hercules, in the twelfth century. On the western border of the lake, about 3 miles off, is the famous pine-tree of Karasaki, of extraordinary age and size. J. M. D.

Ottawa: city; capital of the Dominion of Canada, and of Carleton County, Province of Ontario; at the junction of the Ottawa, the Rideau, and the Gatineau rivers; on the Rideau Canal, and the Canadian Pacific, the Canada Atlantic, the Parry Sound, the St. Lawrence and Ottawa, the Ottawa and Gatineau Valley, the Pontiac and Pacific Junction, the New York and Ottawa, and several branch railways; 95 miles N. E. of Kingston, 120 miles W. of Montreal, 450 miles N. by W. of New York city (for location, see map of Ontario, ref. 2–H). It is on the south bank of the Ottawa river, from which it rises by a succession of bluffs to Parliament Hill, 160 feet above tide-water, on which the principal Government buildings have been erected, and is bisected by the Rideau Canal. The scenery at every turn is very beautiful, comprising a grand display of architectural skill, river, mountain, and forest attractions, and two picturesque waterfalls, Chaudière, on the W. of the city, and Rideau, about a mile E. of the center of the city. The city is laid out in wide and regular streets, which are ornamented with shade trees and drinking fountains, and is lighted with gas and electricity. It has an improved drainage system, and a water-works plant completed in 1874 at a cost of over $1,000,000, which brings water from an intake, some 3,000 feet above Chaudière Falls, to the city by direct pumping, rendering a reservoir unnecessary. There are a number of public parks and squares, including Parliament Hill and Major's Hill, both under control of the Federal Government; Lansdowne Park, on the Rideau Canal; Cartier Square, containing a brick drill-hall, used as a parade-ground by the local militia and as an athletic field by various societies; and Rockcliffe Park, a short distance N. E. of the city, which has become a popular place of recreation and a hot-weather resort. The city is connected with suburban towns and resorts by electric street-railway.

The most notable of the public buildings are those built on three sides of a quadrangle on Parliament Hill. They comprise the Parliament building, the Eastern Departmental building, the Western Departmental building, and the Langevin block, the latter on Wellington Street, nearly facing the Parliament building. They are separate buildings, almost pure Gothic in architecture, and with walks and drives occupy an area of 30 acres. The main building, used by the Senate and House of Commons, has a tower over 220 feet high, and the library building, in the rear of the main structure, is octagonal in shape, with a circular interior 290 feet in diameter. The Langevin block was erected in 1883 at a cost of $787,000, and the total cost of the Government buildings up to 1900 was about $6,000,000. Other Federal buildings are those occupied by the Supreme and Exchequer Courts, the geological and natural history survey, and the national art gallery and fishery exhibit, and the Cartier Square drill-hall. About a mile and a half from the Parliament building is Rideau Hall, in a domain of 78 acres, the official place of residence of the governors-general of the Dominion. The public buildings of the municipality include the city-hall, which cost $90,000; the court-house and jail, the normal and model schools, the University of Ottawa, the Collegiate Institute, the post-office and custom-house, Orphans' Home, Home for the Aged, Carleton General Protestant Hospital, Catholic General Hospital, St. Luke's General Hospital, Lady Stanley Institute for training nurses, Home for Convalescents, and the Rideau and Athletic clubs.

Ottawa is the seat of an Anglican bishopric and of a Roman Catholic archbishopric, and has over forty churches, representing almost every Christian denomination. At the head of the educational institutions is the University of Ottawa, which was founded as a college in 1848, made a university in 1866, and raised by the pope to the rank of a Roman Catholic university in 1889. There are also a model and normal school, a collegiate institute, the Coligny Young Ladies' College, a number of nunneries and convents, the Harmon Ladies' School, and a number of public and private institutions. There are twelve chartered banks, or branches of banks, with an aggregate paid-up capital of $38,745,960, and a reserve of $14,362,033.

Abundant water-power for manufacturing purposes is furnished by the Ottawa river, which is augmented in the vicinity of the city by the Rideau, the Gatineau, the Du Lievres, the Black, the Bonnechère, the Rouge, and the Mattawa rivers. The industrial establishments comprise paper-mills, railway car and repair shops, indurated ware, woodenware, match, carriage, stove, and furniture factories, foundries, planing and flour mills, and granite-works. Ottawa is one of the largest lumber-markets in the world. The first sawmill at Chaudière Falls was erected in 1853, and in that year was cut the first lumber exported from this district to the U. S. The sawed lumber trade has since increased till the capacity of the mills within the city limits alone is about 200,000,000 feet per season. The assessed valuation of Ottawa in 1900 for taxation was $25,067,205.

Ottawa was founded in 1826, when the construction of the Rideau Canal was begun under Lieut.-Col. By, of the Royal Engineers, and was known as Bytown till 1854, when it received a city charter under its present name. In 1858 it was selected to be the permanent seat of government of united Canada, and in 1867 it was made the capital of the Dominion. On Apr. 26, 1900, Hull and a large part of Ottawa were destroyed by fire, causing a loss of more than $15,000,000. Pop. (1881) 31,307; (1891) 44,154; (1900) 58,193. Hull, on the opposite or northern side of the Ottawa, connected by two fine bridges, has about 10,000 more. About one-third of the population of Ottawa is of French-Canadian blood, and about one-half the total population is Roman Catholic. Editor of "Journal."

Ottawa: city (settled in 1830, incorporated as a village in 1838 and as a city in 1853); capital of La Salle co., Ill. (for location, see map of Illinois, ref. 3–E); at the confluence of the Illinois and Fox rivers; on the Illinois and Michigan Canal, and the Burlington Route, and the Chi., Rock Is. and Pac. railways; 83 miles W. S. W. of Chicago, 98 miles E. of Rock Island. It is in a region abounding in coal, brick and pottery clay, and cement and glass-sand, has exceptional transportation facilities, and ships large quantities of grain, produce, and general merchandise. The city occupies a beautiful site, and is tastefully laid out, having several public parks, one of which, South Park, contains a noted medicinal spring. There are gas and electric lights, electric street-railway, sewerage system completed in 1892, water-works supplied by over 150 artesian wells and by suburban springs, 12 churches, 7 public-school buildings, including a high school, public-school property valued at $100,000, St. Francis Xavier's Academy, a driving-park association, 2 national banks with combined capital of $200,000, a private bank, 5 libraries (High School, Illinois Law, Odd Fellows', Reddicks Public, and Young Ladies' Temperance Union) containing about 20,000 volumes, and 3 daily and 8 weekly newspapers. The manufactures include window-glass, glass bottles, lamp-chimneys, pottery, drain-tile, sewer-pipe, fire-brick, tile-roofing, organs, cigars, carriages and wagons, agricultural implements, flour, saddlery and harness, pumps, and lumber. Pop. (1880) 7,834; (1890) 9,985; (1900) 10,588.

Ottawa: city; capital of Franklin co., Kan. (for location, see map of Kansas, ref. 6–J); on the Marais des Cygnes river, and the Atch., Top. and Santa Fé and the Mo. Pac. railways; 27 miles S. of Lawrence, 53 miles S. W. of Kansas City, Mo. It is the seat of Ottawa University (Baptist, chartered in 1860), and has 2 national banks, a private bank,

2 libraries (public and university) containing over 5,500 volumes, a new court-house that cost $50,000, and a daily, 4 weekly, and 2 monthly periodicals. Ottawa has railway repair and machine shops, flour-mills, castor-oil and linseed-oil mills, sorghum, sugar, and sirup factories, grain elevators, foundry, and soap and furniture factories. Pop. (1880) 4,032; (1890) 6,248; (1900) 6,934. EDITOR OF "REPUBLICAN."

Ottawa: village; capital of Putnam co., O. (for location, see map of Ohio, ref. 3–D); on the Cin., Ham. and Day. and the Findlay, Ft. Wayne and West. railways; 50 miles S. W. of Toledo. It is in an agricultural, lumbering, and stock-raising region, and has several flour and saw mills, a private bank, and three weekly newspapers. Pop. (1880) 1,293; (1890) 1,717; (1900) 2,322.

Ottawa Indians: See ALGONQUIAN INDIANS.

Ottawa River: in Canada; is the boundary between the provinces of Ontario and Quebec (except in the very lowest parts of its course). It rises on the divide between the basin of the St. Lawrence and Hudson Bay, and flows S. E. and E., communicating with the St. Lawrence at the west end of Montreal island. It sends off the Rivière des Prairies, between Montreal island and the Isle Jésus, N. of which the Ottawa flows, finally joining the St. Lawrence below the island of Montreal. It has numerous rapids, some of which are flooded out by dams and others surmounted by canals. It has a heavy trade in lumber. Its cataracts afford very great water-power. It is navigated by steamboats and canal-boats. It is connected with Lake Ontario by the Rideau Canal. Its valley contains much fertile land and is rapidly filling with settlers. Length, 791 miles.

Ottawa University: See the Appendix.

Ot'tendorfer, OSWALD: journalist; b. at Zwittau, Moravia, Feb. 26, 1826; studied law at Prague and Vienna; settled in New York 1850; became an editor of the *New Yorker Staats-Zeitung*, and subsequently its manager and proprietor. Under his auspices it became one of the leading German-American papers and a prominent advocate of the interests of the Democratic party. As president of the German Reform Association Mr. Ottendorfer took a leading part in the exposure of dishonesty in the city government in 1871, at which time his paper assumed an independent attitude in politics; was alderman 1872–74, and was an independent candidate for mayor 1874. He built and endowed an educational institution in Zwittau, founded a home for aged and indigent men on Long Island, and established the Ottendorfer free library in New York city. D. Dec. 16, 1900.

Otter: a long-bodied, short-legged animal, with a small, flattish head, long, stout, rounded or slightly flattened tail. Otters are carnivorous mammals, belonging to the family *Mustelidæ* and sub-family *Lutrinæ*. Most species have sharp nails and webbed feet, but those of the genus *Aonyx*, found in Africa, Java, and Sumatra, have the webs small and the nails short or even lacking on some toes. The general color of the long outer coat of hair is a rich brown; the under fur, which in northern species is thick and valuable, is much lighter. Otters are aquatic in their habits, dwell in burrows by the water, and feed on fish. They are fond of sliding down-hill on the snow or mud banks. The common European otter (*Lutra vulgaris*), which is found throughout a great part of Europe and Asia, attains a length of 3 ft. 6 in. and a weight of 18 to 24 lb. The North American species (*Lutra canadensis*), which occurs in favorable localities from Florida to Canada and from Maine to Alaska, is sometimes 4 ft. 6 in. long. Various species of otters inhabit South America, Africa, Asia, and Japan, but the coat of the tropical species is short and commercially of little or no value. In India and China otters are trained for fishing. The sea-otter (*Enhydris lutris*), the sole member of the sub-family *Enhydrinæ*, is a marine species, found from California northward through the Aleutian island to Kamchatka and the Kurile islands. It is a bulky animal, distinguished by its short head, large flattened hind feet, and short tail. It attains a length of 4 feet, feeds on crabs, shellfish and sea-urchins, and is strictly aquatic, being often found in the open sea, sleeping and rearing its young in the water. The fur of this animal, which is very thick, soft, and dark-colored, is extremely valuable, good skins bringing $400 to $600. Owing to this value the animal is much hunted, has become very scarce and is, at least on the American coast, threatened with extermination. F. A. LUCAS.

American otter (*Lutra canadensis*).

Ot'terbein, PHILIP WILLIAM: founder and bishop of the United Brethren in Christ; b. at Dillenburg, Germany, June 4, 1726; entered the Reformed ministry in 1749; went in 1752 to North America as a missionary; labored especially in Pennsylvania and Maryland; founded his new church near Frederick, Md., 1800; was chosen bishop; toiled with great earnestness and success. D. at Baltimore, Nov. 17, 1813. He was a man of learning and piety. See UNITED BRETHREN IN CHRIST, and his *Life*, by A. W. Drury (Dayton, O., 1884).

Otterbein University: the oldest institution of learning under the charge of the United Brethren in Christ; at Westerville, O.; 12 miles N. of Columbus. It was founded in 1847, and chartered with university privileges. There are three buildings at present: the main college building, 170 feet by 109, two and four stories high; Saum Hall, a ladies' dormitory; and the Conservatory of Music. Its new Christian Association building is the first of its kind in the State. The endowment is $90,000. There are four strong literary societies with elegantly furnished halls. The library contains about 9,000 volumes. There are two courses, the classical and philosophical, with three years of preparatory instruction. The faculty consists of eleven regular professors and four instructors. The institution has 300 students and some 500 alumni. In addition to the preparatory and the regular college class, there are post-graduate, normal, art, and music departments. The president, Thomas J. Sanders, A. M., Ph. D., was inaugurated June, 1892. T. J. SANDERS.

Otter Creek: a stream which rises near the south border of Rutland co., Vt.; flows through Rutland and Addison Counties, and reaches Lake Champlain at the town of Ferrisburg. It is 90 miles long, affords good water-power, and is navigable 8 miles to Vergennes.

Otto, WILHELM LUITPOLD: King of Bavaria; b. Apr. 27, 1848; succeeded to the throne June 13, 1886, on the death of his brother, Ludwig II.; but as he was mentally incapacitated for governing, the rule continued in the hands of Prince Luitpold, who had been appointed regent three days previously.

Ot'tocar II.: King of Bohemia from 1253 to 1278; b. about 1230, a son of Wenceslas I.; revolted against his father, but was defeated, and imprisoned for some time. He acquired Austria and Styria by marriage; made a crusade, after succeeding to the throne of Bohemia on the death of his father, against the heathen Prussians; conquered their country and founded Königsberg; defeated the Hungarians on the Marchfeld in 1260, and took possession of parts of Hungary; inherited Carniola and Carinthia in 1269, and ruled with vigor and intelligence his vast empire, which stretched from the Baltic to the Adriatic, and from the Inn, Bavaria, to the Raab, Hungary. In 1273 he opposed the election of Rudolph of Hapsburg as Emperor of Germany, and refused to acknowledge him; the consequence was a war, in which Ottocar was defeated and compelled to cede Austria, Styria, Carniola, and Carinthia. Once more he tried his fortune against Rudolph, but was again defeated, and fell in the battle of Jedenspeng, Aug. 26, 1278. In his internal government he strove to break the power of the feudal lords and encouraged industry and commerce.

Ottoman Empire: See TURKEY.

Otto of Roses: See ATTAR OF ROSES.

Ottumwa: city; capital of Wapello co., Ia. (for location, see map of Iowa, ref. 7–I); on the Des Moines river, and the Burlington Route, the Chi., Ft. Mad. and Des M., the Chi., Mil. and St. P., the Chi., Rock Is. and Pac., the Ia. Cent. and the Wabash railways; 75 miles N. W. of Burlington. It is in the center of the Iowa coal-fields, derives abundant

water-power from the river, and from the extent and variety of its manufactures has become known as "the Lowell of Iowa." The surface rises in terraces from the river to the summit of the bluff, and all the railways enter the city along the river-front. The city contains a U. S. Government post-office building, court-house that cost $150,000, 8 public-school buildings, public-school property valued at over $175,000, high school library, city library, 3 national banks with combined capital of $420,000, 2 savings and 1 State bank with capital of $250,000, and 3 daily and 7 weekly periodicals, an opera-house—one of the finest in the State—a union railway station, several large wholesale houses, a Y. M. C. A. building that cost $40,000, and a $50,000 Episcopal church. There are gas and electric light plants, water-works, electric street-railway, a steam-heating plant for residences and business buildings, and foundries, pork-packing establishments, starch-mill, oil-mill, iron-works, ruffler-works, bridge-works, fine office-furniture, and other factories. The city has a large trade, especially in coal. Pop. (1880) 9,004; (1890) 14,001; (1900) 18,197.

R. H. Moore, editor of "Democrat."

Otum'ba: a town of the republic and state of Mexico; 35 miles N. E. of Mexico city; on the railway to Vera Cruz (see map of Mexico, ref. 6–H). It was the ancient Indian *pueblo* of Otompan; Cortés, after his retreat from Mexico, defeated the Aztec forces here July 8, 1520. Pop. about 500. H. H. S.

Otway, Thomas: dramatist; b. at Trotton, Sussex, England, Mar. 3, 1651; was educated at Winchester and Christ Church, Oxford; became an unsuccessful actor; served for a time as cornet in the Low Countries; and then returned to London and wrote for the stage. His most successful plays were *Don Carlos* (1676); *The Orphan* (1680); *Caius Marius* (1680); *The Soldier's Fortune* (1681); *The Atheists* (1684); and especially *Venice Preserved* (1682), one of the best historical tragedies. D. in London, Apr. 14, 1685.

Revised by H. A. Beers.

Oude, or **Oudh**, owd: a province of British India, forming with the Northwest Provinces one of the thirteen local government and administrative divisions; bounded S. by the Ganges and N. by Nepal. It consists of a large plain watered by the Goggra, Gumti, Sye, and other tributaries of the Ganges. Area, 24,217 sq. miles; pop. (1891) 12,650,831, mostly Hindus. The soil is extremely fertile and well cultivated; all the choicest products of India grow in abundance. The inhabitants are very warlike; they serve in all Indian armies, and formed the famous Sepoy regiments in 1857. Capital, Lucknow.

Oudenarde: See Audenarde.

Oudinot, oo'dē̆'nō', Charles Nicolas, Duke of Reggio: marshal of France; b. at Bar-le-Duc, in the department of Meuse, France, Apr. 26, 1767; was commander of a battalion in 1792, brigadier-general in 1794, general of division in 1799, and distinguished himself especially in the battle of Friedland and at Wagram, when he was made a marshal and created duke. His greatest feat was his manœuver in order to protect the crossing of the Beresina in 1812. In the battle of Leipzig he was wounded, but recovered soon, and remained faithful to Napoleon to the very last. During the Hundred Days he stayed on his estates. After the Restoration he was made a peer of France and commander of the national guard. In 1823 he led the First Corps during the invasion of Spain. D. in Paris, Sept. 13, 1847.—His son, Nicolas Charles Victor: b. Nov. 3, 1791; general in 1835; commanded in 1849 the expedition against the Roman republic, and compelled the city of Rome to unconditional surrender July 2. He protested in the chamber of peers against the *coup d'état*, and was imprisoned, but shortly after was restored to liberty. D. July 7, 1863.

Ouida: See De la Ramé.

Ouimet, Joseph Alderic, LL. B., Q. C.: statesman; b. at St. Rose, P. Q., May 20, 1848; graduated LL. B. at Victoria College in 1869, and was admitted to the bar in 1870. He commanded a battalion during the Northwest rebellion campaign in 1885, and is chairman of the council of the Dominion Rifle Association. He has been a member of the Parliament of Canada since 1873; was Speaker of the House 1887–91; and May 20, 1891, was appointed a member of the Queen's Privy Council for Canada. N. M.

Oulachan, **Eulachon** [native (Amer.-Ind.) name], or **Candle-fish**: a fish of the smelt family (*Argentinidæ*), resembling the smelt and the capelin. Its scientific name is *Thaleichthys pacificus*. In the spring the oulachan enters in great shoals the harbors and fiords of British Columbia and Washington to spawn. The Indians take the fish in immense quantities for food and oil. The fish consist almost entirely of fat. A fish with a strip of bark drawn through it serves as a candle. The oil of the oulachan has been proposed as a substitute for cod-liver oil, but at ordinary temperatures it is white and solid like butter. It is one of the most delicately flavored and delicious of all food-fishes. Revised by D. S. Jordan.

Ouless, oo-less', Walter William: portrait-painter; b. at St. Heliers, Jersey, Sept. 21, 1848; became a Royal Academician 1881; was awarded a second-class medal at the Paris Exposition of 1878; third-class medal 1889. He is one of the most noted British portrait-painters. Studio in London.

W. A. C.

Ounce [from Lat. *un'cia*, a twelfth, especially of a pound or foot (whence O. Eng. *ynce* > Eng. *inch*)]: in troy weight, one-twelfth of a pound, or 480 grains; in avoirdupois weight, one-sixteenth of a pound, or 437½ grains troy. In the U. S. the apothecaries' ounce is the troy ounce; in Great Britain it is now the avoirdupois. In the U. S. the fluid ounce is one-twelfth of a wine-pint, in Great Britain the twelfth of an imperial pint.

Ounce [from Fr. *once*: Span. *onza*: Ital. *lonza* (the *l* may have been dropped in Fr. and Span. from confusion with fem. def. artic. *la*, *l'*) < Lat. *lynx* = Gr. λύνξ, whence Eng. *lynx*]: a large cat (*Felis uncia*) of Northern India and Tibet, resembling the leopard, but lower, rougher, paler, and with a longer and more hairy tail, a thicker fur, and more irregular spots. In parts of South America the jaguar is called the ounce. Revised by F. A. Lucas.

Ouray: town (founded in 1876 and named after a chief of the Ute Indians); capital of Ouray co., Col. (for location, see map of Colorado, ref. 5–B); on the Uncompahgre river, at the foot of Mt. Hayden, and on the Denver and Rio Grande Railroad; 15 miles N. of Silverton, 400 miles S. W. of Denver. It is in a region of grand scenery, at an elevation of 7,200 feet above sea-level; is the natural outlet for the extensive gold and silver products of the region, and is widely known as a resort for invalids because of its hot springs. It contains four churches, a national bank, a private bank, a miners' hospital, and a weekly newspaper. The entire expenses of the town are paid from high-license saloon fees. Pop. (1880) 864; (1890) 2,534; (1900) 2,196.

Editor of "Silverite-Plaindealer."

Ouro Preto, ō'rō-prā'tō, formerly **Villa Rica**: a city; capital of the state of Minas Geraes, Brazil; about 160 miles N. of Rio de Janeiro, with which it is connected by railway; 3,400 feet above the sea (see map of South America, ref. 6–G). It is irregularly built on hilly ground, but many of the more modern houses are well constructed and handsome. There is a thriving trade with the coast, principally in agricultural products, cheese, etc. The climate is very variable and at times insalubrious; rains and heavy fogs are frequent through the year. The place was formerly celebrated for its rich gold mines, and the hills are honeycombed with old works, most of which have been abandoned. Pop. (1892) about 20,000. Herbert H. Smith.

Ouse, ooz: a river of England; flows into the Trent and forms the estuary of the Humber. Its entire length is 60 miles; it is navigable from York, 45 miles from its junction with the Trent.

Ousel: See Ouzel.

Ouseley, ooz'lē̆, Sir Frederick Arthur Gore: musician; son of Sir Gore Ouseley, ambassador to Persia; b. in London, England, Aug. 12, 1825; graduated at Oxford 1846; was curate of a London church 1849–51; became precentor of Hereford Cathedral 1855, and incumbent of St. Michael's, Tenbury, Worcestershire, 1856; distinguished for his attainments in music as a science; took an active part in establishing St. Michael's College, Tenbury, of which institution he was warden; became Professor of Music in Oxford University 1855; author of several esteemed anthems, a *Treatise on Harmony* (1869), a *Treatise on Counterpoint and Fugue* (1869), and *A Treatise on Musical Form and Composition in General*, which are considered valuable contributions to musical literature, and editor of several collections of ancient and modern cathedral music: *Cathedral Services* (1853), *Anglican Psalter Chants* (1872, in conjunction with Dr. Monk), etc. D. in Oxford, Apr. 6, 1889.

Ouseley, Sir William, LL. D.: Orientalist; b. in Monmouthshire, Wales, in 1771; became cornet of dragoons

1788; left the army 1794; engaged in the study of Oriental languages at Leyden; published *Persian Miscellanies* (1795), *Oriental Collections* (3 vols., 1797), numerous other works on similar subjects, and translations from Oriental writers; was secretary to his brother, Sir Gore Ouseley, in his embassy to Persia 1810–12; published *Travels in Persia* (3 vols., 1819–23); brought to England valuable collections of Oriental literature. D. in England in 1842.—His brother, Sir Gore Ouseley (b. about 1768; d. 1844), long a prominent member of the diplomatic corps, was a distinguished Oriental scholar and collector of manuscripts; author of a posthumous work, *Biographical Notices of Persian Poets* (1846).

Ouseley, Sir William Gore, K. C. B., D. C. L.: diplomat; eldest son of Sir William; b. in London, England, July 26, 1797; entered the diplomatic service at an early age; was connected with the British legation at Washington in 1825, when he married a daughter of Gov. Cornelius P. Van Ness, of Vermont; filled difficult and responsible diplomatic posts in Rio de Janeiro, Buenos Ayres, Montevideo, and Asuncion during the wars originated by the dictator Rosas 1832–51; was employed on special missions in Central America and in the U. S. 1857–58; was author of *Remarks on the Statistics and Political Institutions of the United States* (1832); *Notes on the Slave Trade* (1850); *Views in South America, from Original Drawings* (1852); and many miscellaneous, political, and geographical writings. D. in London, Mar. 6, 1866.

Outagamie or **Fox Indians**: See Algonquian Indians.

Outlaw and **Outlawry** [*outlaw* is O. Eng. *ūtlaga*, outlaw; *ūt*, out + *lagu*, law]: in English law, an outlaw is one who has been placed out of the protection of the law on account of willfully avoiding the execution of legal process; and outlawry is the act or process by which he is deprived of the protection of the law. Outlawry has existed in England from ancient times, both in civil and in criminal proceedings, being first used, however, in criminal actions, no one being subject to be outlawed except for felony until some time after the Norman conquest. It was extended from cases of felony to misdemeanors and to civil cases, and is still applicable in criminal proceedings of every kind. In civil cases, originally, a person could be outlawed only in actions of trespass *vi et armis*, in which alone the defendant was then liable to arrest, but subsequently outlawry in civil cases was extended by statute to other actions, and it was used either to enforce the appearance in court of a person against whom a suit had been instituted or to enforce the payment of a judgment.

The process of outlawry in civil cases was early a means of oppression, and acts were passed in the reign of Elizabeth and later to prevent secret outlawries and to facilitate the reversal of outlawries; and the process was finally abolished by the Common Law Procedure Act of 1852, and by the Civil Procedure Acts Repeal Act of 1879. In criminal proceedings it is now but little used, but its existence is recognized by 33 and 34 Vict., c. 23, which act abolishes forfeiture for felony, but expressly provides that nothing therein shall affect the law of forfeiture consequent on outlawry. In some of the U. S. it has been retained as applicable in certain criminal cases, as in prosecutions for treason; but it is so seldom resorted to that it may be said to be wholly disused. Outlawry in civil cases has never existed in the U. S.

The mode of procedure in criminal and civil cases is practically the same. If summary process was issued against the defendant and failed to cause him to appear, and if the sheriff was unable to find the defendant and apprehend him upon the regular writs of arrest, a special writ was issued requiring proclamation to be made in five county courts successively that the defendant should surrender himself; and if the defendant then failed to appear, he was declared an outlaw. If afterward he publicly appeared he might be arrested and committed until the outlawry were reversed. A reversal in civil actions, where outlawry was resorted to to compel the defendant to appear, could readily be obtained upon any plausible cause, however slight, since the only object of the outlawry was to compel the appearance; but in outlawry to enforce a judgment a reversal could be had only upon satisfaction of the judgment.

Effect of Outlawry.—The maxim applicable to outlaws is, "Let them be answerable to all, and none to them." They are therefore liable upon all causes of action existing against them, but can not maintain actions for redress of injuries to them, nor are they deemed to have any legal rights enforceable by a suit at law. Anciently an outlawed felon was said to have a wolf's head (*caput lupinum*), so that any one might kill him as he would a wolf. A different rule, however, was early established, and the life of the outlaw could be lawfully taken only by a sheriff with a warrant.

Outlawry in cases of treason or felony is deemed equivalent to conviction and attainder for the offense charged, and is attended by the same penalties of forfeiture which formerly attached to such convictions; viz., in case of treason, a forfeiture of all his property, both real and personal; and in felony, a forfeiture of goods and chattels and of the profits of his freehold estates in land during his life. (See Forfeiture.) In civil cases and in cases of misdemeanor outlawry entailed the forfeiture of goods and chattels immediately and absolutely to the crown, and of chattels real and profits of real estate upon inquisition during the life of the outlaw. The plaintiff was permitted by the crown to collect his debt from the forfeited property of the outlaw. For further details, see Archbold's *Criminal Pleadings*; Daniel's *Chancery Practice*; Legge's *The Law of Outlawry* (London, 1779); Blackstone's *Commentaries*. F. Sturges Allen.

Outram, oo'trăm, Sir James, G. C. B.: soldier; b. in Derbyshire, England, Jan. 29, 1803; educated at Marischal College, Aberdeen; entered the military service of the East India Company 1819; distinguished himself in campaigns in Khandesh and against the wild Bhil tribes, from whom, after the peace, he formed an irregular military corps; pursued a similar policy respecting some rebel chiefs in Gujerat; was aide-de-camp of Sir John Keane in the Afghan war; took part in the capture of the Beluchi stronghold of Kelat, and, disguised as a native devotee, rode through the Bolan Pass, then held by the enemy, and conveyed the news to Kurrachee; appointed political agent in Lower Sind, with the brevet rank of major, and subsequently commissioner at Hyderabad; opposed Sir Charles Napier's aggressive policy, but had to defend the residency from attack by the populace; became resident at Satara 1845, at Baroda 1847, and at Lucknow 1854; was commander-in-chief of the British forces in the Persian war of 1856–57; arrived in India in the midst of the Sepoy rebellion; relieved Havelock at Cawnpur Sept. 15, then waived the command in favor of Havelock, whom he accompanied to the relief of Lucknow Sept. 25 in his capacity of chief commissioner of Oude; defended the residency and held the Alumbagh (Lucknow) during the subsequent siege by the rebels; aided Sir Colin Campbell in the final recapture of Lucknow Mar., 1858; was knighted and made lieutenant-general 1858; received the thanks of Parliament 1860; became a member of the supreme council of India; retired in broken health 1861. D. in Paris, Mar. 11, 1863. He was buried in Westminster Abbey, and statues of him have been erected in London and Calcutta. See his *Life*, by Sir F. J. Goldsmid (2 vols., London, 1880).

Ouvarovite: See Garnet.

Ouvrard, oov'raar', Gabriel Julien: financier; b. near Clisson, France, Oct. 11, 1770; became a merchant at Nantes, and, having secured in 1797 a contract from the Government for supplying the navy with provisions, made a profit estimated at 15,000,000 francs. He then established a large banking-house in Paris, secured other Government contracts, and undertook to discount the subsidy due from Spain and amounts due from the receivers-general, thereby obtaining control of a large part of the national finances. The scope of his financial operations continually widened. He entered into contracts for supplying the Spanish army and navy, and advanced money for the needs of the imperial court, but Napoleon, becoming distrustful of the company, forced it to give up its assets in 1806, and afterward caused the arrest and imprisonment of Ouvrard, who was confined, first at Vincennes and later at Ste.-Pelagie, till 1813. After the Restoration he gained favor with the Bourbon government, which adopted a financial system proposed by him, but falling again under suspicion of fraudulent conduct in connection with contracts for supplying the French army for the Spanish expedition of 1823, he was imprisoned for five years. He afterward lived in London, where he died in Oct., 1846. See the *Mémoires* written by himself (Paris, 1826).

Ouzel, or **Ousel**, ooz'l [M. Eng. *osel* < O. Eng. *ōsle*: O. H. Germ. *amsala* > Germ. *amsel*, blackbird; cf. Lat. *merula* (for **mesula*), blackbird, whence Eng. *merl*]: a name applied in England to several birds. Thus the "ousel-cock" of Shakspeare was the European blackbird (*Merula merula*); the ring-ouzel of the present day is a very similar bird, the *Merula torquata*. More frequently the name is applied to

the water-ouzel or dipper. (See DIPPERS.) Still other birds receive this name, among them the brook-ouzel (*Rallus aquaticus*), but nearly all are thrushes, or their allies.

Revised by F. A. LUCAS.

Oval [from Fr. *ovale*, egg-shaped, from Lat. *o'vum*, egg]: a curve bearing a resemblance to the section of an egg by a plane through its axis—as for instance, an ellipse. A semi-oval formed by arcs of circles of different radii and tangent to each other is sometimes used by engineers in the construction of arches. Such curves are often called basket-handled curves or basket-handled arches. The Carterian *oval* is a plane curve of the fourth order, first studied by Descartes, from whom it derives its name. The scientific interest attached to it arises from the fact that the surface generated by revolving it about its axis is a surface of *accurate convergence* (that is, a surface which must divide two media of different refracting power, in order that rays of light coming from one point may deviate so as to pass accurately through another point).

Ovam'po, or **Ovambo**: a Bantu people in the northern part of German Southwest Africa, living along the left bank of the Cunene river and some distance S. Ten divisions or tribes of this people have been described by explorers, and they are supposed to number about 100,000. Except near the coast the soil is fertile, but water is not abundant. The people are warlike, industrious, ingenious, and unusually honest. They regard stock-raising as of secondary importance, though they have many cattle. They raise great quantities of native grain. For agricultural purposes their land is the best in German Southwest Africa, but (1894) is undeveloped, owing to the sandy coast strip and lack of transportation facilities. Revised by C. C. ADAMS.

Ovan'do, NICOLAS, de: administrator; b. at Valladolid, Spain, about 1460. He was a distinguished knight of the Order of Alcantara, and held high positions in the Spanish court. In 1501 he was appointed governor of Española, with jurisdiction over all the Spanish discoveries in the New World, except those which had been granted to Pinzon and Ojeda. He left San Lucas Feb. 13, 1502, with the largest fleet which had yet been fitted out for the West Indies, consisting of thirty ships with 2,500 colonists; arrived at Santo Domingo on Apr. 15, and governed until July, 1509. During this period the colony was financially prosperous, but the greater part of the Indian population was destroyed through the system of enforced labor. He refused to let Columbus land in July, 1502. D. in Madrid, about 1518. H. H. S.

Ovaries [Lat. *ova'rium*, deriv. of *ovum*, egg]: the organs in any animal which produce the female reproductive bodies —ova or eggs. These organs have very different conditions in different groups, but a few general statements may be made. The ovary is one of the two sexual organs, or *gonads*, the other being the male organ, or *testis*, which produces the male generative element, or spermatozoa. While in most animals these two occur in different individuals—i. e. the sexes are separate, they may occur together in the same individual, and in exceptional cases the same organ may be ovary in one region, testis in another; or, again, it may act a while as testis and later produce eggs. These facts, with many others, show that ovaries and testes are homologons structures, no instance being known which would not fall in such a category.

In the Hydrozoa the gonads are ectodermal, in the Scyphozoa entodermal; in all other animals they arise from the middle layer (mesoderm; see EMBRYOLOGY), and, where a body-cavity (cœlom) is present, as specializations of its walls. In the lower forms the ovaries may be numerous, but in the higher animals there are usually two—right and left—but these may fuse to form an unpaired organ. In the vertebrates the number two holds, and the organs are placed on either side of the backbone.

The ovaries in adult women are situated on either side of the uterus, in the iliac fossæ; they are included in separate processes from the two pelvic duplicatures of the peritoneum, which are called the broad ligaments. Each ovary is also attached by a round fibrous cord, the ovarian ligament, to the side of the uterus, and by a lesser fibrous cord to the fringed edge of the Fallopian oviduct. These three ligaments support and retain the ovary in its proper position. The ovary is an oblong, ovoid, flattened body, of whitish color and uneven surface. It is one-third to half an inch thick, three-quarters of an inch wide, 1 to 1½ inches long, and weighs from 1 to 2 drachms. (For general description of the minute structure of the ovaries and of the development of the ova, see HISTOLOGY, *Genital Organs*.) The physiological function of the ovary is the formation of ova, their maturation, and their final discharge at periodic menstrual epochs. The distended follicle at the time of rupture

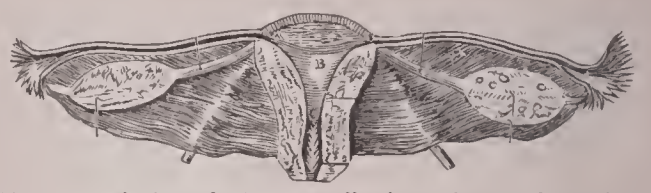

FIG. 1.—Relation of uterus, Fallopian tubes, and ovaries.

may equal in size one-third of the ovary, and many scars exist where former ruptures have taken place. When the ovule escapes from the Graafian follicle it is carried by a gentle current of fluid on the peritoneal surface of the broad ligament and tubo-ovarian ligament to the interior of the tube by which it is conveyed to the uterine cavity. The current setting toward the abdominal ostium of the tube is the result of the action of the ciliated epithelium within the tube and on its fimbria. It is unknown where the ovule is impregnated, although the majority hold that impregnation is in the tube; but intra-uterine impregnation is at least possible. Should impregnation not occur, the ovum disintegrates or passes off with the menstrual discharge. The activity of the ovary develops at puberty—usually the fifteenth or sixteenth year—and ceases with the climacteric—forty-fifth to fifty-second year. The remarkable functional activity of the ovary, including periodic congestions, ruptures, and cicatrization, renders it peculiarly liable to disease. Neuralgia, congestion, and inflammation of the ovary are frequent diseases in women—often temporary and slight, at times chronic, depressing strength and health, and causing hysteria and dementia. Solid tumors, fibrous and cancerous, affect the ovary less often than the uterus. Ovarian dropsy originates in the dropsical distension of one or more Graafian follicles by albuminoid serum. This may arise when the follicles are too deeply situated to rupture and discharge the contained ovum, or prevented by thickening of the surface from previous inflammation; it may also begin by accumulation in the cavity of the corpus luteum. A cyst may be *unilocular*, having but one cavity and arising originally from one follicle; or *multilocular*, having several compartments. In the latter case the mode of formation is yet in dispute, but it is something more than the simple distension of the Graafian follicles with fluid. A proliferation of connective-tissue elements with cystic degeneration, a proliferation of the egg cords in the primordial ovary, and a pathological development of the epithelial cells have been regarded as the cause. The ovarian cyst may contain many quarts of transparent, albuminoid serum.

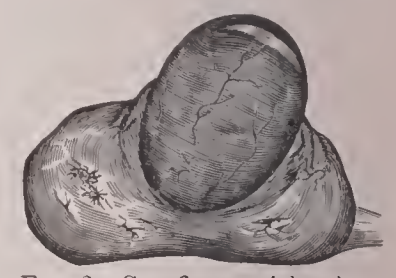

FIG. 2.—Graafian vesicle about to rupture: scars of former rupture.

Ovariotomy, the surgical operation of evacuating ovarian dropsy and eradicating the cyst, was first performed in America by Dr. Ephraim McDowell, of Kentucky; this first case resulted in recovery. Dr. McDowell operated thirteen times—eight successfully. It is now accepted and extensively performed in all countries. The improvement of technique in abdominal surgery has now made this one of the simplest and most successful operations in gynæcology, unless there should be complicating factors, like universal adhesions or suppuration of the sac. A complete list of ovarian tumors is as follows: Carcinoma, sarcoma, papilloma, fibroma, cysto-carcinoma, cysto-sarcoma, cysto-fibroma, cysto-papilloma, dermoid, myxo-adenoma (ovarian cysts, monocystic and polycystic), hydrops folliculorum (distension of the Graafian follicles with fluid). Dermoid cysts of the ovaries are the most peculiar tumors of the body. They are the result of implantation of epidermal structures upon the mass of cells from which the ovary develops during embryonal existence. As a consequence, structures like teeth, hair, sebaceous matter, quite foreign to the ovary itself, are discovered in the tumors. These cysts are prone to degenerative and inflammatory action, especially after childbirth. Aside from this complication, however, they are no more difficult to deal with than the commoner varieties of ovarian cysts. One of the most serious diseases of the ovaries is in-

fectious inflammation and suppuration, following usually childbirth or gonorrhœa, and commonly associated with pyosalpinx and pelvic peritonitis. A timely abdominal section will usually save the patient, but the pus from an ovarian abscess is peculiarly virulent, and diffuse septic peritonitis is always to be dreaded. Revised by B. C. Hirst.

Ovariot'omy: See Ovaries.

Ovary (of a flower): See Flower.

Ovenbird, or **Golden-crowned Thrush**: a North American bird (*Seiurus aurocapillus*) of the family *Mniotiltidæ*. It is called ovenbird from the shape of its nest, which is built upon the ground and roofed over with a dome-shaped covering. It is a shy, retiring bird, of an olive-brown color, 6 inches long, and is often seen running along the ground. The name ovenbird is also given to certain South American birds of the genera *Furnarius* and *Cinclodes*, belonging to the family *Furnariidæ*. They are remarkably bold little birds, and build a dome-shaped nest which is divided by a partition into two rooms, the innermost of which contains the eggs. Revised by F. A. Lucas.

Overbeck, Frederick: painter; b. at Lubeck, Germany, July 3, 1789; studied painting in Vienna from 1806 to 1809; settled in 1810 at Rome; embraced Roman Catholicism in 1814; was an apostle of the sentimental religious school in art; held beauty subordinate to piety; attempted to revive the devotional art of a former ascetic period, and founded a school which was numerously attended and celebrated in its day. His works expressed deep religious feeling, but are thin and artificial. Discarding as heresy the ideas of the moderns, he earned the title Nazarene, which was bestowed on the men of his school. He chose sacred subjects: *The Entrance of Christ into Jerusalem* (Lubeck); *Christ on the Mount of Olives* (Hamburg); *The Entombment* (Lubeck); and *The Triumph of Religion* (Frankfort). These are his best pieces. The great frescoes on the Monte Pincio and in the Villa Massimi were executed by Overbeck in conjunction with others. D. in Rome, Nov. 12, 1869.

Overbeck, Johannes Adolph: archæologist; b. at Antwerp, Belgium, Mar. 27, 1826; studied in Bonn; privat docent 1850; was called to Leipzig as professor of archæology and director of the archæological collections. His best-known works, alike distinguished for their learning and their style, are *Kunstarchäologische Vorlesungen* (1853); *Pompeii* (4th ed. 1884); *Die antiken Schriftquellen zur Geschichte der bildenden Künste bei den Griechen* (1868); *Griechische Kunstmythologie* (5 parts, 1871–87); and *Geschichte der griechischen Plastik* (2 vols., 4th ed. 1892), his masterpiece. Alfred Gudeman.

Overbeek de Meijer, Gillis, van, M. D.: surgeon and hygienist; b. at Rotterdam, Holland, in 1831; studied in the military medical school in Utrecht 1847–51; was a surgeon in the Dutch navy 1851–66; graduated M. D. from the University of Leyden in 1865; was sanitary inspector of the provinces of Gelderland and Utrecht 1866–77; in 1877 was appointed Professor of Hygiene and State Medicine in the University of Utrecht. His most important work is *Scheepsgezondheidsleer* (Tiel, 1861). S. T. A.

Overberg, Bernhard: ecclesiastic and author; b. at Höckel, in the principality of Osnabrück, Hanover, May 1, 1754; was educated in the Franciscan gymnasium at Rheine-on-the-Ems; studied theology at Münster; was ordained a priest in 1780, and was in 1783 appointed teacher in the episcopal seminary. In 1789 he took up his residence in the house of the Princess Galitzin as her confessor, and he exercised a great influence not only on her, but also on her children and on her whole circle. In 1809 he was made director of the episcopal seminary—a position which gave him control over all educational affairs of the diocese. D. at Münster, Nov. 9, 1826. He published *Christkatholisches Handbuch* (1804; 7th ed. 1854); *Katechismus der christkatholischen Lehre* (1804; 24th ed. 1831); *Haussegen* (1807), etc. His *Life* was written by C. F. Krabbe (Münster, 1831; Eng. trans., Derby, 1843). See Josef Galland, *Amalie von Galitzin* (Cologne, 1880). Revised by S. M. Jackson.

Overbury, Sir Thomas: statesman and author; b. at Ilmington, Warwickshire, England, in 1581; educated at Queen's College, Oxford, and graduated 1598; traveled on the Continent; became a resident of Edinburgh 1601, where he was an intimate friend of Robert Carr, afterward Viscount Rochester and Earl of Somerset; was knighted 1608; traveled on the Continent 1609; wrote *Observations upon the State of the Seventeen United Provinces*; incurred the enmity of his former friend, Lord Rochester, and of the Countess of Essex, by his opposition to their criminal intrigues; refused a foreign mission offered him as a means of removing him from the kingdom, and was thereupon thrown into the Tower, where he was cruelly treated, and died Sept. 15, 1613. In 1619 Lord Rochester, then Earl of Somerset, and his countess were convicted of having poisoned Overbury. His popular volume of *Characters* was published posthumously in 1614. Revised by H. A. Beers.

Overreaching: See Farriery.

Overskou, Thomas: dramatist; b. in Copenhagen, Denmark, Oct. 11, 1798. He was first apprenticed to a joiner, but in 1818 took to the stage and played minor parts. His first comedy, *1826* (1826), was a failure, but three dramas, published anonymously (1828), were successfully performed. Of these, *Östergade og Vestergade*, in the style of Sheridan, is his best work. Of his other comedies *Capriciosa* still keeps its place in the repertory of the Royal Theater; but Overskou's most important contribution to literature is *Den danske Skueplads i dens Historie fra dens Begyndelse til vor Tid* (History of the Danish Theater, 7 vols., Copenhagen, 1854–76). D. Nov. 7, 1873. D. K. Dodge.

Overt Act: an open act from which criminal intent is inferred.

Overture [from O. Fr. *overture* (> Fr. *ouverture*), an opening, deriv. of *ovrir*, open]: the name given to the introductory movement, symphony, or elaborate prelude occurring in oratorios, operas, cantatas, and similar compositions. The overture, though complete in itself, is generally so framed as to bring the mind of the hearer into a correspondence of tone and sympathy with the leading traits of the work to which it is prefixed. To effect this it is sometimes sufficient to exhibit in the overture the prevailing sentiment or coloring of the earlier movements (at least) of the work it announces. In other cases the composer ingeniously weaves into the overture some of the leading ideas of the work itself by brief anticipations of its melodies, or anything striking in its modulations, harmonies, or rhythmical forms, thereby predisposing the mind of the hearer to enjoy the recurrence of those points in the after-part of the performance. The introduction of the overture as a distinct and highly wrought species of composition is ascribed to Scarlatti, a Neapolitan of the latter part of the seventeenth century, before whose time its place was occupied by meager preludes or prefatory symphonies, of little account beyond that of an ordinary opening strain. Revised by Dudley Buck.

O'verweg, Adolf: explorer; b. at Hamburg, Germany, July 24, 1822; studied natural science, especially geology, at Bonn and Berlin; joined Barth and Richardson on their explorations of Central Africa in 1850. D. near Lake Tchad, Sept. 27, 1852. His observations, among which was the discovery that the Desert of Sahara is an elevated plateau, and not, as had hitherto been supposed, a depressed plain, were communicated in *Monatsberichte der Gesellschaft für Erdkunde* (Berlin, vols. viii. and ix.), and Petermann's *Zeitschrift für allgemeine Erdkunde* (Gotha, vol. i.).

O'veryssel: a province of the Netherlands, lying between the Zuyder Zee in the W., and Hanover and Westphalia in the E.; area, 1,291 sq. miles. The province is intersected by numerous canals; the soil is mostly light, in many places sandy and covered with heath, in others affording good pasture-grounds. Rye, barley, oats, hemp, potatoes, and buckwheat are raised. Cattle-rearing, digging of turf, and linen manufactures are extensively carried on. Pop. (1899) 333,337. Chief cities, Zwolle, Deventer, and Kampen.

Ovibos: See Musk-ox.

Ovid, or (full Latin name) **Publius Ovidius Naso**: poet; b. Mar. 20, 43 B. C., at Sulmo, in the country of the Pæligni, about 90 miles from Rome, of a rich equestrian family: received an elegant education in the schools of the rhetoricians; traveled afterward in Greece, Asia Minor, and Sicily, and lived then for many years in Rome, idle, frivolous, but brilliant; was intimately connected with Macer and Propertius; acquainted with Horace, moving with freedom and ease in the court circles; admired by all for his wit and his verses, and enjoying, as it seems, to the very dregs, all that could be enjoyed at Rome, until, in the latter part of the year 8 A. D., Augustus suddenly banished him to Tomi. The reason is not known with certainty. Augustus was doubtless offended by the obscenity and immoral tendency of the

Ars Amatoria, but the book had been in free circulation for ten years before this time, and this can not have been more than a pretext. It is more probable that the direct cause was some participation as a confidant in the intrigue of Silanus and Julia, the granddaughter of Augustus, who suffered banishment in the same year with Ovid. At Tomi, a small Getic town on the frontier of the empire, at the delta of the Danube, the fastidious favorite of the metropolis found life intolerable, and month after month sent the most humble supplications to Augustus, but the emperor was immovable, and the poet died in exile in 18 A. D. His works comprise *Heroides*, twenty-one letters from heroines to their lovers, of which fourteen are regarded as genuine; *Amores*, love-elegies, in three books; *Ars Amatoria*, in three books; *Remedia Amoris*; *Metamorphoses*, in fifteen books; *Fasti*, an unfinished poetical commentary on the Roman calendar, in six books; *Tristia*, five books; *Epistolæ ex Ponto*, four books; *Ibis*, a bitter invective directed against an unknown person; *Halieutica*, a fragmentary didactic poem on fishes. The tragedy *Medea* is lost. The most remarkable editions of his collected works are the *editio princeps* (Rome, 1471), that by Heinsius (Leyden, 1629), and that by Burmann (Amsterdam, 1727); recent text editions by Riese (Leipzig, 1871–74), and Merkel and Ehwald (Leipzig, 1888); separate editions, especially of the *Metamorphoses*, are very numerous. Among the translations, likewise very numerous in all modern languages, is one of the *Metamorphoses* by Dryden, Addison, Congreve, and others, edited by Garth. Of all Latin poets Ovid stands nearest to modern civilization, partly on account of his fresh and vivid sense of the beauties of nature—a point in which the Latin literature is generally deficient—partly because his subject is love. His representations of this feeling are often sensuous, but they are graceful and strikingly true. He also excels other Latin poets in the elegance of his form, especially in the character and rhythm of his verses. Revised by M. Warren.

Oviducts: See Fallopian Tubes.

Ovie'do: town of Spain; capital of the province of Oviedo, formerly called Asturias (see map of Spain, ref. 12–D). It is finely laid out, with a large and elegant public square in the center, from which the four main streets lead in opposite directions. It has a beautiful cathedral dating from the eighth century, which contains the remains of fourteen early kings and queens of Asturias; a splendid aqueduct, which provides eleven fountains with abundance of good water; a university (founded in 1574) with a large public library; and manufactures of arms, hats, linen, and leather. In the vicinity are hot springs, which are much used for bathing. Pop. (1887) 42,716.

Oviedo, or **Oviedo y Valdés**, ō-vĕe-ā'dō-ĕe-vaăl-dās', Gonzalo Fernandez, de: historian; b. in Madrid, Spain, in 1478. He was long attached to the Spanish court, witnessed the first return of Columbus 1493, and was intimate with most of the prominent explorers of the New World. In 1514–17 he was with Pedrarias at Darien as a treasury officer; subsequently he was governor of Cartagena, and *alcaide* of the fort at Santo Domingo, and he crossed the Atlantic several times. Appointed royal historiographer he devoted himself especially to the history of America, for which his experience especially fitted him. His principal work is *Historia natural y general de las Indias*, in fifty books. Of these nineteen were published at Seville, 1535, and the twentieth at Valladolid soon after. There were numerous editions and translations of these twenty books, but the first complete edition was published by the Madrid Academy 1851–55. The *Historia* was the first general account of the discoveries in America, and it has remained a standard authority. Oviedo also wrote chronicles of the reigns of Ferdinand and Isabella and Charles V., but these, with his other writings, have never been published. A history of Nicaragua, translated into French from his manuscript, was printed in the Ternaux-Compans collection. D. at Valladolid, 1557. Herbert H. Smith.

Ovip'arous Animals [*oviparous* is from Lat. *ovi'parus*; *o'vum*, egg + *pa'rere*, bring forth]: those animals which bring forth eggs. The term is largely one of convenience, not of strict scientific value, for all animals reproduce by eggs, the difference consisting in the stage of development in which separation from the mother is effected. Strictly speaking, then, oviparous animals are those in which the egg (see Ovum) leaves the maternal body before it has proceeded far in development. In some cases, as in many sharks and snakes, an intermediate condition exists. Here the egg, inclosed in protective membranes, is retained inside of the mother until the young is fully formed, without, however, any intimate (placental) connection existing between parent and offspring. For these forms the term *ovoviviparous* is used. In the contrasted or *viviparous* forms the egg is small, and the young receives nourishment throughout its whole fœtal life from the mother. All mammals, except the Monotremata (which are oviparous), are viviparous.

J. S. Kingsley.

Ovisacs: See Graafian Vesicles.

Ovoca: See Avoca.

O'vule [from Mediæv. Lat. *o'vulum*, dimin. of Lat. *o'vum*, egg]: in botany, a young seed, especially before fertilization. The ovule is morphologically a surface outgrowth, and is to be regarded as a trichome structure, homologous with hairs, scales, prickles, etc. In its earliest stages it is a few-celled mass of cells, projecting above the surface, and having a hemispherical or conical, and later a cylindrical, form, which may remain straight or become somewhat curved upon itself. As it grows a ridge arises upon it encircling it like a collar, and this by extension finally becomes a coat which incloses it. In many plants a second coat forms below (outside of) the first (Fig. 1).

When an ovule has completed the growth of its one or two coats we may then distinguish the stalk (*funiculus*), the integument, and the ovule body (*nucellus*). At the summit of the ovule the integument does not quite close, leaving a minute opening (*micropyle*).

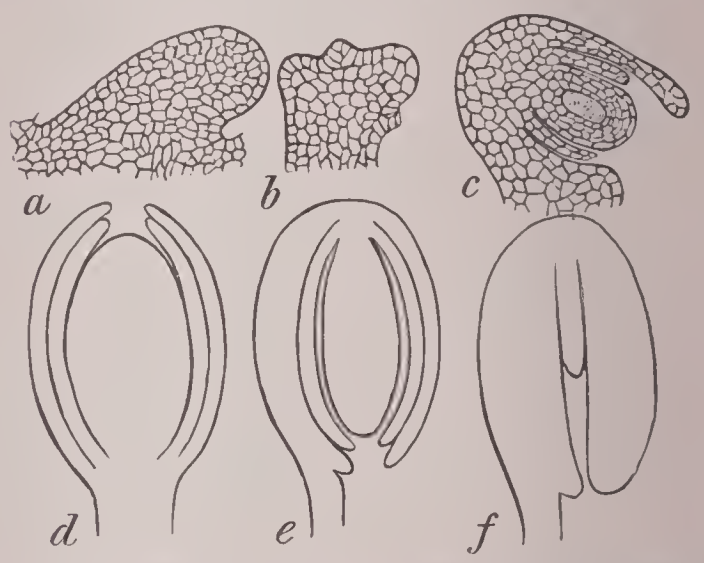

Fig. 1.—*a b c*, development of ovule of evening primrose; *d*, straight (orthotropous) ovule; *e*, inverted (anatropous) ovule; *d e*, with large nucellus, and two coats; *f*, with small nucellus and one thick coat.

In the lower Monocotyledons and Dicotyledons the nucellus is relatively large, but in the higher orders of both sub-classes (Orchidales and most Gamopetalæ) it is relatively very small, consisting of an axial row surrounded by a single layer of cells. The ovules of all, or nearly all, Monocotyledons have two coats, as is the rule with the choripetalous Dicotyledons, while in the Gamopetalæ there is usually but one coat.

Early in the growth of the nucellus an axial cell enlarges (at this stage known as the *archesporium*) and undergoes division, usually into three to four, or rarely into many cells. One of these daughter-cells, commonly the lowermost, enlarges at the expense of the others, and becomes the "embryo-sac." In Gymnosperms the nucleus divides repeatedly, and the daughter-nuclei become the nuclei of cells which are massed together in a rounded or egg-shaped prothallium. In the latter flask-shaped archegones are developed, each of which contains a single germ-cell (oösphere or egg-cell).

In Angiosperms the development of the embryo sac is somewhat different (Fig. 2, *a* to *i*). The primitive nucleus divides, each daughter-cell moving to opposite ends of the cell. Here each divides again, and afterward each couple divides once more, thus giving rise to four nuclei at each end. Now a nucleus from each tetrad moves to the center of the cell, where they unite into a single nucleus, the nucleus of the embryo sac. The nuclei at the base of the sac become invested with protoplasm and soon form a mass of cells, the *endosperm*. In the meantime the upper nuclei also have become surrounded by protoplasm, and two of these cells are elongated and enlarged; these are the synergidæ.

The third nucleus usually lies a little deeper, and with its protoplasm constitutes the germ-cell (oösphere or egg-cell).

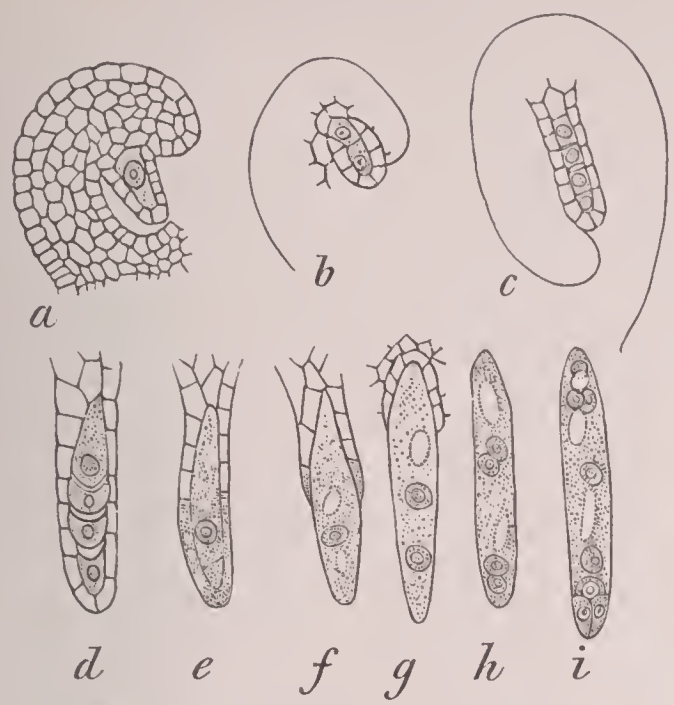

Fig. 2.—Development of the embryo-sac of *Aster* and *Solidago* (after Martin).

After the germ-cell is fertilized (by union with the nucleus of the pollen-tube) it clothes itself with a wall of cellulose, thus constituting the first cell of the new plant. The subsequent development of the embryo belongs to Embryology (*q. v.*). See also Flower. Charles E. Bessey.

Ovum [= Lat., egg]: the female reproductive body in all animals. In its simplest condition it is merely a cell of the body specialized for the purpose of the reproduction of the species, and distinguishable from the other cells chiefly from its larger size. In most forms, however, it has additional features of a nutritive or protective nature. Thus to the protoplasm of the cell there may be added *food-yolk* which is to nourish the germ, and which is frequently so abundant as to render the egg very large. This food-yolk may be variously arranged, and according to its distribution the subsequent development of the egg (see Embryology) is modified. In some cases (e. g. the fresh-water Hydra) protective envelopes are absent. In others they occur, and may be grouped in two categories, primary and secondary. To the first belong the *vitelline membrane*, usually a thin but firm envelope covering the egg and secreted either by the egg or by the tissue in which the egg was formed. This envelope frequently has an opening (*micropyle*) for the entrance of food, and later for the entrance of the impregnating spermatozoön. In some cases, too, the vitelline membrane is perforated by fine tubules, in which case it is called a *zona radiata*. The secondary envelopes are formed by the ducts which convey the egg from the place of its origin (ovary) to the exterior. Of these the most prominent are the shell of the eggs of birds and reptiles, and homologous structures in other forms. The egg as it leaves the ovary is not ready for development; it has first to undergo processes of maturation and impregnation (see Embryology), although in exceptional cases (see Parthenogenesis) the egg may develop without the latter process. The common hen's egg contains not only the essential cell with nucleus and protoplasm, but yolk, membrane, white, and shell. In the hen's egg, as laid, development has proceeded some distance, its products being found in the light spot invariably uppermost on the yolk. See Histology (*Generative Organs*). J. S. Kingsley.

Owatonna: city; capital of Steele co., Minn. (for location, see map of Minnesota, ref. 11–F); on the Straight river, and the Chi. and N. W. and the Chi., Mil. and St. P. railways; 71 miles S. of Minneapolis, 90 miles W. of Winona. It is the seat of Pillsbury Academy (Baptist, chartered in 1877), which in 1894 had six buildings that cost over $300,000, and of the State School for Dependent Children. There are 10 churches, 2 national banks with combined capital of $140,000, electric light, water, and sewerage plants, and 2 weekly newspapers. The city is a trade center for a large section, and has 3 flour-mills and manufactories of churns, seeders, fanning-mills, soap, carriages and wagons, and patent medicines. Pop. (1880) 3,161; (1890) 3,849; (1900) 5,561. Editor of "Journal."

Owego: village; capital of Tioga co., N. Y. (for location, see map of New York, ref. 6–F); on the Susquehanna river, and the Del., Lack. and W., the Erie, and the Lehigh Valley railways; 237 miles W. of New York city. It is in an agricultural region, has a large lumber-trade, and is a popular summer resort. It contains a public library (founded in 1868) with over 5,000 volumes, 3 national banks with combined capital of $250,000, and a daily and 3 weekly papers, and has flour, planing, and woolen mills, foundries, and machine-shops, wagon-works, and other manufactories. Pop. (1890) 5,141; (1900) 5,039. Editor of "Record."

Owen, David Dale, M. D.: geologist; son of Robert Owen, the socialist; b. at New Lanark, Scotland, June 24, 1807; was educated at Hofwyl, Switzerland; went to the U. S. with his father in 1823 to assist him in his social experiment at New Harmony; subsequently studied geology and other natural sciences. In 1837 he made a geological reconnoissance of the State of Indiana; subsequently made an examination of the mineral lands of Iowa, and in 1848 was employed by the Government to take charge of a geological survey of Wisconsin, Iowa, and Minnesota. The results of this survey were published in a quarto volume by Congress in 1852. From 1852 to 1857 he was employed in a geological survey of Kentucky, the results of which were published in four volumes. In 1857 he was appointed State geologist of Arkansas, and the report of his survey was subsequently published in one volume. D. at New Harmony, Ind., Nov. 13, 1860.

Owen, John, D. D.: theologian; b. at Stadham, Oxfordshire, England, in 1616; was educated at Queen's College, Oxford, 1628–37; was an early advocate of the parliamentary cause, and an adversary of Laud's measures; received the living of Fordham, Essex, 1642, which he exchanged for a Presbyterian pastorate at Coggeshall, near by, 1646, where he introduced independent church government. In 1649 he became private chaplain to Oliver Cromwell; in 1651 dean of Christ Church, Oxford; was vice-chancellor of the university 1652–57; was deprived of his deanery 1660, and retired to Stadham; declined a call to Boston, Mass., 1663, and an invitation to become president of Harvard College in 1670; removed to London in 1673; thence, after his second marriage, 1677, to his wife's estate at Ealing, Middlesex, where he died Aug. 24, 1683. He was a man of great piety, learning, and magnanimity, the author of more than eighty theological works, doctrinal, practical, and polemical. His *Exposition of the Epistle to the Hebrews* (1668–84) is his chief work. Though a zealous opponent of Arminianism, Presbyterianism, Episcopacy, and papacy, all parties held him in high esteem. His works, in W. H. Goold's edition (Edinburgh, 1850–55), occupy 24 vols. 8vo; reprinted in Philadelphia (17 vols., 1865–69). See his *Life* by W. Orme (London, 1820). Revised by S. M. Jackson.

Owen, John Jason, D. D., LL. D.: teacher and author; b. at Colebrook, Conn., Aug. 13, 1803; graduated at Middlebury College, Vt., in 1829, and at the Theological Seminary, Andover, Mass., in 1831; entered the Presbyterian ministry in 1832; became in 1836 president of Cornelius Institute, New York; Professor of Latin and Greek in the New York Free Academy 1848, and its vice-principal in 1853; vice-president of the College of the City of New York 1866; prepared editions, with notes, of Xenophon's *Anabasis* (1843); Homer's *Odyssey* (1844); of the *Cyropædia* (1846); of *Thucydides* (1848); of the *Iliad* (1851); the text of the Acts of the Apostles, with notes (1850); a Greek reader (1852); a *Commentary on the Gospels* (3 vols., 1857, *seq.*). D. in New York city, Apr. 18, 1869.

Owen, Sir Richard, K. C. B., F. R. S., LL. D., D. C. L., etc.: comparative anatomist and palæontologist; b. at Lancaster, England, July 20, 1804; served for a time in the navy; studied medicine at Edinburgh and St. Bartholomew's, London; succeeded Sir Charles Bell as Hunterian professor in the Royal College of Surgeons in 1836; became superintendent of the natural history department of the British Museum in 1855, and retired in 1884. He was Fullerian professor in the Royal Institution, a member of many learned societies, and the recipient of many honors. Owen succeeded Cuvier as the leading vertebrate palæontologist of the world. His most important general works are *Lectures on the Comparative Anatomy and Physiology of Invertebrate Animals* (1843); *Lectures on the Comparative Anatomy and Physiol-*

ogy of Vertebrate Animals (1846); *Odontography* (1840–45); *On the Archetypes and Homologies of the Vertebrate System* (1848); *On the Nature of Limbs* (1849); *Palæontology* (1861). He was also a voluminous contributor to the memoirs of scientific societies. D. at Richmond Park, Surrey, Dec. 18, 1892. Revised by G. K. Gilbert.

Owen, Robert: social reformer; b. at Newtown, Montgomeryshire, North Wales, Mar. 14, 1771; the son of poor parents, was forced to earn his own living while still a boy, but was very successful in business, and at the age of eighteen became a partner in a cotton-mill. He induced his firm to buy the cotton-mills of New Lanark, Scotland, where he put into effect a co-operative scheme for the benefit of his employees. It worked well at first, and New Lanark became famous for the prosperity of its inhabitants. He then directed his attention to social questions on a broader scale, publishing in 1812 *New Views of Society, or Essays upon the Formation of the Human Character*, and subsequently *Book of the New Moral World*, in which he advocated doctrines of human equality and the abolition of class distinctions. Having won a large fortune in his business, he was able to give these works and various tracts embodying his views a wide circulation. The Duke of Kent became his patron, and his followers were numerous. His religious views exposed him to much obloquy and a bitter opposition, and after the death of his patron he went to the U. S. in 1823 and founded at his own expense a communist society at New Harmony, Ind. The scheme proving a failure, he returned to England, where he tried several similar experiments with the same result. He also failed in an attempt to establish a "labor exchange" in London. In 1828, by invitation of the Government of Mexico, he went to that country in the hope of carrying out his socialistic schemes, but was disappointed. In spite of his failures he was universally esteemed for his integrity and benevolence. His later years were spent in efforts to promote a religion of reason and to improve the condition of the working-classes, and in his old age he became a believer in Spiritualism. D. at Newtown, Nov. 19, 1858. His followers bore the name of Owenites, and were among the founders of the English Chartist movement. Revised by F. M. Colby.

Owen, Robert Dale, LL. D.: author; eldest son of Robert Owen; b. in Glasgow, Scotland, Nov. 7, 1801; educated at Fellenberg's College, near Berne, Switzerland; removed to the U. S. with his father in 1823, and assisted him in his efforts to found the colony of New Harmony, Ind. On the failure of that experiment he visited France and England, but returned to the U. S. in 1827 and became a citizen; he settled in New Harmony, Ind., where for three successive years (1835–38) he was elected a member of the Legislature. From 1843 to 1847 he represented the first district of Indiana in Congress, acting with the Democratic party; took an active part in the settlement of the northwestern boundary question; introduced the bill organizing the Smithsonian Institution, and served for a time as one of the regents. It was through his efforts that Indiana conferred independent property rights upon women. He was minister to Naples 1855–58. During the civil war in the U. S. he was an earnest advocate of the policy of emancipating the slaves, and his letters on that subject to the President and the members of the cabinet were widely read. His chief works are *Outlines of the System of Education at New Lanark* (Glasgow, 1824); *Moral Physiology* (New York, 1831); *Discussion with Origen Bachelor on the Personality of God and the Authenticity of the Bible* (New York, 1832); *Pocahontas*, an historical drama (New York, 1837); *Hints on Public Architecture*, illustrated (New York, 1849); *Footfalls on the Boundary of Another World* (Philadelphia, 1860); *The Wrong of Slavery and the Right of Freedom* (Philadelphia, 1864); *Beyond the Breakers*, a novel (Philadelphia, 1870); *The Debatable Land between this World and the Next* (New York, 1872); *Treading my Way*, an autobiography (New York, 1874). Mr. Owen received the degree of LL. D. from the University of Indiana in 1872. D. at Lake George, N. Y., June 24, 1877.

Owens, John Edward: comedian; b. in Liverpool, England, May 4, 1824; was taken by his father to the U. S. in 1834. He was educated in Philadelphia, and for some time employed there in business. On Aug. 20, 1846, he made his *début* in the Masonic Hall, Philadelphia, and immediately gained the interest and sympathy of the public by a peculiar blending of humor and pathos. In 1849 he was manager of the Baltimore museum, in 1854 of the Charles Street theater of Baltimore, in 1859 of the Varieties theater of New Orleans. In 1852 he made his first tour in England. His two greatest creations were probably *Solon Shingle* (first played at the opening of the Adelphi theater in London, 1865) and *John Unit* (first played in New York in 1869). In 1882 he accepted an engagement with the New York Madison Square Company, and played in *Esmeralda* in many of the larger cities of the U. S. His declining health during his last few years caused him to retire from the stage. D. near Towson, Md., Dec. 6, 1886. Revised by B. B. Vallentine.

Owensboro: city; capital of Daviess co., Ky. (for location, see map of Kentucky, ref. 3–E); on the Ohio river, and the Louisv. and Nashv. and the Louisv., St. L. and Tex. railways; 40 miles S. E. of Evansville, Ind., 150 miles S. W. of Louisville. It is in the center of the Kentucky and Indiana coal-fields, and in an agricultural, tobacco, timber, building-stone, and brick-clay region; has an elevated site, and is connected with several important places on the river by a line of packets. The city contains 18 churches, a high school, and 4 ward schools, public-school property valued at $85,000, a female college, a public-school library (founded in 1886), a U. S. Government building that cost $50,000, 2 national banks with combined capital of $185,000, 6 State banks (capital of 5 reported $592,500), an incorporated bank with capital of $100,000, and 2 daily and 6 weekly newspapers. The tobacco industry has 23 factories and stemmeries, in which 2,000 persons are employed and 18,000,000 lb. of tobacco handled annually, and the whisky industry has in the city and its vicinity 14 distilleries, operated on a capital of $1,500,000, and yielding sourmash whisky to the value of $5,500,000 annually. There are 4 planing and 3 flour mills, steam-shingle mill, 2 foundries and machine-shops, several brickyards, and ice, sewer-pipe, furniture, and cigar factories. Pop. (1880) 6,231; (1890) 9,837; (1900) 13,189. Editor of "Inquirer."

Owen Sound: port of entry and capital of Grey co., Ontario, Canada; at the head of Owen Sound (a part of Lake Huron); 45 miles W. N. W. of Collingwood (see map of Ontario, ref. 3–C). It has a good water-power, several lumber-mills, foundries, etc. There is a good trade in lumber and grain. Pop. (1891) 7,497.

Owens River: a stream which rises in Southeastern California, S. of Mono Lake; flows southward through a desert valley bordered by lofty and exceedingly rugged mountains for a distance of about 100 miles, and empties into Owens Lake. Like most desert streams, it varies greatly in volume with the seasons, and many of its branches are dry during the summer. Owens Lake, in the western part of Inyo co., Cal., is 18 miles long and 10 miles wide. It is without outlet, and is highly charged with saline matter.

I. C. Russell.

The eagle owl.

Owl [O. Eng. *ūle*: O. H. Germ. *ūwila* < Germ. *eule*]: a general name for the birds of prey of the order *Striges*, most of which are nocturnal in their habits, although a few, like the snowy and hawk owls, hunt by day. They appear strongly built (but this is largely due to their long feathers), have large heads and large eyes, directed forward and surrounded by a circle of radiating feathers. The plumage is soft, flight noiseless, and sense of hearing acute. There are some 200 species of owls distributed throughout the world. They range in size from the great eagle owl (*Bubo maximus*) of Europe and Asia, over 2 feet long, to

the little gnome-owls (*Glaucidium*) of South America, some of which are less than 6 inches in length. Owls breed in old buildings, holes in rocks, and most of all in hollow trees. The smooth, white eggs are from two to four in number. A few exceptional species eat fish, but birds, and especially small rodents, form the chief food of owls. They are of more service to the farmer than any other bird.

F. A. Lucas.

Owl-parrot, or **Kakapo**: a peculiar parrot (*Stringops habroptilus*) restricted to the forests of New Zealand, so called from its owl-like appearance and nocturnal habits. It is a little over 2 feet in length, heavily built, of a sap-green color mottled with brown and yellow. The bird is flightless, for while the wings are of moderate size there is no keel to the sternum, and the breast muscles are small and overlaid with fat. The kakapo climbs low trees, but passes most of its time on the ground, feeds largely on mosses, and lives in holes or fissures in the rocks. Since the introduction of dogs it has diminished in numbers.

F. A. Lucas.

Ownership: See Property.

Owosso: city; Shiawassee co., Mich. (for location, see map of Michigan, ref. 7–J); on the Shiawassee river, and the Detroit, Gr. Haven and Mil., the Mich. Cent., and the Toledo, Ann Arb. and N. Mich. railways; 25 miles N. E. of Lansing, 78 miles N. W. of Detroit. It derives power for manufacturing from the river; is connected with Corunna, the county-seat, by a street-railway; and contains gas and electric light plants, water-works, graded public schools, 2 libraries (Ladies' and Y. M. C. A.), an incorporated bank with capital of $100,000, a private bank, a daily and 5 weekly newspapers, and sash, door, and blind, furniture, casket, tool, cart, and other factories. Pop. (1880) 2,501; (1890) 6,564; (1900) 8,696. Editor of "Reporter."

Ox: See Cattle and Musk-ox.

Oxalates: See Oxalic Acid.

Oxalic Acid [*oxalic* is deriv. of *Oxalis*, name of a botanical genus in which the acid occurs]: an acid consisting of carbon, hydrogen, and oxygen combined in certain proportions. Salt of sorrel, which is an acid potassium oxalate, has for a period unknown been procured in Germany from certain species of oxalis and rumex. Savary first obtained oxalic acid from it in 1773 by sublimation. Scheele afterward obtained it from the same source by precipitation as oxalate of lead and subsequent decomposition of this. This latter chemist also first proved that the acid previously known as prepared by the action of nitric acid on sugar is oxalic acid. Besides the plants above mentioned there are sea-shore plants, *Salsola* and *Salicornia*, which contain it as sodium oxalate. It is found as insoluble calcium oxalate in a great number and variety of plants, and in certain morbid conditions this latter salt is formed largely in the animal body, passing off by the urine, and forming what is called the "mulberry calculus" in the bladder.

All the oxalic acid of commerce is prepared by artificial processes, of which two are in common use: 1. By the action of nitric acid on sugar, starch, or molasses. 2. By fusing a hydrate of an alkali with starch or cellulose. Sawdust is generally used. Potassium hydrate gives more than sodium, and two of potassium to one of sodium hydrate gives still more. In the latter case, when the product is treated with a strong solution of sodium carbonate, potassium carbonate dissolves and sodium oxalate, by virtue of its low solubility, remains behind. From this oxalic acid is readily prepared. When required *pure* for chemical purposes it is sublimed. Great care must be taken in this case not to inhale the vapor, which is highly dangerous. The commercial crystallized acid has the composition $C_2H_2O_4 + 2H_2O$. When heated, it first loses water and becomes $C_2H_2O_4$. By further heating this breaks down, yielding water, carbon monoxide, CO, and carbon dioxide, CO_2. It dissolves in about nine parts of cold and one part of boiling water. When to its solution or that of an oxalate a lime-solution is added, there is thrown down calcium oxalate, an exceedingly insoluble substance, and for lime in solution it is the most delicate test. Except in very weak solutions, it is an exceedingly dangerous, fatal, and rapid poison, and its universal sale in shops and common use in households are greatly to be reprehended. It has been known to produce death in ten minutes, preceded by horrible agonies. It is used in the arts for cleaning leather, for discharging colors in calico-printing, and in scouring metals. For the latter purpose, cleaning brass and copper, it is now much used in households, as well as for removing ink-stains from fabrics. The greatest care should be exercised that it be not mistaken for Epsom salt, which it almost exactly resembles in appearance.

Oxalates.—These are compounds formed by the action of oxalic acid on bases. "Salt of sorrel" is a mixture of the acid potassium salt, KHC_2O_4, and another acid potassium salt of the formula $KH.C_2O_4.C_2H_2O_4 + 2H_2O$.—*Calcium oxalate*, $CaC_2O_4 + H_2O$, is very difficultly soluble in water, and is used for the purpose of detecting calcium. Calcium oxalate is found in nature in the tissues and cells of plants.—An oxalate of iron occurs in the mineral humboldtine, in brown coal.

Revised by Ira Remsen.

Ox'alis [Mod. Lat., from Lat. *o'xalis* = Gr. *ὀξαλίς*, a kind of sorrel, deriv. of *ὀξύς*, sharp, pungent]: a genus of dicotyledonous plants, commonly known as wood-sorrel, and belonging to the Geranium Family (*q. v.*). The sepals and petals are five each, the stamens are ten, in two alternating whorls, and the pistil is composed of five united carpels. The leaves are compound, usually palmately three-foliate, sometimes four-foliate, or even pinnately many-foliate. The species (205) are mostly natives of the sub-tropical regions N. and S. of the equator. A few are natives of Europe (two or three) and North America (fourteen or fifteen); among the latter are the common wood-sorrel (*O. acetosella*), violet wood-sorrel (*O. violacea*), yellow wood-sorrel (*O. corniculata*, var. *stricta*). Many species are cultivated in greenhouses for their fine foliage and pretty flowers. Among these are *O. bowiei*, *O. cernua*, *O. hirta*, and *O. variabilis* from the Cape of Good Hope; *O. crenata*, *O. rosea*, and *O. valdiviensis* from South America; and the curious *O. tetraphylla* from Mexico. Charles E. Bessey.

Oxalu'ria [Mod. Lat.; *oxal-ic* + Gr. *οὖρον*, urine]: a morbid condition of the general system which favors the excessive excretion of oxalic acid by the kidneys. It is also known as the *oxalic acid diathesis*. Theories of the nature of this disorder have varied widely in the past, but it is now pretty generally conceded that oxaluria is merely a symptom of disordered metabolism—that is, the oxalic acid in the urine results from improper transformation of food or tissue elements in the processes of nutrition. This faulty metabolism is very closely allied to that which causes increase of uric acid in the blood and urine, and which constitutes the disease *gout*. Indeed oxaluria in a majority of instances is probably an expression of aberrant gout. It may, however, occur in a variety of affections, such as neurasthenia, anæmia, phthisis, and others, not at all similar to gout. The mere presence of the oxalate of lime in the urine, even in large quantities, must not be taken as sufficient to establish the diagnosis; for after a diet including rhubarb, cranberries, and other vegetables, oxalates are quite naturally present in the urine. The constant excretion of large quantities of oxalic acid in the urine is, however, highly significant. In such cases a characteristic train of symptoms is usually noted, such as emaciation, nervousness, painful susceptibility to external impressions, and hypochondriasis. The patients are incapable of exerting themselves in the least without suffering from fatigue; they are irritable and easily excited. A prominent symptom is a severe and constant pain or sense of weight across the loins. It will be noted that these symptoms are largely of a dyspeptic type. In typical cases of oxaluria of gouty origin we rarely fail to find these symptoms, and especially the nervous and melancholic tendency, but oxaluria may exist and go on to the formation of concretions of oxalate of lime in the kidney without any symptoms at all. Oxalate of lime occurs in the urine in the form of minute octohedral or dumb-bell-shaped crystals, varying in size from a ten-thousandth to a thousandth of an inch in diameter. The formation of oxalic acid in the blood is occasioned by the malassimilation of certain articles of diet, but in exactly what manner has not yet been determined by physiologists. Sugar and all saccharine or starchy matters should be avoided as much as possible, because, as in lithæmia, the readily oxidizable sugars and starches consume all available oxygen and interfere with albuminous transformation. Attention should be paid to the general health, and particularly to the digestive organs. As medicines, the mineral acids, given either alone or combined with tonics, are the favorite remedies.

Revised by William Pepper.

Oxbird: See Dunlin.

Ox'enden, Ashton, D. D.: bishop; b. at Broome Parke, near Canterbury, England, in 1808; educated at University

College, London; was rector of Pluckly-with-Pevington, Kent, 1848–69; became honorary canon of Canterbury Cathedral 1864, and Bishop of Montreal, primate, and metropolitan of Canada 1869; resigned his bishopric in Apr., 1878, feeling himself no longer equal to the fatigues of his diocese, but was instituted to the vicarage of St. Stephen, near Canterbury, in May, 1879. He has published *Decision*; *Prayers for Private Use*; *Sermons on the Christian Life*; *God's Message to the Poor*; *A Plain History of the Christian Church*; *The Pathway of Safety*; *Baptism simply Explained*; *The Lord's Supper simply Explained*; *Lectures on the Gospel*; *The Pastoral Office*; *Fervent Prayer*; *The Barham Tracts*, etc. His writings have had a very large circulation both in Great Britain and in the U. S.

Revised by W. S. Perry.

Oxenford, John: playwright and translator; b. at Camberwell, London, England, in 1812; was called to the bar 1833; was many years theatrical critic for the London *Times*; wrote several dramas and songs, and translated a number of German poems and prose works. Among his works for the stage are *My Fellow-clerk* (1835); *Twice Killed* (1835); *A Day well Spent* (1836); *Porter's Knot* (1869), etc. Among his translations are *Autobiography by Goethe*; *Conversations of Eckermann with Goethe*; and Kuno Fischer's *Essay on Lord Bacon and his Philosophy*. D. in London, Feb. 22, 1877. Revised by H. A. Beers.

Oxenham, Henry Nutcombe: theologian; b. at Harrow, Middlesex, England, Nov. 15, 1829; was educated in the school of his native town and in Baliol College, Oxford; studied theology; became curate of Downinghall, Bucks, in 1854, of St. Bartholomew's, Cripplegate, London, in 1856; joined the Roman Catholic Church in 1857, and was for a time a member of the London Oratory, afterward successively professor of St. Edmund's College, Ware, and master at the Oratory school, Birmingham. D. Mar. 23, 1888. Among his works were *Poems* (1854; 3d ed. 1871); *Church Parties* (1857); *Catholic Doctrine of the Atonement* (1865; 3d revised and enlarged ed. 1881); *Letter to Father Lockhart on Dr. Pusey's Eirenicon* (1866; 2d ed. 1871); *Catholic Eschatology and Universalism: an Essay on the Doctrine of Future Retribution* (1876; 2d ed. 1878); *Eirenicon of the Eighteenth Century*, with introduction, notes, and appendices (1879); *Short Studies, Ethical and Religious* (1888); besides translations of various works by Döllinger, Hefele, and others. Revised by W. S. Perry.

Oxenstjerna, ox'*e*n-sher-nää, Axel, Count: statesman; b. at Fånö, Upland, Sweden, June 16, 1583; studied theology and jurisprudence at Rostock, Jena, and Wittenberg, and was employed, after his return to Sweden in 1602, by Charles IX. in several important diplomatic negotiations, which he carried through with great sagacity and dignity. On the accession of Gustavus Adolphus in 1611 he was made chancellor of Sweden, and as such he negotiated the Peace of Knäröd with Denmark in 1613 and of Stolbowa with Russia in 1617, and the armistice with Poland in 1629, and accompanied Gustavus Adolphus during his campaigns in Germany, taking charge of all diplomatic affairs. After the fall of Gustavus Adolphus at Lützen in 1632 he was empowered by the Swedish representatives to continue the war, and at the congress of Heilbronn in 1633 the Protestant princes chose him head of the league against the emperor. He concluded an alliance with Holland and France, and returned in 1636 to Sweden as chief of the government during the minority of Gustavus Adolphus's daughter Christina. When she became of age in 1644 his influence decreased, and when she abdicated he retired altogether into private life. He died in Stockholm, Aug. 28, 1654. The second part of *Historia Belli Sueco-Germanici*, of which Chemnitz wrote the first part, is generally ascribed to Oxenstjerna, who was an accomplished scholar.

Revised by R. B. Anderson.

Oxford: an old and famous city of England, the capital of Oxfordshire. It is situated 52 miles W. N. W. (63 by rail) of London, on the Thames (here called the Isis), near its junction with the Cherwell, among rich and beautiful surroundings, and contains a great number of splendid edifices (see map of England, ref. 11–I). Its trade and manufactures are comparatively insignificant; it is as a seat of learning it has acquired its fame, its university being the oldest and most celebrated institution of the kind in the United Kingdom. (See Oxford University.) It is also the seat of a bishopric, and it returns one member to Parliament. Pop. (1891) 45,741; (1901) 49,413.

Oxford: city (laid out in 1836, burned down during the war of 1861–65); capital of Lafayette co., Miss. (for location, see map of Mississippi, ref. 4–G); on the Illinois Central Railroad; 73 miles S. E. of Memphis, Tenn., 157 miles N. by E. of Jackson. It is the seat of the University of Mississippi (*q. v.*), of Union Female College (Cumberland Presbyterian, chartered in 1854), and of Warren Female Institute (Baptist, opened in 1866); and contains 5 large brick church buildings for white people and 3 frame ones for colored, graded school building that cost $15,000, U. S. Government building, 2 State banks with combined capital of $110,000, and 2 weekly newspapers. The industrial works include a cotton mill and gin, cotton-compress, planing-mill, and a canning-factory. Pop. (1880) 1,534; (1890) 1,546; (1900) 1,825. Editor of "Weekly Eagle."

Oxford: town; capital of Granville co., N. C. (for location, see map of North Carolina, ref. 2–G); on the Southern Railway; 46 miles N. of Raleigh. It is in a grain and tobacco growing region, has several large tobacco warehouses and manufactories, and contains an orphan asylum, a private bank, and two weekly periodicals. Pop. (1880) 1,349; (1890) 2,907; (1900) 2,059.

Oxford: village; Butler co., O. (for location, see map of Ohio, ref. 6–B); on the Cin., Hamilton and Dayton Railroad; 39 miles N. W. of Cincinnati. It is the seat of Miami University (*q. v.*), of Oxford College, and of Western Female Seminary, and has a national bank with capital of $50,000, and 2 daily papers and 2 monthly periodicals. Pop. (1880) 1,743; (1890) 1,922; (1900) 2,009. Editor of "News."

Oxford; borough: Chester co., Pa. (for location, see map of Pennsylvania, ref. 6–I); on the Lancaster, Ox. and South. and the Phila., Wil. and Balto. railways; 28 miles W. of Wilmington, Del., about midway between Philadelphia and Baltimore. It is in an agricultural region; contains 8 churches, 3 schools, public library, water-works supplied from artesian wells, electric lights, 2 national banks with combined capital of $200,000, a private bank, and a weekly newspaper; and has a flour-mill and candy and carriage factories. It is the seat of Oxford Academy (Presbyterian), and Lincoln University (Presbyterian) for colored students is 3½ miles N. E. of the borough. Pop. (1880) 1,502; (1890) 1,711; (1900) 2,032. Editor of "Press."

Oxford, Robert Harley, Earl of: statesman; b. in London, England, Dec. 5, 1661; raised a cavalry regiment for the service of the Prince of Orange 1688; entered Parliament 1690 as an extreme Whig, but gradually changed his political views until they reached the opposite extreme of Toryism; was chosen speaker Feb., 1701; re-elected in the two succeeding Parliaments; was made chief Secretary of State 1704, chiefly through the influence of Miss Abigail Hill (afterward Lady Masham) with Queen Anne; was made Chancellor of the Exchequer Aug., 1710; was stabbed at the council board by the Marquis of Guiscard, a Frenchman, Mar. 12, 1711, to which event he owed a new lease of public and royal favor; was created Earl of Oxford and Mortimer May 24, and Lord High Treasurer May 29 of the same year; enjoyed from this time very great power, having completely supplanted Marlborough in the queen's favor, and consolidated his own popularity by the Peace of Utrecht, Apr., 1713, but was in turn supplanted by Bolingbroke and dismissed July 27, 1714. Regarded with distrust by George I., he was impeached of high treason by Parliament Aug., 1715; committed to the Tower; acquitted June, 1717; lived thenceforth in retirement; accumulated immense collections of books and manuscripts (see Harleian Collection), and was author of some pamphlets of little merit. D. in London, May 21, 1724.

Oxford Movement: See Tractarianism.

Oxfordshire: an inland county of England, bordering S. on the Thames, and on the other sides on Bucks, Gloucestershire, Warwickshire, and Northamptonshire. Area, 755 sq. miles. The surface is mostly level, but undulating in the southern part, where a branch of the Chiltern Hills rises to a height of nearly 700 feet. The county is watered by several streams, including the Windrush, Evenlode, Cherwell, and Thame, which are affluents of the Thames. The soil is a mixture of gravel and loam, and very fertile. Agriculture and dairy-farming are in an advanced state. Wheat, barley, turnips, butter, and cheese are produced in large quantities. Ironstone is worked near Banbury, while blankets are manufactured at Witney, and paper at Henley and Shiplake. Pop. (1901) 137,118. Principal town, Oxford.

Oxford University: an institution of learning at Oxford, England. The first fairly authenticated notice of Oxford as a seat of learning dates from the time of Edward the Confessor. The first charter was granted to the university by John; in 1201, according to Anthony Wood, the university numbered within its walls 3,000 students. Later on, in the time of Henry III., Wood states that there were 30,000 students at Oxford; "but among these a company of varlets, who pretended to be scholars, shuffled themselves in, and did act much villainy by thieving, whoring, quarrelling, etc." The distinguishing characteristic of the Universities of Oxford and Cambridge is the existence of a number of separate corporations or colleges. There have been colleges at many universities, but nowhere have they ever reached anything like the same influence and importance as at Oxford and Cambridge. The origin of the colleges was due to benevolent persons who desired to relieve a certain number of poor scholars from some of the hardships of their life at the mediæval universities, and in order to do this provided a building in which such scholars could live a common life, and also an endowment for their maintenance. From Henry III.'s time date the foundations of three colleges—University (1249), erected on the site of a much earlier foundation; Baliol (1263), Merton (1270). In the time of Richard II. many members of the university warmly espoused the doctrines of Wyckliff, and in the persecutions that followed on this avowal many of the colleges were thinned, some, indeed, being quite deserted for a short time. The university found a generous patron in Richard III., who, among other bounties, granted the privilege to the university of importing or exporting books at will. During the reign of Edward VI. royal commissioners were appointed, with full powers to examine the affairs of the university. In consequence, the form of government in the university was completely altered; but in the next reign the old order of things was re-established. Queen Elizabeth's reign is remarkable in the history of Oxford University for the foundation by Sir Thomas Bodley of the Bodleian Library, and for the passing of the act which confirmed the university as a corporate body; also Jesus College was established in this reign. Shortly after the succession of James I. the two universities had the privilege granted of sending each two members to Parliament. During the troublous times of Charles I. the university sided throughout with the king, and suffered severely in consequence. In 1650 Cromwell was elected chancellor of the university, when several of the more obnoxious among the royalists were removed, to be reinstated at the Restoration. Under the tyranny of James II. the university came violently into collision with the crown; on the refusal of Magdalen College to receive a president forced upon it by the king all the members of that college, with the exception of two, were expelled. However, at the approach of William of Orange they were reinstated by the tyrant. From this period the university has proceeded on an even course.

Following is a list of the colleges, with statistics for 1900:

Founded.	COLLEGES.	Income from endowments.	Contributed to University	Undergraduates.	Members of convocation.
1437	All Souls	£14,995	£4.400	4	87
1262	Baliol	6,845	168	252	428
1509	Brasenose	10,786	968	131	325
1532	Christ Church	22,616	3,037	313	744
1516	Corpus	10,095	1,819	84	228
1314	Exeter	3,683	80	174	537
1874	Hertford	.....	17	100	145
1571	Jesus	10,795	628	123	134
1869	Keble	... ..	.....	223	208
1427	Lincoln	4,816	.....	85	183
1456	Magdalen	27,846	4,500	172	313
1270	Merton	12,676	2,631	140	255
1386	New College	19,653	1,778	200	353
1326	Oriel	7,533	813	140	227
1624	Pembroke	3,928	52	85	180
1340	Queen's	16,518	312	109	268
1555	St. John's	16,499	627	158	331
1554	Trinity	4,821	385	191	332
1249	University	6,276	150	185	307

The highest officer in the university is the chancellor; the election is determined by the members in convocation, and the office is held for life. For the last 200 years it has been the custom to elect some distinguished nobleman who has been educated at Oxford; the Marquis of Salisbury is the present chancellor. There is no stipend attached to this office. The chancellor's deputy, the vice-chancellor, is nominated by the chancellor from among the heads of colleges; the office is held for four years, and is endowed with a salary of £600 a year. To assist the chancellor and vice-chancellor two other officers are appointed—the high steward and deputy steward. The appointments are at the disposal of the chancellor, subject to the approval of convocation. The business of the university is transacted in two separate assemblies—the house of congregation and the house of convocation. In the former the business is confined to granting ordinary degrees and confirming the nomination of examiners made by the vice-chancellor and the proctors. All other business is conducted in the house of convocation. To facilitate the ordinary legislation of the university there meets every week during term time the hebdomadal council, composed of the heads of colleges and others. Not the least important among the university officers are the proctors. The business of these gentlemen is to guard against any breach of discipline on the part of members of the university. The proctors are two in number, and are assisted by four pro-proctors. Both proctors and pro-proctors must have attained the standing of master of arts, the former for at least four years previous to election.

Before entering the university a preliminary examination, the matriculation, must be undergone, varying in difficulty according to the status of the college. Shortly after entering the student is confronted by responsions, the first public examination; for this a slight knowledge of classics and mathematics is required. In order to get a degree the student must have resided at least twelve continuous terms at the university, and must have passed the necessary examinations. The study of ancient literature, history, and philosophy—*literæ humaniores*—is the study most largely encouraged at Oxford; the degree is usually acquired in the classical schools. There are also schools in modern history, civil law, and theology, in which the examinations are usually attended by men who have passed through the classical schools. For those who go to study mathematics, natural science, etc., there are also schools in those subjects. Attached to each college are fellowships and scholarships, awarded in most cases by open competition. Until lately fellowships were nearly all clerical, but now, to a great extent, restrictions have been removed, and the fellowships are thrown open to the whole university as they become vacant. In most colleges the fellowships are held for life, so long as the holder remains unmarried; but a sensible change is now largely adopted by making the fellowships tenable for ten years, whether the holders choose to marry or not. Scholarships are awarded after competition to undergraduates who have not exceeded a certain number of terms from matriculation, and to young men entering the university; there is in most colleges a limit of age. The value of the scholarships is about £80 or £100 a year, tenable for five years. Instruction is conducted mainly by the college tutors; lectures are also delivered by the university professors. The university year is divided into four terms—Michaelmas, Hilary, Easter, and Trinity. The intervals between terms are short, with the exception of the long vacation, which lasts from the first or second week in June to Oct. 10. *Oxford and her Colleges*, by Goldwin Smith (New York, 1894), is a delightful sketch of the university. See also *Historical Register of the University of Oxford* (1888).

Revised by C. H. THURBER.

Ox-gall: the bile of the domestic ox (*fel bovinum*). It is used in the arts in scouring wool, since into its complicated composition there enters abundance of soda, which gives it a soapy quality. When properly refined from its coagulable and coloring matters it is used by artists in mixing colors, which it often improves in tint, while it fixes them and makes them flow better. It is also used in some kinds of artists' varnish and in cleansing ivory tablets for artists' use. In medicine it is sometimes given when a deficiency of bile is suspected to exist, to aid digestion of fats in the small bowel; in enemata it is believed to dissolve scybalous masses, and as an external application some practitioners consider it powerfully discutient. Revised by H. A. HARE.

Oxides: See OXYGEN.

Oxley, James Macdonald, LL. B.: author; b. in Halifax, Nova Scotia, Oct. 22, 1855; educated at Dalhousie, Halifax, and Harvard Universities; was admitted to the bar, and practiced from 1877 till 1883, when he was appointed legal adviser to the Marine Department, Ottawa. He resigned this office in 1891, and engaged in the life-insurance business in Ottawa, and in 1892 in Montreal. Many of his books have been republished in England. Among his published works are *Nova Scotia Decisions* (3 vols., Halifax, 1880–83); *Young's Admiralty Decision* (Toronto, 1882); *Bert Lloyd's Boyhood* (Philadelphia, 1889); *Up among the Ice Floes* (1890); *The Chore-boy of Camp Kippeway* (1891); *Donald Grant's Development* (1892); *Fergus MacTavish* (1892); *The Good Ship Gryphon* (1893); *In the Swing of the Sea* (1897). Neil Macdonald.

Oxlip: See Primrose.

Oxpecker: See Beef-eater.

Oxus, Amoo′, or **Amu**, also called **Amoo Darya** (anc. *Oxus*; Arab. *Gihon*): a river of Western Asia, which rises on the Belur Tagh, nearly 15,000 feet above the level of the sea; receives many affluents from the mountains of Turkestan and the Hindu Kush, flows through Turkestan, and falls into the Aral Sea. The length of its course is 1,610 miles. According to the treaty of peace concluded in July, 1873, between Russia and Khiva, this river became the permanent boundary-line between Khiva and Bokhara.

Oxychlo′rides, sometimes called **Basic Chlorides**: a class of compounds sometimes formed by the direct action of an oxide of a metal upon the chloride of the same metal, as in the cases of lime, magnesia, zinc, etc. In the latter two cases important cements are founded upon the formation of such oxychlorides. Other classes of oxychlorides are formed by the partial decomposing action of water upon the chlorides of some metals, acting by removing a portion of the acid, as in the cases of antimony and bismuth. There are some native mineral oxychlorides, as atacamite and tallingite, oxychlorides of copper, and matlockite and mendipite, oxychlorides of lead. Other elements besides the metals form oxychlorides, such as silicon, carbon, sulphur, selenium, nitrogen, phosphorus. Oxychloride of phosphorus, $POCl_3$, is a compound of considerable interest.

Oxygen [Gr. *ὀξύς*, sharp, acid + *-gen* of Gr. *γεννᾶν*, and Lat. *genera're*, produce]: the most abundant of all the elements existing in the earth.

Name.—The word oxygen was applied by Lavoisier to represent the generalization which he had arrived at, and which in his day was almost universally accepted, that oxygen was the sole "acidifying principle." Since then it has become more and more apparent that the class of substances called "acids" does not owe its characteristics to the presence of oxygen, and that hydrogen is far better entitled to the designation of the "acidifying principle," if there be any such thing. Thus the term oxygen must be recognized as one of the most remarkable and unfortunate cases we have of a name founded upon a fragmentary and entirely incorrect generalization. In the German language, likewise, oxygen is *Sauerstoff* (acid stuff or material), again perpetuating Lavoisier's view. Condorcet called it "vital air." Scheele called it *Feuerluft*, fiery or fire-supporting air.

History.—Priestley, Aug. 1, 1774, first discovered and prepared in a pure state the life and fire-sustaining gaseous principle of air, which he called "dephlogisticated air," as he was, even up to the time of his death, an adherent of the phlogistic theory of Stahl. He prepared pure oxygen by heating red oxide of mercury, which is dissociated by heat into metallic mercury and oxygen gas. Priestley, who, from his many important discoveries and inventions relative to different gases and the manipulation of gaseous bodies, is known as the "father of pneumatic chemistry," knew well how to collect, preserve, and experiment upon the new gas. He thus easily proved its identity with the active element of the air. To commemorate this great event in scientific history the chemists of the U. S. assembled Aug. 1, 1874, 100 years later, at the grave of Priestley, on the banks of the Susquehanna, at Northumberland, Pa., to celebrate the "centennial of chemistry." One year later than Priestley, in 1775, the great Swedish chemist Scheele made independently the same discovery. Lavoisier may be justly regarded as the discoverer or propounder of the true theory of fire, oxidation, and combustion, as consisting in combination with oxygen of the air. Grotthuss, and especially H. Davy, investigated flame, and advanced some steps in a theory thereof.

Occurrence in Nature.—Oxygen is in an enormous degree the most abundant, as it is in many respects the most important, of the elements of matter, upon our earth at least. The only other element that can compare with it in abundance is silicon, the special element of mineral silicates. Even in these oxygen preponderates largely. The following figures show the proportions of oxygen and silicon in some of the commonest of the minerals that make up nearly the whole mass of the known earth:

MINERALS.	Oxygen per 100.	Silicon per 100.
Quartz	54·0	46·0
Feldspar (orthoclase)	46·75	29·6
Mica (muscovite)	48·27	21·0
Pyroxene	44·6	25·3
Amphibole	46·8	27·6
Limestone	48·0—carbon.	12·0

Oxygen constitutes nearly half the total weight of known matter, and silicon not far from one-third. Of water, the liquid part of the earth, oxygen forms eight-ninths. Of living matter, vegetable and animal, oxygen also forms by far the largest element, by reason of the fact that water is so predominant a constituent of these. Apart, however, from the water existing as such in living beings, much oxygen is contained in their solid or "plastic" constituents when perfectly dry. Thus cellulose and starch both contain 49·38 per cent. of oxygen, albumen 23·5, and gelatin 27·5. Of normal atmospheric air oxygen constitutes from 20·8 to 20·9 per cent. by volume, and by weight about 23 per cent.

Preparation.—Of accomplishing this there are many methods besides that of Priestley above referred to. Peroxides of manganese and barium both evolve oxygen when strongly heated. Peroxide of barium will take the oxygen up again at a lower temperature from a current of moist air, and the alternation of these two operations upon this peroxide, or, which is the same thing, upon anhydrous baryta, constitutes Boussingault's method of making oxygen. The method of Tessie du Motay, by which oxygen has been manufactured for illuminating purposes, consists in the exposure alternately of a salt of manganic acid to a current of air and to one of steam. Sulphuric acid will evolve oxygen from a number of substances when heated therewith, such as bichromate of potash, permanganate of potash, peroxide of manganese, peroxide of lead, etc. It may also be obtained by electrolysis of water. Deville and Debray proposed two new methods, both of which furnish it at first in admixture with sulphurous oxide gas, one being to pass sulphuric acid in vapor over heated platinum, the other to heat white vitriol, or sulphate of zinc, to a high temperature. The method in most general use, both in chemical laboratories and in the manufacture of oxygen for commerce, is to heat potassium chlorate to fusion. The evolution of the oxygen is greatly facilitated and hastened by pulverization of this substance and mixture with small proportions of peroxide of manganese.

Chemical Properties.—Oxygen is a colorless and inodorous gas which has been liquefied by Cailletet in Paris, by Pictet at Geneva, and by Dewar in London, by the application of great pressure and cold. It is magnetic—more so than any other gaseous substance. Its density, air being unity, is 1·10561. Bunsen found that ice-cold water can hold in solution 4·111 per cent. of its volume of oxygen, and water at 20° C. (= 68° F.) only 2·838 per cent. When pure, it manifests the most energetic affinities. A combustible body, as a charred splinter of wood, a candle, or the like, if having but a spark of fire adherent, instantly kindles into flame when immersed in oxygen. In this way it may be distinguished from all other gases except laughing-gas, which has the same power. Oxygen will itself burn with flame in an atmosphere of a combustible gas like hydrogen. Even gaseous ammonia may be substituted for the hydrogen in this experiment. When it burns with hydrogen, two volumes of the latter combine with one volume of oxygen, and the three volumes condense to two volumes of steam. The product of the union of oxygen with another element is called an oxide. Thus when lead is heated in contact with the air it combines with oxygen, forming lead oxide, PbO; charcoal, or carbon, burns, forming carbon dioxide, CO_2; phosphorus burns, forming phosphorus pentoxide, P_2O_5.

Uses of Oxygen.—Outside of the applications of oxygen as a purely scientific and analytical agent in the chemical laboratory, its practical uses have not yet been developed to any great extent, in consequence of the large expense of obtaining it free from nitrogen. Dr. Hare's applications of

it for producing intense heat for fusing metals, and intense light by the invention properly called Hare's lime-light, remain yet the most important uses. In France some hundreds of pounds of platiniridium have been melted at once by Hare's method.

Ozone.—This is a modification of oxygen which, up to this time, stands almost if not altogether alone in some respects. Allotropic modifications of solid and liquid substances are exceedingly common, but those of gaseous bodies are little known, ozone being the only one that has been at all studied. As in the case of all allotropic changes, when oxygen passes to the form of ozone there is found to be a change of volume. Ozone is formed when oxygen is submitted to various agents and operations. The electric spark and the slow oxidation of phosphorus are two of the most familiar. The oxygen formed by electrolysis contains it; also that evolved from a mixture of sulphuric acid and permanganate of potash. It is always readily detectable, when masking odors are absent, by its very singular and characteristic odor, which, once perceived, is always recognizable again. Revised by Ira Remsen.

Medicinal Uses of Oxygen.—Oxygen is locally irritating to raw surfaces, exciting inflammation if too long applied. Inhaled in health with proper precautions to remove carbonic acid and other products of expiration from the inspired gas, it is perfectly respirable, and does not produce much substantial change in the rate of performance of the functions. This circumstance is accounted for by the fact, proved by experiment, that in health the blood can take up as much oxygen from ordinary atmospheric air as when supplied with the pure gas—in other words, as much as it is capable of absorbing—the only difference in the two cases being that where oxygen alone is breathed, the highest point of saturation is reached more speedily than where air is employed. When from any cause there is defective respiration, and the system suffers in consequence from imperfect oxygenation of the blood, the inhaling of pure or slightly diluted oxygen, by enabling something like the normal quantity of the gas to be presented to the blood at each inspiration, affords prompt and decided relief, and is, of course, *pro tanto*, of great benefit. Hence in such affections as asthma, pulmonary emphysema, croup, diphtheria, dyspnœa from heart disease, etc., inhalations of oxygen are often exceedingly useful. In other diseases, generally those of mal-nutrition, such as consumption of the lungs, anæmia, severe dyspepsia, indolent ulcers, etc., experience has shown that in some cases much benefit has followed inhalations of oxygen. Where ulceration or active inflammation is present, the use of the gas requires care, lest its irritant effects do harm. Oxygen for medicinal use must be perfectly pure, and is best prepared by decomposition of potassium chlorate. It is inhaled from a bag connected with the mouth by a tube provided with a proper mouthpiece to keep the expired air from mixing with the gas; and the nostrils being left free, enough air is at the same time inspired to dilute the oxygen somewhat. Inhalations morning and evening of from 1 to 4 gal. generally suffice in chronic affections, but in acute disease the amount must be determined by the necessities of the case. For medicinal use, cylinders holding from 100 to 200 gal. of gas compressed into a moderate compass are exceedingly convenient as portable reservoirs from which to supply the inhaling apparatus. See Hydrogen Peroxide for local uses.

Revised by H. A. Hare.

Oxygenated Water: See Hydrogen Peroxide.

Oxyhæmoglobin: a combination of hæmoglobin, the coloring-matter of the blood, with oxygen. This compound readily renders up its oxygen to the tissues when reduced hæmoglobin results, which in turn becomes oxyhæmoglobin after the blood is aërated in the lungs. The bright-red color of arterial blood is due to this compound, while the darker color of venous blood is due to reduced hæmoglobin.

W. P.

Oxyhy'drogen Blowpipe: an apparatus invented in 1801 by Dr. Robert Hare, of Philadelphia, for the purpose of producing a very high temperature by burning hydrogen and oxygen together. It is now extensively used for melting platinum and for producing the calcium light, by rendering a piece of lime intensely hot. (See Lime-light.) The best form is a jet consisting of a tube for the delivery of oxygen, with a larger tube around it, the hydrogen being delivered through the annular space.

O'yer [from Anglo-Fr., from O. Fr. *oïr* > Fr. *ouïr* < Lat. *audi're*, hear]: in law, a hearing by the common-law rules of pleading. A party to an action who alleged in his pleading any deed upon which he based his claim or his justification in defense was required to make profert of such deed (that is, produce it in court), and thereupon the other party was entitled to demand oyer of the deed, or to hear it read, in order that he might have an opportunity to learn its contents or ascertain its genuineness, and thus be able to prepare his answer or defense. Anciently, when the pleadings were oral, profert consisted in actually bringing the deed into court, and upon a demand of oyer it was read aloud by the party introducing it; but when pleading was conducted by written instruments, profert was made by a merely formal allegation that the deed was brought into court, and a demand of oyer was made in writing upon the party alleging the deed, who was then bound to deliver it into the other's hands for inspection, and, if required, to leave with him a copy. Oyer was demandable only of deeds or instruments under seal, and of letters testamentary or letters of administration, and not of private writings having no seal. The practice of demanding oyer has been superseded in England and generally in the U. S. by more convenient methods, prescribed by statutes, as discovery under oath by one party upon an order obtained by the other, or the inspection of papers upon an order or due notice. See Pleading.

Abridged by F. Sturges Allen.

Oyer and Terminer [from Anglo-Fr. *oyer* (from O. Fr. *oïr*), hear, and *terminer*, limit, determine]: in England, a phrase forming part of the designation of certain higher criminal courts of original jurisdiction, and of the Commission (*q. v.*) by which they are directed to be held. General commissions of oyer and terminer are issued to the justices of Assize (*q. v.*) and other special persons (generally at the same time with the commission of Jail Delivery, *q. v.*) directing them to hear and determine all treasons, felonies, and misdemeanors arising within their jurisdiction. This commission differs from the commission of jail delivery principally in the circumstance that the justices of oyer and terminer can proceed only upon an indictment taken before themselves, whereas justices of jail delivery must try all found in the prison they are to deliver. A special commission of oyer and terminer is issued when there is a sudden insurrection, or riot, or public outrage which demands speedy redress, to hasten the administration of justice and assist the regular courts. The courts of oyer and terminer are of very ancient origin, and their constitution has been hardly altered at all since the time of Edward III. In the U. S. the phrase oyer and terminer is sometimes used in designating criminal courts, but the jurisdiction and organization is generally prescribed by statute. In the State of New York the court of oyer and terminer is the highest court of original jurisdiction. F. S. Allen.

Oyo, or **Awyaw**: the capital of Central Yoruba, in West Africa, N. of the Slave Coast. It is the center of one of the most important native agricultural regions in Africa. The people are fully clothed in well-dyed native cloths, and live in adobe houses built around court-yards. Pop. (1891) estimated, 60,000. See Yoruba.

Oyster [from O. Fr. *oistre* > Fr. *huître* < *os'trea*, *os'treum* = Gr. ὄστρεον, oyster]: the English name common to the species of the family *Ostreidæ* and genus *Ostrea*. All the species of the genus are much alike, and agree in the following characters: The animal has the mantle margin double and finely fringed; the gills are nearly equal; the lips plain; the palpi triangular and attached; the shell is irregular and rough; the left valve adherent and convex; the right free and flat or concave; the hinge toothless. The genus is almost cosmopolitan in range, but is not represented in the polar seas. About seventy recent species have been recognized by various authors, but the true species are probably considerably less. The most notable are the oysters of Europe (*Ostrea edulis*) and the Eastern U. S. (*Ostrea virginiana*). The former is a comparatively small species, found generally in the European seas, and has a coppery flavor; the latter is the common large American species; it has none of the coppery taste characteristic of the European species. The European species is hermaphroditic, the American dicœcious. Both species are subject to considerable variation in form, and the American has by some authors been differentiated into two—a northern roundish form (*Ostrea borealis*), and a southern longish one (*Ostrea virginica*). Revised by J. S. Kingsley.

Oyster-catcher: a name applied to the wading birds of the genus *Hæmatopus*, because they feed on small oysters and other molluscs. There are six or eight widely scattered species, all readily recognized by their stout, brightly colored, compressed bills, and striking black and white plumage, whence the English name of sea-pie. The American oyster-catcher (*Hæmatopus palliatus*) is about 18 inches long; the head and neck are glossy black; back, wings, and outer part of tail blackish brown; under parts, base of tail, and a conspicuous wing patch white. The European bird (*H. ostrilegus*), which is a straggler to Greenland, is slightly smaller, and is darker. F. A. Lucas.

Oyster-culture and **Oyster-fisheries**: the method of raising oysters for market and the means employed for taking them. The shell-heaps of Europe and North America testify to the antiquity of oyster-fisheries. At an early date the Romans imported oysters from Britain, while the oyster industry is still an important branch of the fisheries of various nations, notably of the U. S., Great Britain, and France, in the order given. Oysters are found at various depths, largely depending on the temperature of the water, but in the U. S. the majority are taken in water from 15 to 30 feet deep, although dredges are used down to 15 fathoms. The French and British dredge ordinarily down to 30 fathoms. In shallow water oysters are taken with "tongs," implements like a pair of huge, long-handled rakes, so hinged together as to open and shut like a pair of scissors. In deeper water dredges are used, these being essentially coarse-meshed nets of heavy twine or iron chainwork, secured to a rectangular iron frame, which scrapes over the bottom. The frame is about twice as wide as high, being usually 3 or 4 feet across, and the long sides are sharpened, or more usually furnished with large projecting teeth. The dredge is attached by a long rope to a small winch worked by one or two men, and the larger vessels carry two dredges. Tonging is prosecuted from small boats, dredging from larger vessels, these ranging from 5 to 50 tons burden, and while some exceed this size, the majority are under 30 tons. Oysters are taken at all seasons of the year, but during the warm months, roughly speaking from May to September, the oysters are spawning and are protected by law on public beds. The number of oysters consumed is enormous, so much so that, in most cases, the natural supply can by no means keep pace with the demand, and, as Mr. Stevenson puts it in a recent report on the oyster industry of Maryland, "in every region of the world where the oyster industry has assumed any commercial importance, it has passed, or is apparently passing, through the following four stages: First, the natural reefs in their primitive condition, furnishing the entire supply of oysters; second, those reefs somewhat depleted, producing small oysters, many of which are transplanted to private grounds, and under individual protection permitted to mature; third, the public beds so far depleted that the supply available is very irregular and uncertain, and consists almost entirely of small oysters, which are transplanted to private areas; fourth, the entire dependence of the industry on areas of ground under individual ownership or protection.

"In Europe the greater number of the oyster-producing localities are in the condition of the fourth stage. In the U. S. . . . the industry still depends largely on the public reefs; but were it not for the supply of seed oysters obtained from more southern waters, all those States N. of Connecticut would be practically in the condition of the fourth stage. Connecticut, New York, New Jersey, and Delaware . . . are rapidly passing from the third to the fourth condition. The oyster industry of Chesapeake Bay is in the second stage, but the history of the fishery in other States and countries excites grave fears as to its long continuance in this condition." Oyster-culture proper, that is the raising of oysters from the spawn or spat produced upon the spot, is most extensively and successfully practiced in France. The spawn is collected upon wooden hurdles or tiles, from which the young oysters are removed and transferred to the beds to grow. In the U. S. considerable attention has been paid to the extension or preservation of private oyster-beds by throwing over quantities of oyster or seallop shells on which the spat can collect, but so far it has been found most profitable to transplant young or small oysters from the public grounds to private beds. This practice may be said to have been initiated in Europe by Sergius Orata, who "bedded" oysters at Baiæ 95 B. C. The Japanese are successful ostreaculturists, and the art has been practiced by the Chinese for 1800 years.

The following table from *The Oyster Industry of Maryland* (1894) shows the oyster product of the world:

COUNTRY.	Bushels.	Value.
U. S.	29,796,387	$16,638,805
Great Britain	2,760,000	6,200,000
France	2,000,000	5,000,000
Holland	70,000	444,000
Italy	65,000	200,000
Canada	152,580	183,846
Germany	13,000	75,000
Miscellaneous	400,000	600,000
Totals	35,256,967	$29,341,651

In the U. S. Maryland leads with 11,632,117 bush., having a value of $5,866,120. Connecticut leads in oyster-bedding, while California is remarkable for her rapid development of the oyster industry, her product being worth $698,257. The secondary products of oyster-fisheries, in the shape of shells, have a considerable value. Formerly oysters, raw or burned into lime, were extensively used for manure along the eastern seaboard of the U. S., and the poorer qualities are still so employed in some parts of the Southern States. The refuse shells from the large canneries are burned into lime for use in making gas, or are used as a flux in the manufacture of certain kinds of iron. For information concerning the oyster-fishery, see the Quarto Fishery Reports: the special bulletin of the tenth census of the U. S. on the *Oyster Industry*, by Ernest Ingersoll; the bulletins of the U. S. Fish Commission; *Oysters and All About Them*, by John R. Philpots (London, 1890). F. A. Lucas.

Oyster-plant: See Salsify.

Ozæ'na [Mod. Lat., from Lat. *ozæ'na* = Gr. ὄζαινα, a fetid polypus in the nose, deriv. of ὄζειν, smell]: a disease of the nose, characterized by a discharge of fetid muco-purulent matter from the nostril. Any case of chronic catarrh of the nose may become ozæna if the condition of the patient is depressed. It may depend upon caries, and may be a symptom of cancer, syphilis, glanders, or scurvy. It often follows scarlatina, or even a severe cold. General tonic treatment, good food, and weak local disinfectants are indicated in simple ozæna; but if there be caries, or any specific disease of which it is a symptom, such disease will require attention.

Ozark Mountains: a series of steep and heavily timbered ridges of Southern Missouri, extending into Arkansas and the Indian Territory. They are nowhere of great elevation. They are believed to possess great mineral wealth.

O'zerov, Vladislav Aleksandrovich: poet; b. in the government of Tver, Russia, Sept. 29, 1770. He was well educated, and after a career of some years in the army he entered the civil service. His first literary ventures met with scant success, but in 1804 his tragedy *Œdipus at Athens*, though little more than a translation from the French writer Ducis, at once achieved great popularity. In the following year his *Fingal* (taken from Ossian) was equally fortunate, and in 1807 he won his greatest triumph with his *Dimitriĭ Donskoĭ* (name of an early prince of Moscow, who defeated the Tatars), a patriotic piece first put on the stage a few days before the battle of Eylau and full of allusions to the struggle then going on between Russia and France. His last play, *Polyxena* (1809), if not up to its predecessors, was nevertheless favorably received by the public. D. Nov., 1816. Ozerov is commonly regarded as the last Russian dramatist of the classical school, but he belongs to the romantic in the choice of some of his subjects and in the sentimentality of his works. His style is stately, his verse smooth and melodious, and his feeling usually genuine and well expressed (8th edition of complete works, 1856). His *Fingal* has been translated into French verse (by Dalmas, St. Petersburg, 1818) and prose. A. C. Coolidge.

Ozokerite [from Gr. ὄζειν, smell + κηρός, wax]: a brownish-yellow, wax-like substance found in bituminous sandstones. The largest deposits are in Moldavia and in Utah. In combination with India-rubber, asbestos, etc., it is used to insulate electrical conductors.

Ozone: See Oxygen.

P

: the sixteenth letter of the English alphabet.

Form.—The form P is that of the Roman alphabet derived from the early Greek ⌜, ⌝, or in its square-cornered form ⌐. The Semitic form of the letter was ⌝. Its original shape was an ellipse, and hence its Semitic name.

Name.—The Semitic name of the letter was *pē*, i. e. mouth, which became in Greek πεῖ, later πῖ. The Latin phonetic name *pe* passed through the French *pé* into English as *pe*, now pronounced as rhyming with *tree*.

Sound.—It is a voiceless labial explosive, formed by breaking a closure at the lips with voiceless breath, as in *pat*, or by effecting a check through closing the lips, as in *up*. Sometimes there is in the latter case an additional after-puff caused by again breaking the closure; thus after *s*, as in *asp*, where the after-puff constitutes the only characterization of the sound. Before *n*, *s*, *t*, the *p* is silent, as in *pneumatics*, *psalm*, *receipt*, *Ptolemy*, also in *cupboard*, *raspberry*, and after *m* finally or before *t*, as in *jump*, *tempt*, it has the effect of giving a sharp and definite conclusion to the nasal.

Source.—The sound *p* represents in Teutonic words a Teutonic *p* < Indo-Eur. *b*, which was, however, of rare occurrence, and initially did not exist. Hence no genuine Teutonic word in English begins with *p*. Example of non-initial *p*: *sleep* < O. Eng. *slēpan*: Germ. *schlafen*; cf. O. Bulg. *slabŭ*, weak: Lat. *laba're*, totter. The sound is secondarily developed in, e. g., *empty* < O. Eng. *ēmtig*, *Hampton* < O. Eng. *Hāmtūn*. Otherwise *p* occurs in loan-words, (*a*) from Latin through O. Eng., as *pound* < O. Eng. *pund*, Lat. *pondo*; (*b*) from Latin through O. Fr., as *people* from O. Fr. *pueple* < Lat. *po'pulus*; (*c*) from Lat. through some other Romanic language, as *piazza*, Ital. < Lat. *platea* (Gr. πλατεῖα); (*d*) from Latin or Greek direct, as *pastor*, *pathos*; (*e*) from various other sources, as *plaid* (Celtic), *punch* (Hindi).

Symbolism.—P. = phosphorus (in chemistry); Publius (in Latin); *pondere*, by weight; P. C. = *Patres Conscripti* (Latin); P. M. = *post meridiem*, afternoon; postmaster; Pontifex Maximus (Latin); Pb = plumbum, lead (in chemistry). See ABBREVIATIONS. BENJ. IDE WHEELER.

Paca, paa'kăă [Portug., from the native name]: one of the largest of rodent mammals (*Cœlogenys paca*), a native of South and Central America. It is 2 feet long and generally dark brown with streaks and patches of white. The zygomatic arch is prodigiously developed, so that the cheek pouches are protected by a bony case. Its tail is very small.

The brown paca.

It is destructive to sugar-cane and other growing crops, burrows in the earth, and is remarkably cleanly in its habits. It is clumsy in build, but very active. When wild it bites fiercely if hard pressed. In captivity it is harmless and somewhat stupid. It is valued as food, but is usually very fat and oily. Its fur is worthless, but its thick skin makes a good leather.

Paca, WILLIAM: jurist and Governor of Maryland; b. at Wye Hall, Harford co., Md., Oct. 31, 1740; graduated at Philadelphia College 1758; studied law in the Middle Temple, London, and became a lawyer at Annapolis, Md.; was a leading patriot in 1774; was in Congress 1774–79, and again 1786; signed the Declaration of Independence; was in the State Senate 1777–79; chief justice of Maryland 1778–80; chief justice of the State court of appeals for admiralty and prize cases 1780–82; Governor of Maryland 1782, 1786; was in the convention of 1788 which ratified the U. S. Constitution; was a U. S. district judge 1789–99. D. in 1799.

Pacchio'nian Bodies [Mod. Lat. *glan'dulæ Pacchioni*, Pacchionian glands, named in honor of their discoverer, Antonio Pacchioni (1665–1726)]: a group of numerous small whitish bodies found, in man, on the inner surface of the dura mater, and also within the superior longitudinal sinus and on portions of the pia mater, whence indeed they are originally developed, making their way outward into the dura mater and producing, by pressure and absorption, little depressions in the inner surface of the skull. They are very rarely found in subjects under three years of age, and are sometimes absent in adults. They are not glands, but fibrocellular nodules. Their use is not known.

Pachmann, VLADIMIR, de: See the Appendix.

Pachu'ca: capital of the state of Hidalgo, Mexico; on a branch of the railway from Mexico to Vera Cruz; 55 miles N. N. E. of Mexico city (see map of Mexico, ref. 7–H). It lies in a valley at the foot of a mountain chain which separates it from the valley of Mexico, and 8,150 feet above the sea. Pachuca is noted for its silver mines, which are among the most important in the republic. It is said that they were worked by the Aztecs before the conquest. The Spaniards early took possession of them, and it was here that the amalgamation or *patio* process was discovered by Bartolomeo Medina in 1557. In 1893 there were 14 reduction-mills, and from 70,000 to 90,000 tons of ore are reduced annually. Pop. (1895) 52,189. HERBERT H. SMITH.

Pachyderm'ata [Mod. Lat.; Gr. παχύς, thick + δέρμα, δέρματος, skin]: a name applied by Cuvier to an order containing the horses, tapirs, pigs, elephants, and related forms, including all non-ruminating ungulates. The sea-cows, and even the walrus, have been placed in this "order" by some writers, but the members of this heterogeneous group are now distributed in other orders. F. A. L.

Paci'ficator, The: See FERRY, PAUL.

Pacific Ocean: that part of the aqueous envelope of the earth which separates America from Asia and the East Indies. It is the most extensive and the deepest of the oceans. On the S. it merges with the southern ocean, the parallel of 40° being usually taken as an arbitrary limit. On the N. and E. it is separated from Asia and the Indian Ocean by a chain of seas more or less inclosed by islands and peninsulas. These—the Bering, Okhotsk, Japan, Yellow, China, Sulu, Celebes, Banda, Java, and Arafura Seas—are all regarded as its dependencies. The ocean proper has an area of 50,000,000 sq. miles, or three-eighths of the water-surface of the globe; with its dependencies, 55,500,000, or two-fifths. Its mean depth is 2,475 fathoms, and it contains about three-sevenths of the water of the globe. Counting also the dependencies, the mean depth is 2,285 fathoms, and the ratio of volume five-elevenths. The mean depth is also the general depth, three-fourths of the bottom lying between the planes of 2,000 and 3,000 fathoms.

Configuration of the Bed.—The most extensive plateau lies in the southwestern part of the ocean, and is of an extremely irregular character. From the island of New Guinea it extends E. by S. to the Friendly islands, including also the Fiji, Samoan, Ellice, and Salomon islands, and the New Hebrides. A southward arm extends to New Zealand; another southward arm, bearing New Caledonia, extends to Queensland, and a branch from this joins New Zealand. The area thus indicated rises above the 2,000-fathom line, and considerable parts of it approach within 1,000 fathoms of the surface, while a great number of peaks reach the air. The Caroline islands occupy another plateau, from which narrow branches extend southward to New Ireland and

northwestward, viâ the Ladrone islands, to Japan. Other plateaus of some extent are occupied by the Marshall and Low groups, and a narrow ridge, 1,600 miles in length, extends W. N. W. from the Sandwich islands, sending a few peaks to the surface. An extensive but imperfectly surveyed plateau lies off the coast of Chili.

There is a broad deep between New Zealand and Chatham island on the W. and the Isle of Maria Theresa on the E. A more extensive deep of irregular outline follows the coast of the Kurile and Japanese islands and extends E. in lat. 25° N. Its deepest portion lies close to the line of islands, and includes soundings of about 5,000 fathoms. The vast bed of the Pacific has been surveyed with care in only a few districts, but in those it has been found to be very irregular in detail, abounding in mountains and valleys. It is believed that the peaks whose summits are known as islands and shoals constitute but a small part of the Pacific mountain system.

Circulation.—The parts of the ocean lying N. and S. of the equator are called respectively the North Pacific and the South Pacific, and though the assumed dividing line is arbitrary, it coincides approximately with a natural division related to the system of currents. Each part has its own great eddy, set in motion by the planetary winds, and the reverse current which separates these lies but a few degrees N. of the equator. In the North Pacific a great current runs westward in the tropics, another great current eastward in the temperate zone, and the circuit is completed by a southward current along the California coast and a northward current along the coasts of the Philippine and Japanese islands. The heat-bearing northward current is known along the coast of Japan as the Kuro Siwa, and is the counterpart of that portion of the North Atlantic circulation called the Gulf Stream. N. E. of the principal eddy is a secondary eddy occupying the Gulf of Alaska. It follows the Alaskan coast from Charlotte island northward, westward, and southwestward to the vicinity of Unalaska, where it turns to the S. and E. A monsoon current, following the coast of Central America and Southern Mexico, runs to the northwestward in summer and is reversed in winter. The great eddy of the South Pacific flows westward near the equator and eastward in middle temperate latitudes, where it joins with the circumpolar eddy of the southern ocean and follows the South American coast northward to Cape Blanco. The return southward current is divided by the islands into many streams, and a distinct eddy is recognized between Australia and New Zealand. This is not a reverse eddy, like that of the Alaskan Gulf, but turns from right to left like the great eddy with which it is associated, following the New Zealand coast northward and the Australian southward.

Islands.—The Pacific is distinguished by the abundance of islands, pelagic and continental. The pelagic, which are of great number, are of small extent, and are the summits of conical volcanic mountains built by submarine eruption from the bottom of the sea. Many of those lying within the tropics are capped or surrounded by coral reefs. The continental islands, containing not only volcanic but sedimentary rocks, are for the most part of greater extent and are grouped about the western margin.

See also OCEAN, DEEP-SEA EXPLORATION, and the names of the various islands and archipelagoes. G. K. GILBERT.

Pacinian Corpuscles [named from Filippo Pacini, an Italian anatomist; b. May 25, 1812; d. July 9, 1883]: peculiar structures found as peripheral nerve terminations. They are met with in the subcutaneous layer on the palms of the hands and soles of the feet; on the sympathetic nerve plexuses; behind the peritoneum near the pancreas; and sometimes in the mesentery. Their shape in man is oval or like an egg; the diameter is from one-twentieth to one-sixth of an inch. The structure seems to consist of several concentric layers of connective tissue surrounding the terminal extremity of a nerve-fiber. The corpuscle seems to be one of the modes of termination of the nerves of general sensibility. See HISTOLOGY (*Peripheral Terminations of the Nerves*).

Pacinotti, pä-chē-not'tē, ANTONIO: electrician; b. at Pisa, Italy, in 1841. He is the author of a number of interesting investigations in electricity, but is chiefly known through his invention (1860) of a dynamo-electric machine having a ring armature with closed coils, identical in principle with that subsequently used by Gramme in his well-known dynamos. E. L. N.

Packard, ALPHEUS SPRING, M. D., Ph. D.: entomologist; b. at Brunswick, Me., Feb. 19, 1839; graduated at Bowdoin College 1861; studied natural history under Agassiz, devoting himself particularly to entomology; graduated in medicine at the Maine Medical College 1864; made several scientific expeditions; was for several years lecturer on entomology at Bowdoin College, a curator of the Peabody Academy of Sciences at Salem, Mass., and one of the editors of *The American Naturalist*; in 1878 was appointed Professor of Geology and Zoölogy in Brown University, Providence, R. I.; for several years was a member of the U. S. Entomological Commission. His writings have been very numerous, the principal ones being *Observations on the Glacial Phenomena of Labrador and Maine, with a View of the Recent Invertebrate Fauna of Labrador* (1867); *A Guide to the Study of Insects* (1869); *Our Common Insects* (1873); *Half Hours with Insects* (1875); *Life Histories* (1876); *Zoölogy* (1879); *Entomology for Beginners* (1888), and many more technical papers, chiefly on insects and Limulus.

Revised by D. S. JORDAN.

Packfong: the name in common commercial use for Paktong, or German silver. See PAKTONG.

Pacto'lus (in Gr. Πακτωλός, now *Sarabat*): a small stream, barely 10 feet wide and a foot deep, of Lydia in Asia Minor, which flows from Mt. Tmolus into the Hermus. It was formerly famous for the gold contained in its mud, and was the mythical source of the wealth of Crœsus; but for many centuries no gold has been obtained here. See Perrot and Chipiez, *History of Art in Phrygia, Lydia, Caria, and Lycia* (London, 1892; pp. 247–253). J. R. S. S.

Pacu'vius, MARCUS: dramatist; b. at Brundisium, Italy, about 220 B. C.; nephew of the poet Ennius; lived in Rome; became celebrated as a painter as well as a writer; retired when an old man to Tarentum, where he died about 132 B. C. Pacuvius wrote *saturæ* after the manner of Ennius, and at least one historical drama (*prætexta*), with the title *Paulus*, but his fame rested chiefly upon his tragedies, in which he followed Greek models (Sophocles and Euripides). The fragments of twelve tragedies which have come down to us are found in Ribbeck's *Tragicorum Latinorum Fragmenta* (Leipzig, 2d ed. 1871). See also L. Müller, *De Pacuvii Fabulis* (Berlin, 1889). M. WARREN.

Padang': a division of the Dutch dominions on the west coast of Sumatra, consisting of the districts of Upper and Lower Padang, and containing the city of Padang, occupied by the Dutch since the seventeenth century. The territory comprises some of the loveliest regions found anywhere in the tropical zone. Only the low and marshy coast-land is oppressively hot and unhealthful; the slopes of the high, volcanic mountains have a most agreeable climate and a very fertile soil. The products are coffee, pepper, indigo, and caoutchouc, and gold, iron, copper, and quicksilver. Coffee is extensively cultivated, especially in Upper Padang. Pop. of the district about 1,000,000. The city, which is the residence of the governor, contains a Malay population living in bamboo huts on the left bank of the river, and a population of Europeans and Chinese living in houses of stone on the more elevated right bank. The place is the most prosperous on the west coast and has a large trade. Pop. 25,000. Revised by C. C. ADAMS.

Paddle-fish: popular name of a fish of the Mississippi basin; remarkable for having the nose prolonged into a thin, flat, bony, paddle-shaped appendage, sometimes about as long as the body. Its scientific name is *Polyodon spathula*. It has no scales, has a tough but shark-like flesh, and uses its snout for the purpose of digging in the mud in search of food, which consists of small organisms. It is also called spoonbill and duckbill catfish. Revised by D. S. JORDAN.

Paddock, BENJAMIN HENRY, S. T. D.: bishop; b. at Norwich, Conn., Feb. 28, 1828; graduated at Trinity College, Hartford, 1848; was assistant teacher in the Episcopal Academy, Cheshire, Conn., 1848–49; graduated at the General Theological Seminary 1852; was made deacon 1852, and became assistant minister in the Church of the Epiphany, New York; ordained priest 1853, and became rector of St. Luke's, Portland, Me., but resigned on account of ill-health, and became rector of Trinity Church, Norwich, Conn.; became rector of Christ Church, Detroit, Mich., 1860; declined the missionary bishopric of Oregon and Washington Territory 1868; took charge of Grace Church, Brooklyn, N. Y., 1869; elected bishop of Massachusetts, and consecrated in Brooklyn, Sept. 17, 1873. D. in Boston, Mass., Mar. 9, 1891. Among his published writings are *Ten Years in the Episcopate* (1883) and *The First Century of the Diocese of Massachusetts* (1885).

Pa'derborn: town; in the province of Westphalia, Prussia; 50 miles S. W. of Hanover (see map of German Empire, ref. 3–E). It has a cathedral built at different dates, from the eleventh to the thirteenth century, under which the sources of the Pader burst forth, many good educational institutions, breweries, distilleries, and manufactures of tobacco, oil-cloth, hats, and paper. Pop. (1890) 17,986.

Paderewski, pă̆-dā-rev'skĕe, Ignace Jan: pianist; b. at Podolia, Poland (Russia), Nov. 6, 1860; began to play the piano when three years old; received instruction from local teachers; in 1872 went to Warsaw, and later to Berlin, continuing his studies in both cities. When eighteen years of age he was nominated professor in the Warsaw Conservatory; in 1884 abandoned teaching, and took a course of three years' study at Vienna under Leschetitzky, and made his *début* as a professional pianist in 1887 in Vienna. Since then he has given many concerts, everywhere awakening the greatest enthusiasm. Beginning in 1891 he has made several concert tours in the U. S. which have added to his fame and very materially to his wealth. He produced a successful opera in 1901. D. E. Hervey.

Padilla, pă̆-deel'yă̆, Juan, de: Spanish revolutionist; b. about 1484; joined in the revolt of the Castilian towns against the Flemish officials of Charles V. in 1520, and soon became the leader of the movement. The rebellion was at first partially successful. The insurgents deposed the regent, Cardinal Adrian, of Utrecht, placed the queen-mother at the head of the Government, and demanded of Charles V. a reform of the constitution in the interests of the people; but the nobility, alienated by the democratic spirit of these measures, opposed Padilla, and succeeded in supplanting him in the command by a noble of inferior ability. The insurgents after several reverses recalled Padilla, but, though he gained some advantages, the policy of the revolutionary junta in granting an armistice permitted his ill-disciplined forces to melt away. The royalists forced a battle at Villalar Apr. 23, 1521, defeated the rebels, and captured Padilla, who was executed on the following day.—His widow, Maria Pacheco, held out against the royalists till the spring of 1522, when she fled to Portugal. D. there in 1531.

Pad'ua (Ital. *Padova*, Lat. *Pata'vium*): a city of North Italy; 23 miles W. by S. of Venice; on two branches of the Bacchiglione, just above their confluence with the Brenta (see map of Italy, ref. 3–D). The city is a triangular inclosure, surrounded by a wall 8½ miles in length, the base of the triangle being toward the W. Its streets are not generally attractive; the houses are high, and built upon arcades; but some of the squares and public buildings are very fine. The municipal palace is a rhomboidal structure, built on arches and surrounded by *loggie*, and containing a highly ornamented hall, the Sala della Ragione, which has given its name to the whole building, and is said to be the largest vaulted room in Europe. The university originated in the early part of the thirteenth century, but the present buildings date from the close of the fifteenth. There were (1891) 63 teachers and 1,316 students. The university library, with 158,500 volumes and 2,500 MSS., is in the Palazzo del Capitanio. The Church of St. Antony (1232–1307), of mixed architecture, is surmounted by seven cupolas, the center one of which is over the chapel containing the bones of St. Antony. Padua is a town of great antiquity. At the beginning of the Christian era it was the largest and most prosperous town of Northern Italy. It was plundered by Alaric and Attila, and only partially recovered under Charlemagne, and suffered varying fortunes until in 1405 it was conquered by Venice, in whose possession it remained until it was given in 1797 to Austria, which held it, except from 1805–14, until 1866, when it was united to the kingdom of Italy. There is yet very little commercial or industrial activity in the city. Pop. (1892) 79,500.

Paducah: city (laid out in 1827, incorporated in 1856); capital of McCracken co., Ky. (for location, see map of Kentucky, ref. 4–C); at the junction of the Ohio and the Tennessee rivers; on the Chesapeake, Ohio and S. W., the Paducah, Tenn. and Ala., and the St. Louis, Alt. and Terre Haute railways; 48 miles N. E. of Cairo, 140 miles S. W. of Evansville. It is in a coal, iron, agricultural, and hardwood region, and is principally engaged in manufacturing, agricultural, and river trade. There are lines of daily packets up and down the Ohio river, semi-weekly packets on the Ohio and the Cumberland rivers, and tri-weekly packets on the Tennessee river. The city has gas and electric light plants, a fine system of water-works, electric street-railway, paid fire department, 3 public parks, 6 hotels, 2 hospitals, and U. S. Government building. It is the second primary tobacco-market in the country, having several tobacco-factories and 5 acres of tobacco-warehouses. Other industrial establishments are a ship-yard where steamboats and barges are built, marine railways, ship-timber mill, and wheel-factory. There are 12 churches for white people, and 7 for colored, 7 public-school buildings, public-school property valued at over $92,000, 3 national banks with combined capital of $550,000, 2 State banks with capital of $200,000, and 4 daily and 5 weekly newspapers. Pop. (1800) 8,036; (1890) 12,797; (1900) 19,446.

Editor of "News."

Padus: See Po.

Pæan [Lat. = Gr. *παιάν*, a hymn to Apollo as helper; later to other gods; *παιάν* is the Doric form, *παιών* the Attic]: among the ancient Greeks, a hymn of thanksgiving and joy, such as was sung especially before and after battles. The pæan was originally addressed to the Pythian Apollo, afterward to other gods and even to men. The word is now used to signify a loud and joyous song.

Pædogen'esis [Mod. Lat., from Gr. *παῖς*, *παιδός*, child + *γένεσις*, production]: that acceleration in the life-history of certain animals (as, for instance, the Mexican axolotl and certain flies—*Cecidomyidæ*) in which the larvæ are capable of reproduction. In the latter forms the larvæ produce other larvæ, which feed upon the parent, and eventually escape from the body by its complete destruction. J. S. K.

Pæonine: See Rosolic Acid.

Pæs'tum (in Gr. Ποσειδωνία, mod. Ital. *Pesto*): an ancient town of Southern Italy, on the Gulf of Salerno, about 40 miles S. E. of Naples (see map of Italy, ref. 7–F). It was originally a Greek colony from Sybaris, called Posidonia; it was afterward taken by the Lucanians, who named it *Pæstum*, then by the Romans, and it was finally burned by the Saracens in the ninth century. The ruined walls form a pentagon 3 miles in circumference, the north and east sides being best preserved; one of the eastern gates still exists, and an old street of tombs is traceable beyond the ruins of another. Three very ancient Doric temples remain in a good state of preservation. The largest, that of Neptune, is pure in style, is 196 feet in length and 79 feet in width, with a peristyle of 36 fluted columns (28 feet in height, 7½ feet in diameter), supporting an architrave without moulding, and frieze with the usual triglyphs; the pediments at the two ends are surrounded by a cornice, and are of similar architecture. The cella is of the same form as the exterior, has two rows of eight columns each, and these are surmounted by smaller ones to support the roofs of the aisles, the cella itself having been hypæthral or uncovered. The temple of Ceres (some say of Vesta) has thirteen columns on its flanks and an open vestibule within the peristyle. Between these two temples are the ruins of, probably, a Roman theater and amphitheater. The so-called basilica, S. of the temple of Neptune, is remarkable for having nine columns on its front, with a row of eighteen running down the center of the cella.

Paez, paa'ăth, José Antonio: general; b. in the province of Barinas, Venezuela, June 13, 1790. He joined the patriots in 1810; quickly attained prominence as a leader of the *llanero* cavalry; was made general of division in 1819; took a leading part in the victory of Carabobo 1821; and captured Puerto Cabello, the last Spanish port in Venezuela, in 1823. From 1823 to 1826 he was military commandant of Caracas; having been superseded, he led a rebellion, but was pardoned by Bolivar, and given the military and civil command of Venezuela, with the title of *jefe superior* (1827). In 1829 he headed the revolutionary movement which resulted (1830) in the final dissolution of the old republic of Colombia and the complete independence of Venezuela. Under the centralist constitution, which was then adopted, he was president of Venezuela Mar. 18, 1831, to Feb. 9, 1835. After commanding the army for four years, and putting down two rebellions, he was again president Feb. 1, 1839, to Jan. 28, 1843. In Jan., 1848, he declared against Monagas, but after more than a year of civil war he was defeated, imprisoned for ten months, and finally banished for several years. In 1860 he was minister to the U. S. On the deposition of Gual (Aug. 29, 1860) Paez was proclaimed dictator by the army. He held the post during nearly three years of almost constant civil war, and was finally defeated by the federalists under Falcón and Guzman

Blanco, May, 1863. Most of the remainder of his life was passed in New York, where he died May 7, 1873. He published his *Autobiography* in 1867. HERBERT H. SMITH.

Paganini, pä̆-gä̆-nee'nĕĕ, NICOLO: violinist; b. at Genoa, Italy, Feb. 18, 1784; son of a commission broker; gave, when nine years of age, his first public concert as a violin-player in his native city, and produced an extraordinary enthusiasm by his performance of *La Carmagnole* and the variations upon this air. From 1805 to 1808 he was first violinist to the Princess Eliza of Lucca, a sister of Napoleon. Afterward he led for many years a most adventurous life, sometimes playing for bread in a market-place and sometimes refusing to play though a fortune was offered him. From 1828 to 1833 he made a concert tour from Vienna through Germany, to Paris and London, astonishing every one by his extraordinary playing. Wealthy, but with broken health, he returned in 1834 to Parma, where he bought the Villa Gagona. D. at Nice, May 27, 1840. His compositions, of which the *Carnival of Venice* is one of the most famous, include a sonata, *Napoleon*, composed for one string. None has great musical worth, but for the violinist they are of great interest. His most successful imitator was his pupil Savori.

Paganism [from Late Lat. *paganis'mus*, deriv. of *paga'nus*, pagan, liter., villager, peasant (as the old religion lingered longest in the villages), deriv. of *pa'gus*, district, the country]: a name for heathenism, now used as a general term including all polytheistic religions in opposition to Christianity, Judaism, and Mohammedanism; in the Middle Ages it also included Mohammedanism. In Germany it is also applied to tendencies within Christianity itself which are deemed polytheistic in their nature, such as the worship of the Virgin and the saints in the Roman Catholic Church. Revised by S. M. JACKSON.

Page, DAVID PERKINS: educator; b. at Epping, N. H., July 4, 1810; for his education spent two terms in Hampton Academy, and then taught school, receiving, in 1845, the principalship of the newly established Albany Normal School, where he served till his death Jan. 1, 1848. He possessed in a rare degree the qualities of a great teacher. His *Theory and Practice of Teaching* (1847) has had a prodigious influence. C. H. T.

Page, THOMAS NELSON: author; b. at Oakland, Hanover co., Va., Apr. 23, 1853. His great-grandfather on his mother's side was THOMAS NELSON (*q. v.*); on his paternal side his great-grandfather was Col. John Page, one of the foremost patriots of the Revolution, member of committee of safety, and Governor of Virginia 1801–03. Thomas Nelson Page was educated at Washington and Lee University and the University of Virginia for the law; still practices in Richmond, Va.; is author of *In Ole Virginia, or Marse Chan and Other Stories* (1887); *Two Little Confederates* (1889); *Befo' de War*, dialect poems published with A. C. Gordon (1890); *On Newfound River* (1891); *Elsket and Other Stories* (1891); *Among the Camps* (1891); *The Old South*, essays social and political (1892); *Pastime Stories* (1894); *Red Rock* (1899).

Page, WILLIAM: painter; b. at Albany, N. Y., Jan. 23, 1811. He studied with Herring, the portrait-painter, and with S. F. B. Morse; painted portraits in Albany and New York with eminent success; executed a few compositions, a *Holy Family*, *The Infancy of Henri IV.*, and others; resided in Rome and Florence several years; returned to New York in 1860, and resided there. Page was known as an experimenter in color, and painted many extraordinary pictures to illustrate his ideas—a *Flight into Egypt*, *Moses and Aaron on Horeb*. His *Venus* became famous; it was an attempt to embody what the artist thought the practice of Titian. Page was president of the National Academy, and wrote and lectured on art. He was a man of enthusiastic temperament and daring genius, poetic, and eloquent. D. at Tottenville, N. Y., Oct. 1, 1885.

Pagès: See GARNIER-PAGÈS.

Pag'et, Sir JAMES, F. R. S., LL. D., D. C. L.: surgeon; b. at Yarmouth, England, Jan. 11, 1814; studied in St. Bartholomew's Hospital, London; in 1836 became a member and in 1843 a fellow of the Royal College of Surgeons; became assistant surgeon, surgeon, and consulting surgeon to St. Bartholomew's; sergeant-surgeon to the Queen; surgeon to the Prince of Wales; vice-chancellor of the University of London; was made a baronet in 1871; is president of the Royal College of Surgeons. In his earliest surgical studies he paid great attention to pathology, and through his efforts its importance was recognized throughout English-speaking countries, and for years his *Lectures on Surgical Pathology*, a work that has passed through many editions, has been a text-book in the medical colleges of Great Britain and the U. S. In 1857 he delivered the Croonian lectures, his topic being the cause of the rhythmic motion of the heart. In 1877 he delivered the Hunterian oration. In 1882 he delivered the Bradshawe lectures, on some rare and new diseases. In 1887 he delivered the Morton lecture on cancer.
S. T. ARMSTRONG.

Paget, VIOLET: author; b. in England, 1857. She has resided for many years in Italy, and under the pseudonym of *Vernon Lee* has published many brilliant and suggestive studies of art, literature, and general æstheties. Among her books are *Studies of the Eighteenth Century in Italy* (1880); *Belcaro* (1882); *Ottilie* (1883); *Euphorion* (1884); *Miss Brown* (1884); *Baldwin* (1886); and *Juvenilia* (1887).

Pago'da [from Portug. *pagoda*, from Pers. (and Hind.) *but-kadah*; *but*, idol + *kadah*, house; cf. Chinese *peh-kuh-t'a*, pagoda, liter., white bone tower]: a name applied to a great variety of tower-like, many-storied buildings in the East Indies, China, Japan, etc., used originally to contain relics and other objects of veneration or worship.

Pago Pago: See the Appendix.

Pahlavī, pe-le-vee', or **Pehlevī**: the mediæval Persian of Sassanian times (A. D. 226–651); in a broader sense, Persian from the period of the Achæmenidæ to the rise of the modern language after the Mohammedan conquest. By its etymology the term *Pahlavī* means Parthian (Old. Pers. Inscr. *Parthava*, whence *Pahlav* and *Pahlavī*, relating to the Parthians). In mediæval Oriental literature the appellation *Pahlavī*, owing to the greatness of the Parthian sway, is sometimes extended to denote anything ancient Persian. The restricted usage, however, limiting the application of the name to the language and writings of the Sassanian Zoroastrians down to the ninth century is the more correct, and is in modern times the general one.

1. *Pahlavī Language.*—The Pahlavī is preserved in the form of inscriptions and in an extensive written literature. The language, though it is Persian, presents a strange non-Iranian appearance; there is a curious admixture of Semitic (Aramaic) words and Iranian elements. The fundamental words, those of commonest usage, are Semitic, and Semitic words also stand beside Iranian equivalents; but they are often treated in a way that is quite un-Semitic, or, again, they assume an Iranian look by receiving Iranian endings. This Semitic preponderance, however, is superficial rather than real. Pahlavī, when written, is indeed largely Semitic, but when read it becomes Iranian. We have the authority of Ammianus Marcellinus (xix., 2, 11), and more explicitly of the Arab writer, Ibn Moḳaffa', for the fact that, although Semitic words were written, the Persians in reading Pahlavī regularly substituted Iranian equivalents for Semitic vocables, and the speech when sounded became all Iranian. For example, in Pahlavī *bisrā* (Aramaic), meat, was written, but *gōšt* (Persian) was pronounced; again, *laḥmā*, bread, may have been written, but *nān* (Persian) was read; although the Semitic *malkān malkā* was inscribed on the monuments, the Persians called their "king of kings" *shāhān shāh* in true Iranian style. The phenomenon is thus to be explained: The Persians of Parthian times adopted a Semitic alphabet, but, beside using its characters for writing their own words, they went a step further and adopted for convenience a certain number of written Semitic words to stand for their Iranian equivalents, which were regularly read as if Iranian—much as on a small scale in English the Latin *i. e.*, *e. g.*, *viz.*, *&*, *etc.*, £ (*libra*) are read by us as "that is," "for example," "namely," "and," "and so forth," "pound," being foreign to the eye when written, but becoming native to the ear when read. In Pahlavī there were some 400 of these Semitic logograms, beside about 100 obsolete forms of actual old Iranian words for which the ordinary current Persian words were substituted in reading. This disguised and obsolete element in Pahlavī is known as the *Hūzvārish* portion of the language. In strict reality, therefore, the *Hūzvārish*, or *Uzvārish* (misreading for *Aūzvārishn*), is a form of writing rather than a form of speech. Etymologically the term *Aūzvārishn* has been explained by Haug and West as "antiquity, decrepitude," or perhaps "obsolete," although Darmesteter suggests the explanation "perversion, alteration, disguise," as applicable to the peculiarity of writing.

It often happens that the disguised Pahlavī is transliterated into Avestan or Modern Persian characters, and the Semitic element is eliminated by substitution and ambiguity

disappears; such a text is called Pāzand (Avesta *paitizaiñti*), re-explanation, a term which is applied also to the purely original part of the Pahlavī texts themselves which do not require transposing. This designation was also originally applied to the "re-explanation" of the Pahlavī version of the Avesta, which itself was an explanation, interpretation, or commentary. (See AVESTA.) The appellation *Parsī* is also sometimes given to this transcribed Pāzand.

The two forms above mentioned in which the Pahlavī language is preserved are (1) inscriptions and coins, (2) manuscripts. The earliest rock-inscription, belonging to the first Sassanian monarch, Artakhshīr Pāpakān (A. D. 226–240), is a trilingual record, being engraved in Greek and in the characters of the so-called Chaldæō-Pahlavī and Sassanian Pahlavī. The early inscriptions are of great service in helping toward the solution of the problems which Pahlavī presents—problems arising not so much from the grammatical and syntactical structure of the language as from the defective alphabet and the peculiar manner of writing the speech. The book-Pahlavī alphabet has only fourteen letters to discharge the duty of a complete alphabet; owing to this paucity a single sign has to assume a number of offices; the separate signs, moreover, are further obscured by being combined into ligatures whose elements are exceedingly difficult to decipher. The single symbol  , for example, may denote *s, yī, yad, yag, yaj, dī, dad, dag, daj, gī, gad, gaj, jī, jad, jag, jaj*. The difficulty of determining the precise reading of an obscure group of letters may therefore be imagined, but with regard to the meaning there is generally not a great deal of difficulty; old glossaries, moreover, have been preserved which give useful assistanee on the subject. It may be added that Pahlavī is an analytic language, and its declensional and inflectional system is much reduced, which renders the grammar and the syntax simple.

2. *Pahlavī Literature.*—Omitting the rock-records of Artakhshīr Pāpakān (A. D. 226–240) and his successors above referred to, as well as some early impressions on coins, the extent of Pahlavī literature may be estimated to be about the same as that of the Old Testament. In point of time the literature may be placed between the years A. D. 226 and A. D. 881. Nearly a hundred works have been preserved; these are in part translations of older Avesta texts, or they are works written on religious subjects, though some of them deal with legendary or miscellaneous topics. The principal literary monuments of the language are: (*a*) the Pahlavī version of the Avesta (see AVESTA); (*b*) *Bundahish*, a sort of Iranian Genesis and Revelation; (*c*) *Dīnkarḍ*, on matters of religion; (*d*) *Dāḍīstān-ī Dīnīk*, religious discussions; (*e*) *Maīnōg-ī Khiraḍ*, spirit of wisdom, doctrinal teaching; and (*f*) *Arḍā-ī Vīrāf nāmak*, an Iranian apocalypse; as well as other works chiefly religious in character. The most important of the Pahlavī texts have been translated by West, the most eminent authority on Pahlavī; translations of separate works have also been contributed by other scholars. Pahlavī literature is indispensable for the study of Zoroastrianism, and is important in connection with theological and philosophical studies in general.

Pah-Ute Indians: See SHOSHONEAN INDIANS.

Pailleron, pāā'ye-rōṅ', ÉDOUARD JULES HENRI: poet and dramatist; b. in Paris, France, Sept. 17, 1834. He began life as a notary's clerk, but in 1860 appeared as an author with a volume of satiric verse, *Les Parasites*, and a one-act comedy, *Le Parasite*. He continued to write successfully for the theater, at first in verse, producing among other pieces *Le Mur mitoyen* (1861); *Le Dernier Quartier* (1863); *Le Monde où l'on s'amuse* (1868); *Les Faux Ménages* (1869); *Hélène* (1872); *L'Âge ingrat* (1879). His greatest success was made by *Le monde où l'on s'ennuie* (1881). He wrote also *Le Narcotique* (1882) and *La Souris* (1887). He was elected to the Academy in 1882. D. in Paris, Apr. 20, 1899.

Pain: a peculiar sensation of discomfort or suffering caused by disturbances of the sensory nerves or nerve-cells, which cause a condition of over-excitement. Any of our sensations may become painful if the stimulus is sufficiently strong and prolonged—thus the skin touched lightly affords normal tactile sensations, but if the pressure is severe the impressions become painful; moderate light does not prove of discomfort to the normal eye, but if intense the pain may be severe. Pain may be caused by mechanical, thermal, chemical, electrical or other means, but it is generally due to injuries and various disorders of nutrition and inflammation. There are many varieties—it may be sharp, shooting and lancinating, as in neuralgias; sharp and intermittent, as in colic; sharp, severe and constant, as in peritonitis; dull and gnawing, as in inflammation of the bowels; dull and sickening, as in certain disorders of the ovaries and testicles; throbbing, as in toothache and suppurations; burning, as in inflammations; pressing, constricting or boring, as in various forms of headaches; dragging, as in womb troubles.

Pain is seldom constant in its degree, being generally subject to intermissions or periodic exacerbations. It also varies greatly in its intensity and quality, depending upon the degree of irritation and the special nerve that is excited. Some nerves are infinitely more sensitive than others, so that the same degree of irritation applied to two different nerves may cause severe pain on the one hand and but an insignificant effect on the other. Pain experienced in different parts may be of the same intensity, yet one is borne much easier than another owing to the difference in its quality. The exquisiteness of the pain when the nerves of the teeth or ear are affected is not equaled by that produced in any other part of the body. Pain is said to be referred by the mind to the particular part of the body which is irritated, but this is not strictly true—thus in case of severe toothache the irritation may be confined to the root of a tooth, yet sensations of pain may be referred to the whole side of the face, indeed even to both sides. Irritation of a sensory nerve at any part gives rise to sensations of pain which are referred to the peripheral distribution of the nerve; thus it is that people who have suffered the loss of arms or legs often experience pain just as though the sensations were actually coming from the parts that have long since been amputated—in such cases the cut ends of the nerves in the stump are excited, and the sensations thus produced are referred by the mind to the parts formerly supplied by their fibers.

It is important to observe that the presence of pain invariably indicates an abnormal condition, and that it is one of the most frequent and potent means of nature to warn us of disordered states. Pain is relieved by various methods, the first and most important being the removal of the cause. The use of the hot-salt bag is often efficient in relieving toothache, pain in the bowels, etc.; cold is similarly but less successfully resorted to. The use of drugs, such as opium, morphine, anæsthetics, narcotics, etc., is dangerous, except in the hands of a physician. E. T. REICHERT.

Pain and Pleasure: certain conditions of consciousness which depend upon physical and mental events. No adequate definitions can be given: pain and pleasure must be *felt*. Yet the physical and mental conditions which give so-called hedonic *tone* to consciousness may be pointed out.

1. *Too much stimulation is a cause of pain.* This is true, in the first place, of high *intensities* in stimulation. The actual experience of such painful intensities in the cases of special sensation leads us to look for it in all forms of sensibility. A blinding light is painful; a loud noise

very close to the ear, rapid friction of the skin, great pressure upon the muscles, etc., all give rise to painful feeling. It is true also that very strong tastes and decided odors are disagreeable or soon become so; but the case of these sensations seems to differ in some respect from that of the senses which report acute pain, properly so called. Sensations of temperature, again, either heat or cold, give us positive pain when the degree of either stimulus is very intense. It is possible that the apparent difference between taste and smell and the other sensations, in this respect, may be due to the fact that in them the end organ seems to have a chemical function, while the other end organs are largely mechanical; but it is enough here to point out the fact that some tastes and odors seem to be always pleasurable, and others always unpleasant. The same cause of pain is also seen when the stimulation is of long *duration*, and when it is widely *extended* on the skin, etc. A number of pin-points drawn over the skin give pain, when one of them would not.

2. *Inflammation* is painful, both when local in the muscles and skin, etc., and also when the nervous system is in a state of high excitability.

3. *Summation of stimuli* as a cause of pain. By summation is meant the adding up of processes on the nervous centers so that a greater result is worked in consciousness. Several electric sparks become painful to the eye by stimulation when one is not.

4. *Appetites or impulses when denied* give rise to pains of want. Such pains are usually periodical, and indicate a lack injurious to the organism.

Besides the above, several more special conditions bring about a painful reaction. Exposure to air is a cause of pain to tissue normally protected by the skin; disuse, or too slight stimulation, occasions pain in the more complex of the special senses, as sight; lack of accommodation of the organ to its stimulus has sometimes disagreeable tone, which is exaggerated when the stimulation is intense. The tone of the organic feelings seems to arise from any obstruction of the organic functions, such as laceration, cramp, repletion, etc. Intermittency of stimulation is also a frequent cause of pain, probably from the failure of the organ to accommodate to the broken stimulus.

Empirical Facts concerning Pain.—There are, in addition, certain facts brought out by physiologists which throw light upon pleasure and pain. First may be mentioned the *intermittence of pain*, the greater or less intensity of painful feelings at successive moments, the stimulus remaining constant. It is plainly seen in electrical stimulation—a clear rhythm, or rise and fall, of the painful tone. A headache usually proceeds by throbs, a toothache by jumps, and a felon on the finger changes its feeling from a dull ache to a paroxysm of overpowering severity. That it is due to nervous causes, and indicates the ebb and flow of central processes, is claimed from such phenomena as intermittent fever; but in some cases it evidently depends upon the rhythm of the vascular system, the distension and reaction of the blood-vessels. Another kind of intermittence is brought about by the coming and going of the *attention*. The effect of the attention in increasing the intensity of affective states is familiar; hence we would expect that the concentration and withdrawal of the attention would have a marked influence upon the rise and fall of pain. Further, we know that the attention, even when concentrated as steadily as possible, is rhythmical. Another fact of painful feeling is what is called its irradiation or *diffusion*. The locality of a painful stimulus is less circumscribed as the stimulation becomes intense. Besides the intensity, or quantity, this feeling becomes massive or spread out. It is probably due to a real spreading of the cause of the painful feeling over a greater area, both on the periphery and in the central seat.

Again, we may note a *delay* in the conscious awareness of pain compared with the appearance of the sensation with which it seems to be connected. Even when the stimulation is a very strong one, the sensation is clear in consciousness before any pain is felt. A blow, for example, is felt as contact or pressure a fraction of a second before we begin to suffer from it; a burn is particularly long in reporting itself as pain. This delay may be measured by comparing the reaction time of a painful stimulus—say the decided prick of a pin—with that of a simple contact sensation at the same point on the skin. It is probably due to the fact that the full force of the pain-stimulus is not reported at once, but that the organ accommodates itself to it by a series of partial transmissions. These transmissions are summated at the center, and the result is a sufficiently intense central stimulus to occasion a painful reaction.

Further, the duration, or *lasting quality*, of a painful state of sensibility is remarkable. Pains do not pass away, as painless sensations do, when the stimulation ceases. The recovery of the organism is very slow. What is called an after-image of some sensations seems here to be more truly an after-*fact*. It is probably due to the fact that the intenser degree of stimulation necessary to pain gives more decided and lasting character to the nervous change it works than feeble stimuli do. This is supported by the observation that pains are more distinctly and easily revivable than other affective experiences. A painful experience seems to hover constantly around us, and thrust its unwelcome presence into our gayest hours. When we remember that a revived image occupies the seat of the original experience, we only have to assume a more lasting effect to have resulted from a painful sensation, to account for its more easy reproduction. Finally, pain lowers the temperature of the painful region.

Analgesia, or insensibility to pain, under conditions usually painful, may be brought about by various agencies. Cold of very great intensity has this effect, pain becoming very acute and then subsiding altogether, as the temperature is lowered. The withdrawal of blood from an organ makes it insensible to pain. Lowered sensitiveness to pain, however, is likely to be preceded by exalted sensitiveness, as in the evident case of cold. Apparent absence of pain is experienced when the intensity of a painful stimulus is suddenly lowered, even though the second intensity would be painful under other circumstances.

Pain as Feeling and as Tone.—The conditions of pain now pointed out are conditions in the operation of the various modes of sensibility, general or special; that is, we have been observing pain as hedonic *tone*. The important question arises: Is pain always thus dependent on a definite form of sensibility, or is it itself, as a form of sensibility, ever found independent of its presence as tone? There are some facts which would indicate that pain has a functional independence, whatever we may say as to its anatomical independence—i. e. whether there are special nerve-fibers which conduct pain, a point on which experimental results are conflicting. For instance, pain may be destroyed without impairing any of the other sensibilities, as in analgesia brought on by chloroform; and in general, under the influence of anæsthetics, pain and memory disappear first and together. On the other hand, other sensations may be destroyed, while the painful quality of their stimuli remains. Thus, under pressure, sensations of touch, temperature, and muscular movement may be destroyed while pain remains. So, also, under loss of blood in a member, sensations of touch disappear before pain, and both before temperature, electric feelings, etc.

Conditions of Pleasure.—It is not so easy to point out the physical conditions of pleasure; but in general we find them opposed to those already indicated as carrying painful tone. 1. *Moderate stimulation is pleasurable.* This is readily seen in the exercise of the special sense functions; the eye is pleased with mild colors, and the ear with pure tones. Gentle touch, quiet muscular reaction, moderate tastes are usually agreeable; and it is true of moderate durations and areas of stimulation, as well as of moderate intensities.

There are striking exceptions, however, to this rule. A great many sensations are always painful; when not giving a painful reaction, the organs involved do not affect consciousness at all. So the organic feelings. Certain tastes and odors, also, are always disagreeable. Further, the condition of neutrality seems very nearly reached in the normal exercise of some of the sense functions, as, for example, sight and hearing.

2. *Pleasure arises from the adjustment of an organ to its stimulus.* Muscular sensations are pleasurable within the range of easy effort. Stimuli of longer duration, which give time for the full adjustment of the organ, pass from the painful to the pleasurable. Feelings for which we are ready by anticipation are enjoyable. Yet this is also subject to the qualification that perfect adjustment seems in many cases (eye and ear) to have no feeling accompaniments whatever, either of pleasure or pain.

3. *Activity is enjoyable.* By this is meant function within the limits set by the two conditions already mentioned. If activity is pleasurable, it is the moderate activity of a well-adjusted organ. Yet there seems to be more massive organic

conditions of activity which are pleasurable, even when such a general function involves some particular pain. The foot-ball player enjoys his sport, even though he is never free from the pain of bruises or scratches. In such cases, the vigor and energy of the larger organs brought into play seem to overpower the protests of the smaller, and silence their complaints. A pain which would make one wretched if suffered in passive silence is forgotten altogether in the pleasure of diligent employment. This larger activity, however, which brings pleasure, must itself conform to the conditions of moderation and adjustment. Moreover, these pleasures of activity, such as pleasures of the chase, of sports, of general vigor, are more positive apparently than any other physical pleasures. The claim already noticed, that in the absence of pain many states are not really pleasurable, but merely neutral as regards tone, does not seem to be well taken in this case. A condition of fresh muscular vigor seems to intrude itself into consciousness of its own force, and we become aware of pleasant occupation with no evident reference to the corresponding state of pain. Indeed, the opposite pleasures which result from a cessation of muscular pain—the so-called pleasures of rest—are something quite distinct from these pleasures of activity. Under this head, also, as including any function, and not simply muscular activity, the pleasures arising from the gratification of the organic appetites and instincts appear to fall. They are functions of periodical exercise, and their normal working involves periodical stimulation. They seem to involve pleasure over and above the prompting of painful appetite, though this again is in dispute. Yet it could hardly be said that all the pleasures of the table are due to the cessation of the pangs of hunger.

Relativity of Pleasure and Pain.—The fact referred to above, that many physical pleasures are only relief from preceding states of pain, finds place with other similar phenomena, under the law of relativity. First, we may say that the existence of either state may under certain circumstances arise from the cessation of the other. Cases of seeming pleasure, which is explained as absence of pain, have already been mentioned. Similarly, the cessation of an active pleasure may give us temporary pain and be the only cause of it. An element of higher emotion, however, generally enters in this case. Again, the intensity of pain or pleasure depends largely upon its contrast with a preceding state. After an unusual trip to the country, the painful toil of city life is all the harder to bear; so, after feasting the eyes upon a dish of luscious fruit, the beggar's plate of herbs is all the more unpalatable. So, also, the associations involved often convert pleasure into pain, and the contrary. A little clever deceit will make us enjoy a dish which before we found unpleasant.

Resulting Conception of Bodily Pleasure and Pain.—From the foregoing brief description of the conditions under which sensuous tone arises, we may put all such feelings under two larger physical categories. A careful examination of these conditions will show that all pleasures and pains involve either a state of change in the organic tissue, in the way of *integration* or *disintegration*, or a change in the relation of the organism to its environment, in the way of *adjustment* or *misadjustment*. These two aspects of the case may be considered separately. This brings us to the conclusion, when we reflect upon organic development, that in the life-process we have the *raison d'être* of pleasure and pain; but by life-process we must be careful to include life-development as well as simple life. The simple present life of an organism as constant function is more than covered by the facts as we have observed them; pleasure and pain have a prospective future reference as well—reference to a fuller development and potential growth. Accordingly, bodily pleasure may be defined as *the conscious effect of that which makes for the continuance of the bodily life or its advancement*; and pain, the *conscious effect of that which makes for the decline of the bodily life or its limitation.*

Intellectual Pleasures and Pains.—The further question concerning the higher pleasures of our ideal life of thought and emotion is equally important. Certain conditions of this higher tone may be mentioned also.

1. *Some degree of ideal change.* As physical pain arises from physical function, so higher pain comes with apperception considered as mental function; and in general, the degree of function, measured in terms of the emotional excitement to which it gives rise, indicates also the degree of pleasure or pain. Ideal change, the rearrangement of elements in the apperceptive content of consciousness, is accordingly the general condition of particular ideal tone. We may, accordingly, at once make use of the conception of bodily tone already arrived at, substituting for the physical the apperceptive function, and for the adjustment of end organs that of attention; and expect to find an adequate conception of ideal pleasure and pain. Accordingly, we reach a second condition.

2. *The degree, duration, and relative adjustment of attention*: determining ideal tone as pleasure or as pain. Excessive concentration of the attention is painful; yet the pain is directly merged in the pain involved in the adjustment of the bodily organ. Prolonged attention becomes painful by the law of fatigue. On the other hand, moderate concentration and duration of attention are pleasurable. The conditions which involve distraction, or drawing apart, or doing violence to the attention, are painful; those giving feelings of ease, flow, variety, measured concentration, etc., are pleasurable. It is probable that the most pleasurable adjustment is that of finest and most exact discrimination. Ward formulates this and the preceding condition as follows: there is pleasure "in proportion as the maximum of attention is effectively exercised."

The determinations already reached have evident application to those states of feeling which arise around acts of the attention regardless of the nature of the object to which the attention is directed. There are other emotional states, however, which are pronounced in their contribution to the tone of consciousness. The great expressive emotions (fear, love, anger), the sympathetic, the ethical, and æsthetic are all at times controlling agents of pleasure or pain. The question at once arises: Is it possible to bring them under the formulas already enunciated? This question awaits an answer from the consideration of the genetic conditions under which objects come to be pleasure or pain giving.

1. *Objects of perception and memory excite pleasure or pain only as they have or have had some relation to our physical well or ill being.* PERCEPTION (*q. v.*) is a summing up of sensations in the form of synthesis. Now an object perceived gives us certain sensations only; but it suggests others which belong to the synthesis, and we are thus able to anticipate them. The sight of falling rain prophesies to me the unpleasantness of being wet; the sight of a lion, the pain of being eaten. The tone of perception, therefore, as far as it refers to the object, is intrinsically the prophecy of the tone of the sensations it includes and suggests. To illustrate: A child first sees a fire (yellow light sensation), grasps it (touch sensation), feels pain (sensuous tone, due to damage to the life-process). Again he sees the fire (perception, carrying in it touch and pain memories) and has fear, which is of painful tone. The point advanced is that this latter tone, of fear, also has reference to the life-process. It is nature's way of utilizing simpler pain experiences, just as perception is her way of utilizing sensational experiences. This covers the whole field of emotions which accompany reproduction—memory, passive imagination, illusions, etc. The emotions which such representations excite have qualitative coloring (expectations, dread, etc.), but their tone is again due, as the tone of perception is, to the anticipation of advantage or damage from the pictured object.

2. *The tone of the emotions which accompany conception and thought has reference both* (1) *to physical and* (2) *to intellectual well or ill being.* The reference of conception and thought to physical pleasure and pain is clear in some cases. My conception of the work of dentists, for example, has a painful tone which is as clearly a warning of physical damage as the perception of my particular dentist is. So, also, the science of dentistry, the logical framework of the art, considered merely as a branch of instruction, can not be rid of its physical suggestiveness. The medical student grows faint when he hears his first lecture on blood-letting. Consequently, a positive part of the tone of higher æsthetic, ethical, and logical emotion illustrates the law of physical well-being. In the case of æsthetic emotion, the element contributed by association is largely of this sensational character. Apart from the beauty of the purely sensuous in music, its associations are largely sensuous. A face often becomes handsome from association at the table, the theater, on the promenade, and the pleasure we take in it is a reverberation of these associated pleasures of sense.

We may ask: Does this reference to physical well-being exhaust the range of ideal pleasure and pain? Further consideration convinces us that it does not. There are emotions whose tone seems to violate the law of physical well-being. We would expect, indeed, if consciousness is a synthetic

thing, and if its synthesis becomes explicit in what we call apperception or thought, that such a new thing in nature would have its own principle of development; and we would expect, further, that its development would be a matter of conscious adaptation to its conditions of thinking and willing. The most natural view of ideal pleasure and pain therefore is to consider it an index of healthy or unhealthy *mental* function. As physical pleasures, at first ministering blindly to the welfare of the organism, grow to attach to objects in relation to the organism, so ideal pleasures, while attaching still to attention as a function, yet come to attach to its objects as well. On this view, the tone of many emotions reflects the state of the mental functions primarily. This view is supported by abundant evidence. The pleasures of intellectual pursuit lead their devotees to neglect the body and even to continue this course in the face of acute physical pain. Æsthetic delight is so independent of selfish motives that admiration is often called out by what is destructive and terrifying. Ethical emotion, with the happiness it always brings, may triumph over physical impulse, when they come into conflict. Consequently, we may hold that there is an element of hedonic coloring arising with the changes which occur in the content of consciousness; and we are led to define intellectual pleasure as the conscious effect of that which makes for the continuance of the apperceptive life or its advancement; and pain, the conscious effect of that which makes for the decline of the apperceptive life or its limitation. Summing up all that has been said of pleasure and pain, both bodily and ideal, we may conclude that *pleasure and pain are the affective coloring, respectively, which consciousness takes on in conditions of present or prospective well or ill being.*

Complexity of Hedonic States.—It is now clear that the hedonic coloring of consciousness, at any time, is not a simple thing. Pleasure or pain is reported from the body and from the mind, from many organs of the body at once, and from many mental factors at once. Hope and fear may be struggling within, the will may be painfully paralyzed, attention distracted, and with it all a beating sun may annoy, an aching tooth distress, and all go to make up a complex condition of tone. So mental and physical conditions may combine to produce pleasure; and all possible combinations may, and do, arise in kaleidoscopic order. The elements, however, of this complex effect may be generally distinguished in consciousness. They do not coalesce except in their general tendency to produce emotional excitement, which has its own tone. If the two hands be held under two streams of water, very hot and pleasantly cool, respectively, the two hedonic effects may be clearly distinguished from each other. So the pain of suspense arises from the excitement of alternating hope and dread, and persists apart from the pleasure and pain of those emotions themselves as they struggle in consciousness.

J. Mark Baldwin.

Paine, Elijah: legal writer: b. at Williamstown, Vt., Apr. 10, 1796; a son of Judge Elijah Paine; graduated at Harvard in 1814; studied law at Litchfield, Conn.; assisted in preparing Wheaton's *Reports*; was a judge of the New York superior court 1850–53; author of *Paine's Reports* (U. S. circuit court, second circuit, 1810–40: 1st vol. pub. 1827, 2d vol. 1856), and a joint author of Paine and Duer's *Practice in Civil Actions and Proceedings in the State of New York* (2 vols., 1830). D. in New York, Oct. 6, 1853.

Paine, John Knowles: composer and professor of music; b. at Portland, Me., Jan. 9, 1839; after studying at home and acquiring considerable skill as an organist, in 1858 he went to Berlin for three years, studying under Haupt, Wieprecht, and Teschner. In 1861 he returned home and gave a number of concerts. In 1862 he was appointed instructor of music in Harvard College, and in 1876 made full professor. His compositions are numerous and important. They include a grand mass in D, an oratorio, *St. Peter*; *The Song of Promise*, a cantata for the Cincinnati festival; *Œdipus Tyrannus*, for male voices, for the Harvard students' performance of the play; *Centennial Hymn*, words by Whittier (1876); *Columbian March and Chorus*, for the opening of the Chicago World's Fair Exhibition, Oct. 21, 1892; several cantatas, three symphonies, symphonic poems, and other orchestral pieces, songs, motets, piano solos, chamber music, and others. D. E. Hervey.

Paine, Martyn, M. D., LL. D.: physician; son of Judge Elijah Paine (1757–1842); b. at Williamstown, Vt., July 8, 1794; graduated at Harvard in 1813; studied medicine under Dr. John Warren, of Boston, Mass., and took his medical degree there 1816; practiced his profession at Montreal 1816–22; removed to New York city, where he became one of the leaders of the medical profession; was one of the founders of the University Medical College 1841, in which he subsequently held important professorships. Author of *The Cholera Asphyxia of New York* (1832); *Medical and Physiological Commentaries* (3 vols., 1840–44); treatises on *Materia Medica* (1842, 1848); a very valuable standard treatise on the *Institutes of Medicine* (1847); *The Soul and Instinct* (1849), and other works. D. in New York, Nov. 10, 1877.

Paine, Robert, D. D.: bishop; b. in Person co., N. C., Nov. 12, 1799; while in childhood removed to Tennessee; in 1818 joined the Tennessee conference of the M. E. Church, and did pastoral work till 1830; became president of La Grange College, Alabama, till 1846, when he became bishop; was a member of every general conference from 1824 to 1846; chairman of the committee of nine which reported the plan of separation on the basis of which the M. E. Church was divided; was a prominent member of the Louisville convention in 1845. He had great pulpit ability and great executive ability. His *Life and Times of Bishop McKendree* (2 vols., 1859) is highly esteemed. D. at Aberdeen, Miss., Oct. 20, 1882. Revised by A. Osborn.

Paine, Robert Treat: jurist; b. in Boston, Mass., Mar. 11, 1731; graduated at Harvard College 1749; studied theology and acted as chaplain in the Northern army; subsequently studied law and was admitted to the bar 1759, settling at Taunton; in 1770 was prosecuting officer (in the attorney-general's absence) of Preston and his men for the massacre at Boston; elected to the Legislature 1773; delegate to Continental Congress 1774–78, meanwhile filling various important positions in Massachusetts; was one of the signers of the Declaration of Independence, attorney-general of Massachusetts 1780–90, and judge of the Supreme Court of Massachusetts 1790–1804. With others he founded the American Academy of Massachusetts (1780). D. May 11, 1814.

Paine, Robert Treat: See the Appendix.

Paine, Thomas: radical and deistical writer; b. at Thetford, England, Jan. 29, 1737; son of a Quaker stay-maker; received an indifferent education at the Thetford grammar school, but acquired a considerable range of knowledge by private study while working at his trade as a stay-maker at London, Dover, and Sandwich; served a short time on board a privateer 1756; married in 1759 the daughter of an exciseman, but was left a widower the next year; obtained a post in the revenue service 1762, was discharged for irregular conduct 1765, but restored the next year; had to wait for a vacancy and meanwhile taught school and preached; was exciseman at Lewes 1768; married the daughter of a deceased tobacconist there 1771, whose business he continued; cultivated literature; acquired so clear and forcible a style as to be chosen by the excisemen as their representative in advocating their interests, in which capacity he published a pamphlet, *The Case of the Officers of the Excise* (1772), which probably led to his introduction to Dr. Franklin, and to his dismissal from the service a second time on a trumped-up charge 1774; separated from his wife the same year for an unknown cause. Influenced by the advice of Franklin, he proceeded to America; arrived at Philadelphia Nov., 1774; obtained immediate employment as editor of the *Pennsylvania Magazine*; published in Bradford's *Pennsylvania Journal* in Mar., 1775, an article entitled *African Slavery in America*, which probably hastened the formation of the first American anti-slavery society (Apr. 14, 1775); published, Jan. 10, 1776, his celebrated and widely circulated pamphlet *Common Sense* (120,000 copies were sold in the first three months), which struck the keynote of the situation by advocating independence and a republican government; published in the *Pennsylvania Journal* of Dec. 19, 1776, the first number of *The Crisis*, which appeared at irregular intervals all during the war, and had great influence in maintaining the spirit of the army and the people; was chosen in 1777 secretary to the committee of foreign affairs, from which

post he was dismissed and censured by Congress in 1779 for revealing diplomatic secrets in a controversy with Silas Deane; was soon afterward elected clerk to the General Assembly of Pennsylvania; rendered good service in 1780 in promoting a subscription for relieving the distress of the army; received that year a degree from the University of Pennsylvania; went to France with Col. Laurens, whom he aided in negotiating a loan 1781; received from Congress a grant of $3,000 (1785), from the State of New York an estate at New Rochelle, and from Pennsylvania £500 as rewards for his services; went again to France 1787; set up the following year at Rotherham, Yorkshire, the model of the iron bridge which he had invented some years previously; published in London in 1791–92, in reply to Burke, his *Rights of Man*, a vindication of the French Revolution, which gave him immense popularity in France and led to a bestowal of citizenship and his election to the French National Convention as deputy for Calais 1792; took his seat in that body; usually acted with the Girondists; heroically opposed the execution of the king, advocating his banishment to America; was imprisoned by the faction of Robespierre in the Luxembourg, from Dec. 28, 1793, to Nov. 4, 1794. Immediately prior to his arrest he wrote part of his *Age of Reason*, and during his imprisonment finished it and published it after his release (1795); narrowly escaped the guillotine; again took his seat in the Convention; resided nearly two years in the family of James Monroe, then minister to France; wrote several political letters and pamphlets of minor importance; returned to the U. S. in 1802, making the voyage in a U. S. sloop of war; was cordially received at Washington, Philadelphia, and New York, and by Jefferson at Monticello, but insulted by the Federalists at Trenton and elsewhere; and deprecated by the religious public on account of his deism, he passed his closing years in comparative obscurity at New York and on his estate at New Rochelle. D. at New York, June 8, 1809. He was buried on his estate at New Rochelle, where a monument was erected by his admirers in 1839, though his remains were carried to England in 1819 by William Cobbett. Biographies of Paine have been written by Chalmers, Cobbett, Cheatham, Rickman, Sherwin, and G. Vale, but these are all of little value, and are superseded by that by Moncure D. Conway (2 vols., New York, 1892), who has also brought out the only complete and authoritative edition of his writings (4 vols., New York, 1894–95). Revised by S. M. Jackson.

Paine, William H.: civil engineer; b. in Chester, N. H., May 17, 1828; was engaged in surveying in the western part of the U. S. until 1861, when he entered the Fourth Wisconsin Regiment and served through the civil war with distinction, being appointed captain of engineers. He was connected with the Brooklyn suspension bridge as engineer in charge, and as consulting engineer from its inauguration until 1889. Later he was engaged in construction of cable-railways. D. Dec. 31, 1890.

Painesville: village; capital of Lake co., O. (for location, see map of Ohio, ref. 1–I); on the Grand river, and the Lake Shore and Mich. S., the N. Y., Chi. and St. L., and the Pitts. and West. railways; 3 miles S. of Lake Erie, 29 miles E. N. E. of Cleveland. It is in an agricultural and fruit-growing region, and contains several foundries and machine-shops, flour-mill, tanneries, factories, Lake Erie Female Seminary (non-sectarian, chartered in 1856), 2 libraries, a national bank with capital of $200,000, and 2 daily and 3 weekly newspapers. Pop. (1890) 4,755; (1900) 5,024.

Paint [from Fr. *peint*, deriv. of *peindre* < Lat. *pin'gere*, decorate, paint]: a name which is generally limited to mixtures of insoluble colors or pigments with certain materials which prepare them for application to surfaces of wood, iron, stone, plaster, canvas, etc., by the aid of a brush. When the colors are soluble the preparation is more properly a stain or a dye. Paints are used not only for purposes of decoration, but to protect surfaces from moisture and decay, which they accomplish by closing the pores and excluding the agents of destruction. All paints consist essentially of two parts: (1) the pigment; (2) the vehicle. *The pigments* are very varied in character; the whites are generally white lead, more or less adulterated with barytes, oxide of zinc, prepared chalk, etc.; the yellows are ochers, chromate of lead, etc.; the reds are red oxide of lead, ochers, oxides of iron, red oxide of copper, vermilion, dichromate of lead, carmine, carmine, madder, and other lakes, etc.; the blues are Prussian blue, ultramarine, smalt, Thénard's blue, verditer, etc.; the greens are verdigris, Paris green, verditer, borate of copper, chromate of copper, oxide of chromium, cobalt green, and green lakes, the most common being, however, a mixture of chrome yellow and Prussian blue; the browns are umber, bole, terra di Sienna, bistre, sepia, etc.; the blacks are lampblack, bone-black, anthracite, graphite, etc. (See Lakes.) *The vehicles* determine the character of the paint: we have oil-paints and water-colors.

Oil-paints.—The most common vehicle is linseed oil, which is especially valuable on account of the property it possesses of oxidizing to a resinous body, which holds the paint in a firm water-proof varnish. By boiling this oil with litharge and sulphate of zinc it acquires the property of drying very rapidly, though the color is darkened by the operation. For some purposes other oils, as nut and poppy oils, are substituted for linseed oil; the latter, being colorless, is preferred for very delicate colors, but it dries very slowly. In the preparation of oil-paints the pigment is mixed with a small quantity of raw linseed oil and ground in a mill to make the mixture homogeneous. This is put up in convenient packages for the painter, who mixes it for use with a further quantity of raw and boiled linseed oil, and colors it to any desired shade with colored pigments, which are also furnished ground in oil. As pigment and oil alone would be too thick, a third class of agents is employed in preparing paints, the *thinners*. These are either spirits (oil) of turpentine or benzine—both of which mix freely with the oil-paint and thin it to any desired degree. As it is desirable that the paint, after it has been applied to a surface, should dry speedily before it is contaminated by dust or rubbed off by accident, it is necessary to do something more than boil the linseed oil; a fourth class of substances is used, the *driers* or *siccatives*. Driers are sugar (acetate) of lead, sulphate of zinc, verdigris, binoxide of manganese, red lead, japanner's gold size, etc. By far the most powerful siccative is the borate of manganese, one one-thousandth being sufficient to hasten greatly the drying of linseed oil. This agent is supplied to the painter ground in oil in a convenient form for mixing with the paint. It is always necessary to mix the above-mentioned materials, pigment, oil, thinner, and drier, just before the paint is to be used, as, if the mixture is allowed to stand for any length of time, the pigment settles to the bottom, the thinner evaporates, and the oil absorbs oxygen, becomes thick and ropy, and a hard skin forms over it, which can not be dissolved again. To meet this difficulty a new system of mixing paint has been introduced, by which paints of any color can be made and mixed on a large scale at the factory, and put up in convenient packages which are always ready for use. Any portion which may be left over after painting any work can be returned to the package for future use. The principle involved in the preparation of these ready-mixed paints is the formation of an emulsion which holds the pigment in suspension and prevents its settling.

Water-colors.—For many purposes paints are prepared with the aid of water as a vehicle, glue or gum being added to make the pigments adhere after the evaporation of the water. Such paints can only be used for interior work, walls, and ceilings, for coloring pictures, maps, etc. They must be mixed as they are used, as a solution of glue or gum would mould or putrefy and dry up if kept for any time. The most common paint of this kind is called "kalsomine," and is a mixture of prepared chalk with a solution of glue, to which ultramarine is added to neutralize a faint yellow tint for white, and ochers, etc., for other colors. The solid cakes of water-color are made by mixing the pigments with gum and water to a thick paste, pressing in moulds, and drying in warm air. By rubbing them in water or applying a wet brush to them the color is liquefied for use. Silicate of sodium, soluble glass, has been suggested as a vehicle for pigments, and as specially adapted for application to walls and ceilings, as it produces a very hard and durable surface. Sometimes the silicate of sodium paint is applied to the ceiling, and a thin solution of the clear silicate is afterward sprayed over the entire surface. Naphthas and tars, both coal and wood, are used as vehicles for cheap paints or for paints for special purposes, as for protecting iron, ships' bottoms, etc. Poisonous pigments are also used to prevent the adhesion of barnacles and other marine animals and seaweeds to ships' bottoms, specially copper compounds, the red oxide, etc. Artists' colors are composed of very carefully prepared pigments ground in a small quantity of very fine oil, and put up in metallic tubes.

Luminous paint is made by mixing with the ordinary articles some phosphorescent powder which emits light in

the dark. Powders useful for this purpose are (1) *Canton's phosphorus*, made by calcining a mixture of oyster-shells and sulphur; (2) *Osann's phosphorus*, made by calcining oyster-shells and sulphide of antimony. The subject of phosphorescent powders is fully discussed in Gmelin's *Handbook of Chemistry* (vol. i., p. 193). C. F. CHANDLER.

Painter's Cream: a mixture of mastic, lead acetate, nut oil, and water, applied by artists to unfinished oil-paintings to prevent drying during the interruptions of the work. It is applied with a brush and washed off with water.

Painting: the laying of paint upon a surface; especially of paint in the strict sense—i. e. insoluble color mixed with some liquid or semi-liquid medium. It follows from this that painting is generally considered to be covering with thick and opaque pigment, and that the putting on of thin and nearly liquid color is called *staining*, because it is assumed to soak into the surface, or simply *coloring*. *A painting* means generally a work of fine art in color, and a painted work in light and shade only is spoken of as a "painting in monochrome," or as an "oil monochrome," or the like. PASTEL (*q. v.*) is included in the general art of painting, but a single work is called simply *a pastel* rather than a painting in pastel. For painting as a trade and as a preservative of wood, iron, etc., see PAINT; for decorative painting and the painting of ancient sculpture and architecture, see POLYCHROMY.

The fine art of painting includes DRAWING (*q. v.*). Painter artists must necessarily draw a great deal, both in the production of paintings and in study, and most of them draw in many different ways, some of their drawing passing imperceptibly into painting, or forming an inseparable part of it. FRESCO (*q. v.*) is painting done on damp plaster, the colors being mixed with powdered lime and water. In this case the drawing has been done previously upon sheets of paper, the figures, etc., being of the full size of the intended painting and somewhat elaborately finished, and then transferred to the plaster, as explained under FRESCO. Painting on plaster or stucco which has grown hard is unlike fresco in this, that the artist can draw directly on the plaster, as with charcoal or black chalk. The plaster is usually sprinkled with water, that the color may not dry too rapidly; then the color is applied either as ENCAUSTIC PAINTING (*q. v.*) or distemper or tempera, which is merely painting with colors mixed with some glutinous and adhesive matter, such as white and yolk of egg, i. e. together, yolk of egg alone, either of these with vinegar or some liquid glue. Distemper colors are diluted with water, however, and the modern *calcimine* or *kalsomine* process (see PAINT) is only a variety of this. Ancient paintings on walls, from the time of the early Egyptian tombs to the sixteenth century, were generally upon plaster or stucco of some kind, and these paintings, when not done in fresco, are generally found protected by some varnish or glaze which enters more or less into the substance of the work. It is therefore very difficult to ascertain just how ancient paintings were executed, and great differences of opinion exist as to this. During the later Middle Ages and the early Renaissance movable pictures were painted on wood, generally in *distemper*. Frequently the frame was an elaborate semi-architectural composition of gilded wood, and this and the *panel* upon which the picture was painted were made together as one piece of joiner's work. Altar-pieces and the like were often made up of many separate paintings united by a common system of frames of rich design.

Oil-painting came into use in the fifteenth century. Its power of giving depth of color and richness of effect quickly made it popular. It was not much used, however, upon plaster surfaces. Perhaps this was because oil-painting on plaster grows dark very rapidly, or perhaps it was because plaster is not nearly so agreeable a surface to work on as the prepared canvas. At all events the greater part of the large-scale painting of European peoples has been done in oil-painting upon *canvas*, and less commonly upon *panel* or specially prepared millboard, since its general adoption about 1520. Even the largest pictures of the Venetian school, such as the *Paradise* and the *Crucifixion* by Tintoretto, the *Presentation of the Virgin* by Titian, and the *Supper at Emmaus* and *Christ in the House of Simon* by Paul Veronese, are painted on canvas. Modern decorative painters too, in large paintings intended expressly for special walls which it is desired to adorn permanently, have used canvas, as in the great works of Puvis de Chavannes in the Panthéon in Paris. Indeed, most modern attempts to paint on plaster in fresco or other recently invented processes, such as *water-glass* and *spirit-fresco*, have failed to give the good results expected, and artists have generally returned to oil-painting on canvas. This canvas may be glued fast to the wall or may be stretched on wooden frames with an air-space behind it.

The *fine art of painting* is the most elaborate and complex of all the arts that appeal to the eye. It is therefore the most difficult to understand and appreciate. At the same time, as painting much more than sculpture deals with scenes, incidents, historical events, the illustration of poems and fiction, landscape, and the representation of common objects of all sorts, so it is painting that persons not specially instructed in art are the most apt to care for. The result is that there is no fine art in which the aim of the artist in producing and the feeling of the public in admiring are so widely separated. It is very often true that the painter was hardly conscious as he worked on his picture of that which most of the admirers in the exhibition most admire and enjoy. In a picture of military subject, for instance, the incident, as of rescuing a banner, fighting for a field-piece, or the like, is what attracts most persons, and it is looked at and judged by the greater number of visitors to the gallery somewhat as a dramatic performance is judged, or the poetical narrative of an event. The painter may indeed have taken some care to arrange his figures so as to tell the story intelligibly, or even to tell it with vigor and spirit; but this will not have been his greatest care. His interest is not in the incident, but in the harmony of colors, in the light and shade, in the general composition of graceful lines and of harmonious masses. In other words, to the painter the parallelogram within his frame is a surface which he has filled with a beautiful design, while to most of the spectators it is a piece of story-telling. Painter and spectator find, indeed, one seeming point of agreement, namely, in the truth to nature of the artist's work. But this is rather seeming than real, for the truth to nature which the artist cares about is really inappreciable to most of his public. The painter has at some time noted the beauty of sunlight on certain textures and certain colors, and thinks he has there the possibility of a new artistic effect. This, when he tries to put it into his military picture, will be unsuspected by nine-tenths of those who look at the picture, though it may be the most important part of it to its author. The truth to nature which he thinks his picture contains, and of which he is proud, is generally of this sort, and it is not even suspected by the majority of the spectators. This has always been the case. The comments by ancient writers upon the pictures of their times show an interest in the incidents related and the personages portrayed, and express admiration for supposed skill in copying nature, but no appreciation of any more artistic aim in the artist. Those pictures have perished, but the sculptures of antiquity remain to show us by a sure analogy that the artists 400 years B. C. worked in as purely artistical a way as those of 1500 or of 1890 A. D. That is to say, they cared for nature chiefly because of its suggestions to them as artists; and they cared for incident, for tradition, for the great Tale of Troy or that of the Seven against Thebes, for the Niobe tragedy or the fight with the Centaurs, chiefly as affording scope and room for their own artistic conceptions. It has been thought surprising that the great painters of the Italian Renaissance and the sixteenth century were as ready to paint Madonnas as Venuses and Venuses as Madonnas. The reason for this is merely that Venus and the Madonna alike were to the painter types of feminine grace, and figures upon which he could use his skill as draughtsman and as colorist. To a painter the great thing must always be to paint; to paint as well as possible and to produce as beautiful pictures as possible; little does he care in comparison for the story which he is ordered to tell, or the conventional type which he is bade reproduce. And it is not until the student of pictures seizes this truth and begins to approach good pictures somewhat in the spirit in which they have been conceived and carried out, that much enjoyment from the study of painting is possible. This is true of the other branches of fine art. It is true indeed of the finer handicrafts that a technical and esoteric standard of excellence exists for the workman, almost unsuspected by the spectator. It is especially true of artistic painting because, as has been said above, this is the most elaborate and complex of the fine arts. One can more easily seize the sculptor's secret, or some part of it, than the manifold thing, made up of reminiscences and dreams, of light and dark, of color intermingled with light and dark and putting

on their semblance, of pure form expressible only by means of light and dark and hardly expressible at the same time with color, and of expression of face and gesture and the individuality of persons. Landscape thought is in some ways more unseizable even than figure-painting; probably no such thing as adequate written criticism on landscape-painting exists or can exist; but the student who tries to find in the picture what the painter tried to put there may have an immense delight in tracing it, and may go far toward getting a full share of the artist's delight in his work. Thus it often appears in a landscape-painting that the expression of important natural truth is mingled with artistic merit so as to be indistinguishable from it. The rocky frame of a hill is traceable under its clothing of forest or of heather and bog; this has been seen and felt by the artist, perhaps half unconsciously, and it reappears in his picture.

The painting of antiquity which is known to us is almost wholly decorative. The important works of the celebrated Greek painters have perished, and no certain idea of them can be formed. It can not be too much insisted on that the statements concerning them which we have in the works of ancient writers are of no critical value whatever. The wall decorations of Pompeii and of a few newly discovered ancient houses in Rome help us only to form an idea of the classical style of composition. Painting in the time of the decline of the Roman empire and of the Byzantine empire is chiefly known to us in ILLUMINATED MANUSCRIPTS (*q. v.*). In the Middle Ages painting on walls of churches, etc., was mainly decorative in character. In the fifteenth century in Italy there was a great increase in the power of execution among a small body of painters in Siena, Florence, and other towns; the names most important to us are those of Duccio di Buoninsegna (about 1260–1330) and Guido of Siena, his contemporary Cimabue (1240–1302), and Giotto (1266–1336). Of these, Giotto is the one who came the nearest to the skill and facility of later times, and who established many of the types of legend and of the Bible story as told in painting. His most powerful and original follower was Andrea di Cione, called Orcagna, whose important work is of the middle of the fourteenth century. Florence at that time came to possess the most important school of painting. Of the Florentines, Masaccio (1402–28) seems to have made the most surprising advance in naturalistic power, both in drawing and in conception and composition; but the work of Masolino da Panicale, perhaps his teacher, is hard to distinguish from his. Meantime the purely ecclesiastical and decorative style was maintained by Fra Angelico da Fiesole (1387–1455). Ghirlandajo (1449–94) Filippo and Filippino Lippi (1412–69 and 1457–1504), able men and delightful artists, are, in the sense of mere trained skill and executive power, somewhere between the two standards. Their work seems far more realistic and vigorous than Fra Angelico's, and yet archaic beside Masaccio's. Sandro Botticelli (1474–1515) occupies a place apart, and is one of the original designers of any period. Luca Signorelli (1441–1523) painted chiefly at Orvieto and at Cortona and near Siena; important and well-preserved frescoes exist in the Orvieto cathedral. Andrea del Sarto (1487–1531) seems to close the list of the great men of the Florentine school, except that the long life and the immense achievements of Michelangelo (1475–1564) prolong the celebrity of Florence in other cities and under very different influences. Michelangelo spent only a part of his life in painting, but his achievements in fresco put him among the few greatest masters.

Perugino (1446–1523) and his successor, Raphael (1483–1520), made the Umbrian school famous; but Raphael in early life removed to Rome, and what is called the Roman school consists mainly of him and his pupils. Mantegna (1431–1506) was a powerful and original artist, and yet his work shows the immediate influence of classic relief sculpture and also of Venetian painting. He stands almost alone as the great painter of his time in Padua and Mantua. Leonardo da Vinci (1452–1519), coming from the north and soon returning there, is connected with both the Florentine and the Milanese schools, of which latter school he is the great master.

Meantime the Venetian school took shape in the hands of the two Bellini (Giovanni, 1428–1516, and Gentile, 1421–1507). Its purely artistic value is of the very highest; color was its especial point of superiority; and in the hands of Giorgione (about 1477–1511), Titian (1477–1576), Tintoretto (1512–94), and Paolo Veronese (1528–88), it attained a splendor never reached by any other school. Only individual painters here and there, such as Velasquez and Michelangelo, can be ranked with the great Venetians. Tiepolo (1693–1770) was the latest master of the Venetian school, and the last of those Italians who kept the ancient traditions. The Bolognese school must be mentioned, because of the great admiration which less critical ages than the present have felt for its mannered and artificial work. Ludovico Caracci (1555–1619), Annibale Caracci (1560–1609), and Domenichino (1581–1641), are the most famous names of this the so-called eclectic school. Correggio (1494–1534) is hard to class with any Italian school.

Spanish painting is of far less importance in the history of art; its greatest names are those of Francisco Zurbaran (1598–1662), Velasquez (1599–1660), one of the half-dozen giants of art, and Murillo (1613–82).

German painting has had a curiously uneven history—some great men, such as Albert Dürer (1471–1528) and Holbein (1497–1543), and long lapses of time during which little was achieved.

Dutch and Flemish painting is of the greatest importance after that of Italy. John Van Eyck (1370–about 1440) and his brother Hubert (1366–1426) are wonderful painters, excelling the Italians of their time in many respects. Memling (about 1430–95), Roger Van der Weyden (1400–64), and Quentin Matsys (1450–1529) are strictly mediæval painters, but their great ability distinguishes them from other artists of the pre-Renaissance style. It must not be forgotten that the art movement of the Renaissance was much later in the north than in Italy. Rubens (1577–1640) and Vandyke (1599–1641) are of the next succeeding epoch, and close the history of Flemish art, properly so called. Then the Dutchmen took up landscape art as their special study, and Cuyp (1605–91), Hobbema (1638–1709), and Ruysdael (1630–82), founded that great landscape school which is the peculiar glory of modern art. Two men of singular genius devoted themselves to portraiture and the human figure, Frans Hals (1584–1666) and Rembrandt (1607–69). In executive power each of them belongs to the small list of unsurpassable masters.

French painting was late in its development out of mediæval decoration, and was not of supreme importance, even in the seventeenth and eighteenth centuries; but Nicholas Poussin (1594–1665), Claude Lorrain (1600–82), and Watteau (1684–1721) are of high rank as artists, and a good school of portraiture existed under Louis XV. and Louis XVI.

English painting is also recent in its development. Its greatest names are Reynolds (1723–92), Gainsborough (1727–88), and Hogarth (1697–1764).

Painting in the nineteenth century is curiously affected by the freedom of intercourse among different nations, and also by the thronging of large numbers of persons into the professional life of the painter. The aggregate amount of talent, and even of unmistakable genius, to be found in modern painting is enormously great, but it makes less impression upon the public, because of the great size of modern communities and the large comparative number of persons interested in art. The French school, centered in Paris, is much the most important of modern times. Among those who have been some time dead, Ingres (1780–1867) is the greatest master. With him may be named Gérieault (1791–1824), Delacroix (1799–1863), Rousseau (1812–67), Couture (1815–79), Corot (1796–1875), and J. F. Millet (1814–75). In Great Britain the first half of the nineteenth century saw a great school of landscape art, of which J. M. W. Turner (1775–1851) was much the greatest master, but Constable (1776–1837) the one most widely known during his life, on the Continent as well as in Great Britain. The much-discussed pre-Raphaelite school produced one great and original artist, Dante Gabriel Rossetti (1828–82). Many painters have been popular and admired because of their large and showy pictures of patriotic and other historical subjects, such as Paul Delaroche (1797–1856) in France, Maclise (1806–70) in England, Cornelius (1783–1867) and Wilhelm von Kaulbach (1805–74) in Germany.

A general history of painting in ancient times and down to the close of the Renaissance has been written in German by Alfred Woltmann and Karl Woerman, and translated, with some changes, by Sidney Colvin. Kugler's *History of Art* and Mrs. Heaton's *Concise History of Painting* are much used. The French *Bibliothèque de l'Enseignement des Beaux Arts* contains volumes on French, Italian, Dutch, and other schools, and these volumes are being published in English translation. A very large and elaborate work is Charles Blanc's *Histoire des Peintres de Toutes les Ecoles*, com-

pleted in 1876. Bryan's *Dictionary of Painters and Engravers* (new ed. 1886) is good, and Seubert's *Künstler Lexicon* easy to use for persons with even a slight knowledge of German. The fullest biographical dictionary is Nagler's *Allgemeines Kunst-Lexicon*, but it is out of print and needs revision, and a revised edition which has been undertaken has not been carried very far. For the pictures of Christian religious subjects, Mrs. Jameson's *Sacred and Legendary Art*, *Legends of the Madonna*, and *Legends of the Monastic Orders* should be studied; also Lady Eastlake's continuation of Mrs. Jameson's *History of our Lord*; also Lord Lindsay's *Christian Art*. For Italian painting, the different books by Crowe and Cavalcaselle and by Morelli should be studied. For other schools, Crowe and Cavalcaselle, *Early Flemish Painters*; Stirling-Maxwell, *Annals of the Artists of Spain*; Redgrave, *Dictionary of Artists of the English School*, and *A Century of Painters of the English School*. All of the works of Ernest Chesnau are valuable for criticism, and those of Hamerton for their familiar and popular treatment of the art of painting.

RUSSELL STURGIS.

Paisley; town; in the county of Renfrew, Scotland; on the White Cart, 3 miles from its junction with the Clyde (see map of Scotland, ref. 12–F). It consists of an old town situated on the western bank of the river, and a new town on the opposite bank, paved and well built. The abbey (originally founded in 1203) is historically interesting, and among the modern buildings are the town-hall (1879–82) in the Italian style, the county buildings (1891) with a fine council-hall, and the Coats free library and museum (1871) with an observatory and picture-gallery. The Coats Memorial Baptist church (1891) is said to be the finest ecclesiastical structure erected in Scotland since the Reformation. Of its manufactures cotton thread occupies the first place, the two principal firms employing between them 10,000 hands. There are also works for dyeing, bleaching, distilling, and brewing, and the manufacture of woolen shawls, printed-cottons, handkerchiefs, carpets, soap, and starch: and there are ship-building yards on the Cart, which has been deepened to 18 feet since 1890. Paisley returns one member to Parliament. Pop. (1891) 64,379; (1901) 79,355.

R. A. ROBERTS.

Paiute Indians: See SHOSHONEAN INDIANS.

Paixhans, Fr. pron. pāk'saăn', HENRI JOSEPH: soldier; b. at Metz, Jan. 22, 1783; was educated in the Polytechnic School at Paris; entered the army; served in Napoleon's campaigns, but left active service after the Restoration; was employed in the war ministry and on the committee on the artillery. In 1824 experiments were made at Brest, at Col. Paixhans's suggestion, upon cannon for horizontal shell-firing. The idea was taken up by the British admiralty, and the Paixhans guns were the result. He published *Considérations sur l'Artillerie* (1815); *Nouvelle Force maritime* (1822); and *Force et Faiblesse de la France* (1830). D. near Metz, Aug. 19, 1854.

Paixhans Guns: See ARTILLERY and COLUMBIAD.

Pak'enham, Sir EDWARD MICHAEL, G. C. B.: soldier; a brother of the Earl of Longford; b. in Ireland in 1779; entered the light dragoons in early life, and served with brilliant reputation under Wellington (whose quartermaster-general he became), and also in the West Indies. In 1812 became major-general; in 1814 commanded the expedition against New Orleans; was killed in the battle of New Orleans Jan. 8, 1815, an action in which he displayed great gallantry.

Paktong: the correct name of the Chinese alloy resembling German silver in appearance, which is commercially known as *packfong*, *fong* being an original error for the Chinese *tong*, or *tung*, copper. The name means "white copper," and is pronounced peh-tūng in the mandarin dialect. Paktong is composed of arsenic and copper fused at a low temperature, two parts of arsenic to five of copper. It was once extensively exported to Europe and employed in making philosophical instruments and a great variety of other goods. It can not be fused, for the copper alone will remain after melting. Of late the cheaper nickel alloys have driven this substance out of the European market, but it is still extensively employed by the Chinese. It is probable that the Chinese often manufactured paktong directly from arsenical copper ores. See NICKEL.

Palacio, pāă-laa'sĕĕ-ō, RAIMUNDO ANDUEZA: politician; b. in Venezuela about 1840. He took an active part in politics; was Minister of State under Rojas Paul 1888–90, and at the close of his term was elected president, assuming office Mar. 19, 1890. In 1892 the elections were postponed; a rebellion, headed by Gen. Crespo, broke out; Palacio's forces were defeated near Caracas, and he was forced to resign and leave the country (June, 1892). H. H. S.

Paladilhe, pāă'lăă'dĕĕl', ÉMILE: composer; b. at Montpellier, Hérault, France, June 3, 1844; entered the Paris Conservatory when nine years of age; won first prize in 1857 and Prix de Rome in 1860. He has since won considerable fame as a composer of operas, the most important of which is his grand opera *Patrie*, text from Sardou's drama, produced at the Opera, Paris, Dec. 20, 1886. He has also composed a symphony, masses, and much music for vocal and instrumental solos. D. E. H.

Palæ'mon, QUINTUS REMMIUS: a Roman grammarian of the first century A. D., from Vicenza, whose *Ars* was largely appropriated by later grammarians. See K. Marschall, *De Remmii Palæmonis libris grammaticis* (Leipzig, 1887).

Palæog'raphy [Gr. παλαιός, ancient + γραφή, a writing, deriv. of γράφειν, write]: the science of ancient handwriting. Palæography has to do with manuscripts, as epigraphy with inscriptions; it teaches how to decipher them and to judge of the time and place of their writing. It includes in its scope all handwritings, alphabetic and non-alphabetic, Oriental and Occidental: but its chief concern has been with manuscripts written in the Greek or in the Latin alphabet.

Of the two, Latin palæography is the older. For some time after the invention of printing, as both compositor and scholar were familiar with the mediæval script, no need of palæographic study was felt; but, as the the old contractions disappeared from printed books and the new Italian hand crowded out the crabbed monastic writing, the manuscripts grew unintelligible. At the same time the exposure of such forgeries as the Constantinian Donation and the Pseudo-Isidorian decretals threw doubt on the genuineness of all ancient documents. In their eagerness to save the true at the cost of the false Catholic scholars went almost further than Protestants in their skepticism, and in 1675 the learned Jesuit Papebroch, editor of the Bollandist *Acta Sanctorum*, made a sweeping assault on all charters claiming early Frankish origin. These charters were almost wholly in the hands of the one ancient monastic order of the West, the Benedictines, and the ablest of its scholars, Mabillon, came to the rescue of the questioned documents by the publication in 1681 of his *De re diplomatica*. It created at one stroke a new science. With the sure hand of a master he laid down the criteria and rules for the determination of the age of MSS., illustrating and proving from the ample materials at his hand. Even his Jesuit opponent was convinced, and Mabillon's book remains the foremost in the literature of its subject. The voluminous *Nouveau traité de diplomatique* of his fellow Benedictines Toustain and Tassin, a half-century later (1750–65), only expands and illustrates the work of Mabillon. Thus far the new science aimed at both the decipherment of handwriting and the determination of the genuineness and worth of documents; but, when with the French Revolution the legal value of old charters was swept away, they no longer interested any but historians, while the other manuscript treasures of convent and castle, scattered now to the libraries of Europe, became the heritage of all scholars. Palæography, the science of handwriting, separated itself from diplomatics, the science of documents; and while archivists are now trained in the latter by two or three national schools, like the École Nationale des Chartes at Paris and that founded by Sickel at Vienna, the former has found a place in the curricula of most institutions for the higher learning. Facsimiles, multiplying with the growing ease and cheapness of pictorial reproduction, make the study possible and fruitful anywhere.

The oldest Latin MSS. extant belong to the first centuries of the Christian era. They show already in use two clearly marked hands—a formal book-hand in majuscule (capital) letters closely resembling those of the inscriptions, and a cursive (running) hand clearly derived from the other, but differing nearly as much as the small letters from the capitals of the modern alphabet. The whole story of palæography is the story of the reciprocal influence of these two hands—the majuscule growing more careless under the influence of the cursive, and the cursive more legible under the influence of the majuscule. Thus from the book-hand were developed in times still Roman the easier *uncials*, characterized especially by the rounded forms of *a*, *d*, *e*, *h*, *m*, and soon of *g*, *q*, *t*, *u*, all

taking on nearly their present minuscule shape. From a mixture of uncial and cursive grew, in the Germanized lands of the Continent, a group of national hands—Frankish, Lombard, Visigothic—while the Irish monks and their English disciples metamorphosed the uncial after their own fashion, but in much the same direction. Meanwhile the Roman cursive itself, stiffened into a charter-hand, had given birth to the grotesquely illegible script of the early Frankish diplomas. From the end of the eighth century, however, all these, one by one, gave way to the beautiful minuscule which had come into use at Rome, then the bookmart of the West, or, under the fostering care of Charles the Great and of Alcuin, had been evolved from the Frankish half-uncial in the convent schools of Neustria and Austrasia. Capitals were now banished to head-lines and initials, the script of letters and of charters became by degrees once more identical with that of books, and the Caroline hand was from the tenth century universal in Latin Christendom. After the twelfth century it fell indeed into that angularity which still survives in German book-type, as for long in Old English black letter; but happily the Italian scholars and printers of the Renaissance took as a model the purer Caroline forms of the old MSS. whence they drew the classical texts which were their delight. The chief difficulty of the later mediæval MSS. lies in the ever-multiplying abbreviations which had made writing almost a system of shorthand, and which even survived for a time the invention of printing.

The rise of Greek palæography followed close upon that of Latin. In 1708 the Benedictine Montfaucon published his *Palæographia Græca*, which, even longer than Mabillon's great work, remained the sole and sufficient authority in its field. Only in our own day has it been found necessary to revise his work in the light of ampler material, especially for the earlier periods. Since Montfaucon's time the field of study has been pushed centuries back by the discovery of Greek papyri at Herculaneum and in Egypt. Though we are perhaps but at the beginning of what we may hope from the latter source, we have already enough for a survey of the growth of Greek handwriting from the third century B. C. The development is strikingly parallel to that of Latin. From the first we have side by side two hands: the book-hand of literature and the running hand of ordinary use. In Greek, too, the angular capitals, in the early centuries of our era, took on the rounded forms which bear the name (borrowed from their Latin counterparts) of uncials. This remained the usual book-hand till in the ninth century there was shaped from the cursive a minuscule which thenceforward became the literary hand. Greek palæography has drawn a peculiar interest from its bearing on the transmission of the Christian Scriptures.

For the study of the non-alphabetic handwritings the best book is Wuttke's *Die Entstehung der Schrift*; for the history of the alphabet, Taylor's *The Alphabet* and Kirchhoff's *Studien zur Geschichte des griechischen Alphabets*; for the general history of handwriting, Astle's old but excellent *Origin and Progress of Writing*, Humphrey's *Origin and Progress of the Art of Writing*, Berger's *Histoire de l'Écriture dans l'Antiquité*. For Greek and Latin palæography we have at last an excellent manual in English: Thompson's *Handbook of Greek and Latin Palæography*. Of other modern introductions to palæography, the best for Greek are the German ones of Wattenbach, Gardthausen, and Blass; for Latin, the unwieldy Wailly, and the later textbooks of Wattenbach, Prou, and Paoli, while the convenient little manuals of Chassant and Leist have still a use. These must be supplemented of course by collections of facsimiles. The most comprehensive are still the *Paléographie universelle* of Silvestre, and the vast series of the Palæographical Society; but ample for the student's use are the *Schrifttafeln* of Arndt, the *Album patéographique* of the French National Library, or the *Recueil de fac-similés* of the École Nationale des Chartes. The best dictionary of abbreviations is still the old *Lexicon diplomaticum* of Walther, but the little one of Chassant and that appended to Prou's *Manuel* serve an excellent purpose, and Martin's *Record Interpreter* is of value for English documents. See MANUSCRIPTS. G. L. BURR.

Palæol'ogus: the name of a Byzantine family which gave rulers to the BYZANTINE EMPIRE (*q. v.*) from 1261 to 1453. It produced many able men. One branch held the principality of Montferrat, Northern Italy (1305–1533); another ruled in the Peloponnesus (1380–1462). Sophia, only child of Thomas, chief of the latter branch, married (1472) Ivan III. the Great, Grand Duke of Russia, who in consequence assumed the double-headed Byzantine eagle of Constantinople as the Russian arms. Theodore Palæologus, the last descendant of the Palæologi, died Jan. 21, 1656, and is buried in the Church of Landulph, Cornwall. See CONSTANTINE XIII. E. A. GROSVENOR.

Palæontology: same as PALEONTOLOGY (*q. v.*).

Palæphatus (in Gr. Παλαίφατος): Greek mythographer of uncertain period. The language seems to point to a time not earlier than the second century B. C. To this Palæphatus, for there were several of the name, is usually ascribed a treatise Περὶ ἀπίστων [ἱστοριῶν], *On Incredible Tales*, which was once a favorite school-book. In the extant compilation fifty of the Greek legends are explained historically and allegorically, much after the fashion of EUHEMERUS (*q. v.*), and on the general subject. The treatise has been edited by Fischer (Leipzig, 1789), and by Westermann in his *Mythographi Græci* (Brunswick, 1843). See Grote's *History of Greece* (vol. i., p. 45 foll., Am. ed.) and Wipprecht, *Questiones Palæphateæ* (1892). B. L. GILDERSLEEVE.

Palaihnihan Indians, also called **Palaiks** and **Pit River Indians** [from the Klamath word *p'laikni*, signifying mountaineers, uplanders]: a family of North American Indians, having as their habitat the territory drained by Pit river and its tributaries from Goose Lake to the mouth of Squaw creek, in Modoc, Lassen, Shasta, and Siskiyou Counties, Northern California. The following tribal divisions are recognized: Achomawi, Atuamih, Chumawa, Estakewach, Hantewa, Humawhi, Ilmawi, Pakamalli (?).

The physical appearance of the tribes of Pit river varies greatly. The Humawhi and Estakewach have been described as "most miserable, squalid, peaked-faced, mendicant, and mendacious wretches," the result chiefly of the inroads of the Modok and Mukalnk (who carried into bondage their comeliest maidens and bravest youths whenever opportunity offered) and partly of warfare in former years with white settlers. The Atuamih were much superior in physique. The women of all the tribes are degraded and their positions are servile. Marriage is by purchase, and polygamy prevails. All these tribes were very indifferent hunters. They formerly trapped game in pitfalls covered with brush, grass, and earth. These pits were particularly numerous along the river, hence Pit river, after which the tribes were also named. Cremation is generally practiced in cases where the person died of an unknown disease; all others are buried in a sitting posture. The Ilmawi, however, never burn their dead. Very few of the Palaihnihan Indians survive. Some of them were removed to the Round Valley reservation, California, and these, with some natives from Potter Valley, numbered thirty-four in 1889. See INDIANS OF NORTH AMERICA; also Stephen Powers, *Tribes of California* (*Cont. N. A. Ethnology*, iii.), 267–274 (Washington, 1877). F. W. HODGE.

Palaik Indians: See PALAIHNIHAN INDIANS.

Palamede'idæ [Mod. Lat., named from *Palame'dea*, the first described genus, from Gr. Παλαμήδης, a Trojan hero]: a family of birds most closely related to the ducks (*Anatidæ*), but resembling also the rails (*Rallidæ*), and remarkable for their large feet. In general aspect they resemble the rails more than the ducks. The neck is comparatively short; the head small and decorated with a slender horn-like appendage, from 2 to 3 inches long, rising from the forehead; bill short, compressed; the wings are large and armed at the shoulder with two strong spurs; the tail rather small; legs enlarged, covered with numerous oblong and somewhat hexagonal scales, which extend on the tibiæ as well as tarsi, and with larger oblong scales in transverse rows on the upper surface of the toes; the toes long, the anterior connected by slight scaly webs. In the osteology the species essentially resemble the ducks, and have been combined with them by Huxley under the name *Chenomorphæ* as typical desmognathous birds. The family is composed of but two genera: (1) *Palamedea*, Linn., with one species, *P. cornuta*, and (2) *Chauna*, Illig., with two species. All are inhabitants of South America, and frequent marshy grounds and borders of lakes and rivers. They generally associate together in pairs, but sometimes in troops of many individuals. Their gait when undisturbed is slow, their flight easy and rapid; they soar to great heights; they rest in high trees, and in these they make their nests, wherein the female generally lays two eggs. F. A. LUCAS.

Palanquin'[viâ Fr. and Portng. from Javanese *palangki*, viâ Prakrit. from Sanskr. *paryañka*, bed, couch, liter., a sit-

ting with bent legs on the hams; *pari*, around + *aṅka*, hook, bend, groin]: a portable litter for conveying travelers. Palanquins are employed extensively in India, China, and other Asiatic countries. The Japanese *norimono* and *kago* are but forms of the palanquin. The Indian palanquin has a water-proof cover, with Venetian shutters at the sides. The traveler is carried in a recumbent posture. The palanquin is borne by four men, who are relieved at regular intervals by others. Quite a train of attendants accompany the palanquin on foot, and the bearers while on duty keep up a monotonous chant. The journey is often continued for long distances by day and night.

Palaprat, pȧȧ'lȧȧ'praa', Jean, Seigneur de Bigot: dramatist; b. at Toulouse, France, in 1650. In 1675 he was capitulary of his city; he afterward traveled, lived for a time in Rome, and again in France as secretary of the Duke of Vendôme. D. Oct. 14, 1721. He is known chiefly as the associate of David August de Brueys (1640–1723) in the production of comedies. Their best-known work is the adaptation of the old farce *L'Avocat Patelin*; of their original works, *Le Sot toujours sot*, *Les Quiproquo*, *L'Important*, *Le Muet*, *Le Grondeur*, the last is called the best comedy between Molière and Regnard. A. G. Canfield.

Palatal Bones: a pair of bones in the vertebrate skull, which develop from the anterior part of the cartilage of the upper half of the anterior visceral arch ("palato-pterygo-quadrate arcade"). In the sharks (in which, however, no bone exists) the corresponding cartilage serves to bear teeth, and in the lower *bony* vertebrates (fishes and Batrachia) the bones may be teeth-bearing. In the higher forms, however, these teeth are lost, and the bones here merely form part of the skeleton of the roof of the mouth. In man and other mammals they are irregular in shape, and form part of the floor of the nasal cavity and wall of the orbit as well.

J. S. Kingsley.

Palatalization, or **Palatization** (Germ. *mouillierung*, *palatalisierung*): the modification of a sound toward a palatal articulation. The term is specially applied in historical grammar to the palatal modification either of guttural or of dental consonants under the influence of *e*- or *i*-sounds. Thus in Indo-Iranian the Indo-Europ. velar gutturals *q*, *g*, *gh* became palatalized before the vowels *e*, *i*, so as to become, e. g., in Sanskrit *c*, *j*, *jh*, instead of *k*, *g*, *gh*; cf. Lat. *quod* : *quid* :: Sanskr. *kas*, who? : *cid*. The Indo-Europ. perfect of root *qer*-, "make," is *qeqora* > Sanskr. *cakāra*; of root *gem*, "come," is *gegoma* > Sanskr. *jagāma*. Very similar is the treatment in the Romanic languages of Lat. *c* (=*k*) in *ce* and *ci* in distinction from that in *ca*, *co*, *cu*; thus contrast on the one hand Lat. *centum* > Ital. *cento* (pron. *tšento*) : Fr. *cent* (pron. *sōt*), and on the other Lat. *causa* > Ital. *cosa* (pron. *koza*) : Fr. *chose*, or Lat. *cursus* > Ital. *corso* : Fr. *cours*. The palatalization of a dental may be illustrated by the change of *ni̯* (*ny*) to *ñ* in the Romanic languages, as Lat. *seniorem* > Ital. *signor* : Span. *señor*. Entirely similar are such changes as Gr. *pʰaniō* > *pʰañō* > *φαίνω*. Changes such as *ti̯* to *ts* or *tš*, *di̯* to *dz* or *dž*, which occur in various languages and play often an important part in the development of their phonology, are commonly classed as palatalizations, because the direction of the change is palatal. Cf. Eng. *ort-yard* > *orchard*, pronounced *ortšard*; Gr. *taki̯ō* > *τάσσω*; Lat. *diurnus* > Ital. *giorno* (pronounced *džorno*) : Fr. *jour*; Eng. **verdi̯ure* > *verdure* (pronounced *vəədžur*); Gr. **di̯eus* > *Ζεύς*.

Benj. Ide Wheeler.

Palatals: the sounds formed between the body of the tongue and the hard palate. They are to be distinguished from the velars or gutturals proper, which are formed between the back of the tongue and the soft palate. (See Gutturals.) Palatal explosives are *k* (as in *kiss*, not as in *cot*) and *g* (as in *get*, not as in *got*). Palatal spirants are *ch* or *χ* (as in Germ. *ich*), and ʒ, the voiced variety of the same (as in Mod. Gr. *Αἴγινα*, or in Germ. *lege*, *folge*, *regnen*). The palatal semi-vowel *y* (*i̯*), in Eng. *yet*, *young*, *onion*, *use* (*i̯ūz*), approaches near to the character of a voiced palatal spirant, and is more accurately classified as such. The palatal vowels are the various forms of *e* (as in *ten*, *bat*, *bait*) and of *i* (as *it*, *bit*, *beet*). See Phonetics. Benj. Ide Wheeler.

Palate [from Lat. *pala'tum*, roof of the mouth, palate]: the arch or roof of the mouth. It is made up of two parts, called the hard palate and soft palate, or *velum pendulum palati*. The hard palate, which is situated anteriorly, is bounded in front and at the sides by the gums and alveolar arches, being continuous behind with the soft palate. It consists of a bony structure, formed by the union of the two palate-bones and the palatal portion of the superior maxillary bone. These palate-bones are wedged in between the superior maxillary and pterygoid process of the sphenoid. In form each palate-bone resembles the letter L, and is divided into a superior or vertical plate and an inferior or horizontal plate. The inferior surface of the horizontal plate forms the back part of the hard palate. The anterior border of each palate-bone articulates with the palate process of the superior maxillary bone. The bony structure of the hard palate is covered by periosteum, to which the mucous membrane is firmly attached. A linear ridge or raphe extends along the middle line, terminating anteriorly in a small papilla. The mucous membrane in front of and upon either side of the raphe is pale, thick, and corrugated; behind, it is smooth and deeper in color. A number of small glands are situated in the mucous membrane, the surface of which is covered with squamous epithelium. The *soft palate* is composed of muscular fibers covered by mucous membrane with gland structures embedded in its substance. From the middle of its lower border hangs a conical-shaped process, the *uvula*, and upon either side of the uvula, arching downward and outward from its base, are the pillars of the soft palate. The mucous membrane is thin, covered by squamous epithelium on both surfaces, except near the orifice of the Eustachian tube, where it is columnar and ciliated. The muscles of the soft palate are five in number on either side, viz., the levator palati, tensor palati, palato-glossus, palato-pharyngeus, and azygos uvulæ. Upon either side of the fauces, between the anterior and posterior pillars of the soft palate, are two glandular organs, the tonsils. During the first part of deglutition the food is carried back by the tongue, pressing against the hard palate; at the same time the base of the tongue is retracted and the larynx raised with the pharynx, and carried forward under it. Then the epiglottis closes the entrance to the larynx, and over this the food glides, the palato-glossi muscles contracting at the same time that the levator and tensor palate, with the palato-pharyngei, prevent the passage of the food into the upper part of the pharynx or posterior nares. Thus the palate serves an important part in the act of swallowing or deglutition. When its muscles are paralyzed, as occurs not infrequently after diphtheria, the posterior nares are not closed during deglutition, and food, especially liquids, regurgitates at the mouth. Revised by William Pepper.

Palat'inate, The (in Germ. *Pfalz*): formerly a political division and independent state of Germany, consisted of two separate territories, respectively called the Upper Palatinate, now forming the northern part of the kingdom of Bavaria, and the Lower Palatinate, situated on both sides of the Rhine, and now forming the southern part of Rhenish Prussia, the northern part of the grand duchy of Baden, and the province of Bavaria, called Rhenish Bavaria. From the eleventh century these two territories belonged together and formed an hereditary monarchy, their ruler being one of the electors of the German empire; but in 1648, by the treaty of Westphalia, they were separated, the Upper Palatinate falling to Bavaria while the Lower Palatinate continued a possession of the original dynasty. In 1777 the male line of Bavaria having become extinct, the two Palatinates were reunited, but at the Peace of Lunéville, in 1801, the Lower Palatinate ceased to exist as an independent state, its territory being divided between Hesse-Darmstadt, Baden, France, Leiningen-Dachsburg, and Nassau, and the only alteration which the Congress of Vienna made in this arrangement consisted in transferring to Germany that part of the Palatinate which France had occupied, Bavaria receiving the larger part and Hesse-Darmstadt and Prussia obtaining the rest. Many of its people emigrated to Pennsylvania.

Palatine [from Mediæv. Lat. *palatinus*, palatine, orig. one having an office in a palace, spec. use of Lat. *palati'nus*, belonging to a palace or to the Palatine Hill, deriv. of *Palatium*, the Palatine Hill, the imperial residence, situated on the Palatine Hill]: a term originally applied to persons holding office in a royal palace, later to certain high administrative or judicial officers. Under the Merovingians the counts palatine were attached to the court and palace of the sovereign, and aided him in his judicial duties, but from the time of Charlemagne this title was given to powerful feudal lords who were placed in charge of remote or turbulent provinces, where they maintained a court and

palace in the sovereign's name. This was the origin of the counties palatine. In England the chief counties palatine were Chester, Durham, and Lancaster; the last to lose the distinction was Lancaster (1873). King John divided Ireland into twelve counties palatine. Scotland had anciently a county palatine of Strathearn.

Palatine Hill (*Mons Palatinus*): one of the most important of the seven hills of ancient Rome. It was the site of *Roma Quadrata*, the original city. It is S. of the Capitoline Hill and S. W. of the Forum. It was the official abode of the emperors, and in mediæval times of the highest dignitaries, but has since then fallen into decay. Extensive excavations are being made, bringing to light many valuable remains of the imperial period.

Palatka: city; capital of Putnam co., Fla. (for location, see map of Florida, ref. 3–J); on the St. John's river, and the Fla. S., the Ga. S. and Fla., the Jackson., St. Aug. and Indian River, and the Jackson., Tampa and Key West railways; 30 miles S. W. of St. Augustine, 60 miles S. of Jacksonville. It is in an agricultural region, has a daily steamboat line to Jacksonville, and ships large quantities of cotton, sugar, oranges, pineapples, vegetables, and other products. It contains several hotels, a national bank with capital of $50,000, a savings and trust company with capital of $20,000, and a daily and a weekly newspaper. Pop. (1880) 1,616; (1890) 3,039; (1900) 3,301.

Palazzo del Campidoglio: See CAMPIDOGLIO, PALAZZO DEL.

Paleario, AONIO: b. at Veroli, in the Papal States, 1500; studied in Rome 1520–27; settled at Siena as teacher in 1530; and became one of the most prominent humanists of his age. His *De immortalitate animarum* (a large didactic poem published in 1536) is his principal work, but in 1542 he published *Della pienezza, sufficienza e satisfactione della passione di Christo*, and immediately he was summoned before the Inquisition. He defended himself, however, so brilliantly that he was acquitted, and after that time he became very cautious. He declined an advantageous professorship in Lucca because the Roman curia was too powerful in that place. His *Actio in pontifices Romanos et eorum Asseclas* he kept carefully concealed (it was not published until 1606, at Leipzig). In 1555 he removed to Milan. He was a second time accused of heresy and summoned before the Inquisition, and, having been sent to Rome, was condemned to death Oct. 15, 1569, and burned at the stake July 3, 1570.

Palefits: See LAKE-DWELLINGS.

Pale, Irish: See ENGLISH PALE.

Palembang': a Dutch residency on the east coast of Sumatra. Area, 61,911 sq. miles. Pop. 637,500, including Malays, Chinese, Hindus, Arabs, and Europeans. The coastland is low, marshy, overgrown with jungle, and extremely hot, but it is not unhealthful, except in the immediate neighborhood of the swamps. The interior is higher, and covered with rice-fields and plantations of sugar, cotton, pepper, and tobacco, and with immense forests of gum and cocoanut trees. Coal and oil-springs are found, and gold dust, iron ore, sulphur, and arsenic. The capital is Palembang, where the Dutch governor resides. It is the largest town and the chief trade center in Sumatra, and is built on both sides of the Moesi, a broad and deep river, which admits the largest vessels and forms a fine harbor. The city has about 50,000 inhabitants, and carries on a very active trade both with the interior and with Java, China, and Siam. Revised by C. C. ADAMS.

Palencia, pă-len'thĕc-ăă (anc. *Pallantia*): a province of Spain, consisting of parts of Old Castile; area, 3,126 sq. miles. Pop. (1887) 188,954. With exception of the northern part, which is mountainous, the province is an extensive table-land, cold and treeless, but fertile, well cultivated, and rich in salt, copper, saltpeter, chalk, and coal. Wheat, wine, vegetables, and fruit are produced. The capital, Palencia, has a Gothic cathedral (1321–1504). Pop. 15,028.

Paleontology: the science which treats of the ancient life of the globe. The name is of French origin, though, indirectly, from the Greek, παλαιός, ancient, ὄντα, being, and λόγος, discourse; and in its broadest sense covers the fields of palæozoölogy and paleobotany.

As a branch of science distinct from zoölogy and botany, paleontology owes its origin to the recognition of fossils as the remains of extinct organisms. Cuvier is generally credited with the honor of having first clearly announced the scientific opinion that organisms specifically distinct from the present inhabitants have lived upon the earth. This was done in 1796, in a paper on *The Living and Fossil Species of Elephants*, read before the French Institute of Sciences and Arts, and was founded upon the study of the bones of the Siberian mammoth and of the *Elephas americanus*, which were shown to be specifically different from those of the living Asiatic elephant.

At first the result of the study of fossil organisms was to add new species to the known genera of modern zoölogy and botany; but it was not long before it was found necessary to arrange in the classification for distinct fossil genera, and, as the science has developed, new families and orders have been defined, entirely distinct from any living groups, for the reception of the organisms whose fossil remains have been found in the rocks. Paleontology has not only enlarged the number of species and genera, etc., of animals and plants, but it has enlarged the conception of organisms. So long as these were supposed to be only such organisms as now live, the classifications had to deal with only the differences marking the present inhabitants of the globe, and the organic species was conceivable as a group of individuals having a common parentage. When, however, the idea of extinct forms, unlike anything now living, was introduced into science, the question naturally arose, how did these different kinds of organisms arise? and what relation do they bear to those now living? Paleontology primarily considers organisms as having a history, while zoölogy and botany are primarily concerned with the structure and classification of organisms; thus the former science finds its legitimate field of investigation to be the *history of organisms*. The records of this history are found chiefly in the rocks in the form of fossils, which are either the remains of the hard structures elaborated during the growth of the animal or plant, or tracks left on, or in the sands or muds during its life; but they include as well the skeletons or hard parts of recent animals to be examined after its death, or even while still living. The study of the history involves also the comparison of ancient with more recent types, and the examination of the more minute and perishable structures of living organisms, in order to explain the function or import of the hard parts alone preserved in the rocks.

The mere description of the fossil remains of organisms and their systematic classification is, properly speaking, a part of zoölogy and botany, technically described as palæozoölogy and paleobotany, while paleontology proper is wider in its scope, and is that branch of biology treating of the history of organisms, both vegetable and animal. As botany and zoölogy treat of the characters expressed in the life of the individuals, so paleontology treats of the life of the races, the former discussing the modification of the organs and tissues as adapted to the various life-functions of the individual, the latter the modification of the individual as a part of a fauna or a flora in adaptation to its environment, or as related to its ancestors or successors in the evolution of the race. Paleontology is therefore based upon the sciences of zoölogy and botany on the one hand, the nomenclature and systematic classifications of which are essential to the clear understanding of the historical relations of the organisms, and upon stratigraphical geology on the other hand, in which the records are preserved, and by which the time-relations of the fossils are determined.

The materials studied and described by the paleontologist are of two kinds, fossils and stratified rocks.

Fossils are the buried traces of organisms that have once lived, buried and preserved by natural means; the stratified rocks are the, generally, hardened layers or beds of sediments into which the original organic remains fell and were buried, and in which they have been preserved. A fossil may be an impression, footprint, or trail of the tail, or worm-boring made upon the sediments before they were hardened by the living animal itself; or it may be a bone, a tooth, or shell, or some other hard part of the animal or plant covered and preserved in its original condition; or it may be the petrified remains of some more perishable parts, which by infiltration, or chemical alteration or replacement, have become mineralized, or by pressure, heat, or other means have become metamorphosed into some stable chemical compound. In some cases fossils are the hollow cavities from which the mineral part of the fossil has been removed

by solution, and in other cases such cavities have been filled by mud or sand, or by mineral substances brought in by waters in solution and deposited in the cavities by crystallization. In all these various methods of fossilization the essential part of the fossil is not the material, either chemical or mineral, of which it is composed, but the form it holds; and there may be clear evidences that this, too, has been changed by the distortion of the rocks on which the record is made. Still it matters not of what the fossil is made; from the form it assumes is interpreted the character of the organism which made it. In this particular paleontology is but the science of ancient organisms—paleozoölogy or paleobotany. Fossils reveal the form, in almost every case, of only the hard parts of the organism, such as internal or external skeleton, organs of defense or offense, as scales, scutes, spines, and teeth, or crusts or deposits formed for protection and shelter, as shells, corals, etc. Animals composed entirely of soft tissues would therefore leave little or no record of their existence, and even of the others the preserved remains which are subject to study must be a very small proportion of the actual inhabitants of the earth.

When we consider also the mode of fossilization, the imperfection of the record becomes still more apparent.

Death comes to most animals and to some plants, not by the natural living out of the functions of the body, but by violent means, the killing by more powerful animals. In the process of taking the life and using the organism for food, not only the soft tissues but in many cases the skeletal parts are crushed and partially destroyed. Second, in the formation of sediments for deposition there is always more or less attrition, due to the grinding together of the pebbles and sand as they are tossed by the waves or borne along by the currents of rivers or seas; and thirdly, the organic tissues are unstable chemical compounds, and therefore, so long as they are left within reach of the oxygen of the air, they are liable to decomposition.

For these various reasons, although the substance of the hard parts may be preserved, it must be assumed that in the rocks the forms of only a very small percentage of the organisms that have lived can be recorded, and that those which are preserved are in great part of animals which developed durable hard parts, such as shells, skeletons, and corals; and of these, finally, the fossils must represent mainly inhabitants of the ocean, at the borders of which the great proportion of the sedimentary rocks were formed, or the inhabitants of fresh-water lakes and surrounding land, for the lakes produce deposits similar to those at the edges of the continents.

Paleontology is therefore limited to certain groups of organisms. Not all of them have left their history, and for some groups, such as the Mollusca, Corals, Crinoids, and Crustacea, the history is preserved with a considerable degree of fullness, compared with our knowledge of the living forms.

Imperfections in the stratigraphical series of rocks is another source of difficulty in reading from fossils the full history of organisms. Strata have been formed mainly within 100 miles of the edges of continents or in shallow mediterranean seas. The surface of continents in relation to the mean tide level of the oceans has been, geologically speaking, constantly changing; in one region sinking, at another emerging from the sea. The result to the strata has been that they were not formed continuously in one place, but the locality of the maximum accumulation of sediments has been constantly shifting. Hence any section now made through the strata is of limited extent, and exposes only a small part of the geological formations. The accumulation of evidence therefore requires the comparison of sections made through the strata of separate regions. The fact that at the present time the faunas of the seas at separate regions along the same coast differ in species, and at different depths out from the same point show marked differences in species, makes it evident that mere difference of species of fossils can not be taken as a certain criterion of distinct epoch for the strata containing them; but in making up the geological series of strata different sections must be combined on the basis of correlations of the strata by the contained fossils. In a general way by this means the strata of one country can be correlated with those of another, the strata containing like species being classified as belonging to the same system or formation, however widely separated geographically. The fact of geographical distribution of living species leads to the presumption that the finding of identically the same species at widely separated points on the earth may indicate, not contemporaneousness, but succession in time sufficient to allow of the migration of the species from one region to the other.

The theory of the evolution of species, from earlier species morphologically differing from them, has led to the hypothesis that under differing conditions the evolution of a race may progress more or less rapidly, so that on one side of the globe, for instance, species may appear earlier than in another region on the opposite side, though both were evolved from a common stock. Some paleontologists therefore prefer to interpret the evidence of likeness of fossils in strata of widely separate regions as indicating "homotaxial" rather than "contemporaneous" position of the strata. Undoubtedly the correlation of strata can not be made with minute accuracy when they are widely separated geographically, but so great is the parallelism in the general progress of life for all the known world that even in the present state of science the grander divisions of the geological series can be correlated by the fossils from whatever part of the globe they come.

The geological time-scale is composed of a series of stratified rocks making up the outer crust of the earth. The separate sheets or strata were originally laid down under water, the greater portion of them under marine water, as sediments washed by water from the land. They constitute, therefore, a succession of layers one upon the other, the lower being the older and their relative stratigraphical position expressing relative order of formation.

The strata are composed of various kinds of material, broken fragments of rocks, as sand, mud, pebbles; or of shells or corals, as limestones; or of plant stems or tissues, as coal; or of volcanic ash, tufa, or schalstein; or they may be of chemical origin, in whole or in part, as are some calcareous, siliceous, and ferruginous beds; but in order to constitute geological time-records they must have been accumulated successively, one layer upon another, indicating by their superposition their chronological succession.

Subsequent disturbance of these strata has resulted at some places all along the way in folding, upturning, and breaking them; in pushing those already formed above the surface of the water, thus stopping the process of their formation and subjecting them to erosion and partial or total destruction. In other places the formation may be continuous. By similar disturbances the strata which have been above the surface may be depressed, and upon their uneven edges again receive deposits of newer strata.

The breaks thus formed in the series of strata represent intervals in the time-scale that must needs be filled out by strata in which there was no break for the particular period of time so represented.

Examination of the edges of the strata now above water and making the land of the continents has enabled the geologist to make out a continuous series of strata of a maximum of not less than 100,000 feet in thickness.

In a general sense the thickness of the strata represents duration of time, and on the basis of the estimated rate of the formation of the strata the total length of time represented by this geological time-scale is believed to be at least 50,000,000 years.

Fossils are found imbedded in these strata from the base to the top. Hence the fossils of the strata in a particular part of the series are interpreted to be the remains of organisms which lived during the period of time corresponding to their position in the geological time-scale.

Systems.—The stratigraphical series of rocks has been divided into ten divisions of greater or less thickness called systems, the relative order of which is established with certainty. Their names and order from above downward are as follows:

	Time-ratios, after Dana.	
10. Quaternary and Recent.	1	Cenozoic time.
9. Tertiary.		
8. Cretaceous.	1	Mesozoic time.
7. Jurassic.	1½	
6. Triassic.	1	
5. Carboniferous.	2	Paleozoic time.
4. Devonian.	2	
3. Silurian.	1½	
2. Ordovician.	6 [5]	
Potsdam	1	
1. Cambrian.	[5]	

Below the Cambrian are rocks which originally may have been formed in the same manner, but, so far as at present known, contain no recognizable traces of organisms.

The period of time represented by the several systems is not known in terms of human or solar chronology, but some approximation to the time-ratio expressed is determinable

by a comparison of the thickness and kinds of rocks composing each.

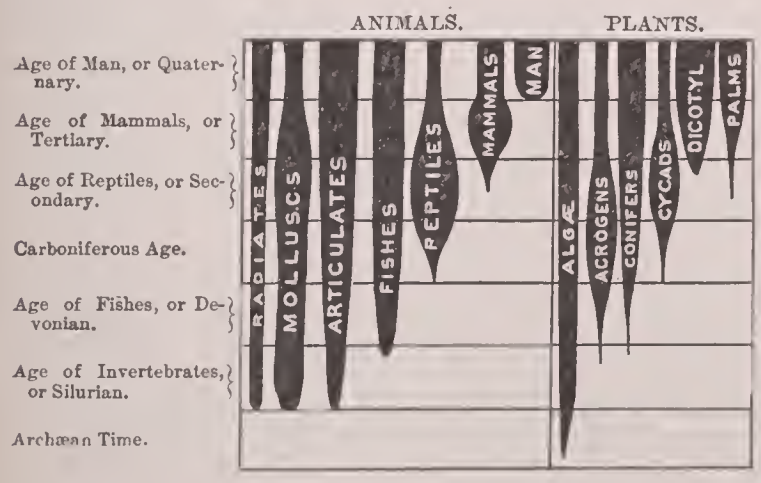
In his *Manual of Geology* Dana has estimated the time-ratios for the several systems to be approximately that of the figures opposite them in the above table, but the lower two may probably now be expressed more accurately by 5 and 5 as expressed in brackets. Grouping the systems, as is commonly done, into three great groups marked conspicuously by the dominant characteristics of the life of the time, there are formed (1) the *Paleozoic*, five times as long as the (2) *Mesozoic*, and fifteen times as long as the (3) *Cenozoic*.

In this grouping of the systems expression is given to one of the fundamental facts observed in the geological history of the globe, viz., the progressive change with the passage of time in the total life of the globe. In the Cenozoic, or more recently formed rocks, are found species the same as those now living, and only this part of the geological series holds fossils which generically are mainly of recent types.

In the Mesozoic time the life holds an intermediate character, mingling ancient with modern generic types. In Paleozoic time the organisms represented are almost entirely of extinct genera. This may be illustrated by the range of the gasteropods (coiled, shell-bearing mollusks, like the snail on land and the whelk in the sea). Of the 59 known families, reported in Zittel's *Paleontology* (1885), only 17 families are known to have had Paleozoic representatives. Taking as a further example one of these families, the *Trochidæ*, out of 75 genera enumerated only a single genus of the Paleozoic is represented by living species; 22 Paleozoic genera are now extinct, and 20 of these became extinct at the close of the Paleozoic. Of the 31 Cenozoic genera about two-thirds began in the Mesozoic. The above is a selected example of the general principles—(1) that the organisms of Paleozoic time were of ancient and now extinct types in a very large majority of cases; (2) that the life of the Mesozoic is specifically almost completely extinct, and a majority of its genera were different from the prevailing forms now living; and (3) the further back we go the greater is the contrast between forms then living and the present life of the globe.

If we select the dominant life reported from each of the successive geological systems, we find another law expressed, viz., that there has been a continuous advance in the rank of the dominant life for each geological age. If we divide geological time on the basis of dominant life on the globe as indicated by the fossils preserved in the rocks, we have, first, the age of Invertebrates, which continued from the Cambrian practically to the base of the Devonian, for although fish, the lower division of the Vertebrates, lived in the Silurian period, and, as Walcott has shown, in the Ordovician (as fossils from Trenton rocks in Colorado have shown), the fishes were not in size, strength, or numbers the rulers of the seas till about the Devonian age. The second age is the age of Fishes, as recorded in the Devonian system of rocks; the third age is the age of Amphibians of the Carboniferous system; the fourth, or age of Reptiles, included the whole of Mesozoic time, in which gigantic reptiles were the rulers of land and air, as well as of the seas, if we may judge from their size, strength, and armor, both offensive and defensive. Mammals, of weak and low types (marsupials), appeared in the Mesozoic, but true mammals became dominant with the opening of Cenozoic time.

This series of facts is illustrated in the following figure from Dana's *Manual*, which shows the kinds of animals and plants which began and were dominant in each age:



It is for zoölogy and botany to classify and determine the genetic relationship of the various known animals and plants, and that part of paleontology which deals with the description and naming of fossils alone is unsatisfactory, unless it is based upon a thorough knowledge of the structure and systematic classification of living organisms.

The study of living forms, however, does not reveal their history, and in order to fully understand the relations of living forms to each other those which have gone before them in geological time must be known; this is the particular province of paleontology.

Embryology reveals the various steps and stages through which the individual passes in attaining the adult form from the primitive ovum; and these steps of development have been found very helpful in suggesting genetic relationships not recognized in adult forms, and thus their study has served to perfect the systematic classification. Paleontology, as the science of the history of organisms and of the races of organisms, throws independent light on their systematic classification by revealing the actual order of succession of adult forms. While it may be reasonably assumed that the embryonic stages of development of the ancestors of any living organism corresponded to its own embryological development, it is not, *a priori*, necessary that the adult forms of the ancestors should have taken on characters expressed in the embryonic stages of their progeny now living. The science of paleontology, while needing light from every possible source in order to interpret its very limited and imperfect facts, has in itself the evidence of the true succession of organic forms in past geologic time, which is its chief function to elaborate and explain.

In attempting to exhibit the more conspicuous facts of paleontology a few words regarding the methods of classification may be appropriate.

Organisms are distinguished, primarily, from inorganic things by performing vital activities or functions, and, secondarily, by the organic structure or tissues which have been seen associated with or performing such functions. Dead organisms, or parts of dead organisms, are known to be such by their morphological likeness to parts or wholes of living organisms. Organisms are classified as of two kingdoms, vegetable and animal. When two or more individual organisms are compared, as, for instance, a dog and a hen, they are found to possess points of likeness and points of difference. By their like characters they are classified together, by their differences they are separated into different groups. The dog and hen both breathe, have blood, bones, and limbs, and they are both classed as Vertebrates. The one has hair, four feet, walks and nurses its young, and is called a mammal; the other has feathers, wings, and lays eggs, and is called a bird. To distinguish the subdivision of the birds other different birds must be compared with this one, and so subdivisions of various rank are established in classifying organisms, and names are given to the several divisions indicative of their rank. The chief of these are, first, the two kingdoms of animals and plants. In each of these there are sub-kingdoms, as branches or types; in each branch are different classes. The subdivisions of classes are orders, under them are families; the families are subdivided into genera; each genus includes one or more species, and species are made up of individuals. These various groupings are artificial, and receive technical scientific names, as in the illustration: *Canis* is the generic name of the dog; *familiaris* its specific name. The wolf belongs to the same genus, but it is a different species—*Canis lupus*. The dogs (*Canis*) and the foxes (*Vulpes*) are generically different, but both belong in the family *Canidæ*. The *Canidæ* and the *Felidæ* (cats, lions, etc.), two distinct families, are both *Carnivora*, which is an order.

The order *Carnivora* and the order *Cheiroptera* (bats) are in the class *Mammalia*, and the birds and reptiles and mammals are several classes of the branch *Vertebrata*.

It is evident therefore that any individual dog is not merely a species, but that it exhibits in its structure and functions all the characteristics—1, of an organism; 2, of an animal; 3, of a vertebrate; 4, of a mammal: 5, of a *Carnivora*; 6, of a *Canidæ*; 7, of a *Canis*; and 8, of the species *Canis familiaris*.

Each organism thus possesses numerous characters which are relatively of greatly varying degrees of importance from the point of view of affinity with other organisms. The particular color of its hair is less important than the number and shape of its teeth, and this, again, is of less importance than the number of its legs; or, in general, we

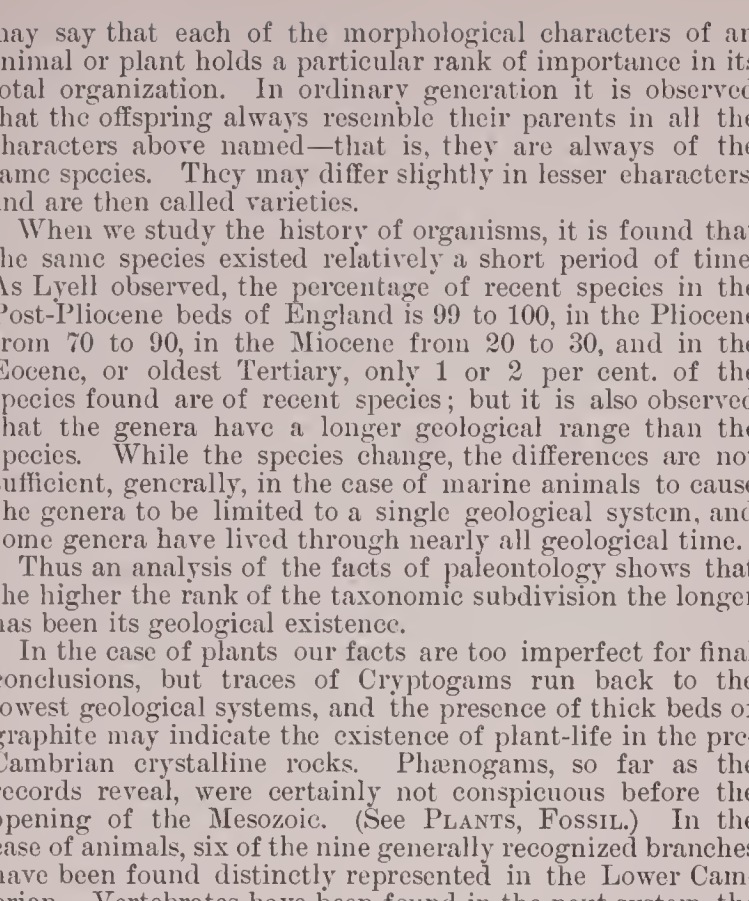
may say that each of the morphological characters of an animal or plant holds a particular rank of importance in its total organization. In ordinary generation it is observed that the offspring always resemble their parents in all the characters above named—that is, they are always of the same species. They may differ slightly in lesser characters, and are then called varieties.

When we study the history of organisms, it is found that the same species existed relatively a short period of time. As Lyell observed, the percentage of recent species in the Post-Pliocene beds of England is 99 to 100, in the Pliocene from 70 to 90, in the Miocene from 20 to 30, and in the Eocene, or oldest Tertiary, only 1 or 2 per cent. of the species found are of recent species; but it is also observed that the genera have a longer geological range than the species. While the species change, the differences are not sufficient, generally, in the case of marine animals to cause the genera to be limited to a single geological system, and some genera have lived through nearly all geological time.

Thus an analysis of the facts of paleontology shows that the higher the rank of the taxonomic subdivision the longer has been its geological existence.

In the case of plants our facts are too imperfect for final conclusions, but traces of Cryptogams run back to the lowest geological systems, and the presence of thick beds of graphite may indicate the existence of plant-life in the pre-Cambrian crystalline rocks. Phænogams, so far as the records reveal, were certainly not conspicuous before the opening of the Mesozoic. (See Plants, Fossil.) In the case of animals, six of the nine generally recognized branches have been found distinctly represented in the Lower Cambrian. Vertebrates have been found in the next system, the Ordovician. It is evident, therefore, that the main divisions of the animal kingdom, and probably of the plants also, date back to the time of the very earliest records at present known; and whatever may have brought about the differentiations of form, the scheme of classification based upon recent forms is applicable in its grander features to all known traces of life on the globe.

The classification and the known range of each branch are given in the following table, in which the vertical spaces indicate the geological systems in their relative order from below upward, from left to right, and the heavy horizontal lines express the range of each of the branches of the animal and vegetable kingdoms named in the list on the left:



From the above table it is evident that no laws of history are expressible in terms of the branches (alone) of the animal kingdom. It is not improbable that each of the branches may have had representatives in the time of the Cambrian system, and has continued ever since.

In regard to plants the same may be said, but it is more probable that the higher forms of land vegetation did not appear till the close of the Paleozoic or the beginning of the Mesozoic. A glance at the diagram of range of plants shows very distinctly the relative succession of appearance of the three great groups—(1) vascular Cryptogams, (2) Gymnosperms, (3) Angiosperms—to coincide exactly with the general rank of complexity and elaboration of organization exhibited in each; the lowest types were evidently first to be conspicuous, and the highest flowering plants were of relatively modern origin. Although nearly 10,000 species of extinct plants have been described, the results from the study of fossil plants are too meager to permit of profitable discussion of them in the present article. The above table expresses the general facts. The ferns, equisetums, and lycopods constituted the bulk of the luxuriant flora of the Carboniferous age. The cycads and pines were as conspicuous in the Mesozoic, and the Cretaceous and Eocene floras were the first to be conspicuously constituted of angiosperms. See Plants, Fossil.

A more minute analysis of the history of animals will reveal some facts illustrating the grander laws of paleontology.

Protozoa.—The Protozoa are for the most part minute, and even microscopic in size. Functionally they have no permanently specialized organs, but in many cases secrete calcareous or siliceous shells of particular form, or of particular mode of aggregation, furnishing means for their morphological classification. Of the three classes (Gregarinida, Rhizopoda, and Infusoria) into which the recent Protozoa are divisible, undoubted remains of only Rhizopoda are found fossil. The Rhizopoda include the orders *Foraminifera*, *Radiolaria*, and *Heliozoa*. The fossil species are chiefly the *Foraminifera*, of which some are of considerable size, i. e. not microscopic, the Fusulina of the Carboniferous reaching a length of half an inch; Nummulites, a thin discoid or coin-shaped fossil, from half an inch to an inch in diameter, which was extremely abundant in the Middle Eocene, forming great deposits, now the nummulitic limestone, reaching a thickness of several thousand feet in Southern Europe and Asia and Northern Africa.

Eighty genera of *Foraminifera* are enumerated in Zittel's list of 1880; of these only one is described from lower than Carboniferous strata, and only twelve genera are Paleozoic, fifty-eight are Mesozoic, and a large majority of the latter genera are known among living forms. This expansion in the historical appearance of the genera is probably due rather to lack of record than to real first appearance of the greater part of the *Foraminifera* in the latter half of geological time. The minute size and the ease of destruction or obliteration of form accounts for the absence of these simplest of animals from the early geological formations. This statement is supported by the fact that of the six families into which the fossil *Foraminifera* are classified, all but one of them is represented among the twelve known genera of the Paleozoic, showing an expansion of all but generic characters almost as great in the Paleozoic as now, and Carpenter concluded, from his study of the order, that there was no evidence of any fundamental modification or advance of the foraminiferous type from the Paleozoic period to the present time.

Cœlenterata.—The Cœlenterates may be divided for our purpose into four classes, viz.: 1, Sponges; 2, Anthozoa (polyps or corals); 3, Hydrozoa (including jellyfish); and 4, Ctenophora.

Of these we may know of fossil remains of sponges, in the form of siliceous and calcareous spicules or composite masses of structure; of the Anthozoa by the calcareous corals they deposit; but the latter two classes, because they develop no solid test or skeletal parts, must be regarded as beyond the possibility of making a record except of very doubtful value. However, undoubted traces of medusa (jellyfish) are found in Cambrian rocks.

Fossil sponges have been detected in the lowest, the Cambrian, and in each of the successive geological systems. Although in the case of sponges the evidence must be very incomplete, their great antiquity is shown by the fact that of the seven orders into which the known sponges are classified by Zittel, six of them are already known from the Carboniferous system, viz.: the *Ceraospongiæ*, the *Monactinellidæ*, the *Tetractinellidæ*, the *Lithistidæ*, the *Hexactinellidæ*, and the *Calcispongiæ*.

The Anthozoa are better represented than any of the animals heretofore mentioned, and in the fossil corals which

they constructed during life we have the record of the evolution of the type in sufficient elaboration to give a somewhat definite idea of the nature of the changes that have taken place.

Opposite each family in the following table is given the number of genera of the various families of Anthozoa recorded (at the time of the publication of Zittel's *Handbuch*) for each geological system:

Genera of the various families of Anthozoa (corals) arranged according to their geological range.	Cambrian.	Ordovician.	Silurian.	Devonian.	Carboniferous.	Triassic.	Jurassic.	Cretaceous.	Tertiary.	Quaternary and Recent.

Totals	..	1	54	39	37	17	84	111	126	131

From this table it will be seen that of the two great divisions of the older (viz., Tetracoralla and Hexacoralla), the first division is characteristic of the Paleozoic, and the latter, although it is represented by a few genera in the Paleozoic, is as dominantly characteristic of the later half of geological time.

The imperfection of record has nothing to do with the general law here illustrated. There were the Tetracoralla with two well-characterized families, which were abundant in genera (which means that there was evolved wide difference in structure and form), and expressed by a great many species and abundance of individuals in the Paleozoic, and this whole group then became extinct (or nearly so, for there are numerous living forms which have been recently studied and are shown to be closely allied to these ancient types).

Again, the Hexacoralla represented by a few forms in the Paleozoic rapidly expanded in variety of form, number of genera, and necessarily in abundance of species and individuals, and, as we may infer, took the place in the oceans of the extinct forms that were evidently so abundant in earlier time.

To use an illustration, the genus *Zaphrentis*, one of the expleta corals, is as characteristically an ancient genus as *Fungia*, one of the Fungida, is characteristically a modern genus.

An important geological group of the Cœlenterata is the Graptolites. They developed delicate stem-like rows of cells in which the polyp lived, and they are characteristic of the lower half of the Paleozoic.

Echinodermata.—The third branch, the Echinodermata, are classified by the zoölogist as follows: viz., Crinoidea (or sea-lilies), Asteroidea (starfish), Echinoidea (sea-urchin), and Holothurians (sea-slugs, trepangs, or sea-cucumbers. Each of the first three develop hard calcareous or chitinous shell, or granules, or spines, which are easily preserved after death, and hence of them a fair record is known. The Holothurians, secreting only a leathery kind of external coating, and fragile calcareous spicular in the inner coatings, are unsatisfactory as paleontological objects of study.

The paleontological history of the several types of Echinoderms may be expressed mathematically by noting the number of different generic forms of each order known in each of the successive geological systems.

As the conditions of preservation of the remains may be supposed to be comparatively alike in the several systems, although the records are very imperfect and the specimens rare, divergence of structural development as indicated by different genera may be safely interpreted as a measure of dominance, vigor of generation, and abundance of the forms expressed in fossil condition. While it is reasonable to suppose that the tables will be greatly modified by future discoveries as to the actual number of species and genera, these discoveries will not be likely materially to change the general relations of the grand divisions of organisms to paleontological history.

The following table expresses this law based upon the facts recorded by Zittel:

Differentiation of the genera of Echinoderms, expressed in the number of genera of each class and order for the various geological systems.	PALEOZOIC.					MESOZOIC.			CENOZOIC.	
	C.	O.	S.	D.	Carb.	T.	J.	K.	Tert.	Rec.

Euechinoidea	..	..	..	..	..	4	45	76	83	74
Asteroidea	..	5	12	4	5	3	11	11	9	15

Analysis of the table shows the general laws of evolution of the Echinoderms to be as follows:

The Crinoids are distinctly an ancient type, represented abundantly and in great variety of generic forms in the Paleozoic, and becoming almost extinct at its close. In the Mesozoic (the Jurassic showing the earliest dominance of the genera) a new subordinal group springs into prominence, the Articulata, and they continue on to the present time, when they are chiefly of deep-sea habitat. The Tesselata and the Articulata are closely related, but possess distinct and permanent characteristics.

The Cystoids were of an irregular form and apparently of lower rank of organization than the Crinoids, and had none or but imperfectly developed arms. As will be seen from the figures they are particularly an ancient type—the earliest to appear in the Cambrian, had their climax in the Lower Silurian or Ordovician, and became extinct at the close of the Paleozoic. Exception to this statement may be made on account of the recent discovery of forms classed with the Cystoids in the deep seas.

Extinct is used to express lack of evidence of the continuance of the race. Species, genera, and orders may still continue to live in the depths of the ocean where the conditions of life have remained remarkably uniform for geological ages, and only the deep-sea dredge can reveal the facts to us. Some remarkable finds have already been made, and it would not surprise paleontologists to hear of the discovery of many supposed extinct ancient types of life in the sea depths.

The Blastoids are a group of beautiful, symmetrical, bud-shaped Crinoids, of the later Paleozoic; they too had their beginning and dominance and finally became extinct.

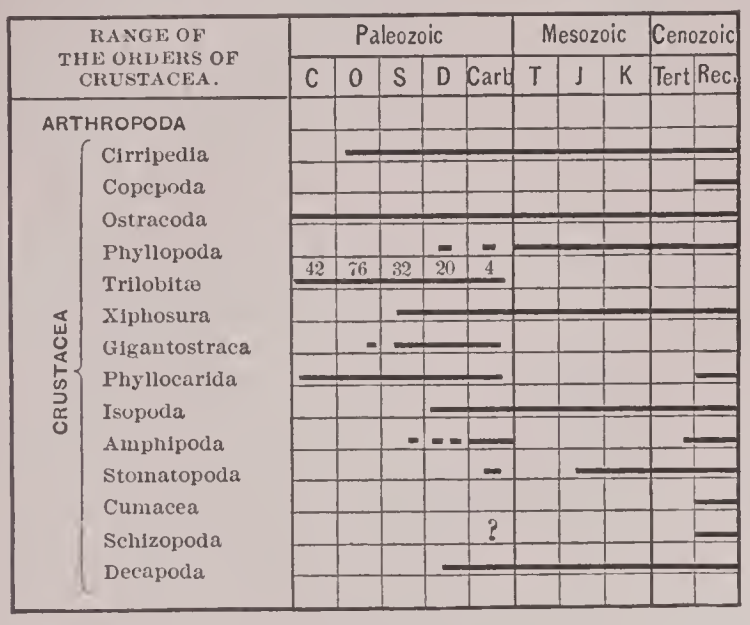
The Echinoids, or sea-urchins, are as characteristic of later geological time as the Crinoids and Cystids are of early time. The Palechinoids are represented in the later Paleozoic by a few characteristically inferior types of Echinoid structure. This is seen in the irregular number and the multiplication of the rows of plates making up the ambulacral and interambulacral series. The true Echinoids (*Euechinoidea*) in both orders (Regulares and Irregulares) began their evolution in the Triassic, rapidly expanded in the Jurassic and Cretaceous, and the largest number of recorded genera was not reached till Tertiary and recent times. The climax of evolution, as expressed by greatest diversity and number of generic forms and abundance of specific and individual forms, was attained for this class certainly not till the Tertiary time.

Vermes.—The fourth branch of the animal kingdom, the worms, has left traces in the earliest sedimentary formations in the form of borings or tracks. From the morphological structure of worms and its relation to that of other branches, it is altogether probable that worms were among the very earliest of animals to appear. On account of the failure to develop hard parts, except of the nature of minute jaws or teeth (Annelida), the history of worms can not be written.

Arthropoda.—The Arthropoda, producing chitinous shells or external skeletons, left valuable records of their history for the paleontologists, and from the study of the fossils we learn that this branch was probably the first to dominate among the inhabitants of the seas.

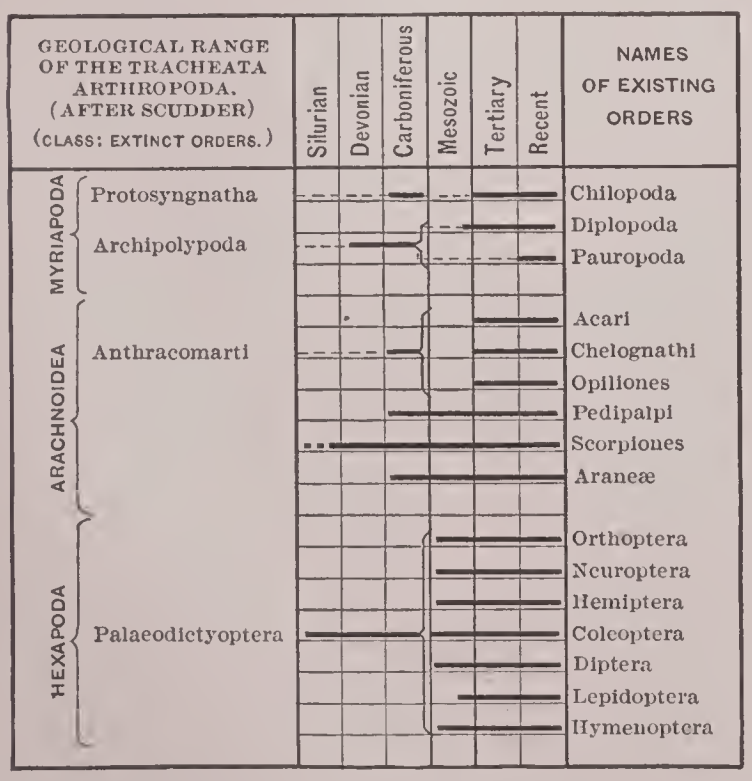
In the following table the geological range of the several orders of Crustacea (the first class of Arthopoda) is given; and opposite Trilobitæ the number of genera known in each system is given in the column corresponding to the Cambrian (C), the Ordovician (O), the Silurian (S), the Devonian

(D), and the Carboniferous (Carb.). It will be seen that the Trilobites were not only an ancient race, but that we already have knowledge of their remarkable expansion into separate genera—42 in the Cambrian, 76 in the Lower Silurian, or Ordovician time. Here, too, there were species of large size; several have been seen which attain 2 feet, or nearly that, in length. The Trilobites furnish the most abundant and characteristic fossils of the Cambrian system, and evidently were the highest and the dominant organisms of their time.



The Ostracoda, the Gigantostraca (the Eurypterus, the Pterygotus, etc.), and the Phyllocarida are ancient types. The Decapoda (including modern crabs and lobsters) is historically a later type, beginning at the close of the Paleozoic, rapidly expanding in the Mesozoic, and including many of the dominant representatives of Crustacea of the present time.

The other classes of Arthropoda are the Myriapoda (thousand-legged worms), the Arachnoidea (spiders, scorpions, etc.), and the insects. The following table, after Scudder, expresses the fundamental facts regarding their paleontological history so far as known:



It will be observed that the Scorpiones are of very early origin. The modern types of insects, spiders and Myriapods, are of more recent origin, although represented by ancient and more or less synthetic types in the Paleozoic.

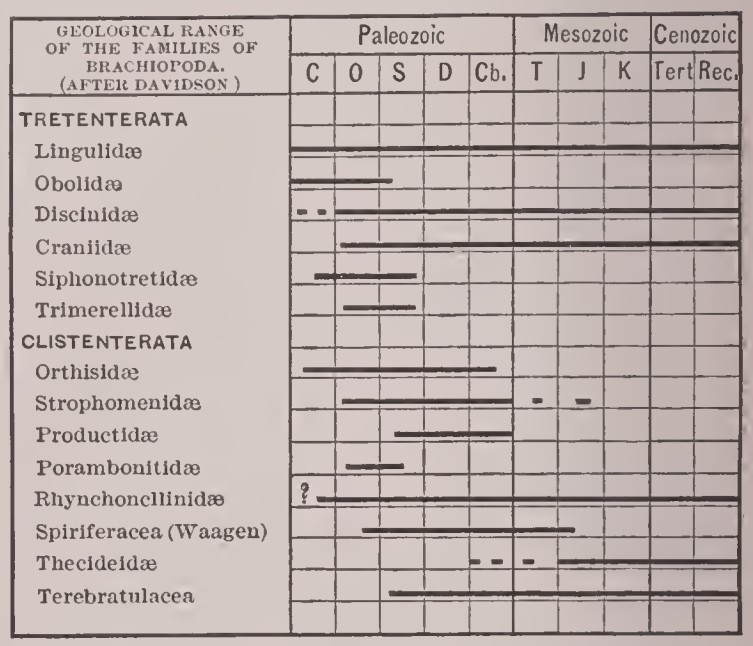
The oldest known insect is *Paleoblattina douvillei* Brongniart of the Middle Silurian. Although insects are so little apt to be preserved in the rocks, there are already described 2,600 fossil species.

Molluscoida.—This branch of the animal kingdom has furnished the most detailed evidence of paleontological history with which the paleontologist is familiar.

The branch includes the two classes Polyzoa (Bryozoa) and Brachiopods. The Polyzoa individually are minute animals, but construct chitinous or calcareous, moss-like colonies of cells, which are preserved abundantly in some of the ancient rocks, and representatives still live in the seas. The Brachiopods form bivalve shells, calcareous and chitinous, which have resisted remarkably the destructive agencies of time, and are among the most frequently appearing fossils in the rocks from the earliest to the latest geological periods. See MOLLUSCOIDEA.

In his description of the *Bryozoa of Illinois*, Ulrich enumerates 138 genera classified under 26 families, all Paleozoic forms. Although individually minute the expansion of the races into modified form and the abundance of individuals characterized the Lower Silurian (Ordovician), and the Polyzoa (Bryozoa) were abundant in the Mesozoic and are still represented by a large number of species and genera in modern times.

The importance of the Brachiopods, in the interpretation of the age of Paleozoic formations, particularly demands fuller discussion than can be given here. In the present state of our knowledge the grouping of the genera into families is not satisfactory, as is the case with the Trilobites, but in order to tabulate and express the more prominent facts in the evolution, the families, as classified by Davidson, will be tabulated in the following table and their range given, without attempting to group them according to relationship, further than to designate the two ordinal groups of hinged (Clistenterata) and unhinged (Tretenterata) forms:



This method of illustration, to be clear, requires the following explanation: In the cases of the Lingulidæ, Discinidæ, and Rhynchonellidæ, represented by living forms, the Lingulidæ are represented in the earlier Paleozoic by several genera which are confined to that part of the scale, and the persistent form is the single genus Lingula. The persistent forms in the other two families named are single genera in each; i. e. Discina and Rhynchonella; much the same fact is true of the Craniidæ. Hence it may be said of the Tretenterata that they are dominantly ancient types, confined mainly to the lower half of the Paleozoic, and are perpetuated by three genera which continued to be represented by species till the present time.

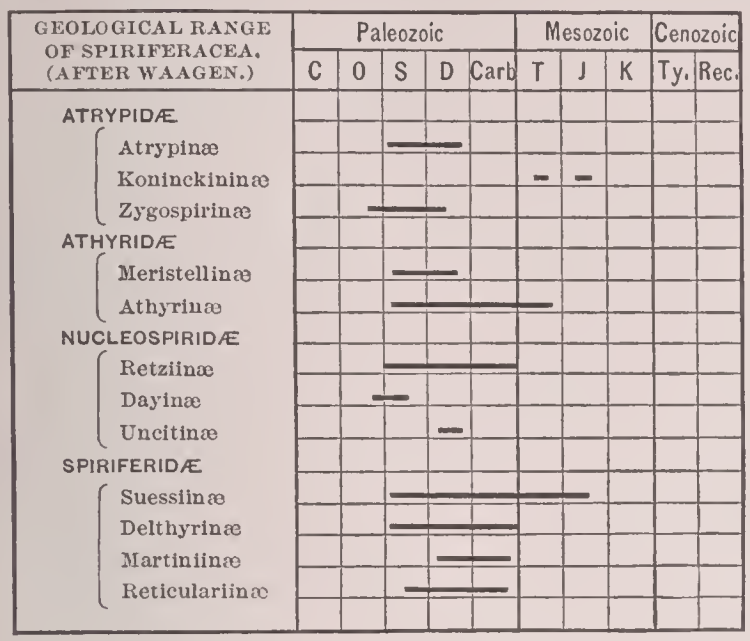
Of the Clistenterata, the Orthis, Strophomena, and Spirifer families are almost entirely Paleozoic, a few rare species appearing in the Mesozoic.

Productus is characteristically of Devonian and Carboniferous age, culminating in the Carboniferous. Some allied genera are known in the Silurian and in the earlier Mesozoic.

Terebratulidæ, a large and prominent group of genera, runs back with several genera into the Paleozoic, but its great expansion in genera and species is in the Mesozoic and later times. These are the most important groups of Brachiopods.

An analysis of the range of the smaller groups of forms, as given in the case of the Spiriferacea by Waagen, will illustrate admirably the very intimate relationship existing

between the morphological differences, as expressed in the classification, and the geological time in which the different forms lived.



From this table it will be seen that likeness of morphological organization, which is the basis of biological classification, is co-ordinate with sameness of time in the geological history of the races. Where a genus has a clearly marked beginning and ending, the different species of the genus are more or less abundantly and continuously represented during the period. Different species which are similar to each other, enough so to be ranked in the same genus, rarely are found in more than two or three adjoining systems, and as a rule the more closely animals are like each other the nearer together in geological time did they live, and in series of related forms the more extreme divergence is found between the earliest and the latest representatives of the race.

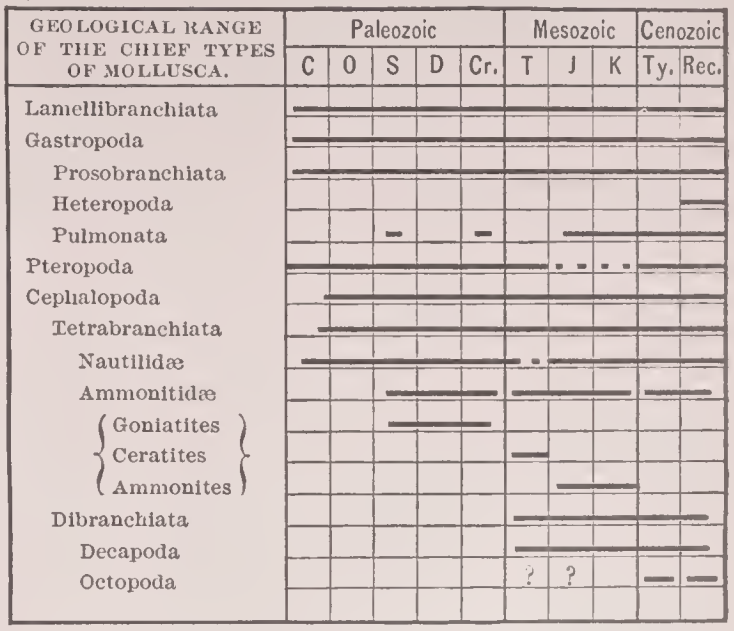
Minute comparison of the variations and specific differences observed in a series of forms of the same genus occurring in successive strata leaves little or no doubt of the existence of continuous races the successive members of which were genetically related, and, as races, with the passage of time they suffered gradual modification in a few or many of their characters, leading to the conviction that species which appear to breed close for a given epoch of time have descended from ancestors from which they differ morphologically enough to be ranked in different species or genera, or in some cases even in groups of higher taxonomic rank.

The slight differences observed in successive representatives of the same race of organisms are called *mutations*, and the differences expressed by the same species living at the same time, but geographically separated, or existing under differing conditions of environment, are called *varieties*.

In many cases, where the facts are sufficiently numerous to illustrate the point, it is observed that in a race of organisms great variability or plasticity of form is characteristic of the earlier stage of the history, while mutations are slow and gradual and in lines already marked out by the variability of the early types.

Mollusca.—The Mollusca are grouped into four classes: Lamellibranchiata, Gasteropoda, Pteropoda, and Cephalopoda. In each class calcareous shells of some kind are developed for most of the orders. In the Lamellibranchs, a bivalve shell like that of the clam; in Gasteropoda, a shell as in the snail. In the Pteropods a frail hyaline shell is developed by many of the recent forms; in the Cephalopods, shells like the pearly Nautilus, or internal shells like the cuttle-bone. These are types of the numerous kinds of shell produced. These hard parts are readily preserved when buried in the mud, and therefore they are prominently represented among fossil remains. In many cases their external form or contour (which, as in the Lamellibranchs, is all that is generally preserved) furnishes small evidence of the more important structural differences distinguishing species, genera, or categories of higher rank. Hence it is difficult to determine for the Paleozoic forms the finer points of their paleontological history.

Each of the classes is of early origin, beginning at least as early as the Ordovician, as will be seen in the following table.



The evidence is clear that for Lamellibranchs and Gasteropods the greater generic expansion was as late as Mesozoic, and probably did not reach its maximum till the Tertiary, as illustrated by the fact that the greatest number of recorded genera for any particular time, previous to recent, was in the Tertiary. This fact may, of course, be due in part to the better knowledge we have of Tertiary shells, but in general the earlier forms that are found belong to fewer genera and families in both of the great classes mentioned.

The Pteropods were more prominent, both in numbers of generic types and in species and individuals, in the lower systems of the Paleozoic. Four genera with fifteen species and two varieties have been described from the Lower Cambrian of North America (Walcott), which is nearly 10 per cent. of the total known American fauna of that formation, including the Trilobites.

The Cephalopods had their chief expansion, for the Nautiloid types, in the Paleozoic, including the straight, chambered Orthoceras, the Gomphoceras, the Gyroceras, Cystoceras, etc., and the earlier representatives of the genus Nautilus which has persisted to the present time in the case of the pearly Nautilus. The Ammonite type, represented by a large number of Goniatites in the Devonian and Carboniferous, found their great expansion and abundance of species and genera in the Mesozoic, and their shells constitute one of the most important and characteristic marks of the Jurassic and Cretaceous, after which they appear to have become suddenly extinct. The Dibranchiate order, represented by the modern octopus and squid, were of still later origin, and no traces of them have been seen lower than the Trias. The order of appearance in the case of the various types of Cephalopods is clearly that of the order of rank of elaboration and of organic structure. The well-known series of genera of Cephalopods—i. e. Nautilus, Goniatites, Ceratites, Ammonites—expresses the law of progressive evolution in its simplest form, in the elaboration of the edges of the chambers as seen in the suture lines of the shells.

The physical relation borne by the successive forms of suture lines in this case is such that it would be physically impossible for the Ammonites' septum and suture to be formed by development without passing through stages represented by those of the Nautilus, Goniatites, and Ceratites successively, thus furnishing almost mathematical proof of the genetic relationship of the later to the earlier types. See Mollusca.

Tunicata.—The few known forms referred to this branch of the animal kingdom develop no structures sufficiently durable to lead to the expectation that their fossil remains could be discovered, except under the most favorable circumstances. They may have lived in the earliest times, but at present undoubted traces of them are not known in the rocks. See Tunicata.

Vertebrata.—The paleontology of the Vertebrates is discussed in other articles of this cyclopædia, and here only the grander facts will be referred to. See Vertebrates, Fossil.

In the first table the geological range of the several classes is given.

GEOLOGICAL RANGE OF THE CLASSES OF VERTEBRATES.	Paleozoic					Mesozoic			Cenozoic	
	C	O	S	D	Car.	T	J	K	Ty.	Rec.
Leptocardii										—
Cyclostomi										—
Pisces		–	–	—	—	—	—	—	—	—
Amphibia					—	—	—	—	—	—
Sauropsida (Huxley)					–	—	—	—	—	—
Mammalia						–	– – –	– – –	—	—

Of the lower and rarer forms of Vertebrates, the Leptocardii and the Cyclostomi, only recent examples are known. The chief classes of Vertebrates made their first appearance, so far as known, and became dominant in the order of their zoölogical rank.

The fishes were the first to appear, in the types of Ganoids and heavily mailed Placoderms, and the ancient types of Cephalaspis and Pteraspis, and early types of Shark.

The earliest known remains of fish are from the Trenton rocks of Colorado. In the Devonian fish remains are abundant, and of the types above mentioned.

In the Carboniferous Amphibian remains appear, not those of the more modern Batrachian type of the toads and tailed salamanders, but of a separate order, Stegocephala; and the species were often of large size, and in some cases protected by scales or plates over part of the body.

The modern type of Amphibia are not known earlier than the Cretaceous.

The modern type of fish, the Teleosts, did not appear till the middle of the Mesozoic, and their chief expansion is in the Tertiary. Of the 45 recorded families of Teleostei, only 16 are reported from below the Tertiary, and only 2—the *Hoplopleuridæ* and the *Clupeidæ*—below the Cretaceous. Species of these two families appear in the Triassic.

The reptiles and birds (paleontological evidences requiring their association in one great class—the Sauropsida) formed their great expansion in the Mesozoic, which on that account has been called by Agassiz the age of Reptiles. A few true reptiles were seen in the Carboniferous, and though a few traces of true birds have appeared in Cretaceous rocks, the birds and the mammals were very insignificant among the faunas previous to the Tertiary.

In the following table the range of the grander divisions of the reptiles and birds is given:

	GEOLOGICAL RANGE OF THE ORDERS OF REPTILES AND BIRDS.	Paleozoic					Mesozoic			Cenozoic	
		C	O	S	D	Car.	T	J	K	Ty.	Rec.
REPTILES	Ichthyosauria						—	—	—		
	Sauropterygia						—	—	—		
	Testudinata (Turtles)						—	—	—	—	—
	Theromorpha					—	—				
	Rhynchocephalia						—	—	—	—	—
	Lepidosauria							—	—	—	—
	Lacertilia (Lizards)							—	—	—	—
	Pythonomorpha								—		
	Ophidia (Serpents)								–	—	—
	Crocodilia						—	—	—	—	—
	Dinosauria						—	—	—		
	Pterosauria						—	—	—		
BIRDS	Saururae							—			
	Ratitæ								—	—	—
	Carinatae								—	—	—

From the table it appears that the gigantic sea-lizards (Ichthyosauria, Sauropterygia) called Enaliosauria, and the sea-serpents, which were equally gigantic, of 70 feet or more in length (the Pythonomorpha), the peculiar type of Theromorpha, the gigantic and truly marvelous land reptiles, the Dinosauria, 25 to 30 feet long, and exceeding in bulk the elephants and rhinoceros of the present time, and the flying reptiles, with long teeth and bat-like wings—Pterosauria—were the dominant races of Mesozoic time, but have all become extinct. The modern reptiles are the turtles, the serpents, the rare Hatteria, and the lizards, all of size inferior to the mammals, and the Crocodilians which preserve somewhat of the importance of the ancient reptilian type.

The Saururæ, tailed, feathered, toothed, and winged animals, combine the characters of birds and reptiles, and have not been discovered later than the Jurassic. The Hesperornis of the Cretaceous, however, is a true bird (Ratitæ) with teeth in its beak, thus showing the intimate genetic relationship between these two great divisions of the animal kingdom, the reptiles and birds, suggesting to Huxley their inclusion in a single class, the Sauropsida.

The study of the fossil mammals reveals some of the most interesting facts of paleontology. See VERTEBRATES, FOSSIL.

With the exception of a few small representatives of the marsupials (Microlestes, Dromatherium, and other related forms from the Triassic and Jurassic), which are interpreted by Marsh as probably insectivorous, and allied with what are now marsupials, the mammals did not appear lower than the Eocene—the base of the Tertiary.

This is perhaps the most remarkable fact exhibited in the paleontological history of organisms—i. e. that the evolution of the highest, now by all means the dominant and most important class of the organisms on the globe, was evolved in all of its most characteristic differences of structure and organization since the beginning of the Eocene. The length of the life history of not only all the species but the genera, families, and orders of mammals is little longer (perhaps twice as long at the greatest) than the average length of life of the majority of the species of Invertebrates now living in the ocean.

The above review of the chief facts of paleontology will suffice to point out the nature of the problems which this comparatively new science reveals. To paleontology we must look for the demonstration of the laws of organic evolution.

HENRY S. WILLIAMS.

Paleozoic Era [Gr. παλαιός, ancient + ζῷον, animal]: one of the greater divisions of geologic time. It is preceded by the Proterozoic era and followed by the Mesozoic and Cenozoic, and it includes the Cambrian, Silurian, Devonian, and Carboniferous periods. See PALEONTOLOGY.

Paleozoic System: See PALEONTOLOGY.

Paler'mo [Ital. < Lat. *Panor'mus*, the ancient name = Gr. Πάνορμος, liter., always fit for landing; πᾶς, πάν, all + ὅρμος, harbor]: city of Sicily; situated on the north coast; in lat. 38° 6′ 44″ N., lon. 13° 20′ E. (see map of Italy, ref. 9–E). It lies on a bay formed by a deep and spacious inland sweep of the sea, between Cape Zafferano on the E. and Monte Pellegrino on the W. This bay has received the name of the *Conca d'Oro*, the Golden Shell, a name also applied to the city and to the plain which extends from the sea to the mountains in the rear—a region favored in its climate, soil, and landscape beauty. The city walls, 4½ miles in circumference, form a square, the four angles corresponding very nearly to the four cardinal points of the compass, and the town is entered by sixteen gates. The harbor lies to the N. of the town, and is sheltered by a huge mole. The Oreto, which, with its many small tributaries, waters the adjoining plain, flows into the sea near the east angle. Two fine streets, the Macqueda or Strada Nuova, and the Vittorio Emanuele, formerly Toledo, intersect each other at right angles near the center of the city, thus dividing it into four sections. Among the public squares are the Villena or Vigliena, decorated with fountains and statues in the Renaissance style, and the public garden on the left of the Porta Felice, abounding in almost tropic vegetation. The favorite promenade is the Marina, running along the shore on the line of the old fortifications.

Notable Buildings.—Palermo is an archbishopric, and has about 300 churches and chapels. The cathedral, built in the twelfth century by an Englishman, Archbishop Walter, contains curious mediæval monuments. San Domenico is the largest church in the city, and will hold 12,000 persons; the Olivella is the most gorgeous church. The royal palace is in part the work of the Arabs, for whom it served as a fortified castle, but it was transformed by the Normans. The chapel and the Sala di Ruggiero are richly incrusted with old mosaics. Of other buildings there is the university (founded in 1447) with (1891) 65 teachers and 1,253 students, the town library with 141,000 volumes and 2,640 MSS., and the national library with 110,000 volumes and 12,000 MSS. Some of the private edifices are remarkable for their antiquity, others for their architecture. The environs of Palermo abound in objects of interest—the great

PALESTINE
Note, The word Jebel is the modern Arabic for Mountain; Nahr for River, Wady for a Valley or Water-course. Where a Scriptural locality is shown, the Modern name is added with a line under it. The names enclosed in a parenthesis are Classical, all others refer to modern names of places Rivers &c.

cathedral of Monreale (see MONREALE); the Castello della Zisa; the Castello della Cuba; and Monte Pellegrino, in which is the grotto of Santa Rosalia, the patroness of the city.

Trade and Industry.—These are active, though not growing. There are manufactures of gloves, essences, and machinery. The number of vessels annually entering the port is about 3,500, with a tonnage of 1,200,000; exports—fruits, wines, silks, gloves, etc.—in 1890 were valued at $6,383,044, of which the U. S. took more than one-half; the imports were valued at (1890) $4,019,604. There is also a coasting trade; imports over $15,000,000, exports about $5,000,000. Pop. (1892) 273,000.

History.—Palermo is probably of Phœnician origin, and is first known in history as a Carthaginian dependency. During the Punic wars it fell into the hands of the Romans and became a great naval station. In the fifth century A. D. it was taken by the Vandals, and was ceded by them to the Goths, who were driven out by Belisarius. In 830 it was conquered by the Saracens, who made it the capital of their Sicilian dominions. In 1071 the Normans, under Count Roger, took Palermo, and it continued the capital of the Sicilian kingdom through the Norman and Swabian dynasties. Charles of Anjou removed his court to Naples (1269), since which time Palermo has never been a permanent royal residence. (For further historical details, see SICILY and SICILIAN VESPERS.) From 1820 the revolutionary failures of Naples were repeated in Palermo until the landing of Garibaldi at Marsala (1860) caused an uprising here, which put to flight 30,000 Bourbon troops, backed by a strong fleet; and by an enthusiastic *plébiscite* the city became a part of the new kingdom of Italy. Revised by R. A. ROBERTS.

Pa'les: in Roman mythology, a divinity of flocks and shepherds, corresponding in some respects to the Greek Pan. This divinity was probably of early origin, but is seldom mentioned, and played in historical times only a subordinate part in the religion of the Romans. It was conceived of sometimes as male and sometimes as female, although the rites of the festival Palilia considered Pales only as female. This festival was celebrated on Apr. 21, and was considered the birthday of Rome. In this festival Pales was invoked to grant protection and increase to flocks and herds. The name Pales is thought to be connected with Palatium. Revised by G. L. HENDRICKSON.

Pal'estine [from Lat. *Palæsti'na* = Gr. Παλαιστίνη, by analogy of πάλαι, anciently, ancient from Heb. *Pᵉlesheth*, Philistia, liter., Land of Wandering, and *Pᵉlishthīm*, Philistines, derivs. of *pelesh*, wander]: a name designating originally only the country of the Philistines, but in the later Greek and Roman period applied, as we now apply it, to the whole country of the Israelites on both sides of the Jordan. Josephus uses the name in both of these senses. The oldest name was the Land of Canaan, or sometimes simply Canaan, lowland, by which was meant, however, only the country W. of the Jordan, which is all that was promised to Abraham. Other Scripture names are Judæa, the Land of Israel, the Land of Promise, and the Holy Land. The last name has for several centuries been more current than any other.

Boundaries and Extent.—The boundaries of Palestine can not be determined exactly. Approximately, they were as follows: On the W. the Mediterranean; on the N. a line beginning near the *Promontorium Album*, S. of Tyre, in lat. 33° 10′, trending northward till, near the southern base of Hermon, it strikes lat. 33° 16′, and then runs straight on to the desert; on the E. the Arabian desert; and on the S. the parallel of lat. 31°, a little S. of Beersheba (31° 15′), curving to take in Kadesh. Within these boundaries, as recently determined, there are, on the west side of the Jordan, about 6,600 square miles, and on the east side, including ancient Moab, S. of the Arnon, more than 5,000, perhaps nearly 6,000, square miles. The length of this territory is about 150 miles; its average breadth W. of the Jordan more than 40, and E. of the Jordan about 40 miles.

Physical Features.—The country is made up of four long parallel strips of territory, lowland and highland alternating. Along the Mediterranean coast is a strip of lowland, in the northern or Phœnician section of it, about 20 miles long and from 4 to 6 broad; in the middle, Sharon section of it, S. of Carmel, more than 30 miles long and about 10 miles broad; and in its southern, Philistine section, 40 miles long and from 10 to 20 broad. This strip of lowland is interrupted by the ridge of Carmel, which branches off from the mountains of Samaria, runs northwestward for 18 miles, rises at one point to the height of 1,810 feet, and thrusts out into the sea a promontory 556 feet high. On all this coast there is not one good harbor. Next comes the highland strip, some 25 or 30 miles broad, which springs from the roots of Lebanon, swells into the hills of Galilee, is interrupted by the plain of Esdraelon, as the lowland strip is interrupted by the ridge of Carmel, swells again into the hills of Samaria, reaches its greatest average height in Judæa, and then sinks away into the desert S. of Beersheba. This broad, high central strip of West Jordanic territory has been compared to a ship's longboat turned upside down. Among its highest points in Galilee are Safed (perhaps the "city set on a hill" of Matt. v. 14), 2,749 feet above the sea, and Jebel Jermûk, near by, nearly 4,000 feet above the sea. In Samaria the highest points are Ebal, 3,077, and Gerizim, 2,849, feet above the sea. In Judæa the highest point of Jerusalem is 2,593, Mount of Olives 2,693, Hebron 3,040, and Beersheba 788, feet above the sea. The Jordan valley, at some points quite narrow and at others from 5 to 10 or 12 miles broad, is one of the wonders of the world. The Jordan itself, in going from its Hasbeiya source to the Dead Sea (115 or 120 miles), plunges down a descent of more than 2,300 feet, from 1,080 feet above to 1,292 feet below the level of the Mediterranean. The fourth parallel strip, E. of the Jordan, is (most of it) high table-land, some of it 3,000 feet above the sea, sinking away eastward into the Arabian desert. As seen from the west side of the Jordan it looks like a purple wall.

Lakes, Rivers, and Springs.—Of the four lakes of Palestine, the northernmost is Phiala, 5 miles E. of Banias, nearly round, about a mile in diameter, and of unknown depth, occupying apparently the crater of an extinct volcano. It is some 3,300 feet above the sea, is not, as was anciently supposed, one of the sources of the Jordan, has neither inlet nor outlet, and abounds in frogs and leeches. Merom (now *Huleh*), 10 miles S. of Banias, in the midst of an extensive papyrus marsh, 7 feet above the sea, is a triangular lake, with its apex pointing southward, about 5 miles long, nearly 4 miles across its base, and 15 feet deep. Ten miles farther down is Gennesaret, 12¼ miles in length, 6¾ miles in its greatest breadth (at Magdala), 165 feet deep, and 682·5 feet below the level of the Mediterranean. The Dead Sea, which is situated at a distance of some 65 miles farther S., is 40 miles long, nearly 10 miles broad, more than 1,300 feet below the level of the Mediterranean, and 1,292 feet deep. No fish live in it. Of rivers, the most important is the Jordan, which has two tributaries emptying into it from the E. (the Yarmuk and the Zerka), and two from the W. (the Jalûd and the Fârah). Many of the so-called rivers of Palestine are merely winter torrents, which run dry in summer. Of the eight permanent rivers emptying into the Mediterranean Sea, the most important are the Belus (now *Nahr Na'man*, near Acre), celebrated for the accidental discovery of the art of making glass; the Kishon, "that ancient river" (now *Nahr el-Mukatta*, river of slaughter), which drains the plain of Esdraelon; the Zerka, just N. of Cæsarea; and the Aujeh (not mentioned in Scripture), a few miles N. of Jaffa, which drains the mountains of Samaria, and is, next to the Jordan, the longest permanent river in Palestine. Three permanent streams empty into the Dead Sea from the E. These are the Zerka Ma'in (not mentioned in Scripture), near which are the four hot springs of Callirrhoë; the Arnon (now *Mojib*), the northern boundary of the Moabites and the southern boundary of the Israelites, about half-way down the sea; and the Zered (now *el-Ahsy*), at the southeast corner of the sea. The springs of Palestine constitute one of its most characteristic features. First in importance are the three sources of the Jordan. Of these, that at Hasbeiya (not mentioned in the Bible) contributes one-seventh, that at Cæsarea Philippi (now *Banias*) two-sevenths, and that at Dan (now *Tell el-Kady*) four-sevenths, of the whole volume of the river. As an indication of the very great multitude of springs in Palestine, Robinson enumerates thirty in a circuit of 8 or 10 miles around Jerusalem.

Geology.—The backbone of the country, on both sides of the Jordan, is hard Jura limestone, full of grottoes and caverns, with sandstone, basalt, and other volcanic rocks also on both sides of the river, but these last more especially on the east side. There are many signs of violent volcanic action in the past, and earthquakes are still occasionally felt, the most severe in modern times being that which occurred in 1837, which partially destroyed both Safed and Tiberias.

Climate and Rainfall.—The climate, on the whole, is mild, inclining, however, toward the extreme of heat rather than toward the extreme of cold. There are only two seasons, summer and winter—the former, from April to Novem-

ber, rainless or nearly so; the latter, from November to April, rainy; but between the middle of December and the middle of February there is generally a kind of intermission, separating "the former and the latter rain." The rainfall at Jerusalem varies from 12 to 42 inches, both extremes being exceptional; 25 inches are considered necessary to insure good crops, and if less than 18 inches fall the harvest is poor and suffering ensues. During the rainy season of 1892–93 the rainfall was 38·4 inches. The average rainfall appears to be less than 25 inches, while on the Atlantic seaboard of the U. S. it is 45, and in California, whose climate is much like that of Palestine, it is only 20. Along the Mediterranean lowlands, and still more in the Jordan valley, the heat of summer is always great, and sometimes exceedingly oppressive, but not so on the higher levels, except during sirocco weather. At Jerusalem, from June, 1851, to Jan., 1855, according to Dr. Barclay's register, the mean temperature was 66·5°, the highest temperature 92°, and the lowest, on one occasion just before sunrise, 28°. In some years the mean is 62° and the highest 86°. Observations made by Dr. Chaplin, for the eight years preceding 1872, show a mean temperature of 62·8°. In May, and also in September, the temperature sometimes rises to 100°; on June 24, 1869, it reached 103·5°, and on Aug. 28 and 30, 1881, it remained for some hours at 112°. Mt. Hermon, nearly 10,000 feet high, and looking down upon the whole of Palestine, is never entirely clear of snow, though late in autumn only slender threads of it are left, as the Arabs say, "like the straggling silver locks on an old man's head." During the winter ice seldom forms, and the ground is seldom, if ever, frozen in any part of the country. With abundant rains, which may generally be counted upon, Palestine was once very fertile, and might be so again; but in order to this, trees must be planted, cisterns built and kept in repair, and the hills terraced, as of old. The products of the soil still range from peas, beans, wheat, and barley to grapes, figs, olives, apricots, lemons, oranges, and dates.

Botany.—The botany of Palestine, unlike that of Egypt, is richly varied. Upward of 3,000 species have been reported, chiefly by the labors and observations of Dr. George E. Post, of Beyrout. For mile on mile, in the proper season, the ground is fairly covered with flowers of all the colors of the rainbow. Everywhere one sees the scarlet anemone, which is thought by some to be our Lord's "lily of the field." The ranunculus and the pheasant's eye (*Adonis palestina*) are also very brilliant. The narcissus, the crocus, and the mallow are all candidates for the honor of being considered "the rose of Sharon." Of shrubs, the most abundant and most beautiful is the oleander. The whole country was once well timbered, and still there are groves, and even forests, of pine and oak beyond the Jordan. On the west side of the river, from Beersheba all the way up to Lebanon, there are very few trees, except on Tabor and Carmel. Since the time of the crusades the pine forest then standing between Jerusalem and Bethlehem has wholly disappeared. Repeated wars and conquests, and dreary centuries of bad government, have gradually reduced the country to its present naked, burnt, and desolate appearance. The tree now most common is the oak, of which Dr. Post enumerates eight different species, the most abundant being the prickly evergreen oak (*Quercus pseudo-coccifera*). The "oaks of Mamre" were not oaks, but terebinths, the most famous specimen of which is the so-called Abraham's Oak, near Hebron, 23 feet in circumference.

Animals and Birds.—The wild animals of the country are much the same as in ancient times, except that the lion has disappeared and the leopard is practically extinct. There are wolves, jackals, hyænas, wild boars, gazelles, the ibex or wild goat of the Bible, the lynx, otters, badgers, the coney, hares, ichneumons, hedgehogs, wild cats, chetahs. Bears are occasionally seen on Mt. Hermon. Of domesticated animals, the horse is less used than the ass, the mule, and the camel. The buffalo, introduced probably by the Persians, has in some sections taken the place of the ox, and the neat cattle of the country in general are neither so numerous nor so well cared for as in ancient times. Sheep and goats are abundant, but swine are scarcely ever seen. The dogs are nearly all of one breed (the shepherd), and are outcasts and scavengers, making night hideous, as the jackals do, by their howling. Of the 360 species of birds which have been observed may be mentioned, as most common, eagles, vultures, hawks, owls, storks, pelicans, ravens, doves, pigeons, partridges, quails, sparrows, and nightingales. Fish still abound, as of old, in the Lake of Galilee, but the natives employ rude methods in taking them: forty-three species of freshwater fishes have been recorded from Palestine, and of this number thirty belong exclusively to the Jordan system and its lakes. The "great fish" of Jonah i. 17, which swallowed the truant prophet, was not a "whale," as the κῆτος of Matt. xii. 40 is unwarrantably rendered in our version, but may have been a specimen of the great white shark (*Canis carcharias*), still found in the Mediterranean, and sometimes 25 or 30 feet long. There are many species of reptiles, upward of thirty species of snakes, and upward of forty species of lizards having been found. The crocodile still occurs occasionally in the marshes of the Zerka. Frogs (three species) are abundant, and two species of toads are known.

History.—The original, prehistoric occupants of Palestine appear to have been a Semitic population, including the Rephaim, Zuzim, Emim, and Horim, E. of the Jordan, and the Anakim and Avim, W. of the river; but the immediate predecessors of the Hebrews were descended from Canaan, the fourth son of Ham. The date of their migration can not be determined. In the original grant to Abraham (Gen. xv. 19–21) ten tribes are named, two of which (the Kenites and the Kenizzites) were probably S. of Palestine, toward Egypt, one of them (the Kadmonites) on the east side of the Jordan, and the remaining seven (the Hittites, Girgashites, Amorites, Canaanites, Perizzites, Hivites, and Jebusites) on the west side. In the time of Moses and Joshua the Ammon-Moab people were on the east side of the river, but had been crowded far south by the Amorites, who held the whole territory from Mt. Hermon to the Arnon. Reuben, Gad, and Half-Manasseh took this territory E. of the Jordan. The remaining nine and a half tribes crossed over and occupied the west side. The Hebrew commonwealth reached the summit of its prosperity and power under David and Solomon. Visible decay began (about 975 B. C.) with the secession of the ten tribes. Assyria crushed the northern kingdom of Israel about 720 B. C., and Babylon crushed the southern kingdom of Judah about 587 B. C. Since then Palestine has been under foreign domination, with hardly more than the shadow of independence at any time. Persians, Greeks, and Romans succeeded one another in the mastery. In the time of Christ, under the Romans, there were four provinces—Galilee, Samaria, and Judæa, on the west side of the river, and Peræa on the east side. Since 637, when Palestine was conquered by the Saracens, it has, with little interruption, been under Mohammedan power. The Seljukian Turks seized the country in 1073, and by their barbarous treatment of Christian pilgrims provoked the crusades. The Latin kingdom, with its nine successive sovereigns, established in 1099, held Jerusalem till 1187, and stayed in Acre till 1291. In 1517 the Ottomans came in, and made the country a part of the Turkish empire. It was snatched from the sultan by Mohammed Ali in 1832, but Europe intervened, and in 1841 it was given back again.

Population.—As no census is ever taken, the population of Palestine can not be exactly determined, but is supposed to be well on toward 400,000, which is less than a tenth of what it probably was in the time of Solomon. Of this number the Jews form a considerable portion, the most recent and reliable estimates placing them at 43,000. In round numbers 27,000 of these are in Jerusalem, 1,200 in Hebron, 6,000 in Safed, 3,000 in Tiberias, the rest being divided between Jaffa, Ramleh, Acre, Haifa, Nablus, and a few colonies. Attempts to colonize Palestine with Jews have not been very successful. The little remnant of the Samaritans at Nablus numbers only about 150. The bulk of the inhabitants are a mixed race, descendants of the ancient Syrians and their Arab conquerors.

Pilgrimages and Explorations.—Pilgrimages to the Holy Land began with Helena, the mother of Constantine, in 326, and have continued ever since. What was then known of the country may be found in the *Onomasticon* of Eusebius and Jerome. During the Middle Ages the principal topographers of Palestine were ignorant, superstitious, and careless monks, whose identifications of sacred places were largely of the legendary and childish sort. It is only within a comparatively recent period that the true critical method has been pursued. Seetzen was there from 1805 to 1807; Burckhardt in 1810; Irby and Mangles in 1817–18; but no one man has ever done so much for the geography of the Holy Land as Dr. Edward Robinson. He was the first to adopt and adhere persistently to the rule of looking for ancient Hebrew names under the disguise of modern Arabic names. Next in rank with respect to the amount and quality of service rendered is Dr. William M. Thomson, of Beyrout,

a native of the U. S., for more than forty years a missionary in Syria and the Holy Land, whose book appeared in 1858. In 1848 the lower Jordan and the Dead Sea were for the first time thoroughly explored and surveyed by Lieut. Lynch, of the U. S. navy. In 1859 Johann Gottfried Wetzstein, Prussian consul at Damascus, explored the northern section of the country E. of the Jordan. In 1866 the marsh and lake of Huleh and the upper Jordan were explored by John MacGregor, of Scotland, and in the same year the Lake of Galilee was accurately surveyed by Capt. Wilson, of the Royal Engineers. This last piece of work was done under the direction of the Palestine Exploration Fund, a society organized in 1865 for the purpose of making an exhaustive exploration and an exact survey of the Holy Land. From 1867 to 1870 Capt. Warren, under the direction of the same society, was making excavations in and around Jerusalem. In 1870 the American Palestine Exploration Society was organized to work on the east side of the Jordan. In the autumn of 1871 the triangulation of Western Palestine was begun by Capt. Stewart, whose health soon broke down, and was completed in 1877 by Lieut. Conder and Lieut. Kitchener. Of 622 biblical sites in Western Palestine they claim to have identified 172 out of the total of 434 which are now considered to have been identified with tolerable certainty. Their large map in twenty-six sheets, on the scale of an inch to the mile, was published in 1880. Seven quarto volumes accompany it—three of memoirs, one of name-lists, one of special papers, one on the Jerusalem work, and one on the flora and fauna of Palestine. The reduced map (on the scale of three-eighths of an inch to a mile) is in four forms—the Old Testament ancient, the New Testament ancient, the modern, and the water-basins. In 1873 the American society sent out its first expedition, under command of Lieut. Edgar Z. Steever, of the U. S. army, detailed for that service by the Secretary of War. A base-line was measured in the desert E. of the Jordan, over against Jericho; the work was carried on through the hottest months of the summer and more than 500 sq. miles were triangulated. Prof. John A. Paine, archæologist and botanist of the expedition, discovered several new species of plants, and examined with great care Mt. Nebo and the adjacent region. In 1875 a second expedition was sent out under command of Col. James C. Lane, who remained in the country but a short time, and the work was put in charge of the archæologist, Dr. Selah Merrill, who made several important expeditions to every part of that interesting country. A reconnoissance survey of the whole Trans-Jordanic region was made (the survey work being done chiefly by Rudolph Meyer), important sites, such as Ramoth-Gilead, Succoth, and others, were identified, and in all about 230 names appeared for the first time in Meyer's map (not published). Dr. Merrill reckons about 240 biblical names E. of the Jordan, besides fourteen mentioned in the Maccabees. Nearly 100 of these he thinks have been identified. At this point the work of triangulation was surrendered to the English society, which entered the field in 1881, surveyed about 500 sq. miles, and was then compelled by the disturbed condition of the country to withdraw. The American society published four *Statements* (1871, 1873, 1875, 1877), and holds in reserve Dr. Merrill's *Notes* upon the Meyer map. Dr. Merrill's finding of a section of the "second wall" outside of which our Lord was crucified was one of the most important discoveries of recent years. This was in 1885. Other discoveries are the finding of the church built by Eudocia (A. D. 460) on the site of the Martyrdom of St. Stephen, and near it the tomb in which she was buried; the finding in the year 1891 of the "monument of Herod," mentioned by Josephus (*Wars*, v., 12, 2); and the unearthing by F. J. Bliss in the ruins of Lachish of a cuneiform tablet belonging to 1400 B. C., when prehistoric Palestine was subject to Egypt.

The event, however, which has attracted most attention was the completion of the Jaffa and Jerusalem railway, the first to be opened in either Palestine or Syria. After two years' labor by a French company the railway was opened for traffic on Sept. 26, 1892, and since then trains have run regularly between these two ancient cities. The road is 54 miles long, and cost not far from $2,000,000.

LITERATURE.—The literature of the subject is of immense extent. Tobler, in his *Bibliotheca Geographica Palestinæ* (1867), enumerates more than 1,000 writers on this one topic. To mention only a few of the most important: The *Onomasticon* of Eusebius (c. 330), translated into Latin, with additions, by Jerome (388), edited by Larsow and Parthey (Berlin, 1862); *Descriptiones Terræ Sanctæ*, by writers of the eighth, ninth, twelfth, and fifteenth centuries, edited by Tobler (Leipzig, 1874); *Early Travels in Palestine*, edited by Wright (London, 1848); the *Historica Theologica, et Moralis Terræ Sanctæ Elucidatio* of Quaresmius (Antwerp, 1639), valuable for the traditions; Maundrell's *Journey from Aleppo to Jerusalem at Easter, 1697* (Oxford, 1703); Reland's *Palestina Illustrata* (Utrecht, 1714), a classic; Hasselquist's *Voyages and Travels in the Levant in the Years 1749, '50, '51, '52*, edited by Linnæus (London, 1766), valuable for the natural history; Burckhardt's *Travels in Syria and the Holy Land* (London, 1822); *Travels in Egypt and Nubia, Syria and Asia Minor, during the Years 1817 and 1818*, by Irby and Mangles, printed but not published (London, 1822); Robinson's *Biblical Researches* (3 vols., Boston, London, and Berlin, 1841); *Later Researches* (1856) and *Physical Geography of the Holy Land* (published posthumously, 1865); Williams's *Holy City* (1845; 2d ed. 1849), defending the traditional sites; Lynch's *Expedition to the Dead Sea and the Jordan* (1849); Stanley's *Sinai and Palestine* (1857), highly graphic; Barclay's *City of the Great King* (1858), valuable for the meteorology; Thomson's *The Land and the Book* (1859; 2d ed. 3 vols., 1880–85); Tobler's *Bethlehem* (1849), *Jerusalem* (1854), and *Nazareth* (1868); MacGregor's *The Rob Roy on the Jordan* (1870); Tristram's *Land of Israel* (1865; new ed. 1876), *Natural History of the Bible* (1867), and *Land of Moab* (1873); Nutt's *Samaritan Targum and History* (1874); Ritter's *Geography of Palestine*, translated by Gage (4 vols., 1866); Porter's *Damascus* (1855), *Giant Cities of Bashan* (1865), *Handbook of Syria and Palestine* (revised ed. 1875); the new edition of the *Handbook for Syria and Palestine* (1892), by Haskett Smith, is very unsatisfactory and faulty in many respects; Palmer's *The Desert of the Exodus* (1872); Conder's *Tent Work in Palestine* (1878); Merrill's *East of the Jordan* (1881; new ed. 1883) and *Galilee in the Time of Christ* (1881); Dawson, *Egypt and Syria* (1885) and *Modern Science in Bible Lands* (1888); also see the many publications of the Palestine Fund. The German Palestine Society has published a journal since 1878. The best maps are those of van de Velde (1866), of Kiepert (1875), and of the English Exploration Fund (1880–83). The best atlases are those of Menke (1868) and of Clark (1868). For further information see special articles, such as ESDRAELON, HAMATH, JERUSALEM, JEWS, and JORDAN.

Revised by SELAH MERRILL.

Palestine: city; capital of Anderson co., Tex. (for location, see map of Texas, ref. 3–J); on the International and Great Northern Railroad; 10 miles E. of Trinity river. It is in an agricultural, fruit-growing, iron ore, and timber region; contains the headquarters of the railway company, 3 banks, and a semi-weekly and 2 weekly newspapers; and has water and electric-light systems, and numerous manufactories. Pop. (1880) 2,997; (1890) 5,838; (1900) 8,297.

EDITOR OF "SEMI-WEEKLY TIMES."

Palestrina, pă̆a-les-tree'nă̆a (anc. *Præneste*): town; in the province of Rome, Italy; situated on a spur of the Apennines, about 1,600 feet above the sea; 18 miles N. E. of Albano, 22 miles E. S. E. of Rome (see map of Italy, ref. 6–E). It covers only a portion of old Præneste, whose strong citadel crowned the height now occupied by the mediæval castle San Pietro. The Church of Santa Rosalia is richly adorned with marbles and alabaster. The Palazzo Barberini, occupying a part of the site of the vast old Temple of Fortune, was erected in the fifteenth century, and with the garden contains many statues, bas-reliefs, mosaics, and inscriptions, etc., from the ancient city. Præneste was a member of the Latin League until in 499 B. C. it joined Rome; it took part, however, in the Latin war against Rome. In 82 B. C. Sulla inflicted upon it the most cruel punishment for harboring the younger Marius, by putting to death more than 12,000 of its citizens; but the town recovered itself, and under the emperors it was a favorite resort of the Roman aristocracy. On the fall of the Western empire it became a part of the papal dominions; but the Colonna family afterward claimed it as their fief, and held it for more than two centuries. In 1297 Boniface VIII. utterly destroyed the town, with the exception of the cathedral. From this time the Colonna never ceased to struggle with the popes for its possession until 1630, when it passed by sale to the Barberini. The modern town is in itself of no interest except as the seat of one of the six suburban bishopries. Pop. 5,855.

Palestrina, GIOVANNI PIER LUIGI, da: composer; b. in Italy about 1528; went to Rome about 1540 to study music

with Goudimel, a Flemish composer, then celebrated. Palestrina published his first works (five masses dedicated to Pope Julius III.) in 1554. This led to his appointment to the pontifical chapel, and for a number of years he filled the part of chapelmaster or conductor at the Lateran and also at Santa Maria Maggiore. The church music of that day had become degraded to an extent difficult for us now to understand. Secular and profane melodies, often of an utterly ribald nature, had been introduced into the service of the Mass, the actual improper text being frequently and unblushingly sung by many of the singers, excepting a relatively small number standing in front who sung the sacred text. So scandalous became this condition of things that the Council of Trent passed a unanimous resolution in favor of reform, which resolution nearly amounted to a decree silencing all music in the churches. In this juncture Pius IV. appointed a commission of eight cardinals (1563) to carry out the wishes of the council. This led to Palestrina's being engaged to write a mass which should serve as a model of what religious music should be, both from the standpoint of the council's strictures and also illustrating the best science of the day. Instead of one he wrote three, the first two winning ample praise, the third creating unbounded enthusiasm. The delighted pope (Pius IV.) declared—"some such music it must have been that St. John heard sung by the heavenly hosts in the vision of the New Jerusalem." From this time Palestrina's position was fixed and his name renowned. During the remaining years of his life both the quality and quantity of his works continued remarkable. D. in Rome, Feb. 2, 1594. His published compositions consist of thirteen books of masses, six books of motets, one book of lamentations, one of hymns, one of litanies, one of sacred madrigals, three of secular madrigals, and a *Stabat Mater*. In Palestrina the ancient musical system found its highest development, thus leading the world up to the logical necessity of a new revelation—viz., a new doctrine of tonality and the birth of harmony in our modern sense. D. B.

Paley, Frederick Apthorp: grandson of William Paley; classical scholar; b. at Easingwold, near York, England, in 1816; graduated at Cambridge 1838; became a Roman Catholic in 1840; Professor of Classical Literature at Kensington 1874. D. at Bournemouth, Dec. 11, 1888. Edited Æschylus, Euripides, Hesiod, Homer, and other classic authors; translated Æschylus (1864) and Pindar (1875) into English. Author of a *Manual of Gothic Mouldings* (1845) and a *Manual of Gothic Architecture* (1846).

Revised by A. Gudeman.

Paley, William, D. D.: theologian; b. at Peterborough, England, in July, 1743; graduated at Christ's College, Cambridge (1763), where he became fellow (1766), a tutor and lecturer upon moral philosophy and divinity (1768); took orders in the Church of England; rector of Musgrove 1775; vicar of Dalston 1776; prebendary of Carlisle 1780; archdeacon of Carlisle 1782; and chancellor 1785; prebendary of St. Paul's, London, 1793; sub-dean of Lincoln and rector of Bishop Wearmouth 1795. Published *Principles of Moral and Political Philosophy* (London, 1785); *Horæ Paulinæ* (1790); *View of the Evidence of Christianity* (1794); and *Natural Theology* (1802). These works have been repeatedly edited and republished, but are now superseded. Their merit was their simple style and lucid illustrations; their defects, their lack of spirituality and their utilitarian morals. D. at Bishop Wearmouth, May 25, 1805. See his *Life*, by W. Meadley, 1809, and in his complete works 1819; n. e. 1834; principal works 1877. Revised by S. M. Jackson.

Palfrey, John Gorham, D. D., LL. D.: author; b. in Boston, Mass., May 2, 1796; was educated at Phillips Exeter Academy and Harvard College 1815; studied theology; succeeded Edward Everett as minister of Brattle Square church in Boston 1818; succeeded Andrews Norton as Professor of Sacred Literature in the Cambridge Divinity School 1831; retired in 1839. From 1842–43 he was member of the House of Representatives, and 1844–47 was secretary of State in Massachusetts. In 1847 he represented the anti-slavery Whigs in Congress; was a leading Republican, one of the creators of the Republican party, a prominent writer and speaker on the anti-slavery side, an able ally of Sumner and Adams; lost his seat in Congress after a fiercely contested struggle against the "compromise" Whigs; ran for Governor of Massachusetts, but was defeated, in 1851; was postmaster of Boston 1861–67, and then retired from public life and devoted himself to literature. Dr. Palfrey was a diligent author. His books are *Evidences of Christianity* (Boston, 2 vols., 1843); *Jewish Scriptures and Antiquities* (4 vols., 1838–52); *History of New England* (Boston, 4 vols., 1858–75); *The Slave Power* (1 vol., 1847), etc. He was editor of *The North American Review* from 1835 to 1842, and in 1851 was one of the editors of *The Commonwealth Newspaper*. D. in Cambridge, Mass., Apr. 26, 1881.

Revised by S. M. Jackson.

Palgrave, William Gifford: traveler and author; son of Sir Francis Palgrave; b. at Westminster, England, Jan. 24, 1826. He graduated with honors at Oxford 1846; was an officer of the native infantry in Bombay 1847–53; subsequently studied theology at the Jesuit Seminary at Laval, France; entered the Roman Catholic priesthood, and was employed as a missionary in Southern India, Palestine, and Syria. In 1862, commissioned by Napoleon III., he made a daring journey through the Wahabite kingdoms of Central Arabia, disguised as a physician. His intimate acquaintance with the Arabic language and customs enabled him to carry out this exploration in safety. In 1864 he severed his connection with the Jesuit order, and in 1865 he was sent to Abyssinia by the British Government to negotiate with King Theodore for the release of English prisoners. Thereafter he held various British consular positions, and from 1884 was minister to Uruguay. His publications include *Central and Eastern Arabia* (2 vols., 1865); *Essays on Eastern Questions* (1872); *Dutch Guiana* (1876); and *Alkamah's Cave, a Story of Nejd* (1875). D. at Montevideo, Uruguay, Oct. 1, 1888. Herbert H. Smith.

Palikao, păă'lĕĕ'kăă'ō, Cousin-Montauban, Count de: soldier and statesman; b. in Paris, France, June 24, 1796; served in Spain, and for twenty years in Africa; rose to be general 1851. In the expedition to China (1860) he commanded the French troops, gaining the victory of Pa-li-k'iao (or Eight-mile Bridge), carried the forts of Taku, and marching to Peking enforced the conditions of peace submitted by the allied powers. He received for these services the cross of the Legion of Honor; was raised to the rank of senator with the title of count. In Aug., 1870, he succeeded M. Ollivier as premier of the French ministry, and acted as Minister of War. He published in 1871 an account of the events of his ministry. D. in Paris, Jan. 8, 1878.

Pāli (paa'lĕĕ) **Language**: the language in which the Buddhist scriptures are written. The word Pāli means text, as distinguished from commentary, and is used by Buddhists as the current name for Māgadhī, the dialect of Magadha, in which they think their sacred books are written. Magadha was the name of the district round Patna on the Ganges at the time when those scriptures were composed—from about 500–250 B. C. Some modern scholars think that the Buddhists are mistaken in identifying Pāli with Māgadhī. Ernst Kuhn would rather identify it with the dialect of Ujjen (*Beiträge zur Pali Grammatik*, p. 7), and Eduard Müller (*Pali Grammar*, p. iii.) with that of Kalinga. Whichever view should turn out to be correct, Pāli is one of the Prākrit dialects into which the old spoken Sanskrit, the Sanskrit of the Vedas, was gradually broken down during the centuries from 1000–600 B. C. while the Sanskrit-speaking Aryan tribes were gradually forcing their way from the Punjaub down into the Ganges valley. It is the only one of those spoken dialects of which we have full and such early records, and it bears about the same relation to Vedic Sanskrit that Italian does to Latin.

We have records of other Prākrit dialects from about the sixth century A. D., and the Jaina Prākrit, in which the sacred books of the Jains were composed still later, is closely allied to it; but the inscriptions of Asoka, the celebrated King of Magadha, in the middle of the third century B. C., come the nearest to Pāli of all the existing linguistic documents of ancient India.

Down to the fifth century A. D. the texts were handed down in Ceylon in Pāli, and the commentaries in Sinhalese, the local dialect of Ceylon. During that century the commentaries also were translated into Pāli, and now exist only in that language. The Pāli of these early commentators differs from that of the texts in the same way as the Latin of Augustine differs from the Latin of Vergil and Cicero.

From the twelfth century A. D. onward there have been a number of works composed from time to time in Ceylon, Burma, and Siam in a Pāli which differs from the two previous stages in much the same way as the Latin of the mediæval theologians and chroniclers differs from the Latin of Augustine and of Cicero. In this third and last stage of

Pāli a large number of words are introduced which are merely retranslations of Sanskrit, Burmese, Siamese, or Sinhalese expressions; and the idiomatic phraseology of the sentences is not seldom a reproduction of the idiom in which the author was accustomed to speak in everyday life.

Of these three stages the pure Pāli, or language of the texts, though considerably older in time than the majority of the books written in so-called classical Sanskrit, is considerably younger in form. The changes shown in it as compared with Sanskrit are allied to the changes which have produced the modern languages of Western Europe out of Latin, and may be summarized as follows:

1. Every word has to end either in a vowel or in a vowel followed by a nasalization (pronounced probably like the English *ng* in *sing*).

2. The groups of consonants which are so characteristic of Sanskrit are softened down by assimilation, elision, or crasis, or are avoided by the insertion of vowels.

3. The vowels *ri*, *rī*, *li*, and *lī* have completely disappeared, the diphthongs *ai* and *au* are replaced by the vowels *e* and *o*; and the three different sorts of *s*'s are all represented by the simple dental *s*.

4. The rules of Sandhi—that is, of the union of adjacent words—are much simplified, so that the words retain very much of their previous form, and Sandhi becomes in Pāli very little more than a set of rules for the elision of vowels in a simple, natural way.

5. The rules for the declension of nouns and the conjugation of verbs are much simplified, not only by the action of the foregoing principles, but also by the loss of the dual number, and by other and similar alterations.

In consequence of these new guiding factors Pāli, like Italian, has become a language at once flowing, melodious, and sonorous; and an examination of its grammar and vocabulary reveals all the distinctive characteristics of a vigorous, spoken, and growing vernacular, as distinguished from the formal hardness of a dead language. There are, as in Sanskrit, a few imported words, such as *chāṭī* and *chumbaṭa*, adopted from Dravidian or other native sources. With these few exceptions the whole of the word-forms in Pāli are derived directly, like the classical Sanskrit, from the older Sanskrit as spoken by the Aryan conquerors of India, before it became a dead language. In about a score of instances Pāli has preserved word-forms peculiar to the ancient Vedic and lost in the classical Sanskrit, and it has preserved the Vedic palatal *l*. In a few cases it has even distinct traces of the still older language of which Sanskrit and all other Aryan languages are the common children. A few instances will make its relation to Sanskrit more clear.

In giving these instances it should be borne in mind that the Pāli books are preserved, in the three countries where it is still studied and used, in the local alphabets—all of them, like the various alphabets in which Sanskrit is written, being derived from the old Pāli alphabet of the inscriptions, now fallen out of use. In transliterating Pāli words into English the vowels have the sound of Italian vowels; double consonants (as in Italian) are pronounced double; and the consonants have their English sounds. The *g* is always hard, as in *gate*, the *ñ* is pronounced as *ny*, and *ṃ* is *ng*, as in *sing*.

About two-fifths of the words in Pāli are identical with their Sanskrit equivalents, these latter being so little complicated in structure that they conform to the principles of Pāli simplicity. Such words as *nāga*, snake, elephant; *gochara*, realm; *āha*, he said; and *ayaṃ*, this, are examples of this sort of word.

There is another class, comprising two-fifths of the Pāli language, in which the change is so slight as to be easily recognizable. Thus *mukta*, free, becomes *mutta*; *kleśa*, sin, becomes *kilesa*; *sthāna*, place, becomes *ṭhāna*; *ambā*, mother, becomes *ammā*; *agni*, fire, becomes *aggi*; *aupamya*, metaphor, becomes *opamma*.

The third class, which looms largest in the works on Pāli philology, but is really very small in comparison with the other two, contains those words in which the change is not so evident—*milakkha*, foreigner, for *mleccha*, in Sanskrit; *upacikā*, ant, for *upādikā*; *dosina*, clear, for *jyautsna*; *samparanka*, friend, for *sampariyanka*; *gaddūhana*, small space, for *dadrūghna*; *vutta*, sown, for *upta*; *jantaggha*, for *yantragṛiha*, bathroom. Some words, certainly identical, are still more unlike in appearance even than these, and the reasons which have brought about changes so considerable are not as yet fully worked out. This unsolved department of Pāli, or rather of Indian linguistics (for it deals with the whole history of speech in India), is full of interest to the trained philologist.

Bibliography.—Childer's *Dictionary of the Pāli Language* (London, 1875; out of print); Eduard Müller, *Pāli Grammar* (London, 1884); Ernst Kuhn, *Beiträge zur Pali Grammatik* (Berlin, 1875); Vincent Fausböll, *Sutta Nipāta*, vol. ii. (Pāli Text Society, 1893, a root dictionary to the work so called); Richard Morris, *Notes and Queries on Pali Philology* (in the *Journals* of the Pāli Text Society, 1884–93); Émile Senart, *Kaccāyana's Pali Grammar* (Pāli text with translation and notes, Paris, 1871); V. Trenckner, *Pāli Miscellany* (London, 1879). T. W. Rhys Davids.

Pāli Literature: a literature consisting of the Buddhist sacred texts, and of other works by Buddhist authors—histories, poems, legends, commentaries, books on ethics, and controversial volumes on the rules of the Buddhist order. Its extent is constantly being increased, for the Pāli language has become the *lingua franca* of the Buddhists in Ceylon, Burma, and Siam, and is still used by authors who wish to be read not only in their native land, but by the Buddhists in all these countries.

The Pāli books containing the sacred texts are divided into three collections called the *Piṭakas* or Baskets—that is to say, the vessels in which the truth is handed on from teacher to scholar. The most important of these for the right understanding of the ethical and philosophical standpoint of Gotama himself and of the early Buddhists is a collection of dialogues in which usually the Buddha himself, but occasionally also one of his principal disciples, is represented as setting forth to an outsider or a disciple some fundamental point of his theory of life. These dialogues are arranged in two books containing respectively the longer and the shorter dialogues (called in Pāli the *Dīgha* and the *Majjhima Nikāyas*). They occupy in the history of Indian thought a position equivalent to that occupied in the history of Greek thought by the *Dialogues* of Plato. As compared with these, while by no means without a peculiar eloquence of their own, they are deficient in the graces of style; but the thought is more original, especially as being free from the ancient soul-theory. They are also much more systematized and worked out, and less charged with logomachies. The two collections were evidently put together at the same time—probably in the fifth century B. C.—and by the same hands; they form, in reality, but one book.

Next in historical importance to these *Dialogues of the Buddha* are the rules of the Buddhist order of mendicants. The whole of this body of canon law (in Pāli the *Vinaya*) was edited in Pāli, by Prof. Oldenberg, of Kiel, in 1879–83 (5 vols.), and an English translation by him and by the present writer of the most important parts of it has appeared under the title of *Vinaya Texts* in three volumes of the Sacred Books of the East (Oxford, 1881–85).

In the *Dialogues* the essential points of what we call Buddhism are all discussed; but each single dialogue deals for the most part with some particular point only, and allied points occur, perhaps, in other dialogues widely separated in the collection. The student has often to piece these various dialogues together before he can arrive at a full understanding of a particular question. This task was already done in a rather loose way by the early Buddhists. They brought together in one collection, called the *Samyutta Nikāya*, the various utterances ascribed to the Buddha, grouped according to particular subjects or particular persons addressed. Then again it is a distinctive characteristic of the Buddhist mode of thought that they arranged their ideas in groups consisting of one, two, three, four, and so on up to twenty or thirty detailed particulars. There is a collection, made by the early Buddhists and included in the Pitakas (called the *Anguttara Nikāya*), which takes each of these groups in order—Book I. dealing with the ones, Book II. with the pairs, Book III. with the triplets, and so on. Whether these two great collections add anything to the materials contained in the *Dialogues* of Gotama, or whether (as is at present generally supposed) they are only a rearrangement of the same matter, they are of the utmost value to the student.

A fifth collection (the *Khuddaka Nikāya*) consists of a number of shorter books of various dates and of various contents. They are: 1. The *Khuddaka Pāṭha*, selected short poems of great beauty. 2. The *Dhamma-pada*, a selection of 423 verses, most of them extracted from the earlier books of the Pitakas. 3. The *Udāna*, eighty short lyrics pur-

porting to be uttered by Gotama under circumstances of strong emotion which are explained in short prose introductions. Many of them are of great beauty and subtlety. 4. The *Iti Vuttaka*, 110 short lyrics of a similar character. A good many of the lyrics in both these tracts have been already traced elsewhere in the Pitakas. 5. The *Sutta Nipāta*, a very valuable collection of some of the most ancient lyrics produced by the early Buddhists. 6 and 7. *Vimāna* and *Peta Vatthu*, short poems on celestial mansions and on disembodied spirits. 8 and 9. The *Thera* and *Therī Gāthā*, poems by the members of the order, men and women respectively. Many of the verses in both collections are to be found in other parts of the Pitakas. 10. The *Jātaka* stories, the most ancient, the most complete, and the most valuable collection of folk-lore extant; edited by Prof. Fausböll, of Copenhagen (first 5 vols., London, 1877–91). A translation was undertaken by the writer (1st vol., *Buddhist Birth Stories*, London, 1881), but is being continued by a syndicate of English scholars under the editorship of Prof. Cowell (1st vol., by Robert Chalmers, Cambridge, 1894). 11. *Niddesa*, a work ascribed to Sāriputta, one of the personal disciples of Gotama, and containing accounts of the principal leaders, whether men or women, in the Buddhist reformation. 12. *Patisambhidā*, a longish treatise on the various mental powers resulting from the Buddhist system of self-culture. 13. The *Apadāna*, stories about Buddhist saints. 14. *Buddha Vansa*, short lines in verse, altogether 1,068 stanzas, of the twenty-five Buddhas. 15. The *Cariyā Piṭaka*, short poetical versions of 334 of the Jātaka stories.

All of the above fifteen books deal in one way or another with the life of ethical and intellectual self-culture which was the *summum bonum* of the early Buddhists. This was necessarily based on a view of psychology, one of the most interesting contributions of the Buddhists to human thought, which is constantly referred to and frequently discussed in scattered passages of these books. These passages have been collected and systematized in a series of works which form the third and last of the three great divisions of the *Pitakas*—the division called *Abhidhamma*. This word has been usually rendered by the misleading translation "metaphysics," but, as the soul theory of life is ignored by the Buddhists, they had of course nothing corresponding to what we understand by metaphysics. Looking at the contents of the *Abhidhamma*, the best translation of the word is psychology. There are seven books dealing with this subject, which is as full of difficulty and obscurity as of interest and value. These are as follows:

1. The *Dhamma Saṅgaṇi* (Concatenation of Qualities), which treats of the way in which a particular state of mind involves or connotes the coexistence of other states. It consists for the most part of long lists with constant repetition, and it is difficult to find the clue which binds these lists together. It presupposes in the reader (or rather in the user, for it was never intended to be read) a knowledge of the general system of Buddhist psychology—very little understood at present in the West. 2. *Vibhaṅga*, of which the contents are unknown. 3. The *Kathā Vatthu*, a discussion, by an author of the time of Asoka, of 219 points then at issue between different schools of Buddhists. The writer has published a full analysis of this treatise, so very valuable for historical purposes, in the *Journal* of the Royal Asiatic Society for 1892. 4. The *Puggala Paññatti*, a short tract on different sorts of individuals from the ethical point of view. 5. The *Dhātu Kathā*, a shorter work than, but similar in character to, the *Dhamma Saṅgaṇi*. 6 and 7. *Yamaka* and *Paṭṭhānn*, The Pairs and The Book of Origins, of which the contents are unknown.

Most of the above works have been edited for the Pāli Text Society of London, and some translations have appeared either for that society or in the Sacred Books of the East. Of works outside the Pitakas, the society has published a Pāli treatise called the *Gandha Vansa* (Account of the Books), giving a very short account of all the Pāli books written down to the fifteenth century. Of these there are accessible to Western students at present only the *Mahā Vansa*, a history of Ceylon; the *Dīpa Vansa*, another history of Ceylon; the *Milinda*, published by Dr. Trenckner (London, 1880); and a number of smaller works, mostly poetry, issued from time to time in the *Journal* of the Pāli Text Society. The *Milinda*, in many respects one of the most interesting of Eastern works known to the West, is a series of controversial conversations between Menander, the Greek King of Baktria, and Nāga sena, a member of the Buddhist order. It has been translated in full, with introductions, by the present writer for the Sacred Books of the East (Oxford, 1890 and 1894). Mention should also be made here of the very complete analysis, published in the Pali Text Society's *Journal* for 1893, of the *Visuddhi Magga* (Path of Purity), a systematic handbook of Buddhism drawn up by the distinguished scholar Buddhaghosa in the fifth century A. D. See PĀLI LANGUAGE. T. W. RHYS DAVIDS.

Pal'impsest [from Lat. *palimpses'tum* = Gr. παλίμψηστον, liter., neutr. of παλίμψηστος, scraped or rubbed out again; πάλιν, again + ψάειν, ψῆν, rub, rub away]: a term used either absolutely, or as an adjective with the word manuscript, to indicate an ancient writing of which the original ink has been washed or scraped away to enable a scribe to use the material again. Both the Greeks and the Latins were familiar with the process. Thus the phrases ὥσπερ παλίμψηστα and ὥσπερ βιβλίον παλίμψηστον occur in Plutarch, and both Catullus and Cicero speak of *palimpsesta*. Ulpian calls this second-hand writing material *charta deleticia*. It was probably used for little else than memoranda and rough drafts, and it is likely that only writings of an ephemeral and trivial nature were allowed to pass under the scraping-knife of the vellum-seller; but, with the decline of the commerce of the Mediterranean and the dwindling of the supply of papyrus, parchment or vellum—always dear, and by no means universally plentiful—soon became enhanced in value; and the large styles of uncial and capital writing then in vogue assisted this dearness by reason of the large amount of writing surface required. Hence naturally, in the last centuries of Rome and in the early Middle Ages, the use of the palimpsest was considerably extended. A Greek synod of 691 found it necessary to forbid the destruction in this way of copies of the Bible and of the Church Fathers; and when, in the West, the condensed and legible minuscule which we still use took the place of the cumbrous uncial and national scripts, the temptation must have been great to mutilate the old quartos with their growingly unfamiliar characters, their lavish pages, and their easily erasable ink. Nearly all our valuable Latin palimpsests come from this period between the seventh century and the ninth. Palæographers no longer credit, however, the charge that the monkish scribes indulged in wholesale destruction of earlier books. As Tischendorf has pointed out, no complete work has yet been found in a palimpsest, and it is improbable that any but worn or damaged books were often sacrificed.

Time brings back to the erased ink something of its color, and at length the manuscripts which had been subjected to the process of obliteration fell under the notice of modern scholars. At first the imperfect knowledge of a means of restoring the faded inks rendered the results unsatisfactory; but in the eighteenth century Knittel, a German theologian, carefully went through the palimpsests at Wolfenbüttel, and was so fortunate as to identify fragments of the Gothic Bible. P. J. Bruns discovered several palimpsests at Rome in the library ceded by Christina of Sweden to the Vatican, among them Cicero's *pro Roscio*, over which had been written a Latin version of the Scriptures. Niebuhr discovered in the same manuscript another oration of Cicero, that *pro M. Fonteio*, and was able to recover the *Institutes* of Gaius almost entire from a palimpsest at Verona. Angelo Mai made himself celebrated in deciphering texts of palimpsests, discovering Cicero's *de Republica* under Augustine's commentary on the Psalms and the *Letters* of Fronto under the acts of the Council of Chalcedon. Many curious morsels of antiquity have since been thus patiently rescued from oblivion, among them some of the most ancient manuscripts of the Christian Scriptures. Double palimpsests—those whose writing has twice been erased—are found. In the restoration of the earlier writing various chemical reagents have been used—an infusion of nutgalls, Gioberti's tincture, the hydrosulphuret of ammonia; but, unfortunately, all with great risk to the manuscript. So high an authority as Wattenbach declares that "more precious manuscripts, in proportion to the existing supply, have been destroyed by the learned experiments of our own time than by the much-abused old monks." One great palæographer (Sickel) points out how much may be gained by simply laying the manuscript in clear water, from which it takes no harm if it be afterward thoroughly dried.

The leading monograph on palimpsests is Mone's *De libris palimpsestis* (Carlsruhe, 1855), but the best discussion of the subject is that of Wattenbach, in his *Schriftwesen im Mittelalter*. For other authorities see MANUSCRIPT and PALÆOGRAPHY. W. D. BIRCH. Revised by GEORGE L. BURR.

Palinu'rus (now *Capo Palinuro*): a promontory on the coast of Lucania, in the Tyrrhenian Sea, between Velia and Buxentum. It received its name from Palinurus, the pilot of Æneas, who, according to tradition, was buried here. Some remains of old buildings still bear the name of the tomb of Palinurus. The place was twice the scene of great disasters, two large Roman fleets being wrecked on the rocky shores, one in 253 B. C., the other in 36 B. C.

Palisades: See FORTIFICATION.

Palisades: a line of cliffs bordering the lower portion of the Hudson, opposite New York city. They have a length of about 20 miles, and a general height of 300 feet. They are formed by the outcrop of an inclined sheet of trap-rock (diabase) which dips westward and was intruded in a molten condition between layers of sandstone and shale belonging to the Newark system, a division of the Jura-Trias. The same trap-sheet forms Bergen Hill to the S. and the Hook Mountains to the N. of the Palisades, and has been left in relief owing to the removal by erosion of the softer beds inclosing it. The trap is columnar, and at the Palisades breaks off so as to form vertical cliffs. The cutting away of the base of the cliffs by the Hudson is now progressing but slowly owing to the protection afforded by talus slopes. See also WATCHUNG MOUNTAINS. ISRAEL C. RUSSELL.

Palissot de Montenoy, pă'lĕe'sō'de-mŏń'te-nwă', CHARLES: author; b. at Nancy, France, Jan. 3, 1730. A precocious student, he entered the congregation of the Oratory, but soon left the order and tried literature. After some unsuccessful tragedies and comedies he found notoriety by bitter attacks on the philosophers. *Le Cercle* (comedy, 1755) satirized Rousseau, and *Petites lettres contre des grands philosophes* (1756) Diderot. His best-known work is the comedy *Les Philosophes* (1760), written with the same purpose. His *Œuvres* were published in 6 volumes (Paris, 1809). D. June 15, 1814. A. G. CANFIELD.

Palissy (Fr. pron. pă'lĕe'see'), BERNARD: potter and author; b. at Capelle Biron, in the department of Lot-et-Garonne, France, about 1510; was apprenticed to a potter, and afterward, on account of his knowledge of geometry, engaged for some time as a land-surveyor, but pursued also the arts of pottery, enameling, glass-painting, etc. He married about 1538 and settled at Saintes, but in 1564 removed to Paris. He was a Protestant, and although exempted from the massacre of St. Bartholomew by special order from the queen, in whose service he stood, he was twice imprisoned as a heretic—in 1557, when he was liberated by the intercession of the constable of Montmorency, and in 1588, when he was thrown into the Bastile and kept there to his death in 1589. The most remarkable of his glass-paintings is a representation of the *Myth of Psyche*, after Rafaello. Of his pottery, vases, ewers, jugs, salvers, etc., generally small in size but highly finished, collections are formed in several of the Paris museums; and these articles are much valued on account of the unique character of their design. His best-known pieces are those decorated with lizards, snakes, etc., in high relief, probably moulded from the actual creatures, and colored in close imitation of nature. None of his work can be compared for beauty with the finest Italian pottery. His writings, containing many new and true observations on the formation of springs, on the fertilizing power of marl, on the best means of purifying water, etc., and on the true origin and nature of fossil remains, were published in 1777 by Faujas de Saint-Fond and Gobet, and in 1844 by A. Cap. As an artist Palissy was well appreciated during his lifetime, but it was not until the time of Buffon and Réaumur that the truth of Palissy's scientific views was understood and recognized. The slighting remarks of Voltaire are simply the result of ignorance. Palissy's writings, published 1557–80, were edited by M. France and republished at Paris in 1880. His *Life* was written by H. Morley (2 vols., London, 1852), and in French by J. Salles (Nîmes, 1855), Audiat (1868), and Berty (1886). See Delange, *Monographie de l'œuvre de B. Palissy* (1862).

Palladio, pă'al-laa'dĕe-ō, ANDREA: architect; b. at Vicenza, Italy, in 1518. Little is known of his family or of his early years. A wealthy patron of Vicenza enabled the youth to travel over Italy and in France wherever Roman remains existed. Vitruvius and Leon Battista Alberti were the authors he studied, and it would seem that Giovanni Fontana, the architect of the castle of Udine, was for a time his master. In 1541 he modernized the palace of Trissino at Cricoli. He competed in 1546 with Giovanni Fontana, and again in 1549 with Giulio Romano, for the renovation of the Sala della Ragione (Palace of Reason) at Vicenza, an ancient monument of Gothic architecture, and won the competition, after which he went to Rome, where he made the façade of the palace of the Grand Duke of Tuscany. His genius was henceforth recognized, and his great learning and culture attracted the friendship and consideration of all the great men of his day. He settled at Vicenza, which, together with the neighboring country, is full of palaces and monuments designed by him. In 1556 he began the restoration of the Palace of Reason in his native city, a labor which lasted all his life. About the year 1560 Sansovino, being then eighty, recommended the Venetian republic to accept Palladio as his successor. His first work in Venice was the monastery Della Carità. Other important works here included the churches of San Giorgio Maggiore and Il Santissimo Redemptore, the façade of San Francesco della Vigna, and some palaces.

When Henry III. of France passed through Venice, the republic, wishing to astonish him by the splendor of the city, commissioned Palladio to decorate it. War prevented him from carrying out his engagement to renovate the cathedral at Brescia, which he had intended to transform into a masterpiece of his art. He commentated on and illustrated with drawings Polybius, and also the *Commentaries* of Cæsar, in a manner which showed careful study of the military tactics of the ancient Romans. His knowledge of hydraulics was also considerable. At Bassano he built a wooden bridge, in which he combined solidity with elegance of design, and this resisted the inundations of the river Brenta till the end of the seventeenth century, when its restoration by Ferracina spoiled its original beauty. Palladio took part in the competition of the greatest architects of his time for the design of a stone bridge to replace the wooden Rialto bridge at Venice, and his project was preferred to all, although Antonio da Ponte's was finally chosen as more within the means the republic had to dispose of. He planned the royal park in Piedmont for Duke Emmanuel Philibert of Savoy, to whom he dedicated his *Treatise on Architecture*, published in Venice in 1570, which has since been reprinted and translated in all languages. Palladio died at Vicenza in 1580. W. J. STILLMAN.

Palladium: a silver-white to steel-gray metal of the platinum group, discovered by Wollaston in 1803 in the mixture of platinum metals (polyxene) from South America. It has nearly the hardness of platinum, but is less ductile; specific gravity, 11·3 to 11·8; when hammered, 12. It does not fuse in ordinary furnaces, but melts in the oxyhydrogen flame and volatilizes. It can be welded like iron or platinum. It does not oxidize readily, but dissolves in hot nitric acid and in aqua regia, and may be combined with sulphur by heat and can be alloyed with various metals, particularly platinum, gold, silver, and copper. Four parts of copper and one of palladium form a white ductile alloy, so, also, with gold. The *oro pudre* or impure gold from Porpez, South America, contains 9·85 per cent. of palladium and 4·17 per cent. of silver. Similarly the *oro preto* (black gold) from Minas Geraes, Brazil, contains from 7·7 to 11·1 per cent. of palladium, according to assays made at the Rio de Janeiro mint. Six parts of gold and one of palladium formed the alloy used at the suggestion of Dr. Wollaston for the graduated part of the mural circle at Greenwich Observatory. Being very white and inalterable in the air, and not tarnishing like silver in sulphurous gases, it has been much used for such purposes. Some of its alloys have been used for the points of pencils, lancets, and as a substitute for gold in dental work. Palladium has the property of occluding hydrogen to an extraordinary degree. This was discovered by Graham, and he regarded hydrogenized palladium as a true alloy containing the hydrogen in the form of the metal hydrogenium, the compound corresponding to the formula Pd_4H_2. This property of the metal was well illustrated at Paris in 1878 by a disk of palladium 100 mm. in diameter and 2 mm. thick, in which nearly 1,000 times its bulk of hydrogen had been occluded. By the absorption of the gas its diameter was increased to 102·5 mm. and its thickness to 2·2 mm. It increased in weight, and became concave.

Brazil appears to be the chief source of this metal; it not only occurs in alloy with gold, as above shown, but separately in mixture with gold and platinum in alluvial sands. A small quantity occurs at Port Orford, on the coast of California, with platinum and iridium. It is reported to

have been found upon the south coast of the Black Sea, in the vicinity of Batum, in auriferous sands, and is associated with platinum in the Ural Mountains. WILLIAM P. BLAKE.

Palladium [= Lat. = Gr. Παλλάδιον, statue of Pallas, liter., dimin. of Παλλάς, Παλλάδος, Pallas]: a wooden image (ξόανον) of Pallas let fall from heaven by Zeus in answer to the prayer of Ilus, in token of his approval of the founding of Ilium. There are other stories of its origin. It was 3 cubits high, with legs stiff and closely pressed together, an uplifted spear in the right hand, and a distaff and spindle or a spear in the left hand. The image represented the protecting goddess, who would not allow the city to be taken as long as the image remained inside its walls. Odysseus and Diomedes crept into Troy by night and stole it. According to one story, Demophoon captured it from Diomedes as he was landing in Attica and placed it on the Athenian Acropolis. but according to another story Diomedes brought it to Argos. According to still another story, the Trojans, fearing that it might be stolen, made an imitation Palladium, which was the one stolen by Odysseus and Diomedes, and concealed the genuine one, which was carried by Æneas to Italy, and for centuries was preserved in the temple of Vesta in Rome, until Heliogabalus placed it in in his temple of the Sun. The theft of the Palladium by Odysseus and Diomedes was a favorite motive with the ancient artists. See the article *Palladium* in Baumeister's *Denkmäler*. J. R. S. STERRETT.

Palla'dius: the name of several distinguished men. (1) RUTILIUS TAURUS ÆMILIANUS. a Roman author, probably from the fourth century; wrote a work on agriculture, *De re Rustica*, in fourteen books, which was much used during the Middle Ages. Edited by J. G. Schneider in his *Scriptores Rei Rusticæ Veteres Latini* (Leipzig, 1795); translated into English by Thomas Owen (London, 1803). Book xiv., a poem in elegiacs on grafting (*De Incitione*) has been separately edited by J. C. Schmidt (Münnerstadt, 1877), and book i., by the same editor (Würzburg, 1876).—(2) A Christian Father; b. in Galatia in 367 A. D.; Bishop of Helenopolis in Bithynia in 400, and of Aspona in Galatia in 420; d. in 430. He wrote the *Historia Lausiaca*, a collection of biographies of hermits, dedicated to Lausus, governor of Cappadocia, published by Meursius (Leyden, 1616) and by Fronto Ducæus in his *Auctarium* (Paris, 1624).—(3) A Greek author on medicine; lived probably in Alexandria in the seventh century, and wrote commentaries on the works of Hippocrates, and a book on fevers, edited by Bernard (Leyden, 1745). M. WARREN.

Pallah [from the native (South African) name]: the *Æpyceros melampus*, a fine dark-red antelope of South Africa (called in Dutch *roode bok*, red antelope). It has a white belly, a black mark upon the croup, and black tufts on the back part of each foot. It has long, handsome horns, somewhat lyrate and ringed. Its flesh is good, though dry. It is very swift, but when surprised has the habit of trying to steal away undiscovered. It is found in considerable herds in bushy places.

Pal'las (in Gr. ἡ Παλλάς and ὁ Πάλλας): 1. A daughter of Triton and a youthful companion of Athene. Once when they were engaged in warlike sport they became angry, and Zeus, seeing that Pallas was about to strike Athene, interposed his ægis, and Pallas fell at the feet of Athene, who made an image in her honor and placed upon its breast the death-dealing ægis. This statue was the Palladium cast down from heaven by Zeus in answer to the prayer of Ilus for a sign of heaven's approval. 2. A Titan. 3. Father of Selene. 4. A giant. 5. The grandfather of Evander, after whom the city built by Evander on the Palatine Hill was named. 6. Son of Pandion, of Athens. 7. Freedman of Antonia, mother of Claudius; he played a prominent *rôle* under Claudius, and was put to death by Nero for the sake of his money. J. R. S. STERRETT.

Pallas, PETER SIMON: traveler and naturalist; b. in Berlin, Germany, Sept. 22, 1741; studied medicine and natural science; visited England and Holland; published in 1766 his *Elenchus Zoophytorum* and *Miscellanea Zoologica*, still of value; was invited by Catherine II. in 1768 to Russia as Professor of Natural Science at the Academy of St. Petersburg; made from 1768 to 1774 a journey of exploration through Southern Siberia to the frontier of China; resided for many years in the Crimea, where the empress gave him extensive estates, and partook with great activity in all scientific undertakings in Russia, but returned at last to Berlin, where he died Sept. 8, 1811. Those of his numerous works best known and still of interest are *Travels through the Southern Provinces of the Russian Empire* (Leipzig, 1799–1801; Eng. trans. 1812); *Flora Rossica* (2 vols., 1784–88, not completed); and *Sammlungen historischer Nachrichten über die mongolischen Völkerschaften* (2 vols., St. Petersburg, 1776–1802).

Pallas Athene (in Gr. Παλλὰς Ἀθήνη, Ἀθηναίη, Ἀθηνᾶ): See ATHENA.

Pallavicino, SFORZA, Cardinal: theologian and scholar; b. in Rome, Italy, Nov. 28, 1607. After studying jurisprudence there he turned to theology, receiving his baccalaureate in 1628. In 1630 he determined to become an ecclesiastic, and was at once given important charges by Pope Urban VIII. In 1637 he became a Jesuit, and for the rest of his life he was one of the most important members of the Society of Jesus, having in charge particularly the direction of its educational policy and work. In 1659 he was made cardinal by Alexander VII., who had long been his intimate friend. He is chiefly famous for his theological works, of which the most important is his *Istoria del Concilio di Trento*, etc. (Rome, 1656–57), written to combat the similar history by the Venetian Paolo Sarpi. In the preparation of this he had access to documents closed to all others; but the violence of his partisanship prevented him from giving scientific exactness to his treatment. To the same field belong (besides his Latin treatises, *Vindicationes Soc. Jesus, Assertionum theologicarum libri*, etc.) his *Arte della perfezione cristiana* (Rome, 1665) and his admirable *Della vita di Alessandro VII. libri cinque* (Prato, 1839–40). Besides being a theologian, Pallavicino was a scholar and poet. He belonged to the Roman academy called Gli Umoristi, and later to the Florentine della Crusca. He wrote a tragedy, *Ermenegildo* (1644); *Del Bene* (dialogues, 1644); *Considerazioni sopra l'arte dello stile del dialogo* (1646); *Avvertimenti grammaticali a chi scrive in italiano* (1661); and a sacred poem, *Fasti sacri*, of which only fragments are preserved. D. in Rome, June 5, 1667. For his life and works, see *Opere edite ed inedite di Sforza Pallavicino* (5 vols., Rome, 1844–48). A. R. MARSH.

Palliser, Sir WILLIAM, C. B.: soldier and inventor; b. in Dublin, Ireland, June 18, 1830; was educated at Rugby, Trinity College, Dublin, Trinity Hall, Cambridge, and Sandhurst College; became ensign in the Rifle Brigade 1855, and joined the Eighteenth Hussars in 1858; became captain 1859, major, unattached, 1864, and retired from the service in 1871. He was the inventor of the Palliser projectiles, designed for piercing armor-plated ships; he also invented an improved method of rifling iron wrought cannon for use both in ships and on fortifications, and of converting smooth-bore cast-iron ordnance into rifled guns. He was knighted by Queen Victoria Jan. 21, 1873. D. Feb. 4, 1882.

Pal'lium [= Lat., liter., cloak, mantle, pall]: in the Roman Catholic Church, a band of white lamb's wool, embroidered with purple crosses, worn upon the neck by the pope and all ecclesiastics of archiepiscopal rank, including metropolitans and patriarchs. It was once made of linen, embroidered with purple, and was worn by all bishops. The pallium has two pendants, one hanging down the back and one down the breast of the wearer. It is the chief badge of the archbishop's authority, is granted by the pope in person, and is worn only upon very solemn occasions. The pope, however, wears it continually. It is always buried with the wearer, and can never be transferred to another person.

Palm: See PALM FAMILY, PALM OIL, and PALM WINE.

Palm, JOHANN PHILIPP: bookseller; b. at Schorndorf, Bavaria, in 1768; succeeded his father-in-law, Stein, as publisher in Nuremberg, where, in 1806, his firm issued a pamphlet entitled *Deutschland in seiner tiefen Erniedrigung* (Germany in her Deep Humiliation), which censured Napoleon and condemned the occupation of Bavaria by the French troops. The book fell into the hands of the French officials and the matter was brought to the notice of Napoleon, who, it is said, gave orders for the arrest, conviction, and speedy execution of the offender, that his death might serve as a warning to others. Palm was seized, hurried before an extraordinary military commission at Braunau, and, though he professed ignorance of the contents of the pamphlet, was condemned to death Aug. 25, 1806. He was shot at Braunau on the following day. Like the execution of the Duc d'Enghien, this act caused general indignation throughout

Europe, and in Germany the hatred of Napoleon was intensified. Some writers have tried to lay the blame of this judicial murder upon Marshal Berthier instead of Napoleon. A bronze statue of Palm was erected at Braunau in 1766. See Schultheiss, *Johann Philipp Palm* (Nuremberg, 1860).

Pal'ma: town of Spain; capital of the province of Baleares, on the southwestern coast of the island of Majorca (see map of Spain, ref. 16–L). It is surrounded with walls and fortified with thirteen bastions, and has a fine harbor with a mole 500 yards long, and lined on both sides with dockyards, in which ship-building is carried on. The city is well built, and contains many elegant buildings, both private and public, among which the most remarkable are the cathedral (1232–1601) in the Gothic style, the Church of St. Francis, containing the tomb of LULL (*q. v.*), the exchange, dating from the fifteenth century, and the governor's palace. It has many good educational institutions and manufactures of silks and woolens, jewelry, soap, brandy, and glass. Pop. (1887) 60,514.

Palma: one of the CANARY ISLANDS (*q. v.*). Area, 330 sq. miles, with 39,622 inhabitants. It contains the interesting, now extinct, volcanoes Caldera and Barraneo, often referred to as exceptionally well-preserved types of volcanic forms. The island produces good timber, and has two fine towns, St. Cruz and Los Llanos.

Palma, JACOPO, called IL VECCHIO (the elder), or PALMA VECCHIO: painter; b. at Serina, near Bergamo, about 1480; d. in Venice in 1528. He went to Venice while still very young and followed Giorgione's method of coloring. His altar picture at San Cassiano is one of his early works, and one of his finest is *Santa Barbara* at Santa Maria Formosa. He soon received orders for altar pieces for the churches in Venice, the surrounding country, and for Serinalta. His picture of *The Epiphany*, now in the Brera at Milan, shows that he had originality. He painted in competition with Gian Bellini and Mansueti in the school of St. Mark the story of the ship bringing St. Mark's body to Venice in a terrible storm. Vasari bestows the highest praise on this work, as also on a portrait of himself which Palma painted for him. The Venetian academy possesses a fine *Assumption* by this master. The Louvre has four pictures by him, and the museum of Brussels one. W. J. S.

Palma, JACOPO, called IL GIOVANE (the younger), or PALMA GIOVANE: painter; date of birth unknown. He was a nephew of Palma Vecchio. His father was his first instructor in painting, but he imitated Titian, and before he was fifteen years of age he became the *protégé* of the Duke of Urbino, who first took him to his capital and then sent him to Rome to study. He returned to Venice in 1570, where his work did not seem much in request until Vittoria, the architect and favorite sculptor of the republic, gave him commissions which enabled him to compete with Tintoretto and Veronese. He painted a *Last Judgment* in the Sala dello Scrutinio, and a picture representing the pope permitting Otho to be reconciled to his father in the Sala del Maggior Consiglio, both in the ducal palace; also Alexis and the crusaders assaulting Constantinople, besides the naval fight on the Po, and the taking of Cremona, which is perhaps his masterpiece. After the death of Tintoretto and Veronese he contented himself with producing mere sketches. He painted innumerable altar-pieces for Venice, and examples of his art are to be found at Cremona, Pesaro, Urbino, and Bologna. D. at Venice in 1628. W. J. S.

Palma, RICARDO: author; b. at Lima, Peru, Feb. 7, 1833. In his younger days he was engaged in a revolt, and in 1860 was exiled to Chili for a short time. After his return he was secretary to President Balta, senator, and finally assistant in the National Library until it was sacked by the Chilians in 1881. In 1884 he undertook its restoration. About 8,000 books, a mere fragment of the original collection, were recovered, and these were supplemented by gifts, principally from foreign governments. The library was reopened under his directorship July 28, 1884. Señor Palma is called the Nestor of Peruvian literature. He has published several romances, sketches of country life, two volumes of poems, and a historical work, *Anales de la Inquisición de Lima* (1863), but he is best known for his volumes on the historical traditions and legends of Peru which have appeared since 1870. HERBERT H. SMITH.

Palma di Montechiaro: city of Italy; in the province of Girgenti, Sicily; 14 miles S. E. of the city of Girgenti (see map of Italy, ref. 10–F). Though at some distance inland it has a port with a considerable coasting trade. Soda, sulphur, wine, and dried fruits are exported. Pop. 11,702.

Palmas, Cape: See CAPE PALMAS.

Palmblad, paalm'blaat, WILHELM FREDRIK: writer; b. in Liljestad, Sweden, 1788. At the age of twenty he founded with ATTERBOM (*q. v.*) the phosphoristic society Auroraförbundet, and both as critic and creative writer he contributed largely to the advancement of the new literary movement. In this his success was the greater because of the comparative conservatism of his views. During the latter part of his life he was a professor at the University of Upsala. His earliest serious efforts consisted of a number of tales, *Amala*, *Holmen i sjön Dall* (The Island in Lake Dall), and others of considerable merit; but his two novels—*Familjen Falkensvärd* and *Aurora Königsmark*—are decidedly inferior, as are also his translations of Æschylus and Sophocles. His principal work, and the best on that subject in the Swedish language, is *Handbok i fysiska och politiska, äldre och nyare geografien* (Manual of Physical and Political Geography, Ancient and Modern, 5 vols.), which, however, was not completed. D. at Upsala, 1852. D. K. DODGE.

Palm-crab: See CRAB.

Palmer: town; Hampden co., Mass.; on the Chicopee, Swift, and Ware rivers, and the Boston and Albany and the Cent. Vt. railways; 15 miles E. of Springfield, 39 miles W. S. W. of Worcester (for location, see map of Massachusetts, ref. 3–E). It comprises several villages, and is noted for its manufactures, which include carpets, woolen dress-goods, cotton goods, wire, wire nails, and foundry and machine-shop products. There are two libraries (Y. M. C. A. and State Primary School), a high school, a national bank with capital of $100,000, a savings-bank with deposits of nearly $1,000,000, and a weekly newspaper. Pop. (1880) 5,504: (1890) 6,520; (1900) 7,801.

Palmer: in mediæval times, a pilgrim returned or returning from the Holy Sepulcher, so called from the fact that he bore branches of palm gathered near Jericho, which were placed upon the church altar after the palmer's return. The palmer also employed the consecrated scrip (a leathern wallet) and staff; and it was further customary for him to visit the holy places of other lands during his return. Thus after his visit to the shrine of St. James the Less at Compostella, he wore the seallop-shell (*Pecten Jacobæus*), the cognizance of the great apostle.

Palmer, BENJAMIN MORGAN, D. D., LL. D.: clergyman; b. in Charleston, S. C., Jan. 25, 1818; was educated at the University of Georgia and the Theological Seminary at Columbia, S. C.; was pastor of the First Presbyterian church, Savannah, Ga., 1841–43; of the First Presbyterian church, Columbia, S. C., 1843–56; and since 1856 of the First Presbyterian church, New Orleans, La. Dr. Palmer was Professor of Church History and Polity in the Theological Seminary, Columbia, S. C., 1853–56; moderator of the first southern assembly, Augusta, Ga., 1861; and has been commissioner to ten general assemblies. Since 1847 he has been one of the editors of *The Southern Presbyterian Review*, of which he was a founder. He is the author of *The Life and Letters of J. H. Thornwell, D. D., LL. D.* (Richmond, 1875); *Sermons* (2 vols., New Orleans, 1875–76); *The Family in its Civil and Churchly Aspects* (New York, 1876); *Formation of Character* (1889); *The Broken Home* (1890); and *Theology of Prayer* (Richmond, 1894). C. K. HOYT.

Palmer, EDWARD HENRY: Orientalist; b. at Cambridge, England, Aug. 7, 1840; graduated at the university of that city 1867; was a member of the Sinai surveying expedition of 1868–69, and the survey of Moab in behalf of the Palestine Exploration Society 1869–70; acquired a practical knowledge of Oriental languages, and became Professor of Arabic at Cambridge 1871. Author of *The Negeb, or South Country of Scripture* (1871); *The Desert of the Exodus* (1871); *Arabic Grammar* (1874); of several translations from and into the Persian language, of a *Persian-English and English-Persian Dictionary* (1876–83); and of the *Qur'an* (1880); *Song of the Reed* (1876); *Poems of Behà ed Din Zoheir* (1876–77). In 1882, during the British military operations in Egypt, he was commissioned to dissuade the Bedouins E. of the Red Sea from allying themselves with Arabi Pasha, but while on a journey from Suez was murdered, with his two companions, by Bedouins Aug. 11. See the *Life* by Walter Besant (1883).

Palmer, ERASTUS DOW: sculptor; b. at Pompey, N. Y., Apr. 2, 1817; was for some years a carpenter at Utica; be-

gan in 1846 to cut cameos; removed to Albany; began as a sculptor 1852; has produced above 100 works in marble, including several portrait-busts of eminent men; has executed various groups, including one representing the landing of the Pilgrims, intended for the Capitol at Washington.

Palmer, GEORGE HERBERT: See the Appendix.

Palmer, JOHN MCCAULEY: soldier; b. at Eagle Creek, Ky., Sept. 13, 1817; removed to Illinois 1831; settled at Carlinville; was admitted to the bar 1839; took an active part in politics; State Senator 1852–55; was prominent in the organization of the Republican party 1856; delegate to the peace convention at Washington, D. C., Feb., 1861; appointed colonel Fourteenth Illinois Volunteers in May; accompanied Gen. Fremont in his expedition to Springfield, Mo.; appointed brigadier-general of volunteers 1861; participated in battles of New Madrid, Island No. 10, Corinth, and Murfreesboro; and was made major-general of volunteers Nov. 29, 1862; was in command of the Fourteenth Corps Oct., 1863, to Aug., 1864; was in Sherman's Atlanta campaign and subsequently in command of department of Kentucky; was mustered out Sept., 1866; Governor of Illinois 1869–73; U. S. Senator 1891; Presidential candidate of the gold democrats in 1896. D. Sept. 25, 1900.

Palmer, JOHN WILLIAMSON, M. D.: author; b. at Baltimore, Md., Apr. 4, 1825; graduated at the University of Maryland 1847; studied medicine in Philadelphia; was city physician of San Francisco, Cal., in 1849; went in 1852 to China; served 1852–53 as surgeon of the East India Company's war-steamer Phlegethon in the Burmese campaign; was active on the Confederate side during the civil war in the U. S.; became afterward an editor in Baltimore, removing to New York city in 1870. Author of *The Golden Dagon* (1853); *The Queen's Heart*, a successful comedy (1858); *The New and the Old* (1859); and *After his Kind*, a novel (1886); has translated Michelet's *L'Amour* and other works from the French; compiled *Folk-songs* (1860) and several other volumes of selected poetry; is widely known for his admirable papers on East Indian life. His poem, *Stonewall Jackson's Way*, was a popular Confederate ballad during the civil war.—His wife, HENRIETTA (*Lee*) PALMER, b. at Baltimore in 1834 and married in 1855, is the author of *The Heroines of Shakspeare* (1858); *The Stratford Gallery*; *Home Life in the Bible*; of translations from the French, etc. Revised by H. A. BEERS.

Palmer, RAY, D. D.: clergyman and hymn-writer; b. at Little Compton, R. I., Nov. 12, 1808; graduated at Yale College 1830; studied theology at New Haven; was pastor of Congregational churches at Bath, Me., 1835–50, and at Albany, N. Y., 1850–66; and secretary of the American Congregational Union at New York 1866–78. He was author of many literary contributions to reviews, some doctrinal works, and several volumes of religious poems, among which is the favorite hymn, *My Faith looks up to Thee*. A collection of his poetical works was issued in 1875. D. at Newark, N. J., Mar. 29, 1887.

Palmer, ROUNDELL, Earl of Selborne, D. C. L.: b. at Mixbury, Oxfordshire, England, Nov. 27, 1812; was educated at Rugby and Winchester schools, and at Trinity College, Oxford, and graduated with high honors 1834, obtaining a fellowship at Magdalen College and the Eldon law scholarship; was called to the bar 1837; entered Parliament 1847; became queen's counsel 1849; knighted and appointed solicitor-general 1861; was attorney-general 1863–66; was counsel of the British Government before the Geneva court of arbitration on the Alabama claims 1871; became Lord Chancellor with the title of Baron Selborne of Selborne, Hampshire, Oct., 1872, retiring from that office Feb., 1874; became Lord Chancellor again in 1880, and Earl of Selborne in 1882. He was author of *The Book of Praise, from the Best English Hymn-writers* (1862), and was well known from his advocacy of the establishment of a law university in London. D. at Petersfield, England, May 4, 1895.

Palmerston, HENRY JOHN TEMPLE, Viscount, and Baron Temple: statesman; b. at Broadlands, Hampshire, England, Oct. 20, 1784; a son of an Irish peer of the family of Sir William Temple; succeeded in 1802 to the title; was educated at Harrow and St. John's College, Cambridge, where he graduated in 1803; declined the election to the House of Lords as a representative peer for Ireland; entered Parliament for Bletchingley 1806; represented Newport in Parliament 1807–11, and Cambridge University 1811–31, and after that represented Bletchingley, South Hants, and Tiverton; became a Junior Lord of the Admiralty 1807; was Secretary of War 1809–28, under five administrations, having abandoned high Tory principles for moderate Liberalism; was Secretary of State for Foreign Affairs 1830–34, 1835–41, and 1846–52, attaining great distinction as a diplomatist. He appears to have sympathized with Napoleon's *coup d'état* of 1851, and his avowal of his views resulted in his withdrawal from the cabinet. He was Secretary of State for Home Affairs 1852–55, and again sided with Napoleon on the outbreak of the Crimean war, favoring an alliance with France against Russia. When the war spirit in Great Britain flagged, he resigned from the cabinet, but returned to office upon receiving pledges of a warlike policy. He was Premier and First Lord of the Treasury 1855–58 and 1859–65. His premiership is distinguished by the warlike spirit shown by the Government in dealing with foreign affairs. He saw the Crimean war to a close, refused to mediate between France and Austria in the Italian war, standing firmly for the expulsion of the latter power from Italy, and on the eve of the Danish war, in conjunction with Napoleon III., he warned Prussia and Austria against any interference with the independence of Denmark; but when Napoleon drew back he looked about for allies with whom to defend Danish rights, but, finding none, left Denmark to her fate. In 1861 he was appointed lord warden of the Cinque Ports, and in 1863 was elected rector of Glasgow University. D. at Brockett Hall, Hertfordshire, Oct. 18, 1865, and was buried in Westminster Abbey. See his *Life*, by Lord Dalling (1870, incomplete).

Palmet'to [from Span. *palmito*, dimin. of *palma*, palm, palm-tree]: properly, a small palm-tree of Southern Europe (*Chamærops humilis*); also any one of certain other small palms. Of these the U. S. has the following: (1) *Sabal palmetto*, the cabbage palmetto, found as far N. as the Cape Fear river, in sandy soil near the coast. Its timber is useful in constructing piers, since it is durable and not subject to the attack of the teredo. The tree sometimes reaches the height of 50 feet. The leaves are largely used in making hats, and the "cabbage," or crown of young leaves, is very palatable when boiled. The root is highly astringent. (2) *Serenoa serrulata*, the saw-palmetto, has a creeping stem from 5 to 8 or more ft. 6 in. in diameter, with thick clusters of fan-shaped leaves, the abode of many rattlesnakes. (3) *Sabal adansonii*, the dwarf palmetto, is stemless and has leaves 2 or 3 feet high. It covers dense patches of ground in low coast regions. (4) *Rhapidophyllum hystrix*, the blue palmetto, is a low palm with long-stemmed fan-like leaves, in the axils of which are sharp needle-like thorns. The roots of the palmettos are in some soils so numerous and strong as to make the plowing of land very difficult and expensive. Much of the palmetto-leaf of commerce is derived from the Palmyra palm. Revised by L. H. BAILEY.

Palm Family [*palm* is from Lat. *palma*, possibly so named from the resemblance of the leaf to the palm of the hand, or possibly a corruption of the Oriental name; cf. Heb. *tamar* (Eng. *tamarind*)]: the *Palmaceæ*, a large group of monocotyledonous trees or tree-like plants, numbering 1,100 or more species, nearly all natives of tropical climates. Their flowers are small, with three sepals and three petals, usually six stamens, and a compound three-celled pistil (Fig. 1) or three simple pistils. Each cell of the ovary contains a single erect, ascending, or even pendulous inverted ovule, but in fruiting, as a rule, but one seed is developed. The embryo is small, conical or cylindrical, and lies imbedded in a large endosperm.

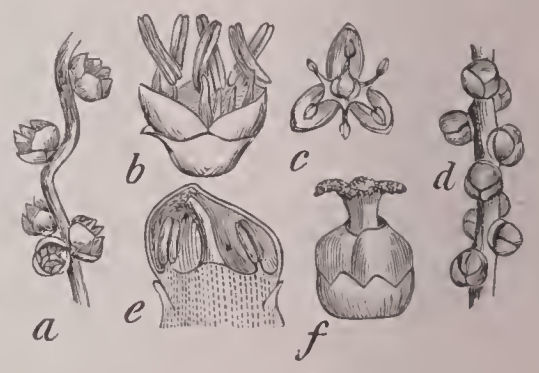

FIG. 1.—Flowers of various palms.

The stems of palms are mostly unbranched, cylindrical, or nearly so, and are covered with the decaying bases of the leaves. The crown of leaves always clothes the summit of the stem, and rises with its elongation, new leaves forming above, while the older ones die away below. The leaves are simple or palmately or pinnately compound, and are often many feet long and broad. (Fig. 3.)

Palms vary greatly in size, some scarcely rising above the ground, while others are 100 feet or more in height. In

their growth they first attain very nearly their full diameter, and then shoot up their cylindrical stems, which subsequently increase in size little or not at all. Some species, especially of the genus *Calamus* and its allies, are long, slender, prickly, climbing shrubs, often attaining a length of 300 feet or more.

It would be impossible in a short article to enumerate the many uses which palms serve for the world at large, and especially for the inhabitants of tropical regions. The grasses

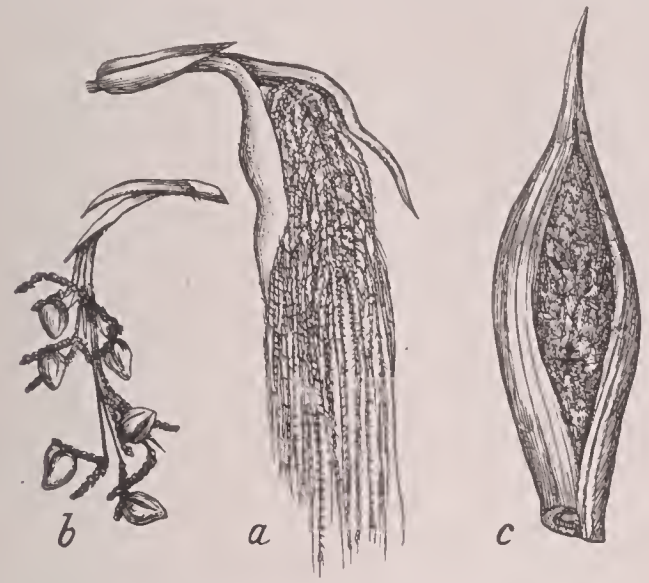

FIG. 2.—Inflorescences of palms.

possibly excepted, no other family of plants excels the palms in economic importance in relation to mankind. Food, clothing, shelter, furniture, utensils, tools, weapons, ornaments, medicines, and intoxicating drinks are sometimes all supplied by one or more species.

The family has been separated into five sub-families by Dr. Oscar Drude, as follows:

Sub-family I. *Coryphinæ* (Fig. 1, *a b c*; Fig. 3, *a b c*), with inflorescence diffusely branched; flowers with three free

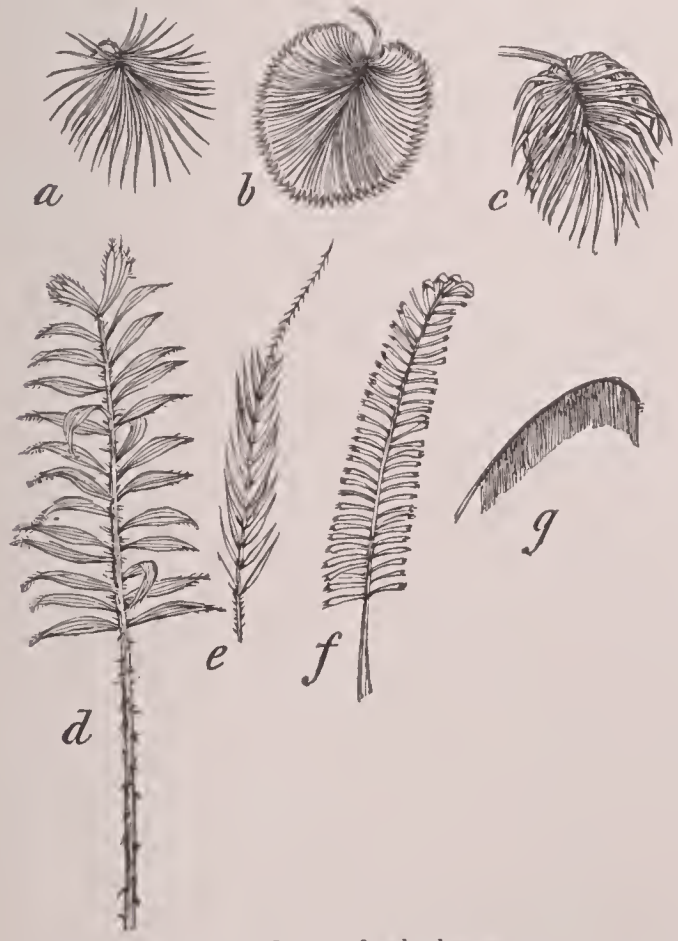

FIG. 3.—Forms of palm leaves.

carpels; fruit, a berry; leaves, pinnate in *Phœnix*, palmate in all others. Important members of this sub-family are the following: The date-palm (*Phœnix dactylifera*) of Western Asia, Northern Africa, and Southern Europe, bears large bunches of the well-known fruits. The talipot-palm (*Corypha umbraculifera*) of Ceylon and Malabar is remarkable for its gigantic leaves, the circular blades of which are sometimes 12 feet in diameter. (Fig. 3, *b*.) The palmetto (*Sabal palmetto*) is a short-stemmed species common in the Southern U. S. The wax-palm (*Copernica cerifera*) of Brazil is notable for the waxy coating on its young leaves, which is collected for making candles. (Fig. 3, *a*.) Nine other species in this sub-family are natives of the U. S.

Sub-family II. *Borassinæ* (Fig. 2, *b*), with inflorescence of simple or little branched, thickened axes; flowers with three united carpels; fruit, a drupe; leaves, palmate. The Doum palm (*Hyphœne thebaica*) of the upper Nile region is remarkable for its branching habit. Its large fruits have the flavor of gingerbread, whence the name gingerbread-palm which is often applied to it. (Fig. 2, *b*.) The Palmyra palm (*Borassus flabelliformis*) of tropical Africa and Asia is a stately tree 20 to 100 feet in height, yielding "Palmyra wood." Wine, toddy, and sugar are made from its juice. The double cocoanut (*Lodoica sechellarum*) of the Seychelles islands is 100 feet high, with a trunk 1½ to 2 feet in diameter. The large fruits weigh 30 to 40 lb. each, and grow in bunches of nine or ten. They take ten years to ripen.

Sub-family III. *Lepidocaryinæ* (Fig. 3, *d e*), with branched inflorescence; flowers with three united carpels; fruit, covered with scales; leaves, palmate or pinnate, generally spiny. The sago-palms (*Metroxylon rumphii* and *M. læve*) of the East Indian Archipelago yield sago, which is obtained by splitting their trunks and extracting the soft pithy central portions, whose cells are filled with starch. The rattan palms (*Calamus rotang*, *C. rudentum*, *C. royleanus*, *C. scipionum*, etc.) of India are much used for making walking-sticks, mattings, chairs, etc.

Sub-family IV. *Ceroxylinæ* (Fig. 1, *d e f*; Fig. 2, *c*; Fig. 3, *f g*), with simple or branched inflorescence; flowers with three united carpels; fruit, a smooth berry or drupe; leaves, pinnate.

The toddy palm (*Caryota urens*) of India attains a height of 50 to 60 feet, and furnishes great quantities of toddy. (Fig. 2, *a*.) The Gomuti palm (*Arenga saccharifera*) of the Indian Archipelago yields fiber, toddy, sugar, sago, casks, utensils, etc. (Fig. 3, *f*.) See GOMUTI PALM.

The Piassaba palm (*Attalea funifera*) of Brazil yields "Coquilla nuts," and a valuable fiber much used in the manufacture of cordage, mats, brooms, etc. The cocoanut-palm (*Cocos nucifera*), a native of the tropical parts of the Old World, now cultivated in all hot countries, yields the well-known cocoanuts of commerce. See COCOANUT.

Two genera of this sub-family, *Pseudophœnix* and *Oreodoxa*, are represented in the Southern and Southwestern U. S. The species of *Chamædorea* of South America are slender stemmed climbers, and are used in the construction of rude suspension bridges. (Fig. 1, *d e f*.)

Sub-family V. *Phytelephantinæ*, with spicate or capitate inflorescence; flowers with three or four united or free carpels; leaves, pinnate.

The ivory-nut palms (*Phytelephas macrocarpa* and *P. microcarpa*) produce very hard nuts, whose endosperm resembles ivory, for which it is used as a substitute.

LITERATURE.—*Popular History of Palms and their Allies*, by Berthold Seeman (London, 1856); *The Illustrated Dictionary of Gardening*, 4 vols., by George Nicholson (London, 1885–89); Bentham and Hooker's *Genera Plantarum* (vol. iii., London, 1883); Engler and Prantl's *Die Natürlichen Pflanzenfamilien* (vol. ii.); *Palmæ*, by Oscar Drude (Leipzig, 1887). CHARLES E. BESSEY.

Palmira, päl-mee'rää: a town of the department of Cauca, Colombia; 7 miles E. of the river Cauca and 86 miles N. N. E. of Popayan; on a plain called the Llanos de Malagana, about 3,200 feet above the sea (see map of South America, ref. 2–B). Until 1860 it was a small village; since then it has become the most important place in the department, after Popayan, and the center of a rich agricultural and grazing district. It is especially noted for its excellent tobacco. The climate is somewhat insalubrious. Pop. (1892) about 10,000. HERBERT H. SMITH.

Palmistry: See CHEIROMANCY.

Palmitic Acid: a fatty acid universally distributed in the fats of the animal and vegetable kingdoms. It is a colorless solid, lighter than water, crystallizes in small shining scales, and is without odor; insoluble in water, but freely so in hot alcohol and ether. Combined with glycerin, it occurs abundantly in palm oil, the fat of certain palms, in Chinese tallow, in Japanese wax, and the wax of *Myrica cerifera*. In the animal kingdom it is found in butter, in beeswax, in spermaceti, in human fat, etc. It is easily pre-

pared from palm oil by saponification with caustic potash, decomposing the soap with sulphuric acid, and recrystallizing the fatty acid several times from hot alcohol till it gives a steady melting-point.

The solutions of palmitic acid are acid, and if concentrated solidify on cooling, or if dilute yield tufts of slender needles with an acid reaction. This acid may be distilled unchanged, and, gently heated, evaporates without residue from an open dish. It burns like other fats with a light smoky flame. It forms with the alkali metals acid-salts analogous to the acid-acetates, and it forms normal or neutral salts with other metals according to their equivalence. The potassium and sodium palmitates are soluble in water and alcohol; the rest are insoluble.

Palmitic acid is made commercially for candle-making by fusing oleic acid with a large excess of caustic potash. The products formed are potassium palmitate, potassium acetate, and hydrogen. The potassium palmitate is washed, decomposed with sulphuric acid, the acid thus obtained washed and distilled.

Palmitins or *glyceryl palmitates* are others known as *mono-*, *di-*, and *tri-palmitin*, all crystalline fats which are artificially formed, of which the last is natural palmitin from palm oil and other fats. Revised by IRA REMSEN.

Palm Oil: the thick oil obtained from the fleshy pericarps of the fruit of *Elais guineensis* and *melanococca*, a palm-tree of Africa, and to some extent from other palms. It is extensively imported and made into soap, candles, and glycerin, and used for lubricating purposes. It is bleached and then pressed, and thus the palmitine is extracted for candle-making, while the elaine is used for lubricating, etc. The fresh oil is of a deep orange red, and has a pleasant smell as of violets. It may be used like butter. The oil palm is now naturalized in South America.

Palm Sunday: the Sunday before Easter, celebrated in the Greek and Roman Catholic and Lutheran Churches in commemoration of the triumphal entry of the Lord into Jerusalem (John xii.), on which occasion the multitude cast branches of trees before him. These branches are represented by sprays of palm, or, in countries where the palm does not grow, by those of other trees, as of the yew, willow, box, and fir. These branches are blessed by a priest and distributed to the congregation, who wear them for the rest of the day. The custom prevails, at least locally, of gathering and preserving the "palms," which are afterward burned, the ashes serving for use upon Ash Wednesday, the ashes of consecrated wood and of the old altar linen being also employed. It was another ancient custom that palmers returning from the Holy Land should bring with them leaves of the palm for service on Palm Sunday.

Palm-tree: See PALM FAMILY.

Palm Wine, or **Toddy**: an alcoholic beverage prepared from the saccharine sap of various species of palm. It yields by distillation a stronger drink called arrack. Palm wine is much used in India and other parts of Asia; it is made in Chili, and is almost the only fermented liquor made in Africa. See Johnston's *Chemistry of Common Life*.

Palmy'ra [Mod. Lat., named from the city of *Palmyra*, in Syria]: one of the noblest of the palm-trees, the *Borassus flabelliformis* of India and Ceylon. Its fruit is a valuable food, its timber is excellent, and it furnishes thatch, cordage, material for hats, fans, umbrellas; its leaves are used for writing tablets; sugar and arrack it produces abundantly. The young shoots are boiled and eaten, the seeds are edible, and the fruit yields a useful oil. This most useful tree is from 20 to 100 feet high and very beautiful, and its leaves are generally about 4 feet long, with stalks of about the same length. Each leaf has from seventy to eighty rays, and the stalks are spiny at the edges. The fruit is somewhat triangular, about the size of a child's head. It has a thick, fibrous, and rather succulent yellowish-brown or glossy-black rind, containing three seeds, each as large as a goose-egg, which are jelly-like and very palatable when young. As the palmyra is of slow growth, the wood near the circumference of the stem in old trees is very hard, black, heavy, durable, susceptible of a high polish, easily divided in a longitudinal direction, but very difficult to cut across. Palmyra-wood is the commercial name of this and of various other palms. In the north of Ceylon multitudes of people almost entirely depend on this tree for the supply of most of their wants, and in the palmyra regions of Southern Dekkan vast numbers of the inhabitants subsist chiefly on the fruit of this palm. The deleb-palm, so important to the inhabitants of Central Africa, is believed to be nearly allied to the palmyra-palm. Revised by L. H. BAILEY.

Palmyra: an ancient city of Upper Syria, situated in an oasis, 150 miles N. E. of Damascus; was founded or enlarged by Solomon (2 Chron. viii. 4), and formed at that time a bulwark against the Bedouin hordes of the desert. It is called in Scripture Tadmor (a name which in the Authorized Version appears in Kings ix. 18, where the Hebrew text and the Revised Version read *Tamar*), of which Palmyra, i. e. the city of palms, is the Greek and Latin equivalent. Under the wars between the Romans and the Parthians it acquired great importance, developed a vast commercial activity, and became a splendid city. In the second century A. D. it was the commercial metropolis of Northern Arabia. In the third century of our era, Odænathus, a native of Palmyra, established an independent Palmyrene kingdom, which was further extended, comprising the whole of Syria, and parts of Mesopotamia, and brought to great prosperity by his widow, Queen Zenobia; but when the queen refused to acknowledge the authority of the Roman emperor, Aurelian defeated her army, dissolved her empire, and captured her capital in 272. A revolt, during which the Roman garrison was slain, occasioned its destruction shortly after, and it never recovered, though in 527 Justinian rebuilt its fortifications and endeavored to restore it. In 633 it was devastated by the Saracens, and again in 744. In 1400 Tamerlane completely destroyed it, and at present it is only a vast field of ruins. A small village, Thadmor, inhabited by a few Syrian shepherds, is situated close by. The ruins, among which some tombs with inscriptions in the old Palmyrene language and characters, and a temple of Baal, are very remarkable, were first visited by English merchants in 1691, and explored by Robert Wood and Dawkins in 1751, who published their researches (London, 1753). See Saint-Mart, *Histoire de Palmyre* (Paris, 1823); Vogüé, *Syrie Centrale* (Paris, 1869); J. Seiff, *Reisen in der asiatischen Türkei* (Leipzig, 1875); also W. Wright, *An Account of Palmyra and Zenobia* (London, 1894). Revised by S. M. JACKSON.

Palmyra: city; capital of Marion co., Mo.; on the Chi., Burl. and Quincy Railroad; 15 miles N. W. of Hannibal, 15 miles S. W. of Quincy (for location, see map of Missouri, ref. 2–H). It is in an agricultural region, and contains waterworks, electric lights, several manufactories, a national bank with capital of $60,000, a State bank with capital of $50,000, and two weekly newspapers. The educational institutions include the Centenary High School (Methodist Episcopal South, opened in 1884), St. Paul's College (Protestant Episcopal, opened as the Ingleside Female College in 1848), and St. Joseph's College (Roman Catholic, opened in 1879). Pop. (1880) 2,479; (1890) 2,515; (1900) 2,323.

Palmyra: village; Wayne co., N. Y.; on the Erie Canal, and the N. Y. Cent. and Hud. Riv. and the W. Shore railways; 13½ miles W. of Lyons, 23 miles E. S. E. of Rochester (for location, see map of New York, ref. 4–E). It is in an agricultural region, has important manufactures, and contains the Palmyra Classical Union School, a national bank with capital of $1,000,000, a private bank, and 3 weekly and 2 monthly periodicals. Pop. (1890) 2,131; (1900) 1,937.

Palo Alto: town; Santa Clara co., Cal. (for location of county, see map of California, ref. 8–C): on the Coast Division of the Southern Pacific Railroad; 16 miles N. W. of San José, the county-seat, 34 miles S. by E. of San Francisco. It comprises a tract of over 8,400 acres, containing the costly mansion built by Leland Stanford and an extensive arboretum filled with a great variety of shrubs and trees, and is one of the three estates which Mr. and Mrs. Stanford deeded to the trustees of the LELAND STANFORD JUNIOR UNIVERSITY (*q. v.*) for university purposes. The beauty and healthfulness of this estate caused it to be chosen as the site for the university buildings. It has a State bank with capital of $20,000, and 1 weekly and 1 semi-weekly newspaper. Pop. (1900) 1,658.

Palpitation of the Heart [*palpitation* is from Lat. *palpita'tio*, deriv. of *palpita're*, throb, beat, intensive of *palpa're*, feel, stroke, whence Eng. *palpable*]: the forcible pulsations of the heart which make themselves felt or produce unpleasant sensations. Palpitation may be due to organic disease of the heart, but in perhaps a majority of all cases the heart itself will be found normal and the cause of the palpitation will be discovered elsewhere. The most direct and immediate extraneous cause of purely functional or non-organic

palpitation is pressure upon the heart by some pleural effusion, some tumor-mass, or a flatulent and distended stomach. Diseases of the stomach, however, act in a double way, not only by the pressure in cases of flatulence, but also through the nervous system by reflex action. The latter cause also applies to diseases of the ovaries or uterus and other organs. Reflex excitability is furthered by causes increasing the general nervous instability of the patient. Among these is the overuse of stimulants, such as tea, coffee, tobacco, and alcohol. Anæmic and hysterical or otherwise neurotic subjects are for a similar reason prone to palpitations: and in exophthalmic goiter, a form of nervous disease, cardiac palpitation is the most important symptom. Finally, there are the cases of palpitation due to diseases of the heart itself—such as hypertrophy, valvular disease, fatty heart, etc. See HEART DISEASE.

Palpitation is a paroxysmal affection, attacks coming on with greater or less frequency, lasting a short time or perhaps a day and then subsiding. The pulse is generally rapid, from 100 to 150 per minute; but there are persons with all the subjective sensations of extreme palpitation in whom the pulse-rate is actually less than normal. On the other hand, there are cases in which the most excessive rapidity, as much as 300 per minute, may occasion no subjective sensations, or very little. These cases are designated *tachycardia*. Constant or frequently repeated palpitation leads to hypertrophy of the heart from over-exercise, as in exophthalmic goiter, athletes, etc.

The treatment of palpitation varies with the cause. In nervous cases or in palpitation from fright, excitement, and the like, sedatives, such as bromide of potassium, valerian, or camphor are called for. When the heart is weakened by organic disease and palpitates from inefficient power of the individual contractions, digitalis and other stimulants are needed. Finally, local treatment directed to the stomach, ovaries, or uterus, or constitutional remedies to improve the condition of the blood, or the simple correction of dietetic errors may suffice to control long-standing tendency to palpitation. WILLIAM PEPPER.

Palpus (pl. PALPI): See ENTOMOLOGY.

Palsy: another term for PARALYSIS (*q. v.*).

Paludan-Müller, pää'loo-daan-mü'ler, CASPAR PETER, Ph. D.: historian; b. in Kjerteminde, Denmark, 1805; studied theology, but became a teacher; in 1840 rector of a Latin school; in 1872 Professor of History at the University of Copenhagen. His principal works are *Grevens Feide* (The Counts' Feud, 2 vols., 1853–54) and *De første Konger af den Oldenborgske slægt* (The Earliest Kings of the Oldenborg Line, 1874). D. in 1882. D. K. D.

Paludan-Müller, FREDERIK: poet; b. at Kjerteminde, in the island of Fünen, Denmark, Feb. 7, 1809; studied law, but never practiced; visited Germany, Holland, France, Switzerland, and Italy 1838–40. His principal work, *Adam Homo* (3 vols., 1841–48), is a novel written in verse, in the strophe of Byron's *Don Juan*. In its contents the book is national and original; in its form it is an imitation of Byron. It is a satire upon the spirit of worldliness and compromise of our time as represented in the person of the hero. Among his other novels and tales, *Dandserinden* (1833) is the best known. Of his dramas some treat mythological subjects, *Amor og Psyche*, *Dryadens Bryllup*, etc.; others romantic, *Alf og Rose*, *Prinds og Page*, etc.; and others biblical, *Adam og Eva*. Prominent among his works are *Kalanus*, an Indian tragedy (1861), and *Adonis*, a romance in verse (1874). D. Dec. 27, 1876. His *Poetiske Skrifter* were published at Copenhagen (8 vols., 1878–79).
Revised by D. K. DODGE.

Paludico'læ [Lat. pl. of *paludicola*, a marsh-dweller; *palus*, marsh + *colere*, inhabit]: an order, or sub-order, of birds containing the cranes, rails, and their allies; synonymous with ALECTORIDES (*q. v.*).

Paludism: See MIASMA.

Pamir Dialects: the Iranian dialects spoken in the central Asiatic table-land, the plateau of Pamir. Most important of these is the Munjī or Munjānī, spoken in the region of Mungān, near Kāfiristān; this tongue presents interesting resemblances to the ancient language of the AVESTA (*q. v.*). Other dialects are the Sanglichī, Ishkāshāmī, Wakhī, Shighnī, and the Yaghnōbī, or speech of the Galchas near the source of the Zarafshān. (See IRANIAN LANGUAGES AND LITERATURE.) Consult Tomaschek, *Centralasiatische Studien*, vol. ii., *Die Pamir-Dialekte* (Vienna, 1880), and W. Geiger, *Die Pamir-Gebiete* in Penck's *Geographische Abhandlungen*, vol. ii., 1 (Vienna, 1887). A. V. WILLIAMS JACKSON.

Pamirs: the geographical designation of the elevated region in Central Asia between lat. 36° and 39° N. and lon. 70° to 76° E. Politically it is divided between Chinese and Russian Turkestan, Bokhara, Afghanistan, and a number of petty states and independent tribes N. of the Punjaub. It extends from the Trans-Alai Mountains on the N. to the Hindu Kush on the S., and from the plains of Kashgar to the upper tributaries of the Oxus. It is a complex of mountains, valleys, and limited plains, all at elevations above 12,000 feet, and the mountains sometimes reaching 20,000 and 25,000 feet. It is divided into several individual isolated plains, as, from S. to N., the Little Pamir, the Great Pamir, Pamir Alichur, Pamir Rang-Kul, Pamir Sariz, Pamir Khartosh. The Pamir region is sometimes referred to as the "Roof of the World." It is traditionally the birthplace of the Aryan race, and some of the names of places still in use there present curious similarity to corresponding ones found in Genesis. The Anglo-Russian rectification of the Afghan boundary omitted the consideration of the Pamirs, as the region was little known and considered impassable. This omission attracted Russian and then British attention to it very strongly, and its resulting strategic importance has led to many explorations from both N. and S. since 1870. See Morgan, *The Pamir*, *Scot. Geog. Mag.*, viii., 1892, and Immanuel, *Die Pamirfrage*, *Petermanns Mitteilungen*, xxxviii., 1892—each article with a map. M. W. H.

Pamlico (or **Pamplico**) **Sound**: the largest of the sounds of North Carolina; fenced by long low islands from the open sea, with which it communicates by Ocracoke, Hatteras, Loggerhead, New, and other inlets. It is about 20 feet in average depth, with great areas of shoal water. It communicates with Albemarle Sound on the N. Its shores are low and often marshy. The fisheries are important. The Neuse and Pamlico are its largest tributaries.

Pampa, La: an ill-defined territory of the Argentine Republic, W. of Buenos Ayres and N. of the river Colorado; variously estimated to contain from 58,000 to 91,342 sq. miles. It lies partly in the region of the pampas, but there are also extensive tracts of woodland and hills of considerable size, especially toward the N.; in the open lands are numerous lagoons, often surrounded by *médanos*, or shifting sand-dunes. Since 1879, when the hostile Indian tribes were exterminated or driven beyond the Rio Negro, the land has been rapidly taken up by colonists. Sheep and cattle breeding are almost the sole industries. Pop. (1893) about 50,000. Acha, or General Acha, the capital, has about 2,500 inhabitants. HERBERT H. SMITH.

Pam'pas [plur. of *pam'pa*, probably Peruv. *bamba*, a plain]: in the southern and western parts of South America, any large open plains or rolling lands; hence the word is synonymous, or nearly so, with the terms llanos, savannas, prairies, etc., used in other parts of America. In a special geographical sense, the vast grassy plains which occupy a portion of the Argentine Republic. Roughly defined, they comprise an area of over 300,000 sq. miles, between the Paraná and the Atlantic on the E., the hills of Córdoba, San Luis, and Los Andes on the W., the Rio Salado on the N., and the Rio Negro on the S. The Gran Chaco and the eastern part of Patagonia are plains continuous with the pampas, but they are sufficiently distinguished by their vegetation and geological structure. To the eye the pampas are perfectly level; there is, however, a gentle slope southeastward, from 1,300 feet above sea-level, near Córdoba, to 50 or 60 feet by the Atlantic, S. of the Rio de la Plata. Slight depressions are occupied by shallow lakes and swamps; many streams are lost in these, and others have excavated deep ravines or *barrancas*; the western side of the Paraná presents a long line of clay cliffs, the cut edges of the plains. The soil is somewhat impregnated with salt; there are extensive salines, and in the northern and western districts many of the lakes and even the streams are brackish. The vegetation consists entirely of grasses and herbs, more luxuriant and perennially green in the depressions; in other parts they dry up in July and August, leaving the ground bare. The soil in the depressions is often well suited for agriculture, and good crops of grain and vegetables are raised; but the pampas are above all adapted for grazing, and they are famous for the immense herds of cattle and flocks of sheep which are pastured on them. The half-wild *gauchos*, or herdsmen of mixed race, who were formerly the only inhabitants, are gradually

giving place to European immigrants, who have introduced better methods of planting and herding. The clays composing the pampas are of late Tertiary and Quaternary age, and contain the bones of many species of extinct mammalia, including the *Megatherium*, *Scelidotherium*, and *Mylodon*. See PLAIN and ARGENTINE REPUBLIC.

AUTHORITIES.—Darwin's *Voyage of a Naturalist*; Napp, *The Argentine Republic* (1876); Ramon Lista, *Exploración de la Pampa* (1885). HERBERT H. SMITH.

Pampas del Sacramen'to: an extensive tract of more or less open land in Northern Peru, between the rivers Huallaga and Ucayali, similar in character to the Brazilian plateau. They were discovered by Simon Zara, a Jesuit missionary, in 1732, and until 1767 supported important missions, but are now nearly deserted. The area is at least 20,000 sq. miles. H. H. S.

Pampas Grass: the *Gynerium argenteum*, a reed-like grass from the temperate regions of South America, much cultivated for ornament. The recurved slender leaves are clustered thickly at the ground. From the middle of the tuft the flowering stems rise 6 to 12 feet high, and bear an ample silvery panicle. The staminate and pistillate flowers are borne by different plants; the flower-clusters of the female plant are distinguished by their larger size and greater spread; it is therefore the most ornamental.

Pam'philus: martyr; b. at Berytus in Phœnicia about 240 A. D.; embraced Christianity; became a friend and associate of Eusebius; founded a library at Cæsarea in Palestine, which he bequeathed to the Christian church there, and suffered martyrdom in 309. He wrote an apology for Origen, of which only the Latin translation by Rufinus of the first book has come down to us.

Pamphyl'ia (in Gr. Παμφυλία): an ancient district of Asia Minor, extending along the Mediterranean from Cilicia on the E. to Lycia on the W. With the exception of the plain of Perge-Aspendus, it is mountainous, being covered with ramifications of the Taurus Mountains, which formed its northern boundary. The inhabitants were a mixed race, composed of Greek colonists and aboriginal tribes, and their language and institutions exhibited a similar mixed character, half Greek and half barbarian. The country belonged to the Persian empire, and after its fall to the Macedonians. When Alexander died it fell to Syria, and became subsequently a Roman province. Its chief cities were Olbia, Attalia, Perge, Aspendus, Sylleum, and Cibyra. Its chief rivers were the Cestrus and the Eurymedon. See the monumental work of Niemann and Petersen, *Städte Pamphyliens und Pisidiens* (Vienna, 1890), vol. i., *Pamphylien*; Ramsay, *Historical Geography of Asia Minor* (London, 1890, p. 415 ff.). J. R. S. STERRETT.

Pamplo'na, or **Pampelu'na** (anc. *Pompeiopolis*): capital of the province of Navarre, Spain; situated on the Arga, a tributary of the Ebro (see map of Spain, ref. 12–H). It is fortified and defended with a strong citadel (modeled on that of Antwerp), and has a Gothic cathedral (1397), a natural history collection, a bull-ring (accommodating 8,000 spectators), a magnificent aqueduct on ninety-seven arches, manufactures of silk, leather, pottery, and a trade in wine. Originally a town of the Vascones, it was rebuilt by Pompey, from whom it derived its name. It was the capital of Navarre after 907. In the fourteenth century it was greatly strengthened by Charles III. It was taken by the French in 1808 and held until 1813, when it was freed by Wellington. In 1873–76 it was a point of attack by the Carlists, but never taken. Pop. (1887), 26,663.

Pamplona: a town of the department of Santander, Colombia; 84 miles N. E. of Socorro; in a mountain valley, 7,000 feet above the sea (see map of South America, ref. 2–C). It was founded by Pedro de Ursua in 1549, and soon after rich gold mines were discovered in the vicinity; these are now abandoned, and the town has lost much of its ancient importance. It is the seat of a bishopric and contains many old convents, etc. The climate is healthful, but the frequent thick mists make it disagreeable. Pop. about 9,000. H. H. S.

Pamun'key River: a stream formed in Virginia by the confluence of the North and South Anna rivers. It flows S. E. and at West Point joins the Mattapony to form the York river. Navigation by vessels of considerable draught once extended to Hanover Court-house, more than 60 miles, but the river is now shallow and full of sand-bars, and navigable only some 12 miles to White House.

Pan (in Gr. Πάν): a son of Hermes by a daughter of Dryops (or of Zeus by Callisto). He was a genuine Greek god, and was originally a light-god (*φάων*), though in poetry and art he was the patron of flocks and pasturage (*πάω* = *pasco*). The Greek conception of Pan is given beautifully in *Hom. Hymn.*, xix. (cf. *Theocritus*, i., 16 ff.). Pan had goat's legs, horns, beard, tail, ears, and face; he was so ugly that his mother was terrified when she first saw him. He was the inventor of the syrinx and of pastoral music; had a loud voice by which he frightened the wayfarer and even put armies to flight, wherefore such sudden flight is called *panic* (*πανικὸς φόβος*). He must not be confounded with the Satyrs, Sileni, or Roman Fauns. For Pan in art, see the article *Pan* in Baumeister's *Denkmäler*.

J. R. S. STERRETT.

Pana: city; Christian co., Ill. (for location, see map of Illinois, ref. 7–E); on the Balt. and Ohio S. West., the Cleve., Cin., Chi. and St. L., and the Ill. Cent. railways; 35 miles S. by W. of Decatur, 42 miles S. E. of Springfield. It is in a coal-mining region, and has considerable trade, a national bank with capital of $50,000, a private bank, and a daily and two weekly newspapers. Pop. (1880) 3,009; (1890) 5,077; (1900) 5,530.

Panætius (in Gr. Παναίτιος): Stoic philosopher of the second century B. C.; friend of Lælius and Scipio Africanus; author of a lost work *On Duty* (*περὶ τοῦ καθήκοντος*), which forms the basis of Cicero's *De officiis*. See H. N. Fowler, *Panætii fragmenta* (1885). B. L. G.

Panama': a department of Colombia, including the Isthmus of Panama to the confines of Costa Rica; area, 32,380 sq. miles. About half the territory, principally in the middle and western parts, is settled; the remainder is peopled only by a few roving Indians. The grazing industry has attained some importance in the western districts; agriculture is everywhere backward, and the manufactures are insignificant. Gold is mined in small quantities, and coal and other minerals are reported. The forests are rich in cabinet woods. The pearl-fisheries of the Pacific coast have existed since the conquest, and are still important. Panama was the first region in continental America settled by Europeans (see DARIEN), and since 1535 it has had a special importance owing to the trade across the isthmus. In 1698–1700 an unsuccessful attempt was made to plant a Scotch colony on San Blas Bay. The isthmus was incorporated with the viceroyalty of New Granada in 1718. It was independent from 1857 to 1860. Pop. (1885) 315,000. See PANAMA, ISTHMUS OF. H. H. S.

Panama: capital and largest city of the department of the same name; on the southern or Pacific side of the isthmus, at the head of the Bay of Panama; terminus of the Panama Railway, which connects it with Aspinwall (see map of Central America, ref. 9–N). It is the oldest city of European origin in continental America, having been founded by Pedro Arias Davila in 1519. The old city, 6 miles S. E. of the present one, was burned by the buccaneer Henry Morgan in 1670, and is now marked only by ruins. Panama was long the most important port on the Pacific side of Spanish America; the trade of Peru, Chili, Central America, and a portion of that of the East Indies, entered here; and there was a regular commerce with Spain through the Caribbean ports of Nombre de Dios and Portobello. With the development of the route around Cape Horn, and the transference of much of the Peruvian trade to the land route through New Granada, Panama declined in importance. The completion of the isthmian railway in 1855 gave it a new impetus; but it has suffered greatly from revolutions and from destructive fires. The modern city is built on a rocky peninsula. There is no proper harbor for large vessels; the anchorage, 11 miles from the city, is partly protected by reefs and islands, but during the prevalence of north winds it is inconvenient and sometimes dangerous. Owing to the force of the tides, which rise from 12 to 22 feet, landings can be effected with safety only at certain hours; small steamers and lighters are used to transfer passengers and freight. The port is free, and besides the commerce in transit there is a considerable trade with Central America and the Pacific ports of Colombia. Among the interesting old buildings are the cathedral (one of the largest in America), convents, the palace of the Audiencia, and the ancient walls and fortifications, which were of great strength. The climate is warm and damp, but more healthful than that of other parts of the isthmus. Pop. (1892) about 25,000. HERBERT H. SMITH.

Panama, Isthmus of: a neck of land connecting North America with South America, and separating the Caribbean Sea from the Pacific Ocean. Broadly speaking, the isthmal portion of the continent includes all of Central America and Southern Mexico; but the name is generally restricted to the narrow portion extending from the Bay of Chiriqui to the river Atrato, lying entirely in Colombia and including the department of Panama, with a small portion of Cauca. It extends from W. to E., forming a double curve. The length is nearly 470 miles, and the average width is nearly 70 miles. The bays of Panama and San Miguel on the S., and of Chiriqui and Urabá on the N., form three minor constrictions which bear distinctive names. Beginning at the W., the Isthmus of Chiriqui, opposite the bay of that name, has a minimum width of about 45 miles. Beyond this the neck is broadened to 118 miles by the Azuero Peninsula on the S. The Bay of Panama reduces it to 31 miles opposite the Bay of San Blas, or about 35 miles between Panama and Aspinwall; this is known as the Isthmus of Panama proper, or of San Blas. The Isthmus of Darien (a name sometimes applied to the whole neck) is properly the portion between the Gulfs of Urabá and San Miguel, 35 miles in minimum width. An irregular mountain chain, the Cordillera de Baudó, runs the whole length of the isthmus, generally near the northern coast; westward it has volcanic peaks said to be over 7,000 feet high; but eastward it subsides to a range of hills, with passes less than 400 feet above sea-level. Humboldt's theory that this range formed a continuation of the Andes has not been confirmed by later explorations. It is separated from the Andes by the valley of the river Atrato, which forms the true limit of the South American continent; the head of the Atrato is separated from the Pacific only by low hills, and the region between the river and the ocean may be regarded as a part of the isthmus. The coasts of the isthmus are generally low, swampy, hot, and often very insalubrious; there are numerous fringing islets and larger outlying islands, especially on the Pacific side. Many small rivers descend to both coasts. On the southern slopes of the Cordillera there are considerable tracts of natural grassland; all the rest of the surface, where uncleared, is covered with matted forest. Rains are very abundant during nine months of the year, with frequent violent thunder-storms. The dry months are February, March, and April; from August to October the heat is very great, except in the mountains. Balboa, who first established the existence of the isthmus in 1513, crossed it in the part known as the Isthmus of Darien. The difficulties of this route, and of that opposite the Bay of Chiriqui, early led to their abandonment in favor of the easier road from Panama, by the valley of the river Chagres. This has continued to be the ordinary route across the isthmus, and it attained a new importance during the early rush for the California gold-fields. Here the Panama Railway (opened in 1855) crosses by a pass only 263 feet above tide-water; and it was the route chosen for the Panama ship-canal. See SHIP-CANALS. HERBERT H. SMITH.

Panama Ship-canal: See SHIP-CANALS.

Pan-American Congress: a conference of representatives of the U. S. and the republics of Mexico, Central and South America, Haiti, San Domingo, and the empire of Brazil, held at Washington for the purpose of discussing and recommending measures to regulate and improve the international relations, business intercourse, and means of direct communication between these countries. It was summoned in accordance with the provisions of an act of the U. S. Congress of May 24, 1888, and met at Washington Oct. 2, 1889, but in consequence of the invitation of the U. S. Government to the delegates of the congress to visit different parts of the U. S. before entering upon their labors, it adjourned to Nov. 18, 1889, when it began its regular sittings. The idea of such a congress was not new. Henry Clay's scheme for a Panama congress comprised several features of the later plan, but was never carried out. To James G. Blaine more than to any one else was due the assembling of such a body. Among the subjects discussed by the congress, without definite results, were the establishment of an international bank, the protection of copyrights and patent rights, the granting of subsidies to steamship companies, and the adoption of an extradition treaty. Among the measures which the congress voted to recommend to the various governments for adoption were a uniform system of weights and measures, a uniform commercial coinage, and a common method of legalizing documents. Another important recommendation was that reciprocity treaties be adopted between the states. It adjourned Apr. 19, 1890.

Pan-American Exposition: See EXPOSITION.

Panard, păă'naar', CHARLES FRANÇOIS: song-writer; b. at Courville, near Chartres, France, Nov. 4, 1694; went early to Paris, where he became a Government clerk. Possessed of a great facility in rhyming, he composed more than eight hundred songs and vaudevilles. These were mainly improvised, written only on odd scraps of paper if written at all, and sung at a tavern for the delight of his companions. They are gay, light, and seldom coarse pictures of the manners of the time in a vein of good-humored satire, and are masterpieces of their kind. Only part of them were collected in *Théâtre et Œuvres diverses* (4 vols., Paris, 1764) and *Œuvres choisies de Panard*, published by A. Gonffé (3 vols., Paris, 1803). D. June 13, 1765. A. G. CANFIELD.

Panas, PHOTINOS, M. D.: ophthalmologist; b. in Cephalonia, one of the Ionian islands, Jan. 30, 1832; graduated M. D. at the School of Medicine in Paris in 1860; settled in Paris and was naturalized as a citizen; in 1863 was made an associate professor and surgeon to the Central Bureau; was appointed ophthalmic surgeon to the Bicêtre Hospital in 1864, to the Lourcine and the Midi hospitals in 1865, to the St. Antoine and St. Louis hospitals in 1868, to the Lariboisière Hospital in 1872, and to the Hôtel Dieu in 1879; in 1879 he was appointed professor of ophthalmology. He has published many papers on subjects connected with his specialty in medical journals, and he is the author of a number of works, among the most important of which are: *Leçons sur le strabisme, les paralysies oculaires*, etc. (Paris, (1873); *Leçons sur les kératites*, etc. (1876); *Leçons sur les affections de l'appareil lacrymal*, etc. (1877): *Leçons sur les rétinites* (1878). S. T. ARMSTRONG.

Panchatantra [Sanskr., having five books or sections]: an ancient Sanskrit collection of fables and tales, of ethico-didactic purpose. The form of the teaching bears much resemblance to that of the Buddhists, as exemplified in the Jātaka. The substance of the work is neither specifically Brahmanic nor Buddhistic, but rather, in general, Indic. The date of the extant form of the work is uncertain. The *Panchatantra*, or perhaps rather the earlier but now lost original thereof, has had a most remarkable history, and been transmitted through translations and translations of translations, sometimes under the name of the *Fables of Pilpay*, to almost all the peoples of Europe. The first known translation was the one into Pahlavī, about 550 A. D. Among the most notable are the Syriac version, Kalilag and Damnag (570 A. D.), text and translation by Bickell (Leipzig, 1876); the Arabic, edited by Silvestre de Sacy (Paris, 1816); Duke Eberhard's *Buch der Beispiele*, of marvelous popularity between 1483 and 1592; and Doni's *La moral filosophia* (Venice, 1552); of special interest as the immediate source of the first English version, that by Sir Thomas North (London, 1570). The last has been reprinted by Joseph Jacobs (London, 1888), under the title *The Fables of Bidpai*, with an introduction. Text edition by Kielhorn and Bühler (Bombay, 1885, 1891). Translations into German by Benfey, with famous introduction (Leipzig, 1859), and by Fritze (Leipzig, 1884); into French by Lancereau (Paris, 1871). For an account of the history of the work, see Lanman, *Sanskrit Reader*, pp. 311–316, or Jacobs's introduction. C. R. LANMAN.

Pancoast, JOSEPH, M. D.: surgeon; b. in Burlington co., N. J., Nov. 23, 1805; took his medical degree at the University of Pennsylvania in 1828; became, in 1831, an instructor in anatomy and surgery; surgeon to the Philadelphia Hospital 1838–45; Professor of Surgery 1838, and of Anatomy 1861–74, in the Jefferson Medical College, Philadelphia. He invented a number of new surgical operations; published *Operative Surgery*, *Essays and Lectures*, and other works; edited various reprints and translations of European works, and was author of many professional papers; and member of various learned societies. D. in Philadelphia, Mar. 7, 1882. Revised by S. T. ARMSTRONG.

Pancreas, or **Sweetbread** [*pancreas* is from Gr. *πάγκρεας*, sweetbread; *πᾶς*, *πάν*, all + *κρέας*, flesh]: a gland which in the human being is found behind the stomach, extending across the abdominal cavity. It weighs from 2 to 6 oz., though it seldom exceeds 5. A small posterior part (lesser pancreas) is sometimes detached. The right extremity is called the head, the left the tail, and the rest the body. In the octopus, a mollusc, the pancreas is a long,

convoluted, single cæcum. In other mollusks it is either absent or rudimentary. Some insects have analogous organs. (*Siebold.*) The pancreas of the cod is a cluster of cæcal follicles; in the higher cartilaginous fishes a number of such clusters are bound together into a glandular mass, with several distinct excretory ducts. In the higher vertebrates there is sometimes but one duct (the canal of Wirsung), but there are very often two even in man. In the human subject the larger canal usually unites with the common choledic duct. The minute structure and general aspect of the pancreas resemble those of the salivary glands. The secretion of the gland (called the pancreatic juice) is normally alkaline, viscid, and coagulable by heat. It is secreted in abundance only during digestion. Its specific gravity, according to Bernard (who derived his specimens generally from the dog by artificial fistulæ), is 1·040. It contains the principle PANCREATIN (*q. v.*), with other organic matters, and from 6 to 10 parts in 1,000 of ash. It is probable that it does not normally acidify the fats of the food, although it does so in the test-tube.

Revised by W. PEPPER.

Pancreatin: an extract derived from the pancreas. It should contain the four pancreatic ferments: trypsin, which digests proteids; steapsin, which splits up and emulsifies fat; amylopsin, which converts starch into sugar; and a milk-curdling ferment. It is by far the most important and most useful of the digestive ferments, either when administered by the physician or when acting in the secretion of the pancreas of the individual, and is used for the purpose of peptonizing foods. See PEPTONIZED FOOD. H. A. H.

Panda: See AILURUS.

Pandects: See ROMAN LAW.

Pando'ra [= Lat.= Gr. Πανδώρα, liter., all-gifted; πᾶς, all + δῶρον, gift]: in the old Greek legend, the first woman on earth, sent by Zeus to mankind in vengeance for Prometheus's theft of the heavenly fire. Aphrodite gave her beauty, Hermes cunning, and each of the gods bestowed on her some fatal gift for the punishment of mankind (Hesiod, *Works and Days*, 42–104). Again, it is said that the gods gave her a box full of blessings for mankind, but, prompted by curiosity, she opened the box, and all the blessings flew away except hope. Revised by J. R. S. STERRETT.

Paneas: See CÆSAREA PHILIPPI.

Pangenesis [Mod. Lat.; Gr. πᾶς, πάν, all + γένεσις, production]: a theory of reproduction propounded by Darwin in his *Animals and Plants under Domestication*, and best given in his own words: "It is universally admitted that the cells or units of the body increase by self-division or proliferation, retaining the same nature, and that they ultimately become converted into the various tissues and substances of the body. But besides this means of increase I assume that the units throw off minute granules which are dispersed throughout the whole system; that these, when supplied with proper nutriment, multiply by self-division, and are ultimately developed into units like those from which they were originally derived. These granules may be called gemmules. They are collected from all parts of the system to constitute the sexual elements, and their development in the next generation forms a new being; but they are likewise capable of transmission in a dormant state to future generations, and may then be developed. Their development depends on their union with other partially developed or nascent cells which precede them in the regular course of growth. . . . Gemmules are supposed to be thrown off by every unit, not only during the adult state, but during each stage of development of every organism; but not necessarily during the continued existence of the same unit. Lastly I assume that the gemmules in their dormant state have a mutual affinity for each other, leading to their aggregation into buds or into the sexual elements. Hence it is not the reproductive organs or buds which generate new organisms, but the units of which each individual is composed." F. A. LUCAS.

Pan'golin [from Malay *pangūlang*]: a common name synonymous with Manis, for any member of the MANIDIDÆ (*q. v.*).

Panicale, pä̆a-nē̆e-kaa'lā, MASOLINO, da: painter; b. at Valdesa, Italy, in 1378. He was a pupil of Lorenzo Ghiberti, and in early youth was an excellent goldsmith and engraver. At nineteen he gave himself up to painting and studied under Starnina for a while, then went to Rome, where he painted a room for the Orsini family. On his return to Florence he painted at the Carmine a figure of St. Peter beside the Chapel of the Crucifix. This work was so much praised that the Brancacci chapel was intrusted to him to adorn with subjects from the life of St. Peter. He is reported to have died in Hungary in 1415.

Panic, Commercial: See COMMERCIAL CRISES.

Pāṇini: the greatest of Sanskrit grammarians. His date is uncertain, but is probably to be set several centuries before Christ. He is believed to have been born in the extreme N. W. of India, at Çalātura, near Attock on the Indus. He had doubtless many predecessors, but his own work attained an authority which made it powerful in shaping the language of the later Sanskrit literature. It is composed in a style of enigmatical brevity, and its point of view is wholly different from ours. The principal Occidental work upon Pāṇini is by Böhtlingk (2 vols., Leipzig, 1886–87), with text, translation, explanations, indices, etc.

C. R. LANMAN.

Paniz'zi, Sir ANTONIO, K. C. B.: librarian; b. at Brescello, in the duchy of Modena, Sept. 16, 1797; took his university degree at Parma in 1818; was implicated in the revolutionary plot of 1821 and obliged to flee; after spending some years on the Continent and in England was offered the professorship of Italian in University College, London; in 1831 became an assistant in the British Museum; in 1837 was appointed keeper of printed books, and in 1856 succeeded Sir Henry Ellis as principal librarian. He reorganized the library, planned the catalogue, and designed the new library building. His most important literary works are critical editions of *Orlando Innamorato* and *Orlando Furioso* (London, 1830–34) and *Sonetti e Canzoni* (London, 1835). D. in London, Apr. 8, 1879.

Panjab: See PUNJAUB.

Panmixia: See EVOLUTION.

Panno'nia: province of the Roman empire; lying between the Danube and the Alps; bounded N. and E. by the Danube, which separated it from Germania and Dacia, S. by the Save, which separated it from Illyria, and W. by the mountains of Noricum. It was conquered and made a Roman province in the reign of Augustus, and 100 years later was divided into Upper and Lower Pannonia. Frequent rebellions compelled the Romans to build a large number of fortresses in the country, of which Vindobona, the present Vienna, was the most remarkable, and to keep large garrisons in the cities. During the decline of the Roman empire, Pannonia fell into the hands of the Huns, and from them it passed successively to the Ostrogoths, Longobards, and Slavs, till, in the ninth century, the Magyars settled on it and kept it.

Pannus: See GRANULAR LIDS.

Panopolis (Egypt. *Khemmis*; now *Ekhmîm*, or *Akhmîm*): one of the most ancient cities of Egypt; on the east side of the Nile (26° 36′ N. lat.). It contained one of the principal sanctuaries for the priapian worship of Min (whom the Greeks identified with Pan). The local ruins are disappointing and are falling into rapid decay. A necropolis, discovered by Maspero in 1884, furnished many mummies and other antiquities, some of them going back to the sixth dynasty. It is now a thriving town containing 10,000 inhabitants. CHARLES R. GILLETT.

Panormita'nus: the common surname of the great canonist Nicholas de Tudeschis; b. at Catania, in Sicily, in 1386; entered the Benedictine order in 1400; studied canon law at Bologna, and afterward taught it with eminent success at Siena, Parma, and Bologna. In 1425 he was made auditor of the Rota and *referendarius apostolicus* by Martin V., who also gave him the abbey of Maviaeum, in the diocese of Messina. In 1427, however, he entered the service of King Alfonso of Sicily, whom he represented at the Council of Basel. In 1440 he was made a cardinal by Felix V. D. at Palermo in 1445. His commentaries on the decretals of Gregory X. and on the Clementines, as well as his *Quæstiones, Consilia*, and other treatises on canon law, were considered authoritative by his contemporaries and nearest successors, and were quoted as such even by Melanchthon. They appeared in a collected edition at Venice (9 vols., 1617). See Schulte's *Geschichte der Quellen des canonischen Rechts* (2 vols., 1877).

Panormus: See PALERMO.

Panorpa'ta (*Panorpa*, a generic name): an order of insects frequently called Mecaptera (see ENTOMOLOGY), in

which there is a complete metamorphosis, jaws fitted for biting placed at the end of a beak-like prolongation of the head, and two similar membranous wings with few cross veins. These forms were formerly included in the Neuroptera, but their larvæ are more like those of the Lepidoptera, being caterpillar-like, the abdomen being furnished with eight pairs of fleshy legs. The scorpion-flies (*Panorpa*) are the most abundant members of the order. They derive the common name from the fact that the end of the abdomen of the male bears some resemblance to that of the scorpion, but in reality it is furnished not with a sting, but with a pair of clasping organs. *Boreus* contains the snowflies, brown or blackish forms found on the snow in the entire winter. All of the *Panorpata*, so far as known, are carnivorous. J. S. KINGSLEY.

Pan-Presbyterian Council: See PRESBYTERIAN CHURCH and ALLIANCE OF THE REFORMED CHURCHES.

Pansy: See VIOLET.

Pantellaria, păn-tel-laă-ree'ăă: a small island between Africa and Sicily, in the Strait of Sicily; included in the Italian province of Trapani. Area, 58 sq. miles. The soil is volcanic and well suited to the vine, the caper-plant, and to cotton, all of which are cultivated. The mineral springs have some reputation. The principal town, of the same name, is on the northwest coast. The island, anciently called *Cosyra*, was used by Roman emperors as a place of banishment for offenders. Pop. 8,000.
Revised by C. C. ADAMS.

Pan'theism: a word first used by Toland at the beginning of the eighteenth century to designate absolute monism; the identification of the totality of being with God. See the article GOD.

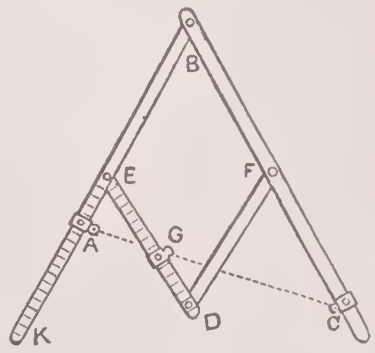
Pan'theon, or **Panthe'on, The** [= Lat. = Gr. *πάνθειον* (sc. *ἱερόν*, temple), temple dedicated to all the gods, liter., neut. of *πάνθειος*, of or belonging to all the gods, *πᾶς*, all + *θεός*, god]: the most perfectly preserved and one of the most admired structures of ancient Rome; situated in the Campus Martius (Piazza della Rotonda), and now used as a Christian church, St. Maria Rotonda. The building proper consists of a cylinder 142½ feet in interior diameter, surmounted by a hemispherical dome of same height above the floor. The walls of the structure are of concrete faced with brick, and are about 20 feet thick. In these there are alternating semicircular and square niches, seven in number, in addition to the opening for the door. The recess opposite the door contained originally a statue of Cæsar, flanked on either hand by statues of Mars and Venus. The remaining niches contained statues of gods, but their names have not been preserved. The building is lighted by a single opening in the center of the dome nearly 30 feet in diameter. Before the entrance opening there is a pronaos or portico 52 feet deep and 114 feet in width, which is faced by eight columns bearing an architrave with the inscription, *M. Agrippa L. f. cos. tertium fecit* (constructed by Marcus Agrippa, son of Lucius, in his third consulship, i. e. 27 B. C.). Another inscription in the building attests that it was restored by Severus and Caracalla in 202 A. D. It was transformed into a Christian church in 607 A. D.

There is no building at Rome which presents so many perplexing and baffling problems of an historical as well as an architectural character, and it has appropriately been called the Sphinx of the Campus Martius. Even the purpose for which it was originally intended has been a matter of dispute, many archæologists contending that it was originally designed for a warm bath (*calidarium*) in connection with the adjacent baths of Agrippa, and that its use as a temple was an afterthonght, occasioning the addition of the pronaos. This was argued partly from the form of the main structure and partly from the fact that the pronaos does not either in design or execution fit the edifice behind it. Later discoveries, however, have thrown much light on these problems. That the whole edifice dated from the Augustan period, in accordance with the evidence of the inscription on the architrave, was almost universally believed up to the winter of 1891–92, when some necessary repairs of the dome gave an opportunity for more thorough investigation than had been possible since the restoration of 1747. At this time a French architect, Chedanne, found that all of the bricks, made visible by the repairs in progress, bore the stamp of brick-makers from the time of Hadrian. Other portions of the building were then examined, and it was established beyond question that the whole structure, with perhaps the exception of the pronaos, dates from the reign of Hadrian and probably from the years 120–124 A. D. Further investigation in the floor revealed two pavements below the present surface, the lower one doubtless being the floor of the original Pantheon of Agrippa, the intermediate one belonging probably to the restoration of Domitian. Excavations beneath the floor of the portico revealed at a level corresponding to the lower floor within the edifice foundations for a larger portico, with places for ten instead of eight columns. These facts would seem to indicate that the present portico belonged originally to a building of different character (perhaps rectangular, as Lanciani suggests), and, having escaped the destruction which befell the original Pantheon of Agrippa, was removed from its site and with some alterations, placed back upon the present level by Hadrian.

LITERATURE.—R. Lanciani, *New Facts concerning the Pantheon* (in *Atlantic Monthly*, June, 1893); E. Guillaume, *Le Panthéon d'Agrippa* (in *Revue des Deux Mondes*, Aug., 1892); A. Michaelis, *Das Pantheon* (*Preussische Jahrbücher*, 1893), pp. 208–224; and especially Ch. Hülsen's review of the investigations in vol. viii. (1893), fasc. 4, pp. 305–318, of the *Mittheilungen des k. deutschen Archäologischen Instituts*. G. L. HENDRICKSON.

Panther [from O. Fr. *panthére* < Lat. *panthe'ra*, from Gr. *πάνθηρ*]: a name originally applied to the Old World leopard (*Felis pardus*; L.), but in the U. S. used for the puma (*Felis concolor*).

Pantograph [Gr. *πᾶς*, *παντός*, all, every + *γράφειν*, write]: an instrument used in copying maps and other drawings, either on the same or on some other scale.



The principle of the pantograph may be illustrated by the engraving, which shows the essential parts of the instrument in common use. It consists essentially of four brass bars with hinge-joints at B F D and E, forming a rhombus B F D E in every position. The sides B F and B E are extended so that F C and E K shall each be equal to one side of the rhombus. The parts E K and E D are graduated and numbered so that a line A G through two corresponding divisions shall always pass through C. This requires the graduation to be such that E A : E G :: B A : B C. The whole apparatus is supported by delicately formed castors. Three boxes, each fitted to hold either a pencil or a metallic tracing-point, are fitted to the beams, the one at C being fixed, and those at A and G capable of sliding along the beams, so that they may be set at corresponding points of the bars E K and E D. From the description already given, it is obvious that the three points A G and C will always remain in the same straight line, and that we shall always have A G : A C : G C :: A E : A B : E B; hence if either of these points is taken as a center of motion, the other two will trace out similar figures, whose homologous lines bear to each other a fixed ratio.

To use the instrument, the boxes A and G are clamped to the bars, so that A G and G C shall have the proper ratio, both being at corresponding points of the graduated scales. A metallic tracing-point is then clamped in the box C, which is taken as the center of motion; a second tracing-point is clamped in the box corresponding to the drawing to be copied; and a pencil is clamped in the remaining box; the tracing-points and the pencil are all arranged so as to press with proper firmness against the plane of the paper. When thus adjusted, the movable tracing-point is carried along the lines to be copied, and the pencil traces out a similar figure. If the movable tracing-point is at G, the copy is larger than the original; if at A, the copy is smaller than the original. If G is taken as the center of motion, the movable tracing-point and the pencil being at A and C, the copy will be reversed. In this manner the engraver is enabled to transfer the outlines of a drawing to the surface of the block or plate to be engraved, and either enlarge or diminish it in any given ratio. If the box A is at K and the box G at D, the copy will be of the same size as the original, but reversed. By copying the reversed drawing with the same relation of parts, a result will be obtained equal in all respects to the original.

The pantograph just explained was invented in 1603 by Christopher Scheiner, and was described by him in a pamphlet published in 1623. A more perfect instrument for accomplishing the same object was invented by Prof. Wallace, of Edinburgh; but as enlargements and reductions can now be made with more exactness and ease by photography. there is not so much use for the pantograph as formerly.

Pan'tomime [viâ Fr. and Lat. from Gr. *παντόμιμος*, pantomimic actor, liter., all-imitating; *πᾶς*, *παντός*, all + *μιμεῖσθαι*, imitate, mimic]: the art of representing thought, sentiment, will, and action by mimicry only, by attitude, gesture, and movement. It is a Roman invention (though the name is Greek), and originated in the time of Augustus. The Romans, who had more practical acuteness than imagination, had also more sense for virtuosity than for art. They seized on each single element of the representation and enjoyed it separately, the declamation through an elocutionist, the mimical expression through a pantomimist, the dance as a ballet, and the music as a concert. Of the old Roman *atellanæ*, a sort of improvised comedy performed at the festivals of the nobles by their own sons and for the sake of amusement only, the mimical imitation of what was awkward and ridiculous and the display of bodily adroitness and skill formed the principal part. In the last years of the republic these *atellanæ* received an artistic form through the *mimes* of Decimus Laberius and Publius Syrus. The *mime* was an imitation of everyday life, in the same manner as the modern comedy; but although the speech was written down and often elaborated with the greatest care, the acting or the mimical representation was still considered a most essential element. In general, mimical expression and imitation were highly appreciated by the Romans. Cicero and Roscius vied with each other as to who could express a certain state of mind best, the one with his eloquence, the other with his mimicry; and under Augustus the pantomime became the reigning fashion. Pylades and Hylas were celebrated pantomimists in the tragical line, Bathyllus in the comical; and of the rivalry between the first two, who danced *Agamemnon* and *Œdipus*, Macrobius tells some very amusing stories. Not only in public life, however, in the theater, but also in private life, at the dinner-party, the pantomime played a very conspicuous part during the time of the first Roman emperors. The social position of the pantomimist was nevertheless very low. Hylas was flogged publicly, at the prætor's request, on account of some blunder he had made on the stage. Augustus forbade such interference of the prætor with the actors, but under Tiberius it became a law that a senator who visited the dwelling of a pantomimist or was seen in his company in the streets should lose his senatorship. The reason for thus throwing contempt on a class of artists who happened to be very fashionable was not the old Roman prejudice against actors and acting, but the character of the art itself. The obscenity and indecency which these pantomimes displayed exceeded all description; that the female pantomimist often danced entirely naked on the stage was not the worst feature. At the fall of the Roman empire this, like all the other arts, decayed and lost its former prestige. It did not perish, however; and we have reason to believe that during the whole mediæval period pantomimists continued to exist, though mingled with the motley crowd of singers, jesters, acrobats, and other popular entertainers so vehemently denounced by the Church writers. Later they were now and then employed at the performance of the mysteries, and later still, by associating themselves with the *commedia dell' arte*, their representations assumed the form under which we now know them. They borrowed the masks Harlequin, Perrot, Columbine, and Pantalone from the *commedia dell' arte*, formed a loose plot, mostly of comical elements, and filled out the scheme in a manner half acrobatic, half ballet. In that form, however, they have continued to exercise a great charm over the mind. In all capitals of Europe, and at certain seasons in all the larger towns, there are found theaters which are exclusively devoted to the representation of pantomimes. See E. Munk, *De fabulis Atellanis* (Breslau, 1840); A. d'Ancona, *Origini del Teatro in Italia* (2d ed. 2 vols., 1893); E. du Méril, *Les Origines latines du Théâtre moderne* (1849); E. du Méril, *Histoire de la Comédie* (1864–69); Maurice Sand, *Masques et Bouffons*; Magnin, *Histoire des Marionnettes*.

Panwe: See Fans.

Panyas'sis, or **Pany'asis** (in Gr. *Πανύασσις*), of Halicarnassus: Greek poet of the fifth century B. C.; has been called the regenerator of the epos. A kinsman of Herodotus (*q. v.*), and, like him, involved in a struggle for freedom, he was put to death by Lygdamis, the tyrant of Halicarnassus, about the time that Herodotus withdrew from his native city. See Krausse, *De Panyasside* (1891). B. L. G.

Paola: city; capital of Miami co., Kan.; on Peoria creek, and the Kan. City, Ft. Scott and Mem., the Mo., Kan. and Tex., and the Mo. Pac. railways; 22 miles E. by S. of Ottawa, 34 miles S. S. E. of Lawrence (for location, see map of Kansas, ref. 6–K). It is in an agricultural, oil, coal, lime, and natural-gas region, and contains 3 national banks with combined capital of $200,000, 2 libraries (Normal School, founded 1879, and Free City, founded 1880) containing nearly 10,000 volumes, and 3 weekly newspapers. Pop. (1880) 2,312; (1890) 2,943; (1900) 3,144.

Paoli, Pasquale: revolutionist; b. near Morosaglia, Corsica, in 1726; was educated at Naples, where his father had taken refuge. after being exiled from the island in 1739 for participation in the revolt against Genoa; returned to Corsica in 1755; became the leader of the party which strove to expel the Genoese; defeated their army and even their fleet in several engagements, and deprived them of nearly all their strongholds in the island, at the same time introducing important reforms, improving the laws, and bringing the agriculture, commerce, and industry of the country to a flourishing state by his wise and energetic administration. His success was almost complete, and excited great sympathy in Europe; but in 1768 the Genoese sold their claims on Corsica to France, and in 1769 Paoli was driven from the island by a French army of 22,000 men. He fled to England, where he was held in general esteem, and received from the Government a large pension. After the outbreak of the Revolution in France he was appointed chief both of the civil and military administration in Corsica; but the anarchical state of the Government soon occasioned collisions. He again placed himself at the head of a revolution; but despairing of winning independence without foreign aid, he appealed to Great Britain, and proclaimed George III. King of Corsica, but he was not appointed viceroy, as he had expected, and he again went to England, where he died, near London, Feb. 5, 1807. See Boswell, *Account of Corsica* (Glasgow, 1768). and *Biographies* by Arrighi (Paris, 1843), Klose (Brunswick, 1853). and Bartoli (Ajaccio, 1867).

Papacy: See Papal States and Pope.

Papal States, or States of the Church [*papal* is from Lat. *pa'pa*, papa, bishop, (later) pope]: that portion of Central Italy which, before the unification of the kingdom, was under the temporal government of the holy see. They extended, though with a very irregular shape, from the Adriatic to the Mediterranean; bounded S. by Naples, and on the W. and N. by Tuscany, Modena, and the Austrian possessions, and comprised an area of about 16,000 sq. miles, with 3,124,668 inhabitants, had Rome for their capital, and yielded (in 1859) a revenue of 14,453,325 scudi. The pope possessed temporal authority over a part of this region from the time of Constantine the Great, who is said to have endowed the episcopal see of Rome with large landed possessions. The spiritual supremacy of the holy see gave to it an impressiveness and dignity that facilitated the extension of its temporal power. In the centuries after the fall of the Roman empire, when the barbarians pushed forward to Rome and the Byzantine emperors showed themselves unable to defend their possessions in Italy, the so-called exarchate, it was quite natural that the people of Rome should look on the pope not only as their head, but as their leader. The strongest of the barbarous tribes, the Franks, had become orthodox Christians, and their kings supported the popes against their enemies. Charles Martel was about to enter Italy and defend the Roman see against the Lombards when he died, but his son, Pepin le Bref, fulfilled his promise. He defeated Aistolf, the king of the Lombards, and compelled him to yield up to the pope, Stephen III., the exarchate of Ravenna, comprising, besides the so-called Pentapolis or the five cities of Rimini, Pesaro, Fano, Sinigaglia, and Ancona, seventeen other cities, mostly situated on the coast of the Adriatic, and thus the foundation of the papal states was laid. Pepin's son, Charlemagne, confirmed and enlarged the donation, but in the ninth and tenth centuries much of the papal territory was lost, and in the first

half of the eleventh century the temporal jurisdiction of the pope was not recognized beyond Rome and its immediate vicinity. In 1053 the pope obtained the city of Benevento, and in 1114 the Countess Matilda of Tuscany left all her fiefs, consisting of Parma, Modena, Mantua, and Tuscany, to the pope, who secured the possession of them, though only after a long strife with the German emperors. The chief difficulty attending the establishment of the temporal sovereignty of the pope lay in the vague and undefined relation in which he stood to the German emperor. Pope Leo III. had crowned Charlemagne emperor of the Romans, and the emperor had given Leo III. the exarchate of Ravenna, Rome, and other Italian possessions. The title of Roman emperor was inherited by the German successors of Charlemagne, and they evidently meant to transform the title into a real authority. Hence the severe struggles between Gregory VII. and Henry IV. and between Innocent III., Henry VI., and Otho IV., and it was not until 1278 that Pope Nicholas III. succeeded in compelling the German emperor, Rudolf I. of Hapsburg, to acknowledge him as a free sovereign, thereby establishing the papal states as an independent empire. The Great Schism and the removal of the popes to Avignon brought confusion and misgovernment to the papal domains in the fourteenth century. The strife between the Guelphs and the Ghibellines kept Rome in constant turmoil, and in 1347 the popular leader Rienzi became the chief magistrate of a short-lived republic. The pontificates of Alexander VI. (1492–1503) and of his successor, the warlike Julius II. (1503–13), were marked by the consolidation and extension of the papal territory. It underwent some changes during the wars of Napoleon, being at one time entirely incorporated with France, but in 1814 it was restored to the pope with nearly its former boundaries. The administration, however, of the papal government, especially during the reign of Gregory XVI., caused a great fermentation in the population. Revolutions broke out in 1831 at Bologna and other places, and Gregory XVI. depended entirely on Austrian troops for the maintenance of his sovereignty. Pius IX. made some attempts at reform, but failed. In 1848 the revolution broke out in Rome, and the pope fled in disguise to Gaëta. He was restored by French soldiers, who held the city of Rome from 1849 to 1870. In the meanwhile, after the Italian war of 1859, the legations voted for annexation to Sardinia, and the troops of Victor Emmanuel entered Umbria and the Marches and defeated the papal forces at Castelfidardo. Rome and the patrimony of St. Peter were all that was left to the pope. The French garrison evacuated the city Aug. 2, 1870, and on Sept. 20 King Victor Emmanuel took possession of Rome, declaring it the capital of Italy, and thereby abolishing the temporal power of the pope, who was nevertheless guaranteed the possession of the Vatican and Lateran palaces, and continued to enjoy the honors and immunities of a sovereign. See Rome. Revised by F. M. Colby.

Papaveraceæ: See Poppy Family.

Papaw' [from Span. *papaya* (whence Mod. Lat.), from the native West Indian name]: (1) the fruit of a small tropical American tree (*Carica papaya*) of the family *Passifloraceæ*. This fruit is eaten, but is not very palatable. It has an acrid quality, and when boiled with meats renders them tender. The juice, at least before the fruit is ripe, contains a remarkable albuminous substance resembling or identical with fibrin, is anthelmintic, and has detergent powers. The root has an offensive odor. (2) In the U. S. the name papaw, or pawpaw, is given to *Asimina triloba*, *parviflora*, *grandiflora*, and *pygmæa*, handsome shrubs, or the first a small tree, of the family *Anonaceæ*. The pulpy fruit of the first mentioned is edible, but is not generally esteemed. Revised by L. H. Bailey.

Papayotin: a substance derived from a plant called *Carica papaya*, the juice of which possesses proteolytic power, or, in other words, is capable of transforming proteids into peptones. It is supposed to differ from pepsin not only in its vegetable origin, but also because it acts in the presence of either an alkali or acid. Other derivatives of the juice of *Carica papaya* have been introduced into medicine by various firms, the chief of which are papain and papoid, which it is claimed possess certain advantages not present in other preparations. H. A. Hare.

Paper [from O. Fr. *papier* < Lat. *papy'rus* = Gr. *πάπυρος*, papyrus, paper made of papyrus]: a substance made in the form of sheets or leaves, in varying thicknesses, and employed for writing or printing upon; also for wrapping purposes, and in the manufacture of various articles of common use or of industrial and scientific application.

Base.—Vegetable fiber is the base and chief component of the article of commerce known as paper. This is used in various forms and with different intermixtures, animal as well as mineral fibers being at times incorporated into its substance, with loading or filling material and coloring-matter. In its pure state vegetable fiber is known as cellulose. It is white, translucent, slightly heavier than water, without taste or odor, and is insoluble in all simple solvents; its chemical formula is $C_6H_{10}O_5$. All vegetable growths contain cellulose, some being specially valuable, and holding high rank as paper-making material, while others are of inferior importance. Generally, paper-making material is a by-product, derived from the waste or refuse of other manufactures—as rags, old bagging, old rope, waste paper, etc.—supplemented by other good fibers obtained so plentifully and cheaply as to warrant their conversion into paper pulp.

Leading Fibers.—The fibers chiefly used in the manufacture of paper are those of cotton, bast (as linen, jute, and hemp), those derived from whole stems or leaves and associated with various vessels and cells not properly fibers (as straw, esparto, sorghum, and bamboo), and lastly those derived from wood.

History.—It seems strange that nations known to have been adept in arts and sciences centuries in advance of the Christian era should have failed to produce an article at once so important and of so great simplicity of manufacture as is paper. Even the Maoris of New Zealand roughly produced it prior to contact with European civilization by chewing and macerating the leaves of certain plants and spreading the pulp so obtained on a flat stone to dry in the sun. Paper derives its name from an aquatic plant, the papyrus (*Cyperus papyrus*), which grew in Egypt. The material obtained from this plant was the first product, so far as known to us (except the wasp's nest), resembling that which we call paper. (See Papyrus.) The manufacture originated with the Egyptians at least 2,000 years before the Christian era, and the use of papyrus extended into Greece and Italy. The Egyptian reed held undisputed command of the market for hundreds of years: in Europe till

Fig. 1.—Illustration of a paper-mill of the sixteenth century, from Jost Amman's *Panoplia omnium liberalium mechanicarum et sedentariarum Artium Genera continens*, etc. (Frankfort, 1564).

the twelfth-century attempts were made to supersede it, notably by the use of parchment, but success in this direction was not attained until the introduction of paper made from cotton fiber. The Chinese are credited with the discovery of the art of paper-making by the use of fibers reduced to a pulp in water. Their raw materials were the inner bark of the mulberry-tree, bamboo, rice-straw, rags, etc. A Chinese mandarin is said to have invented a process of making paper from the bark of trees combined with the fibers of silk and hemp. This was in the year 95 A. D.

Two hundred years later the Romans made strong brown paper from the bark of trees, and 300 years afterward the same material continued in use. About the year 610 the bark of the paper-mulberry was employed as a paper-making material in Korea. The Aztecs also made a paper, resembling papyrus, from the fibers of the maguey (*Agave americana*) plant; but it is not known that any data exist to establish the date of its earliest use or invention.

The Chinese communicated their discovery to the Hindus, Persians, and Arabs, and in the latter part of the sixth or early in the seventh century the Arabians established factories, one of which is reported to have been in existence at Mecca. Another paper-mill is said to have been in operation at about the same time at Samarcand, in Turkestan. At these localities paper was made from cotton, reputedly the raw fiber. The art was carried to Spain, where the Moors, besides linen, hemp, and cotton, used rags as paper-making material. From Spain the business extended to other European countries. The earliest Italian paper-mill is said to have been started in 1250; the first in Germany, 1290; in France, 1340; in Switzerland, 1350; in Austria, 1356; in Belgium, 1405; in England, 1498, or a few years earlier; in America (at Roxborough, now in Philadelphia) in 1690; and in Russia in 1712. Holland probably began paper-making in the fourteenth century, although a much later date has been given. The growth of the industry was much increased by the discovery of printing in 1450.

Hand-made Paper.—The Chinese method of manufacturing paper embodies the principle on which all paper is made. Improvements in processes and appliances have all been in the direction of the more ready manipulation of paper-making material and increase in the production of the finished article. The cost of manufacture in China, even without the facilities afforded the paper-makers of Europe and America, is less than in Occidental countries, cheaper labor and material operating to this end. Chinese paper-makers use a variety of fibers, including those from hemp, rags, linen and cotton, cane, the paper-mulberry, and the bamboo. With all of these the first operation is to make the stock tender, that is, to bring it into a condition in which it may be readily reduced to pulp. This is done by retting, without allowing it to go too far in decomposition. The stalks of bamboo, for example, are soaked in running water, or in water which is frequently changed, for 100 days or more, until the outer covering of the fiber is sufficiently softened. The material is then beaten with mallets until the fibers are separated from the bark or outer covering, after which they are cooked in a vat to which slaked lime has been added, a continuous operation taking about eight days. The fibers are next washed in clean water, and again boiled in water made alkaline with wood ashes, after which they are subjected to another bath of water and ashes until they begin to decompose; they are then taken out, rewashed, and reduced to the degree of fineness required in mortars operated when possible by water-power. The pulp thus prepared is mixed in a vat with water to the necessary degree of diluteness, after which the work of the person who makes the sheet of paper begins. This workman has a mould or sieve made with a bamboo frame to which a fine network of threads of silk or other material is attached; he dips his mould into the dilute pulp, and, taking it out with a motion which serves to interlace the fibers, turns the thin film thus formed upon a flat, wooden surface. The sheets are laid one upon the other until a pile is made; a plank is then placed upon the heap, and pressure is applied until the water has been sufficiently pressed out of the sheets, which are then removed to an oven to be dried. Hand-made paper is manufactured in Europe* on almost the same lines, after the pulp has been prepared by machinery. The mould is covered on one side with fine wire-cloth, and has a movable frame, called the deckle, both forming a shallow tray. The vatman takes a mould and lays it upon the deckle; he then dips the mould into the pulp, which is kept uniformly mixed with the water in the vat by means of an agitator, and lifts up as much of the pulp as will form a sheet of paper; to this he gives a shake from him and back again, and then from right to left and back again; this done, he transfers the mould to his assistant, who is known as the coucher, at the same time removing the deckle, which he connects to another mould and proceeds as before. The coucher turns the mould upside down on a piece of woolen felt, and places another piece of felt on the sheet of paper thus deposited. The felts and sheets of paper are alternated until a pile is formed, which is then submitted to great pressure. When this pressure is taken off the felts and sheets of paper are drawn out and laid in separate piles. The paper is afterward put into another press to remove the felt marks and to get rid of more moisture; it is next hung up, sheet by sheet, to dry, after which it is sized with gelatin. The paper is again pressed, dried, sorted, counted, packed, and in this finished condition goes to market.

Western Methods of Preparing the Pulp.—The process of making the sheet of paper by hand has been described, but not the preliminary processes for reducing the raw material to pulp, as practiced in Europe and America. During the eighteenth century and at the beginning of the nineteenth the rags used in paper-making were sold unsorted to the paper-maker. They were therefore carefully picked over when they reached the mill, and graded, chiefly according to color. This work is now done to a certain extent by the packers or rag-gatherers. The rags were then cut into small pieces, soaked in water, and piled in vaults to ferment or rot. After the necessary stage of tendering or decomposition had been reached they were washed, and the next process consisted in reducing them to pulp. In the early days of paper-making this was done in mortars, or cylinders provided with stamps moved by water-power. Wooden troughs in which stamps operated were also used. About 1750 a machine was invented which in time superseded these rude appliances in Europe and America. This was brought out in Holland, and is known as the Hollander or beating-engine. The preliminary treatment of the rags has also changed, the retting process being done away with. When the rags reach the mill they are unpacked from the bale and sorted by hand, women being employed for the purpose. The first handling is for the purpose of removing all extraneous substances, and it includes the threshing, dusting, sorting and cutting, opening seams, removing buttons, pieces of metal, India-rubber, and other foreign materials. They are then cut into small pieces by machinery, or, for special grades of paper, by hand, at long tables, to which scythe-blades are fixed at intervals. After a final dusting the rags are put into large, cylindrical boilers, called rotaries, which are set horizontally. These boilers are provided with manholes, and steam-pipes pass through their trunnions to their interiors. A rotary is packed with rags, and milk of lime and water are added, after which the manholes are closed. The boiler is then slowly rotated, steam being admitted under pressure. Other kinds of boiling apparatus are sometimes used, such as kiers, into which the rags are run on small cars or trucks, which are withdrawn when the operation is completed, thus dispensing with the emptying necessary where rotary boilers are employed. This cooking thoroughly softens the grease or any dirt remaining in the rags, and the latter are in a condition which renders them more readily susceptible to treatment in the washing and beating engines. After draining, the cooked rags are taken to the engine-room, and are there washed by a stream of water through the washing-engine until the water runs clear. The washing-engine consists of an oblong tub or trough made of wood or iron, rounded at the ends. It is made in various sizes, to accommodate from 100 to 1,500 lb. of rags. In the center of the tub there is a partition, the "midfeather," with a passageway at each end for the circulation of the water and rags through the engine. On one side of the "midfeather," occupying the space between it and the wall of the tub, is a cylinder or roll set with a series of steel knives, and beneath this roll is a bedplate, also furnished with steel knives and set in the floor of the trough, which at this point rises with an inclination to and surrounding the roll at a short distance therefrom, and then drops in an inclined plane known as the "backfall" to the level of the tub bottom. On the other side of the "midfeather" the floor of the tub is flat and level with the ends, and on this side is located the washing apparatus, which consists of one or two cylinders, whose framework is covered with wire-gauze. The roll and the washing-cylinders are mounted in such a manner as to be raised or lowered at both ends. When the washing is going on the washing-cylinder is partially submerged in the contents of the engine, the water which passes through its gauze covering being discharged through an opening in the journal which rotates it. During the process of washing the stock or material is also treated in such a way by the knives on the engine-roll that the fibers are separated and drawn out so as to be long and flexible.

In some mills the stock is bleached in an engine inter-

* There is only one paper-mill in the U. S. where hand-made papers are produced. There are many vat-mills in Europe.

mediate between the washing-engine and the beating-engine; in others the bleaching is done in the washing-engine. It is effected by adding to the "half-stuff" in the engine a solution of bleaching-powder (chloride of lime), which oxidizes the fibers, its action being accelerated by the addition of a little sulphuric acid. Having reached this point the engine is emptied by the withdrawal of a plug or valve, which lets the "half-stuff" down through a pipe into large vats known as "drainers," and provided with stone flooring, in which there are minute perforations. Here the material remains until it is sufficiently acted upon by the bleaching agent, after which it is conveyed to the beating-engine.

The next operation is that of beating, in which process the "half-stuff" is reduced to that stage of fineness requisite to convert it into paper. The beating-engine is of the same type and form as the washing-engine, but it is provided with sharper knives and the roll is set down closer to the bed-plate. The cylinder-washer is employed for a short time to wash out the bleaching solution, and to eliminate entirely the action of the chlorine a solution of hyposulphite of soda or "antichlor" is added as a neutralizing agent. When this operation is completed, the beating is continued until the fibers are reduced to the proper length. The fibers during this process are in such condition that the cutting action does not impair their strength. Next follows the sizing if engine-sized papers are to be made; also the

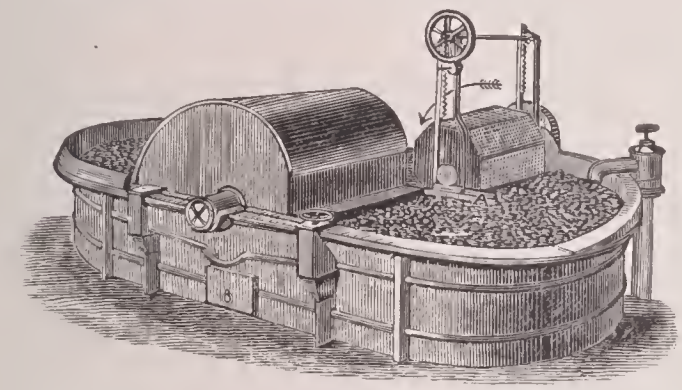

Fig. 2.—Beating-engine.

"loading." The material used for loading or filling purposes not only adds to the weight, but further serves the useful purpose of filling the pores and giving a finer surface to the paper when it is finished. The ordinary filling is china clay, but other substances in a state of fine subdivision are also employed. Among these are sulphate of lime and talc. Engine-sizing consists in adding to the pulp a resin soap made by boiling powdered resin with soda-ash, or crystals of soda, the alkali having been previously dissolved in water. If not thus sized the paper is treated with animal size as described below, or it may be both engine-sized and animal-sized. The coloring material is also applied in the beating-engine, or in making white papers the pulp is given an addition of ultramarine or other necessary color, mixed in water and strained. This "brings up" the tone of the paper and destroys the yellow tint which the paper would otherwise have.

At this stage the pulp is emptied from the beating-engine into the stuff-chests, which are large cylindrical vats, provided with agitators, in which more water is added to the pulp until it is well mixed and dilute enough to be transferred by means of a stuff-pump to a regulating-box, the function of which is to provide a regular supply of pulp to the machine; thence the pulp is carried to the screen, or strainer, an apparatus covered with smooth brass or bronze plates, having their faces cut into a number of long and narrow slits which widen on the under side to admit of the easier flow of the pulp. This strainer has a jogging motion, and while the pulp flows through the plates all knots and lumps are arrested. On leaving the strainer the pulp passes into a vat in which there is an agitator to keep it well mixed in suspension with the water.

There are numerous modifications of the beating-engine, designed with a view to economy of space, the more rapid and even treatment of the material, etc.

The greatest departure from the original form of the Hollander or beating-engine is in that class of machines known as refiners, of which the Jordan is the original type. This machine has no tub. It consists of a conical casing closed at both ends and having its interior surface provided with knives; inside of this casing there is fitted a plug or cone provided with knives on its exterior surface. The half-stuff is fed into this engine through a box located at its smaller end, and, power being applied to the shaft carrying the plug,

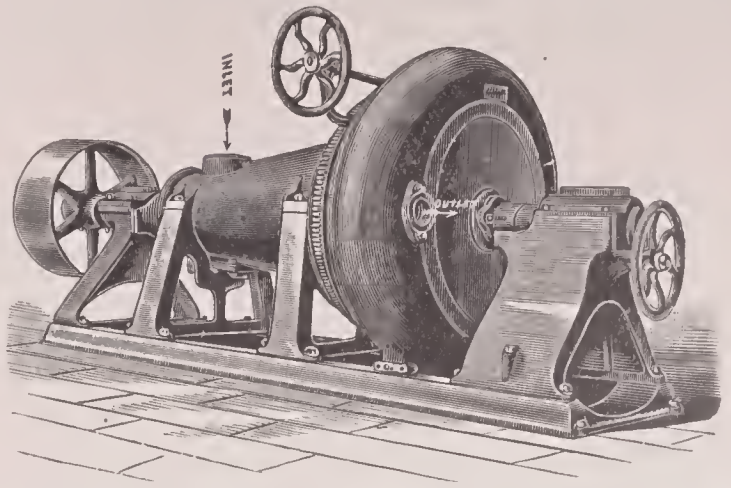

Fig. 3.—Refining-engine.

the material is drawn by the centrifugal operation of the machines from the small to the large end, where it is discharged through outlets, having undergone the action of the knives in its passage. The Marshall refining-engine is of the same character, except that at the large end of the casing there is a disk fitted with steel knives, which also operate upon the half-stuff and reduce it to the finished state necessary before running it to the machine stuff-chests. The refining-engine saves about one-third of the time usually consumed in beating the stock in the Hollander, from which it takes the material before it is thoroughly reduced; it "brushes out" the fiber, making it "mellow."

The Fourdrinier Machine.—We now come to the paper-making machine, of which there are several types. In 1799 Louis Robert invented a machine which successfully made paper in a continuous web. He put it in operation at the paper-mill of François Didot, in France, and secured a patent for it. In 1801 John Gamble, an Englishman, who accompanied Leger Didot from Paris with Robert's invention, obtained the first patent in England for that machine. Several improvements were patented both in England and France in the succeeding year, but it was not until 1803 that Bryan Donkin, who had been intrusted by Didot and Gamble with the construction of such a machine, succeeded in building one on the plan suggested by Robert, and in 1804 the second machine made by him was set up at Two Waters, England, and ran successfully. In this year Henry and Sealy Fourdrinier, stationers and paper-manufacturers in London, bought the English patents for the machine, and after making various improvements so perfected it that it has since been called the Fourdrinier machine. In 1805 this machine was capable of doing the work of six vats in one day, and the gain in time and labor, at that time so considerable, has been largely exceeded since. So many improvements have been added that the Fourdrinier machine of to-day is as a giant to its original model, not only as to size, but also as to its speed and capacity. The first Fourdrinier machine in the U. S. was set up in 1827.

The processes of paper-making have been described up to the point where the Fourdrinier machine is brought into action. From the vat into which the pulp discharges after it has passed the screens or strainers it flows down over an apron to the endless wire-cloth of the machine. This wire-cloth is generally from 32 to 40 feet long, its width being variable and based upon the greatest width of the sheet of paper which it is intended to make. The widest machine yet constructed is 136 inches in breadth of wire. The wire-cloth is made of fine brass wire woven specially for the purpose, the meshes varying from sixty threads upward to the inch. The ends of the cloth are sewn together with very fine wire. It is necessary that the wire-cloth shall preserve a uniformly even surface, and for this purpose it is supported on a series of brass rolls of small diameter, known as tube-rolls, placed near together, but not so closely as to be in contact. By this means uniformity in the layer of the pulp on the wire is gained, if the stuff in the vat is maintained of even consistency. These tube-rolls are supported in an iron frame to which a violent lateral motion is given by a device known as the "shake." This is done to cause the fibers as they enter upon the wire to interlace in various directions, and thus form a sheet which shall be nearly, if

not quite, as strong in one direction of its texture as another. The water drains from the pulp through the wire-cloth, and is received in a shallow box or trough called the "save-all," as it also catches fine particles of pulp which escape through the wire. The frame in addition to the tube-rolls carries a "breast-roll," a "guide-roll," on which there is a self-acting guide, and several other rolls. On top of the frame at the point where the pulp flows on the machine, and extending lengthwise of it for about two-thirds of the length of the wire, there is a "deckle-frame" supporting two endless rubber straps, each about $1\frac{1}{4}$ inches thick, and running over pulleys, one on each side of the machine. These "deckle-straps" rest upon the wire-cloth and prevent the pulp from spreading or flowing over its edges, and thus regulate the width of the paper. By the time the pulp has passed the deckles the sheet is formed, although yet in a very moist and weak condition. Next and near to the deckles is located the "dandy-roll," a cylindrical framework of brass covered with fine wire-cloth, which presses on the surface of the wet layer of pulp, and aids in expressing the moisture; it also performs the function of impressing what is known as the "water-mark" upon the paper. This impression is given by means of designs made from wire and soldered to the exterior wire covering of the roll, which thins the sheet at every point where it touches or indents it. If the paper is not intended to receive any special design, but is to be alike on both sides, no device is fixed to the exterior of the dandy-roll, and the impressions made by the latter upon the moist pulp are the same as those received from the machine wire on its under surface. In this case the paper produced is known as "wove." "Laid" paper is that which has parallel lines watermarked at equidistant intervals, the marking being done by a series of wires encircling the exterior of the dandy-roll. For the purpose of extracting a further amount of moisture from the pulp-layer before it leaves the wire, there are two or more suction-boxes having open or perforated tops. A suction-pump attached to these suction-boxes creates a partial vacuum in them, and the pressure of the air upon the pulp assists in withdrawing more of the water therefrom. At this stage the paper has acquired sufficient consistency to pass without breaking to the couch-rolls, two in number, the lower one carrying the wire-cloth and giving it motion. Both couch-rolls are "jacketed" with woolen felt. From the couch-rolls the web is conveyed on an endless woolen felt known as the "wet felt" between the two "first-press rolls." The paper is then carried to the "second-press," where it is transferred to another endless felt, which in turn conveys it further on its way to the "driers." Having come so far the paper is in pretty good condition, having gained in strength by reason of the loss of the greater part of its moisture. The "driers" are metal cylinders of large diameter heated by steam. These drying-cylinders vary in number on different machines, and are ranged one after the other, or in two tiers, one row above the other. A passageway between the second-press and the driers permits the machine-tender or his assistant to pass from one side of the machine to the other. The paper is carried from one drying-cylinder to another, and so on through the whole series, and is pressed against their heated surfaces by means of a felt, whereby it is made perfectly dry. Having passed the driers, the web is passed between a series of polished rolls, or "calenders," mounted one above the other in a frame, to form a "stack," their purpose being

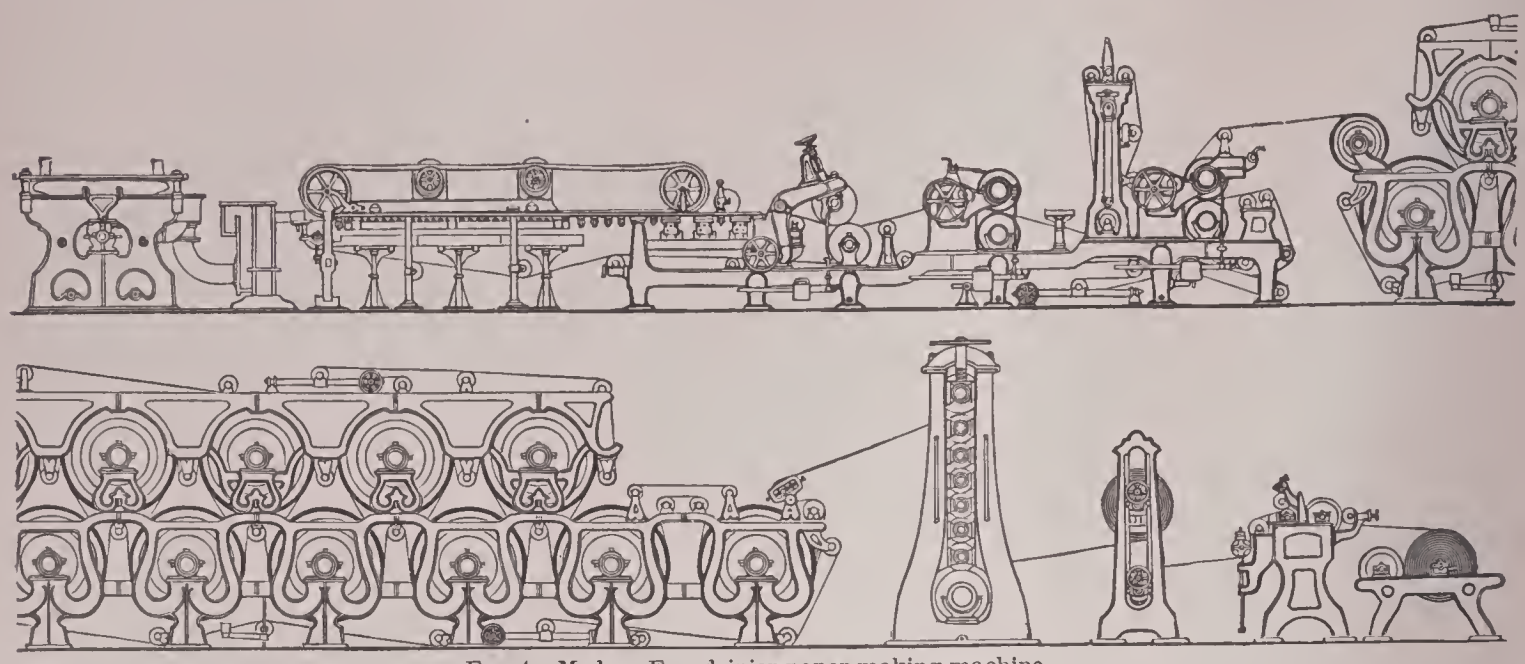

FIG. 4.—Modern Fourdrinier paper-making machine.

to give the paper a smooth surface. Leaving the calenders the web is wound on reels, and thence it goes to the cutter, where it is divided into sheets. Where the paper is intended for use on a web printing-press, it is always supplied in rolls. Should it be desired to give the paper a higher finish than it has so far received, it is taken to the finishing-room, where it is subjected to the action of super-calenders having rolls made from disks of paper or cotton-batting, mounted on steel shafts, and so solidly compressed by hydraulic pressure that they can be turned off truly cylindrical in a lathe. These rolls alternate with chilled-iron rolls in a frame. Another method of surfacing is to pass the sheets of paper between highly polished metal plates, through two heavy rolls which give a powerful pressure. So treated the paper is said to be "plated," and the apparatus is known as a "plating-machine." This mode of finishing or smoothing the otherwise rough surface of paper superseded that of pressing between two heated metal plates.

The paper-making machine is driven by power derived from a water-wheel or steam-engine carried through intermediate shafting and gearing, and generally directly connected. The latest form of communicating motion is through an improved driving-train of coned pulleys, subdivided to run the several parts of the machine at variable and graded speeds.

Sizing.—The method of sizing in the engine has been outlined. The sizing is done for the purpose of removing the porous and absorbent character of the paper, so that it can be written on. Further sizing is given on the machine, a weak solution of gelatin or animal size being placed in a shallow box through which the paper passes midway of the driers, going thence between two "squeeze-rolls," which remove the superfluous size; this is known as "tub-sizing" as well as "machine-sizing." Animal-sized paper is sometimes dried by passing it over a series of wire cylinders exposed to the action of currents of air. At other times it is dried, after being cut into sheets, by hanging it in a loft or drying-room, where an evenly warm temperature is maintained, and thus treated it is said to be "loft-dried." The best grades of writing-papers are thus manipulated.

The Cylinder Machine.—An English paper-maker named Dickinson is credited with the invention of the cylinder paper-making machine in 1809. This machine is of an entirely different type from the Fourdrinier in that part on which the web of paper is formed. It consists of a large and square vat, in which is mounted a framework of brass covered with coarse wire-cloth, over which an outer covering of fine wire is smoothly fitted. This is known as the making cylinder; it is of large diameter, and fits closely by means of interposed packing to the sides of the vat in which it rotates. The latter is kept supplied with pulp in the required state of dilution by an even flow, which maintains a uniform level of the fluid. As the cylinder rotates it takes up on its surface a thin film of pulp, which, as it encounters atmospheric pressure, is drained of some of its

water through the wire covering of the mould, the water passing out through the end of the cylinder and through the side of the vat. At the top of the vat, and connected therewith, is a framework carrying a couch-roll, which rests upon the face of the making cylinder, and rotates with the latter. An endless felt runs over the surface of the couch-roll, and passes to and between the first press-rolls, which are located in a stand next to the vat. As the thin film of pulp forms on the cylinder-mould it is brought up and in contact with the felt passing over the couch-roll, and, being taken up by the felt, is carried continuously onward to the first-press, where it loses a further proportion of moisture, thence to the second-press, as on the Fourdrinier machine, and then to the driers and calenders. There is less waste of pulp on the cylinder machine, but as there is no "shake" to give lateral motion to the fibers, the latter lie mostly in the line of travel of the web, the paper thus made being weaker across the grain than lengthwise. A double or triple cylinder machine consists in the combination of two or three vats and making cylinders, such a combination sometimes including twelve vats and cylinders. In such machines as many webs of paper as there are cylinder-moulds are formed and brought in contact prior to going through the press-rolls, where they are pressed together. Thus it is possible to make sheets of varying degrees of thickness. The inner layers may be made of cheaper stock, while the exterior surfaces may be of a better grade of material and colored as fancy may direct.

Wet-machine.—This is the first part of a single cylinder machine, having first-press rolls, and is arranged to wind the sheet of paper in continuous layers upon the upper press-roll until the desired thickness of material has accumulated upon the roll. When this has been attained an alarm-bell rings, and the attendant then operates a hand-lever which moves a knife down and on to the roll, by this means cutting open the paper cylinder formed on the roll and releasing the sheet. For some classes of work the upper press-roll is grooved along its length, so that the attendant by inserting a knife in the groove can cut the paper, or "board" as it is then called, dispensing with the lever knife arrangement. The wet-machine is used for making binders' board, wood-pulp board, leather-board, etc., and sometimes for straw-board.

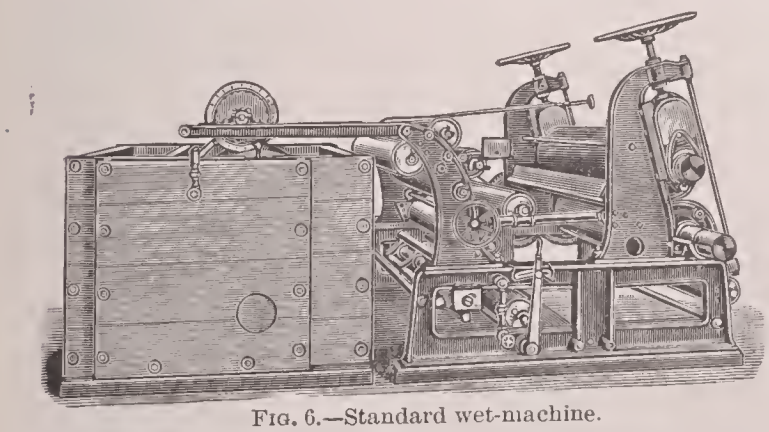

FIG. 6.—Standard wet-machine.

Harper's improved Fourdrinier is a combination of the Fourdrinier and cylinder machines. It has the wire-cloth and attachments of the Fourdrinier until it reaches the couchers, the lower roll of which is an open forming cylinder, on which the Fourdrinier wire is substituted for the fixed wire-cloth. The upper couch-roll rests on levers, and the wet felt passes thence upward and above the wire of the machine inversely to the direction of the formation of the web of paper and then to the press-rolls.

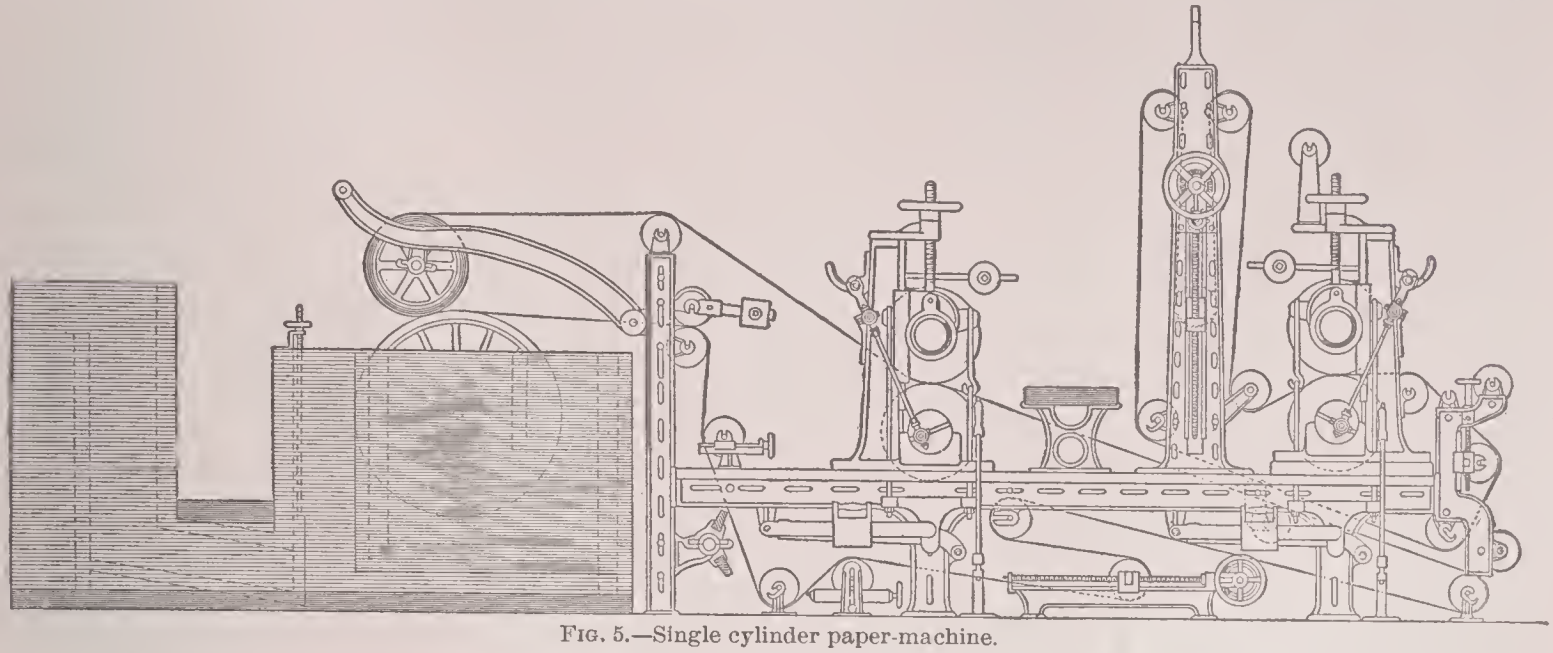

FIG. 5.—Single cylinder paper-machine.

In *mould-machines* the pulp is deposited on an endless series of square moulds similar to those used for making hand-made paper, but operating continuously after the fashion of the Fourdrinier machine, depositing the sheets on felts or carriers. These machines have found some use in Europe.

Wood and Esparto as Paper-making Materials.—Esparto grass (see ESPARTO), otherwise known as alfa and Spanish grass, is used to a great extent in Europe. When it is received at the paper-mill it is picked over by hand on a special apparatus having a traveling-apron, on either side of which the sorters are stationed. Roots, weeds, etc., are removed, and the grass is then shaken and dusted. It is then packed uncut in boilers, although in some mills open tubs are used. In general, the cooking is done under pressure in vertical boilers, a solution of caustic soda (10°) in water being used. This deprives the esparto of its silica and other incrustations. The fiber after bleaching is white, soft, and of excellent quality. A similar boiling process is employed for the production of pulp from ordinary straw. The alkali in the residuum is recovered by evaporation, in special apparatus, to the extent of about 80 per cent.

Wood-pulp.—One of the most important paper-making materials is derived from wood. There is a distinction between wood-pulp and wood-fiber. The first is obtained by mechanical means and the second by chemical treatment. Wood-pulp is produced by grinding. The apparatus for this purpose consists of a rotating grindstone inclosed in an iron casing provided with openings covered by pockets containing blocks of wood, which are kept in bearing against the periphery of the stone by means of pistons controlled by hydraulic pressure. The wood is first prepared by being deprived of its bark and knots, after which it is cut into convenient lengths, and then placed in the pockets of the grinder. Power being applied, the stone is rotated, tearing off the fiber of the wood. Water is introduced into the grinder during this operation, and the particles of wood are carried against a wire screen, which admits of the passage of the finer fibers, but retains the coarser for further treatment. When the wood has been thus reduced it may be shipped with a certain percentage of moisture to the paper-mill, where it undergoes the ordinary beating treatment, or it may be run off in sheets or made into wood-pulp board. This apparatus was invented by Henry Voelter, a German, in 1860, and is largely used in Europe and in North America. Wood-pulp has been the great cheapening agent in what are known as print-papers. While paper can be made entirely from wood-pulp, or mechanical pulp, as it is sometimes called, the fiber is too weak to make a sheet of paper of sufficient strength for most of the ordinary purposes of daily use, and for this reason it is mixed in varying proportions with

other material, wood- (chemical) fiber being the chief admixture.

Wood-fiber.—This is commonly known as chemical fiber. It is produced by two methods—the alkali and the acid processes. The alkali or soda process was invented in England by Charles Watt, who was aided by Hugh Burgess in bringing it into operation. This was in 1853, and since 1854, when Burgess constructed works in the U. S., it has maintained its position as a leading process for the manufacture of paper-pulp from wood. The incrustating matter of wood is easily operated upon by dilute alkali, the power of which is increased at a higher and increasing temperature. The alkali has a solvent and saponifying effect, and the acid products which result from the resolution of the wood are brought into the liquor as salts of soda. Poplar is the wood generally employed in the soda process, although other woods can be and are utilized, including pine, spruce, and hemlock. The wood is denuded of its bark and cut into chips, which, after being dusted, are put into boilers commonly known as digesters. These are about 22 feet long by 7 feet in diameter, and are heated by coils supplied with steam through the journals and rotating with the boiler. Sometimes "globe" or spherical boilers are used; at other times upright digesters are employed. The chipped wood having been packed in the digester, a solution of caustic soda is added to it, the strength of the liquor being from 8° to 15° Baumé. A steam-pressure of about 90 to 100 lb. from eight to ten hours is requisite to cook the wood. The resultant fiber, when washed and bleached, is almost entirely pure cellulose, soft and of a fair degree of strength. The alkali employed in the solution is afterward recovered by evaporation, the apparatus producing the best results, it is believed, being that known as a multiple effect, originally invented for the evaporation of saccharine liquor employed in the manufacture of sugar. The sulphate process is a modification of the soda process, and was invented by Dahl in 1888. In this the carbonate of soda is substituted to a large degree by the sulphate of soda.

The acid or bisulphite process has taken a leading position in the manufacture of wood-fiber. It was invented by Benjamin C. Tilghman, a native of the U. S., in 1867, but was not developed fully by him because of the difficulty at that time of securing the necessary apparatus. This invention is the foundation on which the acid fiber industry has been built up to large proportions. The process consists in boiling the previously prepared wood in a solution of bisulphite of lime. This solution is ordinarily made by burning sulphur or iron pyrites in a furnace, and combining the sulphurous acid thus obtained with water containing lime. Other bisulphites, such as bisulphite of magnesium or sodium, may be used, notably the former, which is employed in the Ekman process. This invention was taken up by Fry and Ekman in Sweden, and by Mitscherlich, Kellner, and others in Germany and elsewhere, but not until the apparatus for putting it into successful operation had been invented in Europe was it brought into action in the U. S. The wood is first prepared with great care, the bark and knots being removed, and also all decayed and stained pieces; it is then cut into chips or into disks about 1¼ inches thick, after which it is packed in the digester. The sulphite liquor is then run in quickly, the digester is closed, and steam-pressure is gradually turned on. The strength of the liquor is generally about 10° T., carrying about 3½ per cent. of sulphurous acid. The corrosive action of the bisulphite liquor is such that it is necessary to line the digesters with acid-resisting coatings. Lead has been used for this purpose to some extent, but is giving place to linings of enameled or glazed bricks set in cement with a leaden backing, or to cement linings, and again to coatings of sulphite of lime deposited by varying methods upon the interior of the steel shell of the digester. The woods chiefly utilized are spruce and Swedish fir and pine. The cooking takes from sixteen hours with high pressure to seventy-two hours at lower pressures. When the "cook" is complete the wood is washed in the digester and is then emptied out, or if the digester has been blown off into a drainer it is washed there, afterward going through the processes of washing, bleaching, and beating in the engines prior to conversion into paper. Unbleached sulphite fiber is of a light-brown color with a pinkish tinge, sometimes harsh and translucent, or again soft and nearly white, its variable quality being due to the treatment which the wood has undergone. When the fiber is well cooked and bleached it is soft, strong, and of pure color.

Classifications of Paper.

Paper is classified under various heads in different countries, and its subdivisions are known by varying names. Its chief divisions are printings, writings, wrappings, and boards. These include nearly all of the grades, there being some special products which do not come distinctly under these heads. Each class has numerous subdivisions. The different named sizes of papers are given in the subjoined table. The figures denote inches, and it will be observed that a name sometimes stands for several sizes. These differences are due to various classifications of paper.

NAMED SIZES OF PAPER.

Folded Paper.—Although sheets of paper vary in size, when folded to make up in book-form they have other designations, according to the number of leaves into which a sheet is subdivided. Thus a sheet of paper when folded is described as follows:

Folio,	folded once	=	2 leaves	=	4 pages,		folio.
Quarto,	" twice	=	4 "	=	8 "		4to.
Octavo,	" four times	=	8 "	=	16 "		8vo.
Duodecimo,	" six "	=	12 "	=	24 "		12mo.
Sexto-decimo,	" eight "	=	16 "	=	32 "		16mo.
Octo-decimo,	" nine "	=	18 "	=	36 "		18mo.
Quarto-vigesimo,	" twelve "	=	24 "	=	48 "		24mo.
Secundo-trigesimo,	" sixteen "	=	32 "	=	64 "		32mo.

Special Kinds of Paper.

There are several kinds of paper which call for special description. Some of these are used in the form in which they come from the mill, while others are subjected to treatment in various ways at the hands of manufacturers, broadly known as converters, who prepare the product for special uses. The following are of the first class, except that *coated paper*, *safety-paper*, and *tracing-paper* are also sometimes produced by converters. *Asbestos-paper* is not one of the regular makes of paper, but is a special product consisting

principally of asbestos-fiber, with which a certain proportion of paper-pulp is incorporated. It is used for roofing purposes and for covering steam-pipes to prevent radiation of heat. *Blotting-paper* is a bibulous product, unsized, and used for absorbing ink and fluids. *Cigarette-paper* is a thin tissue from which all chemicals have been removed or neutralized. It is used with tobacco for making cigarettes. The best is said to be made from straw, and it has been asserted that the finest quality is produced from the worn-out straw sandals of the Basque peasantry in Spain. There is a variety of cigarette-paper called *rice-paper*, but this is not the true product bearing that name.

Coated paper is a print paper to which a coating of white material, sometimes china clay, or gypsum, sulphate of barytes, etc., is applied. It is chiefly used for books or for fine prints from wood-cuts and process blocks. The coating is applied by machine brushes, after which the paper is dried in the web, and receives its final finish. White coated paper has a smooth, finely finished surface, enough only of the coating material being applied to fill up the pores of the paper and get the degree of finish desired. In this respect it does not come under the same classification as *surface-coated papers*, so called because a heavier coating is applied to their surfaces, various colors and shades of color, to which a glazed or dull finish is given, being used; *enameled papers* come under this class. Coated book-paper for printing upon with fine wood-cuts or half-tone plates was first adopted in the U. S., where the system of printing with hard packing on the cylinder of the printing-press prevails, and its use has established a distinct advance in the art of the printer.

Copying-paper is a thin tissue made specially for taking copies of letters, bills of lading, etc. *Detail-paper* is a special grade of heavy Manilla-paper for the use of artists and draftsmen, its surface being such as to submit to erasures without destroying the texture of the paper. *Enameled paper* is a glazed paper to the surface of which a metallic pigment has been applied and polished. *Filter-paper* is unsized, thick, and spongy, and is employed for filtering solutions in pharmaceutical or laboratory practice. The best is made in Sweden.

India-paper is used for taking those impressions from fine engravings on steel or copper known as India-proofs. It has also been utilized for proofs of the finest wood-cuts and photo-mechanical plates. It is of different qualities, and is made from the inner fiber of the bamboo, which, after separation from its outer covering and incrustating substances, is well beaten, the pulp being then spread on a polished flat surface, which gives it a smooth finish, the upper or reverse side of the sheet being rough. It is of thin, soft texture, taking a mark upon the slightest pressure, and when properly dampened showing the finest line. Cotton-fiber is sometimes used as an admixture in the manufacture of this paper. *Oxford India-paper* is a specialty of the Clarendon Press at Oxford, England, and is the thinnest of opaque papers, so thin indeed that five original octavo volumes of the Bible, containing 2,688 pages, have been printed on it and included in the space of one volume. *Ivory-paper* is Bristol-board coated with animal size, with an admixture of white pigment, and then polished.

Japan-paper.—The Government of Japan has a paper-mill at Opi, where a dozen different kinds of paper, including the silkiest tissue-paper, thick parchment paper, Bristol-board, and the paper much prized by artists, etchers, and plate-printers, are made. The last, generally known as Japan-paper, is made from the fiber of the paper-mulberry, which is also employed in other manufactures of this mill. It is produced in varying thicknesses, sometimes quite thin, and is of strong texture and a creamy color. There are several varieties of the paper-mulberry cultivated in Japan expressly for paper-making purposes, the best being that known as Ts'kuri-kake; but this is scarce and expensive. In making this paper the mulberry stalks are steamed, stripped, washed, and then boiled in water made alkaline with the ashes of buckwheat husks. After this treatment the fiber is again washed, and then a paste or size made from tororo-root or from rice is added. Then follows the pounding or beating of the fibers, the dilution of the stuff in a tub or vat, and the ordinary process of manufacture by hand or on the machine.

Localized Fiber-paper.—This is a specialty adopted by the U. S. Government for use in its Treasury notes and other certificates of indebtedness. It is a bank-note paper containing fibers of colored silk, which are added to the pulp as it is made into paper. *Manifold-paper* is a thin tissue used for writing upon with a stylus, which produces a number of copies upon as many sheets between which strips of carbon-paper are interposed. It is known in newspaper offices as "flimsy." *Nepaul-paper*, the bark of the *Daphne papyraceæ*, is after treatment converted into a strong unsized paper bearing this name. It is made in sizes many yards square.

Parchment-paper is made by passing unsized paper through a bath of dilute sulphuric acid. When dried it has a translucent, semi-transparent character, the paper gaining greatly in strength and resembling parchment. The paper is washed in water and then in dilute ammonia after undergoing the action of the acid bath. Glycerin is sometimes combined with the acid. Chloride of zinc is also employed for parchmentizing paper. A tough paper made in the ordinary way at paper-mills is called parchment-paper, but is not like the true parchment-paper or vegetable parchment.

Rice-paper is not paper in the ordinary sense of the word. True rice-paper is made from the pith of a tree indigenous to Asia, and known as *Fatsia papyrifera*. This grows to a height of 20 feet, and the pith is cut with a sharp knife into laminæ snow white in color. The sheets are sometimes 95 by 140 inches in size, and are subjected to pressure to make them smooth. Rice-paper is made into artificial flowers, and is also used for taking impressions of fine engravings. Another variety of this paper is made from the pith of the *Aralia papyrifera*. The pith of the *Echynome aspera* is also employed for this purpose, as well as that from the *Hydrangea paniculata* and the *Hibiscus manihot*. There is another so-called rice-paper made by the ordinary processes of paper-making, but it is of different material, and so made the name is a misnomer.

Safety-paper, sometimes known as *protective paper*, is chemically or mechanically prepared so that tampering with any printing or writing upon it may be detected. The chemicals may be applied to the surface or incorporated in the pulp, so that erasures or the action of acids or alkalies will change or discolor the paper. Water-marks of a special design are sometimes employed, as in the Bank of England notes, or silk threads are embodied in the fiber.

Silver tissue is a fine thin paper used for wrapping silverware. It is carefully prepared by the elimination of all chemicals likely to tarnish or discolor the bright surface of the ware, and also averts to a great extent the oxidizing influence of the atmosphere. It is sometimes known as *grass-bleached tissue*. *Sponge-paper* is made from paper-pulp containing pieces of sponge in a state of fine subdivision; used in surgery. *Toned paper or tinted paper* is tinted or has its whiteness subdued or modified by a very slight addition of color to the pulp.

Tracing-paper is thin paper which has been treated with oil or a thin solution of resin to make it transparent. It is used by artists and draughtsmen, and is made in various sizes and in rolls. Some kinds of tracing-papers are thin tissues without any treatment with oil, etc. A variety of this paper is known as *pounce-paper*.

The following papers are of the class known as converted papers:

Carbolic acid paper is a paper treated with carbolic acid in combination with stearin and paraffin. *Carbon-paper* is a thin tissue, saturated with a pigment carried in oil, and capable of imparting color to sheets of paper with which it may be brought in contact. It is used in connection with manifold-paper. *Emery-paper* is a tough paper to which a coating of glue is applied, powdered emery being then dusted on the glutinous surface. It is used for rubbing down rough surfaces of metal, etc. *Glass-paper* is an abrading agent, made by coating paper with glue and applying finely ground glass to the surface thus prepared. It is employed for rubbing down the rough surfaces of wood and metal. *Gold-* (or *gilt-*) *paper* is a paper on which a film or coating of gold-leaf, or metal simulating gold, is applied, and retained by means of size. It comes plain and embossed in fancy patterns. *Lace-paper.*—A soft paper with perforations and open-work patterns simulating lace. It is made by rubbing off the elevated sections of paper which has been embossed in various designs. The latest method of manufacture is by machines provided with special cutting dies. *Shelf-paper*, so called because it is used for covering and giving a decoration to the edges of shelving, comes under this head. *Lithographic transfer-paper* is prepared by coating paper with starch paste, and is used for transferring designs from one lithographic stone to another. Chinese (India-proof) paper is employed

for this purpose; also Saxe-paper and good book or writing paper. *Marbled Paper.*—A paper ornamented in various designs in colors representing the striations of marble. It is prepared by depositing the paper upon a surface of a thick solution of gum contained in a trough on which various mineral pigments in dilution are thrown or sprinkled, the disposition of the marbling being regulated by the use of tools which make varied patterns. The colors adhere to the surface of the paper, which when taken up and dried is polished by burnishing. *Moth-paper.*—A Manilla-paper impregnated with carbolic acid, tar, or other strong and malodorous solutions, and used for enwrapping furs and woolens, or for placing in closets, chests, etc., to prevent the incursions of moths. *Music-paper* is ruled with lines of the musical staff. *Oiled paper* is a thin paper saturated with an oil and then dried. It is used for tracing purposes. *Oiled board* is a thicker paper of the same character employed to interpose between leaves of paper in books used for copying letters or other written documents. *Pasteboards* are thick sheets made by pasting a number of sheets of coarse and common wrapping-papers together, and finished by glazing between friction calenders. *Pasted Bristols* are a variety of Bristol-boards made by pasting a number of sheets of unruled writing-paper together, after which a finished surface is given by passing the sheets through super-calenders or plating-machines. These are thus distinguished from *mill Bristols*, which are made of required thicknesses on the machine. The very best grades of stock are presumably used in making pasted Bristols. *Photographic paper* is coated or impregnated with various chemical constituents sensitive to light. It occurs under many different names. *Sand-paper* is made by coating paper with glue and applying fine sand, which is dusted over the surface. It is used in smoothing wooden and metal surfaces. *Satin-paper* has a fine glossy surface imparted by means of a satining machine, in which a brush operates in contact with the face of the web of paper. *Silver-papers* are sheets to which silver or white metal-leaf is attached by means of size. It is made plain and in embossed patterns. *Test-paper* is prepared by dipping paper into a solution or decoction sensitive to different reagents and then drying it. When used it is for the purpose of determining the presence of a substance in solution capable of changing the color of the paper. *Litmus-paper*, which is most commonly used, is made in two different colors—blue which changes to red in the presence of an acid, and red to blue in contact with an alkali. Other kinds of test-paper are *Brazil-wood paper*, *buckthorn-paper*, *cherry-juice paper*, *dahlia-paper*, *indigo-paper*, *iodine-paper*, *lead-paper*, *rose-paper*, *starch-paper*, and *turmeric-paper*. *Touch-paper* is a paper saturated with a solution of nitrate of potash and dried.

Velvet-paper and *wall-papers* are described under PAPER-HANGINGS.

Statistics.—The annual production of paper can only be a matter of rough estimate. The returns from the mills in the U. S. afford the nearest approximate for judging of capacity. Data gathered for *Lockwood's Directory of the Paper, Stationery, and Allied Trades for 1894–95* show that there were 1,231 paper and pulp mills in the U. S. at that date. The total daily producing capacity of the mills thus reported is given at 20,986,180 lb. The increase since 1881 (thirteen years) is almost 295 per cent. JAMES A. COLVIN.

Paper-hangings, or **Wall-papers**: ornamental papers intended to be pasted on the walls or ceilings of apartments. Paper-hangings are reported to have been made in Spain and Holland before 1555, but their manufacture has only in more recent times become a leading industry. The choicest wall-papers are made of good material, but for the low grade large quantities of woolen, hempen, and jute waste are employed. The paper was formerly all printed by hand, either by the process of block-printing or stencil. Cylinder-printing is now used, identical in principle with the processes employed in CALICO-PRINTING (*q. v.*); but choice styles are still hand-printed, the blocks being either engraved wholly in wood or partly made up with metal for the thinner lines. Some striped papers are colored by a simple process which can not be called printing, the colors being imparted through apertures, underneath which the paper is rapidly drawn. Flock-printing is done by printing the pattern in with varnish and then sprinkling on colored flocks, in powder, the flocks being the shearings of woolen cloth. Such papers are generally called velvet-paper. Satin-papers are finished with powdered steatite and polished.

Paper-mulberry: See FIBER.

Paper-nautilus: See ARGONAUT.

Paphlago'nia: in ancient times a district of Asia Minor, extending along the southern shore of the Euxine Sea, from Pontus to Bithynia, and bounded S. by Galatia. It was inhabited by wild and warlike tribes belonging to the Semitic race, and it was celebrated for the excellent horses it produced. Originally it formed an independent state, but it was conquered by Crœsus, and subsequently incorporated in the Persian empire. After the death of Alexander it became independent once more, but was conquered by Mithridates, and after his fall it was made a part of the Roman province of Galatia.

Pa'phos: the name of two ancient cities of the island of Cyprus. One of them, the present *Kukla*, was often called *Palaipaphos* (Old Paphos), and was famous for its temple of Aphrodite, who was said to have been born here from the foam of the waves. The other, the present *Baffa*, was called *Neopaphos* (New Paphos), and was the place where St. Paul preached to the proconsul Sergius.

Pa'pias: a Christian Father of the second century, Bishop of Hierapolis in Phrygia, according to Irenæus a disciple of John the apostle, and a companion of Polycarp. He suffered martyrdom at Pergamus during the persecutions of Marcus Aurelius about 163. Of his Λογίων Κυριακῶν Ἐξήγησις only eleven fragments have come down to us. It was a collection of sayings of the Lord, the apostles, and the disciples, with explanatory notes derived from oral tradition. The work existed as late as the thirteenth century, and it is not necessary to give up all hope of its recovery. See *Reliquiæ Sacræ* of Routh (Oxford, 1814; 2d ed. 1846); the *Apostolic Fathers* of Bishop Lightfoot (edited by Harmer, London and New York, 1893), pp. 515–525, and the translation, pp. 527–535. Trans. also in *Ante-Nicene Fathers* (New York), i., 151–155. He was a very strong millenarian.

Revised by S. M. JACKSON.

Papier-maché [= Fr., liter., chewed or macerated paper]: a manufactured material composed chiefly of paper-pulp or of paper in sheets, combined with various adhesive substances, coloring-matters, etc.; usually pressed to the desired form in suitable moulds. This material, although comparatively modern among civilized nations, is nevertheless of great antiquity in China, where doubtless it originated. In Kashmir the manufacture has long been established, and under the name of *kar-i-kalamdani*, or pen-tray work, the production of boxes, trays, and cases of papier-maché is a prominent industry. Paper-pulp was combined with gums and china clay by Martin, a German snuff-box maker, who is said to have learned the art in France about 1740. There are three processes by which the bodies of papier-maché articles are manufactured—the first consists in mixing paper-pulp with gum, resin, paste, or glue, and then placing a sufficient quantity of the mixture in a mould and subjecting it to heavy pressure; in the second process heavy sheets of softened mill-board made from pulp are pressed to the desired shape in moulds; the third process (invented by Henry Clay, of Birmingham, in 1772) employs spongy paper (similar to thin blotting-paper), layers of which are glued or pasted together and pressed into moulds. This process is considered the best, as from the uniformity of its substance it produces the strongest work; but the other methods are cheaper, and are still used for many small articles.

When the bodies of the articles are removed from the moulds, they are dried, filed, smoothed, varnished, ornamented, and polished. Soon after the invention of Henry Clay's process the manufacture of papier-maché in Birmingham rapidly increased, and in 1780 embraced a large variety of articles, such as tables, chairs, cabinets, tea-trays, caddies, panels for doors and ceilings, coaches, sedan-chairs, snuff-boxes, etc.

Pearl-shell inlaying was patented by George Santer in 1825. There is also a process of transferring colored designs from tracing-paper, which was patented in England in 1856. These methods of decoration have been used in a most extravagant and inartistic manner, and have contributed in no small degree to cause a decline in the popular appreciation of manufactures of papier-maché, which is a very suitable material for a large variety of decorative and constructive uses, being a light, tough, strong, durable substance, possessed of some elasticity, little liable to warp or fracture, and unaffected by damp. W. F. DURFEE.

Papiliona'ceæ: See LEGUMINOSÆ.

Pap'in, Denis: physicist and inventor; b. at Blois, France, Aug. 22, 1647; studied medicine at Paris and practiced for some time as a physician, but devoted himself subsequently to the study of physics and mathematics under Huyghens; visited England, and received in 1687 a professorship in mathematics at Marburg in the present Prussian province of Hesse, where he died about 1712. His writings are numerous, but are scattered in *Acta Eruditorum*, *Recueil de diverses Pièces*, *Philosophical Transactions*, etc.; they contain many valuable discoveries, most of which, however, were not fully recognized during his lifetime. He was the inventor of the so-called Papin's digester. (See Digester, Papin's.) It also appears that in 1707 he tried on the river Fulda a vessel propelled by paddles operated by a steam-engine. He improved the pneumatic machine invented by Otto von Guericke, and was active in the controversy with Leibnitz concerning the so-called "dead" and "living" forces.

Papineau, pä'pē'nō', Louis Joseph: political leader; b. at Montreal, Oct., 1789; studied at the Seminary of Quebec, and became an advocate; in 1809 entered the Canadian Parliament, and in 1815, and again in 1827, was Speaker of the lower house; but Lord Dalhousie, who had tried in vain to conciliate him with the conservative party, in the latter year adjourned the Parliament to prevent Papineau from acting as Speaker. He was after that the acknowledged leader of the Lower Canadian radicals, or French party, and after the breaking out of the rebellion of 1837 (which he did not approve) was accused of high treason and escaped to the U. S., and thence in 1839 went to France. In 1847 he returned to Canada, and though sent to Parliament and highly popular with the French element, he never again assumed leadership. D. at Montebello, Quebec, Sept. 23, 1871.

Papinia'nus, Æmilius: a Roman jurist, probably from Syria, who held high and influential positions under the reign of Septimius Severus, and was præfectus prætorio 205–212, but was put to death in 212 by Caracalla. His works—37 books of *Quæstiones*, 19 of *Responsa*, 2 of *Definitiones*, etc.—were considered the highest authority in Roman jurisprudence, and several of the most eminent Roman jurists, as, for instance, Ulpian and Paulus, were his disciples. The *Digests* contain 595 extracts from his works, but generally they are very short. See also Huschke, *Jurisprudentiæ antejustinianeæ*, pp. 436–449 (Leipzig, 1886).

Revised by M. Warren.

Pap'pus (in Gr. Πάππος) of Alexandria: a mathematician who flourished in the second half of either the third or fourth century A. D. His most important work was the Μαθηματικαὶ Συναγωγαί (Mathematical Collections), containing besides his own work explanations of earlier mathematicians, with extracts and his own criticisms on them, in eight books, of which the last six and part of the second have been preserved. These are of value in the history of mathematics. A Latin translation appeared in 1588, and portions of the Greek text have been published several times. A complete edition is by Friedrich Hultsch (3 vols., Berlin; 1875–78).

Papua: See New Guinea.

Papy'rus [= Lat. = Gr. πάπυρος]: a large reed, various parts of which were employed by the Egyptians in the construction of boats, mats, baskets, and other woven fabrics, but particularly in the preparation of writing-paper. It is known as *Cyperus papyrus* (*papyrus antiquorum*), and is extinct in Egypt, being found only in remote parts of Abyssinia. It is also said to occur in Western Asia. There is some doubt whether it was native to Egypt, but the representations on the monuments, showing rank papyrus-grown swamps where water-fowl abounded, indicate an absence of regular culture. In the hieroglyphic writing the papyrus plant is employed as the symbol of Lower Egypt. The stalks were triangular, from 4 to 6 inches in diameter, and 12 to 15 feet high. The roots were used for fuel, and a part of the inside of the stalk was edible. For paper-making a piece of the stalk of a length corresponding to the width of paper required was cut off, the rind was removed, and the inner portion was unrolled with a needle or a sharp knife. Upon this sheet another was placed transversely, and the two were joined by the juice of the plant or by a thin gum, the union being enforced by heavy pressure. The sheets were smoothed and afterward bleached by exposure to the sun. The color varied from a gray or yellow to a rich brown. The sheets varied from 6 to 17 inches in width, and any required length was obtained by fastening a number of sheets together end to end. The usual width was about 8 inches. The *Papyrus harris* in the British Museum is the longest known, being 135 feet, and a fairly full copy of the Ritual of the Dead (*q. v.*) required a roll 15 inches wide and from 80 to 90 feet long. The better qualities had only two layers of fibers; three layers indicate inferior grades. Specimens have been preserved which date from the Middle Kingdom, and the use of papyrus continued till the twelfth century in Europe. For a long time it was an article of Egyptian export, and in great demand. Probably it was never cheap even in Egypt, if we may judge by the fact that it was often used a second time, the first writing having been removed by washing. In later times there were various grades which were known as charta regia, Augusta, hieratica, Livia, Saitica, etc. Fanniana was the name given to a papyrus retreated and improved at Rome. With regard to writing on papyrus, its methods and subjects, see Egyptian Language and Literature. See also Taylor, *Transmission of Ancient Books*; Birt, *Das antike Buchwesen*; and Budge, *The Mummy*. See also Sedge Family.

Charles R. Gillett.

Pará: a state of Brazil, occupying the lower portion of the Amazon valley; bounded N. by British, Dutch, and French Guiana, N. E. by the Atlantic, E. by Maranhão, S. by Goyaz and Matto Grosso, and W. by Amazonas. Area (allowing the Brazilian claims for disputed boundaries on the side of Guiana), about 714,000 sq. miles. Pop. (estimated, 1892) 495,417. The Guiana table-lands, in the northern part, have an elevation of some 2,700 feet, and outlying portions near the Amazon are nearly 1,000 feet high; the Brazilian plateau, 2,500 feet high on the confines of Matto Grosso, falls gradually to about 300 feet near the Amazon. Between these the plains of the Amazonian depression are in some places not more than 30 miles wide, but broaden out westward into the state of Amazonas and eastward toward the Atlantic; the flood-lands of the river have an average width of about 25 miles above the mouth of the Xingú, and below it they are much wider. The Amazon itself, with its numerous side channels, forms an unrivaled system of interior communication. This is supplemented by the Pará and Tocantins, with a network of channels connecting them with the Amazon. The whole state seems covered with forest; but, hidden from the river by lines of trees, there are extensive tracts of grass on the flood-plains, and especially on the great island of Marajo; large areas on the plateaus, with some near the river, have only the low, scrubby growth of the Brazilian *campos*. Though the state is directly under the equator, the climate, tempered by the trade winds, is nowhere excessively warm; its equability and general healthfulness make it especially beneficial for invalids. Malarial fevers are confined to portions of the swampy lowlands and to the branches of the Amazon; yellow fever is rarely epidemic; the African disease called beri-beri is sometimes prevalent on the flood-lands. From the first the settlement of Pará proceeded along the lines of the rivers, and it has never gone much beyond them; with only one short railway and hardly any common roads, communication is almost entirely by steamboats or canoes. A few Indians wander wild in the interior, but the greater part are civilized or submissive to the whites, forming the mass of the country population. The most important industries are the extraction of forest products, especially rubber; sugar-cane (used mainly for making rum), cacao or chocolate beans, tobacco, and manioc are the principal agricultural products; and on the open lands the grazing industry has attained some importance. The principal exports, in the order of their value, are rubber, cacao, hides, and Brazil-nuts; much of the trade is with the U. S. The revenue is derived mainly from a tax on rubber, and the state has nearly always a surplus. The Portuguese settled Pará in 1616, driving out Dutch and French traders. After Brazil became independent this region was ravaged by a rebellion of the lower classes, 1835–37. Amazonas was separated from Pará in 1852. See H. H. Smith, *Brazil* (1879); the *Travels* of H. W. Bates, A. R. Wallace, and William H. Edwards; *The State of Pará: Notes for the Exposition of Chicago* (1893).

Herbert H. Smith.

Pará, officially *Belem*: capital and principal city of the state of Pará; on a low point at the mouth of the river Guamá in the Pará; 85 miles from the mouth of the latter in the Atlantic (see map of South America, ref. 3–F). It is regularly laid out with wide streets, which, except in the

business portion, are adorned with mangrove and other trees. The principal public buildings are the cathedral, the custom-house (formerly a Jesuit convent), and the Government theater; the president's and bishop's palaces and the house of the legislature are plain buildings. The finest residences are in the quarter called Nazaré, formerly a suburb; many of them are surrounded by extensive gardens, which are often allowed to run partly to waste, presenting an exceedingly picturesque appearance. The chapel of Nazaré is a noted resort, and the yearly festival held here attracts thousands of visitors. Tropical forest, swampy in many places, comes close to the city, and the suburban streets require constant care to keep them from the encroachments of vegetation. Pará has a marine arsenal, a botanical garden, a small museum, library, theological seminary, and good public and private schools. It is the commercial metropolis of the Amazon valley; its exports of rubber far exceed those of any other port in the world, averaging (including that in transit) over 8,000,000 lb. annually. Owing to strong tides and shallows near the city the harbor facilities are poor; light-draught river-steamers discharge directly at wharves, but large vessels are obliged to anchor some miles below. Pop. (1892) estimated with suburbs, 65,000. H. H. Smith.

Parable [from O. Fr. *parable, parabole* > Fr. *parabole* < Lat. *para'bola* = Gr. παραβολή, a placing beside, comparison, parable, liter., a throwing alongside; παρά, beside + βάλλειν, throw]: a short fictitious narrative intended to illustrate some point in moral or religious teaching. Parables abound alike in the teaching of Christ and in the Jewish Talmudical writings; but the parables of Christ (not used by him in the beginning of his ministry, but only after he had encountered opposition) immensely surpass all others.

Parab'ola [Mod. Lat., from Gr. παραβολή, parabola, liter., a throwing alongside, so called from its direction as compared to a side or element of the cone. See Parable]: a plane curve of the second degree, with a single branch extending to infinity. In modern geometry it is defined as a curve of the second degree, touching the line at infinity. (See Geometry.) This curve is the section of a right cone by a plane parallel to one of its tangent planes, from which point of view it was originally considered.

It is a property of the parabola that every part of the curve is equally distant from a fixed point and from a given straight line. The fixed point is called the *focus*, the given line is the *directrix*, and a straight line through the focus perpendicular to the directrix is the *principal axis*. At every point of the curve the line from the focus and a parallel to the axis make equal angles with the tangent—that is, the two first lines are reflections of each other with regard to the surface formed by the revolution of the curve round its axis. (See Paraboloid.) Any line parallel to the principal axis is called a *diameter*, and every diameter bisects all the chords of the curve that are parallel to the tangent at the point where it meets the curve. The principal axis is therefore a line of *right* symmetry, and every other diameter is a line of *oblique* symmetry. The breadth of the curve through the focus is called the *parameter* of the curve; it is also called the parameter of the principal axis. The parameter of any diameter, including the parameter of the principal axis, is equal to four times the distance from the focus to the vertex of that diameter. If we neglect the resistance of the air and consider gravity as acting in parallel lines, the path of a projectile is a parabola with its axis vertical and its vertex at the highest point of the path. The equation of the parabola in Cartesian co-ordinates is $y^2 = px$, where p is the parameter, and it has this form if the curve be referred to any diameter and the tangent at the point where it meets the curve. The curves included in the form $y^n = px^m$, where m and n are positive integer numbers, have been called parabolas. Thus the curve $y = px^3$ is called the cubical parabola and $y^2 = px^3$ the semi-cubical parabola. The curve $y = a + bx + cx^2 + dx^3 +$ etc. $+ fx^n$ has also been called a parabola of the nth degree.

Revised by R. A. Roberts.

Parab'oloid [Gr. παραβολή, parabola + suffix *-oid*, having the form of]: a surface of the second order whose plane sections parallel to a certain right line are parabolas. In modern geometry it is defined as a surface of the second degree, touching the plane at infinity. There are two principal kinds, the elliptic and the hyperbolic. In both paraboloids all sections parallel to the straight line called the axis are parabolas, while in the elliptic paraboloid all other sections are ellipses. If the sections of the latter perpendicular to the axis are circles, the surface is generated by the revolution of a parabola about its axis. This surface is such that parallel rays of light falling upon it in the direction of the axis are accurately reflected to a fixed point called the focus. (See Parabola.) It is also the form of the free boundary of a fluid rotating under the action of gravity. (See Hydrostatics, *Surface of Liquids.*) Hyperbolic paraboloids are ruled surfaces admitting of two modes of generation. All sections except by tangent planes and those mentioned above are hyperbolas. R. A. Roberts.

Paracatú: a town in the western part of the state of Minas Geraes, Brazil; close to the boundary of Goyaz; near a river of the same name, a western affluent of the São Francisco. It was formerly noted for its rich gold washings, which are now nearly abandoned; it is the center of a rich grazing district, and has a thriving trade with Goyaz and Bahia. Coffee and sugar-cane are grown on a considerable scale in the vicinity. Pop. 10,000. H. H. S.

Paracel'sus: physician and author; the assumed name of Philippus Aureolus Theophrastus Bombastus von Hohenheim; b. at Einsiedeln, Switzerland, in 1493; the son of a physician. He read the works of the alchemists and magicians, and traveled on foot far and wide collecting information regarding the healing art from barbers, blacksmiths, and wise women; spent much time in the mines of the Tyrol; took the degree of doctor in medicine; served for a time as a military surgeon in Denmark, the Low Countries, and Italy, and then resumed his wanderings. Œcolampadius procured him a professorship of medicine and surgery at Basel (1526), but he was soon compelled to leave the place (1527) by the Galenic physicians, for he openly burned Galen's books and denounced the Arabian masters, then so generally studied. Erasmus was one of his patients. If we may believe his adversaries, Paracelsus was almost always drunk, and was guilty of gross irregularities; certain it is that he had to resume his wandering life, and that after many strange vicissitudes he was thrown from a window and killed by the servants of a physician at Salzburg, Sept. 23, 1541. He left six professional treatises, besides a large number of works which bear his name, some of which were written by his enemies to injure his reputation, and others by fanatical admirers. His lectures also were delivered with great rapidity, and published by his hearers in a very imperfect state. Paracelsus, though he displayed many traits of the charlatan, lived a useful life. The profession of medicine at his time needed reformation quite as much as the Church did. He destroyed the humoral pathology, broke the tyranny of Galen and his Arabian followers, and introduced many new and valuable remedies. His empiricism was based upon the principles of careful observation now universally recognized. He paid great attention to diet, condemned the use of strong evacuants and the abuse of mercury, avoided the excessive mixing of drugs, and strove to reduce the overdosing then so prevalent. He is called an alchemist, although he condemned the search for the transmutation of gold, and an astrologist, although he opposed the study of astrology. A curious work regarding spirits is ascribed to him, and the strange jargon regarding sylphs, pygmies, undines, gnomes, salamanders, and other "elemental spirits" is commonly thought to have been invented by him; so that believers in the existence of such beings are called Paracelsists; but it is probable that he never wrote the work (*Liber de Nymphis*, etc., Basel, 1590), for he elsewhere ridicules all such ideas. He taught a singular theosophy—a kind of pantheistic system in which the Cabbalah was combined with natural science founded on experience and experiment, but the distinction he made between faith and reason as two different organs of perception, each with its own field of activity, resembles modern attempts of the same tendency. See *The Hermetic and Alchemical Writings of Paracelsus* (2 vols., London, 1894).

Parachute [= Fr. (by analogy of Lat. *para're*, get ready, ward off, or of words beginning with prefix *para-*); *parer*, prepare, ward off + *chute*, fall]: a machine first successfully employed by Blanchard at Strassburg in 1787, and designed to enable aëronauts to descend safely to the ground from a balloon. It is shaped like an umbrella, and is taken up in a collapsed or closed form. The car is first attached beneath the parachute, and the balloon above the whole; a rope passing through the hollow stem of the parachute attaches the balloon to the car; this rope is cut at the proper time, the car falls rapidly, and the parachute is expanded by the action of the air. The car's downward motion is thus

checked, and it descends slowly toward the earth. In practice, the parachute is not to be depended upon. It is liable to oscillations, which frequently prove fatal to the aëronaut.

Paradise [from O. Fr. *paradis* < Lat. *paradi'sus* = Gr. παράδεισος, from Zend *pairidaēza*, inclosure; *pairi*, around + *diz*, throw up, pile up]: a park or pleasure-ground; especially the Hebrew Eden (*q. v.*). The Bible uses the term in a double sense—first, for the garden of Eden, and next for the abode of the blessed in heaven (Luke xxiii. 43). It is remarkable, however, that in the discourses of Christ, public or private, the word occurs only this one time, in the words which Christ spoke to the penitent robber. Metaphorically, it is often used synonymously with heaven, denoting the future bliss which awaits the righteous. See Heaven.

Paradise'idæ [Mod. Lat. See Paradise]: a family of birds containing the Birds of Paradise (*q. v.*), distinguished by their curious plumage, and closely related to the *Corvidæ*. The bill is moderately elongated, strong, slightly decurved; the base of the bill, as well as nostrils, is covered to a greater or less extent by short feathers; the wings are long and rounded; in addition to the ordinary plumage are developed feathers of various forms and styles, diverging from the shoulders, sides, and caudal region; the feet are robust; the toes with long curved claws. The species are confined to the islands of New Guinea and its vicinity. Something like forty-five species are known, most of which are described and figured in Elliot's *Monograph of the Paradiseidæ*. Revised by F. A. Lucas.

Paradise of the West: See Sukhāvatī.

Paradox'ure [from Mod. Lat. name *Paradoxu'rus*; Gr. παράδοξος, incredible + οὐρά, tail]: any member of the genus *Paradoxurus* of the family Viverridæ (*q. v.*).

Paræsthesia: See Formication.

Paraffin, or **Paraffine** [Lat. *pa'rum*, little, too little + *affi'nis*, akin]: a beautiful white waxy solid which occurs native in the mineral wax ozokerite, found in Galicia, Utah, and elsewhere, and in some kinds of petroleum, and also found in coal and shale oil, and the products of the destructive distillation of many other organic bodies, as oil, fats, wax, wood, peat, albertite, grahamite, etc. It was discovered by Reichenbach in 1830 in wood-tar.

Preparation.—(1) Paraffin is obtained from ozokerite by distillation, cooling, and pressing the product, and purifying it by treatment with sulphuric acid and caustic soda, washing and pressing. It is also purified by repeatedly melting it with petroleum naphtha and subjecting it to pressure. (2) By similar means it is prepared from the heavier portions of coal oil and petroleum, which solidify on cooling, owing to the crystallization of the paraffin.

Composition.—Paraffin is generally a mixture of two or more members of the paraffin series of hydrocarbons, $C_{27}H_{56}$, $C_{28}H_{58}$, $C_{29}H_{60}$, $C_{30}H_{62}$, etc. $C_{27}H_{56}$ contains carbon 85·26 and hydrogen 14·74; $C_{30}H_{62}$ contains carbon 85·31 and hydrogen 14·69.

Properties.—A translucent crystalline solid, white in masses, odorless and tasteless, resembling spermaceti. Its specific gravity is about 0·870; it melts at from 113° to 149° F., and forms a colorless oil which solidifies into a crystalline mass. It boils at about 600° F., and may be distilled with but little decomposition, especially if the distillation is aided by a current of superheated steam. That obtained from ozokerite has the highest melting-point, and is consequently preferred for the manufacture of candles. It is insoluble in water, but dissolves in 2·85 parts of boiling alcohol, separating almost completely on cooling, in crystals. It is more soluble in ether, oils, and naphthas. Acids, alkalies, and chlorine have little effect upon it; whence its name. By the long-continued action of nitro-sulphuric acid it is converted into paraffinic acid. Heated with sulphur, it yields impure sulphuretted hydrogen.

Uses.—Paraffin has numerous important applications in the arts. Beautiful candles are made from it, but when the more fusible varieties are employed, the candles are liable to droop and lose their form. The crystalline structure also interferes with the manufacture of candles, but this is met by the use of small percentages of wax, etc., and by chilling the moulds, after the melted paraffin is poured into them, by placing them in cold water. It is extensively used for waterproofing fabrics, cloth, and leather for shoes, even dress silks, which are thus protected from stains. It is used for protecting from rust or decay, and putrefaction, meat, fruit, timber, metals, cartridges, pills, etc.; for making tight the stoppers of acid bottles; as a substitute for sulphur in the manufacture of matches; for oil-baths of constant temperature; for refining alcohol and spirits, by passing the vapor during distillation through melted paraffin, which abstracts the fusel oil; considerable quantities are used for chewing-gum. Uncrystallized or amorphous paraffin is in very common use in the well-known vaseline or petroleum ointment. See Bitumen, Hydrocarbons, and Petroleum.

Revised by S. F. Peckham.

Paraguay, par'ăă-gwī (Sp. *República del Paraguay*): the smallest of the South American republics, except Uruguay; between Bolivia on the N., Brazil on the N. and E., and the Argentine Republic on the S. E., S., and W. Area, according to official figures, 97,707 sq. miles; but this is only approximate, as the boundary with Bolivia is unsettled.

Topography.—The river Paraguay divides the country into two well-marked sections. The portion W. of the Paraguay is a low plain, a wilderness of swamps, forest, and grass-lands. This region, the Paraguayan Chaco, is described in the article Gran Chaco (*q. v.*). The remaining and larger portion (about 62,000 sq. miles) is sometimes distinguished as Paraguay proper. It occupies a peninsula formed by the rivers Paraguay and upper Paraná, which unite at the southwestern extremity; the northern boundary is the river Apa, a branch of the Paraguay, and the northeastern is formed by lines of hills, the continuation of a line of heights which begins about 75 miles E. S. E. of Asuncion, and extends N. N. E. across the country. The heights, improperly called *sierras* and *cordilleras*, appear to be nothing more than the eastern and southern edges of an extension of the Brazilian plateau, which occupies all the northern and central parts of Paraguay; but this plateau is so cut up by river valleys and varied with hills that it has lost the character of a table-land. The maximum elevation is probably less than 2,500 feet. The steep edges are, at the highest part, close to the divide between the affluents of the Paraguay and Paraná. On the western side the country falls irregularly but gradually to the rolling lands and plains bordering the Paraguay. The hills of Southern Paraguay and the upper Paraná valley are spurs and outlying portions of the same plateau. The southwestern corner of the country is nearly all occupied by an extensive swampy plain, with several shallow lakes; and there are smaller swamps farther N., along the course of the Paraguay. A large portion of the valley of the upper Paraná and the central hills are covered with forest; toward the Paraguay this gives place to open lands suitable for grazing. The rivers Paraguay and Paraná (*qq. v.*) are natural highways of great importance. The Jejuy and Tibicuary, affluents of the Paraguay, are both navigable, and promise to be of great commercial value. The other Paraguayan branches of the two rivers are numerous, but generally short and navigable for only a few miles.

Climate.—Though two-thirds of the republic is in the south temperate zone, the climate is tropical; but the temperature varies considerably, according to the prevalence of S. or N. E. winds. The mean for the year is about 73° F.; in December and January the thermometer occasionally rises above 100° at Asuncion, and from May to August light frosts are sometimes felt when the S. wind blows. There is no well-marked dry season; showers are more abundant in the warm months, from October to April. In November and December and in June there are frequent tempests, with torrential rains. The whole of Paraguay is healthful, even in the swampy districts of the southwest; malarial fevers are not common, and destructive epidemics are rare. The common diseases arise mainly from poor and insufficient food; lung troubles are almost unknown. Goitre and elephantiasis are endemic in a few districts.

Fauna, Flora, etc.—The animals and plants resemble those of Brazil, but there is an intermixture of the temperate forms of the Argentine Republic. Jaguars, tapirs, deer, wild hogs, etc., are abundant in the wilder districts, and the Paraguay, especially, swarms with alligators. The river-fisheries are very productive. The forests are rich in almost untouched cabinet woods and various drugs. The most valuable forest product is mate or Paraguay tea. The soil, especially in the forest districts, is very fertile. Paraguay is poor in minerals; iron, which is abundant, is little utilized, owing to the lack of coal; copper is reported, and limestone and some varieties of marble are quarried on a small scale.

Population.—Nearly all the civilized population is found in the southern part in a strip along the east side of the Paraguay. The first Spanish conquerors formed numerous unions with the native Guarany women, and their offspring became the ruling class of the country. This half-and-half stock has been perpetuated by intermarriages; it is still the most influential, and by courtesy is called white. The great mass of the population contains far more Indian, and some Negro, blood; almost the only pure whites are a few thousand foreigners. A corruption of the Guarany tongue is still the common language, though Spanish is also spoken in the larger places. The very imperfect census returns of 1886 gave a population of 239,774, evidently much below the truth. The white population was officially estimated in 1898 at 565,000. The wild Indians, nearly all in the Chaco, probably do not exceed 100,000. Before the bloody war of 1864–70 the population was larger. This war was especially destructive to the males, and the excess of women over men is even now very noticeable, especially in the cities. Education and refinement are confined to a small class; the mass of the population is densely ignorant and very poor.

Industries.—The only important industries are agriculture, grazing, mate-gathering, and timber-cutting. The common crops are mandioca, maize, beans, sugar-cane, oranges, and tobacco. The small Paraguayan cigars are greatly esteemed in the Platine states. The republic has (1899) about 2,500,000 head of cattle, principally on large *estancias* in the western and northern districts. There are few good roads, and the only railway runs from Asuncion 156 miles E. and S. E. to Villa Rica, Caazapá, and Pirapó. Ocean steamers ascend regularly to Asuncion and beyond, and there is telegraphic communication with Europe. Owing to its poverty and its inland position, Paraguay is ill able to compete in trade with other South American countries. The exports, generally less in value than 3,000,000 pesos annually, are mainly to the Argentine Republic; the principal items are mate, tobacco and cigars, timber, hides, and oranges. See PARAGUAY in the Appendix.

Government.—The government is a centralized republic; the president is elected for four years, and congress consists of two houses. The recognized and common religion is the Roman Catholic, but all sects are tolerated. Education is nominally compulsory; in 1897 there were about 400 Government or subsidized schools, and there is a national college at Asuncion. The army and navy are insignificant. Owing to bad faith little benefit was derived from foreign loans made soon after the war of 1864–70; and though obligations have been partly met by the sale of public lands, there have been recurring deficits and even default of interest on the foreign debt. A large amount of inconvertible paper currency has been issued. Aside from this the internal debt is small; the entire foreign debt, on Jan. 1, 1893, was 26,523,712 pesos. The basis of value is the silver peso or dollar, nominally worth about 96 cents U. S. currency, but commercially much less. The metric system is legalized, but the old Spanish weights and measures are still in general use.

History.—Sebastian Cabot, seeking a more direct route to Peru, explored the lower Paraguay in 1527. After Pedro de Mendoza founded the first colony of Buenos Ayres, he sent an expedition up the Paraguay under Ayolas, who founded Asuncion about Sept., 1536; Buenos Ayres was abandoned soon after, and Asuncion became the capital of Paraguay, a name which then included the whole Platine region; this was soon after attached to the viceroyalty of Peru. The Guarany Indians, who inhabited the country E. of the Paraguay, were at first very friendly, and though they subsequently rebelled, they were easily subdued. The more warlike Indians of the Chaco resisted the whites from the first, and there were constant struggles with them until the tribes were exterminated or driven into the interior. In 1620 Buenos Ayres was separated from Paraguay, both remaining provinces of Peru until 1776, when Paraguay was attached to the new viceroyalty of Buenos Ayres or La Plata. The Jesuit order had little power in Paraguay until 1611, when it was practically given control of the whole Indian and rural population. Among the Guaranies the missionaries formed numerous and rich establishments, principally in the valley of the upper Paraná and in Misiones (now in Argentina). Each mission was a huge, well-ordered farm; all work was under the absolute control of the Jesuit director, and all produce, after providing for the needs of the workmen, was sold for the benefit of the mission or the order. This system saved the Indians from want and from Spanish slavery, and gave them the rudiments of religious instruction; but it left them childish and fit tools for the political tyrants of later times. The Jesuits had many disputes with the civil and ecclesiastical authorities at Asuncion; several times they were temporarily expelled, and at others they had entire control of the Government. After 1685 the missions suffered severely from the incursions of Portuguese slave-hunters from São Paulo. The order was expelled in 1767, the missions fell into decay, and only the ruins of their fine churches and buildings remain in the forest. Paraguay, following Buenos Ayres, declared its independence in 1811; but it fell almost immediately under the dictatorship of Francia, and took no further part in the struggle for South American independence. Francia was succeeded, after a short interval, by Carlos Antonio Lopez (1841), who bequeathed the government (1862) to his son, Francisco Solano Lopez. All these dictators or presidents continued the policy of isolation which had been introduced by the Jesuits. Foreigners were seldom allowed to enter the country or Paraguayans to leave it, and ignorance and low morals were deliberately fostered. Under cover of this isolation nearly all industries and commerce were drawn into the hands of the chief of state, who practically managed the country as his own property. Though the country made hardly any material or intellectual progress, it was free from debt and generally at peace. The mad ambition of the younger Lopez plunged it into a war with Brazil, the Argentine Republic, and Uruguay, which lasted from 1864 to 1870. (For events of this war see LOPEZ, FRANCISCO SOLANO.) It ended with the death of Lopez, but left the whole country ruined, and its population reduced to little over one-third. Misiones, part of the Chaco, and a considerable territory on the N., were given up to Argentina and Brazil. The present constitution was adopted soon after the war, and since then the republic has enjoyed internal and external peace, but its recovery is necessarily slow. The tide of immigration is slowly increasing. In 1894 an unpopular president was deposed by a bloodless revolution—the first since the war. A boundary dispute with the Argentine Republic, involving part of the Chaco, was referred to the arbitration of the President of the U. S., and in 1878 was decided in favor of Paraguay.

See Demersey, *Histoire physique, économique, et politique du Paraguay* (2 vols., 1860–64); du Graty, *La république du Paraguay* (1865); Washburn, *History of Paraguay* (2 vols., 1871); Bourgade la Dardye, *Paraguay* (Eng. trans. by Ravenstein, with map, 1892).

HERBERT H. SMITH.

Paraguay River: a river of South America; rises near the center of the continent, on the Brazilian plateau of Matto Grosso; flows S. through Brazil, between Brazil and Bolivia, through Paraguay and between Paraguay and the Argentine Republic, and finally joins the upper Paraná to form the lower Paraná near lat. 27° 13′ S. The Paraguay rises in a group of little ponds, the Sete Lagôas, on a low part of the Brazilian plateau, 1,000 feet above the sea. Swelled by numerous affluents it is already a large stream at Villa Maria; 30 miles below and only 400 feet above the sea it enters the great depression of the Paraguay and Paraná. This is a continuous low plain occupying all of Southwestern Matto Grosso, Eastern Bolivia, Western Paraguay, and a large tract in the Argentine Republic W. of the two rivers. By its vegetation and its relations to the river it is divided into three regions—the Charaés marshes, the Gran Chaco, and the pampas. The two latter are described in separate articles. The Charaés marshes, called the Pantanaes by Brazilians, form the northern end of the plain, a tract about 400 miles long from N. to S., and at least 150 miles wide in parts. The Brazilian plateau falls to it sharply, often precipitously, on the N. and E. On the W. there are hills bordering the Paraguay, but through breaks in these the marshes extend far into Bolivia. On this side the great depression is separated from the head-waters of the Madeira only by a low ridge. The Charaés marshes are a confused labyrinth of channels, islands, marshes, and lakes, through which only an experienced pilot can follow the Paraguay and its branches. Most of the land is open, but narrow strips of forest generally follow the channels. The only inhabitants are a few Guató Indians; the few Brazilian settlements are on the highlands bordering the west shore of the river. The Paraguay in this region rises every year, sometimes 40 feet, overflowing the plain and barely leaving a few acres dry here and there. It is remarkable

that the highest waters are toward the end of the dry season (July and August) and the lowest during the rainy season. The reason is that it takes several months for the rains which have fallen on the plateau to spread themselves over this vast basin, and several more mouths are required to drain them off. Near the southern end of the Charaés spurs of the plateau and isolated hills border the river. The Feeho dos Morros (lat. 21° 26′ 40″ S.) is a narrow pass where the river runs between two of these hills. Below this the river hugs the highlands on the eastern side of the great plain and cuts deeper and deeper into the plain itself, which is thus beyond reach of the overflow. In the Chaco, however, large tracts are swampy or are flooded by the rains. The Paraguay is over 1,800 feet wide at Asuncion, and about three-quarters of a mile at its confluence with the Paraná. The longest affluents are the Pileomayo and Bermejo, which join it from the W. in the Chaco region, but they are tortuous and only navigable for short distances. Nearly all the other branches are on the eastern side. The most important navigable ones are the São Lourenço (with its branch, the Cuyabá), the Jaquary, and Miranda in Brazil, and the Jejuy and Tebicuary in Paraguay. The main river is open to free navigation; it is the only commercial outlet of Paraguay and Matto Grosso. Steamers drawing 9 feet ascend to Corumbá, Brazil, at all seasons, and smaller ones to Villa Maria and by the branches to Cuyabá and Miranda. The Paraguay was discovered by Cabot (1526), and explored nearly to its source by Irala and others before 1550. See Page, *La Plata, the Argentine Confederation and Paraguay* (1859); Fonseca, *Viagem ao redor do Brazil* (1880). H. H. S.

Paraguay Tea: See MATE.

Parahyba, păă-răă-ee′băă: one of the smallest states of Brazil; on the extreme eastern part of the coast, between Rio Grande do Norte on the N. and Pernambuco on the S. Area, 28,849 sq. miles; pop. (1894) estimated, 559,271. The coast lands for 30 or 40 miles inland are low; the country then rises abruptly to the Brazilian plateau. As in Ceará, the dry season (April to October) is strongly marked, the vegetation drying up except in favored places; occasionally there are severe droughts, lasting several years. The only river of importance is the Parahyba do Norte, and its mouth forms the only harbor. The principal occupations are grazing and agriculture; the exports are hides, sugar, cotton, tobacco, and rubber. Parahyba, the capital and largest town, is on the right bank of the river Parahyba do Norte, 11 miles above its mouth; pop. about 15,000 (see map of South America, ref. 4–H). It is one of the oldest towns in Brazil, dating from 1579; among the ancient buildings are the cathedral and the college of the Jesuits; the modern Government buildings are unpretentious. Only light-draught vessels can ascend to this point, larger ones anchor at Cabadello, near the mouth of the river, a thriving little town which is rapidly superseding Parahyba as a commercial center. HERBERT H. SMITH.

Parahyba, or **Parahyba do Sul**: a river of Southeastern Brazil; rises in São Paulo, flows eastward between Minas Geraes and Rio de Janeiro, nearly parallel to the coast, and enters the Atlantic near lat. 21° 38′ S. Length (with its principal head, the Parahytinga), 658 miles. The valley of the Parahyba, which separates the Serra do Mar from the Serra da Mantiqueira, is populous, and is one of the richest coffee regions in Brazil. Vessels of light draught ascend to São Fidelis, 54 miles, and an upper section of 193 miles is also navigable for small steamers. H. H. S.

Paral′dehyde: a clear, colorless liquid, having a peculiar ethereal odor and a warm followed by a cold taste. It is prepared by treating ordinary aldehyde at a moderate temperature with small quantities of hydrochloric acid, and is purified by repeated freezing and rectifying. It is employed in medicine as a hypnotic, but has the disadvantage that it is apt to disturb the stomach and that the dose is bulky.

Paralepid′idæ [Mod. Lat., named from *Para′lepis*, the typical genus; Gr. παρά, beside, near + λεπίς, λεπίδος, scale]: a remarkable family of fishes of the open seas, allied to the *Scopelidæ*. The form is elongate and pike-like; the body covered with deciduous scales; the head pointed; opercular apparatus with the subopercular much reduced; the upper jaw with its margin formed by the intermaxillaries, behind which, and closely adherent to it, are the supramaxillaries; teeth on the jaws as well as palate; branchial apertures enlarged; dorsal fin short, far behind, and still farther behind an adipose fin; anal elongated; caudal emarginate; pectorals well developed; ventrals small, inserted below or in front of the dorsal fin. The species are few and confined to northern waters, some occurring at considerable depth, others chiefly in the Arctic. Revised by D. S. JORDAN.

Parallax [from Gr. παράλλαξις, alternation, change in direction between two lines forming an angle, parallax; deriv. of παραλλάσσειν, change alongside of, go aside, deviate; παρά, beside + ἀλλάσσειν, change]: in the most general sense of the word, the difference in the directions of an object as seen from two different points. It is evident that if two observers, A and B, look at the same object, the direction in which they see it will be different according to their distance apart and the character of the triangle which they form with it. The term is mostly used in astronomy, and is applied in a variety of ways, according to circumstances.

In its common acceptation the word is used to mean the difference between the direction of a body from the center of the earth and from any point on its surface. Let us, for illustration, take the case of the moon. From no two points on the earth's surface will the moon appear in absolutely the same direction. Hence in the astronomical ephemeris the direction of the moon at any moment is given as it would be were it seen from the center of the earth; in other words, the right ascension and direction of the moon are those corresponding to a line drawn from the center of the earth to the center of the moon. Actual observations of the moon, however, are made from the surface of the earth. Hence the difference between the direction as seen from the center and from the surface must be computed. If the position of the moon is given by right ascension and declination the difference in question is called *parallax in right ascension* and in *declination*, respectively. If the altitude of the moon above the horizon is in question, the difference between the altitudes as seen from the earth's center and from the position occupied by the observer is called *parallax in altitude*. The same appellations are used in the case of a planet or any other body of the solar system.

As a standard of parallax astronomers take the difference between the direction of a body as it would appear in the horizon to an observer at the equator and as it is seen from the center of the earth. This difference is called the *equatorial horizontal parallax*. It is equal to the angle subtended by the earth's equatorial radius as seen from the object itself, and is therefore an index to the distance of the latter. Actually it is calculated by the aid of the known distance of the body.

The fixed stars are so distant that they appear in absolutely the same direction from every point of the earth. They have therefore no parallax in the preceding sense; but the refined measurements of recent times have shown that there is a slight difference in the direction of a few of the nearest stars as seen from one part of the earth's orbit and from the opposite part. This gives rise to a new parallax, called *annual*, which is defined as the difference between the direction of a star seen from the sun and seen from the earth. This difference does not in any case amount to a single second of arc. Since the parallax of a body depends on its distance, the determination of the distance of the sun, the moon, or a planet is the same as that of determining its equatorial horizontal parallax. For the determination of the parallax or distance of the sun, see SOLAR PARALLAX. S. NEWCOMB.

Parallel′ogram [from Gr. παραλληλόγραμμον; παράλληλος, parallel + γράφειν, write, draw]: a quadrilateral whose opposite sides, taken two and two, are parallel. If one angle of a parallelogram is a right angle, all the other angles are right angles, and the figure is a rectangle. If two adjacent sides are equal, the other sides are also equal, and the figure is a rhombus. The diagonals of a parallelogram mutually bisect each other; conversely, if the diagonals of a quadrilateral bisect each other, the figure is a parallelogram. If the diagonals of a parallelogram are equal, the figure is a rectangle; if they are perpendicular to each other, the figure is a rhombus; if they are equal and perpendicular, the figure is a square. The area of a parallelogram is equal to the product of its base and altitude.

Parallelogram of Forces: See COMPOSITION OF FORCES.

Parallelopi′ped [from Gr. παραλληλεπίπεδον, liter., neut. of παραλληλεπίπεδος, having parallel sides or surfaces; παράλληλος, parallel + ἐπίπεδον, a plane (liter., neut. of ἐπίπεδος, on the ground, level; ἐπί, on + πέδον, ground]: a polyhedron bounded by six parallelograms. If the faces are rectangles, the volume is a rectangular parallelopiped; if the faces are

squares, the volume is a cube. In any parallelopiped opposite faces are equal to each other, as are also diagonally opposite polyhedral angles. A plane through two diagonally opposite edges divides the volume into equivalent triangular prisms. The volume of any parallelopiped is equal to the product of its altitude and the area of its base.

Parallels of Latitude [*parallel* is from Gr. παράλληλος, parallel, liter., alongside of each other; παρά, beside + ἀλλήλων, (of) one another]: on the terrestrial sphere circles drawn around the earth on planes parallel to the equator. Through the center of each circle passes the earth's axis. The equator itself is the only one of these parallels which is a great circle. The others are smaller circles, whose limits are the great circle (the equator) on the one hand, and zero (at the poles) on the other. The tropics and polar circles are important parallels. See EARTH.

Paralysis [= Lat. = Gr. παράλυσις, palsy, deriv. of παραλύειν, disable on (one) side; παρά, beside + λύειν, loosen, dissolve, destroy]: loss of voluntary or reflex motion, generally through failure of nervous excitation. A partial loss of motion is termed *paresis*. A knowledge of the causes of paralysis is easily gained. There are on the surface of the brain certain areas known as motor centers, in which all impulses to voluntary motion originate. From these centers nerve-fibers travel downward, converging at the base of the brain to enter the spinal column. In the latter are secondary motor cells or centers which produce motion only after receiving impulses from the brain, through the fibers indicated. From the secondary spinal-cells originate nerve-fibers which constitute the nerves of the body, and which carry the impulse to the muscles. Paralysis may be due to disease or some destructive change anywhere along this tract, from the cells of the surface of the brain down to the terminal nerve-fiber as it enters the muscle. If the disease is in the brain, we speak of cerebral paralysis, as in apoplexies; if in the spinal cord, of spinal paralysis, as in essential palsy of infants; if in the nerves, of peripheral palsy, as in paralysis from pressure of a crutch on the recurrent spiral nerve of the arm. It is conceivable and possible also to have paralysis due to disease of the muscle without affection of any part of the nervous system, but such cases are exceedingly rare. Idiopathic muscular atrophy is an example of this form of paralysis.

Any part of the body containing muscle fibers, either striped or unstriped, may be paralyzed. Thus we have paralysis of the heart, of the arteries (vaso-motor paralysis), of the intestines, of the limbs, the face, the eyeballs, the pupil, etc. In the study of paralysis it is customary to divide the cases into groups according to the parts of the body affected. HEMIPLEGIA (*q. v.*) is the name used to designate paralysis of one lateral half of the body. It is generally due to a cerebral lesion, and nearly always follows after cerebral hæmorrhage or APOPLEXY (*q. v.*). Sometimes the face is paralyzed on one side, while the arm and leg of the opposite side are affected. This "crossed palsy" is due to disease in the *pons Varolii*. PARAPLEGIA (*q. v.*) is paralysis of the lower half of the body, affecting both legs and perhaps part of the trunk. It is due to disease of the spinal cord, or more rarely of the nerves of the legs. It is practically, though not theoretically, impossible to have paraplegia of cerebral causation. *Monoplegia* is the paralysis of a single member, as one arm or leg. It is due to disease of the peripheral nerves, or to affection of the motor center on the surface of the brain. In the lower part of the brain and in the spinal cord a diseased area is more apt to involve fibers of many muscles.

Multiple paralysis is the term by which are designated groups of palsies of irregular distribution. Glossoplegia (paralysis of the tongue), cycloplegia (paralysis of the pupil), laryngeal palsy, etc., are instances of *local paralysis*, in which only a certain muscle or group of muscles is affected. See FACIAL PARALYSIS, and for *General Paralysis* see INSANITY.

WILLIAM PEPPER.

Paralysis Agitans, or **Shaking Palsy**: a disease of advanced age, characterized by weakness, tremor, and rigidity of the muscles. Men are more often affected than women, and worries and mental strain are important causes. Sometimes the shaking of fear has been followed directly by this disease. There is a fine and continuous tremor of the hands, feet, and less commonly of the head, which, however, ceases during sleep. The muscles are apt to be rigid, and a peculiar mask-like immobility of the facial expression is a marked characteristic. The weakness of the muscles is rarely marked, but is a constant symptom. There is a peculiar staggering gait in which, as one author remarks, the patient seems to be running after his center of gravity. The disease is incurable.

WILLIAM PEPPER.

Paramar'ibo: capital and principal town and port of Dutch Guiana; on flat land by the right bank of the Surinam river, which is navigable beyond this point; 19 miles above its mouth (see map of South America ref. 2–E). It presents a very fresh and pleasing appearance, owing to its wide streets, shaded with orange and tamarind trees, and the gardens around most of the houses. Nearly all the buildings, and even the governor's mansion, are of wood. There are many Protestant and Catholic churches, hospitals, barracks, etc. The climate is warm, and the place has a reputation for unhealthfulness, but it is improving in this respect. The principal export is sugar. Paramaribo dates from the end of the sixteenth century; it was twice bombarded by the French, and has repeatedly been almost destroyed by fire, the last time in 1822. Pop. (1890) 28,831.

HERBERT H. SMITH.

Paramat'ta: town of New South Wales, Australia; on a river of the same name, near its entrance into Port Jackson, on which Sydney is situated (see map of Australia, ref. 7–I). It is a well-built and growing town. Pop. (1891) 11,680.

Revised by C. C. ADAMS.

Param'eter [Gr. παρά, beside + μέτρον, measure]: in mathematics, a term generally expressing a quantity, by whose variation systems of equations or curves, etc., are represented. Thus if the shape and magnitude of a curve be considered, but not its position, the radius is the sole parameter of a circle, and the major and minor axes of an ellipse are its two parameters. The coefficients in the equation, or equations, of a curve may be considered as parameters determining its shape, magnitude, and position in a plane or in space, as the latter differ from those of another curve of the same species. In particular if a conic section be written in rectangular co-ordinates

$$y^2 = px \pm mx^2$$

(which represents a parabola if $m = o$), the quantity p is called the parameter. (See PARABOLA.) Further, a parameter is also used to denote a variable, in terms of which the co-ordinates of a point on a curve can be expressed. If the co-ordinates involve the parameter rationally, that is, without square roots or other radicals, the entire curve can be described by continuous motion of a point, and is said to be *unicursal*.

R. A. ROBERTS.

Pāramitās [Sanskr.]: in Buddhism, "transcendent virtues," the practice of which leads to Nirvāna, or "the other shore." These are six in number, but other four are sometimes added. They are (1) charity, or generosity in giving to all who ask; (2) moral conduct; (3) patience; (4) energy or fortitude; (5) fixed contemplation, or meditation (see DHYÁNA); and (6) wisdom. The four added virtues are variously given. Those usually enumerated are (*a*) truth; (*b*) steadfastness of resolution, or fixedness of purpose; (*c*) good-will, or kindness; and (*d*) imperturbability, or apathy.

R. LILLEY.

Paraná, păă-răă-naa': a southern state of Brazil, bounded N. by São Paulo, E. by the Atlantic, S. by Santa Catharina, and W. by the river Paraná, which separates it from Paraguay and Matto Grosso. Area, 85,438 sq. miles; pop. (1894) estimated, 223,942. A strip of low and often swampy land along the coast is succeeded, 20 miles inland, by the Brazilian coast range, which here rises in parts to more than 5,000 feet, but with passes below 3,200 feet; the mountains and coast strip are covered with forest, the most abundant trees above 3,000 feet being Araucaria pines. W. of the coast range is the open table-land of Curitiba, 3,000 feet above the sea; farther inland this falls, by a succession of terraces, toward the Paraná; the western part of the state is an almost unknown forest, with intervals of open land, and is inhabited only by roving Indians. All the important rivers flow to the Paraná; the principal ones are the Paranápanéma on the northern frontier, the Ivahy, the Piquiry, the Taquary, and the Iguassú on the southern boundary; none of these is freely navigable. Nearly all the population is gathered on the high plateau, where there are considerable colonies of German and Italian immigrants. Paraná is one of the poorest and most backward of the Brazilian states, though it has abundance of fertile land, especially in the western part. Agriculture, grazing on the open lands, and the collection of mate are the only important industries; almost the sole export is mate. The capital, Curitiba,

is connected with the principal port, Paranaguá, by railway. Paraná was separated from São Paulo in 1853. See Bigg-Wither, *Pioneering in South Brazil* (1878). H. H. S.

Paraná (originally *Bajada del Paraná*): capital and largest town of the province of Entre Rios, Argentine Republic; on a bluff overlooking the right bank of the river Paraná, nearly opposite the mouth of the Salado (see map of South America, ref. 8–E). It is the center of a rich grazing region, and in the vicinity are thriving colonies of Germans, Swiss, and Italians; steamers ascending the river touch regularly at this port, which is connected by railway with Concepcion, on the Uruguay. Paraná was founded in 1730. From 1852 to 1861 it was the capital of the Argentine Republic. Pop. (1892) about 20,000. H. H. S.

Paraná: one of the largest rivers in South America; draining, with the Paraguay, nearly all the space between the Brazilian coast range and the Andes, from about lat. 16° to lat. 35° S. It rises in Brazil, flows at first S. W., then S. and W. along the borders of Paraguay, separating that country from Brazil and the Argentine Republic; and finally, after being joined by the Paraguay, keeps a southward course through the Argentine to the Rio de la Plata and the Atlantic. The upper Paraná, or the portion above the junction of the Paraguay, is essentially a highland river. Its two main heads are the Parnahyba, 500 miles long, rising in the Pyreneos Mountains of Goyaz, and the Grande, 650 miles long, rising in the Brazilian coast range of Minas Geraes; both are obstructed by rapids and falls. They meet at the angles of the states of Minas Geraes, São Paulo, Matto Grosso, and Goyaz, near lat. 19° S. The united flood, now called the Paraná, separates São Paulo and Paraná from Matto Grosso. Shortly below the junction is the little-known cataract of Urubú-ponga. Below this the river flows over the table-land without serious obstruction for 600 miles. At the foot of this navigable part it is broken by a large island, and forms a lake-like expanse. Suddenly the whole flood is poured into more than twenty narrow clefts, spreading over an arc 2 miles wide, and converging in a basin 70 feet below. In each chasm the water leaps over a fall, and then rushes down a slope with immense velocity. This is the celebrated but seldom visited cataract of Guayrá, or the Sete Quedas, where the Paraná begins to form the frontier of Paraguay (lat. 24° 2′ 59″ S.). Below it the river rushes for 400 miles through a deep valley, often between cliffs, and with a constant succession of rocky shallows and rapids. The last obstruction is the rapid of Apipé, 150 miles from the junction of the Paraguay, and marking the limit of navigation on the lower river. The valley of the upper Paraná, above Apipé, has few civilized inhabitants, and from the Guayrá fall down it is occupied by an extensive forest. In direct contrast the lower Paraná is a river of the plains—like the Paraguay. It is, indeed, properly a continuation of the Paraguay (*q. v.*), pursuing the same southerly course; but in length and volume of water the Paraguay is the lesser of the confluents. The lower Paraná has cut rather deeply into the pampas, which appear as clay cliffs on the west side. In parts it is over 2 miles wide, and by its sea-like reaches resembles the Amazon. It is entirely navigable for large vessels. The most difficult navigation is near the mouth in the Plata, where for over 200 miles a multitude of low islands forms a delta. The deepest channels in this region give over 15 feet when the river is lowest. The Rio de la Plata is properly the estuary of the Paraná, though also receiving the Uruguay, which may be regarded as a branch. The length of the lower Paraná is 850 miles, or, with the Plata, 1,080 miles. From the mouth of the Plata to the head of the Rio Grande, which may be regarded as the source of the Paraná, the distance by the rivers is about 2,950 miles. Aside from the Paraguay with its numerous branches, the principal affluent of the lower Paraná is the Salado, on the western side, and it is not navigable. The chief branches of the upper Paraná are on the eastern side, in Brazil (São Paulo and Paraná). The most important are the Pardo, Tiete, Agoapehy, Paranapanéma, Piquiry, and Iguassú. These rise on the well-peopled western slope of the coast range, and they are navigable for greater or less distances in their upper courses, but are obstructed by falls and rapids as they approach the Paraná. Those which join it in the great gorge below the Guayrá fall often have cataracts at or near their mouths. One of these, on the Iguassú (or Yguazú), 6 miles above its mouth, is easily accessible, and hence has often been visited by travelers. The river, divided into several channels, falls over a horseshoe-shaped precipice nearly 200 feet high, forming a scene said to rival Niagara. Herbert H. Smith.

Paranaguá, pă̆ă-ră̆ă-nă̆ă-gwaa′ (sometimes written *Parnaguá*): principal seaport of the state of Paraná, Brazil; on Paranaguá Bay; terminus of a railway which crosses the mountains to Curitiba (see map of South America, ref. 7–F). Pop. about 7,000. The harbor is large and good, but there is little commercial activity. The principal export is mate. There are few good buildings, the streets are badly paved, and the climate is hot and often unhealthful. H. H. S.

Paranahyba: See Parnahyba.

Paranaphthalene: See Anthracene.

Paranhos, José Maria da Silva: See Silva Paranhos.

Parapet: See Fortification.

Paraple′gia [Mod. Lat., from Gr. παραπληγία, hemiplegia, deriv. of παραπλήσσειν, to strike beside or at the side; παρά, beside + πλήσσειν, strike]: loss of motor power in both legs. It is almost always due to injury or disease of the spinal cord or its membranes, though it sometimes happens that a neuritis involves the nerves of the legs alone. The onset is sudden when caused by wounds, hæmorrhage into the substance of the cord, or fracture or dislocation of the spinal column, rapid when caused by myelitis or meningitis, and slow when due to pressure from a tumor or from Pott's disease. Paralysis of the bladder and rectum are generally present. The character of the palsy varies with the level of the lesion in the cord. If it involve the whole transverse area of the cord there is complete loss of sensation below. If it be in the lumbar region, there is absence of the reflexes and wasting of the muscles. If higher up, there is rigidity, no wasting, and the reflexes are increased. The term is sometimes used, but improperly, to include cases in which the arms as well as the legs are palsied. See Paralysis.
William Pepper and C. W. Burr.

Pará River: a large inlet in the coast of Brazil, state of Pará, S. E. of the island of Marajó, generally regarded as the southern mouth of the Amazon. Physically, it is the estuary of the river Tocantins, but through a network of channels S. and W. of Marajó it receives a volume of Amazonian water exceeding that of the Tocantins itself. These channels are navigable for large vessels, and owing to the strong currents and unsheltered banks of the true mouths of the Amazon, the Pará has always formed the natural outlet of that river. The Pará, up to the junction of the Amazonian channels, is 120 miles long, 10 miles wide above and over 30 miles at the mouth. The effect of the tides is felt in strong currents, but no salt water enters it.
Herbert H. Smith.

Par′asang [from Gr. παρασάγγης, from O. Pers.; cf. Pers. *farsang*]: a Persian measure of distance. Herodotus (ii., 6, etc.), Xenophon (*Anab.* ii., 2, § 6), Suidas, and Hesychius are all agreed in estimating the parasang at 30 stadia, or about $3\frac{2}{5}$ miles. Afterward the measure seems to have varied; for in a Byzantine writer, Agathias (about 530 A. D.), we find the parasang reckoned at 21 stadia. Strabo (xi., p. 518) states that it was variously reckoned at 30, 40, and even 60, stadia. According to Pliny (*Nat. Hist.*, vi., 30), the Persians themselves were divided as to its length. The parasang is still in use among the Persians. Modern travelers concur with Herodotus and Xenophon in fixing its length variously at from $3\frac{1}{2}$ to 4 miles.

Paraselenæ: See Halo.

Parasita: a sub-order of insects which includes the Lice (*q. v.*). See also Entomology.

Parasites [from Gr. παράσιτος, liter., eating beside or at another's table; παρά, beside + σιτεῖν, to take food, deriv. of σῖτος, food]: originally, persons who flattered the rich and were fed at their tables; in zoölogy, animals that live in or on other animals. In its broad sense parasitism includes all cases where one organism depends upon another for its food; but, as more usually employed, it is limited to those still numerous cases where there is a more or less intimate connection between the gainer in the process, the *parasite*, and the form lived upon, the *host*. Even with these limits there are different degrees of parasitism to be recognized, which may be grouped under the heads commensalism, symbiosis, and parasitism proper. In commensalism there is an association of forms wherein, so to speak, one profits from the crumbs which fall from the other's table. Thus in the mouth of the menhaden there frequently occurs a crustacean "messmate" which holds to the roof of the mouth by

its sharp legs, and there selects its food from the objects eaten by the fish. In symbiosis there is a reciprocity which does not exist in commensalism. Each profits to a greater or less extent by the other's presence. Thus we have certain hermit-crabs which constantly bear sea-anemones about upon the shell which they inhabit; the anemone profits from the particles of food dropped by the crab, while the crab receives protection from its enemies, many of which do not care to brave the nettle-cells of the anemone. Slightly different is the case of the "yellow cells" of the Radiolaria. Here we have an association of animal and plant, the former profiting by the oxygen given off by the latter, while the plant in turn uses the carbon dioxide produced by the animal. In parasitism proper the parasite lives directly upon the substance of the host. The union between them may be only temporary, as in the case of the leeches, which attach themselves to other animals only while sucking blood; or it may be permanent, as in the great majority of parasitic worms. In the latter there may be external or internal parasitism; but in all cases there is such an adjustment of one to the other that while the host is weakened by the drain, it but rarely, and then slowly, succumbs. Its preservation is necessary to the perpetuation of the parasitic species.

In one way or another all groups of the animal kingdom present instances of parasites. Passing by the tapeworms, trichina, etc., we may here instance a few of the more interesting cases. Among the vertebrates the fishes alone afford cases of parasitism, and prominent here are the lampreys and hagfishes, the former living upon the slime excreted from the bodies of other fishes, the latter actually burrowing their way into the body-cavity of the cod. Among the molluses parasites are rare. Most striking is the case of *Entoconcha*, the young of which is a true gasteropod, while the adult, an elongate worm-like body without a trace of mollusean features, lives in the intestine of certain holothurians (*Synapta*). In the Crustacea parasites occur among the Isopoda, the barnacles, and especially among the Copepoda, and in the latter group almost every grade can be found to illustrate that law of nature that the more perfect and more prolonged the parasitism, the more complete the resulting degradation. Thus in the Lerneans almost every crustacean feature has disappeared; all that remains may be summed up as means of fixation and absorption, combined with enormous organs for the reproduction of the species. True parasitism is rare among the Cœlenterates, but here must be instanced the hydroid *Hydrichthys*, described by Fewkes as parasitic upon certain fishes.

LITERATURE.—Cobbold, *Entozoa* (London, 1864); P. J. van Beneden, *Animal Parasites and Messmates* (New York, 1876); Leuckart, *Die Menschlichen Parasiten* (Leipzig, 1863–68).

J. S. KINGSLEY.

Parasites, Human: Man is liable to invasion of a considerable variety of parasitic organisms, both animal and vegetable. The latter, by far the more important and numerous, belong to the families of bacteria. Upon them are dependent many of the infectious diseases, such as tuberculosis, typhoid fever, and diphtheria. (See BACTERIOLOGY.) The animal parasites are much less varied and frequent, but are still quite numerous. Some forms live upon the exterior parts of the body, and are known as *Ectozoa*; others within the cavities or tissues, and are called *Entozoa*.

Ectozoa.—These include representatives of the Inseeta, such as lice, fleas, chiggers, etc.; and of the Arachnoidea, such as the mites found in acne pimples, or the itch-mite. A very important class of lower organisms belonging to the Protozoa have recently been discovered in certain skin diseases, such as molluscum contagiosum and Paget's disease of the nipple. These belong to the genus *Coccidium*. They invade the epithelial cells of the skin and lead to their destruction. A similar organism is claimed as the cause of cancer. The evidence is not yet conclusive, but is very suggestive.

Entozoa.—Among the internal parasites are species of various families of Protozoa, Arachnoidea, and Vermes. Of the Protozoa, to which of late attention has been specially directed, the important forms are the *Amœba coli*, which occupies the intestinal canal and causes certain forms of dysentery; the *plasmodium malariæ*, an organism which thrives in the blood in malarial fever and is doubtless the cause of this disease. The *coccidia* occur in the intestines and liver as well as in the skin. Other Protozoa of the intestinal canal, such as *Trichomonas* and *Cercomonas*, *Megastoma entericum* and *Paranœcium coli*, are relatively unimportant.

Of the Arachnoids but one occurs, and that rarely—the *Pentastoma tœnioides*. This organism occupies the nasal cavities and frontal sinuses of various animals, and occasionally of man. Its larvæ, *Pentastoma denticulatum*, are found in the liver or spleen, less frequently in other organs, of man and various animals.

By far the most important group of animal parasites of man are the worms, of which the cestodes or tapeworms, the trematodes or flukeworms, and the nematodes or roundworms are the subdivisions met with. The commonest of the tapeworms in America is the *Tœnia saginata*, the beef tapeworm, but occasionally *Tœnia solium* (pig), and *Tœnia elliptica* (cat and dog), and *Bothriocephalus latus* (fish) are met with. The last named is very common in parts of Switzerland, Norway, and other countries. Man is the occasional host of the adult *Tœnia echinoccous*, a dog tapeworm; but very frequently the larvæ of this form occur in man, producing the so-called hydatid cysts of the liver and other parts. This disease is common in Iceland and Australia. Rarer tapeworms of man are *Tœnia nana*, *T. flavopunctata*, *T. madagascariensis*, *T. negré*, *T. tarella*, *T. algeriana*, *T. of Cape of Good Hope*, also *Bothriocephalus cordatus* and *cristatus*.

The trematodes or flukeworms are comparatively unimportant, being much less frequent. There is a number of the genus *Distoma*, including *D. hepaticum*, the liver fluke, *D. hæmatobium*, the blood fluke, and the less frequent *D. lanceolatum*, *D. conjunctum*, *D. rathonisi*, *D. heterophyes*, *D. spathalatum*. An interesting form is *D. pulmonale*, the lung fluke of Japan, Korea, and other Eastern countries. *Monostoma lentis* and *Amphistoma hominis* are rare forms.

The nematodes include some of the most frequent and important forms, such as the common roundworm, *Ascaris lumbricoides*, the seatworm or pinworm, *Oxyaris vermicularis*, and the destructive *Trichina spiralis*, derived from improperly cooked meat of the hog. Relatively unimportant forms are *Ascaris mystax*, *Anchylostoma duodenale* (the organism so prevalent among the workers at St. Gothard's tunnel), *Strongylus longevaginatus*, *Eustrongylus gigas*, *Rhabdonema intestinalis*, *Trichocephalus dispar* (the whipworm), *Filaria bancroftii*, *medinensis*, and *loa*. *Echinorhynchus hominis* is the only representative of the Acanthocephali.

It will be seen that the number of animal parasites is large, and that the variety of forms is very great: moreover, very frequently several forms are found coexisting, and a patient may suffer invasion by a number of the same or different forms in succession. Habits of uncleanliness are the greatest cause of internal and external parasites. The larvæ are carried to the mouth or exterior of the body by unclean hands, clothing, and the like. Tapeworms are conveyed to man in the larval form in "measled" flesh of the beef, hog, or fish, or more directly by the eggs being taken in water or food. The prevention of parasites therefore requires careful attention to habits of cleanliness and to the proper preparation of food.

WILLIAM PEPPER.

Parasites, Vegetable: plants which live upon other living organisms, and obtain their food wholly or in part from their living tissues. They are to be distinguished from SAPROPHYTES (*q. v.*), which obtain their food from dead tissues.

As in animals, so in plants, we must regard all parasites as having been derived from non-parasitic forms. In many cases this derivation is quite obvious: thus the dodders (species of *Cuscuta*) are clearly modified members of the morning-glory family (*Convolvulaceæ*), the Indian pipe (*Monotropa*) is essentially a modified heath (*Ericaceæ*), the downy mildews (*Peronosporaceæ*) are structurally so nearly like the green felts (*Vaucheriaceæ*) that they have been long associated with them, etc. In other cases their derivation is not so obvious, as in the black fungi, rusts, and smuts.

It is a well-known law that parasitism is always followed by structural degradation, especially of the vegetative organs, and where the parasitism is excessive, all parts of the organism suffer degradation. Thus parasitic flowering plants are usually leafless, or nearly so, as in *Cuscuta* and *Monotropa*, and the degradation has been carried so far in *Rafflesia* and its relatives, and in *Balanophoraceæ*, that the ovules and seeds are reduced to a state of great simplicity. Where the parasitism is partial, as in the Mistletoe, the leaves are still well developed, both structurally and functionally, but with an increased dependence of the parasite

upon its host the leaves are chlorophyll-less and bract-like, as in *Arceuthobium*, a relative of the mistletoe.

The principal families in which parasites occur in the vegetable kingdom are distributed as follows: In the Protophytes, the bacteria; in the Phycophytes, the black moulds, fly-fungi, water-moulds, downy mildews, etc.; in the Carpophytes, many families (twenty or more) of the fungi; in the Anthophytes, the orchids (a few genera), vine-rapes (*Cytinaceæ*), mistletoes (*Loranthaceæ*), Balanophorads, Indian pipes (*Monotropeæ*), morning-glories (the dodders, of the genus *Cuscuta*), and broom-rapes (*Orobanchaceæ*). Few, if any, of the mossworts and fernworts are true parasites, and none of the Gymnosperms. It is impossible to give the total number of parasites in the vegetable kingdom, but from 12,000 to 15,000 lower plants (Protophytes, Phycophytes, and Carpophytes), and about 1,000 Anthophytes are true parasites. To these should be added also many species which are partially parasitic. See DEGENERATION and VEGETABLE KINGDOM.

CHARLES E. BESSEY.

Parasols: See UMBRELLAS.

Parcæ: See FATES.

Parchments [M. Eng. *parchemin*, from O. Fr. *parcamin*, *parchemin* : Ital. *pergamena* : Span. *pergamino* < Vulg. Lat. **pergami'num* for *pergame'num*, deriv. of Pergamum, a city in Mysia where parchment is said to have been first used]: the well-cleansed and carefully dried skins of hares, rabbits, calves, asses, or sheep. Common parchment is prepared from sheepskins, but vellum, a far finer variety, is made from the skins of young calves, goats, or still-born lambs. Sheepskins are often split and made to yield two sheets of parchment. The skins are soaked in water, and then subjected to the action of milk of lime. The wool or hair is then removed, the skins are washed, planed with a sharp knife to remove superfluous parts, and then stretched on frames singly and dried in the air. For bookbinders' use the dried parchment is planed to impart a rough surface, capable of being dyed or written upon. The dried parchment is finally dusted over with chalk and rubbed with pumice-stone. Drum-heads are made from calves' skins, heads of kettle-drums from asses' skins, sieves for gunpowder-mills from hogs' skins. Parchment was known long before the invention of paper. It is made at Bentheim and Schuttorf in Hanover, at Augsburg, Nuremberg, Breslau, and Dantzic, and in Holland, England, and France.

Revised by IRA REMSEN.

Pardessus, pär'dā'sü', JEAN MARIE: jurist; b. at Blois, France, Aug. 11, 1772; studied jurisprudence; became mayor of Blois in 1805; member of the Legislative Assembly in 1807; Professor of Mercantile Law at Paris in 1810; member of the Chamber of Deputies 1815–16 and 1824–27, but retired from public life after the Revolution of 1830. D. on his estates near Blois, May 26, 1853. By his numerous works, of which the most prominent are *Traité des Servitudes* (1806), *Traité du Contrat et des Lettres de Change* (1809), *Éléments de Jurisprudence commerciale* (1811), *Cours de Droit commercial* (1814–19), *Collection des Lois maritimes antérieures au 18e siècle* (6 vols., 1828–45), *Us et Coutumes de la Mer* (1847), a *Collection des Ordonnances des Rois de France*, with an introductory essay on the organization of the French courts, etc., he exercised a great influence on French jurisprudence.

Par'do, MANUEL: statesman; b. at Lima, Peru, Aug. 12, 1834. He came of a wealthy family, was educated in Chili and Europe, and was established as a banker in Lima, besides conducting several large plantations and holding various public positions. From Aug. 2, 1872, to Aug. 2, 1876, he was president of Peru. He was the first civilian ever elected to this office, and was one of the best and most popular presidents that Peru ever had. Subsequently he was president of the senate. He was assassinated by an obscure person, who attacked him in front of the senate-house at Lima, Nov. 16, 1878. HERBERT H. SMITH.

Pardo Bazán, EMILIA: novelist and critic; b. at Corunna, Galicia, Spain, in 1852. In 1868 she was married to Señor Quirogariche, a proprietor in her native province. Later, however, she lived mainly in Madrid, though her imagination still preferred Galician themes. As a novelist she is distinguished by great truth of local coloring, and by the kind of realism in depicting life and action of which Mr. Howells is the chief representative in the U. S. Among her novels may be mentioned *Los Pazos de Ulloa* and its continuation, *La madre naturaleza*; *La piedra angular*; *La tribuna*; the novelettes *Insolación* and *Morriña*; *Pascual Lopez, autobiografía de un estudiante de medicina*; the collection of tales, *Cuentos de Marineda*; *El Cisne de Vilamorta*; *Una Cristiana* and its sequel, *La Prueba*. As critic she has written *Estudio crítico de las obras del P. Feijóo* (1876); *San Francisco de Asis*; *Siglo XIII.* (2d ed. 1886); *La Revolución y la Novela en Rusia* (1887); *La Cuestión palpitante* (realism *vs.* romanticism, 4th ed. 1891). In *Mi Romería* (1888) and *De mi Tierra* (1888) we have impressions, recollections, and reflections of a more serious kind connected with her Galician home. This also is the character of her studies in folk-lore—*Folk-lore gallego*—*Miscelánea* (1884). In 1891 she began to issue a periodical, devoted to theatrical criticism, written wholly by her own pen—*Nuevo Teatro crítico*. On the whole, she is the most important woman of letters now writing in Spain. Her *Obras Completas* in a new edition began to appear in Madrid in 1891 (9 vols., 1891–93). A. R. MARSH.

Pardon [from O. Fr. *pardon*, deriv. of *pardonner*, concede, indulge, pardon; *par-* (< Lat. *per-*), thoroughly + *donner*, give]: an act of grace by which an offender is released from the consequences of his offense, so far as such release is practicable and within the control of the pardoning power. In monarchies it is a prerogative of the king, who is deemed the source of justice. It is properly employed to correct some injustice for which the ordinary judicial machinery does not provide, or to make allowances for exceptional circumstances, or from considerations of public policy.

Power to Pardon.—A serviceable Parliament once declared that the King of Great Britain hath the whole and sole power of pardon, "united and knit to the imperial crown of this realm." (27 Hen. VIII., c. 24.) The royal prerogative, however, even in the matter of pardons, has been greatly curtailed since the age of the Tudors. A pardon can not be pleaded to an IMPEACHMENT (*q. v.*). The committing any person to prison out of the realm is unpardonable by the crown. (31 Car. II., c. 2.) Nor can the British sovereign by pardon inflict an injury on an innocent person, "as in the case of a nuisance yet unredressed, or of a breach of certain statutes after an informer has become entitled to a reward payable out of the penalty." The pardon can operate only to relieve the offender from his liability to the crown. It can not affect the private rights of individuals. At present the sovereign exercises this prerogative upon the recommendation of the Home Secretary. It is rarely employed, save in cases of serious miscarriage of justice, which can not be remedied otherwise: or in the cases of political offenders who engaged in riots, unlawful assemblies, or other like proceedings for the purpose of influencing the action of Parliament or public officials.

In the U. S. the pardoning power is the subject of constitutional provision. It is generally vested in the executive. The Federal Constitution authorizes the President "to grant reprieves and pardons for offenses against the U. S., except in cases of impeachment." (Art. ii., § 2.) It is to be noticed that "offenses against the U. S." can be pardoned only by the President. Offenses against the several States are pardonable by the injured State alone. Again, the private consequences of a wrong are not subject to the pardoning power of the President. Within the constitutional domain, however, the President's prerogative of pardon is unlimited; "it conveys the idea of the power exercised by the English crown, or by its representatives in the colonies"; it "extends to every offense known to the law, and is not subject to legislative control." (*Ex parte* Wells, 18 Howard 307; *ex parte* Garland, 4 Wallace 333.) It may be exercised before conviction, or even before indictment; and there is judicial authority for the doctrine that it extends to persons committed for contempt of court. (*Re* Mullee, 7 Blatchford 23.) This view has been severely criticised. See 45 *Albany Law Journal*, 1, and authorities cited.

Forms of Pardon.—In Great Britain a warrant of pardon must be certified by the great seal affixed by the Lord Chancellor, or, in cases of felony, by the sovereign's sign-manual countersigned by a principal Secretary of State. In the U. S. the usual form is a writing signed by the executive, with the great seal attached. Where this form is employed, delivery and acceptance are necessary to its validity. A pardon may be limited to a specified individual and a particular crime, or it may be framed to include a number of named individuals, or even a class of persons designated otherwise than by name. It may be granted by a general

proclamation, and take effect from the time it is signed. It may be absolute, or it may be given upon a condition precedent or subsequent. It may also take the form of a commutation of punishment, though it can not substitute a punishment of a different nature.

Its Effect.—An absolute pardon releases the offender from all disabilities imposed by public law, and restores him to all his civil rights, in the absence of a statute to the contrary—e. g. 2 N. Y. R. S. 139, § 7. It gives him a new credit and capacity. It does not make amends for the past, nor afford relief for what has been suffered by imprisonment, forced labor, or otherwise. (*Knote* vs. *U. S.*, 95 U. S. 149, 153.) It restores a convicted criminal's competency as a witness, even though it recites that it was granted because his testimony was desired by the Government (*Boyd* vs. *U. S.*, 142 U. S. 450); but the conviction may be used to affect his credit. If the pardon is granted upon a condition precedent, the condition must be performed before the pardon takes effect. If the condition is subsequent, its breach operates to annul the pardon, and to transform its effect into a reprieve or stay of execution. In such a case the prisoner can not be arrested and remanded to his original punishment upon the mere order of the executive, unless the pardon contains an express provision, or a statute gives clear authority therefor; but he is entitled to a hearing before a competent court, though not to a jury trial, upon the question whether he has broken the condition. (*State ex rel. O'Connor* vs. *Wolfer*, 53 Minn. 135.) A pardon induced by deception is void. An executive pardon must be brought to the attention of the court by appropriate procedure, generally by a special plea; but courts are bound to take judicial notice of a pardon by act of Parliament.

FRANCIS M. BURDICK.

Paré, păă′rā′, AMBROISE: surgeon and author; b. at Bourg-Hersent, near Laval, Maine, France, 1517; became an apprentice to a barber-surgeon in Paris; also studied surgery; joined the society of St. Côme, and in 1536 entered the army in Italy as a surgeon. His introduction of the ligature for bleeding arteries after amputation was the foundation of modern surgery, and he wrote a work on gunshot wounds which is still of value. His great invention dates from 1536. When the supply of oil failed the army in Piedmont (for up to that time hot oil was used to stanch bleeding), he was obliged to tie arteries with a thread, and found that cases where the ligature was employed did much better than the others. From 1552 to 1590 he was surgeon to four French kings. He was a devout Huguenot (although Malgaigne denies it), but his reputation for surgical skill saved him at the massacre of St. Bartholomew and at other critical junctures. His professional works are very much in advance of his times, in spite of the fact that he was only a barber-surgeon, and as such unrecognized by the surgical faculty. His principal work was *Cinq Livres de Chirurgie* (1562). D. in Paris, Dec. 22, 1590. See the *Life* by Paulmier (Paris, 1884), and the article SURGERY.

Paregoric [from Lat. *parego'ricus* = Gr. παρηγορικός, deriv. of παρήγορος, soothing, consoling; παρά, beside + ἀγορεύειν, speak, harangue, deriv. of ἀγορά, assembly]: a well-known anodyne compound (*tinctura opii camphorata*), made by taking 4 grammes of powdered opium, benzoic acid, and camphor, and adding 4 cc. of oil of anise, 40 cc. of glycerine, and enough diluted alcohol to make 1,000 cc. The preparation is completed by shaking, maceration, and filtration. It is a mild anodyne and antispasmodic.

Pareira Brava [Portug.; *pareira*, from the Brazilian name + *brava*, brave, i. e. of full strength]: the dried woody root of some South American climbing plants of the family *Menispermaceæ*. It is a tonic and diuretic drug, used especially in chronic inflammations of the bladder and the urinary passages. The plant in question was long supposed to be the *Cissampelos pareira*, but Hanbury ascertained that it is *Chondodendron tomentosum* of Ruiz and Pavon, *Cocculus chondodendron*, D. C.

Parenchyma: See HISTOLOGY, VEGETABLE (*Soft Tissue*).

Parent and Child: English common law secures to the parent the right to the custody and discipline of his minor children, and to their services.

Custody and Discipline.—This right is accorded to the parent that he may properly train his offspring, and give them a proper education in learning, morals, and religion. It is subject to the state's supervision. A serious abuse of it by the parent, or by one to whom he has delegated it—for example, a school-teacher—is treated as a CRIME (*q. v.*), and will also sustain an action in TORT (*q. v.*) against the offending delegate. It has been held, however, that public policy forbids the maintenance of a tort action by the child against the parent in such case (*Hewlett* vs. *Ragsdall*, 68 Miss. 703); but its abuse may work a forfeiture of the parental right. In *Wellesley* vs. *Duke of Beaufort*, 2 Russell's Reports, the father insisted "that a man and his children ought to go to the devil in their own way if he please;" but Lord Eldon decided that the law recognized no such right. It is well settled that if a father is guilty of gross ill-treatment or cruelty toward his infant children, or if he habitually indulges in drunkenness, or blasphemy, or gross debauchery, or if his domestic associations tend to the corruption of his children, or if his acts are in any manner seriously injurious to their morals or interests, a court of chancery will deprive him of their custody and discipline, and appoint a suitable person as their guardian, to care for them and superintend their education. This practice is based upon the doctrine that parents have no right of property in their offspring; that their parental rights are accorded to enable them to perform their parental duties, and that such rights are held in trust to be forfeited to the state by their abuse. However, courts will interfere between parents and children with great caution, and only in cases where the parent's wrongdoing and the child's danger are clearly established. In many of the U. S. societies for the prevention of cruelty to children have been incorporated, with authority to institute various proceedings on behalf of minors whose parents, guardians, or custodians treat them unlawfully. See ch. 122 *N. Y. Session Laws*, 1876.

Services.—The parent has a legal right to the services of his minor children while within his custody, and to any wages which they may earn in the service of others. He may waive this right by emancipating or freeing the child from parental subjection; or, in some States, by his failure to notify the employer, pursuant to statutory requirement, that the wages must be paid to him and not to the child. According to the prevailing view, the legal marriage of a minor emancipates him or her from parental control. (*Commonwealth* vs. *Graham*, 157 Mass. 73.) An unlawful injury to the child, which invades any parental right, will subject the wrongdoers to an action by the parent as well as to one by the child. Hence where a child had recovered $2,800 for personal injuries, the parent was allowed to recover against the same defendant for loss of service and for reasonable expenses in the care and cure of the injured child. *Horgan* vs. *Pacific Mills*, 158 Mass. 402.

Parental Duties.—It is generally declared that these are maintenance, protection, and education, though to what extent the common law obliges parents to perform them is a matter of much diversity of opinion. The weight of judicial authority in England favors the doctrine that the parent is under no common-law duty to support his child; that his legal duty in this regard is the creature of statute. According to this view, if a parent refuses to provide for his child the latter can not pledge the former's credit for necessaries, nor can he maintain any legal proceeding against the parent. His "only resource, in the absence of anything to show a contract on the parent's part, is to apply to the parish," which may take the proper steps to enforce the parent's statutory duty. The same view prevails in some of the U. S. (*Kelley* vs. *Davis*, 49 N. H. 187.) Other State courts have held that "the duty of the parent to maintain his offspring until they attain the age of maturity is a perfect common-law duty." (*Porter* vs. *Powell*, 79 Ia. 151.) In these jurisdictions, persons who supply minor children with necessaries (see INFANT) which the parent refuses or neglects to provide can recover their value from the parent on a quasi-contract. Where a child possesses an estate in his own right, a court of equity will authorize the father, in a proper case, and the mother in almost every case, to use the income, or even the principal, of such estate for the infant's suitable maintenance and education. A parent may lawfully resort to force in repelling an attack upon his child, as he may in repelling an ASSAULT (*q. v.*) upon himself. If he incurs a great risk in attempting to save his child from injury, he is not chargeable with NEGLIGENCE (*q. v.*), and he may uphold his children in their lawsuits without being guilty of MAINTENANCE (*q. v.*). Although the parental right of protection is unequivocal, the law does not compel its exercise. The parental duty of educating children, which was very imperfect at common law, has been regulated to some extent by recent statutes both in Britain and in the U. S. (See EDUCATION.) A

parent's duty to support his children does not survive him, but he is free, in the absence of a statute on the subject, to disinherit them. The parental liability upon the contracts and the torts of his children is governed by the law of MASTER AND SERVANT (*q. v.*). A husband does not assume the legal relation of parent to his wife's children by a former marriage. While they remain in his family he has the right to control them, and the law presumes, in the absence of any contract on the subject, that he supports them and they render services to him without charge.

Under modern legislation, though not at common law, the legal relation of parent and child may be instituted by ADOPTION (*q. v.*). While the adopted person becomes the legal child of the adopter, he retains the right of inheriting from his natural parents, unless the statute expressly deprives him of such right. *Wagner* vs. *Varmer*, 50 Iowa 532.

Filial Rights and Duties.—Most of these have been set forth in presenting the duties and rights of parents. At common law the child was not legally bound to maintain his parents, but modern legislation has subjected him to an enforceable duty in this respect.

For the rules of law relating to illegitimate children, see BASTARD.

LITERATURE.—Schouler's *Domestic Relations*; Blackstone's *Commentaries*, bk. i., ch. xvi.; Kent's *Commentaries*, lect. 29; Church's *Habeas Corpus*; Story's *Equity Jurisprudence*. FRANCIS M. BURDICK.

Parepa-Rosa: See ROSA.

Par'esis: loss of power less marked than that to which the term paralysis is applied. The causes and the manifestations of paresis are similar to those of PARALYSIS (*q. v.*), differing only in degree.

Paresis, General: See INSANITY (*General Paralysis*).

Parga: town; in the vilayet of Yanina, European Turkey; surrounded on three sides by the sea and defended on the fourth by an almost impregnable citadel (see map of Turkey, ref. 5–B). From 1401 to 1797 it was a prosperous commercial republic under the protection of Venice. From 1797 to 1814 it was nominally subject to the Ottomans, who gave it to Ali Pasha of Yanina. The inhabitants, about 5,000 Christian Albanians, refused to submit, and by desperate exertions maintained their independence, being aided after the treaty of Tilsit (1807) by the French. On the fall of Napoleon the Pargiotes solicited and obtained the protection of Great Britain, which placed a British garrison in the city; but in 1819 the British Government quietly delivered Parga to Ali Pasha, whereupon the Pargiotes dug up the bones of their ancestors, burnt them, abandoned their city, and went into exile. See Mustoxides's *Exposé des faits qui precedèrent et suivirent la cession de Parga* (Paris, 1819). E. A. GROSVENOR.

Parhelia: See HALO.

Paria, paa'rĕē-ăă, **Gulf of**: a small inland sea (105 miles long from E. to W.; 40 miles wide) between the lowlands at the mouth of the Orinoco, the island of Trinidad, and the peninsula of Paria, a rocky extension of the Venezuelan coast range. It communicates with the Caribbean Sea by the Boca del Drago, or Dragon's Mouth (between Trinidad and the peninsula), and with the Atlantic on the S. E. by the Boca de la Sierpe, or Serpent's Mouth. Columbus, who discovered and named these straits in 1498, had great difficulty in passing through them owing to their strong currents. Here he first saw the continent.

HERBERT H. SMITH.

Pa'riah [from Tamil *paraiyan*, a man of low caste performing the lowest menial services, liter., a drummer (the pariahs being hereditary drum-beaters), deriv. of *parai*, a large drum used at certain festivals]: one of the lowest class in India, which does not belong to any of the four castes. The pariahs have woolly hair and thick lips, and are found especially in the south of India; they are supposed to represent the aboriginal race conquered by the Sudras. In the Madras Presidency they number more than 4,000,000. They are very degraded, are not allowed to approach within many feet of any Hindu, and have to some extent adopted a system of caste among themselves. Chandalas and outcasts sink to the rank of pariahs. Successful efforts are being made by missionaries and others to elevate the character and intellect of these wretched beings. See CASTE.

Paridæ [Mod. Lat., from Lat. *parus*, a titmouse (the typical genus) + *idæ*, family termination]: a family of small thick-set birds, containing the titmice, characterized by soft, loose plumage; short, stout, rather conical bill; strong feet, with a pad beneath the hind toe; ten primaries, first short or spurious. The titmice are nearly all confined to the northern hemisphere, and occur in temperate or cold regions of both worlds. See TITMOUSE. F. A. L.

Pari'etal Bones [*parietal* is from Lat. *pa'ries*, wall, partition]: in vertebrates, the two bones which close in the skull above. They are never preformed in cartilage, but arise from the ossification of membranes, ossification in each proceeding from a single center.

Parietal Eye: a vestigial organ peculiar to vertebrates. In the brain of all vertebrates there has long been known a structure of unknown functions, called the pineal gland. It arises from the roof of the brain, between the cerebrum and mid-brain, and in the human being, where it is a structure about the size of a pea, it is completely covered by the cerebrum as it folds back over the cerebellum. In the lower vertebrates, where the cerebrum is less developed, it is exposed upon cutting into the cranial cavity. One of the most brilliant discoveries of recent years was Spencer's demonstration that this problematical organ was a vestigial eye, and that in certain lizards it reached nearly to the surface of the head, retaining in its most complete development lens, retina, pigment, and traces of a nerve. In these forms its presence can be recognized from the exterior in a small spot between the parietal bones, whence the name. Since Spencer's paper numerous investigators have studied the structure, and they recognize in it a compound organ, the anterior part of which alone develops the eye, while the posterior (for which the name epiphysis is retained) is more lymphoid in nature. It would, however, appear probable from the recent investigations of Klinckomstrow and Locy (1894) that the parietal eye is paired in origin, and that the epiphysis may be a second eye, behind the first, which has become more degenerated than its fellow. So far as is known this eye is no longer functional, but in some of the fossil vertebrates a cavity exists in the skull in the right position and of proper size to accommodate a third eye with its appropriate muscles. One of the most interesting features connected with the parietal eye is that it is built upon the invertebrate type; that is, the retinal layer is not inverted as it is in the functional vertebrate eye. See Spencer, *Quarterly Journal Micros. Science* (xviii., 1887); Leydig, Senckenberg. *Abhandl.* (1889); Ritter, *Bulletin Mus. Comparative Zoölogy* (xx., 1891). J. S. KINGSLEY.

Parima, Sp. pron. păă-ree'măă, **Serra**, or **Sierra de**: a line of highlands forming the divide between the headwaters of the Orinoco on the W. and the Rio Branco, a secondary affluent of the Amazon, on the E.; marking part of the boundary between Venezuela and Brazil. According to Codazzi, some points are over 7,000 feet high. On the side of the Orinoco the general trend appears to be from N. W. to S. E. The name is often extended to all the central highlands of GUIANA (*q. v.*). Originally it was given to a mythical lake of large size supposed to exist in this region and connected with the story of El Dorado. H. H. S.

Parini, GIUSEPPE: poet; b. at Bosisio (Brianza), May 23, 1729; d. at Milan, Aug. 15, 1799. Of humble family, he made his way by pure ability into the best society of Milan, and thus acquired the knowledge of its manners necessary for his satiric purposes. His actual career was that of a teacher, though he was also a priest; and from 1773 to his death he was Professor of Belles-lettres in the Academy of the Brera at Milan. He was a member of several of the literary academies so popular in Italy in his time, notably of the Trasformati of Milan and of the Milanese offshoot of the Roman Arcadia. His life was not an eventful one, though at its end he endured some unhappiness through unfortunate mingling in public affairs, and consequent retirement into something like actual poverty. His fame as a poet chiefly rests on his satiric poem, *Il Giorno*, begun by him in 1760. This appeared in four parts—*Il Mattino* (1763), *Il Mezzogiorno* (1765), *Il Vespro* and *La Notte* (the last incomplete, both published after Parini's death in the Reina edition of his *Works*, 6 vols., Milan, 1801). The work is an ironic description of the daily occupations of the Milanese aristocracy, its effeminate and too often corrupt customs, its idleness, its vanity. Pretty episodes are interwoven, and at times the author finds opportunity for noble and sincere protests against social injustices. Besides this poem we have from Parini's pen a number of odes (1st ed. Milan, 1791) and several occasional poems. In these the

neo-classicism of the Arcadia is everywhere to be seen—modified, however, by a certain intentional roughness, which is the poet's protest against the too soft and delicate manner of his contemporaries. A good edition of *Il Giorno* is that by A. Borgognoni (Verona, 1892); of the *Odi*, that of F. Salveraglio (Bologna, 1882). See also A. Giannini, *La vita e le opere di G. Parini* (Salerno, 1891); G. Carducci, *Storia del Giorno di G. Parini* (Bologna, 1892); C. Cantù, *L'abbate Parini e la Lombardia nel secolo passato* (Milan, 1854).

A. R. Marsh.

Paris [< Late Lat. *Pari'sii* (Lat. *Lute'tia Parisio'rum*, Lutetia of the *Pari'sii*, a people of Celtic Gaul, bordering on the Senones]: the capital of France; on both sides of the Seine, 110 miles by rail from the river's mouth; in lat. 48° 50′ N. and lon. 2° 20′ E. of Greenwich (see map of France, ref. 3–F). It has a mean elevation of 120 feet, and lies in a basin between lines of heights, which reach 404 feet on the north side and 190 feet on the south side. The Seine enters Paris on the west and leaves it on the southeast side, forming in its passage the islands of St.-Louis and La Cité. The granitic substratum is covered by Jurassic, Cretaceous, and Tertiary formations, and at several points a light-colored limestone is quarried, which has been used in constructing most of the buildings of the city.

Area and Population.—The present boundary coincides with a line of ramparts, 22⅓ miles in length; it includes an area of 78 sq. km. (a little over 30 sq. miles), of which one-fifth is occupied by the streets, 458 acres by squares and gardens, and 642½ acres by the river and canals. In 1896 the population was 2,536,834. Barely a third were born in Paris, and of the remainder more than 11 per cent. were foreigners. At the end of the thirteenth century the population was 200,000; in 1675, under Louis XIV., 540,000; in 1789, at the outbreak of the Revolution, 600,000; in 1851, at the beginning of the Second Empire, about 1,000,000; ten years later, 1,500,000, an increase chiefly due to the extension of the boundary; in 1871, on the advent of the Third Republic, nearly 2,000,000. The increase is now at the rate of about 25,000 a year. The population is denser than in any other great European city. Marriages average annually 26,500; births, 75,000; deaths, 70,000.

Climate.—The climate is fairly uniform, but liable to changes at all seasons, and on the whole is healthful and agreeable. The average temperature is 51° F. The highest temperature recorded in the nineteenth century was in July, 1881, when it was over 100°; the lowest was in Dec., 1879, when it sank to about −7°. From 1804 to 1876 the average temperature for each season was as follows: winter, 39°; spring, 51°; summer, 64°; autumn, 52°. January is the coldest and July the warmest month. The Seine seldom freezes; generally there is skating for a few days only each year, and the snowfall is slight. The average height of the barometer is 29·55 inches. During an average year there are about 143 rainy days, divided about equally among the four seasons.

Fortifications.—Paris is entirely surrounded by a fortified wall, which, with the first line of detached forts, was constructed between 1840 and 1860. This first line of forts, eighteen in number, is situated at a distance of about 1,600 yards from the city walls. The second line of forts, built since the war of 1870–71, is several miles distant from the city and consists of eighteen forts, placed on the various heights which surround Paris. The capital is now believed to be impregnable from a military point of view.

Streets.—The streets of no city in the world are so fascinating as those of Paris. They are well paved with stone, wood, or asphalt, or are macadamized; they are well lighted with electricity or gas, many of the lamp-posts being in bronze, and some of them being real objects of art. The sidewalks, though rather narrow in the small and old streets, are extremely wide in the boulevards and many of the avenues, and are in all cases smooth and neat. The streets are cleaned daily, and sprinkled frequently, while the gutters are washed out with running water once or twice every twenty-four hours. Trees, shrubs, and flower-beds abound. Comfortable benches are scattered along all the boulevards and avenues. Paper-stands, fruit-stands, etc., are generally neat, and all are constructed on the same models. A system of pneumatic tube telegraphy supplements the postal service. The means of conveyance are chiefly by cabs, omnibuses, and horse-cars, and an underground railway is being constructed. There are also steamboats plying up the river to Charenton and down to Suresnes; and a circular railway, the Chemin de Fer de Ceinture, runs round the city just within the walls. The names of the streets are at all the street-corners, and the numbers on the houses are large and conspicuous. The dwellings and public edifices, almost always built of limestone, are well constructed, and for the most part are of about the same height and same style of architecture. On their fronts, in scores of cases, are tablets bearing historic inscriptions, informing the public that on this or that site or in this or that house some famous man lived or died, or some great event happened. No two streets bear the same name. Most of the names are given to perpetuate the memory of famous men or women of all ages and nations, or to recall celebrated historical and political events. Among the citizens of the U. S. who are thus remembered are Washington, Lincoln, Franklin, and Fulton.

From the Madeleine to the Bastille the line of boulevards, 3 miles in length, forms the busiest and most fashionable thoroughfare in the world. The thoroughfare of the boulevards of Sébastopol and Strasbourg stretches N. and S. between the Gare de l'Est and the Seine, and then by the Boulevard du Palais and Boulevard St.-Michel reaches the observatory, the total length being 2½ miles. The Rue Royale, the Malesherbes and Haussmann boulevards, and the Avenue de l'Opéra are among the finest quarters of the town. The Rue de la Paix, Rue Auber, and Rue 4 Septembre are remarkable for their shops. The Place de l'Étoile is the center of twelve avenues issuing from it like the spokes of a wheel. On the south side the main thoroughfare is the Boulevard St.-Germain.

Bridges.—The Seine is of the proper width to favor the construction of graceful bridges, which are among the most attractive ornaments of the city. The oldest are Notre Dame, occupying the site of a Roman bridge; the Pont Marie, constructed between 1614 and 1628; the Pont d'Austerlitz, begun under the first Napoleon, rebuilt during the Second Empire, and enlarged during the Third Republic. The names of the principal officers killed at the battle of Austerlitz are inscribed on the ornamental portion of this structure. The present Pont au Double, which dates from 1880, supplanted a bridge of the seventeenth century, where a toll of a *double*, an old piece of money worth the sixth of a sou, was collected. The Pont St.-Michel, rebuilt several times since the fourteenth century, is one of the widest and most frequented. The famous Pont Neuf is now the oldest of the Paris bridges. It was begun in 1578 under Henry III. and finished under Henry IV., whose statue adorns it. Mansart was the architect of the Pont Royal, which was constructed between 1685 and 1689. The Pont de Solférino commemorates the chief French victories during the Italian campaign of 1859. The Pont d'Iéna dates from the closing years of the First Empire. The bridge and viaduct of Auteuil, one of the finest of the kind in existence, was built in 1866. It serves for railway, vehicle, and foot traffic.

Parks and Gardens.—The public garden of the Tuileries covers about 70 acres, and was laid out in 1665 by Le Nôtre, the landscape-gardener of Louis XIV.; but the original plan has been much altered. The garden contains many fine, large trees and numerous pieces of sculpture by famous French artists. The Luxembourg Garden is a little smaller than the Tuileries. The hothouses, sixteen in number, contain more than 25,000 plants. Besides other statuary there is a series of portraits of famous French women, erected during the reign of Louis Philippe (1830–48). The Palais Royal garden, in the form of a large parallelogram, is much smaller than the two gardens already mentioned. It is surrounded on all four sides by buildings and an arcade, where are many fine jewelry-shops.

The Jardin des Plantes, which is a little larger than the Tuileries, was designed by Guy la Brosse, Louis XIII.'s physician, and was first opened to the public in 1650. At that time it contained only medicinal herbs. To-day the botanical school has a reserve of nearly 5 acres filled with some 13,000 kinds of plants. Most foreign trees and shrubs which can live out of doors in the climate of Paris are found here, and are labeled. There are nearly 2,000 varieties of fruit-trees and many hothouses. A zoölogical collection forms a part of the garden. The Monceau Park was laid out in 1778 by the father of Louis Philippe, but did not become public property till the Second Empire. It contains several bits of historical ruins, notable modern statues, and is surrounded by some of the most fashionable streets and magnificent private residences of Paris. The Trocadéro Park dates from the Exhibition of 1878. After the foun-

tain and palace the most interesting object is the aquarium. The Buttes-Chaumont Park is in the extreme northeast part of Paris on the Belleville hill. Till the end of the Second Empire what is now a beautiful park of over 55 acres was a waste quarry-ground. A fine view of Paris may be had from the heights of this park. The Montsouris Park (nearly 40 acres) is on the southern outskirts of the city, and contains the meteorological observatory.

The Champ de Mars, which used to be a sandy field for military manœuvering, is now laid out as a public garden. It is surrounded by the principal buildings of the Exhibition of 1889, and in the center is the Eiffel Tower (*q. v.*). At the southeast end is the military school. The Champs Élysées is the most frequented garden of Paris.

Outside of the walls are the two great parks, the Bois de Boulogne and the Bois de Vincennes. The first, of about 2,000 acres, contains two large lakes, many beautiful drives and walks, and a race-course—Longchamps—where the Grand Prix is run for and where the grand annual military review takes place. A fashionable skating-rink is opened here in winter. The aristocratic drive is the Allée des Acacias. The Garden of Acclimatation, situated here, embraces the finest zoölogical collection in Paris. The Bois de Vincennes contains over 2,075 acres. In the center is a large field for military manœuvers and also a race-course.

Public Monuments.—The streets, squares, and parks contain many groups of statuary by noted sculptors, and numerous monuments. The most remarkable monument is the Arc de Triomphe in the Place de l'Étoile, begun by Napoleon I. and completed by Louis Philippe. It is about 160 feet in height. Another triumphal arch stands in the Place du Carrousel, and commemorates the campaign of 1806. In the Place Vendôme is a shaft 143 feet in height, with bas-reliefs commemorating Napoleon's campaigns in 1805. *The Column of July*, a bronze pillar 154 feet in height, stands in the Place de la Bastille, and is dedicated to the citizens who fell in the Revolution of 1830. In the center of the Place de la Concorde, on the spot where stood the guillotine used during the Revolution, is the obelisk of Luxor, 75 feet in height. (See Obelisk.) It was removed from Egypt in 1833, and in 1836 was set up where it now stands. A colossal lion in the Place Denfert symbolizes the defense of Paris in 1871. A reduction of Bartholdi's *Liberty Enlightening the World*, a gift of citizens of the U. S., stands on one of the islands in the Seine. Among those to whose memory statues have been erected are Charlemagne, Joan of Arc, Louis XIV., Napoleon, Danton, Gambetta, Dante, Shakspeare, Béranger, Voltaire, and Dumas. The Medici fountain in the Luxembourg garden, the two fountains in the Place de la Concorde, copies of those at St. Peter's, Rome; the fountain in the Place Louvois, the Fountain of Victory in the Place du Châtelet, the Cuvier fountain near the Jardin des Plantes, the fountain at the north end of the Boulevard St.-Michel, the fountain at the north end of the Avenue de l'Observatoire, that in the Place de Notre Dame, that by Bouchardon in the Rue de Grenelle, and the colossal fountain in the Champ de Mars, are a few of the works of art of this kind that adorn the city. The great Trocadéro fountain may be termed a cascade.

Palaces.—Paris is rich in splendid palaces. The origin of the Louvre is almost coeval with the French monarchy, although the name first appears about the year 1204, during the reign of Philip Augustus, who entirely rebuilt it. The Louvre was then an exceedingly strong fortress. Catherine de Medicis was the first royal personage to take up a residence in the Louvre. Here in 1610 Henry IV. was laid out in state after his assassination. When Louis XIII. died the Louvre was abandoned as a royal residence, till occupied by the widow of Charles I. Louis XIV. held a *lit-de-justice* there, and during the same reign Molière's troop of actors played in one part of the palace. On the outbreak of the Revolution of 1789 the Louvre was in a semi-abandoned state; but the Convention made a complete change in its management by converting it into a grand picture gallery and museum.

The Tuileries (*q. v.*), on the right bank of the Seine, was begun in 1564, and was the scene of many historic events. The whole central portion and a part of the wing along the Rue de Rivoli were burned by the Communists in 1871. This wing was rebuilt during 1875–76, while a few years later, the ruins of the historic central part were leveled to the ground and a garden laid out on the site.

The Élysée Palace was built in 1718. Among its early occupants were Mme. de Pompadour and, later, Murat. Napoleon retired thither after his defeat at Waterloo, and there signed his abdication. It was Louis Napoleon's official residence when he was president of the Second Republic, and there he prepared the *coup d'état* of Dec. 2, 1851. Since the establishment of the Third Republic the Élysée has been the residence of the president.

On the site of the Palais Royal once stood the *hôtels* of Mercœur and Rambouillet, celebrated in literary history. Cardinal Richelieu bought these two *hôtels*, tore them down, and constructed on the ground a palace which was completed in 1634. Here he died eight years later. In 1643 Anne of Austria took possession of the palace with her two sons, one of whom afterward came to the throne as Louis XIV. It was Philippe Égalité, father of King Louis Philippe, who surrounded the garden with the shops which still stand, and whose rentage enabled him to keep up his expensive establishment. It was in the garden of the Palais Royal that Camille Desmoulins gave the first popular impulse to the Revolution. Between 1872 and 1876 it was reconstructed and restored, having been partially burned during the Commune, and is now occupied by state bodies.

The Luxembourg Palace is an ancient royal residence, built by Marie de Médicis in the beginning of the seventeenth century. Among other famous personages who have lived there are Mlle. de Montpensier, Louis XIV., and Louis XVIII. The Revolution converted the palace into a prison, and here were confined the future Empress Josephine, Danton, Camille Desmoulins, Thomas Paine, and others. Toward the end of the eighteenth century it became the seat of executive or legislative bodies, and has continued to be used for this purpose down to the present day, the Senate now occupying it. Here in 1815 Ney, in 1830 the ministers of Charles X., and in 1840 Prince Louis Napoleon after his landing at Boulogne, were imprisoned and tried; and here, during the republic of 1848, Louis Blanc established a sort of official labor bureau. The interior of the palace is rich and spacious, and contains many objects of historic and artistic value. A large public garden is connected with the palace, and a gallery of modern pictures and sculptures is established in an annex. The historic Petit Luxembourg, a wing of the larger palace, is now the official residence of the president of the Senate.

The Palais Bourbon was built in 1722, but has been much enlarged since that time. Here sat the Council of Five Hundred, and here, under different names, the Chamber of Deputies has met, with slight interruptions, since the Restoration down to the present day. In this hall the greatest parliamentary orators of France have been heard, and here occurred several of the most famous scenes in the political history of France during the nineteenth century. The palace occupied by the president of the Chamber of Deputies is connected with the Palais Bourbon. Here Gambetta once resided.

The palace of the Legion of Honor was built in 1786 for the Prince of Salm; but during the Revolution it was put up at lottery and won by a baker. In 1803 the offices of the Legion of Honor were established here. The edifice was burned by the Commune, but was restored.

The Palace of the Institute is due to Cardinal Mazarin, and was finished in 1662. It was at first used as the College of the Four Nations. During the early days of the Revolution it became a jail, and later the meeting place of the Committee of Public Safety. The First Empire established the Institute of France in this edifice, and there it has since remained. The famous French Academy, which forms a part of the Institute, meets here.

Museums and Picture Galleries.—Paris is remarkably rich in museums and picture galleries, there being nearly fifty in all. The most important is that of the Louvre, whose origin was a private collection of pictures which belonged to Francis I. Louis XIV., Louis XV., and Louis XVI. increased the collection, and on the eve of the Revolution the Louvre Gallery was one of the finest in the world. Additions were made during the Revolution, and during the wars which followed Napoleon sent to Paris the most famous works of art of all Europe, many of which became the permanent property of the Louvre. Its most noted piece of ancient sculpture is the Venus of Milo, discovered in 1820, and bought by the French Government. Since 1870 valuable gifts and the results of artistic and scientific expeditions under Government authority have considerably increased the value and extent of the collections.

Among the other important museums and galleries are the Carnavalet, specially devoted to the history of Paris and

the Revolution; the Cluny, mediæval art, containing over 10,000 objects; the natural history collections in the Jardin des Plantes, one of the largest of its kind in the world; the Luxembourg, a gallery of living painters and sculptors; the Artillery Museum in the Hôtel des Invalides, embracing some 4,000 specimens of military weapons of all kinds and of all countries and ages; the Trocadéro, comparative sculpture, architecture, and ethnology; the Guimet, devoted to the religions of the far East; the Galliera, a miscellaneous art collection housed in a magnificent stone structure which was ten years (1878–88) in building; the mint, containing a large collection of coins and other curiosities; the National Archives, a great mass of original documents, some of which may be seen by the general public, autographs, the keys of the Bastille, etc.; the Dupuytren, at the School of Medicine, a valuable collection bearing on pathological anatomy, formed in 1835; the art collection at the School of Fine Arts; and the scientific collections at the School of Mines.

Libraries.—There are many great book collections in Paris. The National Library, the largest in the world, contains some 3,000,000 volumes. It was begun by Charles V. (1364–80), and went on increasing steadily, but it was the suppression of the convents and the confiscation of their libraries, during the Revolution, that placed it, with one bound, at the head of the list. Besides its books the library contains some 300,000 maps from all parts of the world, over 90,000 volumes of manuscripts, ancient and modern, many volumes of rare autographs, more than 200,000 coins and medals, and 14,500 volumes and 4,000 portfolios of engravings.

The Ste.-Geneviève Library, near the Panthéon, is of ecclesiastical origin, and contains some 196,000 volumes, 4,000 manuscripts, and 25,000 engravings. Its books are mostly of an encyclopædic nature. Nearly 150,000 persons enter this library every year. The Mazarin Library, at the Institute, begun by Cardinal Mazarin, has 250,000 volumes, 6,000 manuscripts, and 1,700 incunabula, and is one of the leading libraries in France in bibliographical rarities. It is, furthermore, a museum, containing many scientific curiosities and objects of art. The Arsenal Library has 200,000 volumes and 8,000 manuscripts, and is notable for its works of the early minor French poets and for documents relating to the theater. The Library of the Opéra, kept in the Opera-house, is devoted principally to the history of the theater and music. It contains 15,000 bound volumes and pamphlets, 60,000 engravings, and the original drawings for the costumes of 200 operas or ballets.

Theaters.—The drama being one of the chief sources of amusement in Paris, there are many theaters. Four of them —the Opéra, Théâtre Français, Opéra Comique, and Odéon —receive state aid. The Opéra is one of the finest theatrical edifices in the world. It cost some 30,000,000 francs, covers an area of about 11,000 sq. yards, and can seat 2,156 spectators. It took over ten years to build the edifice, which was first thrown open to the public in 1875. The architect was Charles Garnier. The grand staircase and the *foyer* are the most admired portions of the structure. The annual subvention is 800,000 francs.

The leading theater of France and of the world is the Théâtre Français, or Comédie Française. It has a large and talented stock company, which enjoys many privileges. The present edifice was built in 1782, and contains, besides a large auditorium and handsome *foyer*, numerous busts and portraits in oil of celebrated dramatists and actors, and other interesting histrionic objects; also a curious collection of autographs and objects associated with famous actors. The Théâtre Français was created in 1680, and receives an annual subvention of 240,000 francs. Among its most famous actors have been Talma, Mars, Rachel, Coquelin, and Sarah Bernhardt.

The Opéra Comique was burned in 1887, but a new building is being erected. The Odéon, opened in 1782, was burned in 1799, rebuilt in 1808, and again burned in 1818, but immediately rebuilt. It contains one of the best auditoriums in Paris, and enjoys a subvention of 100,000 francs.

Among the non-subventioned theaters are the Gymnase, founded in 1820, which owed its early prosperity to Scribe, whose pieces were first brought out on its stage; the Palais Royal, whose troupe has contained many celebrated actors; the Porte St.-Martin; the Château d'Eau, which has the largest auditorium of all Paris theaters; the Vaudeville, Variétés, Renaissance, Gaîté, Châtelet, Nouveautés, etc. Several circuses, concerts, *cafés-chantants*, etc., complete the list of places of amusement.

Restaurants and Cafés.—In no other city is restaurant and *café* life so highly developed as in Paris. At the Café Américain congregate literary men and painters; bankers and brokers predominate at the Café Riche; at the Café du Helder are found army and navy officers and St.-Cyr cadets; rich foreigners frequent the Café de la Paix; the Café de Madrid is the headquarters of journalists; actors are numerous at the Café de Suède and the Café des Variétés; the Café Vachette, in the Quartier Latin, is patronized by students; the Café de la Régence is the meeting-place of Scandinavians and chess-players. The principal Montmartre quarter *cafés* were the Rochefoucauld and the Nouvelle Athènes, but the famous *café* of the Chat Noir has eclipsed them and has become one of the curiosities of Paris. There are fashionable restaurants in the Champs Élysées, where one may dine and watch at the same time the performances of the *cafés-chantants*. In the Bois de Boulogne are some *cafés* and restaurants, the Cascade restaurant being very popular in summer, when it is used as a resting-place after an evening drive.

Educational Institutions.—The Panthéon may be considered the center of the Quartier Latin, the students' part of Paris. Here, within five minutes' walk of one another, are the Sorbonne, the heart of the UNIVERSITY (*q. v.*); the Collège de France, which might be called the Post-graduate University; the special schools of law, medicine, mines, pharmacy, fine arts, Oriental languages, etc., the historic École Polytechnique, the École Normale Supérieure, etc. In the faculties are over 325 professors, and more than 100 lectures are delivered every day. The thousands of students in attendance come from almost all the nations of the earth; there are over 5,000 at the medical school alone.

Churches.—There are seventy parish churches, of which Notre Dame, the metropolitan cathedral, is the largest and most famous. Its corner-stone was laid in 1163 by Pope Alexander III., then a refugee in France, but the edifice was not completed till nearly a century later. In 1845 a thorough restoration of the church was begun. Notre Dame is one of the finest specimens in France of the ogival style of architecture. The interior is 132 yards long, 53 wide, and 37 high, and contains thirty-seven chapels. There are three grand rose windows, whose stained glass dates from the thirteenth century. The large bell in the south tower was cast in 1686, and weighs about 30,000 lb. The Sainte Chapelle is perhaps the most beautiful structure in Paris. It was built by St. Louis to house the supposed crown of thorns and a portion of the true cross. It was finished in 1247, and restored at the end of Louis Philippe's reign. The Chapelle Expiatoire, on the Boulevard Haussmann, was built by order of Louis XVIII. (1814–24), and finished in 1826. It is consecrated to the memory of his brother and sister-in-law, Louis XVI. and Marie Antoinette, who were buried on this spot, and to the memory of the victims of the Revolution. The first church bearing the name St. Étienne-du-Mont dates from the thirteenth century, but was reconstructed in 1517 under Francis I. The jube, or rood-loft, the work of the sculptor Biard, senior, was made at the beginning of the seventeenth century, and is considered a masterpiece. The stained-glass windows of this church are also notable, representing the work of the best artists from the middle of the sixteenth to the end of the seventeenth centuries.

St.-Germain-des-Prés is a remnant of the ancient abbey of that name. It was begun in 1001, but was not completed till the twelfth century. Near by was the prison of the abbey, which was the scene of much bloodshed during the Reign of Terror. It disappeared in 1860.

There was a church on the site of St.-Germain-l'Auxerrois as early as 560. Some portions of the present edifice date from the twelfth century. A cloister once surrounded the church, and was in the days of Charlemagne the seat of a famous school. On Aug. 24, 1572, its bell rang out the signal for the massacre of St. Bartholomew.

The Madeleine was begun by Louis XV., but was not opened till 1842. Napoleon I. intended it to be a Greek temple, dedicated to the soldiers of the Grand Army. It is now one of the most richly ornamented and fashionable churches of Paris. The corner-stone of St.-Roch was laid by Louis XIV. in 1653. On the top of the flight of steps leading up to the doors of this church, Bonaparte placed the cannon which checked the uprising against the Convention Oct. 5, 1795. Corneille, the dramatist, is buried here. The Church of the Sacred Heart on the heights of Montmartre is a large and conspicuous basilica in Byzantine

style, whose construction was decreed in 1874 by the National Assembly. A fine view of Paris can be obtained here.

St.-Sulpice was begun in 1646. During the Convention it was known as the Temple of Victory. Val-de-Grâce was raised by Anne of Austria as a thank-offering to God for the birth of the future Louis XIV. The cupola, which is considered to be the best imitation in France of the cupola of St. Peter's, Rome, is decorated with a large composition by Pierre Mignard—*Gloire des Bienheureux*—containing over 200 figures. Henrietta, queen of Charles I. of England, and daughter of Henry IV. of France, is buried here.

Among the other churches may be mentioned St.-Vincent de Paul, with its frieze over 170 yards long and 3 high, by Hippolyte Flandrin; Ste.-Élisabeth, Rue du Temple, whose cornerstone was laid in 1628 by Marie de Medicis; St.-Eustache (1532–1642), where Colbert is buried; Notre Dame de Lorette, in imitation of a Roman basilica; Notre Dame des Victoires, remarkable for the large number of *ex-votos* which cover the interior walls; and the Chapel of the Sorbonne, now the center of the immense parallelogram of new university buildings, and noted for its tomb of Richelieu. Of the forty-five or more Protestant churches the Oratoire is the most conspicuous.

Cemeteries.—Paris has nineteen cemeteries, thirteen of which are inside the walls. Of the latter, only three are of historic interest: Père Lachaise, Montmartre, and Montparnasse. The largest and most notable is the first named. It covers about 100 acres, and here are the tombs, among those of other celebrities, of Arago, Thiers, Rachel, Cuvier, Béranger, Molière, Ingres, and Balzac. It is also provided with a crematory, the first and only one established in Paris. In the Montmartre Cemetery are buried Delaroche, Gautier, Comte and the heart of Marshal Lannes, whose body is in the Panthéon. At Montparnasse are the graves of Henri Martin, Rude, Le Verrier, Malte-Brun, and Sainte-Beuve. La Fayette is buried in the little cemetery of Picpus, near the eastern extremity of Paris, and in the Passy Cemetery is the conspicuous tomb of Marie Bashkirtseff.

Reviews and Journals.—The oldest of the reviews published in Paris is the *Revue Britannique*, founded in 1825; the most important, which has a worldwide reputation, is the *Revue des Deux Mondes*, founded in 1829; and among the others may be mentioned Mme. Adam's *Nouvelle Revue*, the *Revue Historique*, Ribot's *Revue Philosophique*, *Revue Bleue*, which enjoyed considerable popularity during the life of its founder, Eugène Yung, the recently established *Revue de Paris*, and Richet's *Revue Scientifique*. Among the illustrated and artistic journals are *L'Illustration*, founded in 1843, the *Journal Amusant*, the *Journal Illustré*, the *Magasin Pittoresque*, founded in 1833, the *Monde Illustré*, the *Univers Illustré*, *La Vie Parisienne*, *L'Art*, one of the high art publications, the *Gazette des Beaux-Arts*, and the *Revue des Beaux-Arts*. Among the daily papers of note are *Figaro*, *Le Temps*, the leading evening newspaper; the *République Française*, founded by Gambetta; the venerable *Journal des Débats*; the *Rappel*, which used to be Victor Hugo's organ; the *Univers* and *Monde*, the two Roman Catholic organs; the *Petit Journal*, a one-sou morning paper with over 1,000,000 readers, the largest circulation in France; the *Gaulois*, which circulates largely in the fashionable world; and the *Journal Officiel*, the official organ of the Government.

Hospitals.—The oldest of the Paris hospitals is the Hôtel-Dieu, founded about 660 and rebuilt between 1868 and 1878. It contains nearly 600 beds. La Charité, founded in 1602 by Marie de Médicis, is the chief lying-in hospital. The Lariboisière takes its name from the Comtesse de Lariboisière, who left nearly 3,000,000 francs to the Paris poor. The hospital contains 690 beds. The Necker is named from the mother of Mme. de Staël, who used to found it a sum given her for charitable purposes by Louis XVI. La Pitié was built by Louis XIII., and has 729 beds. St.-Antoine is another of the early hospitals. It is surrounded by large gardens and has 647 beds. St.-Louis dates from 1607, during the reign of Henry IV., and is given up to patients suffering from skin diseases. The Midi is confined to the venereal diseases of men and the Lourcine to those of women. The Maternité occupies the old abbey of Port-Royal, which was used as a prison during the Revolution. There is attached to it a school of midwifery for female pupils. The hospital of the *accouchement* clinic, 89 Rue d'Assas, possesses a fine obstetric museum. The hospital for sick children in the Rue de Sèvres contains over 650 beds. The Trousseau, founded in 1660, is also devoted to children.

Prisons.—The Dépôt is a temporary lock-up at the prefecture of police, where prisoners are first sent when arrested. Mazas is filled chiefly with prisoners awaiting trial. The Conciergeric is the most famous, politically and historically. There Marie Antoinette passed the last days of her life, and was succeeded by Danton, Mme. Roland, Camille Desmoulins, Robespierre, etc. In Sept., 1792, 288 prisoners were murdered there. Georges Cadoudal, during the First Empire, and Prince Napoleon and the Duke of Orleans during the Third Republic, were confined there. The Roquette can accommodate nearly 450 convicts. Those condemned to suffer capital punishment are held here. In the street in front of the central door is the spot where the guillotine is put up. Ste.-Pélagie is the lock-up of journalists and writers who violate the press laws. Béranger, Lamennais, Proudhon, and a host of other French literary celebrities have been confined there. La Santé is another of the large prisons. St.-Lazare receives only women; during the Convention it was used as a political prison.

Government and Administration.—The city is divided into twenty *arrondissements*, each of which is subdivided into four quarters. Each of the latter elects, by universal suffrage, a member of the municipal council. The functionaries of the *arrondissement* are a mayor and three deputies, nominated by the prefect, or governor, of the department of the Seine, who act as registrars and take charge of the poor relief, and a justice of the peace nominated by the Government. The municipal council discusses and votes upon the budget of the city. The prefect of the Seine and the prefect of police, both government officials, represent the executive central authority as opposed to the municipal council. The prefecture of the Seine comprises a departmental service and a municipal service, the latter much the more important. Elections, taxes, the municipal debt, city schools, public lands, markets, cemeteries, etc., are under the control of the prefecture of the Seine. The prefecture of police includes the whole department of the Seine and part of Seine-et-Oise. It consists of three sections, the political police, the police of public safety, and the administrative police; but the two former are rather national than municipal.

Markets.—Wholesale trade in foodstuffs is carried on in the central markets—Les Halles. These comprise ten pavilions of glass and iron, each about half an acre in size, and separated from each other by covered streets. Butcher's meat is also sold in the market attached to the La Villette abattoir. The Chemin de Fer de Ceinture brings the cattle-trucks into this market, which, with the abattoirs, extends over an area of 111 acres. The places of sale are capable of holding 4,600 horned cattle, 4,000 calves, 22,000 sheep, and 7,000 pigs. Close to Les Halles is the corn-market; but the greater part of the grain arriving in Paris does not pass through this building; it is either stored at the stations or taken directly to the warehouses or the bakers. There are three great markets for wine and spirits at Bercy, Quai St.-Bernard and Pont de Flandre. There are also important markets for skins and hides, horses, charcoal, etc. The curious Marché du Temple, rebuilt in 1864, is devoted to the sale of second-hand articles of all kinds.

Water-supply and Drainage.—Paris derives its water-supply chiefly from (1) the Seine, whose water is pumped up and stored in reservoirs at the highest points in Passy, Montmartre, Charonne, and Gentilly. (2) The Marne, a loop of which, closed by a canal at St.-Maur, supplies several districts by means of the head of water and the application of steam-pressure. (3) The Ourcq Canal, also used as a waterway, which comes from the department of Aisne and terminates at the La Villette basin. (4) The Dhuis and the Vanne, two streams of La Champagne. The former is diverted near Château-Thierry and conveyed by an aqueduct 81 miles long to the Ménilmontant reservoirs. The aqueduct from the Vanne ends in reservoirs at Montrouge. (5) The Aure, a tributary of the Eure. The water is diverted near the junction with the Vigne and brought by an aqueduct 63 miles long, by turns under and above the ground, to the Montretout reservoirs at St.-Cloud (opened Mar. 30, 1893). The last is calculated to have raised the daily water supply from 150,000 to 270,000 cubic meters, so that Seine water is no longer used for drinking purposes.

The drainage on both sides of the river is collected in a great sewer terminating in the Seine at Clichy. The two main sewers on both sides are connected by a siphon which passes under the Seine by a tunnel near the Pont de l'Alma. A departmental sewer receiving the drainage of the higher districts on the north side ends at St.-Denis. The sewers in

general are also used as passages for water-pipes, gas-pipes, telegraph wires and pneumatic tubes. (See PNEUMATIC TRANSMISSION.) The largest class have a height of 17½ feet at the keystone and a width of 17 feet at the spring of the arch.

Financial Institutions.—After the Bank of France (see BANK) the chief financial establishments are the Caisse des Dépôts et des Consignations, which receives voluntary deposits and those obligatory in cases fixed by law; the Crédit Foncier de France, which makes advances on real estate; and the Comptoir National d'Escompte. There are also numerous private joint-stock banks. The Bourse is open from noon to 3 P. M. for dealings in stocks and shares, and from 3 P. M. to 6 P. M. for commercial transactions. The former are effected by means of *agents de change*, named by ministerial decree and possessing nominally the exclusive right to act as brokers; but a large business is done by the unauthorized brokers called *coulissiers*.

Manufactures and Commerce.—In proportion to its population Paris can not be regarded as pre-eminently a manufacturing or commercial city. It contains a great number of officials, on account of the highly centralized government of France. It is a great financial center; and as it offers a variety of attractions appealing to the appetites, the senses, the æsthetic feeling, and the intellect, it is the residence of wealthy men from all parts of the world, as well as of numerous authors, artists, and scientific men. The chief industries are the production of articles not depending upon the cost of material, but upon the skill and taste of intelligent workmen, such as bronzes, jewelry, decorative furniture, and *articles de Paris*. The publishing business of France has been almost monopolized by Paris, and has reached a very high state of development, especially in the production of engravings and illustrated books. The larger manufacturing establishments include engineering works, chiefly in connection with the railways, foundries, and sugar-refineries. Among Government works are two tobacco-factories, the national printing establishment, the mint, and the Gobelins tapestry-factory and dye-works. Next come the chemical-factories, printing-offices, cabinet-makers' workshops, tailoring establishments, and hat-factories. Several plans have been discussed with the object of making Paris a seaport in the modern sense, and it has at length been decided to open up the port by the canalization of the Seine. In 1891 the plans were completed, the final estimates being: length of canal, 112 miles; depth, 20½ feet; cost, $27,000,000. The goods arriving by the Seine are chiefly building materials, timber, grain, coal, coke, charcoal, and wines; building materials and flour are brought by the Canal de l'Ourcq, and coal and coke from the north of France, Belgium, and England by the Canal St.-Denis. By the Seine, Paris dispatches manure, pyrites, and refined sugars. To the traffic of the river should be added that of the canals, especially of La Villette, on the Canals St.-Denis and Ourcq, which is the third port in France, measured by its traffic.

History.—The generally accepted opinion is that the city was primitively one of those many fishing villages which the early Gauls established on the islets scattered along the course of the Seine, for the heart of the city is even to-day known as the Île de la Cité and the Île St.-Louis. The first historic mention of Paris and its inhabitants occurs in the year 52 B. C., when Cæsar says in his *Commentaries*, book vii.: "Labienus leaves for Lutetia with four legions. This is the fortress of the Parisii, situated on an island in the river Seine." At the end of the fourth century Lutetia, *Lutèce* in French, had become the seat of a bishop and was called Paris, from the name of the little nation whose capital it was. The Roman emperor Constantius Chlorus is said to have fixed his residence there (292–306), and Julian was there proclaimed emperor by his soldiers (360). In 506 Paris became the residence of Clovis, and later Charlemagne sometimes visited it, though in his time it ceased to be the capital. The growing town suffered from the devastations of the Normans. In 885–886 30,000 of them encamped in front of the Île de la Cité, which was besieged, but in vain, during thirteen months. "By this heroic siege," says the French historian Henri Martin, "Paris took the first step toward its grand destiny; thenceforth it was the head and heart of France." In 987 Hugh Capet, the first of the dynasty, made Paris the capital of his kingdom, and his successors resided there. During the reign of Philip Augustus (1180–1223) the city's growth was great. The streets were then first paved with stone, the two wooden bridges which connected the Île de la Cité with the mainland were rebuilt in stone, three colleges were founded, and soon 20,000 students flocked to the city from all parts of France and foreign countries. This was the foundation of the university, which did much to increase the population and importance of the city. Under Louis IX. (1215–70) was founded a theological college, which became the celebrated Sorbonne. Philip the Fair added greatly to the importance of the city by making it the seat of the highest court in the kingdom—the *Parlement*, which he organized in the opening years of the fourteenth century. During the reign of Charles IX. (1560–74) religious and civil wars checked the development of the city, and Henry III. in the closing years of his reign found himself excluded from his own capital, which fell completely under the control of the League. Both he and his successor, Henry IV., were obliged to lay siege to it, the second siege lasting four years, and bringing terrible sufferings upon the inhabitants (1590–94). During the minority of Louis XIV. the city sustained another siege, and suffered from frequent riots in the streets. (See FRONDE.) During the reign of Louis XIV. (1643–1715) the streets began to be lighted at night with lanterns containing candles, but only when there was no moon. Colbert was put in charge of public works, and he effected great improvements. He was ably seconded by Perrault and Mansart, the architects, and by the great sculptors and painters of the age. The centralizing policy of Louis XIV. and his opposition to the residence of the nobility on their estates drew to Paris the most brilliant and distinguished men of France. From his time the history of the city becomes in a sense the history of France, and for an account of the principal events see that title. Paris suffered severely from the excesses of the Revolution, whose worst crimes were committed within its limits. It was the scene of the Revolutions of 1830 and 1848, and it suffered from siege in the FRANCO-GERMAN WAR (*q. v.*) and from the violence of the Commune. See COMMUNE OF PARIS and FRANCE, HISTORY OF.

BIBLIOGRAPHY.—Among the vast number of works on Paris only a few of the modern ones can be mentioned. See Baedeker's and Murray's guides; Dickens's *Dictionary of Paris*; the official *Annuaire Statistique*; *Guide de Paris par les principaux écrivains et artistes de la France* (1867–68); A. Joanne, *Paris illustré* (1881); Philip G. Hamerton, *Paris in Old and Present Times* (1884); *Histoire Générale de la ville de Paris*, published by the municipality since 1866; Lacomb, *Bibliographie de Paris* (1886).

THEODORE STANTON.

Paris: a port of entry of Brant co., Ontario, Canada; on the Grand river; at the junction of two branches of the Grand Trunk Railway; 61 miles S. W. of Toronto (see map of Ontario, ref. 5–D). It has valuable beds of gypsum, great water-power, many mills, foundries, knitting-works, and other industries, and two weekly newspapers. Pop. (1891) 3,094.

Paris: city; capital of Edgar co., Ill. (for location, see map of Illinois, ref. 7–G); on the Cleve., Cin., Chi. and St. L. and the Vandalia line railways; 170 miles S. of Chicago, 200 miles E. of St. Louis. It is the center of a rich agricultural region, and is an important grain, produce, and stock market. There are 2 national banks with combined capital of $208,000, a private bank, a new court-house, and a monthly, 3 daily, and 4 weekly periodicals. Pop. (1880) 4,373; (1890) 4,996; (1900) 6,105. EDITOR OF "BEACON."

Paris: city; capital of Bourbon co., Ky.; on Stoner creek, and the Louisv. and Nashv. and the Ky. Midland railways; 19 miles N. E. of Lexington, 80 miles S. by E. of Covington (for location, see map of Kentucky, ref. 3–I). It is the principal place of manufacture of Bourbon whisky, has large live-stock and tobacco interests, and contains five State banks with combined capital of $800,000, several classical and female institutes, and a semi-weekly and a weekly newspaper. Pop. (1880) 3,204; (1890) 4,218; (1900) 4,603.

Paris: city (founded in 1823); capital of Henry co., Tenn. (for location, see map of Tennessee, ref. 6–C); on the Louisv. and Nashv. and the Paducah, Tenn. and Ala. railways; 110 miles W. of Nashville, 130 miles N. E. of Memphis. It is in a wheat and tobacco growing region, and contains 5 churches, high school, university training-school, public school for colored youth, 2 cotton-factories, 2 grist-mills, a roller-mill, 2 tobacco-factories, a pottery, a barrel-factory, headquarters of the Henry County Fair and Trotting-horse Association, and 2 weekly newspapers. Pop. (1880) 1,767; (1890) 1,917; (1900) 2,018.

EDITOR OF "POST-INTELLIGENCER."

Paris: city; capital of Lamar co., Tex. (for location, see map of Texas, ref. 2–J); on the Gulf, Col. and S. Fé, the St. L. and San Fran., and the Tex. and Pac. railways; 15 miles S. of the Red river, 64 miles E. of Sherman. It is in a wheat and cotton growing region and is the trade center of a large territory. There are 15 churches, 3 public-school buildings, public-school property valued at over $65,000, the North Texas University, 4 banks, cottonseed-oil mill, canning-factory, and 2 daily and 2 weekly newspapers. Pop. (1890) 8,254; (1900) 9,358. EDITOR OF "NEWS."

Par'is, or **Alexander** (in Gr. Πάρις, Ἀλέξανδρος): a son of Priam, the King of Troy, and Hecuba. He carried off Helen, the wife of Menelaus, King of Sparta, thereby bringing on the war between the Greeks and Trojans. By Homer he is described as shrewd, but cowardly; in art he is represented as a youthful and handsome man, though somewhat effeminate in appearance. Being wounded during the siege by a poisoned arrow, he died before the capture of the city. For Paris in art, see the article *Paris und Parisurtheil* in Baumeister's *Denkmäler*; Overbeck, *Die Bildwerke zum Thebischen und Troischen Heldenkreis* (Stuttgart, 1857), pp. 206–263. J. R. S. STERRETT.

Paris, ALEXIS PAULIN: French author; b. at Avenay, Marne, France, Mar. 25, 1800; studied at the *lycée* at Reims and afterward in Paris, where he began the study of law, but soon devoted himself to literature and history, and became distinguished for his knowledge of mediæval French literature. He became connected with the great library, now the Bibliothèque Nationale, in 1828, and was attached to the department of manuscripts in it. In 1837 he was made a member of the Académie des Inscriptions et Belles-Lettres. He was Professor of the French Language and Literature at the Collège de France from 1853 to 1872, when he retired with the title of honorary professor, leaving at the same time his position at the Bibliothèque Nationale. His writings deal mostly with the mediæval literature of France, including text editions, modernizations, and studies, but are not limited to that field. Among them are *Apologie de l'école romantique* (1826); a translation of Byron's *Don Juan* (1827); *Li romans de Berte aus grans piés* (1832); *Li romans de Garin le Loherain*, 1833 (the same *en nouveau langage*, etc., 1862); *Le romancero français* (1833); *Les grandes chroniques de France* (6 vols., 1836–38); *De la conqueste de Constantinoble par Joffroi de Villehardouin et Henri de Valenciennes* (1838); *Les manuscrits français de la bibliothèque du roi* (7 vols., 1836–48); *La chanson d'Antioche* (1848); *Les aventures de Maître Renart*, etc. (1861); *Les romans de la Table Ronde mis en nouveau langage* (5 vols., 1868–77); *Étude sur François I.*, etc. (2 vols., 1885); further a large part of the contents of vols. xx.–xxiii., xxv.–xxviii. of the *Histoire littéraire de la France*, notably the articles on the *Chansons de geste* in vols. xxii., xxv., xxvi. D. in Paris, Feb. 13, 1881. E. S. SHELDON.

Paris, GASTON BRUNO PAULIN: philologist; b. at Avenay, France, Aug. 9, 1839. Graduating at the Collège Rollin, he studied Romance philology at Göttingen and Bonn. Returning to Paris, he became in 1865 instructor in Romance languages in the École Pratique des Hautes Études, and in 1866 and 1869 lectured at the Collège de France in place of his father, Paulin Paris (1800–81), whom he succeeded in 1872. He was an untiring contributor to the early history of French language and literature, and the flourishing young school of Romance philologists in France is largely due to his influence and composed of his pupils. He was one of the founders of the *Revue Critique* (1865) and of the *Romania* (1872), which he continues to direct, and in which many of his studies have appeared. Among his more considerable works are: *Étude sur le rôle de l'accent latin dans la langue française* (1862); *Histoire poétique de Charlemagne* (1866); *Les contes orientaux dans la littérature française du moyen âge* (1875); *La vie de saint Alexis* (1872); *La Poésie du moyen âge* (1885); *La Littérature française du moyen âge* (1888). A. G. CANFIELD.

Paris, paa'ris, JOHN AYRTON, M. D., D. C. L.: therapeutist; b. at Cambridge, England, Aug. 7, 1785; graduated in medicine at Cambridge University 1808; resided some time in London, and several years at Penzance, Cornwall, where he founded the Royal Geological Society of Cornwall; returned to London 1817; lectured on *materia medica* and the philosophy of medicine at the Royal College of Physicians, of which body he was president from 1854 until his death; invented the tamping-bar, an implement coated with copper for the protection of miners from the perils caused by the sparks emitted from iron bars; published, among other works, a *Memoir* of Sir H. Davy (1810); *Pharmacologia, or the History of Medical Substances* (1819); *A Treatise on Diet* (1826); *Philosophy in Sport made Science in Earnest* (3 vols., 1827); *Elements of Medical Chemistry* (1833); and *Medical Jurisprudence* (3 vols., 1823), in which he was aided by J. S. M. Fonblanque. D. Dec. 24, 1856.
Revised by S. T. ARMSTRONG.

Paris, pāā'ree', LOUIS PHILIPPE ALBERT D'ORLÉANS, Comte de: claimant to the French throne; son of the Duc d'Orléans and grandson of King Louis Philippe; b. in Paris, Aug. 24, 1838; appeared with his mother in the French Chamber of Deputies in the Revolution of 1848, but his claims to the throne were not recognized, and he was taken to England and lived at Claremont, where he received his education. After traveling in Greece, Egypt, and the East, the prince and his brother, the Duc de Chartres, accompanied their uncle, the Prince de Joinville, to the U. S., Aug., 1861, and offering their services to the Federal Government, were attached to the personal staff of Gen. McClellan with rank of captain, but free at any moment to relinquish the service and return to Europe. They remained with the army for several months, serving with bravery and efficiency, especially in the battle of Gaines's Mill. In 1864 the count married his cousin, the Princess Isabella, eldest daughter of the Duc de Montpensier. In 1871 he was admitted as a member of the National Assembly, and in the following year that body voted the restitution of the property of his family. In 1873 he acknowledged the Comte de Chambord as the head of the royal house of France, but after the latter's death in 1883 the Comte de Paris united in his person the claims of both branches of the Bourbons, and was accepted by most of the legitimists as the successor of Chambord. He was again forced to leave France in 1886, in consequence of the Expulsion Act, which forbade the heirs of former reigning families to live in France. After this he lived in England, and in spite of occasional manifestoes calling upon his compatriots to restore the monarchy he did not receive a large share of public notice till 1890, when the escapade of his son, the Duc d'Orléans, who tried to enlist in the French army in violation of the law of exile, caused considerable excitement among the royalists, and revived for a time the popular interest in their cause. D. in Stowe House, Buckinghamshire, England, Sept. 8, 1894. The Comte de Paris won some fame as a writer, especially by his *Histoire de la guerre civile en Amérique* (1874–89). He also wrote *Situations des ouvriers en Angleterre*, and various articles in periodicals.

Park: in the usual sense of the term, a considerable extent of ground laid out and maintained as a public pleasure-ground. In the course of its development first comes the glade and meadow with woods and waters where the hunter seeks his game. Inclosed by wall or fence this becomes the *chace*, and is still mainly devoted to the preservation of game. Finally the desire for open-air pleasures felt by the home-dweller asserts itself, and walks and resting-places are made for the quiet enjoyment of outdoor features. In this way at last came the gentleman's country-place of to-day. Notwithstanding this increasing desire for the peaceful enjoyment of woods and waters, paths and resting-places, there still remained the green or common. This continued to exist, but beside it grew up the park modeled on the gentleman's country-place, and comprising certain other features, such as roads and open spaces, required for public use.

History.—The Egyptians doubtless had parks earlier than the earliest records on their monuments. Their parks were formal, rectangular, little more than promenades full of architectural features, colonnades, and sculptured objects of diverse form and significance. Parks to them meant little more than a cluster of gardens. In the mountainous regions of Assyria glimpses of the modern idea of a park began to appear. Idealized conceptions of the mountain idea have been ascribed to the "hanging gardens of Nebuchadnezzar," and the paradises of the Assyrian Semiramis and the later Persians with wild animals and birds, trees and flowers, approached still nearer the park of modern Europe.

The Greeks derived much of their science and art from Egypt, and their landscape architecture apparently came in large part from the same source. There is little evidence that they comprehended the true park idea in design. The Romans, however, developed a great love for parks, and Rome became in the time of the Cæsars one great pleasure-ground. Lanciani says that there were at this time eight campi or commons for foot-races and thirty parks or gardens belonging to the city. The largest common was the Campus Martius, a vast level space with buildings, playgrounds, and water-works on an extraordinary scale, surrounded by miles of sumptuous colonnaded porticoes inclosing beautiful gardens. The Golden House of Nero included miles of gardens in the very heart of Rome. In every direction the architectural masses were broken and enframed by the green of gardens and parks, while the water was used in canals, fountain-basins, and cascades to an extent unknown before or since.

During the Middle Ages little attention was paid to gardening as an art. (See LANDSCAPE-GARDENING.) In the days of the Renaissance, however, the taste for public works of this sort gradually increased, and in France during the reign of Louis XIV. the great parks and gardens by Le Nôtre and others appeared, and the kings of Spain, Germany, and Poland sought to signalize their reigns in the same manner. Paris and two or three other great cities remained for a long time the only seats of these public enterprises.

In the nineteenth century, as a consequence of the revival among poets and painters of a love for natural effects, public parks have sprung up all over Europe and North America.

Different Styles of Park-making.—The different styles of park-making have been divided into the regular, mixed, and irregular or natural. The division is arbitrary, and in some of the finest public parks the different styles mingle. There is a quality about the formal style that suits it to the immediate surroundings of great public buildings like those of Paris or Rome. The mixed style enables the designer to preserve valuable formal features, such as ruins, straight promenades, and regularly laid-out flower-gardens. This system has been adopted in many of the parks of Europe. The natural style lends itself better to all the requirements of a public park than any other. The essentials of a public park, whether regular or irregular and natural, are public ways laid out in conjunction with greensward and planted with shade trees. Climate, topography, and surroundings must determine which style is to be used, and if both styles are employed the one should be isolated from the other and one predominant character given to the entire park. A ruin, a formal old-fashioned flower-garden, a system of gay parterres and regular walks, may all be retained, but they must be masked and isolated by trees and shrubbery.

The keynote of the composition of natural park landscape is peace and restfulness, the pastoral idea. Meadows, hedgerows, shaded lanes are the types for the study of the park-maker. There should be as much open meadow, with bordering shrub and tree plantation, as possible, and the rugged effects of rock and hillside should be toned down to the semblance of somewhat cultivated or not unkempt mountain scenery. All violent contrasts of form and coloring are to be carefully avoided in the composition of the general mass of natural park landscape as well as in the arrangement of the smallest details.

The Selection of Park Lands.—A level site or a slightly undulating one is preferable to one that is hilly or rocky, and great variety of effect may be secured on the level site by means of planting and other landscape-gardening devices. Among hills, ravines, and rocks, drainage and roads are difficult to design and construct, and the open lawn effect characteristic of the true park idea may be almost impossible of attainment. An excellent selection of park lands has been made in the Prince's Street Gardens site in Edinburgh. Here a steep hillside slopes down from the castle to a valley that borders on Prince's Street. It is not a large territory, but gains greatly in its appearance of size from the hollowing contour lines of its valley and the picturesque and artistic disposition of its shrubbery and trees. Wherever rough land is selected for a park its peculiar features should be intensified rather than obliterated.

The Making of a Park.—In the preparation of the plan of a park various landscape pictures must be secured by the arrangement of plantations and other devices, and at the same time the necessary convenience of the public must be considered. There must be also unity of idea governing the entire design. In the execution of the plan a landscape architect, a constructing engineer, and a superintendent of labor are needed to carry it out on the ground. The landscape architect or park-maker should control the execution of the plan, and decide whether the lines are laid out correctly and what changes should be made. No map can be worked out so precisely on paper as to prevent the necessity of frequent changes that have been indicated by the experience of actual execution.

Drainage, grades, road and building construction, and all engineering problems should be under the control of the engineer of construction, but on the superintendent of labor, more than on any one else, depends the successful execution of the architect's plans. The offices of landscape architect and constructing engineer can be hardly held successfully by the same person, for the reason that the engineer is trained to use mathematical straight lines or segments of a circle, while the landscape architect, except in strictly formal designs, never uses them; but one person may serve well as both landscape architect and superintendent. It is also important that the landscape architect should continue to control the execution of the design until, after years, it has reached its full development.

Walks.—Primarily, parks should be laid out with special reference to the needs of the pedestrian who seeks open air, skies, stretches of greensward, and shady trees. The walks should never run parallel with anything, or be of uniform width, unless the entire design is strictly formal. They should run above or below the road or lawn they border, and should widen or narrow as the designer sees fit. In no case should they run nearer the road than 10 feet, that space being needed for trees and groups of shrubs. They should be constructed with broken-stone foundation and covered with asphalt or cement for comfort, and with gravel if the most harmonious effect be desired.

Roads.—Roads should be laid out with a view of reaching the landscapes and other attractive features of the park. The masses of the park, the open meadows, and large groves should be determined by the course of the roads. Sometimes, as in Central Park, New York, the arrangement of a road that comes in at a corner and bends off diagonally increases the apparent size of the park greatly, or, in the case of the English Garden at Berlin, a narrow park will have its roads forced close together to the diminution of the apparent size of the park. This has been overcome in the English Garden by skillfully devised masking plantations. Park roads should be laid out on long and easy curves for the safety of the driving public and to avoid abruptness, and should be built 45 to 50 feet wide. A greater width tends to dwarf the lawns and diminish the appearance of breadth throughout the park. All roads should have a foundation of a foot or more of broken stone and a surface of gravel or fine broken stone, and should be bordered with low graded edgings of turf.

Lawns.—A bit of greensward is the most essential and characteristic feature of a park. The pictorial element of park-making is found to a large extent in the greensward or meadow. Trees and shrubs frame and develop the lawn, and thus serve a purpose more important than the exhibition of their own attractions. The comparatively level line of the meadow inspires a sense of serenity, and produces far-reaching sky effects. No path should traverse the main parts of a meadow, or tree or shrub mar the restfulness of its surface. There should be a recognition of the original topography of the region, a smoothing out and blending of minor inequalities which will leave a play of long lines of slightly undulating surface.

Treatment of Water.—The employment of the level line in park-making may be much extended by designing various water effects, and this is one of the most difficult problems of park-making. An abundant supply of pure water should be always at hand. Natural positions where watercourses or pools already exist are preferred to purely artificial ones. Every landscape feature in park-making should be suggested by actual conditions of the original surface. The charm of water lies chiefly in its broad, level, glass-like reflecting surface, and in the play of ripples, but of almost equal importance is the picturesque treatment of the shore by means of small promontories, bays, creeks, inlets, and islets. By this means the whole extent of the water is not seen at once, and the sense of size and distance is greatly increased. Rustic buildings, rocks, or some fine tree or bush may also be so arranged as to be reflected in the water, and seats

may be placed that will command the best views. The most attractive reflections are those of water-plants, lilies, lotuses, flags, and rushes. Grass should be encouraged to grow to the surface of the water, except where an actual beach has been constructed. Drooping trees and shrubs should also be permitted to dip their branches in the water.

Employment of Rocks in Parks.—A desire for natural effects in park-making leads to the employment of groups of rocks at certain points, but they should be used only where neighboring rocks create a reason for their presence. They should peep out of the earth on some curved surface or mound and along the borders of walks and steps and pools and streams of water. They should have rounded or weather-beaten surfaces, and should be so buried as to give no adequate conception of their size. Rocks should not be planted irregularly in a mass, to support a bank of earth. The bank should be, if possible, so graded as to support itself, and a regular dry wall of stone should be constructed if this is not possible.

Park Plantations.—Shade trees are the most important park plantations. Along all drives and walks shade trees should be set at intervals of 50 or 60 feet. The masking plantations of the park, the framework that with the greensward produces the vistas and landscape pictures, should be made up of a series of groups of trees and shrubs. There should be groves of trees and entire groups of low shrubs, but both trees and shrubs should be skirted by a border of drooping bushes. Outlying specimens of both trees and shrubs may stand on the flanks of the main shrub group. The sky-line of these groups should be waving with emphatic points, and the outlines of the base should be varied into bays and points of foliage. Groups and single specimens of trees and shrubs planted near them should be disposed around the lawns and down the hillsides and along the water-courses, so as to secure the greatest possible apparent length of vista and breadth of greensward, and at the same time most surprising, varied, and mysterious effects.

Plantations of trees and shrubs should mask all roads and paths as far as the opening of vistas and broad stretches of greensward will permit. It is important especially that they should mask completely the junction of different roads and paths. The sense of variety, surprise, and mystery, and the rural effect are thereby greatly increased.

Trees and shrubs may be used effectively at the top of steep hills, where the presence of such trees as the Lombardy poplar and the birch tend to intensify the suggestion of mountain scenery. A few of the trees valuable for shade and mixed groups are the American elm, the sugar, Norway, and scarlet maple, the linden, the tulip, poplar, the honey locust, the horse-chestnut, the birch and the beech, and the white-oak and pin-oak. Vigorous hardy shrubs are *Spiræa opulifolia*, privet, snowball, viburnum, mock-orange, bush honeysuckle (*Lonicera fragrantissima*), golden bell (*Forsythia*), weigela, red-twigged dogwood (*Cornus sanguinea*), *Rhodotypus kerrioides*, Japan quince (*Cydonia japonica*), *Spiræa thunbergii*, and *Berberis thunbergii*. The best coniferous evergreen trees are the white pine (*Pinus strobus*), blue Colorado spruce (*Abies pungens*), Mugho pine (*Pinus mughus*), hemlock (*Abies canadensis*), atlas cedar (*Cedrus atlantica*), Nordman fir (*Abies nordimanniana*), Japan yew (*Taxus cuspidata*), and Japanese cypress (*Retinospora obtusa*).

Good broad-leaved evergreens are the American laurel (*Kalmia latifolia*), the rhododendron, the Japanese azalea (*Azalea amœna*), and the tree-box (*Buxus arborescens*). Overcrowding these trees and shrubs should be carefully avoided. The large-growing trees, such as the elm or maple, should all be planted 50 feet apart, and the smaller 25 feet. Large shrubs, such as privet, should be 10 feet apart, and smaller ones, as the Japan quince, 6 to 8 feet; even the smallest should be allowed from 3 to 4 feet.

Along the borders of many shrub groups and rocky places should be planted hardy herbaceous plants, i. e. perennials, or wild flowers, such as larkspurs, daisies, phloxes, asters, sedums, irises. These perennials should stray out over the turf in irregular belts, and should constitute an intermediate gradation between the lower-sized shrubs and the grass.

Bedding-plants, cannas, coleuses, geraniums, etc., should be planted as a framework around buildings and other architectural structures in the park, and nowhere else. Their treatment must be somewhat formal and should be considered as an ornamentation of the building and not an integral part of the park itself; but since the outer portions of these beds must connect with the grass and make a part of the lawn, the same principles of design should apply to them as to the tree and shrub group.

Generally high plants should be in the middle or at the back, and low plants in front or on the borders, but this rule should be frequently broken in the interest of true art by thrusting high plants directly over the border-line, and in the case of single specimens by setting them outside near points of the bed in the greensward.

The outline of the border, like that of shrub groups, should be wavering, running in and out in promontories and smooth slopes and bays, and the curves should never be segments of a circle. Form combinations of the most artistic design can be thus contrived, and the blending and the contrast of both form and color made more subtle and brilliant than any carpet bed plants where the contrasts of color are nearly always strong and not artistic and the form flat and ill proportioned.

Plants suitable for bedding are musas, cannas, achalyphas, geraniums, begonias, coleuses, alternantheras, salvias, bouvardias, castor-oil plants, solanums, and achyranthus and periwinkles. Groups of lilies, lotuses, and other water plants should be treated in the same artistic way.

Climbing vines should be used over rocks, banks, walls, bridges, and buildings. Wherever they appear they add to the variety and picturesqueness of the landscape. Useful vines are the honeysuckle, Virginia creeper, Japan ivy (*Ampelopsis tricuspidata*), clematis, Dutchman's pipe (*Aristolochia sipho*), wistaria, trumpet creeper, climbing rose, and akebia.

Architectural Structures.—All architectural structures in a park should be of simple, unobtrusive design and thoroughly masked by trees, shrubs, and vines. No statues should be allowed in a rural park, except at the entrances and adjoining buildings. Stone bridges should be rough-faced and rustic in character, with as small amount of wall effect as possible. Bridges over walks and roads for the safety of the public should not be multiplied to the detriment of the general rural effect of the park. All entrances to bridges should be masked by planting. Stone steps should be made of rough-faced blue or neutral-tinted stone, and the borders protected by narrow strips or curbs of the same material. The earth all about the steps should be mounded up until from most directions only slight glimpses of the stonework can be obtained.

On the higher parts a few single rocks may be buried with good effect, provided there are other rocks in the neighborhood. Stone walls suit the outer boundaries of parks better than any other fence. They should be made of neutral-tinted, gray, or brown stone.

Arbors, summer-houses, and seats may be built successfully of knotty and crooked gnarled wood. All bark should be peeled off, and the most durable kinds of material employed, such as locust, red cedar, and sassafras.

Rights of the Public in Parks.—Much confusion often arises as to the rights of the public in parks, and great injury comes in this way from people who wish to secure fair-grounds, grounds for military parades, speeding-tracks, and for shows of all kinds. Parks are for the use of the public, and occupation of ground by one set of people to the exclusion of others is an infringement of personal rights. Games of all kinds may be played on the lawns, provided every one who desires is allowed to take part in them. An exception is made in the case of children, who, it is conceded, should have their ball-ground, swings, merry-go-round, and arbor. Music should be isolated in some spot arranged for the purpose, where the crowds will not mar the restful effect of the remainder of the park.

City Squares and Places.—City squares are hardly recognized as parks in the usual sense of the term. They must be somewhat more formal in effect on account of the proximity of city buildings, but the principles on which they are constructed should be the same as those of the largest parks. The boundaries should be planted with a series of masking trees and shrubs, and as much open lawn secured as the general design will permit. Architectural structures, statues, and fountain-basins find an appropriate home in the small squares of the city. Around these structures brilliant beds of cannas, geraniums, and begonias may be arranged in an effective manner. Children's playgrounds may be also devised after the manner of some Paris parks, by making a special widening of the walk in one of the angles of the territory, and there planting one or more shade trees.

Noted Parks.—Among the best-known parks of the pres-

ent day are Hyde Park (with Kensington Gardens), 598 acres, Regent's Park, 472 acres, Victoria Park, 300, Battersea Park, 250 acres, all in London; Princes Street Gardens, Edinburgh; Phœnix Park, nearly 2,000 acres, Dublin; Central Park, 862 acres, New York; Prospect Park, 515 acres, Brooklyn; Thier Garten, 200 acres, Berlin; the Bois de la Cambre, 124 acres, Brussels; the Garden La Flora, Cologne; the English Garden, 500 acres, Munich; the Prater Gardens, 1,500 acres, Vienna; Paulovsk Park, near St. Petersburg; the Bois de Boulogne, 2,000 acres, and Bois de Vincennes, 2,075 acres, Paris. SAMUEL PARSONS, Jr.

Park, EDWARDS AMASA, D. D., LL. D.: theologian; b. at Providence, R. I., Dec. 29, 1808; graduated at Brown University 1826 and at Andover Seminary 1831; became in 1831 Congregational pastor at Braintree, Mass.; was 1835–36 Professor of Moral and Intellectual Philosophy in Amherst College; held the Bartlet professorship of Sacred Rhetoric in Andover Theological Seminary 1836–47, and in the latter year became Abbot Professor of Sacred Theology in the same institution, resigning in 1881. He was one of the editors and translators of *Selections from German Literature* (1839). In 1869–70 he traveled extensively in Europe and the East; was one of the founders and (1844–83) one of the principal editors of the *Bibliotheca Sacra*; author of *Lives* of Hopkins (1852), Emmons (1861), D. B. Edwards (1853), and W. B. Homer (1849), prefixed respectively to editions of their writings; a *Life* of S. H. Taylor; edition of *Discourses and Treatises on the Atonement* (1859); *Discourses on some Theological Doctrines as related to the Religious Character* (1885); author of numerous published discourses, sermons, essays, etc.; a preacher and theological teacher of great ability. Revised by G. P. FISHER.

Park, MUNGO: traveler; b. at Fowlshiels, Scotland, Sept. 10, 1771; studied surgery at Edinburgh, and was 1792–93 assistant surgeon in India. Under the auspices of the African Association, London, he was the pioneer in the modern exploration of Africa. He journeyed up the Gambia (1795), suffering extreme hardships, and being a prisoner for some time in the hands of a Moorish king. Escaping on July 1, 1796, he reached the upper Niger, the great object of his search, at Segu, and followed the river toward Timbuctoo as far as Silla, where he was compelled to turn back. After seven months' illness and great hardships he reached the mouth of the Gambia, having been nineteen months in the interior. This journey was described in his book *Travels in the Interior of Africa*. The British Government sent him (1805) to descend the Niger from the upper river, and trace its entire course. Most of his party died of fever, and before the Niger was reached only five white men were left out of forty-four. The party set sail down the river, at first in two canoes, but soon built a little schooner, with which they descended the Niger some 1,500 miles, when they were treacherously attacked by a large party of natives, and Park and all his company perished in the attempt to escape by swimming. The journals he sent home and information collected by Clapperton and Lander have given all the facts that are known of his last expedition. Revised by C. C. ADAMS.

Park, ROSWELL, M. D.: surgeon; b. at Pomfret, Conn., May 4, 1852; educated at Racine College and Chicago Medical College; demonstrator and Adjunct Professor of Anatomy, Chicago Medical College, 1877–82; lecturer on surgery, Rush Medical College, 1882–83; Professor of Surgery, Medical Department, University of Buffalo, since 1883; author of *The Mütter Lectures on Surgical Pathology* (1892); of numerous encyclopædia articles and surgical monographs; and one of the joint authors of *An American Text-book of Surgery* (1892). He was editor of the Chicago *Weekly Medical Review*; then of *The Medical Press of Western New York*; and associate editor of the *Annals of Surgery*.

Park City: city; Summit co., Utah; on the Union Pac. and the Utah Cent. railways; 30 miles E. of Salt Lake City, the Territorial capital (for location, see map of Utah, ref. 4–M). It is in a mining region, and contains a valuable silver mine, sampling-works, several quartz-mills, sawmills, a national bank with capital of $50,000, and a weekly newspaper. Pop. (1880) 1,542; (1890) 2,850; (1900) 3,759.

Parke, JOHN GRUBB: soldier; b. near Coatesville, Pa., Sept. 22, 1827; graduated at the U. S. Military Academy July 1, 1849, when he was appointed brevet second lieutenant, topographical engineers (first lieutenant July, 1856; captain Sept. 9, 1861), being engaged in various surveys in the Western States, as secretary of the lighthouse board, and for many years as chief astronomer and surveyor in locating the northwestern boundary of the U. S. Appointed brigadier-general of volunteers Nov., 1861, he accompanied Burnside to North Carolina, and commanded at the capture of Fort Macon; promoted to be major-general Aug., 1862, he served as chief of staff of the Ninth Corps in the battles of South Mountain and Antietam, and on Gen. Burnside's succeeding to the command of the Army of the Potomac was retained by the latter as his chief of staff, participating in the battle of Fredericksburg; was in command of the Ninth Corps during its march to Vicksburg, and for a time of the left wing of Gen. Sherman's army; in command of a division of the Ninth Corps on Gen. Burnside's reassuming command, and engaged in Tennessee in siege of Knoxville, etc.; and in Richmond campaign of 1864, again attaining command of the Ninth Corps before Petersburg (Aug., 1864), which he retained till the end of the war. He received the brevets of colonel for gallantry at Jackson, of brigadier-general at Knoxville, and major-general at Fort Steadman, Virginia. Mustered out of volunteer service July, 1866, he resumed the duties of his corps. In 1864 he became a major of the Corps of Engineers, lieutenant-colonel in 1879, and colonel in 1884. During these years he was engaged upon boundary surveys, improvements of rivers and harbors, and works of fortification. From 1868 to 1887 he was senior assistant in the office of the chief of engineers, frequently acting as chief. He became superintendent of U. S. Military Academy July 1, 1887, and was retired from active service at his own request July 2, 1889. D. Dec. 16, 1900.
Revised by JAMES MERCUR.

Parker, AMASA JUNIUS, LL. D. (of Hobart College): b. at Sharon, Conn., June 2, 1807; removed in 1816 to Greenville, N. Y., and graduated from Union College in 1825. He held many positions of public and private trust during his life; was a member of the Legislature in 1833; chosen a regent of the university in 1835; in Congress 1837–39; vice-chancellor and circuit judge 1844–47; and (under the new Constitution) judge of the Supreme Court 1847–55. He was one of the founders of the Albany Law School, and for twenty years one of its professors. His chief literary work was the publication of reports of criminal cases (6 vols., 1855–69), work in the preparation of the revised statutes of 1859, and editorial work upon the third edition of Reeve's *Law of Baron and Femme*. D. at Albany, May 13, 1890.
F. STURGES ALLEN.

Parker, EDWIN POND, D. D.: clergyman; b. at Castine, Me., Jan. 13, 1836; graduated at Bowdoin College 1856, and at Bangor Theological Seminary; has been pastor of the South Congregational church in Hartford, Conn., since 1860. Dr. Parker is the author of *Book of Praise*; *Sunday-school Songs*; *Christian Hymnal*; *Memorial of Horace Bushnell*; *The Ministry of Natural Beauty*. He has composed many hymn-tunes and several hymns, which have found acceptance. It was at his ordination that the question of continued probation after death first came into public discussion in the Congregational churches of New England. G. P. FISHER.

Parker, FOXHALL ALEXANDER: commodore; b. in New York city, Aug. 5, 1821; was appointed a midshipman in the navy Mar. 11, 1837; graduated from the Naval School at Philadelphia June 3, 1843; was commissioned lieutenant Sept. 21, 1850; served at the Washington navy-yard as executive officer 1861–62; appointed commander July 16, 1862; commanded the steam gunboat Mahaska (1862–63) in active service off Wilmington and Yorktown; commanded the Wabash off Charleston June to Sept., 1863; commanded the Potomac flotilla from Dec., 1863, until the close of the civil war; was promoted to a captaincy July, 1866; was chief of staff to the North Atlantic fleet 1872; appointed chief signal-officer of the navy July 1, 1873. Published *Fleet Tactics under Steam* and *Squadron Tactics under Steam* (1863); *The Naval Howitzer Afloat* (1865); and *The Naval Howitzer Ashore* (1866); also *Elia, or Spain Fifty Years Ago* (translated from the Spanish, 1866). He was one of the founders of the Naval Institute at Annapolis. In Dec., 1874, he was appointed chief of staff of the united fleets in Florida waters; commanded navy-yard, Boston, 1877; superintendent Naval Academy from 1878 till his death, June 10, 1879.

Parker, FRANCIS WAYLAND: See the Appendix.

Parker, HORATIO GILBERT: See the Appendix.

Parker, HORATIO WILLIAM: composer and organist; b. at Auburndale, Mass., Sept. 15, 1863; studied in Boston and

Munich. His first important composition was the cantata *King Trojan* (1885), produced in Munich. He has also composed *The Kobolds*, a short cantata, and *Hora Novissima*, a sacred cantata (1892) for the Church Choral Association of New York, besides much other music, sacred and secular. From 1885 to 1893 he was Professor of Music at the Cathedral School of St. Paul, Garden City, L. I., and organist of Holy Trinity church, New York; then became organist of Trinity church, Boston; was elected Professor of the Theory of Music at Yale University in 1894. D. E. Hervey.

Parker, Joel, LL. D.: lawyer; b. at Monmouth, N. J., Nov. 24, 1816; graduated at Princeton in 1839; admitted to the bar in 1842; elected to the State Legislature in 1847; subsequently county attorney. On the breaking out of the civil war he was made major-general of volunteers; in 1862 was elected Governor of New Jersey, and again in 1871. He was an associate justice of the Supreme Court of New Jersey. D. in Philadelphia, Pa., Jan. 2, 1888.

Parker, John Adams: See the Appendix.

Parker, Joseph, D. D.: preacher and author; b. in Hexham, England, Apr. 9, 1830; educated privately and at University College, London; settled at Banbury in 1858; was pastor of Cavendish Chapel (Congregational), Manchester, 1858–69; of Poultry Chapel, London, 1869–93; and is now (1894) in charge of City Temple, High Holborn; visited the U. S. in 1888, and received the degree of D. D. from Chicago University. Author of *Ecce Deus* (1868); *The People's Bible* (vol. i., 1885); and other works, most of which have been reprinted in the U. S. Revised by G. P. Fisher.

Parker, Matthew, D. D.: archbishop; b. at Norwich, England, Aug. 6, 1504; educated at Corpus Christi College, Cambridge; took priests' orders 1527, the same year became M. A. and fellow of his college; chaplain to Anne Boleyn 1533; dean of Stoke Clare College, Suffolk, 1535; chaplain to Henry VIII. 1537; prebendary of Ely 1541; master of Corpus Christi College 1544; dean of Lincoln 1552; was deprived by Queen Mary 1553 for having married; appointed Archbishop of Canterbury in 1559 through the influence of Nicholas Bacon and Cecil, for Queen Elizabeth was at that time violently opposed to the marriage of the clergy. The Bishops' Bible was printed at his expense. Later he became an enemy of conventicles and of the nonconforming spirit. He published Anglo-Saxon and other early English chronicles, and collected a valuable library, which he bequeathed to Corpus Christi College, Cambridge. D. May 17, 1575. The Parker Society, named in his honor, published from 1841 to 1855 a series of fifty-five volumes of English ecclesiastical writings of the Elizabethan age.

Parker, Peter, M. D.: missionary and diplomat; b. at Framingham, Mass., June 18, 1804; graduated at Yale College 1831; studied theology and medicine at New Haven; went to Canton, China, as a missionary 1834; established a hospital; had great success both in surgery and medicine, and trained many Chinese students; returned to the U. S. 1840–42; became interpreter and secretary of legation to the American mission in China 1845, retaining charge of the hospital; again visited the U. S. 1855, but went to China the same year as commissioner with power to revise the treaty; finally returned to America in 1857, after which he resided at Washington, D. C.; was a regent of Smithsonian Institution, and filled other honorable scientific posts. D. at Washington, Jan. 10, 1888.

Parker, Samuel, D. D.: bishop; b. at Portsmouth, N. H., Aug. 28, 1744; graduated at Harvard 1764; was an instructor for nine years; ordained to the Anglican ministry 1774 by the Bishop of London; until 1779 assistant minister, and then rector, of Trinity church, Boston; conformed the Prayer-book services to the changed condition of civil affairs directly on the receipt in Boston of news of the signing of the Declaration of Independence; was an active promoter of a union between Bishop Seabury and the New England churches, and Bishops White and Provoost and the churches of the Middle and Southern States, which in 1789 united the Episcopal Church in the U. S.; in 1804 consecrated bishop of the Protestant Episcopal Church for the diocese of Massachusetts. D. at Boston, Dec. 6, 1804.

Parker, Theodore: theological leader; b. at Lexington, Mass., Aug. 24, 1810; was a grandson of Capt. John Parker, who commanded the company of minutemen fired on by British troops at Lexington Apr. 19, 1775; studied Latin, Greek, and mental philosophy while working on the farm or in the tool-shop; taught school at the age of seventeen; studied at Lexington Academy; entered Harvard College 1830, but did not pursue the regular course, being obliged to carry on his studies at home and teach private classes at Boston and Watertown; became proficient in many languages; entered the Cambridge Divinity School 1834, graduating 1836; was settled at West Roxbury as pastor of the Second (Unitarian) church June, 1837; soon arrived at religious views widely differing from those of conservative Unitarians, and became the leader of a school of theology which rejected as unhistorical many portions of the canonical Scriptures, renounced all belief in the supernatural, and exercised great freedom in the definition of the Christianity which he continued to profess; laid down the principles of his new transcendental system in a series of five lectures delivered at Boston in the autumn of 1841, published under the title *A Discourse of Matters Pertaining to Religion* (1842); followed in the autumn of 1842 by a series of six *Sermons for the Times*; wrote articles in *The Dial*; published a volume of *Critical and Miscellaneous Writings* (1843), and a translation of De Wette's *Introduction to the Old Testament* (2 vols., 1843); spent nearly two years (1843–44) traveling in Europe; returned to Boston in the autumn of 1844, when a controversy grew warm within the Unitarian denomination, arising from the act of several pastors of churches at Boston, who admitted him to their pulpits. As the result, Mr. Parker established an organization at Boston known as the Twenty-eighth Congregational Society (1846), which worshiped at the Melodeon, and subsequently for many years at the Music Hall, where his audiences were large and his teachings embraced a wide scope of subjects; founded and edited for three years the *Massachusetts Quarterly*; was earnestly opposed to the Mexican war, to slavery, and intemperance; was indicted in the U. S. court (June, 1854) for resistance to the Fugitive Slave Law in the case of Anthony Burns, the offense being an address at Faneuil Hall, but was never brought to trial; Jan., 1859, he was prostrated by an attack of bleeding at the lungs; visited the West Indies, where he wrote a small work entitled *Theodore Parker's Experience as a Minister*; proceeded thence to Europe; resided successively in Switzerland and at Rome 1860, obtaining no relief. He died at Florence, Italy, May 10, 1860, and was buried in the Protestant cemetery outside the walls. He bequeathed 13,000 volumes to the Boston Public Library. His complete works were edited by Frances Power Cobbe (12 vols., London, 1863–65) and by H. B. Fuller (10 vols., Boston, 1870); his *Life and Correspondence* was published by Rev. John Weiss (2 vols., New York, 1864); and his *Life* by Rev. O. B. Frothingham (New York, 1874). A French compendium, entitled *Théodore Parker, sa Vie et ses Œuvres* (1865), was prepared by Rev. Albert Réville. This has been translated (London, 1865). See *West Roxbury Sermons* (1892), with an introduction by Rev. S. J. Barrows and a biographical sketch by Frank B. Sanborn. Revised by J. W. Chadwick.

Parker, Willard, M. D., LL. D.: surgeon; b. at Lyndeborough, Hillsborough co., N. H., Sept. 2, 1800; graduated at Harvard 1826; studied medicine and surgery under Prof. John C. Warren; became Professor of Anatomy in the Vermont Medical College, and also in that of Berkshire 1830; Professor of Surgery in the latter institution 1833, and at Cincinnati 1836; spent some time in the hospitals of Paris and London; was for thirty years (1839–69) Professor of Surgery in the New York College of Physicians and Surgeons, after which he exchanged into the chair of Clinical Surgery, which he held for many years. In 1854 he first described and reported cases of what is now known as malignant pustule. Dr. Parker became president of the New York State Inebriate Asylum at Binghamton in 1865; was the first to call attention to the phenomena of concussion of the nerves as distinguished from that of the nerve-centers, formerly erroneously considered identical with a state of inflammation, and made several important discoveries in practical surgery, including the operation of cystotomy for the relief of chronic cystitis, and that for the cure of abscess of the appendix vermiformis. D. in New York city, Apr. 25, 1884.

Parker, William Kitchen, F. R. S., F. Z. S., F. L. S.: anatomist; b. at Dogsthorpe, near Peterborough, England, June 23, 1823; d. July 3, 1890. He was educated at Charing Cross and King's College Hospitals, and from 1873 to 1883 was Hunterian professor at the Royal College of Surgeons, London. His attention was early given to the Foraminifera, concerning which he published about thirty-six

papers, mostly in conjunction with Prof. T. Rupert Jones and Dr. H. B. Brady. He subsequently devoted himself to the study of the vertebrate skeleton, and particularly to the development and morphology of the skull, and on these subjects published about sixty papers, many of them monographic in their character. He was a skilled dissecter, an accurate observer, and a good draughtsman. Among Dr. Parker's principal papers are those *On the Osteology and Systematic Position of Balæniceps* (1860); *Palamedea* (1863); *Gallinaceous Birds and Tinamous* (1862–66); published in the *Transactions* of the Zöological Society of London a *Monograph on the Structure and Development of the Shoulder Girdle and Sternum in the Vertebrata* (1868); *The Skull of Batrachia* (1878); *Sturgeon* (1882); *Edentata* (1886); and *Insectivora* (1886), in the *Transactions* of the Royal Society of London. F. A. Lucas.

Parkersburg: city; capital of Wood co., W. Va. (for location, see map of West Virginia, ref. 6–E); at the confluence of the Ohio and the Little Kanawha rivers; on the Balt. and O., the Balt. and O. S. W., and the Ohio River railways; 96 miles S. by W. of Wheeling. It is in a rich oil and natural-gas region; contains 12 churches, 6 public-school buildings, high school, a seminary, the Academy of the Visitation, U. S. Government building, 4 national banks with combined capital of $636,000, and a monthly, 2 daily, and 2 weekly periodicals; and has the shops of the Ohio River Railroad, 5 oil-refineries, 5 machine-shops, 3 iron-foundries, 2 boiler-shops, lumber-mills, furniture-factory, and acid-works. The city has a water-system with sufficient pressure to render fire-engines unnecessary. The Ohio river is here crossed by a railway bridge over 1¼ miles long, excluding approaches, which cost over $1,000,000. Pop. (1880) 6,582; (1890) 8,408; (1900) 11,703. The suburbs have a population of about 4,000.

Proprietors of "State Journal."

Parkes, Sir Harry Smith: diplomatist; b. near Walsall, Staffordshire, England, Feb. 28, 1828. Left an orphan in 1833 he became a charge of his kinsman, Rev. Charles Gutzlaff, Chinese missionary and scholar. He was a student-interpreter on the staff of Sir Henry Pottinger in the China war of 1842, served in various grades of the British consular service in the far East, and was commissioner when the British troops occupied Canton. Captured treacherously by the Chinese in 1860 when under a flag of truce, he was thrown into a dungeon and tortured. His indomitable resolution carried him safely through this cruel experience, and finally he was released, most of his companions having meanwhile perished. From 1865 to 1883 he occupied the post of minister at the Japanese court, and was much dreaded by that nation, whose history he helped to mould, his sympathies being entirely with the imperialists. Sir Harry was a diplomatist of the Palmerston school, and very popular with his fellow countrymen; he enjoys the reputation of being the "only foreigner whom the Japanese could not twist round their little finger." He was transferred to Peking in 1883; d. there, Mar. 22, 1885. See his *Life*, by Stanley Lane-Poole (1894). J. M. Dixon.

Parkes, Sir Henry: See the Appendix.

Parkesburg: borough; Chester co., Pa. (for location, see map of Pennsylvania, ref. 6–I); on the Penn. Railroad; 45 miles W. of Philadelphia. It is in an agricultural region, and contains 5 churches, 6 public schools, an academy, rolling-mill, steam flour and planing mills, and a weekly and a monthly periodical. Pop. (1890) 1,514; (1900) 1,788.

Parkhurst, Charles Henry, D. D.: clergyman; b. at Framingham, Mass., Apr. 17, 1842; graduated at Amherst 1866; studied theology at Halle (1869–70) and Leipzig (1872–73), in Germany, having meanwhile taught (1870–71) in Williston Seminary, Easthampton, Mass.; was settled over the Congregational church in Lenox, Mass., 1874–80; in 1880 became pastor of the Madison Square Presbyterian church in New York city. In 1891 he became president of the Society for the Prevention of Crime, and soon after made the assertion that as the result of his own investigations he could prove that the New York police were the accomplices of the criminal classes, and that the corruption permeated the department of public justice. This led to an investigation by a committee of the State Legislature, a reorganization of the police department, and many reforms. He has published *Forms of the Latin Verb Illustrated by the Sanskrit* (Boston, 1870), and volumes of sermons under the titles *The Blind Man's Creed* (New York, 1883); *The Pattern in the Mount* (1885); and *Three Gates on a Side* (1891).

Parkinson, John, known by the fantastic name of **Paradi'sus in So'le** (Park-in-sun): botanist; b. in London in 1567; was apothecary to James I. and *botanicus regius primarius* to Charles I. Author of *Paradisus Terrestris* (1629–56) and *Theatrum Botanicum* (1640). He is one of the best of the old herbalists, and is commemorated by Plumier's genus *Parkinsonia*, order *Leguminosæ*. The year of his death is not known.

Parkinson-Fortescue, Chichester Samuel: statesman; b. in 1823; graduated B. A. at Christ Church, Oxford University, in 1844; was elected a Liberal member of Parliament for the county of Louth in 1847; was a Lord of the Treasury 1854–55; Under-Secretary of State for the Colonies 1857–58 and 1859–65; was made Chief Secretary for Ireland Nov. 20, 1865, and again in Dec., 1868, having been sworn a privy councilor in 1864. In Dec., 1868, he was a member of Gladstone's cabinet, and Jan., 1871, president of the Board of Trade. He was created Baron Carlingford 1874; Lord Privy Seal in Gladstone's cabinet 1881–85; Lord President of the Council 1883–85.

Parkman, Francis: historian; b. at Boston, Mass., Sept. 16, 1823; graduated at Harvard College in 1844, and from the Dane Law School in 1846; and in May, 1846, set out on a tour in the far West. The fruit of his travels was *The Oregon Trail*, which appeared in *The Knickerbocker Magazine* in 1847, and was republished in book form in 1849. His first historical work, *The Conspiracy of Pontiac*, appeared in 1851. This was followed by *Vassall Morton*, a novel (1856), published at a time when the author was suffering from a severe chronic disease, which postponed further literary work for several years. His principal work is *France and England in North America*, consisting of the following parts: *Pioneers of France in the New World* (1865); *The Jesuits of North America in the Seventeenth Century* (1867); *La Salle and the Discovery of the Great West* (1869); *The Old Régime in Canada* (1874); *Count Frontenac and New France under Louis XIV.* (1877); *Montcalm and Wolfe* (1884); and *A Half Century of Conflict* (1892). The whole work is one of immense research, perfect candor, and very rare ability. D. at Boston, Nov. 8, 1893.

Revised by F. M. Colby.

Parley, Peter: See Goodrich, Samuel Griswold.

Parliament [(with spelling adapted to Mediæv. Lat.) from O. Fr. *parlement*, liter., a speaking, deriv. of *parler*, speak]: a deliberative assembly or legislative body. The term is chiefly restricted to the legislatures of Great Britain, the Dominion of Canada, New South Wales, and other British self-governing colonies. The constitution of the colonial governments is treated in the articles on the various colonies; only the British Parliament is discussed here. The origin of parliamentary government in England, like that of many other British institutions, is involved in much obscurity. There can, however, be no doubt that alike in Saxon and Norman times the English people had always some share in making the laws whereby they were governed. The Witenagemote (or assembly of the wise) of the Saxon period, and the Parliament (or free-speaking council), which is traceable both in etymology and function to Norman influence, were at once the outgrowth and the guardians of popular rights and liberties. It is true that the earlier councils and assemblies have left no record of their proceedings, and probably they met at irregular intervals, being in some measure dependent on the caprice or necessities of the monarch. The taxes and crown levies could only be raised through the sanction of the people themselves; and it is one of the oldest as well as one of the most imperishable traditions of British government that there ought to be no taxation without representation. Successive sovereigns after the Conquest (1066) had encroached upon popular prerogative, until, in the reign of King John, the evil culminated in practical absolutism on the part of the crown. The result was a violent recoil and a resolute demand for the restoration of baronial and popular rights, which led to the signing of the Great Charter (Magna Charta, *q. v.*) on the field of Runnymede (1215). The Great Charter contained no new idea touching rights and liberties, every one of its clauses embodying an English tradition. In truth, it was only a revival of the English constitution; and the provision for calling a parliament whenever money was wanted was one of the first principles of ancient English politics. Little is known of the manner in which the pledges of the sovereign were kept for half a century after the signing of Magna Charta, but writs are still extant which were issued in the

reign of Henry III. (1265) summoning the knights, citizens, and burgesses to meet in Parliament. The government was even more democratic during the Middle Ages than it subsequently became, for the nobles and commons met in the same chamber, debating and voting promiscuously. Historians have failed to discover the date at which the legislature was separated into two chambers, but the present arrangement was in force during the fifteenth century. Numerous changes, sometimes violent and at other times mild and gradual, have been made in the machinery of British parliamentary government, but certain great principles have survived all these transmutations. Parliament can best be considered under three heads: (I.) its constituents, (II.) its powers, and (III.) its forms.

I. *Of what does Parliament consist?*—The imperial Parliament consists of the monarch, the lords, and the commons. The three estates of the realm are the lords spiritual, the lords temporal, and the commons. The sovereign is the executive authority, and is charged with the duty of enforcing the will of Parliament; but in the matter of legislation the sovereign is no more than a constituent part of Parliament, acting in conjunction with the three estates of the realm. In ordinary times there can be no meeting of Parliament unless the monarch is present at the opening of it, either in person or by commissioners. We say "in ordinary times," for there have been exceptions to this rule. The Convention Parliament which restored Charles II. could not, in the nature of things, satisfy the above condition, but proceeded to do a supreme parliamentary act without any summons or sanction from the sovereign. Though Charles held himself to be king *de jure* before Parliament restored him, still he was sagacious enough not to insist upon his sovereign rights, which at the time a majority of the English people would have questioned. The self-constituted Parliament sat several months after the Restoration, and enacted laws which are still recognized as binding by English tribunals. Lest, however, the authority of this assembly should be questioned by the judges, an act was passed after the return of Charles, and signed by that monarch, confirming all that it had done. Such a precaution was generally held by lawyers to be superfluous, as the convention acted *ex necessitate rei*. Another departure from the rule laid down above occurred in 1688, when the two houses of Parliament met on the summons of the Prince of Orange and proceeded to dispose of the crown itself; but the events of that period constitute, by universal consent, a revolution. At the same time it is worthy of observation that even in disposing of the crown and kingdom by revolutionary force the English people have always kept as close to constitutional tradition as circumstances would permit.

The House of Lords in 1900 was constituted as follows:

Lords Spiritual.

Archbishops (Canterbury and York)	2
English bishops	24

Lords Temporal.

Peers of the blood royal	5
Dukes	22
Marquises	22
Earls	123
Viscounts	30
Barons	320
Scotch representative peers	16
Irish representative peers	28
Total	592

Four Irish prelates sat in the House of Lords until 1869, when, under the provisions of the act for disestablishing the Irish Church, they became disqualified to sit. The last consecrated of the twenty-five diocesan English prelates, provided he holds one of the inferior sees, has no seat in the House of Lords, and the same disability applies to suffragan and coadjutor bishops. A bishop is not a peer, but is only a lord of Parliament in virtue of holding an imaginary barony under the Queen. In latter days there has been a steady diminution in the number of marquises, earls, and viscounts, but more than a corresponding increase in the number of barons. The creation of peerages is vested unreservedly in the crown, and it is well known that the House of Lords consented to the passing of the Reform Bill in 1832 because the king had given his consent to the creation of as many new peers as would have served to outvote the opponents of the bill. All peerages are hereditary, the House of Lords having decided that a life-peer can not, as one of their number, discharge any legislative functions. The question was raised in 1858, when the Queen conferred on Sir James Parke a peerage "for and during the term of his natural life," under the title of Baron Wensleydale. Acting on the report of a committee, the House of Lords decided that it was not competent for him to take his seat in Parliament with such a patent of nobility. The Scottish representative peers are elected for one Parliament, the electors being those Scottish peers whose titles are older than the union of England and Scotland. The Irish representative peers sit for life, and are elected by the whole body of Irish peers, no matter from what period their titles date. The Queen can create only one Irish peerage for every three which become extinct. As there is a feeling that an Irish peer who is not a lord of Parliament is a political anomaly, the House of Lords has requested her Majesty to forego her right to issue patents of nobility of this class, and the Queen has signified her willingness to hold in abeyance that part of her prerogative. Provision was made in 1876 and modified in 1887 for four Lords of Appeal to be appointed for life on account of their eminent judicial attainments, and to sit in judicial cases appealed to the House of Lords.

The House of Commons has varied much in number of members. Under Edward I. there were two representatives for each of 37 counties and 166 boroughs, and under the Stuarts the house numbered usually about 500 members. The Reform Acts of 1832 and 1867–68 made extensive changes in the constituencies, the latter giving England and Wales 493 members, Scotland 60, and Ireland 103. By the Reform Act of 1884 and the Redistribution of Seats Act of 1885 the total number was raised to 670, as follows:

England and Wales.

Members for counties	253	
" " boroughs	237	
" " universities	5	495

Scotland.

Members for counties	39	
" " boroughs	31	
" " universities	2	72

Ireland.

Members for counties	85	
" " boroughs	16	
" " universities	2	103
United Kingdom. Total		670

Certain persons are disqualified to become members of Parliament. Minors, lunatics, outlaws, and aliens are excluded; so also are the common-law judges, the clergy of the Established churches of England and Scotland, and Roman Catholic priests; likewise pensioners under the crown during pleasure or for a term of years, contractors with Government, members of the India Council, and peers of Parliament. By the act of 1858 property qualification was abolished. Prior to that date an estate of £600 a year was requisite in England and Ireland to qualify for a county, and £300 a year for a borough, except in the case of the eldest sons of peers and bishops. In Scotland and for the universities no property qualification was ever necessary. A member of the House of Commons can not resign his seat; but if he accept any office of profit under the crown, his seat is vacated *ipso facto*. When a member wishes to be relieved from parliamentary duties, he accepts the stewardship of the Chiltern Hundreds (*q. v.*), or some one of certain other similar sinecures. Being, however, a place of *profit*, it furnishes a convenient back-door for wearied members to make their escape into the retirement of private life. Members of the House of Commons are now elected by secret ballot in all the constituencies of the United Kingdom, with the exception of the universities. No religious test whatsoever is imposed upon members, the only oath taken by them being the oath of allegiance. Previous to 1858, Jews were incapacitated to sit on account of the oath including the words "on the true faith of a Christian."

II. *The Powers of Parliament.*—The House of Lords has two functions, the legislative and the judicial. In legislation it acts in concert with the Queen and the Commons, the assent of all three being necessary to give validity to a bill, which then becomes an act of Parliament. Practically, the law lords alone sit in a judicial capacity, though every peer has a legal right to take part in trying appeals. The crimi-

nal cases which come before the House of Lords are those in which a person is impeached by the Commons, or those in which a true bill has been found by a grand jury against a peer of the realm. Peers can no longer vote by proxy in any case. Every peer, when dissatisfied with a decision of the House, has a right, with leave, to enter a protest on the journals. When sitting in his judicial capacity, he gives judgment on his honor and not on his oath; but when summoned as a witness in any cause, he must be sworn. All bills affecting the rights and privileges of peers must originate with the House of Lords, and they may not be amended, but may be rejected by the Commons. The House of Commons is vested with the right of imposing taxes and voting money for the public service. Until 1867 the Commons decided for themselves all questions touching the election of members, but since that date election petitions are tried by the common-law judges. Both branches of the legislature have certain privileges and powers for the protection of their own dignity, independence, and honor. At the beginning of every Parliament the Speaker of the House of Commons claims for the members, in presence of the Queen or her commissioners, freedom of speech and that the best construction shall be placed on all their words. To publish the debates of the House is a breach of privilege, but this rule has long been disregarded, though peccant publishers may still be summoned to the bar of the House to answer for their contumacy. Strangers are admitted to the House, but are not "seen" by the Speaker. For a long time, whenever a member called the Speaker's attention to the presence of strangers he immediately ordered the sergeant-at-arms to clear the House. During one session of Parliament strangers were thus "espied" in the gallery, the Prince of Wales being one of the number. The Speaker's attention being called to the fact, he had no alternative but to eject all, including the heir to the throne. The incident led to a modification in the rules of procedure, and the law now is, when strangers are "seen," a vote is taken at once, without debate, whether they shall be ordered to withdraw or not. Ladies are not admitted within the House, but a clumsy evasion of this rule is effected by permitting them to sit in a gallery behind a grating, whence they can see and hear without being seen themselves. These regulations, however, are of small account when compared with the vast prerogatives which Parliament claims as a legislature and as the grand inquest of the nation. It makes and unmakes laws, and is, in fact, superior to all human law; for in the constitution of the United Kingdom despotic power lies in Parliament, there being no remedy for that which Parliament does wrong except in the same or another Parliament, summoned by the crown and elected by the people. Any grievance which defies the ordinary remedies of law can be redressed by Parliament. It can determine the succession to the throne, and has done it. It can alter the established religion of the country, and can abolish an established Church altogether, as it has done in the case of Ireland. It can amend its own constitution, and can say how long a Parliament shall last. At present members are elected for seven years, but there was a time when each Parliament lasted only three years. It was a saying of Cecil that "England could only be ruined by a Parliament." That ruin could be brought about if it violated the fundamental maxims of its own constitution. One of these is that the people, whom it professes to represent, can be taxed only with their own consent. By attempting to defy this maxim in the case of the American colonies in the reign of George III. a rupture of the empire was brought about, and English colonies became independent commonwealths.

III. *The Forms of Parliament.*—Parliament assembles on the summons of the sovereign; and although the law provides that not more than an interval of three years shall elapse from the dissolution of one Parliament to the assembling of the next, the practice of voting money for the public service annually has rendered this statute superfluous, as the Government could not be carried on without an annual meeting of the House of Commons. Should the sovereign die between the dissolution of a Parliament and the issuing of writs for a new election, the old Parliament revives, and may continue to sit for a period not exceeding six months. At the beginning of each session the Queen states her reasons for convening the Lords and Commons, and gives an outline of the legislation contemplated by her ministers. This statement is known as "the speech from the throne," and is either delivered personally or by commissioners. Adjournment is decided by each House for itself, but prorogation and dissolution are the sole acts of the sovereign. Prior to the reign of William and Mary the sovereign determined the duration of a Parliament. By the triennial act (William and Mary) the duration was limited to three years, and by the septennial act (George I.), still in force, a Parliament expires at the end of seven years. The sovereign, however, usually puts an end to it by dissolution, and does not allow it to expire by efflux of time. When the estimates are laid before the House of Commons, a member may move and carry the reduction of a vote, but no additional grant of public money can be made without a recommendation from the Queen. A member of either House can not be questioned outside of Parliament for anything he has said in his place; but if he afterward publish his speech, he is liable to an action for libelous imputations, and is not protected by the privilege of his position as a member of Parliament. The persons of members are free from arrest in civil causes, but they may be adjudged bankrupts, and their goods are liable to distress on legal process, like those of private citizens. Every bill before it becomes an act must be read three times in each House, and also be reviewed clause by clause in a committee of the whole House or by a select committee. When a bill has passed both Houses, the sovereign's assent is given, usually by commission, the Commons being summoned to the bar of the House of Lords, with the Speaker at their head, to hear the announcement of the Queen's will. In the case of a public bill, the clerk of the Parliament reads its title and pronounces these words: "*La reigne le vaut.*" When it is a private bill, the words are, "*Soit fait comme il est desiré.*" There are numerous forms and details touching the election of Speaker, mode of addressing the House, putting the question in the two Houses respectively, divisions, presenting of petitions, right of putting questions to cabinet ministers, conferences of the two Houses, powers of committees, and various other matters of procedure, of which the reader will find ample information in the works enumerated below. The power of the House of Commons has steadily increased during the nineteenth century, and in any serious conflict between the two Houses of Parliament the Lords invariably deem it prudent to give way. The House of Lords frequently rejects bills which have passed the Commons, such as the burial bills, the marriage with a deceased wife's sister bill, and the Home Rule Bill of 1893, but in no case does the upper chamber reject a measure which has obtained the unmistakable approval of the nation at a general election. The will of the people is paramount, in the long run, in all the departments of British legislation, and the friends of freedom desire that it should remain so for the future. The House of Lords acts as a conservative element of great power to prevent precipitate or imperfectly considered action; but, if the opinion of the people is clearly expressed, that opinion at once is decisive.

LITERATURE.—The following works are recommended to the reader as books of reference: *Rules, Orders, and Forms of Proceeding of the House of Commons relating to Public Business* (1874); *History of the House of Commons*, by W. C. Townsend (2 vols.); *How We are Governed*, by A. Fonblanque; *Constitutional History of England*, by Henry Hallam; *A Treatise upon the Law, Privileges, Proceedings, and Usage of Parliament*, by Sir Thomas Erskine May; *Essay on the Practice of the British Government*, by G. F. Leckie; *Essay on British Government*, by Francis Jeffrey; *History of the Anglo-Saxons*, by Sharon Turner; *The English Constitution*, by J. L. de Lolme, William Stubbs, and Thomas Erskine May. Of recent authorities the most important are Creasy, *Rise and Progress of the English Constitution*; Bagehot, *English Constitution*; Todd, *Parliamentary Government in England*; Taswell-Langmead, *English Constitutional History*; Hearn, *Government of England*; Cox, *Institutions of the English Government*; Ewald, *The Crown and its Advisers*; Palgrave, *The House of Commons*; and Gneist's *English Parliament*.

Revised by C. K. ADAMS.

Parliamentary Law: the law governing the proceedings of deliberative assemblies. Among English-speaking people it is derived from the practice of the English Parliament, which gradually solved the problem of how to conduct its proceedings so as to obtain the deliberate sense of the assembly with the least restraint and inconvenience to individual members—the object of all parliamentary rules. In the U. S. the old English parliamentary law has been gradually modified in practice, so as to be better adapted to

the people. New motions have been introduced and others so changed as to preserve only their old name; thus to *reconsider* is purely a new motion designed to counteract partially the evil incident to hasty action; while the previous question has so completely changed that in the U. S. it is demanded by those who intend to vote for it, while in Great Britain it is demanded by those who vote against it. As a result of this growth of parliamentary law there is a certain amount of confusion, the growth being more rapid in certain sections than in others. Thus in certain parts of the U. S. many still hold to the ruling that ordering the previous question cuts off pending amendments and brings the assembly to an immediate vote on the pending resolution. This was once sound parliamentary law, but has long ceased to be, the previous question in the U. S. being now merely a motion to stop debate and proceed to vote on the pending question, even though it be an amendment. The practice is not the same even in the two houses of Congress, motions being allowed in one that are prohibited in the other, and the order of precedence of other motions being different. To avoid confusion, every deliberative assembly should adopt some published work as its authority on all points of parliamentary law not covered by its own special rules. It will generally be found best to supplement the adopted authority by some rules adapted to meet the special wants of each separate organization. A large political convention, a small debating society, and a city council would need different rules to supplement the ordinary parliamentary law. If the U. S. House of Representatives had continued to be essentially a deliberative assembly, like the English House of Commons, with its presiding officer abstaining from partisanship, so as to retain the chair notwithstanding the change in the party in power, then the practice of Congress would determine the parliamentary law of the republic in all matters common to all deliberative bodies; but the lower house of Congress has almost ceased to be a deliberative assembly, placing in the chair the leader of the majority, and allowing him to appoint some sixty committees to whom are referred, without reading, the bills that are presented. Practically, legislation is done by committees, Congress, with few exceptions, merely formally adopting, without any real deliberation, what the committees recommend. As a general rule, however, parliamentary law in the U. S. is based upon the rules and practice of Congress, except where they are evidently not adapted to a *bona fide* deliberative assembly, when recourse must be had to the old common parliamentary law and the best practice of the numerous deliberative assemblies throughout the country. A careful examination of the following outline of parliamentary law as practiced in the U. S. will show that such law is not arbitrary, but is based upon well-defined principles, from which it varies only for good reasons.

Officers.—The necessary officers of a deliberative assembly are a presiding officer or chairman (variously called president, speaker, moderator, etc.), and a recording officer, usually known as secretary or clerk. It is the duty of the chairman to call the assembly to order; preside over the meetings; state every question coming properly before the assembly previous to recognizing a member to speak or make another motion; put to vote the questions before the assembly in their proper order; announce the business before the assembly in its order; enforce the rules; preserve order and decorum in the meeting; and decide all questions of order and practice, subject to an appeal by any two members. The chairman should rarely participate in the debate, as it diminishes the confidence of the assembly in his impartiality. He can vote whenever his vote would affect the result and whenever the vote is by ballot. It is the duty of the secretary to keep a record of the proceedings of the assembly, the extent of which record depends upon circumstances, but it should always include every resolution adopted, and the names of every member of every committee appointed. The official records and other documents of the assembly are in the custody of the secretary, but they are open to inspection by members, and the chairman may even direct certain ones to be turned over to a committee that needs them. The record of the proceedings, which is also known as the minutes of the meeting, should always be signed by the secretary, or, in his absence, by the secretary *pro tem.*

The Resolution or Motion.—Business is usually brought before the assembly originally in the form of a resolution which is offered by a member, who moves its adoption, or that it be agreed to. The question on its adoption is called the main or principal question. A resolution should always begin with the words "*Resolved*, That." When it is desired to give a reason for the resolution this reason should be placed in a paragraph preceding the resolution, called the preamble, which should begin with "Whereas" and end with "therefore," or "therefore, be it." The preamble, as well as the resolution proper, is included in the term resolution. Where a resolution can not be well expressed in one sentence, each sentence should be placed in a separate paragraph beginning "*Resolved*, That," or the paragraphs after the first may begin thus: "1. That," "2. That." In order to offer a resolution it is necessary for the member to rise in his place and address the presiding officer by his proper title, preceded by Mr., if a man, and Madame, Mrs., or Miss, if a woman. The chairman then recognizes him, preferably by announcing his name, but commonly by merely bowing to him; in legislative bodies a member is recognized or referred to as the member from such and such a district. No member is entitled to make a motion or speak until recognized. It is customary to require important motions to be seconded in order to prevent wasting the time of the assembly on questions favored by only one member. It is not necessary to obtain the floor for this purpose, but any member in his seat can say, "I second the motion." In Congress such seconds are not required. The chair now clearly states the question before the assembly, after which he recognizes the mover of the motion as having the floor, if he claims it, and otherwise the member who first rises and addresses the chair.

Precedence.—During the consideration of a question it is not in order to introduce any other principal question, but it is allowable to make other motions that will aid in disposing of the main question, or that arise incidentally during the proceedings, or that relate to the enforcement of the rules, or to the privileges of the assembly or its members, or to closing the meeting, or to the time of the next meeting. The most common of these have the following order of precedence, any one being in order (except to amend) when one of lower rank is pending, and every one being out of order when one of higher rank is pending: To fix the time to which to adjourn, adjourn, orders of the day, lay on the table, previous question, postpone to a certain time, commit or refer, amend, and postpone indefinitely. Questions incidental to those before the assembly take precedence and must be decided first.

Debate.—Every motion is debatable, except such as from their nature or privilege can not be debated without injury to the business before the assembly. Debate can not be allowed on highly privileged motions, as to adjourn, or they could be used to prevent the assembly from transacting any business. A motion to close debate must necessarily be undebatable, or its very object could be defeated. The following motions can not be debated: Fix the time to which to adjourn; adjourn; for the orders of the day and questions relating to priority of business; appeal when previous question is pending or when relating to indecorum or to transgression of rules of speaking or to priority of business; objection to consideration of question; lay on the table or take from the table; previous question, and all motions extending, limiting, or closing debate or allowing one to continue speaking after being guilty of indecorum in debate; reconsider an undebatable question; question relating to suspending the rules, withdrawing a motion, or reading papers. Debate must be confined to the one question before the assembly at the time, other questions being discussed only so far as they have a bearing on the question immediately before the assembly, except that when the decision of the pending question finally disposes of the main question, then the latter is open to debate also. Thus the motion to postpone indefinitely, having the effect of rejecting the question, if carried, opens to debate the merits of the question it is proposed to postpone; but the motion to postpone to a certain time, if carried, does not finally dispose of the question, and therefore debate is limited to the propriety of the postponement. The common parliamentary law, and the rules of Congress till quite recently, made one exception to this principle, by making the motion to refer to a committee open the main question to debate, evidently on the ground that the discussion would aid the committee in understanding the views of the assembly. Under the House rules, however, it is rare that there is a motion or vote on referring anything to a committee, the reference being made by the chair without a vote as provided for by the rules, or as requested by the member introducing it; if a motion to refer is made it is now very properly undebat-

able. The common parliamentary law rule is better adapted to ordinary deliberative assemblies, for, if the motion to refer were undebatable, it would enable a bare majority immediately to suppress a question without debate by moving to refer it to an unfriendly committee. A motion to reconsider a debatable question or to rescind a vote opens for discussion the merits of the main question.

Debate can be closed or its limits diminished or increased by a two-thirds vote. The motions for these purposes are as follows: (*a*) The previous question, which cuts off debate and brings the assembly at once to a vote on the pending question, which, in case of the motions to commit or to amend, includes the question to be committed or amended, unless it is demanded simply on the motion to commit, or on the amendment, or on an amendment to the amendment; (*b*) a motion limiting debate as to the number and length of speeches, or specifying the time at which debate upon the question shall close; (*c*) a motion extending these limits in general or for a single speaker. Any of these motions may be applied to a single amendment, and, after it is voted on, the main question is still open for amendment and debate.

Amendments.—The assembly can modify the main question by adopting amendments, or it may be referred to a committee who can report amendments for adoption by the assembly. An amendment may be by adding or inserting, by striking out, by striking out and inserting, by substituting, or by dividing the question. An amendment may itself be amended, but not so as to alter its form, nor can any parliamentary motion be amended so as to become a motion of another form. Thus a motion to strike out can not be amended so as to become a motion to strike out and insert, nor can to postpone to a certain time be amended so as to become a motion to postpone indefinitely. An amendment of an amendment can not be amended. While an amendment is pending it is not in order to make another motion to amend the resolution, but after one amendment is disposed of another can be offered and so on without limit. In legislative bodies it is found best in addition to an amendment of the second order to permit an amendment in the nature of a substitute and one amendment to the latter, all to be pending at the same time. While this is useful in legislative and analogous bodies, it would merely produce confusion in ordinary deliberative assemblies. The following motions can not be amended: Adjourn (when unqualified), for the orders of the day, all incidental questions, lay on the table, the previous question, an amendment of an amendment, postpone indefinitely, and reconsider.

Postponing and Suppressing Questions.—Action upon a question may be deferred by postponing it to a certain time; or, if it is intended to reserve the power to take it up at any time, it should be laid on the table; or, if it is desired to set apart a particular time when it shall have special right of way, it should be made a special order for a certain time, which motion requires a two-thirds vote for its adoption. The assembly may suppress the question as follows: (*a*) When first introduced, before debate or action thereon, any member may, even while the mover has the floor, object to the introduction of the question, and if the objection is sustained by a two-thirds vote, the question is dismissed for that session, thus enabling the assembly to avoid having its time taken up with irrelevant or profitless questions. (*b*) After the question has been debated, the proper way to suppress the question is to vote it down or postpone it indefinitely, which has the same effect, except that if it fails the original question is not adopted as it would have been had the vote been taken on adopting the main question. Since to postpone indefinitely opens the main question to debate, when this motion is made with a view to suppressing the question immediately, it is necessary also to demand the previous question, just as it is when it is desired to bring the assembly to an immediate vote on the main question. (*c*) While the fundamental principles of parliamentary law require a two-thirds vote to suppress the question without free debate, yet in most cases it can be practically accomplished by a majority vote on the motion to lay the question on the table. In the U. S. Congress, where the calendar is so full and party lines strictly drawn, the most common method of killing a question is to lay it on the table. In voluntary organizations, where mutual good feeling and co-operation are desired, questions should not be suppressed without debate unless by a two-thirds vote, as described above, and the motion to lay on the table should be confined to its strict parliamentary use of laying aside a question to be taken up at a more convenient time. Where it is desired to kill simply an amendment, it will not do to lay it on the table, as this carries with it the resolution also.

Reconsideration.—To protect the assembly from having questions reintroduced repeatedly at the same session, and yet to give reasonable freedom for correcting errors due to hasty action, parliamentary law in the U. S. provides that no principal question (resolution or report) or amendment that has been once acted upon shall be again taken up at that session except by a motion to reconsider or rescind; but the motion to adjourn can be renewed if there has been progress in debate or any business transacted, and, as a general rule, privileged, incidental, or subsidiary motions (excepting to suspend the rules for the same purpose, and for the orders of the day while the same principal question is pending) can be renewed if a motion has been made that alters the state of affairs. On the day a vote is taken, or on the next day if a meeting is held then, a member who voted on the prevailing side can move to reconsider the vote, and this motion can be made when any other question is before the assembly, or even when another member has the floor; but in such case it is only entered on the record to be called up afterward, as it can not interrupt pending business. After the motion has been made all action under the resolution is suspended until the reconsideration is disposed of. If the mover does not call up the motion within the time allowed for making it, then any one can call it up and have a vote taken. If the motion to reconsider is carried the question is in the same condition as immediately before the vote was taken, and therefore must be disposed of in the same way. Where the assembly regrets action that it has taken and it is too late to reconsider the vote, the proper way is to rescind the objectionable vote, which a majority can do.

Adoption of Motions.—A majority of the votes cast when a quorum is present is all that is necessary, in the absence of a special rule to the contrary, for the adoption of any motion (except those stated below) that does not suspend or change any rule or custom of deliberative bodies or of the assembly. A quorum, or the number that must be present in order that business may be transacted, is a majority of all the members of the organization where there is no number specified by rule, which should always be done. It is sometimes less than 1 per cent. of the members, as in the British House of Lords, where it is 3 out of about 450 members. The following motions come under the above exception, and require a two-thirds vote for their adoption: To amend or suspend the rules; to make a special order or take up a question out of its proper order; to object to the consideration of a question; to close or limit or extend the limits of debate; and the previous question. The right to introduce questions germane to the objects of the assembly, and discuss them before their final disposition, is inherent to the fundamental idea of a deliberative assembly; but these rights, like that of having the rules enforced, must yield to the convenience of an overwhelming majority. A two-thirds vote can not, however, suspend any article of the constitution or by-laws (unless they provide for such suspension of a specified by-law), nor can it suspend any right or privilege given to less than one-third of the members present, as otherwise the privilege would be of little value.

Committees.—If an assemblage is large, or even when small, if it has much business to transact, its work can be greatly expedited by having all questions first considered by committees, which may be standing (appointed for a term, as a year or session), or select (one for a special purpose), or committee of the whole (i. e. the whole assembly). The first member named on a standing or select committee, and in his absence the next, should act as chairman, unless the committee elect some one else, which it can do, if the chairman has not been appointed by the assembly. If the committee is one for action, it should be small and contain only friends of the object for which it was appointed: if for deliberation or investigation, it should be larger, and all sides should be fairly represented. In committee the chairman usually takes the most active part, members do not rise to speak, motions are not seconded, and in small committees they are not always made, but they should be voted upon; the chairman usually votes. A paper referred to a committee must be returned to the assembly intact, its amendments being written on another sheet. In such case the only report of the committee is a verbal one that the committee has instructed the members to submit certain amendments and move their adoption. The member who submits a written report from a committee should always move its

adoption. If the report is adopted, or accepted, or agreed to, the opinions and doings of the committee become the opinions and doings of the assembly. If the committee wishes action taken, it should close its report with recommending the adoption of certain resolutions, which should either accompany or form a part of the report. In the latter case the adoption of the report carries the resolution with it; in the former, instead of a motion to adopt the report, one is made to adopt the resolutions, and no further action is taken on the report. The committee is discharged without any formal vote when it has completed its work. When the assembly desires to consider a question with all the freedom of a committee, it resolves itself into a committee of the whole, to consider the particular question. The chairman calls some member to the chair, takes his place as a member of the committee, and the assembly proceeds to discuss and amend the resolution or matter before it. Every member can speak as many times as he can obtain the floor. No motions are in order except to amend and to adopt, and to rise and report, which is used instead of to adjourn. When the committee has risen and the presiding officer has resumed the chair, the chairman of the committee reports to the assembly as instructed by the committee. The assembly then acts upon this report as in the case of the report of any other committee. HENRY M. ROBERT.

Par'ma: town, in the province of Parma, Italy; on the river Parma; about 12 miles S. of the Po and 79 miles S. E. by rail of Milan (see map of Italy, ref. 3-C). The town is circular in form, is surrounded by ramparts and bastions, and has a citadel built in 1591. The Via Emilia crosses it from E. to W. The streets are broad and in good condition, the squares large, and there is a public promenade near the citadel on the south side of the town, and a public park in the northwest angle. Among the public buildings is the Cathedral of the Assumption (Roman Byzantine, begun in 1060 and consecrated by Paschal II., 1106), which contains, among other superior works of art, many frescoes by Correggio, but much restored; the baptistery (begun in 1196), a fine specimen of Lombard architecture; the Church of S. Giovanni Evangelista, with frescoes by Correggio; the Madonna della Steccata, a church of the Renaissance, containing sepulchral monuments of the Farnese and Bourbon rulers of Parma and a celebrated picture by Mazzuoli. The municipal museum, the academy of fine arts, the school of design, and the Farnese theater are in the great building known as the Pilotta, which was intended to form a part of a colossal ducal palace never completed. The national theater was erected by Maria Louisa; the communal palace is a fine but unfinished structure. There is also a university founded in 1521, with (1891) 41 teachers and 276 students, and a royal public library with 213,995 volumes and 4,500 MSS. Parma, however, owes its chief attraction to the masterpieces of Correggio in the academy of fine arts, and to his well-preserved frescoes in the Camera di San Paolo. There are manufactures of pianos, silk, linen and cotton stuffs, leather, glass, crystal, earthenware, and cast-iron wares; and there is a considerable trade in grain, cattle, and dairy produce. The cheese called Parmesan is, however, now better made elsewhere. Parma, though lying in the old Etruscan territory, does not appear in history until the time of the Roman republic. Being nearly destroyed by Mark Antony, it was partially rebuilt by the first Cæsars, who gave it successively the names of *Julia* and *Augusta*. After suffering cruelly from the barbarians, it was again restored and rewalled by Theodoric. Narses took it and gave it the name of *Chrysopolis*, or the Golden City. Charlemagne made a bishop (it has been an episcopal see from very early Christian times) its temporal lord, with the title of count. After the death of Frederick Barbarossa (1190) Parma declared itself a republic; but in 1303 it became the prey of feudal lords. At last it fell into the hands of the popes, who retained possession of it (except during a short occupation by the French) until 1545, when Paul III. included it in the duchy which he conferred on his son Pier-Luigi Farnese. (See FARNESE.) The government of the Farnese dukes was generally popular with the middle and lower classes, but was not acceptable to the nobility, who conspired frequently against them. In 1701, the direct Farnese line being extinct, the duchy passed to the royal family of Spain. In 1802 the French took possession of it, and in 1814 it was conferred (Spain protesting) as a sovereign duchy on the ex-empress Maria Louisa. In 1817 this arrangement was confirmed, with the stipulation, however, that the succession should fall on the Duke of Lucca, the rightful heir in the Spanish line. The duke was supported in a reactionary policy by Austria, and in 1848 he was compelled to fly from his dominions. In 1849 he was succeeded by his son Charles III., who was assassinated in 1854; and finally in 1860 the territory was annexed to the new kingdom of Italy. Pop. (1892) 51,500. The province has an area of 1,250 sq. miles. Pop. (1892) 272,040.

Revised by R. A. ROBERTS.

Parma, DUKES OF: See FARNESE.

Parma, Duchy of: one of the political divisions of Italy previous to the formation of the Italian kingdom in 1860, embracing the present provinces of Parma and Piacenza.

Parmen'ides (in Gr. Παρμενίδης): son of Pyrrhes; the most notable of the philosophers of the Eleatic School; b. at Elea, a Phocæan colony situated in Lucania, about the year 519 B. C. (cf. Grote, *Hist. of Greece*, chap. lxvii.). He is said to have been the pupil of Xenophanes, founder of the Eleatic School (Aristotle, *Metaph.*, i., 5), and to have to a considerable extent adopted the mode of living of the Pythagoreans, with two of whom, Ameinias and Diochætes, he was very intimate. He took an active part in the government of his native city and drew up a code of laws, to which the Eleans annually swore to conform. He disseminated his philosophy both by teaching and writing. He appears to have attained a ripe old age, and, if we may believe Plato (*Parmenides*, 127 B.), to have become personally acquainted with Socrates.

Writings.—The only work of Parmenides known to the ancients was that bearing the general and oft-imitated title *On Nature* (Περὶ Φύσεως), written, according to the custom of the time, in dactylic hexameters. It was divided into three parts: 1, An introduction, describing in highly figurative language the manner in which the philosopher reached the citadel of truth: 2, a treatise *On Truth* (τὰ πρὸς Ἀληθείην); and 3, a treatise *On Opinion* (τὰ πρὸς Δόξαν). The doctrines put in the mouth of Parmenides in the Platonic dialogue bearing his name are mostly the property of Plato, or of whoever was its author. The known extant fragments of Parmenides are comprised in something less than 160 hexameters. They are collected mainly from the writings of Plato, Aristotle, Clemens Alexandrinus, Sextus Empiricus, Plotinus, and Simplicius. There are editions of them by Brandis (1813), Karsten (1835), Mullach (1845; reprinted in the Didot *Fragmenta Philosophorum Græcorum*, Paris, 1860), and by Stein in *Symbola Philologorum Bonnensium* (1864–67), pp. 763–806. The best are those of Karsten and Stein. There is a translation into English hexameters of all the extant fragments, in the *Journal of Speculative Philosophy*, vol. vi. For bibliography, see Ueberweg, *History of Philosophy* (Eng. trans.), vol. i., p. 50.

Philosophy.—Parmenides was, with the exception perhaps of Heraclitus, the greatest of the pre-Socratic thinkers. The kernel of his thought is the notion of pure Being, which he identifies with pure Thinking, and labors to define by every means afforded by the undeveloped philosophic diction of his day. Pure Being, the common basis of finite existence and finite Thought, alone *is*. Non-Being and all the array of finite thoughts and things which its assumption entails are delusions, unavoidable perhaps for the uncultured mind, but transparent enough to the true thinker. Being is

> . . . Birthless and deathless,
> Whole and only-begotten, and moveless and ever-enduring:
> Never it was or shall be: but the *all* simultaneously now is,
> One continuous one.

The philosophy of Parmenides largely affected all subsequent thought, and even so powerful a thinker as Aristotle could not shake off his cosmological ideas. Nowhere else have the rational and the sensuous been more clearly opposed. This is so true that some writers, notably Gladisch (*Die Eleaten und die Inder*), have endeavored to connect it with the Hindu philosophy. Cf. Aristotle, *Metaph.*, A. 5; Plotinus, *Enneads*, v., 1, 8; Buroni, *Dell' Essere e del Conoscere*; *Studii su Parmenide, Platone e Rosmini*; Hegel, *Gesch. der Philos.*, vol. i.; Zeller, *Philos. der Griechen*, vol. i.; and Ueberweg and Schwegler. THOMAS DAVIDSON.

Parmigianino and **Parmigiano**: See MAZZUOLI.

Parnahyba, pär-nä-ee'bä (also written *Parnahiba*, *Parnaiba*, or *Paranahyba*): the name of two considerable rivers in Brazil: (1) One of the head streams of the PARANÁ (*q. v.*), separating Minas Geraes from Goyaz. (2) A river of Northern Brazil, separating the states of Piauhy and Ma-

ranhão; flowing N. E. and entering the Atlantic near lat. 3° 15′ S.; length about 850 miles (according to Pompeu, 1,000 miles). Its basin of 135,000 sq. miles embraces the whole of Piauhy, in which it has many affluents, and about 20,000 sq. miles in Maranhão. It has few rapids, and during the annual floods canoes can ascend nearly to the head of the main river and tributaries; small steamers ascend regularly to São Pedro de Alcantara, about half way to the head, and most of the commerce of Piauhy is by this route. Vessels drawing 11½ feet ascend to the town of Parnahyba, near the mouth of the river; it is the commercial center of Piauhy. HERBERT H. SMITH.

Parnassiens: name given to a group of French poets of the Second Empire, from the name of the volume, *Parnasse contemporain*, in which their first poems were collected in 1866. Their common qualities are a great and almost exclusive cultivation of the metrical form and the rejection of emotion in favor of plastic or pictorial subjects as poetic material. A. G. C.

Parnas'sus (in Gr. *Παρνασσός*): a mountain of Greece in the district of Phocis, rising 8,068 feet above the level of the sea. Its three peaks are covered with snow for the greatest part of the year; its sides are covered with beautiful forests and abound in crags and caverns. In ancient times it was consecrated to Apollo and the Muses. Delphi, with its famous oracle and the Castalian fountain, was situated on its southwestern slope. The Corycian cavern, the abode of Pan and the Muses, was on its western slope, and on its highest top were celebrated the wild orgies of Dionysus. Revised by J. R. S. STERRETT.

Par'nell: See CONGLETON, LORD.

Parnell, CHARLES STEWART: Irish party leader; b. at Avondale, County Wicklow, Ireland, in 1846; was educated at Cambridge, and entered Parliament in 1875 as a member for Meath. In 1877 he brought in the Irish Church Act Amendment Bill, the object of which was to facilitate the purchase of their holdings by the tenantry of the disestablished Irish Church; but the bill was thrown out by 150 to 110 votes. He then became the leader of the obstructionists in Parliament, and in 1879 he founded the Irish National Land League, whose purposes were, first, to bring about a reduction of rack-rents; and, secondly, to facilitate the obtaining of the ownership of the soil by the occupiers. From this time his fortunes are identified with the history of the Home Rule party, and for an account of the principal events of his political career see the articles HOME RULE and LAND LEAGUE. In the same year he visited the U. S. and lectured in all the large cities in order to raise funds for the new organization. In 1880 he was returned for three constituencies, Meath, Mayo, and Cork city, and chose to sit for the last, but in the same year informations were laid against him by the Irish attorney-general. The trial resulted in a disagreement of the jury, but, the Land League having been declared by the Government an illegal association, he was arrested and conveyed to Kilmainham jail. He was soon released, however, and in the session of 1883 he took a very active part in procuring the passage of the Arrears Act and the Tramways and Laborers Acts. The Land League was revived under the name of the National League, with Mr. Parnell at its head. He led the Irish parliamentary party in 1884–85, and afterward supported Gladstone's proposed Home Rule. He was often charged by his enemies with favoring and even abetting acts of violence on the part of the Irish tenantry, and in 1887 these charges took definite shape in a series of articles published by *The Times*, accusing him of complicity in crime and supporting the charge by the publication of certain letters purporting to have been written by him. These Parnell declared to be forgeries, and he was sustained in this statement by the finding of the so-called Parnell commission, appointed to investigate the matter. Parnell then brought suit for libel against *The Times*, and was awarded £5,000 damages. With this victory he reached the height of his influence, but in 1890 he was named co-respondent in the divorce suit of his friend, Capt. O'Shea, and proved in court to have been guilty of adultery with O'Shea's wife. Gladstone declared him unfit for the leadership of the Irish party, and he was advised to withdraw. He refused, and the result was a breach in the party, the majority choosing Justin McCarthy as their chief, the others, known as the Parnellites, adhering to their old leader. The latter made several bitter speeches against the Liberals, and threw himself into the contest with the McCarthyites in the North Kilkenny election, but the hostility of the priesthood was added to the other opposing influences, and the Parnellites were defeated Dec. 22, 1890. In the following June he married Mrs. O'Shea. He continued to attend public meetings in Ireland, but his candidates were repeatedly defeated in the elections. At length his strength began to fail under these reverses and the constant attacks of his political opponents, and his death, which occurred at Brighton Oct. 6, 1891, was doubtless hastened by his misfortunes. F. M. COLBY.

Parnell, THOMAS: poet; b. at Dublin, Ireland, in 1679; educated at Trinity College, Dublin; took orders in the Church of England 1700; became archdeacon of Clogher 1705, prebendary in the cathedral of Dublin 1713, and vicar of Finglass 1716; resided chiefly in England; assisted Pope in his translation of Homer, and wrote the *Life* of Homer prefixed to the *Iliad*. D. at Chester, July, 1717. Pope published in 1722 a volume of posthumous poems attributed to Parnell, the best of which was the *Hermit*. See the *Life*, by Goldsmith, in the Globe edition of Goldsmith's works (1881). Revised by W. S. PERRY.

Parol, or **Parole** [from Fr. *parole*, word, promise: Ital. *parola*: O. Span. *paraula*: Portug. *palavra* (cf. Eng. *palaver*) < Lat. *para'bola*, parable, word = Gr. *παραβολή*, comparison]: literally, a word, word of mouth; in law, a term used generally to designate oral evidence as distinguished from written evidence (see EVIDENCE), but also to designate any contract or agreement, either oral or in writing, which is not under seal. Pleadings formerly when given *viva voce*, orally, in court were frequently termed the *parol*.

Paropam'isus, or the **Paropamisan Mountains**: in ancient geography, a name of somewhat uncertain signification, sometimes limited to the range which forms the northern boundary of Cabul, sometimes extended to the whole group connecting the Caucasus with the Himalaya, but generally corresponding to the modern Hindu-Kush.

Paroquet: See PARRAKEET.

Paros: island in the Ægean Sea, belonging to Greece; one of the Cyclades. It is a flattened mountain, about 36 miles in circumference and toward the center 2,450 feet in height. Well cultivated and naturally fertile, it suffers from scarcity of water. Some of its little harbors are deep and well sheltered. It exports honey and wax, but its most precious product by far is the Parian marble, famous from all antiquity for purity and whiteness. The Arundel or Oxford marbles, which give the Greek chronology from Cecrops to Alexander, were discovered here in 1627. Pop. (1890) 3,048. E. A. GROSVENOR.

Parot'id Gland [*parotid* is from Gr. *παρά*, beside + *οὖς*, *ὠτός*, ear]: the largest of the salivary glands, in man as well as in many other animals. In the human subject the parotid glands lie on the sides of the face, below and forward of the ear. Each gland weighs about 1 oz., and discharges its secretion by a duct 2½ inches long, called the duct of Steno, which opens on the inside of the cheek, opposite the second molar tooth of the upper jaw. The parotid secretion in man is less viscid than the saliva of the other glands, and differs somewhat in its composition, but its functional uses are essentially similar. The most important diseased condition of the parotid is MUMPS (*q. v.*).
Revised by W. PEPPER.

Parquet, JACQUES DIEL DU: See DIEL DU PARQUET.

Parr: the young of the salmon and trout, after it has passed the fry stage and before it has reached that of smolt. These stages appear to be of indefinite duration, varying according to the food-supply and other conditions. It was once thought that the parr (called also samlet, pisit, or brandling) was a distinct species of fish. All the salmon and trout pass through a parr stage, during which the body is marked by dark cross-bands. Revised by D. S. JORDAN.

Parr, CATHARINE: See CATHARINE PARR.

Parr, SAMUEL, LL. D.: clergyman and author; b. at Harrow-on-the-Hill, England, Jan. 15, 1747; studied two years at the University of Cambridge 1765–67; was assistant master of Harrow School 1767–72; kept a private school at Stanmore 1772–76; became head master of Colchester School 1776, of Norwich School 1778; took orders in the Church of England; became curate of Hythe 1778, rector of Asterby 1780, and perpetual curate of Hatton, Warwickshire, 1786, rector of Wadenhoe 1790, and of Graffnam 1802, and head chaplain to Queen Caroline 1820; prebendary of St. Paul's, London. Cambridge gave him an LL. D. in

1781. He resided from 1786 at Hatton, engaged in literary pursuits and the classical training of pupils; was a brilliant but overbearing and quarrelsome talker, an ardent Whig partisan, possessed an extensive knowledge of Latin literature, was regarded by many of his contemporaries as an intellectual prodigy, and came near receiving the bishopric of Gloucester. Posterity wonders at his contemporary fame, as he has left nothing to justify it. D. at Hatton, Mar. 6, 1825. See De Quincey's essay. Revised by S. M. Jackson.

Parr, Thomas, commonly known as **Old Parr**: said to have been born in the year 1483, at Winnington, Shropshire; was taken to London by the Earl of Arundel, Sept., 1635, and introduced at court as being 152 years old. A metrical narrative of his career was published at the same time by John Taylor, "the water poet," under the title *The Olde, Olde, Very Olde Man*, in which Parr was represented as having been born during the reign of Edward IV. and as having lived through the reigns of ten sovereigns. D. in London, Nov. 14, 1635. An autopsy was made by Dr. Harvey, and he was buried in Westminster Abbey, where a monument commemorates his alleged longevity. Thoms, in his *Human Longevity* (1873), tries to show that Parr was not more than 101 or 102 years old when he died. See Longevity.

Parrakeet, or **Paroquet** [from Fr. *perroquet*, a parrot]: a popular name for numerous small parrots with rather long, wedge-shaped tails. While the word has no exact scientific meaning, it is simply used to distinguish those birds with wedge-shaped tails from the parrot, macaw, lory, and Cockatoo (*q. v.*), which, as a rule, are names applied to larger birds, usually with square tails. The ground-parrakeet (*Pezoporus formosus*) and grass-parrakeet (*Melopsittacus undulatus*) of Australia are familiar examples, and the species of the genera *Palæornis*, *Platycercus*, and *Nymphicus* are typical parrakeets. F. A. Lucas.

Parrha'sius (in Gr. Παρράσιος): a Greek painter; b. in Ephesus; a contemporary and rival of Zeuxis. He flourished 400–380 B. C. While Zeuxis deceived the birds by his painted grapes, Parrhasius deceived Zeuxis himself by his painting of a curtain. See Reber, *History of Ancient Art* (New York, 1887, p. 373, ff.). J. R. S. S.

Par'ridæ [Mod. Lat., named from *Par'ra*, the typical genus, from Lat. *par'ra*, barn-owl]: a family of birds (also called *Jacanidæ*) containing the jacanas (see Jacana), distinguished by long legs and enormous toes. In form they resemble rails and coots; the bill is elongated, rather slender; the nostrils longitudinally oval, near the middle of the bill, and in long grooves; the wings large and pointed; the legs long and provided with transverse scales, which extend on the tibiæ as well as tarsi; claws very long, nearly straight, or even somewhat curved upward. The family is represented by a small number of tropical birds of doubtful affinities, some authors placing them near the plovers, and others with the *Rallidæ*. Species of *Parra* are found in South America, Africa, Asia, and Australia; the single representative of *Hydrophasianus* in India. Revised by F. A. Lucas.

Parris, Samuel: clergyman; b. in London, England, 1653; emigrated to Massachusetts in youth; studied at Harvard, but did not graduate; was for a time a merchant at Boston; became minister of a church in that part of Salem now called Danvers 1689; obtained notoriety through the great delusion called Salem witchcraft, which originated in his family, his daughter and niece having accused an Indian slave from the West Indies of bewitching them. He was active in prosecuting those who were apprehended, and afterward his church brought charges against him. He acknowledged his error, but in 1696 was dismissed and left the place. Subsequently he preached in Stow, Concord, and other towns. D. at Sudbury, Mass., Feb. 27, 1720.

Parrish, Stephen: See the Appendix.

Parrot: a common name for any member of the order *Psittaci*; in a restricted popular sense it is applied to the moderate-sized species with square tails, such as the gray African parrot (*Psittacus erithracus*) and the Mexican yellow-headed parrot (*Amazona levaillanti*). The large species, with long, pointed tails are termed macaws, the smaller *parrakeets* or *lories*, the large, crested, square-tailed species are known as cockatoos. Parrots are readily distinguished by their stout, hooked bills, which are hinged upon the cranium; by their short legs and rough feet, and by having the outer toe turned backward. They range in size from the great macaws to the little *Nasiterna*, scarcely larger than a sparrow. There are more than 350 species, found most abundantly in the tropics, but also, as in Australia and New Zealand, occurring in the temperate zone. One small species (*Cyanoramphus erythrotis*) inhabits Macquaries island in 50° S. lat. America has the most species, 150; Australia is richest in peculiar genera; no parrots are found in Europe, and they are not common in Africa or Asia. Many species are very gaudily colored, bright green being a common hue, while red, blue, and yellow are frequent. The most delicately colored forms are among the lories of the Australian region. Their food consists largely of fruit, but they also eat nuts, seeds, and buds, while a few eat insects and occasionally flesh. They breed in hollow trees, holes in rocks, and deserted buildings. The eggs are smooth, white, and rounded, most commonly two in number. Notwithstanding the fact that their voice is naturally loud and harsh, many can be taught to articulate words. The well-known African gray and Mexican "yellow head" are among the best talkers. A single species, the Carolina parrakeet (*Conurus carolinensis*), occurs within the limits of the U. S., and this is threatened with extermination. It is about 12 or 13 inches long, half of this being due to the long tail; the prevailing color is green; the head is yellow and the cheeks are red. The technical characters are given under Psittaci. See also Cockatoo, Macaw, Parrakeet, and Owl-parrot. F. A. Lucas.

Parrot-fish: a name applied to many fishes of the families Labridæ and Scaridæ (*q. v.*).

Parrott, Robert Parker: inventor; b. at Lee, N. H., Oct. 5, 1804; graduated at the U. S. Military Academy 1824; entered the army as second lieutenant of artillery, remaining, however, at the academy as assistant professor until 1829; was transferred to the ordnance corps in 1836, in which year he resigned and became superintendent of the West Point iron and cannon foundry, Cold Spring, N. Y.; was judge of court of common pleas, Putnam County, 1843–47; and was the inventor of the system of rifled guns bearing his name, and of their projectiles. (See Artillery.) D. at Cold Spring, N. Y., Dec. 24, 1877.
Revised by James Mercur.

Parry: See Fencing.

Parry, Charles Christopher, M. D.: botanist; b. at Admington, Worcestershire, England, Aug. 28, 1823; removed to the U. S. in 1832; graduated at Union College, and in 1846 removed to Davenport, Ia., where he practiced medicine for several years, and studied the flora of the adjacent region. He was botanist to David Dale Owen's geological survey of the Northwest (1848), botanist to the Mexican boundary survey (1849–52), botanist to the Pacific Railroad survey of the 35th parallel (1867), botanist of the Department of Agriculture (1869–71). In 1861, 1862, 1864, and again in 1872 and 1873 he collected extensively in the Rocky Mountains, and later in Utah, Texas, and California. Among his publications are *Botanical Observations in Western Wyoming, etc.* (1874); *Botanical Observations in Southern Utah* (1875); *Revision of the United States Pacific Coast Species of Arctostaphylos* (1883); *Revision of the Genus Chorizanthe* (1884); *The North American Genus Ceanothus* (1888). D. at Davenport, Ia., Feb. 20, 1890.
Charles E. Bessey.

Parry, Charles Hubert Hastings: composer; b. in England, Feb. 27, 1848; graduated at Oxford 1870; received Mus. Bac. degree from Oxford 1867, and Mus. Doc. from Cambridge in 1883 and from Oxford in 1884. He has composed largely for orchestral instruments, both solo and concerted; also *Judith*, *Job*, and *King Saul* oratorios; music to *The Birds* of Aristophanes, *Prometheus Unbound* of Shelley, *De Profundis* for a twelve-part chorus, *Ode on St. Cecilia's Day*, *Blest Pair of Sirens*, *Funeral Ode*, *The Glories of our Blood and State*, *L'Allegro*, *The Lotus-eaters*, and other odes and cantatas. Much of his music was composed for the various English musical festivals. D. E. H.

Parry, Sir William Edward: Arctic explorer; b. at Bath, England, Dec. 19, 1790; entered the navy 1803; was engaged in the naval service on the American coast during the war of 1812; was a member of Sir John Ross's Arctic expedition 1818; commanded another expedition 1819–20, with which he penetrated farther W. within the Arctic Circle than any previous explorer, thereby gaining a reward of £5,000 offered by Parliament; made other expeditions 1821–23, and in 1827 set out in boats that could be fitted to sledges from North Spitzbergen and attained the highest

north (82° 45′ N. lat.) ever reached until Markham (1876) beat it. He was knighted 1829; became rear-admiral 1852; governor of Greenwich Hospital 1853; and died at Ems, Germany, July 8, 1855. He wrote several volumes, the most important being his *Journal of a Second Voyage for the Discovery of the Northwest Passage* (1824), and *Narrative of the Attempt to reach the North Pole in Boats* (1828).

Revised by C. C. Adams.

Parry Sound: chief town of the provisional district of Parry Sound, Ontario, Canada; at the eastern extremity of Parry Sound, an inlet of Georgian Bay; 70 miles N. E. of Collingwood, and the western terminus of the Canada Atlantic Railway (for location, see map of Ontario, ref. 2–D). Pop. (1891) 1,982.

Parsees, or **Parsis** (plur. of *Par'see*, or *Parsi* = Hind. and Pers. *pārsī*, Persian, fire-worshiper; cf. Eng. *Persian*]: the name generally employed to designate the modern followers of Zoroaster. The Parsis form a small community, now living chiefly in Bombay, or still scattered here and there in Persia, their original home. They are the descendants of the early Persian race, and their name is derived from the province of Pars, or Fars, broadly employed for Persia in general. With the Arab invasion and conquest of Persia, and Caliph Omar's victory over Yazdegard in the battle of Nahavand (A. D. 641), the Sassanian monarchy fell, and the power of Zoroastrianism that had swayed Iran for centuries was crushed before the faith of Islam. Most of the Zoroastrians accepted the creed of Mohammed; only a small number clung to the national religion, and these were subjected to severe persecution. The Mohammedans called them *Guebres*, infidels, and allowed them to settle only in the poorest districts of the country around Yezd and Kirmān. A goodly number, in order to avoid persecution, sought refuge in exile, and emigrated to the west coast of India, settling among other places at Navsari, Surat, Ahmedabad, and especially in Bombay. Those who remained in Persia suffered much oppression at the hands of the fanatical Mohammedans; they sank into poverty and decreased in numbers. They number only 7,000 or 8,000, but they are much respected on account of their honesty. Those, on the contrary, who went to India prospered much, though at one time they, too, were exposed to persecution by the Mohammedans. They number about 90,000; among them are some of the wealthiest merchants of Bombay.

In consequence of their emigration from Persia and their contact with the Hindus, certain of the ideas and observances of the Parsis in India underwent some changes which gave rise to schismatic tendencies and to religious factions among themselves; but with the establishment of reform associations the Indian Parsis have remained in close touch with their persecuted Persian brethren, and do all that is possible to alleviate their oppressed condition. Among the numerous striking religious practices for which the Parsi faith is peculiar is the strange custom of exposing the dead to be devoured by vultures on the "towers of silence." The Parsis, it may be added, strenuously object to the misleading designation "fire-worship," which is sometimes given their religion. In their daily life they have an acknowledged reputation for uprightness, high-mindedness, and morality, for benevolence and generosity, and furthermore for exceedingly keen business instincts. They form in general a community which, though small, is highly respected, and which is especially well disposed to European civilization. See Avesta and Zoroaster, and consult Dosabhai Framji Karaka's *History of the Parsis* (2 vols., London, 1884).

Revised by A. V. Williams Jackson.

Parsley [M. Eng. *perseley*, *persil*, from O. Fr. *persil*: Span. *perejil* < Lat. *petroseli'num* = Gr. πετροσέλινον, rock-parsley; πέτρα, rock + σέλινον, parsley (whence Eng. *celery*)]: *Petroselinum sativum*, a biennial umbelliferous herb cultivated in gardens. There are several varieties. The leaves of most are used in garnishing meats. Others are sometimes cultivated for the rich white root, which resembles the parsnip. The root of common parsley has medicinal qualities.

Revised by L. H. Bailey.

Parsnip, formerly often written **Pastnip** [M. Eng. *parsnepe*, viâ O. Fr. from Lat. *pastina'ca*, parsnip, deriv. of *pasti'num*, a kind of dibble. The Eng. form has perhaps been influenced by *turnip*]: an umbelliferous plant (*Pastinaca sativa*), usually biennial, found wild in Southern and Central Europe, in England, and in the southern parts of Russian Asia. There is a considerable difference between the wild and the cultivated parsnip, the root of the latter being larger, without branches, softer, and more fleshy. It succeeds best in light rich soil. The Guernsey parsnip has a root 4 feet long; the Dutch, only from 20 to 30 inches. To many this root is a great relish; the Romans cultivated it carefully and appreciated it much. To others, however, it is distasteful on account of its sweetness. As fodder, though not much used, it possesses value for some kinds of stock. The wild parsnip has an acrid taste, and sometimes malignant consequences when eaten; the cultivated assumes the same acrid taste when it begins to grow in spring. There are only three or four important named varieties in cultivation in the U. S.

Revised by L. H. Bailey.

Parson, or **Rector** and **Vicar**: in English ecclesiastical law, strictly, a parish priest of the established church in England, who, in addition to his spiritual functions, has the legal ownership and possession of all the temporal rights belonging to the parochial church. He is called parson (a variant form of *person*, Lat. *persona*) because by his person the church is represented, and he is in himself a corporation sole, in order to protect the rights of the church, which he personates by a perpetual succession. The word parson, at first used only in the sense above noted, gradually came to signify any incumbent of a benefice who officiated in place of the parson (as noted below), and is now popularly used to signify any clergyman or person authorized by ecclesiastical authority to preach. In the technical sense, instead of the term *parson*, the word *rector* (that is the person who has the direction of the affairs of the church) is now more commonly used.

The parson or rector, as distinguished from other parish priests, is a kind of life-tenant, having a freehold ownership of the church, the parsonage, the glebe, the tithes, and all the parochial dues; and he may commit certain kinds of waste, and must repair and insure the property. In the early history of the English Church these temporalities were sometimes perpetually annexed to, and held by, some spiritual corporation, in which case they were said to be *appropriated*. The corporation then became the parson of the parochial church, and was bound to provide for the performance of the ecclesiastical services of the church. Later on these church temporalities were in some cases granted to laymen (*lay parsons*), in which cases they are (according to some authorities) properly said to be impropriated. This distinction between *impropriate* and *appropriate* is probably without basis, the words having probably been originally used, as often now, interchangeably. Probably, however, in the case of appropriated benefices, the parson appropriate, or appropriator, was required to depute or appoint some one to perform the ecclesiastical duties of the church. This deputy was called the vicar (i. e. agent or deputy), and originally was little more than the stipendary curate of the present day. His stipend was entirely in the discretion of the appropriator, and he was removable at pleasure. By statute, however (4 Henry IV., c. 12), it was required that a secular ecclesiastic should be appointed; that he should be canonically instituted and inducted; that his office should be perpetual; and that he should be sufficiently endowed. His endowment now consists generally of the small tithes, and of a portion of the glebe, or the land belonging to the parsonage. The principal distinction between a rector and a vicar now is that the rector has the sole right to all ecclesiastical dues within his parish. Where the incumbencies were not endowed under the statute above mentioned they were called *perpetual curacies*, and the incumbent appointed to perform the ecclesiastical duties a *perpetual curate*. Since 1868 (by virtue of 31 and 32 Vict., c. 117) the incumbent of the church of every parish, or parish for ecclesiastical purposes, not being a rectory, who is authorized to publish banns and to solemnize marriages, churchings, and baptism in such church, and receive the fees for his own use, is for the purpose of style and designation, but not for any other purpose, deemed and styled a vicar, and his benefice a vicarage.

In order that a person may become a parson or a vicar he must be in holy orders (that is, a consecrated priest in accordance with the rights of the established church), be presented to the living by its patron, be instituted into the spiritual cure by the bishop, and be inducted into the possession of the church and other temporalities of the parish. His principal duties are to care for the church property, answer the questions of the bishop, perform divine services, administer the sacraments, solemnize marriage, churchings, and baptism, and officiate at burials of the dead. He has

complete control over the organist, the choir, and the bell-ringer. He is responsible for all that his curate or that other clergymen may do in his church with his sanction or permission. For further information, see Phillimore's *Ecclesiastical Law*; Cripp's *Law of the Clergy*: Whitehead's *Church Law*; T. Eustace Smith's *Summary of the Law and Practice of the Ecclesiastical Courts.* F. STURGES ALLEN.

Parson-bird: a characteristic bird of New Zealand (*Prosthemadera nova-zelandica*). Its glossy black coat and a tuft of white feathers on either side of the throat suggest the garb of a clergyman.

Parsons: city; Labette co., Kan. (for location, see map of Kansas, ref. 8–J); on the Kan. City, Ft. Scott and Mem. and the Mo., Kan. and Tex. railways; 32 miles N. E. of Independence, 48 miles S. S. W. of Fort Scott. It is an agricultural and manufacturing center, contains general railway offices, railway works and shops, a foundry, and furniture and other factories, and has a national bank, a State bank, a public library, and 3 daily and 4 weekly newspapers. Pop. (1900) 7,682.

Parsons, ALBERT ROSS: See the Appendix.

Parsons, CHARLES: See the Appendix.

Parsons, or **Persons**, ROBERT: ecclesiastic; b. at Nether Stowey, Somersetshire, England, June 24, 1546; educated at St. Mary's Hall and at Baliol College, Oxford, where he graduated 1568, and became dean; left Oxford in 1574, in consequence of his conversion to Roman Catholicism; resided for a time in the Netherlands; studied medicine and law at the University of Padua; entered the Society of Jesuits at Rome July, 1575; studied divinity in the Jesuits' College at Rome; took orders as a priest; was sent by Pope Gregory XIII. to England, along with Edmund Campion and other Jesuits, July, 1580, to attempt the conversion of that kingdom to Roman Catholicism; traveled in disguise among his coreligionists; became the object of energetic measures on the part of the English Government; escaped to the Continent 1581; opened a seminary for English youth at Eu in Normandy 1584; became rector of the English college at Rome and provincial of the English missions; communicated with James VI. of Scotland in behalf of his mother, Mary, Queen of Scots, then awaiting execution, and visited in her behalf the courts of France, Spain, and Portugal; founded seminaries for English Roman Catholics at Valladolid, San Lucar, Seville, and Lisbon, and at St.-Omer, France, 1593; became a second time rector of the English College at Rome (1598–1610), and resisted all attempts to make him a cardinal after the death of Cardinal Allen. D. at Rome, Apr. 18, 1610. He was the author of several treatises in favor of the doctrines of the Church of Rome, which appeared in London under assumed names, among which were *A Brief Discourse* (1584); *The Christian Directory* (1583–91); *A Conference about the Next Succession to the Crown of England* (1594); and *A Treatise of the Three Conversions of England* (1603–04). For issuing the first and the third of these works the printers were hanged and quartered, and it was made high treason to own a copy of the latter book, which advocated the claims of the Infanta of Spain to the English throne. Gibbon attributed his youthful conversion to Roman Catholicism to the writings of Parsons, who was a man of brilliant talents and a vigorous writer, industrious, prudent, and zealous. He possessed much influence at the court of Spain, and was more dreaded by the English court than any other ecclesiastic. See Dodd's *Church History of England* and Foley's *Records of the English Province of the Society of Jesus.*

Revised by J. J. KEANE.

Parsons, SAMUEL HOLDEN: soldier and jurist; b. at Lyme, Conn., May 14, 1737; graduated at Harvard 1756; studied law at Lyme in the office of his uncle, Gov. Matthew Griswold; was admitted to the bar 1759; was representative in the Legislature many years in succession from 1762; became king's attorney 1774, when he removed to New London; was a member of the Connecticut committee of correspondence 1775, in which year he took command of the Sixth Connecticut Regiment at the siege of Boston; took part in the battle of Long Island; was chosen by Congress brigadier-general Aug. 9, 1776; succeeded Putnam in command of the Connecticut line 1779; became major-general Oct. 23, 1780; practiced law at Middletown after the peace; was commissioner to treat with the Miami Indians 1785; member of the Connecticut convention for the ratification of the Constitution of the U. S. Jan., 1788; was appointed by Washington first judge of the Northwest Territory; was commissioner of Connecticut to purchase from the Wyandot Indians the tract in Northeastern Ohio known as the Connecticut or Western Reserve 1789; settled near the Ohio river; published a paper on the antiquities of the Western States in the *Transactions* of the American Academy (vol. ii.); was drowned in the rapids of the Big Beaver river, Ohio, Nov. 17, 1789.

Parsons, THEOPHILUS, LL. D.: jurist; son of Rev. Moses Parsons; b. at Byfield, Mass., Feb. 24, 1750; graduated at Harvard 1769; taught school at Falmouth, Mass. (now Portland, Me.); was admitted to the bar there 1774; returned to Byfield in consequence of the destruction of Falmouth by a British squadron in Oct., 1775, and began legal practice at Newburyport in 1777. He was a member of the patriotic association called the "Essex Junto," and author of the famous pamphlet known as the *Essex Result* (1778), which contributed largely to the defeat of the State constitution then proposed by the Legislature, and the establishment of the prevailing New England conservative school of constitutional doctrine; was a member of the convention held in 1779 which framed a new constitution, and of the convention of 1788 for the ratification of the Federal Constitution. Although not active in public affairs, he was several times elected to the State Legislature. He removed to Boston in 1800, and became in 1806 chief justice of the Supreme Judicial Court, which post he held until his death, in Boston, Oct. 30, 1813. His decisions, which fill vols. ii. to x. of the Massachusetts *Reports*, have given him a vast legal reputation. He was a man of a remarkable memory, a versatile mind, an exact student, and exhibited a universal readiness in his practice of law. See *Memoir of Chief Justice Theophilus Parsons*, by his son, Theophilus Parsons (Boston, 1859). Revised by F. STURGES ALLEN.

Parsons, THEOPHILUS, LL. D.: jurist; son of the eminent jurist of the same name; b. at Newburyport, Mass., May 17, 1797; graduated at Harvard 1815: studied law in the office of Judge William Prescott; visited Europe; practiced some years at the bar at Taunton, and afterward at Boston; was a frequent contributor to *The North American Review* and other magazines and periodicals; founded the *United States Literary Gazette*; published three volumes of *Essays* in support of the doctrines of the Swedenborgian or New Jerusalem Church; became in 1847 Dane Professor of Law at Harvard Law School; was author of some fifteen volumes of legal treatises on the laws of contracts, mercantile business, shipping and admiralty, notes and bills of exchange, marine insurance; *Treatise on the Law of Contracts* (1853; 5th ed. 1864); *Elements of Mercantile Law* (1856); *The Laws of Business* (1857); *Treatise on Maritime Law* (1859); *Treatise on the Law of Promissory Notes and Bills of Exchange* (1860); *Laws of Partnership* (1867); *Treatise on Marine Insurance* (1875); *The Political, Personal, and Property Rights of a Citizen of the United States* (1875), etc. He also wrote a *Memoir of Chief Justice Theophilus Parsons* (1859); several theological works; *Essays* (1845); *Deus Homo* (1867); *The Infinite and the Finite* (1872); *Outlines of the Religion and Philosophy of Swedenborg*, and other religious works. D. at Cambridge, Mass., Jan. 26, 1882. Revised by F. STURGES ALLEN.

Partan'na: town of Italy; in the province of Trapani, Sicily; on a mountain-slope 1,250 feet above sea-level; 19 miles S. E. of Trapani (see map of Italy, ref. 9–E). It commands a fine view of the Mediterranean and of the beautiful plain between Cape Lilibeo and the promontory of Sciacca. The Chiesa Madre contains some noticeable works of art. This town was originally a Greek colony, and terra-cotta vases of Greek workmanship are frequently disinterred in the vicinity. The Saracens erected three castles here, the ruins of which still exist. In the revolution of 1860 Partanna furnished important assistance to Garibaldi. Pop. 13,144.

Parthe'nius: Greek elegiac poet of Nicæa in Bithynia; went to Rome about 72 B. C. and taught Vergil Greek at Naples. His poems, two of which were imitated in the extant Latin poems *Moretum* and *Ciris*, have perished, and the only production of his that has survived is a collection of doleful love stories (*περὶ ἐρωτικῶν παθημάτων*), a practical manual of themes for elegies prepared for the benefit of Cornelius Gallus, the Roman poet. Ed. by Westermann in his *Μυθογράφοι* (1843). B. L. G.

Parthenogen'esis [Gr. *παρθένος*, virgin + *γένεσις*, production]: that type of reproduction where unfertilized eggs de-

velop into adults. It occurs in various groups of invertebrates, especially in land and fresh-water forms which are exposed to seasonal changes. Instances are most numerous among the Rotifers, the lower Crustacea, and insects. In some Crustacea it is almost the rule, and in the Phyllopod *Apus* males are so rare that for many years they were not known to exist. Parthenogenesis may occur occasionally in forms like butterflies and silkworms, when sexual reproduction is the rule, or it may occur as a normal condition in the production of one sex, as among the honey-bees, where the drones are developed from non-fertilized eggs, the workers and queens being developed from impregnated ova. In some of the lower Crustacea (*Otracodes*, *Cladocera*) parthenogenetic and normal generations alternate according to the season. In these the two types of eggs differ considerably in appearance. Among the plant-lice (Aphides) parthenogenetic reproduction prevails during the warmer months, the females producing eggs which develop, without fertilization, inside the mother, the young being born alive. In the autumn true males and females appear, and fertilized eggs are laid which carry the species through the winter months. Here the normal females differ from the parthenogenetic ones, since the latter possess wings and lack those organs necessary for copulation. A last type to be mentioned are certain pædogenetic flies, in which not the adult but the larva or pupa produces parthenogenetic eggs.

An explanation of parthenogenesis which shall fulfill all conditions is yet to be given. The latest and most nearly satisfactory is that of Weismann. Normal eggs in their maturation throw off two polar globules (see EMBRYOLOGY), but apparently, in at least some instances, parthenogenetic eggs throw off but one. The second globule is hence assumed to be equivalent in some respects to the male element (spermatozoön), and since it is retained in the egg, no addition of outside material is necessary. The whole subject is, however, obscure. The reader is referred to von Siebold, *Parthenogenesis* (London, 1857), and Weismann, *Essays on Heredity*.

J. S. KINGSLEY.

Par'thenon [= Lat. = Gr. Παρθενών, deriv. of παρθένος, a virgin, an especial epithet of Athene]: a temple of Athena Parthenos at Athens. It was built by Pericles about 438 B. C. The architects were Ictinus and Callicrates, and a part of the sculptured decorations are thought to have been from the hand of Phidias. It stands upon the Acropolis. It is of the Doric order, built of Pentelic marble, is 228 feet long and 101 feet wide. It is generally believed that it was painted within and without. There were 46 columns in its peristyle, 8 at each end and 17 on each side, reckoning the corner columns twice. It stood almost entire until 1687, when, during a siege by the Venetians, a large part of the central portion was destroyed by the explosion of some gunpowder stored in it by the Turks. It is regarded as the finest production of Greek architecture. The statues from the pediments, so far as preserved, many of the metopes, and a large part of the frieze on the outer wall of the cella were taken by Lord Elgin, and are among the chief treasures of the British Museum. See ARCHITECTURE and ATHENS.

Revised by RUSSELL STURGIS.

Par'thia: an ancient territory of Western Asia; situated S. E. of the Caspian Sea, corresponding nearly to the modern Persian province of Khorassan. It was wholly mountainous and inhabited by a rough, wild, and warlike people of Scythian descent, famous for their horsemanship and skill with the bow. Agriculture and trade they despised; war was their only occupation. They belonged successively to the Assyrian, Persian, Macedonian, and Syrian empires, but in 250 B. C. they established an independent kingdom under Arsaces, whose dynasty, the Arsacidæ, ruled till 226 A. D. and formed a vast empire, extending from the Euphrates to the Indus. The Romans attacked them several times, but without success; but Artabanus IV. was killed in 226 A. D. in a rebellion, and the dynasty of the Arsacidæ was followed by that of the Sassanidæ, a Persian family. The Persian influence now became the ruling one in Asia till the Mohammedan conquest, 651 A. D.

Participle [through the Fr. *participe* from Lat. *participium*, a deriv. of *par'ticeps*, sharing, participating; *pars*, part + *ca'pere*, take. The Lat. word is merely a translation of the Gr. μετοχή, deriv. of μετέχειν, to share; μετά, among + ἔχω, have]: an adjective verbal; an adjective formation, closely attached to the verb, and sharing with it meaning, the government of cases, and tense. In the parent Indo-European the boundary-line between participles and adjectives was less clearly fixed than it appears in the separate languages. The participle had not become an established part of the mechanism of the parent speech. Indo-European adjective suffixes have therefore been employed to form participles in these languages; thus *-to-*, *-no-* (*-ono-*), *-io-*, *-teuo-*, *-lo-*, *-ent-*, *-meno-*. Of these the English uses three: (1) *-tó-*, which forms the past passive participle of the regular or weak verbs, as in *tamed*: Germ. *ge-zāhmt*: Goth. *ga-tamida-* < Indo-Europ. *domətó-s* > Sanskr. *damitá-*: Lat. *domitus*. Three forms of the suffix appear, as in *blesséd*, *loved*, *blest*. (2) *-ono-*, which forms the past passive participles of the irregular or strong verbs, as in *given*: Germ. *gegeben*: Goth. *gibans*; cf. Germ. *ge-worden*, Goth. *waúrþans*, Sanskr. *vavṛtāná-s*. The prefix *ga-* (*ge-*, *gi-*) which commonly attached itself as a characteristic of past participles in Teutonic survives in English only in traces in a few archaizing words, like *yclept*. In German the compound verbs with inseparable prefix omit the *ge*, as *erfunden*, *verschwunden*. Relics of old participles with omitted *ge-* are also found in *können*, *lassen*, etc., e. g. in *hat singen können*, *hat kommen lassen*. (3) *-ent-* (*-nt*), which forms the present active participles, like *loving*, *singing*. This ending (M. Eng. *singinge*) succeeded to O. Eng. *-ende* in late Middle English, and soon caused confusion with the substantives in *-ing* (O. Eng. *-ung*, *-ing*), like *learning* (O. Eng. *leornung*). The original ending appears in *bearing*: Germ. *gebärend*: Goth. *bairands*; Sanskr. *bhárant-*: Gr. φέρων (*-οντ-*): Lat. *ferens*. The present participle in English may be used passively, as in *The house was building*, but the necessity of avoiding the ambiguity involved in cases like *The boy was whipping*, for *being whipped*, is bringing into standard use the substitute *is being built*.

BENJ. IDE WHEELER.

Partinico, pär-tee'nĕe-ko, or **Partenico**: town; in the province of Palermo, Sicily; about 17 miles W. of the city of Palermo (see map of Italy, ref. 9–E). It is situated in a wide valley, and is surrounded by calcareous mountains rising in the form of isolated pyramids. The vine and the olive thrive in this region, and the inhabitants are chiefly occupied with the manufacture and sale of wine and oil. Pop. 21,000.

Partition: See JOINT OWNERSHIP.

Partnership [deriv. of *partner* (by anal. of *part*) for *parcener*, from O. Fr. *parsonnier*, liter., portioner, deriv. of *parson*, portion < Lat. *parti'tio*, division]: "the relation which subsists between persons carrying on a business in common with a view of profit." (British Partnership Act, 1890, § 1.) The English law of partnership is modern—the product mainly of the nineteenth century. Blackstone barely refers to it. The earliest treatise on the subject was published in 1794 by W. Watson, who asserts that "the true use of partnership was discovered" during Elizabeth's reign. In the early English digests partnership cases are presented under the titles *Merchants* or *Lex Mercatoria*; and very naturally, as the decisions are rested on the customs of merchants. (*Jeffreys* vs. *Small*, 1 Vernon 217, A. D. 1683.) Although our law of partnership had its origin in mercantile customs, its development has been seriously affected by common-law rules, which have been applied in some instances by the courts with unfortunate results.

Nature of Partnership.—The mercantile conception of a partnership is that of an entity distinct from the partners. This view has been championed by distinguished judges in England and the U. S. Chief Justice Hornblower, in *Curtis* vs. *Hollingshead* (2 Green, N. J. Law, at p. 410), declares, "A partnership is considered in law as an artificial person, or being, distinct from the individuals composing it." Master of the Rolls Jessell, in *Pooley* vs. *Driver* (5 Chancery Division, at p. 476), asserts: "Everybody knows that partnership is a sort of agency, but a very peculiar one. You can not grasp the notion of agency, properly speaking, unless you grasp the notion of the existence of the firm as a separate entity from the existence of the partners." Similar but more guarded statements of the same doctrine are found in *Bank of Buffalo* vs. *Thompson* (121 N. Y. 280) and in *Meehan* vs. *Valentine* (145 U. S. 611). On the other hand, the mercantile view has been expressly, almost contemptuously, repudiated by other judges. In *Hallowell* vs. *Blackstone Bank* (154 Mass. 359) Justice Holmes says: "Cory on accounts and Lindley on partnership have made it popular to refer to a mercantile distinction between the firm and its members; but we have no doubt that our merchants are perfectly aware that claims against their firms are claims against them." Lord Justice Kay (*In re* Beauchamp Brothers (1894), 1

Queen's Bench, at p. 7), referring to counsel's argument that a partnership is an entity, asserts, "It is no such thing, and the rules do not mean anything of the kind." Had the courts accepted and consistently enforced the mercantile conception of a partnership, this branch of the law would have been much simplified and improved. While they have not adopted it, they have established certain doctrines, as will appear from our subsequent discussion, which fully recognize its soundness. The Partnership Act of 1890 declares, "In Scotland a firm is a legal person distinct from the partners of whom it is composed."

At common law any number of persons may unite in a partnership. This is sometimes modified by statute, as by the Companies Act, 1862 (25 and 26 Vict., c. 89), which limits the members of a banking partnership to ten, and those of a partnership for any other purpose to twenty persons. In the absence of prohibitory legislation, a partnership may divide its capital into transferable shares (see JOINT-STOCK COMPANY), and thus enable any of its members to dispose of their interests to strangers without dissolving the firm. The shares in mining partnerships are thus transferable, by mercantile custom. In the normal partnership, however, *delectus personarum* is a fundamental rule; each partner has the right to choose his associates, and no one can become a member of the firm without the consent of every member. This relation is presumed to be founded on personal confidence between the partners, for the incapacity or dishonesty of any one may inflict irreparable injury upon his associates.

How Created.—A true partnership originates in an agreement of the partners. It follows that the members of a firm must possess contractual capacity (see ALIEN, CONTRACT, CORPORATION, INFANTS, and MARRIED WOMEN), and that if the partnership be illegal it has no legally enforceable rights against third persons, nor have its members any against each other. Persons may enter into an association by agreement without becoming partners. Their association, to be a partnership, must be organized to carry on a business with a view of profit. Hence a social club, or a charitable organization, or a political committee, or an association formed to open and grade a street, or to resist the claims of a particular patentee or to build a meeting-house which is to be the property of the associates in the proportion of their payments, or to buy and divide lands, or to cultivate a farm on shares, or to engage in the production of articles which are to be divided among the associates, is not a partnership. In neither of these cases is a business carried on in common with a view of profit. It must be admitted that the term business is somewhat vague, and that judicial definitions of it are not harmonious. The tendency of modern decisions, however, is fairly expressed in the Partnership Act, which defines the expression as including "every trade, occupation, or profession."

While an agreement between persons is necessary to institute the relation of partnership, such agreement need not declare expressly their intention to become partners. On the other hand, it may call them partners without creating a partnership. (*Livingston* vs. *Lynch*, 4 Johnson's Chancery, at pp. 592–593.) Whether this relationship has been instituted is in each case a question of intention, to be determined as a fact from all the language and acts of the parties. It is not essential that they should plan actually to become partners. They may have been ignorant of the law, and unconscious of the legal results of their conduct; or they may have tried to evade the law by giving to the transaction the appearance of a loan of money, or the use of property or personal services, on the part of one or more of the associates to his fellows, while securing to such one or more all of the advantages of a partnership; yet if they have carried on intentionally a business in common with a view of profit, they are partners. While the business must be carried on in common, it is not necessary that each partner engage in the management. It is enough that it be carried on in his behalf as a common proprietor. Nor is it essential that each partner should share in the losses of the business. One or more may be guaranteed against loss by his copartners.

That the intention of the contracting associates to carry on a business in common with a view of profit is the true test of a partnership, has not always been recognized by the courts. In England, until the decision of the House of Lords in *Cox* vs. *Hickman* (8 House of Lords Cases 268, A. D. 1860), it was generally understood that participation in the profits, or at least in the net profits of a business, constituted one a partner. "He who takes a moiety of all profits," it was said, "shall by operation of law be made liable to losses, if losses arise, upon the principle that by taking a part of the profits he takes from the creditors a part of the fund which is the proper security to them for the payment of their debts." (*Waugh* vs. *Carver*, 2 H. Blackstone 235, A. D. 1793.) Various exceptions were established from time to time, and in *Cox* vs. *Hickman* the House of Lords declared that this doctrine was not a part of the law of England: that "the real ground of the liability" of a partner "is that the trade has been carried on by persons on his behalf"; that in determining whether it so has been carried on, participation in the profits is an important but not a decisive fact; that the question is to be answered in accordance with the terms of the contract between the parties. The principles of this decision have been followed by the English courts in subsequent cases, and are now a part of the statute law of Britain. *Cox* vs. *Hickman* had been anticipated by several State decisions (e. g. *Loomis* vs. *Marshall*, 12 Conn. 69, and *Polk* vs. *Buchanan*, 5 Sneed (Tenn.) 721), and its doctrine is enforced by most of the courts in the U. S. Even the New York court of appeals, while professing still the form of the older English doctrine, has discarded its substance. In a recent decision, after restating the old rule and the grounds upon which it was based, the court said: "Exceptions to the rule are, however, found in cases where a share in profits is contracted to be paid as a measure of compensation to employees, for services rendered in the business, or for the use of moneys loaned in aid of the enterprise; but where the agreement extends beyond this, and provides for a proprietary interest in the profits as a compensation for moneys advanced and time and services bestowed as a principal in its prosecution, we think that the rule still requires such party to be held as a partner." *Hackett* vs. *Stanley*, 115 N. Y. 625.

The partnership contract sometimes provides that the interest of a partner in case of his death shall remain in the business until a certain date. Such a provision does not give to the executor a right to enter the firm, nor does it subject him to the liabilities of a partner. Where the contract provides that the executor shall be admitted to the firm, it does not compel him to enter the partnership; but if he does, he becomes personally liable for the firm debts, and is entitled to indemnity to the extent of the share of the estate embarked by the will in the business, and no further. *Wild* vs. *Davenport*, 48 N. J. Law 129.

Quasi-partnership.—There is some judicial authority and an abundance of judicial dicta for the proposition that a partnership may exist as to third persons, where there is none between the parties, but it has been rejected by the great majority of courts as indefensible. Its unsoundness was never exposed more clearly than by Baron Bramwell in *Bullen* vs. *Sharp* (Law Reports, 1 Common Pleas 86): "Partnership means a certain relation between two parties. How, then, can it be correct to say that A and B are not in partnership as between themselves; they have not held themselves out as being so, and yet a third person has a right to say they are so as relates to him? That must mean *inter se*; for partnership is a relation *inter se*, and the words can not be used except to signify that relation. A is not the agent of B; B has never held him out as such; yet C is entitled, as between himself and B, to say that A is the agent of B! Why is he so entitled if the fact is not so, and B has not so represented?" According to the prevailing view, then, there is no true partnership as to third persons where there is none between the parties; but the parties, by holding themselves out to third persons as partners, may subject themselves to a partnership liability to such persons. This holding out may be by express statement or by conduct. One who asserts that he is a member of a firm, or who knowingly suffers himself to be represented as a member, is liable as a partner to those who give credit to the firm on the strength of such assertion or representation. It is often said that one who holds himself out to the world as a partner is liable as such to every one who deals with the firm, whether the holding out was known to the third person or not; and there is some judicial authority for this doctrine based upon considerations of public policy. (*Poillon* vs. *Secor*, 61 N. Y. 456; *Bartlett* vs. *Raymond*, 139 Mass. 275, 277.) The better view, however, is that the liability of a "holding out" or quasi-partner rests upon the principle of estoppel, which is that one who has induced another to believe in and act upon the existence of a particular state of facts can not be heard, as against that other, to deny the truth of those facts. *Thompson* vs. *Bank*, 111 U. S. 530.

Title to Partnership Property.—In dealing with this branch of the subject the courts have been forced to accept, to a greater or less extent, the mercantile idea of a partnership. Personalty may be transferred to or by the firm in the firm name, and title thereto is in the firm and not in its members as individuals. A chattel mortgage on firm property by one partner to secure his separate debt, or the levy of an execution thereon, issued on a separate judgment, does not subject it to a lien as against the firm or its creditors. All that is encumbered in either case is the debtor partner's share. This is not the interest of a tenant in common, for the transferer of a partner's share gets no title to an undivided share of any chattel; he obtains only a chose in action, a right to an account, and to any surplus of proceeds which may belong to the debtor partner on account of the property mortgaged or levied on, after the payment of firm debts and the adjustment of the equities between the partners. It is not the interest of a joint tenant, for the full legal and equitable title does not survive as between partners.

The tendency of modern decisions is to treat firm real estate as partnership stock or personalty, so far as the rules of conveyancing and of the recording acts will permit. In Britain this doctrine has been carried to its logical conclusion. The Partnership Act provides: "Where land or any heritable interest therein has become partnership property, it shall, unless the contrary intention appears, be treated as between the partners (including the representatives of a deceased partner), and also as between the heirs of a deceased partner and his executors or administrators, as personal or movable and not real or heritable estate" (§ 22). Sir Frederick Pollock has expressed the belief that this rule was well settled before the statute, and may safely be accepted in other common-law jurisdictions. However, the doctrine which prevails in most of the U. S. does not sustain fully his view. It treats partnership realty as converted into personalty only for the purposes of paying partnership liabilities. The surplus retains all the incidents of real estate. For example, a deceased partner's share passes to the heir and not the personal representative, and is subject to dower.

The deed of real estate to a firm should contain the individual names of the partners and the firm name. If the firm name is employed as that of the grantee, the effect of the deed will vary with the jurisdiction. In some States it will operate not as a conveyance, but as a contract to convey. In others it will pass the legal title to any of the partners whose names appear in the firm appellation, but if this does not contain the name of a member, the deed will be inoperative, and the grantor will retain the legal title in trust for the firm. In still others it will pass the legal title to the persons composing the firm at the time of the transfer. Wherever firm real estate stands in the name of a partner, the equitable title is in the firm, and he may be compelled to deal with it as firm property. While he holds the legal title a purchaser for value from him without notice of the partnership's rights may get good title. In case he disposes of the property to such a purchaser, and reinvests the proceeds in other lands, these become firm property.

A Partner's Powers.—Each partner is a general agent of the firm, and therefore has full authority to do any act which is necessary to the transaction of the firm's business in the way in which it is usually carried on. Whether an act in question is within the scope of the partner's apparent authority is "to be determined by the nature of the business and by the practice of persons engaged in it." The authority of partners in a trading firm is much more extensive than that of non-trading partners. In case of the latter—such as lawyers, farmers, mine or quarry owners, hotelkeepers, theater-managers—a partner has apparent authority to sell any of the personal chattels of the firm, or to purchase for it any chattels ordinarily used in its business, or to receive payment and give receipts and releases of debts, or to engage servants for the business. A member of a trading firm has apparent authority to do any of these acts, and also to bind his firm by negotiable paper, by borrowing money on the firm's credit, and by pledging its property as security therefor. He has not apparent authority to bind his firm by a sealed instrument, for the firm has no seal; nor to make a general assignment of firm property for the benefit of creditors, since this necessarily puts an end to the firm's business; nor submit a firm claim to arbitration; nor to make the firm a surety for third persons, unless the usage of the firm or of others engaged in the like business warrants such an act; nor to change in any material respect the business of the partnership. The ordinary authority of a member in either a trading or non-trading firm may be limited by an agreement of the partners, which is communicated to those dealing with the firm. As a partner is the general agent of the firm, his admissions and declarations relating to the affairs of the partnership and in the ordinary course of its business are its admissions and declarations. His representations as to the existence of a firm, or as to his authority to bind it, are clearly not within this rule. Whether a partner's authority to bind the firm by admissions and declarations concerning partnership transactions continues after dissolution, is a question upon which the courts differ. One line of decisions, following a leading English case (*Wood* vs. *Braddick*, 1 Taunton 104, A. D. 1808), holds that it does, while the opposite doctrine is maintained by decisions as numerous and respectable which follow a leading New York case. (*Hackley* vs. *Patrick*, 3 Johnson 536, A. D. 1808.) The former seems to be the sounder view. The courts have also disagreed as to the power of a partner to waive the statute of limitations after dissolution; but the weight of argument and authority is against his possession of it. "Notice to any partner, who habitually acts in the partnership business, of any matter relating to partnership affairs, operates as notice to the firm, except in the case of a fraud on the firm committed by or with the consent of that partner." Partnership Act, § 16.

Liability of Partners.—The members of a firm are jointly liable for all its contract obligations. Such has been always the prevailing doctrine in the U. S., except as modified by statute; but in England, until the decision of *Kendall* vs. *Hamilton* (4 Appeal Cases 504, A. D. 1879), it was understood that the liability was joint and several in equity. Several liability is still the rule in Scotland (Partnership Act, § 9), and in the U. S., as well as in Britain, the estate of a deceased partner is severally liable for partnership obligations. In most of the U. S., however, a firm creditor is not allowed to proceed against the estate of a deceased partner, unless the firm and the surviving partner are insolvent. The liability of partners for the torts of one or more within the scope of a partner's apparent authority is joint and several.

Although, as a rule, the liability of partners is joint, a judgment in an action against all is enforceable at law against the property of the firm or against that of any member at the creditor's option, as the entire fortune of each partner is liable for firm debts.

Duties of Partners.—Because of the power which the law gives to each partner, it requires him to exercise it with the utmost good faith. He is bound to render true accounts and full information of all partnership affairs. If, without his partners' consent, he derives any benefit from any firm transaction, or from any use by him of the property, name, or business connection of the partnership, this belongs to the firm; and he is not allowed, without his partners' consent, to carry on any competing business. It is the duty of the minority of a firm to acquiesce in the decision of the majority where differences arise as to ordinary matters connected with the partnership business, but not in a decision which works any change in the nature of the business, or in the membership of the firm. Each member is bound to devote his time and energies to the affairs of the firm without special remuneration. Of course these duties may be, and often are, varied by the agreement of the parties.

Dissolution and its Consequences.—A partnership may be dissolved by the agreement of the parties, by the operation of law, or by the decree of a court. The dissolution may be expressly provided for in the partnership contract, or the agreement of the parties may be inferred from the circumstances of the case. If the partnership is for a single adventure, it terminates with the close of that adventure. If it is organized to carry on a business for an undefined time, it is a partnership at will, terminable by notice from either partner. Where it is entered into for a fixed term, the better doctrine seems to be that it can not be dissolved by the mere act of one single partner, although there is considerable authority in the U. S. for the view that it can. (See *Solomon* vs. *Kirkwood*, 55 Mich. 256.) The happening of any event which makes the business of a firm unlawful, or the partnership relation between its members unlawful, works its dissolution by the operation of law, as does the death or the bankruptcy of any partner in the absence of an agreement to the contrary. A court may decree the dissolution of a firm because of the insanity or permanent incapacity of a partner, or because a member other than the one

suing has been guilty of serious misconduct, or because the circumstanees of the case show that a decree of dissolution will be just and equitable.

Unless the dissolution is produced by operation of law, it is important that notice thereof be given, or the retiring partners may be made liable for the debts of the new business. Actual notice must be given to those who have dealt with the old firm, but no particular form is required, while notice by publication in a newspaper of general circulation in the vicinity is sufficient as to all others. It is the legal duty of all members to coneur in sueh notification.

After a firm is dissolved, the authority of each partner, unless bankrupt, and his partnership rights and obligations continue for the purposes of winding up the firm's affairs only. All executory contracts of the partnership are to be performed; its assets, including the good will of the business, are to be converted into cash and to be applied first to the payment of firm creditors, next to the payment of advances, if any, by the respective partners, then to the payment of the capital furnished by each partner, and the residue is to be divided among the partners in the proportion in which profits are divisible. In the absenee of an agreement on the subject, profits are divisible equally between the partners, and not in proportion to their contributions of capital. The losses of a partnership business are payable first out of the profits, next out of capital, and then by the various partners in the proportion in which profits are divisible. In ease any of the partners are wholly insolvent, the losses are to be borne ratably by the others.

The position of a surviving partner has been rendered anomalous by the failure of the courts to aceept the entity idea of a partnership. He holds the legal title to the firm personalty. If sued on a separate debt, he can set off a firm claim; and if he sues on a firm credit his separate indebtedness may set off against it. He ean make a general assignment of firm property for the benefit of firm creditors with preferences. Yet he has not a joint tenant's benefit of survivorship. He is bound to a partner's good faith in disposing of the firm property and in distributing it to firm ereditors and to the representatives of deceased members. In Britain, however, this duty does not amount to a trust, and a deceased partner's representative has not the rights of a *cestui que trust* in the firm property; his claim is only "a debt accruing at the date of the death"; "there is nothing fiduciary between the surviving partner and the dead partner's representative, except that they may respectively sue each other in equity." (Partnership Act, § 43; *Knox* vs. *Gye*, Law Reports, 5 House of Lords 656.) The prevailing view in the U. S. is somewhat different. It is fairly indicated in *Preston* vs. *Fitch* (137 N. Y., at pp. 56–58), where it is said that "the property of a late firm comes to the surviving partner impressed with a certain kind of a trust, founded upon his duty to dispose of or realize upon such assets, and therefrom to pay the debts of the late firm, and to pay over the share of any balance to the estate of the deceased partner." The exact nature of this trust and the respeetive legal rights of the survivor and of the deceased partner's estate remain quite indefinite; and it is impossible to deduee from the decisions, even within a single jurisdiction, a body of consistent rules upon this topie.

We have seen that a firm creditor may enforce at law his judgment against the firm property or that of any partner. In case of the death of a partner, or of the insolvency or bankruptcy of a firm or any of its members, and of the administration of the partnership and individual estates, a different rule obtains, except in a few jurisdictions (e. g. Connectieut, Louisiana, South Carolina, Vermont, Virginia), and firm property is applied first to firm debts, while the separate property of each partner is applied first to his individual debts, any surplus from either estate being carried to the other. This rule was adopted in early bankruptcy eases as "a sort of rough code of justice," and has been adhered to as a matter of convenience, although at variance with the mercantile system of settling accounts, and open to severe criticism. A joint and several obligation of the partners, incurred in the firm business, or an obligation upon whieh the firm and its members, or any of them, are successively liable, as a note made by the firm and indorsed by the partners individually, is entitled to share in each estate until paid in full. As a rule, the firm ean not prove against the estate of one of its partners in eompetition with his separate ereditors, nor can a partner prove against the firm estate or the estate of any copartner in competition with firm creditors. An exception is made in case the property of the firm has been fraudulently converted by a partner, or that of a partner has been so converted by the firm without consent or subsequent ratification, and in Britain in the case of debts accruing between distinct trades carried on respectively by the firm and by a partner.

Limited Partnership.—New York, first among common-law States, adopted this institution in 1822, borrowing many of its features from the *société en commandite* of the French law. Later in the same year Connectieut introduced it into her legal system, and these two statutes have formed the models for legislation upon this subject by most of the U. S Several attempts have been made to introduce it into Britain, but without suceess. Limited partnership statutes, it is judicially declared, have two main objects: (1) To enable capitalists, without incurring the risks of general partners, to invest money, and thus promote trade, and to help those who have not sufficient wealth to earry on business ventures for whieh they have the requisite integrity and capacity; (2) to protect those dealing with the firm. The leading eharacteristics of this system are: (1) The publication of the names of the general and those of the special partners, of the amount of capital, of the nature and location of the business, and of the date of its commencement and termination; (2) the aetual eontribution of the avowed capital; (3) the protection of this partnership fund from secret and improper diminution for the benefit of the special partner or favored ereditors. A limited partnership must eontain one or more general partners, who have the authority and are subjeet to the liabilities of common-law partners; while the special partners are prohibited from taking part in the active management of the business, and are not liable for its obligations beyond the amount of their eapital. Such a partnership ean be organized only by eomplying strictly with all the substantial requirements of the statute. An honest intention to comply with its terms will not suffiee, and a firm which has failed to conform to the statutory provisions is a general partnership with all its eommon-law liabilities. Although this institution was borrowed from the civil law, the eourts have resorted rarely to civil-law authorities when dealing with questions relating to it, but have applied to them, so far as possible, the common-law rules. At first they were disposed to give to limited partnership statutes a very strict eonstruetion in favor of firm ereditors, but at present they look upon this legislation "as serving a purpose consistent with the public welfare, and entitled to a reasonable construction for the protection of speeial partners as well as for that of others." (*Fifth Avenue Bank* vs. *Colgate*, 120 New York 381.) For the special rules governing the formation of limited partnerships, their renewal, the eonduet of their business, and their dissolution, the statutes of each jurisdiction should be consulted.

Standard treatises on the subjeet of this article are those of Bates and of Troubat on *Limited Partnership*; of Bates, Lindley, Parsons, and Story on *Partnership*. A valuable collection of cases on partnership has been published by Prof. Ames. FRANCIS M. BURDICK.

Parton, ARTHUR: See the Appendix.

Parton, ERNEST: See the Appendix.

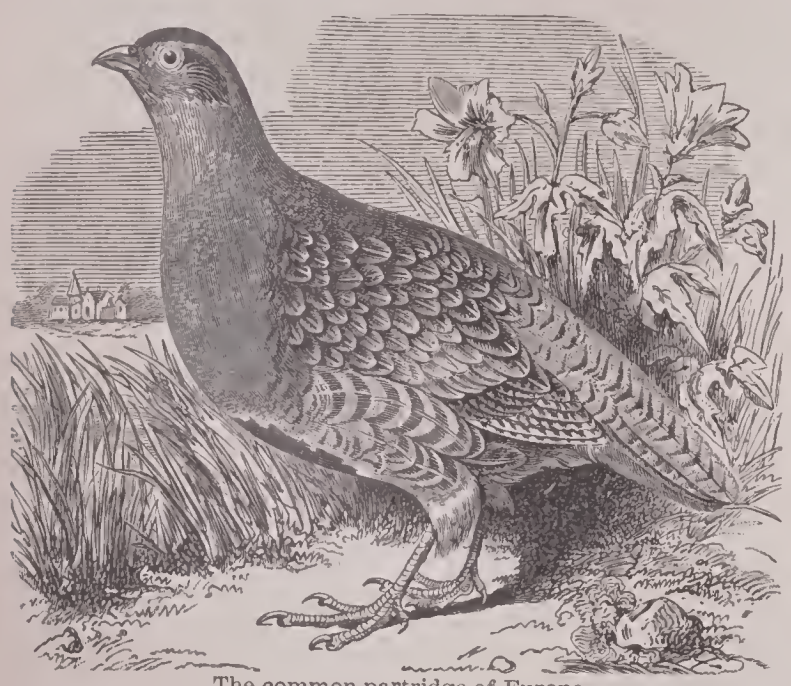
Parton, JAMES: author; b. at Canterbury, England, Feb. 9, 1822; was taken to New York when five years of age; educated in an aeademy at White Plains, where he became a teaeher at the age of nineteen; subsequently taught school in Philadelphia and New York; was for some years assistant editor of *The Home Journal*; was a prolific author and a leeturer on literary, social, and political topics; in 1856 married the story-writer "Fanny Fern"; resided in New York until Mar., 1875, when he became a resident of Newburyport, Mass. Among his works are *Biographies* of Horace Greeley (1855; new ed. 1868), Aaron Burr (1857; new ed. 2 vols., 1864), Andrew Jaekson (3 vols., 1860), Benjamin Franklin (2 vols., 1864); Thomas Jefferson (1874), and Voltaire (1881); *Humorous Poetry of the English Language* (1857); *People's Book of Biography* (1868); *Smoking and Drinking* (1868); *Famous Americans of Recent Times* (1870); *Topics of the Time* (1871); *Triumphs of Enterprise* (1871); *Words of Washington* (1872); *Caricature in all Times and Lands* (1877); *Captains of Industry* (1884; 2d series 1891). D. at Newburyport, Oct. 17, 1891.

Parton, SARAH PAYSON (*Willis*): story-writer; wife of James Parton and sister of Nathaniel P. Willis: b. at Portland, Me., July 7, 1811; married Charles H. Eldredge, of Boston, a bank eashier, on whose death she resorted to literature as a means of subsistence; obtained great success by her

short humorous essays entitled *Fern Leaves from Fanny's Portfolio* (2 vols., 1853–54); *Little Ferns for Fanny's Little Friends* (1853); wrote regularly for many years for *The New York Ledger*; issued several volumes of collected articles, and was author of two novels, *Ruth Hall* and *Rose Clark*. D. in New York, Oct. 10, 1872. See *Fanny Fern: a Memorial Volume, containing her Select Writings and a Memoir*, by James Parton (1873). Revised by H. A. Beers.

Part-ownership: a species of title to personal property which is employed mainly in the case of Shipping (*q. v.*). It is distinguished from joint tenancy by the absence of survivorship, from tenancy in common by the absence of the right to force a severance of the various owners' interests, and from partnership title by the fact that each person interested owns an undivided share of a chattel instead of a share in the business. Part-owners do not constitute a business entity, and are not, like partners, agents by reason of their business relations. In order to subject his associates to any obligation, or their interests in the common property to any lien, a part owner must obtain from them the authority therefor in fact; he possesses none by operation of law. Francis M. Burdick.

Partridge [M. Eng. *partriche*, from O. Fr. *pertris*, *perdrix*: Ital. *perdice*, *pernice*: Span. Portug. *perdiz* < Lat. *perdix* = Gr. πέρδιξ, connected, either as a derivative or an assimilation (folk-etym.), with πέρδομαι]: a name applied to various medium-sized game birds of the grouse family (*Tetraonidæ*). In England the partridge is *Perdix cinerea*, a bird about a foot long, of a delicate mottled gray. The



The common partridge of Europe.

red-legged partridge (*Caccabis rubra*) of Europe is slightly larger and more handsome. In the northern parts of the U. S. the name is given to the ruffed grouse (*Bonasa umbellus*), while in the southern this bird is known as the pheasant and the term partridge bestowed upon the quail, or bobwhite (*Colinus virginianus*). Finally, sportsmen in Australia have dubbed the true quail (*Turnix*) partridge, and in South America given the name to some of the larger tinamous, birds of a totally different group. F. A. Lucas.

Partridge, Alden, A. M.: soldier; b. in Norwich, Vt., about 1785; graduated at the U. S. Military Academy Oct. 30, 1806, when he was appointed first lieutenant of engineers; captain 1810; was retained at the academy as Assistant Professor of Mathematics until Apr., 1813, when he was appointed Professor, and in Sept., 1813, Professor of Engineering; commanded at West Point Jan., 1815, Nov., 1816, and Jan. to July, 1817; resigned Apr., 1818, and in 1819 was appointed principal of the surveying party to determine the northwest boundary of the U. S. In 1820 he founded a military school at Norwich, Vt., subsequently incorporated in the Norwich University, of which he was appointed president. He also established military schools in New Hampshire, Connecticut, Delaware, Pennsylvania, and Virginia, and delivered lectures on military matters throughout the U. S. He was appointed surveyor-general of Vermont 1822, and was a member of the Vermont Legislature 1833–34 and 1839. D. at Norwich, Vt., Jan 17, 1854.

Partridge, William Ordway: See the Appendix.

Partridgeberry, or **Checkerberry**: the common name of a trailing evergreen herb, *Mitchella repens*, belonging to the Madder Family (*q. v.*); found in the U. S., Canada, Mexico, and some parts of South America. It bears a red fruit, about the size of a whortleberry, which remains on the stem all winter. The wintergreen (*Gaultheria procumbens* of the Heath family) is sometimes, but incorrectly, called partridgeberry or checkerberry.

Revised by Charles E. Bessey.

Partridge-wood: a name applied in commerce and the arts to several handsome tropical woods used for veneering and for making small ornamental wares. It is more generally given to the wood of *Andira inermis*, a leguminous tree of the West Indies and South America. This wood is hard, and in Brazil is used in ship-building.

Party Wall: as commonly understood, a wall which stands on the line between two adjoining lots of land belonging to different owners, and in which both proprietors have common rights and a common use. Provided such common rights exist, it is not, however, essential that the wall stand on the line between the adjoining lots in order to have the character of a party wall. It may have that character though it stands wholly on the land of one proprietor (see Metropolitan Building Act, 18 and 19 Vict., ch. 122), and under some circumstances even where the wall does not abut on the line. (*Rogers* vs. *Sinsheimer*, 50 N. Y. 646.) In the common case, where the wall rests on both lots, the adjoining proprietors are, by the English common law, regarded as tenants in common of the wall, and probably, for the time being at least, of the land on which it stands; and the rights and obligations of the parties are such as pertain to that relation. (See Joint Ownership.) In the U. S., however, each of the adjoining owners retains the fee of the portion of the wall which rests upon his own soil and has an easement of user and support in the portion resting on the soil of his neighbor. From these principles are derived a number of special rules in respect to the use and maintenance of the wall, its repair, additions to its height, its rebuilding when necessary, etc., which differ in some important particulars from those which regulate the relations of the parties under the English doctrine. In England (so far at least as the London metropolitan district is concerned) and in several of the U. S. the mutual rights and obligations of the parties are carefully regulated by statute. The special rules above referred to will be found set forth at length in Washburne on *Easements and Servitudes* and in the *American and English Encyclopædia of Law*, title *Party Walls*. George W. Kirchwey.

Párvatī' [= Sanskr. *Pārvatī*, liter., femin. of *pārvata*, belonging to or coming from a mountain; so called because originally a personification of the mountain stream *Durgā*, flowing from (i. e. born of) the mountain Himavant]: a female divinity of the ancient Hindu pantheon, the consort of Siva. See Hinduism.

Parvin, Theophilus, A. M., M. D., LL. D.: obstetrician; b. in Buenos Ayres, Argentine Republic, Jan. 9, 1829; received his literary education at Lafayette College and at the State University of Indiana, where he graduated in 1847: graduated M. D. from the University of Pennsylvania in 1852; the following year began to practice medicine in Indianapolis; was Professor of Obstetrics in the Medical College of Ohio, in the medical department of the University of Louisville, in the Medical College of Indiana, and in the Jefferson Medical College, Philadelphia, where he now holds that chair. He has been president of the Indiana State Medical Society, of the Association of American Medical Journalists, of the American Academy of Medicine, of the American Medical Association, and of the American Gynæcological Society. His principal work is *The Science and Art of Obstetrics* (Philadelphia, 1886). He also edited *Winckel on Diseases of Women*. S. T. Armstrong.

Pasadena: city; Los Angeles co., Cal. (for location, see map of California, ref. 12–F); on the Los Angeles Terminal and the Southern Pac. railways; 9 miles N. E. of Los Angeles. It is at the foot of the Sierra Madre Mountains, at an elevation of 850 feet above sea-level, and is in the beautiful San Gabriel valley, noted for its orange and lemon groves and the cultivation of smaller fruit. The city is largely a residential place, and its unsurpassed climate and attractive scenery have given it wide repute as a winter resort. There are 9 grammar schools, a high school, the Throop Polytechnic Institute, the only institution of its

kind on the Pacific coast, 2 private preparatory schools, several kindergartens and other private schools, a public library, 2 national banks with combined capital of $200,000, a State bank with capital of $50,000, and 2 daily and 1 weekly newspapers. The Mount Lowe Railway ascends the Sierra Madre Mountains here. Pop. (1880) 391; (1890) 4,882; (1900) 9,117.

EDITOR OF "EVENING STAR."

Pascagou'la River: a stream formed in Greene co., Miss., by the union of Chickasawha and Leaf rivers. It flows S. into Pascagoula Bay, a beautiful arm of the Mississippi Sound. The river sometimes floods its valley at high water. It is navigated by small steamboats. Much timber is cut in its pine forests for the New Orleans market.

Pascal', BLAISE: mathematician and moralist; b. at Clermont-Ferrand, Auvergne, France, June 19, 1623. He was a precocious child, and in 1631 his father removed to Paris the better to care for his education. At the age of twelve he rediscovered by himself elementary geometry, which he had not been allowed to study; at seventeen his treatise on *Conic Sections* made him celebrated; at nineteen he made a calculating-machine to aid his father, who had removed to Rouen to take an office in the treasury department. These mathematical studies he followed up with valuable investigations in physics, on the weight of the atmosphere. When little over twenty he came under the influence of the Jansenist writers of Port-Royal, and gave himself up to fervent piety; but the severity of his study had undermined his health; his physician forbade him all work, and recommended the diversions of society. For a time these diversions, in a group of rather gay epicureans, absorbed him; but the entrance of his sister into Port Royal, his narrow escape from death in an accident at the bridge of Neuilly, and other events, brought him back to his former religious fervor, and he retired to Port-Royal. Though he returned from time to time to mathematical studies, developing the calculus of probabilities, and giving a solution of the problem of the cycloid (*Traité général de la Roulette*, 1659), his main interest was henceforth fixed on questions of morals, philosophy, and religion. He spent his last years, broken in health and wracked with pain, in the practice of a severe asceticism. D. Aug. 19, 1662. His two great works are the *Lettres provinciales* and the *Pensées*. The former was written in defense of his friend, Antoine Arnauld, who, involved in the Jansenist controversy, was the central object of the Jesuits' attack on Port-Royal. The first four letters are limited to a defense of Arnauld on the points at issue; but the remaining fourteen are a vigorous and eloquent attack upon the moral and religious principles and practices of the Jesuits. The *Lettres provinciales* were intended to carry the cause before the bar of public opinion, and the qualities of style, grace and clear precision, incisive wit, delicate and biting irony, intense earnestness, rising to indignant eloquence, caught the popular attention. In them French prose revealed a new power, and they are of the first importance in the development of French prose style. In their first separate and fugitive appearance (1656–57), and in the collected edition prepared by Nicole, they had an immense circulation, and they have been reprinted in a vast number and variety of editions. The other great work of Pascal, the *Pensées*, consists of the fragmentary materials of a projected *Apologie de la religion catholique*, which his health did not allow him to finish: they are "thoughts," single reflections or aphorisms, often of remarkable depth, of a soul that felt keenly the intellectual difficulties, and at the same time the imperious need of a firm religious faith. The minor works of Pascal comprise a *Discours sur les passions de l'amour*, *L'Esprit géométrique*, *L'Art de persuader*, three *Discours sur la condition des grands*, *Prière pour demander le bon usage des maladies*, and a few letters. An excellent edition, with a *Life* and notes, is that of E. Havet (2 vols., Paris, 1882). Cf. Sainte-Beuve, *Port-Royal*, liv. iii. The best English translation of Pascal's *Thoughts* is by C. Kegan Paul (1885); latest translation of *Provincial Letters* 1889.

A. G. CANFIELD.

Pascal, JACQUELINE: See the Appendix.

Pas'chal I.: pope; b. at Rome; became abbot of St. Stephanus; succeeded Stephen IV. in 817; crowned Lothaire as emperor 823. D. Feb. 10, 824.—PASCHAL II. (*Raniero*), b. at Bleda, Italy, about 1050; was a Cluniac monk; became a cardinal-priest, and in 1099 succeeded Urban II.; was involved in life-long contests with the Henrys (IV. and V.) of Germany concerning investitures. Henry V. kept the pope in prison for some time. Similar troubles with Henry I. of England were settled by compromise, by which Henry kept the substance of his former rights, but made unimportant concessions to the pope, and like concessions were made by the King of France. D. Jan. 21, 1118.

Paschal I.: antipope; a Roman archdeacon; elected pope by a faction of the Roman people and supported by the exarch of Ravenna in 687 A. D. Theodorus II., antipope, was chosen by another faction, but Sergius I. was declared the true successor of Conon, the deceased pope. Paschal was imprisoned as a simonial and pronounced a magician. D. in 694.—PASCHAL III., antipope (*Guido di Crema*); b. in Lombardy; became in 1155 a cardinal-deacon, and in 1164 was declared pope by Frederick Barbarossa, whose partisan he was. D. at Rome, Sept. 20, 1168.

Pasco: See CERRO DE PASCO.

Pas-de-Calais, paa'de-kaa'lā': department of France, formed out of the provinces of Artois and Picardy; bordering N. and W. on the Strait of Dover and the English Channel; area, 2,551 sq. miles. A range of low hills, rich in coal, iron ore, marble, and slate, traverses the department, ending in Cape Gris-Nez, and forming for a distance of several miles along the coast a row of cliffs similar to those on the opposite English coast. On both sides of this range of hills the ground is low, with a very fertile soil, except along the coast, which generally is marshy or sandy. Its agriculture and manufactures are in a very advanced state. Wheat, hemp, and fruits are largely cultivated; iron-foundries, glass-works, tanneries, mills, and beetroot-sugar factories are in operation, and important fisheries along the coast are carried on, especially in the neighborhood of Boulogne. Pop. (1896) 906,249.

Revised by R. A. ROBERTS.

Pa'sha, Pa'cha, or **Ba'shaw** [from Turk. *bash*, head, or from Persian *pa*, foot + *shāh*, king, the foot of the king): an honorary Turkish title; originally given to princes of the blood, and afterward to persons honored with high official functions. The title is now, as a mark of favor, sometimes conferred on persons holding no office. Pashas are of three classes, the symbol of their rank being formerly one, two, or three horsetails, which were carried before them on state occasions. A district or province governed by a pasha is called a pashalik. The male members of the reigning house, with the exception of the sultan, are called effendi. E. A. G.

Pasht: See BUBASTIS.

Pasini, paa-see'neĕ, ALBERTO: genre-painter; b. at Busseto, near Parma, Italy, in 1820; pupil of Eugenio Ciceri, E. Isabey, and Théodore Rousseau; was awarded third-class medal, Paris Salon, 1859; second-class 1863; medal of honor, Paris Exposition, 1878; officer Legion of Honor 1878. His subjects are chiefly scenes in Turkey and other Oriental countries, and his pictures are notable for skillful painting and rich effects of color. His *Entrance to a Mosque* is in the Wolfe collection, Metropolitan Museum, New York. His studio is in Paris, but he spends much of his time in the East.

WILLIAM A. COFFIN.

Pasiph'aë (in Gr. Πασιφάη): in Grecian mythology, a daughter of Helius, wife of Minos, King of Crete. Minos, when seeking to become king, thought to strengthen his claim on the throne by the assertion that the gods would grant whatever request he might make. In proof thereof he prayed to Poseidon to send him a bull from the depths of the sea for the alleged purpose of sacrificing him to Poseidon. Poseidon sent the bull, and the astonished Cretans made Minos king, but Minos kept the miraculous bull, and in his stead offered in sacrifice to Poseidon a less magnificent animal from his own herd. Enraged at the perfidy of Minos, Poseidon made the bull insane and caused Queen Pasiphaë to fall desperately in love with him. With the help of Dædalus Pasiphaë succeeded in holding intercourse with the bull, and the result of this union was the MINOTAUR (*q. v.*).

J. R. S. STERRETT.

Pas'kevitch, IVAN FEDOROVITCH: field-marshal; Count of Erivan, Prince of Warsaw; b. at Poltava, Russia, May 19, 1782; was educated as a page at the court of Paul I. at St. Petersburg; entered the army in 1800; distinguished himself in the campaigns against Napoleon, and was made a general in 1814; conducted in 1826 the expedition against Persia, and took Erivan; commanded in 1829 a Russian army in Asia against the Turks, and captured Erzeroum; suppressed in 1831 the revolution in Poland, compelled Warsaw to capitulate, and was appointed viceroy. As such he governed with severity, but with justice; the principles

he held were detested by the Poles, but not the man. In 1849 he led the Russian armies into Hungary and quelled the revolution, and in 1854 he commanded the Russian army on the Danube against the Turks. This time, however, he met with nothing but defeat and repulses. He resigned and retired to Warsaw. D. at Warsaw, Feb. 1, 1856.

Paso del Norte: See El Paso, Texas.

Paso del Norte, now called *Ciudad Juarez*: See Juarez.

Paspatis, Alexander George, M. D., LL. D.: philologist and historian; b. in the island of Scio in the Ægean Sea, 1814. Seized during the massacre of 1822, he was sold as a slave at Smyrna. Set free by his purchaser, he was taken by a philanthropist to the U. S., and graduated at Amherst College in 1831. He studied medicine at the universities of Paris and Pisa (1834–39); practiced his profession at Constantinople (1840–78); then removing to Athens was professor in the university and president of the leading Athenian literary and philanthropic societies. D. Dec. 24, 1891. Well versed in sixteen languages, he published principally in English, French, and Greek. His chief publications are Ὑπόμνημα περὶ τοῦ Γραικικοῦ Νοσοκομείου τῶν Ἑπτὰ Πύργων (1862); *Études sur les Tchinghianés ou Bohémiens de l'Empire Ottoman* (1870); Βυζαντιναὶ Μελέται (1877); *The English Version of the Revised New Testament* (1882); Τὰ Βυζαντινὰ Ἀνάκτωρα καὶ τὰ πέριξ Αὐτῶν Ἱδρύματα (1885); Χιακὸν Γλωσσάριον (1888); Πολιορκία καὶ Ἅλωσις τῆς Κωνσταντινουπόλεως ὑπὸ τῶν Τούρκων (1890). He left unfinished, though almost complete, Τὸ Γλωσσάριον τῶν Ἑλληνικῶν Διαλέκτων and Ἡ Κατάκτησις τῆς Πελοποννήσου. E. A. Grosvenor.

Pasque Flower [i. e. Easter flower. See Passover]: a name given to a ranunculaceous herb of Europe and Asia (*Anemone pulsatilla*), and also to some other species of *Pulsatilla*. They are spring-blooming plants, with poisonous and medicinal qualities. See the article Anemone.

Pasquinade: an anonymous attack, of a witty or sarcastic character. The name is derived from a certain mutilated marble statue, or group, in Rome, placed at the corner of the Palazzo Braschi (the present ministry of the interior), upon which ever since the fifteenth century it has been the custom to paste such attacks. This torso, which really represents Menelaus with the body of Patroclus, looking for succor in the midst of the battle, is popularly called *Pasquino*, as it is said, from a certain cobbler (or tailor, according to Castelvetro) of the end of the fifteenth century, Antonio Pasquino by name, at whose shop, close by the present situation of the fragment, idlers used to gather and make jests on passers-by and on the events of the time. It was the custom to frame the so-called *pasquinate*, or *pasquinades*, in the form of questions or answers directed to another famous statue, called Marforio, situated in the Via di Marforio, opposite the Mamertine prison. This latter statue, a colossal river-god, probably the Rhine or Danube, is now placed in the middle of the court (*cortile*) on the ground floor of the Capitoline Museum. A. R. Marsh.

Passaglia, päas-säal'yäa, Carlo: theologian; b. near Lucca, Italy, Mar. 2, 1812; was educated in Rome, entered the Society of Jesus, and was appointed Professor of Theology in the Sapienza in Rome. He was considered one of the most learned theologians of Italy, and was very popular on account of the enthusiasm with which he embraced the liberal policy of Pius IX.; but in 1861 he had to flee in disguise from Rome, having published his *Pro causa Italica ad episcopos Italianos*, in which he declared that the temporal power of the pope was unnecessary, and exhorted Pius IX. to sacrifice his secular power for the unity of Italy. He was immediately appointed Professór of Moral Philosophy at the University of Turin, and continued his polemics against the pope in a series of brilliantly written pamphlets. In 1863 he was elected a member of the Italian parliament, and openly reproached the Government for cowardice on account of the continued occupation of Rome by the French. Among his works are a treatise on eternal punishment and a criticism of Renan's *Vie de Jésus*. D. in Turin, Mar. 14, 1887.

Passaic: city (formerly known as Acquackanonk); Passaic co., N. J.; on the Passaic river, and the Erie, the Del., Lack. and W., and Susquehanna railways; 5 miles S. E. of Paterson, the county-seat, 12 miles N. W. of New York city (for location, see map of New Jersey, ref. 2–E) It has gas and electric light plants, 3 electric street-railways, system of water-works supplied from above the Passaic falls, 4 miles distant, 24 churches, 6 public-school buildings, public-school property valued at over $120,000, free public library, a national bank with capital of $100,000, 3 incorporated banks, and 2 daily and 5 weekly newspapers. The industrial establishments include dye and print works, rubber-works, 2 woolen-factories, worsted-mill, satinet-mill, 2 bleacheries, 2 planing-mills, 2 brick-yards, extensive vineyards, large winery, and chemical-works. The city has a picturesque and healthful location, and contains the residences of many New York business men. Pop. (1880) 6,532; (1890) 13,028; (1900) 27,777. Editor of "News."

Passaic River: a stream which rises in Morris co., N. J., and after a tortuous course of 100 miles flows into Newark Bay, 3 miles from Newark. It is navigable for 13 miles. At Paterson it has a remarkable fall of 72 feet, affording a very valuable water-power.

Passamaquod'dy Bay: an inlet of the Atlantic Ocean, forming part of the boundary between Maine and New Brunswick. It abounds in good and deep harbors and in fine views. Picturesque islands are numerous and the fisheries are important. Its tides average 25 feet in rise. It receives the noble estuary of the St. Croix.

Passau, paa'sow: town of Bavaria; at the confluence of the Ilz, Inn, and Danube; 72 miles by rail S. E. of Ratisbon (see map of German Empire, ref. 6–G). It consists of three different parts, built on the wooded hills between the rivers and defended by two fortresses and eight detached forts. It has several fine buildings, breweries, distilleries, manufactures of tobacco, leather, porcelain, metal-ware and mirrors, and a considerable trade in iron, timber, wheat, and Passau crucibles. The town grew up round an ancient Roman camp, and in 739 was made the seat of a bishopric founded by St. Bonifacc. By the treaty signed here in 1552 by Charles V. and the allied Protestant princes religious liberty was conferred on the Protestants of Germany. The cathedral and a great part of the town were destroyed by fire in 1662. It was annexed to Bavaria in 1805. Pop. (1890) 16,633. Revised by R. A. Roberts.

Passavant', Johann David: art critic; b. at Frankfort-on-the-Main, Germany, Sept. 18, 1787; studied the art of painting in Paris and Rome, but devoted himself subsequently to the theoretical and critical treatment of the art, and became inspector of the Städel Museum in his native city, where he died Aug. 12, 1861. He wrote *Rafael von Urbino und sein Vater Giovanni Santo* (3 vols., 1839–58); *Die christliche Kunst in Spanien* (1853); *Le Peintre-Graveur* (6 vols., 1860–64).

Passavant, William Alfred, D. D.: philanthropist; b. of Huguenot ancestry at Zelienople, Butler co., Pa., Oct. 9, 1821; graduated at Jefferson College, Canonsburg, 1840, and at Lutheran Theological Seminary, Gettysburg, 1842; was pastor at Baltimore, Md., 1842–44, and at Pittsburg, Pa., 1844–55. After 1855 his life was devoted to the service of various benevolent institutions, founded by his instrumentality. He founded successively hospitals in Pittsburg (1849), Milwaukee (1864), Chicago, and Jacksonville, Ill., and orphanages at Zelienople and Rochester, Pa., and Mt. Vernon, N. Y., besides being closely identified with the beginning of the orphanages at Germantown, Pa., and Boston, Mass. With a layman, A. Louis Thiel, he founded in 1870 Thiel College, Greenville, Pa. In 1891 he established the Lutheran Theological Seminary in Chicago. For these institutions it is estimated that he secured during his lifetime over $1,000,000. He was the first to introduce the order of deaconesses into the U. S. He was editor of *The Missionary*, Pittsburg, from 1845 until, in 1861, it was united with *The Lutheran*, Philadelphia, of which he was for many years coeditor. In 1880 he founded at Pittsburg *The Workman*, which was still in his care at his death June 3, 1894. He was the founder of the Pittsburg Synod, and the great organizer of the missionary work in the Americanized portion of the Lutheran Church. He was one of the founders of the Emigrant House and Mission in New York, and of the General Council of the Lutheran Church in America. He had superior gifts as a preacher, but they were subordinated to his special calling as an organizer of Church work. H. E. Jacobs.

Passavant, William Alfred, Jr.: clergyman; b. at Pittsburg, Pa., Jan. 23, 1857; educated at Western University, Pittsburg, Muhlenberg College and Theological Seminary, Philadelphia; entered the ministry 1879; was pastor at Baden, Pa., and Pittsburg (East End). Editor of *The Work-*

man, with his father, 1881–86. In 1887 he became sole editor of *The Workman*, and in 1889 superintendent of English Home Missions of the General Council. Upon his father's death, in 1894, he succeeded him as director of benevolent institutions and editor. H. E. Jacobs.

Pass Christian: town; Harrison co., Miss. (for location, see map of Mississippi, ref. 9–H); on Mississippi Sound, and the Louisv. and Nashv. Railroad; 58 miles E. N. E. of New Orleans, 82 miles W. S. W. of Mobile. It is the largest health resort on the Gulf coast, and has a water frontage of 6 miles, along which is a broad shell-paved avenue lying under the shade of magnificent live-oaks and lofty magnolias. Projecting into the sound are numerous fishing and promenade piers, dotted with picturesque pagodas. The average winter temperature is 60° F., and the prevailing winter breezes are from the southward across the Gulf of Mexico. The town has four large hotels and many boarding-houses and tasteful cottages, and is in an agricultural and stock-raising region. Resident pop. (1890) 1,705; (1900) 2,028.

Passenger-pigeon: a wild pigeon (*Ectopistes migratorius*) of Central and Eastern North America, deriving its name from its long migrations in search of food. The body is about 8 inches in length, and the tail is the same length. The bird is slaty blue above, shaded with olive gray on the back and wings, pale-purplish chestnut below, changing into white on the belly, iridescent on the sides of the neck. It builds a flimsy nest in trees and bushes, and lays one white egg, sometimes two. The passenger-pigeon feeds on various seeds, but is specially fond of acorns, beech-nuts, and rice. It is gregarious and formerly occurred in vast flocks, sometimes numbering millions. Owing to continued persecution on its breeding-grounds, where thousands were taken in nets, these enormous flocks are no longer found, and in the greater part of its natural habitat the bird has been practically exterminated. F. A. Lucas.

Passerat, pȧs'raa', Jean: Latinist and poet; b. at Troyes, France, in 1534. He led a rather unsettled life till 1569, when he went to Paris and found a protector in Henri de Mesme. He succeeded Ramus at the Collège de France, where he attracted many pupils. He wrote commentaries on Catullus, Tibullus, and Propertius, composed epigrams in Latin and French, and poems distinguished by alert grace, gay wit, and *esprit gaulois*, and was one of the chief authors of the *Satire Ménippée*, a satire on the Ligue. D. Sept. 12, 1602. His works were edited by P. Blanchemain (Paris, 1881). A. G. Canfield.

Pas'seres [Mod. Lat. (plur.), from Lat. *passer*, a typical perching bird]: name applied to a group of birds containing the typical song-birds, or perching birds, variously considered as an order, sub-order, or even as of lower value. Besides other technical characters, they have an ægithognathus palate, the deep plantar tendons free, manubrium Y-shaped, and tarsus with four to six tendinal perforations. There are, except in one genus, four toes, on the same level, and the fourth is never turned backward. The group includes something like 5,000 species, and is the equivalent of Huxley's *Coracomorphæ*; it comprises the Clamatores and Oscines (*q. v.*), and corresponds pretty nearly to the Insessores of other authors. F. A. Lucas.

Passion-flower: a name in its widest sense applicable to nearly all the species of *Passiflora*, the principal genus and type of the family *Passifloraceæ*, mostly climbing plants of tropical America, and a few other ornamental species in common cultivation. The name is derived from the fancied resemblance of the various parts of the flower to the means of our Lord's passion and death; the nails, the crown of thorns, the five wounds, and even the hammer and the cross itself, having been identified in the blossom. There are nearly 150 species of true passion-flower. Some of these bear edible fruits (called *granadilla*); many have active medicinal powers, and many others are cultivated in greenhouses for their beautiful flowers. Of these the best-known is the *Passiflora cærulea*, a native of Brazil. The U. S. has about ten native species, of which *P. incarnata* is showy, and the best known. Its fruit, called May-pop, is eaten in the Southern States. Revised by L. H. Bailey.

Passion-flower Family: the *Passifloraceæ*, a small group (250 species) of dicotyledonous trees, shrubs, and herbs, natives for the most part of tropical and sub-tropical regions, especially of the New World. The flowers, which are usually showy, have a superior compound ovary, three-lobed style, five stamens, five petals, and five sepals, the perianth segments often being united (gamosepalous or gamopetalous). Many species of the principal genus, *Passiflora*, are climbers, and are grown for ornamental purposes. Their beautiful flowers have a remarkable structure; the shallow calyx-tube bears the petals and a "crown" consisting of several concentric series of colored filaments, surrounding a columnar extension of the receptacle on which are borne first the stamens, and still higher the ovary with its three spreading styles. Charles E. Bessey.

Passionists, Congregation of the: a religious congregation in the Roman Catholic Church, founded at Ovado, Piedmont, in 1720 by Paul of the Cross (1694–1775). It was confirmed by Benedict XIV. in 1741 and 1746, and by Pius VI. in 1775. A congregation of women was added before the founder's death. The Passionists are numerous in the U. S. and Europe. They practice many austerities, and devote themselves to local missions and the work of preaching. The mother-house is on the Celian Hill in Rome. See *History of Religious Orders*, by Rev. C. W. Currier (1894), p. 463. Revised by J. J. Keane.

Passion-plays: See Miracle-plays and Ober Ammergau.

Passion-tide: a name given to the last two weeks of Lent, the first week of which is Passion Week and the last Holy Week (*q. v.*); but popularly, Holy Week is called Passion Week also.

Passive State (or **Passivity**) **of Metals**: terms applied by chemists to certain phenomena having a very wide range, and as yet very inadequately investigated, which do not all seem likely to be referred ultimately to the same cause. It is found that a number of the metals which are acted on and dissolved with energy by certain acids and other chemical solvents may under special circumstances become what is called "passive," the action of the acid or other agent being totally suspended, and the metal remaining immersed therein often with a clean, brilliant metallic surface, and having lost entirely the power to decompose the liquid. Strong nitric acid is the solvent that has been best investigated in this relation, though many other agents behave similarly. Keir first observed the phenomenon in the case of iron immersed in strong nitric acid and solution of nitrate of silver, and Schönbein, Faraday, and Herschel have been among its most distinguished investigators. Iron is made passive toward nitric acid of density = 1·2 to 1·35 by a number of different methods. A wire heated at one end till enfilmed with black ferroso-ferric oxide becomes passive, not only where heated, but for a certain distance beyond, showing that it is not the film which merely protects mechanically. If first dipped in fuming nitric acid or in a mixture of weaker acid with oil of vitriol, it becomes passive toward the weaker acid itself. Contact of an iron wire which is being powerfully acted on with another wire in the passive state, or with a platinum or gold wire, will often instantly transform the first wire to the passive condition. An iron wire which is made the positive pole of a voltaic circuit, the negative pole being platinum, becomes passive, and remains so when the current ceases. All the phenomena of passivity are usually referred to voltaic action, but it is as yet doubtful whether they are all of this nature; and it must be stated that little or no progress has yet been made toward a clear understanding of their causes. Revised by Ira Remsen.

Passover [transl. of Heb. *pesach*, passover, Easter (liter., a passing over, deriv. of *pāsach*, pass over), whence Gr. πάσχα, whence Lat. *pas'cha*, whence O. Eng. *pascha* > Eng. *pasch*; cf. *paschal*]: the first and the greatest of the three annual festivals of the Jews; instituted by Moses in commemoration of the deliverance of the Israelites from Egyptian bondage, and celebrated from the 15th to the 21st day of Nisan, both inclusive, thus falling between our March and April, at the time of the first full moon in the spring. The first and the last day of the festival were kept holy and observed by abstaining from all work, by prayers, hymns, thanksgivings, and other ceremonies, and during the whole period the bread was eaten without leaven, whence the name of the Feast of Unleavened Bread. On the evening of the 14th the Passover lamb was killed by the head of the family. The animal should be one year old, male, without blemish, and it should be roasted entire, with unbroken bones, and consumed entirely in one meal. The blood was sprinkled on the doorsill in commemoration of the night preceding the exodus from Egypt, when the angel went through the country and slew all the first-born, but passed

over the houses of the Israelites. The fat pieces were burned on the altar as a sacrifice, and the family, clad in traveling garb, gathered to partake of the roasted lamb, with prayers and hymns. On account of some uncertainty with respect to the fixing of the new moon by the Sanhedrin at Jerusalem, the Jews who lived in foreign countries in "exile" were ordered to celebrate all their festivals on two successive days—a law which is still in force among the orthodox. At present, however, the Passover feast has generally simply the character of a hallowed family feast among the Jews; but as the death and resurrection of Christ coincided with the celebration of the Passover, many of the symbols, commemorations, and ceremonies of this Jewish festival passed into the Christian Easter feast, receiving a broader and more ideal signification. For an interesting account of the Samaritan Passover, still observed on Mt. Gerizim, see John Mills's *Three Months' Residence at Nablus* (1864). For modern Jewish practice, see Edersheim, *Home and Synagogue of the Modern Jew*, and Bodenschatz, *Kirchliche Verfassung der Juden*. Revised by S. M. Jackson.

Pas'sow, Franz Ludwig Karl Friedrich: philologist; b. at Ludwigslust, Germany, Sept. 20, 1786; was educated at Gotha and Leipzig; became in 1807 Greek professor at Weimar; was 1810–14 director of the Conradinum at Jenkau near Dantzic; became in 1815 Professor of Ancient Literature in the University of Breslau; in 1829 became also director of the academic museum of art. D. at Breslau, Mar. 11, 1833. He published texts and translations of *Persius* (1809); *Musæus* (1810); *Longus* (1811); author of *Turnziel* (Breslau, 1818); an admirable Greek-German lexicon (Leipzig, 1819–24; 4th ed. 1831); *Grundzüge der griechischen und römischen Literatur und Kuntsgeschichte* (Berlin, 1816; 2d ed. 1829); and *Opuscula Academica* (edited by Bach, Leipzig, 1835). See Wachler, *Passows Leben und Briefe* (Breslau, 1839).

Pas'ta, Giuditta Nigri: opera-singer; b. at Saronno, near Milan, Italy, Apr. 9, 1798, of Jewish parentage; received her musical education in the Conservatory of Milan; made her *début* as a singer in 1815 on the minor stages of Leghorn and Parma; sang in 1816 in Paris and London without producing any great impression; returned to Italy and appeared with better success in Venice and Milan in 1819. Her great career began at Verona during the congress of 1822. In the following years she sang with great success in Paris and London, and subsequently in Naples, where Pacini wrote his *Niobe* for her, and in Milan, where Bellini composed his *Norma* and *La Sonnambula* for her. Her last engagement was at St. Petersburg in 1840. D. at her villa on Lake Como, Apr. 1, 1865. Revised by B. B. Vallentine.

Pas'tel [= Fr. from Ital. *pastello*, liter., a small loaf, pastry, dimin. of *pasto*, food < Lat. *pas'tus*, deriv. of *pas'cere*, *pastum*, feed]: a colored crayon made of pipeclay or other opaque material mixed with gum-water and some pigment. Pastel pictures are executed on roughened paper and parchment, and the color is generally worked on with the finger. This kind of picture has to be protected by glass, as every touch mars the surface.

Pasteur', Louis, D. Sc.: chemist and biologist; b. at Dôle, department of Jura, France, Dec. 27, 1822; studied physical sciences, especially chemistry, graduating D. Sc. from the École Normale in 1847, and was appointed professor in 1848 at Dijon, in 1849 at Strassburg, in 1854 at Lille, in 1857 at Paris, where he was director of the École Normale; in 1863 Professor of Geology, Physics, and Chemistry at the École des Beaux-Arts, and in 1867 Professor of Chemistry at the Sorbonne. Besides a number of essays in *Annales de Chimie*, he wrote *Nouvel Exemple de Fermentation* (1863); *Études sur le Vin* (1866); *Études sur le Vinaigre* (1868); *Études sur la Maladie des Vers de Soie* (1870); *Les Microbes* (1878). Several of his chemical works received prizes, and in 1874 the French Government gave him a pension, increasing it the following year, in consideration of his services to science and industry. In 1884 he laid before the Institute a method of curing or preventing Hydrophobia (*q. v.*) by inoculating with the poisonous virus in an attenuated form, and the commission of investigation declared the method efficacious. (See *Louis Pusteur; his Life and Labors*, 1885.) The Pasteur Institute, at Paris, was formally opened Nov. 14, 1888, in the presence of President Carnot and other distinguished persons. Pasteur was a member of many foreign and domestic scientific societies, and had been decorated by most of the European governments. D. Sept. 28, 1895. Revised by S. T. Armstrong.

Pasteurized Milk: See Milk.

Pas'to: a town in the southern part of the department of Cauca, Colombia; on a high plateau at the foot of the volcano of Pasto; about 50 miles from the boundary of Ecuador; 8,650 feet above sea-level (see map of South America, ref. 3–B). Pop. about 10,000. It is one of the oldest towns of the republic (founded 1539), is beautifully situated, has a healthful and cool climate, and is the center of a wheat-growing and grazing district; there is an active trade with Ecuador. Pasto is a bishop's see. It was an important Spanish stronghold during the war for independence. In 1834 it was destroyed by an earthquake. The volcano of Pasto, or La Galera, is the culminating point (13,990 feet) of the "knot" whence the three cordilleras of the Colombian Andes diverge. It is frequently in eruption. H. H. S.

Pastor [Mod. Lat., from Lat. *pas'tor*, herdsman, shepherd, deriv. of *pas'cere*, *pas'tum*, feed, pasture]: a genus of starlings, having representatives in Europe and the Old World tropical regions. They are extremely useful as destroyers of insects, but sometimes are destructive to small fruits. *P. roseus*, the rose-colored pastor of Europe, is a handsome bird, a good singer, and a favorite cage-bird.

The rose-colored pastor.

Pastoral Poetry: poetry which affects the matter or manner of rustic life, not for the purposes of accurate, even though sympathetic, description, but as a purely artistic device for conveying the interests and emotions of the poet himself, and of the society, not rural, in which he lives. The pastoral forms are many—idyls, eclogues, plays, or romances, in which the leading *rôles* are given to shepherds, shepherdesses, or other country folk, all bearing this generic name. Contradictory though it appear at first sight, the pastoral has historically been one of the most elaborate and artificial of all literary varieties, and has generally been produced only in societies that had reached an advanced stage of refinement. This by no means implies, however, as has sometimes been said, that it is the natural expression of luxurious and corrupt manners and morals, or that it always indicates in both poet and audience the lassitude and the disenchantment with real life which mark culture over-ripe and turning to decay.

The beginning of the pastoral, as we know it, is to be found in the *Idyls* of Theocritus (*q. v.*), who seems indeed to have been himself the literary inventor of it. Not that he had not, probably, much upon which to base the new form. There is a tradition from his own time that bucolic songs in dialogue had a religious origin, and were connected either with the cult of Artemis (cf. the ancient note *περὶ τῆς εὑρέσεως τῶν βουκολικῶν* given in the editions of the poet) or with the sorrows of Daphnis (cf. Ælian, *Var. Hist.*, x., 18). That there is some truth in this is made more probable by the fact that the famous Indian pastoral-drama the *Gîta-govinda* of Jayadeva deals with a religious theme—the love of Krishna, in guise of a shepherd, for the fair shepherdess Râdhâ. None the less, Theocritus has the honor of having first seen the literary possibilities of the *genre*, and, above all, of having used pastoral dialogue as a veil for his own sentiments and those of other real persons in the refined society in which he lived. This was the one original invention of the Alexandrian period of Greek literature, and it deservedly proved an immense success.

The Greek followers of Theocritus are not many nor very

important. The best known are Bion and Moschus, poets of the same school; and Longus (*q. v.*), whose date is uncertain, but whose *Daphnis and Chloë*, a prose romance, represents a stage of development of the pastoral removed by centuries from its origin. Far more important for literary history is the fact that the pastoral was taken up by Roman writers, and thus acclimated in Western Europe. Vergil seems to have been the first to write Latin idyls (*eclogæ*, as he called them), and he remains the chief pastoral poet of Rome. The pastoral idea, however, already began to transcend the narrow limits of the idyl proper, and to appear in various guises. Horace, Catullus, and Tibullus all show the influence of it; and toward the end of the empire, as in Ausonius and Claudian, it is a permanent motive in poetry. Even in the Latin poetry of the Middle Ages it is to be found, as in the work of Alcuin and other writers of Charlemagne's court.

In the twelfth and thirteenth centuries, a new and apparently independent stream added itself to the current of the classic pastoral tradition. This was the period when the courtly and chivalric poetry, both lyric and narrative, of the Middle Ages fully effloresced; and among the numerous poetic forms then invented and widely used appears the pastoral lyric, called in French *pastourelle*, in Provençal *pastoreta* or *pastorela*. Similar forms are to be found in almost all the Romance literatures of the time, and it is very difficult to say whether they reproduce with some exactness veritable popular songs, or are really, as they seem to be, completely artificial in character. At any rate, there can be no doubt of their wide popularity.

It was in Italy that the fusion was to come between these pastorals and the older classical ones, and it was in Italy, also, that the great extension of the pastoral to romances and dramas, as well as idyls, was to take place. The first notable examples of imitation of the classic idyl by Italians are the *eclogæ* that have come down to us, purporting to have passed between Dante and a certain Giovanni del Virgilio, teacher of grammar at Bologna. Whether the attribution be just or not, there is no doubt that these date from the first quarter of the fourteenth century. As was to be expected, the humanistic revival of classical studies that begins with Petrarch greatly helped the spread of the eclogue. The twelve poems of Petrarch's own *Carmen bucolicum* are the beginning of a long series of imitations, many of them remarkably beautiful, of the pastoral manner of Vergil. In Boccaccio, the friend and coadjutor of Petrarch in humanism, but in whom the mediæval poet and story-teller was much stronger, we have the beginning of the amplification of the pastoral, of which mention has been made. Naturally, he tried his hand, though with poor success, at the Latin eclogue (in his *Bucolicon*); but in his Italian pastorals, both in prose and in verse, we have an important addition to the imaginative forms of European literature. These pastorals are all of them directly or indirectly connected with Boccaccio's life at Naples and his love for Maria, natural daughter of King Robert ("Fiammetta"). The circumstances of this passion made it all the more natural for the poet to veil his account of it in pastoral allegory, as he does in his prose *Fiammetta* and *Ninfale d'Ameto* (the latter interspersed with songs), and his *Ninfale fiesolano* in *ottava rima*.

The example of Boccaccio proved fruitful. As the Renaissance advanced, as the knowledge of first the Latin then the Greek classics extended itself, Italian poets and romancers inclined more and more to strive for an ideal beauty remote from the uglinesses of real life, such as could be found only in the idyllic world of Theocritus, Vergil, and Longus. There is no stranger or more interesting phenomenon in the history of human culture than this growth in the fifteenth and sixteenth centuries of the dream of a primitive and unspoiled time, an Arcadia—a golden, Saturnian age, as Vergil had called it. Imaginations turned eagerly to those classics that were thought to have depicted such a world; and it is deeply significant that of all the Greek poets, Theocritus should have been the first to be printed (1481). It will be impossible here to mention even a tithe of the works, whether in Latin or Italian, that belong to this tendency. We can dwell in passing only on those that mark the perfection of the chief pastoral forms. Of these, two in particular, the romance and the drama, had a remarkable vogue both in and out of Italy.

The pure pastoral romance may be said to have reached its final stage in the *Arcadia* of the Neapolitan Sannazaro (1453–1530). Written in alternate prose and verse, this work contains within itself all the elements that had been tending to unite themselves in one artistic whole. Everywhere in it appear reminiscences of the classics, everywhere idyllic dreams. The influence of Boccaccio is strong, love of nature and of the rustic life of the fair country about Naples gives romantic charm, and finally the poet has known how to make the whole alive with a certain veiled, but none the less certainly personal, feeling. It is no wonder that the *Arcadia* swiftly made its way throughout Europe, and initiated a new style in all the chief literatures.

The rise of the pastoral drama was somewhat later than that of the romance. Apparently its origin is to be sought in the amœbæic recitation of Latin and Italian eclogues of which we hear in the fifteenth century. The Italian drama, as a whole, however, did not till this time free itself from its religious associations; and it is interesting to find that the first wholly secular play, Politian's *Orfeo* (recited at Mantua in July, 1471), is to all intents and purposes a pastoral. Through the sixteenth century we can follow the series of dramatic eclogues and pastoral dramas until at the end we have those ultimate specimens of the *genre*—Tasso's *Aminta* (written in 1573) and Guarini's *Pastor Fido* (1st ed. 1590).

During the sixteenth century all Europe was feeling the influence of the Italian Renaissance, and it is not surprising to find that the pastoral in all its forms was speedily imitated in every cultivated literature. We see this first perhaps in the Spanish Peninsula, where very early in the century we find Juan de la Encina and his school writing pastoral plays, *eglogas* as they call them. A little later the Portuguese Christóvam Falcão and Bernardim Ribeiro give great popularity both to the eclogue proper and to the pastoral romance; and soon their countryman Montemayor, though he wrote in Spanish, produced in his *Diana Enamorada* a pastoral tale that speedily became known all over the Continent. From this on the literature of the Spanish *Siglo de Oro* is filled with the Arcadian ideal and its pastoral expression.

In France much the same thing happened, though not so early or so completely as in Spain and Portugal. Perhaps the more purely French allegorism of the Middle Ages—that of the *Roman de la Rose*, for example—which had by no means died out even in Marot's time, prevented somewhat the acceptance of the pastoral allegory. Still the Pléiade began to devote itself somewhat to the cultivation of the latter, and in the *Bergeries* of Remi Belleau (1565–72) we have direct imitation of Sannazaro's *Arcadia*. Amyot's translation of the *Daphnis and Chloë* of Longus (1559) also did much to diffuse a taste for the pastoral romance. The results of these influences appear later in the great series of romances, half pastoral, half chivalrous, initiated by the *Astrée* of Honoré d'Urfé (1567–1625). They appear also still later in the well-known masquerading of the regency and the reign of Louis XV., and in the paintings of Watteau.

England, even more completely than France, made welcome the pastoral motive. During the sixteenth century, as is well known, both Italian and Spanish books were eagerly read in England; and Sir Philip Sidney, in his *Arcadia*, shows familiarity not only with Sannazaro, but also with Montemayor and Ribeiro, to say nothing of the French. So deeply was the fancy of the English touched by the Arcadian ideal that it became a permanent element in the work of almost all the great Elizabethans. We can mention only by way of illustration Spenser's *Shepherd's Calendar*, Shakspeare's *As You Like It*, Fletcher's *Faithful Shepherdess*, and the *Masques* of Ben Jonson and his group. Milton still felt deeply the charm of the pastoral form, as his *Comus* and *Lycidas* show. It had not wholly evaporated in the early eighteenth century, as is proved by Shenstone's *Pastoral Ballads*; and even Allan Ramsay's *Gentle Shepherd* (1725), which initiates the true English description of nature and rural life as they really are, is not without reminiscences of an earlier pastoral time when poets dreamed of rustic loves and joys rather than inquired into them.

And now finally we must speak briefly of the diffusion of the pastoral in Germany. Here it was from France, rather than directly from Italy, that the form made its appearance. The *Hercynia* of Opitz, published in 1622, is mentioned as the first veritable example; and this was inspired by d'Urfé and by that insignificant work, *Les Bergeries*, of Racan. Throughout the seventeenth and early eighteenth centuries the German pastoral flourished wondrously, though with

the charm mostly lost and the allegory terribly exaggerated. Not till 1754 did what may be called a classical work appear—Gessner's *Daphnis*, followed two years later by his famous *Idyllen*. The fame of these echoed even beyond the limits of Germany, and within those limits they had many imitators. Two great examples of the form must further be mentioned, though in both the invading realism of the nineteenth century makes itself harmfully felt. These are the *Luise* of Johann Heinrich Voss, published in 1795, and the better-known poem which it inspired, Goethe's *Hermann und Dorothea*, published in 1797.

The nineteenth century has not tolerated the pastoral. Here and there a poet has given something of idyllic charm to his description of country scenes; here and there a novelist in revolt against convention has sought relief in an impossible rustic world (e. g. George Sand in *La Mare au Diable* and other novels); but the day of the old gracious pastoral dream is for the mass of writers and of men past.

There exists as yet no general work on the history of the pastoral. A. R. Marsh.

Patago'nia [from Span. *patagón*, a large foot, in allusion to gigantic footprints said to have been found by the first discoverers]: a name originally applied to all the southern part of South America, with a vague limit northward, about lat. 38°, or 39° S.; it is still used for convenience, but is generally restricted to the portion E. of the Andes and S. of the Rio Negro, forming the Argentine territories of Neuquen, Rio Negro, Chubut, and Santa Cruz (*qq. v.*), with a small strip at the southern end belonging to Chili. Generally speaking, the surface of this region consists of plateaus which form a series of terraces from the eastern slope of the Andes to the sea; much of the soil is arid, composed of sand, shingle, or bowlders, and impregnated with salts; but portions are suitable for grazing, and some of the valleys of the Andes and near the coast are well adapted for wheat-growing. The climate is dry, and during the summer months (November to April) warm, but subject to violent winds; the winters, especially in the southern part, are cold and are ushered in by storms. Settlements are rapidly springing up near the coast; the interior is inhabited only by wandering Indians, now greatly reduced in number. These Indians are of several tribes, classed together as Patagonians, but called Tehuelches or Southern People by the Araucanians; they are unusually tall (many of the men being over 6 feet in height), but the descriptions of giants given by old explorers were probably exaggerated. They number about 20,000, and most of them are now more or less friendly to the whites. Patagonia, as originally defined (including the narrow strip W. of the Andes), was practically abandoned to the Indians until about 1860. It was nominally attached to the viceroyalty of La Plata or Buenos Ayres, and the whole of it was claimed, after the revolution, by the Argentine Confederation. The Chilian settlements, as they were extended southward, encroached on the western slope, and gave rise to many disputes. In 1881 all the strip W. of the summits of the Andes, together with the borders of the strait of Magellan, was definitely given up to Chili; it now constitutes the province of Llanquihue and the territory of Magallanes; area, 83,115 sq. miles, and an estimated population of about 85,000. The other portion, which is now incorporated into Argentina, and is divided into five territories, has an area of 268,000 sq. miles and a population of about 100,000. See Darwin's *Voyage of a Naturalist*; Lady Florence Dixie, *Across Patagonia* (1880); Fontana, *Exploración en la Patagonia Austral* (in *Boletin del Instituto geográfico Argentino*, 1886), and many recent papers in the same bulletins; also, Hudson, *Idle Days in Patagonia* (1893).
Herbert H. Smith.

Pataps'co River: a stream which rises in Carroll co., Md.; flows 80 miles S. and S. E., and enters Chesapeake Bay by a fine estuary, on which stands Baltimore. In its upper course it is very rapid, affording much water-power. Its estuary admits first-class ships.

Patchogue, pa-chōg': village (incorporated in 1893); Suffolk co., N. Y. (for location, see map of New York, ref. 8–D); on the Long Island Railroad; 53 miles E. of New York city; near Blue Point, on Great South Bay. It is the chief harbor for the fishing and oyster boats of the bay, has a beautiful lake at each extremity, and is one of the most popular places of resort on the Long Island coast. There are several hotels and boarding-houses, good dock facilities, a union free school, 5 churches, a State bank with capital of $75,000, and 2 weekly newspapers. The industries comprise fishing and oystering, and the manufacture of lace, paper, and brass goods. Pop. (1900) 2,926. John M. Price.

Patchou'li, or **Patchouly** [= Fr., from East Indian name]: an odoriferous labiate plant (*Pogostemon patchouli*) of Southern Asia. It is extensively used in perfumery and against the ravages of clothes-moths. India ink and India shawls derive their peculiar odor from this plant. The Orientals use it for stuffing mattresses and to ward off contagion and vermin. They also mix it with tobacco for smoking. It grows to a height of 2 or 3 feet, bears spikes of densely whorled small flowers, and ovate leaves 2 or 3 inches long.

Patel'la, or **Knee-pan** [*patella* = Lat. kneepan, liter., a small pan, dimin. of *pa'tena*, pan, dish, deriv. of *pate're*, lie or spread open]: a probably sesamoid bone found in the tendon of the quadriceps extensor muscle of the thigh, just anterior to the knee-joint. It develops from one or two centers. It does not begin to form until the child is from three to six years of age.

Patents [deriv. of *patent* in *letters patent*, i. e. letters open to the perusal of all, from Lat. *pa'tens*, pres. partic. of *pate're*, lie open]: letters issued by a government granting to inventors the exclusive use of their inventions for definite periods.

I. *Their History.*—The practice of thus inciting inventors to improvements in arts and industries is of remote origin. So far as concerns modern jurisprudence, however, it was first adopted by the English, and the common law gave to the king the power of granting such privileges; but this power was abused, and patents were granted not only to projectors who deserved them, but to favorites and venal speculators, who thus obtained monopolies of the traffic in many of the necessaries of life and not a few of its conveniences, the right to which had existed in the public from time immemorial. The term *patent* was thus early applied indiscriminately to the rightful privileges by which inventors were rewarded for creating new and valuable improvements which had never belonged to the people, because they had never before existed, and to the wrongful monopolies, like those for the sale of salt, currants, vinegar, potash, pilchards, and many other articles, the right to traffic in which had always and undeniably belonged to the public. It was the latter class of patents, the wrongful monopolies, that constituted the inciting cause of the Great Revolution. And the same enactment, the famous Statute of Monopolies, that swept away the arbitrary and unconstitutional power of the British kings excepted from its operation the patents granted to inventors. As this statute did not establish, but confirmed, the practice of thus encouraging improvements in the useful arts, such practice may be traced unbroken from the complex systems of statute jurisprudence and equity practice of fifty-eight nationalities, states, and colonies to-day back to the time when Edward III. issued the first recorded patent to "two friars and two aldermen" for an alleged discovery of the philosopher's stone; but the separation of patents for new inventions, rightfully granted to those who added to the wealth of their country by increasing its industrial resources, from the wrongful monopolies that crushed the people was a matter of slow growth. It may be said to have taken first positive and decided form in a hot debate in Parliament on Nov. 20, 1601, in the reign of Elizabeth, and it ended only with the dethronement of the Stuarts; but the Statute of Monopolies in 1623 (21 James I.), although it did not end the struggle, defined and made clear the principles of the common law. For by this last "the crown, as the patron of science and art and guardian of the common weal, had power to grant many privileges," even "although, *primâ facie*, as it was said, they appear to be against the common right; the *consideration* was the invention of a new manufacture or the introduction of a new trade; the grant could only be by charter or letters patent, and the term of privilege was to be reasonable." (See *Coryton on Patents*, p. 27.) The earliest form of these privileges was that of "conducting exclusively *new* trades, or dealing in objects of commerce *hitherto unknown*, as a *reward* and *encouragement* to parties introducing them." The common-law granting of patents has, it may be remarked, an apt illustration in the Scottish practice, for in Scotland, up to 1852, patents were issued to inventors in the total absence of a statute on the subject.

The earlier patents were based upon the condition that the invention be *worked* within the realm, this *working* being the consideration paid by the patentee for the protec-

tion afforded. In some cases a tax or a portion of the profits was paid to the crown—the former still a feature of the British patent laws, from which it has passed to those of France and Belgium; but the secret of the invention was not required to be revealed until after the expiration of the patent. From this it resulted that the inventor frequently succeeded in keeping his invention from the public even after the expiration of the term, and hence the *making known* of the invention became, subsequently, an essential part of the consideration for which the patent was issued. To this end it was at a very early date required as a preliminary to the issue of a patent that the inventor should place on record a description of his invention so "full, clear, and exact" that any one skilled in the art could proceed to put it in practice, and so definite in its statements as clearly to distinguish between what is new and what is old. The development of the patent law has been coincident with that development of the industries which has been due for the most part to the law itself. The earliest triumphs of modern invention, Watt's steam-engine, Arkwright's spinning-machinery. Cort's puddling process, Dudley iron manufacture, furnished in the litigation of the patents thereon the established precedents upon which the decisions of courts in patent cases all over the world are based. Previous to 1852 the British patent law related only to England. Scotland, as previously remarked, granted patents under the common law; Ireland had a separate patent law so costly and imperfect that many British inventors lost their inventions in the latter island before they could patent them there. In 1852 this was remedied by the law still in force, which embraces in one patent "England, Scotland, Ireland, the principality of Wales, the Isle of Man, and Berwick-upon-Tweed." The British patent law has from the beginning placed the introducer of a new improvement on the same footing as an original inventor. It requires no preliminary examination to determine the question of novelty, and declares a patent invalid if the invention has been previously publicly known in the realm. Prior to the Patents, Designs, and Trade-marks Act of 1883 the initial expense of obtaining a British patent was onerous, but this has been practically reduced to one-third of the former expense by the act just mentioned. Renewal fees, payable before the expiration of the fourth year of the term of the patent, and annually thereafter, are required to keep the patent alive. In lieu of these the renewal fees may be paid in two lump sums, one before the end of the fourth and the other before the end of the eighth year of the term, at the option of the patentee.

The patent system of Great Britain was the parent stem from which all others have sprung. In 1641 the general court of Massachusetts granted a ten years' patent to Samuel Winslow for a process of making salt. In 1672 the printed statutes of Connecticut provided that "there shall be no monopolies granted among us but of such new inventions as shall be judged profitable and for the benefit of the country, and for such time as the general court shall judge meet." Massachusetts and Connecticut were pioneers in transplanting the British system, although similar examples are found in the other colonies (or States) up to the time when the first U. S. patent law, the act of 1790, came into force.

The statute of 1790 provided for the granting of letters patent on "any useful art, manufacture, engine, machine, or device, or any improvement therein, not before known or used." The petition for the grant was to the Secretary of State, the Secretary of War, and the Attorney-General. The patent was issued on the approval of these officials or any two of them. The description of the invention was certified by the Attorney-General, and the President caused the great seal of the U. S. to be affixed on the issue of the patent. The term of the patent was for "any term not exceeding fourteen years" in the discretion of the aforenamed members of the cabinet. Although discretionary power was vested in these last, no preliminary examination to determine actual patentability was, in practice, instituted by the act. Provision was duly made for punishing infringers, the English idea of patentable novelty substantially adopted, and a schedule of Government fees, that, exclusive of 10 cents per 100 words for copying specification on filing same, amounted to $3.70. A patent could be issued "to any person," no distinction between citizens and foreigners being made. In 1793 a new statute was passed, repealing that of 1790, although retaining much of its substance. This act of 1793 restricted the grant of patents to citizens of the U. S.; provided that the petition should be to the Secretary of State; that owners of patents from any State should be incapable of holding a patent from the U. S. except on condition of relinquishing the State patent; that interfering applications should be decided by arbitrators; that patents obtained "surreptitiously or upon false suggestion" could be declared void on motion made and proof produced before the U. S. district court of the district wherein the patentee resided, if made within three years from the date of the patent, but not afterward; and provided further that the Government fee paid by applicant for a patent be $30. This act of 1793 also provided that infringers should pay at least triple damages to the patentee. In 1794 a supplement permitted parties to suits set aside, suspended, or abated by the act of 1793 to revive them. During the following forty years various amendments were made to the patent laws, and in 1833 all previous statutes on this subject were repealed. The act of 1833, while retaining many features of the old law, introduced many changes. It attached to the department of state "an office to be denominated the Patent Office, the chief officer of which shall be called the commissioner of patents." This law was the first to institute the system of preliminary examinations to determine the patentability of inventions before issue of patents thereon, and from the single examiner appointed under it has come the immense staff of examiners and the complicated system of examinations, appeals, etc., that now obtains; and which, while undoubtedly productive of much good, has just as undoubtedly been the means of robbing many a poor inventor of the rights that belonged to him in justice, equity, and law. This statute provided a board of appeal, to which appeal could be had from adverse decisions of the examiner and commissioner. Aliens resident in the U. S. for one year, and who had made declaration of intention to become citizens, were allowed to take out patents for the same fees as citizens; but for a subject of the King of Great Britain, the fee was $500, and for all other foreigners $300. This law provided also for the filing of caveats on partially perfected inventions, confirmed the right of reissue, fixed the standard of damages in infringement cases at the actual damages, except where exemplary damages were held by the court to be warranted, and in such cases limited the award to three times the actual damage; and placed the power of extending patents for an additional term of seven years after the expiration of the original fourteen in the hands of a board composed of the commissioner of patents, the Secretary of State, and solicitor of the treasury. From 1836 to 1873 the patent laws were frequently amended. In the latter year they were codified in title 60, chapter i., of the U. S. Revised Statutes, in which form, with a few amendments, they still remain. Some of the important provisions of this statute are the extension of the term of patents from fourteen to seventeen years; the abrogation of extensions of patents granted since Mar. 2, 1861, by the commissioner; the compulsory attendance of witnesses in patent cases; the establishment of a board of examiners-in-chief, intermediate between the examiners and the commissioner, to hear appeals from the decisions of the former; the repeal of the provision permitting withdrawal of two-thirds of the fee in case of rejection, and the sweeping away of all distinctions between citizens and foreigners in the granting of patents. It caused a decided advance in the utility of the patent office by providing for the printing of all patents as fast as issued. Brief abstracts, together with decisions of the courts in patent cases, decisions of the commissioner, etc., are published weekly in the official gazette.

II. *The Law relating to Patents.*—Patent laws are laws which prescribe under what formalities and conditions patents may be granted, and provide for enforcing the protection which the patent grants. A patent to a first inventor is not, as is often erroneously supposed, a grant of right to the *invention*. It is merely a grant of right to *protection* in the exclusive use of the invention. An inventor has a right to use his invention without a patent. The grant of protection to an inventor in the exclusive use of his invention for a limited time is so well founded in justice and public policy that, although not of remote origin, it has been adopted by all civilized nations. In many dependencies, having no patent laws of their own, inventions receive the protection of the patent laws of the mother-countries. Thus, for instance, a patent granted in Spain protects the invention in Cuba and the Philippines, and in nearly all of them the protection is granted to the first inventor. In Great Britain it is granted to the first introducer of the

invention, whether he be the inventor or an importer of the invention. In most countries this protection is granted on condition of a forfeiture of the right unless the invention be put into use by the patentee within a specified time. The length of time for which the protection is granted in different countries varies from three to twenty-one years, but is generally limited to the shortest term during which protection, if any, has been previously granted for the same invention in any other country. The authority for the patent laws in the U. S. is the clause in the Constitution which declares that Congress shall have power "to promote the progress of science and useful arts by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." In consequence of this delegation of power by the several States, legislation on the subject of patents for new inventions belongs especially to Congress, and by such legislation jurisdiction for the administration of the patent laws belongs to the Federal courts.

For what Subjects-matter Patents may be Granted.—The act now in force provides "that any person who has invented or discovered any new and useful art, machine, manufacture, or composition of matter, or any new and useful improvement thereof not known or used by others in this country, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, and not in public use or on sale for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the duty required by law and other due proceedings had, obtain a patent therefor." It will be noticed that, by the language of the Constitution, Congress was given power to secure to inventors the exclusive right to their "discoveries," while the statute purports to secure what has been "invented or discovered." As the statute puts "invented or discovered" in the alternative, thereby indicating that Congress understood those terms to refer to different things or to things of different origin, it appears as if Congress had exceeded its authority in providing protection for *inventions* as well as for *discoveries.* Notwithstanding this disjunctive use in the statute of the terms "invented" or "discovered," the courts have held that, with reference to patentable subjects-matter, *discovery* is synonymous with *invention*, and such, from previous adjudications which had taken place in England, was well understood to be the import of those terms at the time of the adoption of the Constitution of the U. S., and the verbal discrepancy has been disregarded to effectuate the known intent of the organic law. It will be noticed that only four classes of patentable subjects-matter are mentioned in the U. S. statute; but these are sufficient to comprehend patentable improvements of any kind. In the English law only one was mentioned, being "manufacture," but the courts of England by construction give that one term sufficient scope to embrace all kinds of patentable subjects-matter. As used in the statute, the term "machine" includes all kinds of mechanism, whether machines proper or apparatus which have a mode of operation in working out or producing a result. The term "manufacture," according to the patent laws of the U. S., includes all kinds of useful articles which are made, except machines and compositions of matter, such, for example, as fabrics, tools, implements, wearing apparel, household furniture, etc. The designation "composition of matter" includes all kinds of mixture or compounds of substances, such as medicines, articles of food and drink, perfumeries, paints, dyes, etc. The term "art" comprehends all methods and processes which may consist of modes of procedure with or without new ingredients or materials. It is often difficult to determine to which of the four classes of subjects-matter mentioned in the statute an invention belongs, and it frequently happens that an inventor is entitled to separate patents for three kinds of subject-matter, all having reference to the same production: for the article itself, the method of producing it, and the machinery used therein.

To whom Patents may be Granted.—Patents are granted to original and first inventors. This is subject to the qualification that a foreign inventor who has not made his invention known in the U. S. will not be permitted to step into the place of an inventor who, in the U. S., has *bona fide* made the invention. Patents may be applied for and obtained by the executors and administrators of inventors. An inventor may assign his invention and may have a patent issue to the assignee. An invention by joint inventors must be patented to both.

What constitutes Patentable Inventions.—The mere conception of an idea is not patentable. An invention to be patentable must be capable of use without the addition of further invention or the necessity of further experiment apart from the exercise of mere workshop skill. It must be so matured that the means of producing the result can be accurately and fully set forth. When the invention consists of a process or of a composition of matter, it is not necessary, in order to entitle its author to a patent, that he should understand the rationale of the chemical changes involved. He has brought such an invention to a patentable condition when he has ascertained what articles are to be used and how they are to be used to produce the desired result. Some inventions are new in kind, while others are only new as improvements on something which in kind had prior existence. The former are patentable much more broadly than the latter. When an invention consists of doing by a machine what had previously been done by hand only, or had never been done at all, it is new in kind. The first sewing-machine and the first recording telegraph are instances of inventions which were new in kind. To give an invention patentable novelty it is immaterial whether it was the result of much or little research or labor. An invention or discovery made by accident is none the less patentable. New combinations of either new or old elements are patentable, but a combination of old elements, to be patentable, must produce some new result due to the co-operative or reciprocal action of the combined parts. The mere addition of one old device to another, each producing its own result in such manner that their combination produces those same two results and no other, is not patentable, and is not invention, this being commonly designated as an aggregation merely, and owing its origin to workshop skill or judgment as distinguished from the exercise of the inventive faculty. Any part in a machine which does not participate in the mode of operation of the machine is regarded as a dead part. Nearly all patents on machinery are for combinations of parts some or all of which are old. When a single part or any combination of parts less than the combination of the whole is new, then such part or such sub-combination of parts is patentable, as well as the entire combination, and they can be patented by separate claims in one patent or by a plurality of patents. Although an invention, to be patentable, must, with the exception mentioned, be new and useful, it does not follow that all new and useful productions are patentable. There are many things which, though both new and useful, are not patentable. Any change which was so obvious as to exclude the possibility of the exercise of the inventive faculties being necessary to produce it is not the subject of a patent. Any improvement which is merely the result of mechanical skill or superior workmanship is not patentable. A new discovery of a law of nature or of an abstract principle is not patentable. A discovery consisting of the adoption of a known equivalent of what was already in use is not patentable; such, for illustration, as the removal from a machine of one of the elements which it has in combination with other elements, and the substitution in its place of another known element possessing only the same function and performing only the same office in the combination as did the part for which it was substituted. In a process or composition of matter the substitution of one known chemical agent for another having only the same function is not patentable. Combinations in mechanism consisting of a mere assemblage of old parts, each part possessing only the same function and performing only the same office in the combination as it did out of it, and none of the parts co-operating with the others to produce any new or improved result, are not patentable combinations, but in judgment of law are mere aggregations of old elements. A new use of an old thing, called a double use, is not patentable; that is to say, if a machine or an instrument be known and used for one purpose, a discovery that it can be used to advantage for another purpose, accompanied by an actual application of it unchanged to such new purpose, is not patentable, but in such cases a very slight adaptation of it for the new use will render it patentable. This exclusion of a new use of an old thing from patentability is for the reason that when an invention is made, its author, having created it, is entitled to all its attributes, whether discovered by him or by any one else subsequently to his invention; and when that right passes from him to the public, it becomes vested with the same right. Anything which is injurious to public health, to good morals, or public policy is not patentable.

Utility.—Although the statute requires the invention to be useful, yet no particular degree of utility is necessary to render an invention patentable. It need not be more useful than what was previously known for the same purpose. The requirements of the law are answered so far as utility is concerned if the invention be not absolutely frivolous or injurious to the public.

How an Inventor may Lose his Right to a Patent.—An inventor who has acquired a right to a patent may lose it in two ways: 1. By neglecting to apply for a patent for more than two years after the invention has been put into public use or on sale. The "public use" mentioned in the statute is not limited to a continuous public use for more than two years, but comprehends also a single instance of such use more than two years before the application for a patent. Public use has been judicially defined to be a use in public. The loss of an inventor's right to a patent by neglecting to apply for it for more than two years after the invention has been either used in public or put on sale is in the nature of a forfeiture of his right, and does not depend upon his intention. Nor is the lapse prevented by ignorance on his part of such public use. The contrary was held for many years, but a recent decision of the U. S. Supreme Court has reversed the former practice. A patent expires with the expiration of the term of a foreign patent previously obtained on the same invention, but not with the lapse of the former patent from non-payment of the taxes or the non-working of the invention required by the patent laws of various countries. 2. An inventor may so deal with his invention as to create an abandonment or dedication of it to the public at any time. This he may do either by express declaration or by his silence while with his knowledge its use is generally adopted by others. Such a surrender of an inventor's right is a matter of intention on his part, but intention may be inferred from existing facts. Delay alone to apply for a patent, no matter for how long, will not constitute abandonment, but unreasonable delay, associated with the fact of the same invention being originated by another and patented or put into general use by him, will constitute abandonment. Hence if a person unreasonably neglect to apply for a patent after completing his invention, he does so at the peril of losing his right. The issue of a patent is no guaranty to its owner of the right which it purports to secure. A patent is only *primâ facie* evidence of such right. It gives to its owner a right of action against infringers of the patent, and authorizes him to contest his right to the thing patented. Proof against a patent at any time during its term, in a suit brought for an infringement, that the patentee was not the first inventor of the thing patented, or that its subject-matter was not patentable, or that the inventor lost his right by forfeiture or abandonment, or any other fact against the validity of the patent, will invalidate the patent. When an invention has been previously patented in a foreign country, the U. S. patent will expire with the term of the foreign patent, or, if there be more than one, with that having the shortest term. If an inventor disclaims a part of his invention in his original application, he will be precluded from claiming it afterward. If an inventor has neglected to claim the whole of his invention he must file his application for reissue with due diligence—ordinarily, within two years—or he loses the right to receive a claim commensurate with the actual invention, there being, however, some exceptions to this rule. Certain irregularities in the proceedings incident to obtaining a patent may restrict the scope of the grant or even invalidate the grant.

How Patents are Obtained.—Patents are obtained by applications in the form of petitions to the commissioner of patents, accompanied by a description, including drawings. Models may be demanded by the Patent Office, but for several years past have not often been required. When the invention is of a composition of matter, specimens may in like manner be required by the commissioner. The commissioner of patents is the head of the Patent Office, and has a corps of assistants called examiners, among whom the different patentable subjects-matter are divided, and whose duty it is to examine applications to ascertain whether the papers are in proper form and whether the invention described therein is, so far as they can ascertain, new and useful. On the commissioner receiving an application for a patent, he refers it to the proper primary examiner for his examination into the state of the art to which the invention appertains, and for his report of the result of his examination to the commissioner. If no reason is found against granting the patent, it is allowed and issued. If any cause is found by the examiner against the grant, it in such case is reported to the applicant; and if he can by explanation or argument remove the objection, the patent will still be issued, otherwise it will be refused by the primary examiner. From the decision of the primary examiner an appeal lies to a board of three examiners, designated examiners-in-chief. From a decision of the board of examiners-in-chief an appeal lies to the commissioner of patents, and from his decision an appeal lies to the Supreme Court of the District of Columbia. When an application is made for a patent which in the opinion of the commissioner would interfere with any pending application or with any existing patent, notice is given to the parties interested, and an opportunity granted to them to show by evidence which was prior in date of invention; and the patent will be issued to the one proved to be the first. The business in the Patent Office has become so extensive that there has grown up a class of persons known as patent agents or solicitors of patents, who conduct Patent Office business in behalf of inventors, and, being located in different parts of the U. S., are always accessible to inventors. The term for which patents for inventions issue in the U. S. is seventeen years. If an inventor, after conceiving the outlines of his invention, desires further time to mature the same, and in the meantime to guard against any other patent being granted for the invention, he may do so by filing in the patent office a caveat, setting forth the design and distinguishing characteristics of his invention and praying protection of his right until he shall have matured his invention. Such caveat will be preserved in secrecy by the commissioner of patents, and the effect of it will be to entitle the caveator for one year to notice from the commissioner of any application which may be made for a patent which would in any way interfere with his right. After receiving such notice, if any be given, the caveator will be allowed three months in which to file a complete application.

Designs.—New designs are also patentable, such as a design for a manufacture, bust, statue, alto-relievo, or bas-relief; designs for printed fabrics; ornaments, patterns, prints, or pictures to be placed on or worked into any article of manufacture; also new shapes.

Amendment of Patents.—A patent may be amended by being surrendered to the commissioner and the grant of an amended one, called a reissue, in its stead, or by filing with the commissioner a disclaimer of so much of the thing patented as the patentee was not the first inventor of. To amend by a reissue, the original patent and an amended specification must be delivered to the commissioner, asking an acceptance of the surrender and a grant of a reissue in conformity with the amended specification. A patent may by a reissue be amended in either its descriptive parts or its claims so as to conform to what the patentee was the first inventor of; but no new matter can be introduced into the reissue, nor, in case of a machine patent, can the model deposited on the original application or the drawings attached to the patent be amended except each by the other; but when there is neither model nor drawing, amendments may be made upon proof satisfactory to the commissioner that such new matter or amendment was a part of the original invention and was omitted from the original specification by inadvertence, accident, or mistake. Under late decisions, however, this provision is little more than nugatory. A reissue in which the claims are expanded should be applied for with diligence, and not delayed long after the issue of the original patent.

Repeal of Patents.—There is no statutory provision for the repeal of patents; but where patents interfere by each claiming the same invention, any one interested in either patent may institute a suit in equity against the owners of the other patent, in which case the court has power to declare either patent invalid in whole or in part. It is also understood that the Attorney-General of the U. S. has a right of action to invalidate a patent where there was fraud in the issuing of it.

Sale and Transfer of Patents.—A patentee may sell his entire patent or any undivided part of it for the whole or any specified part of the U. S. The conveyance of such an interest, to be valid, must be in writing, and is called an assignment. Such an assignment will be void as against any subsequent purchaser or mortgagee for a valuable consideration without notice that such assignment had been made, unless it be recorded in the Patent Office within three months from its date. Parties having an undivided interest in a patent are not thereby constituted partners, but are

tenants in common; and any of such parties may grant licenses to others to use the invention in making, using, and vending the patented article, and receive and retain the consideration for the same without liability to their co-owners. Licenses under patents need not be in writing. They may be oral or implied. A license to a party to use the invention is not divisible or assignable unless expressly made so by its terms. A license, although in writing, need not be recorded. An invention not patented is assignable, but an invention is not salable or assignable before it is made, because a thing not *in esse* is not the subject of sale. An agreement, however, to assign an invention when made will be operative upon it as soon as it shall be made.

Remedies for the Protection of Patent Rights.—The law protects patentees against false representations of others. It provides that any person who, without authority from the patentee, shall in any manner mark upon anything made, used, or sold by him, for which he has not obtained a patent, the name, or any imitation of the name, of any person who has obtained a patent therefor, or who shall in any manner work upon or affix to any such patented article the word "patent" or "patented" or the words "letters patent," or any word of like import, with the intent to imitate or counterfeit the mark or device of the patentee, or who shall in any manner mark upon or affix to any unpatented article the word "patent" or any word importing that the same is patented, for the purpose of deceiving the public, shall be liable for every such offense to a penalty of $100. In case of an infringement of a patent, the law gives its owner right to remuneration for past infringement and to have further infringement prevented. He has a right to an action at law for a trial by jury, in which his recovery will be the actual damages he has sustained from the infringement. He also has a right to sue in equity, in which he can recover not only damages, but, in addition thereto, according to the statute, the profits realized by the defendant from the infringement, and obtain an injunction restraining further infringement; and where no serious doubt is raised respecting the validity of the patent or on the question of infringement, he may, on short notice, have a preliminary injunction restraining the infringement during the pendency of the suit. In suits for infringement all of the owners of undivided interests in the patent for the territory in which the infringement has been committed must be joined as coplaintiffs or cocomplainants. Where there has been a joint infringement, the infringers are jointly and severally liable for the infringement. Ignorance on the part of an infringer of the existence of a patent at the time of infringement is immaterial, so far as his liability for the infringement is concerned. To entitle a patentee to recover for an infringement of his patent, he is not required to show that the infringer knew of the existence of the patent. Still, neither the patentee nor his assigns are allowed to recover damages for infringement, unless it appear that they marked the patented articles made or sold by them "patented," together with date of patent, or that the defendant was personally notified of the infringement and continued to infringe after such notice.

Relation of a Patentee to the Government.—The relation between the public and the inventor is that of contracting parties. It will be noticed that in forming this relation the public neither promises nor imparts anything to the inventor except legal protection to his property, while it receives a valuable addition to its productive resources. From this relation of the inventor to the public, it will be realized how strong is his claim to a full and efficient protection to his right, because (1) he has purchased the protection to his property in the invention for a special and valuable consideration; (2) he receives no greater protection than is furnished to others for other property without a special purchase; and (3) the protection is only for a limited time, while for tangible property the protection is without limitation of time; but notwithstanding this manifestly superior claim of patentees to full protection for their property in patented inventions, their title to such property is treated with comparative indifference, and trespass upon it by others is not held in the same disrepute as is trespass upon other kinds of property. Patents have been, and to a considerable extent still are, regarded as monopolies, creating undue restriction upon the rights of the public and appropriating to individuals what belongs equally to all. One cause of this false impression is a mistake as to what a patent grants, and an assumption that by it the government grants to a patentee an exclusive right to something of which the public was previously in possession; while another is found in the fact that patents for new inventions had their rise, and for a considerable time their progress, in England in the society of other grants, which did confer upon individuals privileges which belonged of right to the public, and which were therefore odious monopolies, and which in the course of time became so obnoxious to the people as to be entirely abolished. From the fact that patents for new inventions were introduced in the form of and contemporaneously with oppressive monopolies which took rights from the public and gave them to individuals, they caught and have retained some of the odium, and even the name, of monopolies. The distinction between a monopoly and a meritorious patent was drawn in the Statute of Monopolies, which declared "that all monopolies, and all commissions, grants, licenses, charters, and letters patent heretofore made or granted, or hereafter to be made or granted, to any person or persons, bodies politic or corporate whatsoever, of or for the sole buying, selling, making, working, or using of anything within this realm, . . . are altogether contrary to the laws of this realm, and so are and shall be utterly void and of none effect, and in nowise to be put in use or execution," and qualified this declaration by the proviso following, viz.: "That any declaration before mentioned shall not extend to any letters patent and grants of privilege for the term of fourteen years or under hereafter to be made of the sole working or making of any manner of *new manufactures* within this realm to the *true and first inventor and inventors* of such manufactures." From the causes above stated the courts of England, for many years after the introduction of patents, treated them with disfavor, and whenever they became the subject of litigation struggled to invalidate them. Patents for new inventions, however, are not monopolies, have none of their properties, and were never considered as such by the common law or intended to be so regarded by the Statute of Monopolies. The common-law definition of a monopoly is given by Lord Coke in the following words: "A monopoly is an institution or an allowance by the king, by his grant, commission, or otherwise, to any person or persons, bodies politic or corporate, of or for the sole buying, selling, making, working, or using of anything *whereby any person or persons are sought to be restrained of any freedom or liberty which they had before or hindered in their lawful trade.*" Justice and consistency require that the property of an inventor, the creation of his own mind, should be exonerated from any idea of his being the grantee of an odious monopoly. Patents should be regarded in their true light of rewards dictated by sound public policy to meritorious men who contribute by their creations to the welfare of the country and of the world.

Pater, WALTER HORATIO: author; b. in London, Aug. 4, 1839. He proceeded to Queen's College, Oxford, and graduated in 1862, and was elected to an open fellowship at Brasenose College. He was a subtle critic of art and literature, and master of a very graceful prose style. His works are *The Renaissance* (1877; 3d ed. 1888); *Marius the Epicurean* (1885); *Imaginary Portraits* (1887); and *Appreciations* (1889; 2d ed. 1890), besides many articles in the principal reviews. D. in Oxford, July 30, 1894. H. A. B.

Pater'culus, GAIUS VELLEIUS: historian; b. about 19 B. C.; entered early the Roman army, and served from 1 to 13 A. D. under Tiberius in Germania, Pannonia, and Dalmatia. The year of his death is unknown, but his *Historiæ Romanæ ad M. Vinicium Cos. Libri II.* reached to 30 A. D. The first manuscript of this book, and the only one that has come down to us, was discovered by Beatus Rhenanus at Murbach in Alsace, and printed at Basel in 1520. The best editions are that by Orelli (Leipzig, 1835), that by Kritz (2d ed. Leipzig, 1840), and the text by Haase (2d ed. with emendations by Mommsen, 1863) and by Halm (Leipzig, 1876). The beginning is wanting, and there is also a portion lost after the eighth chapter of the first book.

Revised by M. WARREN.

Pater'no: town of Italy; in the province of Catania, Sicily; situated at the foot of the western slope of Etna, about 9 miles from the city of Catania, on one of the routes to the summit of the volcano (see map of Italy, ref. 10-G). Remains of ancient aqueducts and the ruins of an old bridge over the Simeto may be seen here, and other traces of the Roman period. There is an old Norman castle, occupying an elevated position. Paterno has been supposed to occupy the site of the ancient *Hybla Major*. The vicinity is fertile in grapes, olives, hemp, etc. Pop. 15,230.

Pa'ter Nos'ter [Lat., Our Father, the opening words of the Lord's Prayer]: the name given by Roman Catholics to the Lord's Prayer. In the ancient Church it was regarded as so sacred that its formula was kept a secret from the uninitiated. (See ARCANI DISCIPLINA.) In later times this prayer was repeated by the vulgar as a charm. The closing words, "For thine is the kingdom," etc., are not present in all the versions, and some Christians do not use them.

Paterson: city (founded in 1791, incorporated in 1850, known as the "Lyons of America"); capital of Passaic co., N. J. (for location, see map of New Jersey, ref. 2–E); on the Passaic river, the Morris Canal, and the Erie, the Del., Lack. and West., and the N. Y., Susquehanna and West. railways; 15¾ miles N. W. of New York city. It is built partly on a broad plain and partly on the slopes of ranges of hills that inclose it on three sides, Garret Mountain, about 500 feet high, overlooking it on the S. W. The river, which affords exceptional power for manufacturing, runs through the city, and Passaic Falls, 72 feet high, are within its limits. The city is lighted by electricity and gas. In 1900 there were 880 manufacturing establishments (representing 132 industries) reported. These had a combined capital of $37,800,621, employed 29,625 persons, paid $48,628,932 for wages and $20,516,000 for materials, and had products valued at $92,682,498. The principal industry was the manufacture of silk and silk goods, which had 126 establishments and $26,948,868 capital, employed 20,480 persons, paid $12,420,061 for wages and $20,438,460 for materials, and had products valued at $50,948,287. Then followed foundry and machine-shop products, which had 44 establishments and $4,106,021 capital, employed 6,027 persons, and had products valued at $8,110,261; malt liquors, 7 establishments, $1,000,000 capital, and products valued at $2,176,208; iron and steel, 5 establishments, $2,126,426 capital, and products valued at $3,210,284; dyeing and finishing textiles, 10 establishments, $2,866,281 capital, and products valued at $6,415,876; and jute and jute goods, 1 establishment, with products valued at $950,640. The foundry and machine-shop products included locomotives, metal bridges, steam fire-engines, cotton machinery, heavy castings and brass and plumbers' goods. The city is connected by trolley-lines with Passaic, Rutherford, Newark, Hoboken, and Jersey City. Many mills are supplied with power from a raceway that runs through the manufacturing district. Paterson contains 76 churches, 22 public schools, several private schools of high grade, 3 hospitals, 2 orphan asylums, free eye and ear infirmary, Old Ladies' Home, Children's Day Nursery, free public library, electric street-railways, 3 national banks, combined capital $850,000, savings-bank, capital $100,000, 3 trust companies with a combined capital of $350,000. There are 5 daily, 6 weekly, and 4 monthly periodicals. Pop. (1890) 78,347; (1900) 105,771. HARRY B. HAINES.

Paterson, WILLIAM: merchant; b. at Skipmyre, Dumfriesshire, Scotland, in 1665; was persecuted as a Covenanter by Charles II.; settled at London as a merchant; visited the West Indies, where he obtained much information about the localities of the Spanish Main from the buccaneers; issued proposals for the establishment of the Bank of England, of which, upon its establishment in 1694, he was one of the directors. Paterson made unsuccessful efforts in England in the same year to organize a scheme of colonization in Darien; obtained from the Scottish Parliament in 1695 an act of incorporation; obtained large subscriptions, and proceeded to Darien with a considerable number of emigrants; was unsuccessful on account of quarrels, fever, famine, and the opposition of the Dutch, Spanish, and English Governments; returned to Scotland 1700; was an advocate of the union of Scotland with England; entered Parliament 1708; obtained some compensation for his losses about 1715; wrote several treatises on economical subjects. D. at Westminster, Jan. 22, 1719. See *Biographies* by Bannister (1858) and Pagan (1865), and the *Works* of Paterson (edited by Bannister, 3 vols., 1859).

Pathology [Gr. *πάθος*, suffering, disease + *λόγος*, discourse, reason]: that branch of medical science which treats of disease. It includes the study of the pathological alterations of the body, their causes, and their effects. Generally the subject is divided into ætiology, which treats of the causes of disease; pathological anatomy, which treats of the character of the structural alterations; and general pathology, which treats of the laws under which pathological alterations are produced, and the effect which they have on the function and structure of the other parts of the body.

Under disease we mean a definite alteration in some part of the body which produces a definite series of functional disturbances which we call symptoms. By the study of these symptoms we are able to recognize the situation of alteration and its character. The structural alterations of the body are divided into those which are congenital, and due to imperfections in the development and growth of the organism, and those which are the result of disease. All anatomical changes in the body not due to defects of development are the result of influences not inherent in the body, but acting on it from without.

We may regard life as due to the sum of external influences acting on the body. The character of these influences must be such that under them all the organs of the body act in a normal or physiological manner. When an ordinary external influence is increased to a great degree it may become a cause of disease. Disease is, however, most generally produced by the action of influences different from those ordinarily acting. When an organ is diseased it may be that injurious substances are brought to the organ by the circulation, or it may be that the blood while of a normal quality may vary from the normal quantity, or the part may become affected from direct injury or from its proximity to another diseased organ. These structural alterations of part have an effect not only in impairing their functions, but the impaired function of one organ, if it be an important one, has an effect on the function and structure of the other organs.

The infectious diseases are due to the action of microscopic living organisms which find suitable conditions for their development in the animal body, and as a result of their growth produce various alterations. Experimental pathology forms an important branch of pathology, and to its development a great deal of recent progress made in the increase of our knowledge of disease is due. In this lesions are produced in lower animals, or they are given various diseases by inoculating them with the organisms causing the disease. In such experiments there is the advantage that the effect of the lesions on the functions of the parts can be studied more closely, and by killing the animals at various stages of the disease its gradual course can be traced out.

W. T. COUNCILMAN.

Pathology, Vegetable: a department of botany which deals with the diseased conditions of plants. It is coextensive with physiology, which deals with plants and their organs in their normal, active state. The subject is thus too large to be treated in any but a summary way in this article, which professes to give no more than a mere outline.

Scientifically speaking, "disease is a condition in which the functions of the organism are improperly discharged" (*Ward*). While this general statement applies equally to plants and animals, it must not be assumed that there is a complete identity between their pathological conditions. In a plant nearly all cells are short-lived, and in the growth of an organ or member death follows close after the advancing mass of living, active cells. In a long-lived tree it is its normal condition that perhaps more than 99 per cent. of its mass is dead tissue. Again, in such a tree we observe the periodic death and separation of great masses of tissue in the fall of the leaves and flowers, and the ripening and fall of fruits. These examples will suffice to show why a reference to many languishing or dying cells is excluded from this discussion, which is confined to that part of the subject which deals with what may be called the abnormal pathology of cells, tissues, and organs.

1. *Unfavorable Habitat.*—For ordinary land-plants this includes not only such matters as altitude above sea-level, forest or plain conditions, etc., but even more, the particular conditions of the soil. In a hard soil, even if it is fertile, many plants starve because their roots can not penetrate it. The same thing takes place in a barren soil, although it may be soft and easily penetrated. In a soil which is too dry the plant starves not only for want of water (its most important food), but also for want of the solutions of nitrogenous and other solid food-matters. On the other hand, most land-plants soon languish if their roots are long in a soil which is filled with water. Here it appears that many of the roots die, and the plant starves in the midst of plenty. Sachs has shown that ordinary soil-roots die in completely wet soil, on account of the exclusion of air. In addition to this, in field-culture a wet soil is always colder than one which is moist; thus the absorption of nutritive solutions by the roots may be so checked as to result in starvation.

Occasionally the soil contains injurious or poisonous sub-

stances. Some salts, as those of potash, and soda are sometimes so abundant as to destroy nearly all vegetation. The presence of mineral oils or of some gases in the soil quickly kills the roots of all plants. Here again, as in the preceding cases, it appears that the plant is in fact starved by the cutting off of the supply of water and other food.

2. *Unfavorable Atmospheric Conditions.*—When the air is very dry the loss of water by the plant is excessive, and when this exceeds the water-supply the cells lose their turgidity, become enfeebled and almost inactive. Such cells may regain, to a great extent, their normal activity when the humidity of the air is increased.

Many gases in the air act as poisons to the cells with which they come in contact. The gases from burning coal, especially from that which contains sulphur, and those which escape from chemical-factories are often very destructive to vegetation. "Hydrochloric acid gas, nitric acid in vapor, and chlorine are also very destructive to vegetation, even when in such minute amounts as to be unnoticed on account of their odor" (*Goodale*).

Too intense or too feeble light is injurious to plants. Pringsheim has shown that in very intense white light the chlorophyll granules lose their color, and the cell is soon killed. In deficient light, as when plants are more or less shaded, they lose their color and become slender and weak. To a large extent this loss of strength is doubtless due to lack of nutrition through the inability of the chloroplasts to assimilate carbon.

When subjected to a temperature which is too high the plant wilts, and by the rapid loss of water by evaporation the leaves and younger stems become dry, as if scorched. In a low temperature (but not freezing) the activities of the cells are mostly suspended, and if this is prolonged the plant suffers from a loss of nutrition. When actual freezing takes place death usually follows on account of the withdrawal of the water from the protoplasm. A quick alternation from heat to cold appears to be more harmful than when the change is a gradual one. The so-called sun-scald upon the trunks of apple-trees appears to be the result of the heating of the tissues of the inner bark and younger wood by the afternoon sun on bright winter days followed quickly by a low temperature. The cells are made active by the heat, and when the temperature suddenly falls they are killed.

3. *Mechanical Injuries.*—Here may be mentioned the wounds, as by the breaking or removal of branches, the injuries from hail and lightning, and the twisting and rupturing of the tissues of the stems and leaves by violent winds, in all of which many cells are at once destroyed, exposing others, which in turn are usually injured also by drying, decay, or the attacks of harmful organisms (bacteria, fungi, or insects). Even when the wound has become covered by the growth of living tissue over it, the dead tissues of the original wound are frequently the origin of a more or less rapidly spreading decay, usually hastened by the presence of fungous filaments.

Most of the injuries produced by insects and other small animals are mechanical. The roots, stems, leaves, flowers, and fruits are often badly wounded by biting insects (*Coleoptera*, *Orthoptera*, and the larvæ of *Lepidoptera* and *Hymenoptera*). Here the injury to the plant is twofold; it suffers from the wounds as such, and also from lack of nutrition. The sucking insects (*Hemiptera*), by withdrawing water and other food-matters, to this extent decrease the nutrition of the plant. In addition, in some cases the insect injects a poisonous or irritating fluid, which either kills the tissues or causes abnormal growths, the latter resulting in the formation of galls of various kinds.

4. *Parasitism.*—One of the most fruitful sources of diseased conditions is the presence of parasitic vegetable organisms in the tissues. In a few cases these are phanerogams, as in the dodder and mistletoe, but by far the greater number are fungi and bacteria. The diseases produced by fungi and bacteria manifest themselves in many ways, and are known as anthracnose, blights, gummosis, mildews, rot, rusts, scab, smuts, spots, etc. In some of these there is a slow invasion of the tissues of the host by the parasite, with little apparent harm to the former, while again there may be very great changes in the tissues, resulting in the atrophy of organs, or much more commonly in their hypertrophy. In some again the tissues tend to dry and shrivel up, while in others they are turned into foul, decaying masses. The presence in root-cells of the cabbage and turnip of those low organisms of doubtful affinity, the *Mycetozoa*, gives rise to the distorted growths known as "club-root."

5. *Teratogeny.*—Doubtless we must regard the monstrous growths so frequently found in plants as involving pathological conditions of the tissues of the parts concerned. We know little as to the cause of these malformations, and may here do no more than indicate in a very general way their kinds, as described by Masters, as follows: (1) Abnormal union of parts; (2) abnormal separation of parts; (3) abnormal positions of parts; (4) arrest of development (stasismorphy); (5) over-development (pleiomorphy); (6) perverted development (metamorphy); (7) irregular development (heteromorphy); (8) multiplication of parts; (9) suppression of parts; (10) overgrowth (hypertrophy); (11) undergrowth (atrophy).

See further the articles Blight, Mildews, Rot, Rusts, Scab, and Smuts.

Charles E. Bessey.

Pathros [Egypt. *Pa-ta-res*, the South Land; Septuagint, Παθούρης]: the Hebrew name of Upper Egypt as distinguished from the Delta region, which was usually known as Mizraim (Isa. xi. 11; Jer. xliv. 1, 15; Ezek. xxix. 14).

Pat'kul. Johann Reinhold, von: soldier and diplomat; b. about 1660 of a wealthy and influential family of Livonian nobility; received a military education, and served as a captain in the army, but became famous afterward as a diplomatist, or rather as an intriguer. Livonia was at that time a possession of the Swedish crown; and in the controversies between the Livonian nobility and the Swedish king Patkul played a conspicuous part. Accused of rebellion, he was summoned to Stockholm, but on his arrival there he soon discovered that the judgment was sure to go against him. He escaped to Courland, but was sentenced to death, and his estates were confiscated. For some time he lived in Switzerland and France, occupied in scientific studies, but in 1698 he entered the service of Augustus II. of Saxony and Poland, and the formidable alliance which was formed shortly after against Charles XII. by Augustus II., Peter the Great, and Frederick IV. of Denmark was principally Patkul's work. It seems, however, as if he could serve no friend and no purpose with full faith. In 1705 Augustus II. arrested him and put him in the dungeons of Sonnenstein; and when Charles XII. made Patkul's surrender one of the conditions of peace, Augustus II. consented. On leaving Saxony the Swedes carried him away with them, and Oct. 10, 1707, he was broken on the wheel and beheaded in the convent of Kazimierz near Posen.

Patmore, Coventry Kearsey Dighton: poet; b. at Woodford, Essex, England, July 23, 1823; son of Peter George Patmore, a man of letters. He was assistant librarian in the British Museum 1846–68; author of *Poems* (1844); *Tamerton Church Tower* (1853); *The Angel in the House* (4 parts, 1854–62), and other works; edited the *Autobiography* of Barry Cornwall. A collective edition of his poems was issued in 1886. D. Nov. 26, 1896. H. A. B.

Patmos, or **Patinos** [Gr. Πάτμος, Mediæv. *Palmo'sa*]: an island in the Ægean Sea; one of the Sporades, all of which belong to Turkey; 29 miles W. from Asia Minor, and 18 miles S. of the western extremity of Samos. Steamships pass near it when going from Constantinople to Egypt or Syria. It is a jagged, irregular mass of rock, 9 miles long and 5 miles broad, composed of two unequal parts which are united by a narrow isthmus, on the east side of which is an excellent harbor. Barren and dreary, it was a dreaded place of banishment under the Romans. St. John was confined here under Domitian, and released on the tyrant's death (96). According to Greek tradition he wrote his Gospel in the little village of Katavafsis, which no longer exists, and the Apocalypse in the south part of the island in a grotto now included in the tiny chapel of St. Anne, half way up the hill overlooking the town. This hill is crowned by the forest-like monastery of St. John the Theologian, erected in 1088, and now occupied by about forty monks. In the library are 239 manuscripts. The archives contain valuable ecclesiastical documents. The air is remarkably healthful, and pest and cholera are unknown. The inhabitants, numbering about 4,000, are industrious Greeks who gain a scanty subsistence by fishing, navigation, weaving a coarse kind of cloth, and working in Asia Minor or on the larger islands.

Pat'na: city; in the province of Bengal, British India; on the right bank of the Ganges, 285 miles N. W. of Calcutta (see map of N. India, ref. 6–H). It extends with its suburbs along the river for a distance of 7½ miles. It is indifferently built, handsome brick buildings alternating with mud huts covered with tiles or thatched; but it has some manufactures of shawls, table-cloths, lacquered ware, and, being situated on the East India Railway, it has become the center of the opium-trade. It is the chief seat of Mohammedanism in India. Pop. (1891) 165,192.

Paton, John Gibson, D. D.: missionary; b. on the farm of Braehead, parish of Kirkmahoe, near Dumfries, Scotland, May 24, 1824; during his educational course in the University of Glasgow and the Reformed Presbyterian Divinity Hall, he was missionary in Glasgow; was missionary in Tanna, New Hebrides, from 1858 till 1862, when he was driven away; traveled in the interests of the New Hebrides mission, in Australia 1862–63, in Great Britain 1863–64, in the Australian colonies 1865, in Great Britain and North America 1892–94; and since 1865 has been missionary in Aniwa, New Hebrides. Dr. Paton was moderator of the Synod of the Reformed Presbyterian Church in Scotland 1863; delegate to the Pan-Presbyterian Council in Belfast 1884, and at Toronto 1892. An account of his life has appeared in two forms—an autobiography edited by his brother, *John G. Paton, Missionary to the New Hebrides* (2 vols., London and New York, 1889–90; new ed. Chicago, 1 vol., 1892), and *The Story of John G. Paton Told for Young Folks* (New York, 1892). C. K. Hoyt.

Paton, Sir Joseph Noel: historical painter; b. at Dunfermline, Scotland, Dec. 13, 1821. He was a designer for a manufactory of damask fabrics, and went to London at the age of twenty, where he entered the schools of the Royal Academy. In 1847 his pictures entitled *Christ Bearing the Cross* and *The Reconciliation of Oberon and Titania* won for him a prize of £300 at the Westminster Hall competition. The latter work is in the National Gallery, Edinburgh. He was elected a member of the Royal Scottish Academy in 1850, and in 1867 was knighted. He is a sculptor of ability and a writer on archæological subjects. Studio in Edinburgh. William A. Coffin.

Patras: fortified town of Greece, in the Morea, on the Gulf of Patras; capital of the nome of Achaia and Elis; has a large though precarious harbor; is connected by rail with Athens (see map of Greece, ref. 16–J). Its customs receipts are larger than those of any other town in Southern Greece. The city is the seat of an archbishopric; and is well built and prosperous. It exports oranges, lemons, and currants, which are extensively cultivated in the vicinity. Pop. (1896) 37,958. E. A. G.

Patriarch [Gr. *πατριάρχης*, father or chief of a race, family, or country, patriarch; *πατριά*, fatherhood, paternal lineage, clan + *ἄρχειν*, rule]: a title. In the Old Testament it was applied to heads of families till the time of the twelve sons of Jacob, who were the last patriarchs. In Jewish post-Christian history the Jewish pontiff, whose authority centered at Tiberias and extended over all the Jews W. of the Euphrates from about 175 to 415, was called Patriarch of the Jews. In ecclesiastical history, in the fourth century the Bishops of Rome, Antioch, and Alexandria assumed the title, as representative of the Christians in Europe, Asia, and Africa respectively. To them were added the patriarchs of Constantinople and Jerusalem. The Roman Catholic Church reckoned twelve patriarchs attached to her communion; namely, of Constantinople, Jerusalem, Antioch, Venice, West Indies, Lisbon, Antioch (of the Melchites), Antioch (of the Maronites), Antioch (of the Syrians), of the Catholic Armenians in Cilicia, and the Chaldeans or Nestorians of Babylon; and also the Bishops of Aquileia and Bourges. The Eastern Orthodox or Greek Church reckoned five: of Constantinople, Rome, Alexandria, Antioch, and Jerusalem. Considering the patriarchate of Rome as vacant through heresy, she established the patriarchate of Russia in 1437, which was suppressed in 1700 by Peter the Great. Various other ancient Christian communities, as specially the Armenians, retain the same office and title. Patriarchal functions are mainly of precedence and supervisory.

Patriarchies: See Ethnology; also Indians of North America.

Patrician [from Lat. *patri'cius*, pertaining to the nobility, of senatorial rank, deriv. of *pa'tres*, nobles, senators, liter., fathers]: a name given to the members of the Roman *gentes*, constituting the original *populus Romanus*. The Roman historians supposed that originally the *patricii* were the sons of the senators or patres. So Livy: "Patres certe ab honore, patriciique progenies eorum appellati" (Liv. I. 8). Doubtless the true explanation of the word patrician is that offered by Mommsen; he says: "Whoever was begotten in an illegal marriage or out of marriage was excluded from the membership of the community. On this account the Roman burgesses assumed the names of the 'father's children' (*patricii*), inasmuch as they alone in the eye of the law had a father." (*Hist. of Rome*, ch. v., vol. i., p. 69, Eng. trans.) It is certain that the patricians were the original burgesses of Rome; in the earliest times there was no plebeian class inside the state. The patricians were divided into certain clans, *gentes* as they were called: the gentes were divided into families, and all these families were connected together by certain religious rites called *sacra gentilicia*. Attached to each household were the slaves and the clients, the latter including foreign refugees and emancipated slaves. Sometimes a patrician would marry a client's daughter, in which case the children resulting from the marriage would take rank neither with the patricians nor the clients; they would have no political rights, but would be independent. There were many ways in which a state of independency might be attained by the clients; as, for instance, when a patron died and left no heir. Thus there soon arose in Rome a third class, the plebeians. To the class so formed were added many citizens among the conquered tribes round about Rome; after the conquest of Alba many of their citizens were brought to Rome, only a few being received as burgesses, while the majority joined the plebeians. The civil history of Rome for more than four centuries after the foundation of the city presents a constant struggle between the two orders of patricians and plebeians. At the beginning of the struggle the whole political, judicial, and hierarchical power was in the hands of the patricians; at the end of it a perfect equalization had taken place. The first great advantage gained by the plebeians was the establishment of magistrates of their own, tribunes of the plebs (495 B. C.), for the sole object of the protection of plebeians. During the next half century from that date rapid advances were made; intermarriage between the two orders was sanctioned; the consulship was for a while discontinued and the office of military tribune established, to which plebeians were made eligible; and a way into the senate was prepared for the plebeians by throwing open the quæstorship. The patricians, however, at this date still retained some of the highest offices; they alone were eligible for the augurships and the pontificate. Further, two new offices were created—offices of the highest power—the censorship and the prætorship of the city. By the coming of the Gauls (390 B. C.) the work of equalization was thrown back somewhat, but only for a time. By the Licinian rogations the consulship was restored, and it was definitely arranged that one of the two consuls should be a plebeian. In B. C. 356 a plebeian was raised to the dictatorship; in 351 the censorship was thrown open; the prætorship followed soon after; and at length, in 300 B. C., the plebeians were elected to the highest sacred offices, the pontificate and the augurships. Some offices of no political significance continued to be reserved to patricians, but in general from this time forward the title of patrician carried with it no advantages apart from the respect which was considered due to high birth and the memory of noble ancestry. After the transference by Constantine of the seat of imperial authority to Byzantium the term *patricius* was made a personal title, indicating a rank a grade lower than that of consul. Revised by G. L. Hendrickson.

Patrick, Saint (Lat. form *Patricius*): the apostle and patron saint of Ireland. His baptismal name was *Succat* (brave in battle). His name as a captive was Cothraighe; later he was called Magonus, or Imigonus, or Maun; on his ordination he took the name Patricius. His birthplace is not certainly known, and his dates are all disputed. The dates in this article are probably only approximations. He says of himself, in his *Confession*, that he was born at "Bannavem Taberniæ," which may probably be identified with Kirkpatrick, near Glasgow, in Scotland. He was born about 372; was a captive and the slave of the King of Dalaradia in Ireland from 388 to 395; went to Gaul, and was there ordained priest and bishop; went to Ireland as a missionary in 432, and died at Saul, near Strangford Lough,

County Down, Ulster, where many years before he had founded his first church, on Mar. 17, 465, the day now sacred to his memory. Ireland was then occupied by a great number of petty tribes, most of which were evangelized by Patrick. So well was the work accomplished that Ireland became known as the "island of the saints." The method employed was that of dealing cautiously and gently with the old paganism of the people. The chieftains were first won over, and then their clans. Much that has been related of Patrick is fabulous; but his autobiographical *Confession* and his *Epistle to Coroticus*, both unquestionably genuine, reveal a devout, simple-minded, unlettered man, and a most discreet and energetic missionary. It is a very curious fact that in these writings of his we find no mention of the pope, and no trace of purgatory, auricular confession, transubstantiation, or worship of the Virgin; while salvation by faith and all the related doctrines are clearly taught. See W. D. Killen's *Ecclesiastical History of Ireland* (2 vols., London, 1875); Whitley Stokes's *The Tripartite Life of St. Patrick, with other Documents relating to that Saint* (1887); Eng. trans. of all his writings, by C. H. H. Wright (1889). Revised by S. M. Jackson.

Patriotic Societies in the U. S.: See the Appendix.

Patripas'sians, or **Monarchians** [*Patripassians* is from Lat. *pa'ter*, *pa'tris*, father + *pa'ti*, *pas'sus*, suffer; *Monarchians* is from Gr. *μόνος*, single + *ἀρχή*, first place, beginning, principle]: Antitrinitarians of the ancient Christian Church, who either taught, or were charged with teaching, either expressly or by implication, that God the Father was incarnated and suffered in the person of Jesus Christ. They denied the doctrine of Three Persons in the Godhead, teaching only three manifestations of the One Person. For themselves, they claimed that they were emphasizing both the unity of God and the divinity of Christ. Of those who held to the heresy in its bolder form, the most eminent were Praxeas of Asia Minor, who was in Rome between 190–200 A. D., Noëtus, who was excommunicated at Smyrna shortly after 200, and the two popes Zephyrinus (202–218) and Callistus (218–223). A much finer type of the heresy was developed by Beryllus of Bostra, recovered to orthodoxy by Origen in 244, and by Sabellius of Ptolemais in Egypt, 250–260 A. D., whose system has frequently reappeared, especially in Occidental Christendom. See Christology.

Patroclus (in Gr. *Πάτροκλος*): the friend of Achilles; a son of Menoëtius of Opus, a brother of Peleus, the father of Achilles. Of his participation in the Trojan war, his death by the hand of Hector, and the frightful revenge which Achilles took, the *Iliad* contains a grand picture in its songs xvi.–xxiii.

Patronage [from Lat. *patro'nus*, protector, patron, deriv. of *pa'ter*, father]: in general, the right of making appointments to vacant benefices, but it is commonly limited to the right of presenting candidates to vacant ecclesiastical benefices. So long as the Christian Church was chiefly missionary there could, of course, be no question of patronage. In the district or diocese which was placed under his superintendence the bishop fixed his residence at the religious house, where he lived together with a number of priests, as many as were sufficient for the religious instruction of the population of the diocese, and the whole establishment was maintained at the expense of the episcopal treasury. In course of time the bishop at the cathedral church would establish and endow branch churches in his diocese and nominate a priest among the *episcopi clerus*, who enjoyed the revenues of the parish endowment. Soon, however, when Christianity became the generally accepted religion, the bishop became unable to provide his whole diocese with churches or the churches with revenues. Private persons of wealth and piety then took the duty upon themselves. The count, the baron, the lord of the castle, built on his domain a church and endowed it with land or other property sufficient to maintain the building and the priest. He now became the patron of this church; and he enjoyed the right of nominating a person in holy orders to be the officiating minister. So far the development was natural and sound. The third Lateran Council of 1179, and also the fourth of 1215, decreed that presentation by the patron, or induction, as it was called, was by itself not sufficient to confer any ecclesiastical benefice, as it referred only to the temporalities of the office; institution or investment, with its spiritualities, was furthermore necessary; and as this could only be given by the Church, the bishop, or the pope, the patron's right of appointment was thereby actually annulled. In the thirteenth century the pope claimed for himself the patronage of all benefices whose incumbents died at the court of Rome; and as the number of ecclesiastics of all ranks and from all countries who visited Rome was very great, this claim was of considerable importance. The pope also gave dispensations for non-residence and for holding several benefices at the same time, and even assumed the right of giving away bishopries, abbacies, and other ecclesiastical benefices before they were vacant—a measure which roused general indignation, so much the more as it was well known that he sold them. In England, under Edward I., an act of Parliament made every one subject to heavy penalties who should venture to enforce the authority of such papal provisions in England. France also made vigorous and successful protest. (See Gallican Church.) With the Reformation the patronage generally returned to the original possessor, the founder of the church. In England it is treated exactly like any other piece of property; it may be connected with the manor, and is then called *appendant advowson*, and it may have been separated from it and belong to a person, in which case it is called *advowson in gross*. In Scotland it was twice canceled and twice re-established; it still exists there, but in a somewhat restricted form. In Denmark it was abolished by the constitution of 1848. In the Episcopal Church in the U. S. the right of appointing to vacant ecclesiastical positions, such as rectorships or the position of an assistant minister, rests with the vestry as representing the congregation. Sometimes the bishop has a coordinate power with the vestry, or the right to choose one from two or more nominations. Rarely, if the clergyman is not liable to episcopal censure, can the bishop veto the appointment of one of his vestries. In unorganized congregations or missions the bishop usually nominates the incumbent. Revised by W. S. Perry.

Patronage (in politics): See Civil Service.

Patrons of Husbandry: a secret order having for its object the mutual protection and advancement of the interests of the agricultural classes.

At the close of the civil war in the U. S. the agricultural interests in the Southern States were greatly depressed; the poverty of the farmers, the difficulty in obtaining efficient labor, the imperfect and ruinous methods of cultivation, and the absence of mixed husbandry were sufficient causes for this depression. In order to seek relief, President Johnson appointed O. H. Kelly, of the Bureau of Agriculture, as agent of the Department of Agriculture of the South, to collect statistical information for publication with a view to encouraging immigration to the South. While on this mission he conceived the idea of an association that would not only improve the condition of agriculturists in all parts of the U. S., but would also bind them into one great brotherhood. He communicated his conclusions to several employees of the Government at Washington, who received Kelly's plan of organization with favor, and held a conference with him on Nov. 15, 1867, when "Patrons of Husbandry" was adopted as the name of the order and the "grange" as the name of its constituent bodies and place of meeting. On Dec. 4 of the same year another meeting was held, officers were elected and the National grange formally organized. The early growth of the order was slow, and many obstacles seemed almost insurmountable for the time being. In Jan., 1871, not more than eighty-eight subordinate granges and three State granges were in existence, but during that year the number of granges was more than doubled and for many years each succeeding year brought many new granges and greatly increased membership. In 1892 nearly every State and Territory contained granges, and many were reported in Canada.

In States where granges are most numerous they have been a potent factor in improving the condition of the farmer and his family. The saving in money by combining orders and purchasing for cash, encouraging the practice of selling direct to the consumer and buying from the manufacturer, the combining of granges in one or more counties to form mutual fire relief associations—all have aided in improving the financial condition of the members of this order; yet even greater benefits have been derived from the discussion and practice of improved methods of agriculture, the establishment of grange libraries and reading-circles, and the great prominence given to educational work.

Comparatively early in the history of the order the granges in several of the Western States undertook the control of the railways, elevators, and other commercial enter-

prises, with indifferent success for the time being: afterward they succeeded in bringing about more favorable legislation for the agriculturist. The founders made it a part of the fundamental law that the order should not meddle with political questions. Agriculturists of all political parties and of none are equally welcome in the order, but they must not bring into it discussion of partisan politics or party measures under penalty of expulsion.

Though the National grange was formed first the *subordinate grange* is really the unit of organization, and must consist of fifteen members, of whom not less than four must be women. A complete grange must have thirteen officers, viz.: Master, overseer, lecturer, steward, assistant steward, chaplain, treasurer, secretary, and gate-keeper may be all men: Ceres, Pomona, Flora, and lady assistant steward must be all women. These each have their appropriate insignia of office and their well-defined duties. There is also an executive committee of three persons, and often an organist and librarian. Subordinate granges confer four degrees, and all business meetings are held in the last or fourth degree. The meetings of subordinate granges are held monthly or oftener, and may determine upon such measures as shall promote the interests of the grange and its members. *Pomona granges* are county or district organizations composed of masters and past masters of subordinate granges and their wives, who are members with other fourth degree members in good standing, who are recommended by subordinate granges in the county for the fifth degree. The Pomona grange is essentially a fifth degree grange, although its business, aside from degree work, is done in the fourth degree. *State granges* are composed of masters of subordinate granges and their wives, who are members of subordinate granges. It is, however, provided that when these become so numerous as to render the body too large, delegates shall be selected to represent the whole body upon such a basis as the grange shall decide. The sixth degree belongs to the State grange, though it may confer the fifth degree at pleasure. The *National grange* is the highest in authority, and the laws enacted by the State, Pomona, and subordinate granges must not conflict in any way with those enacted by this body. The National grange confers the sixth and seventh degrees. The State and National granges meet annually. The officers of the State and National granges are the same as those of the subordinate grange. The officers of the subordinate granges are elected for one year, those of the State and National granges for two years. GEORGE C. WATSON.

Patronymic [from Gr. *πατρωνυμικός*, like the father's (sc. *ὄνομα*, name); *πατήρ*, father + *ὄνομα*, name]: a proper name formed upon the basis of a father's or ancestor's name, and indicating descent. Family names like Johnson, Williamson, Peterson, were originally patronymics attached to the Christian name of an individual for the sake of more precise distinction. The element *Mac-* in Irish names like MacCarthy signifies "son of" (O. Ir. *macc*, boy), and is cognate with Goth. *magus*, boy, from which Goth. *magaþs*, girl: Germ. *magd*: Eng. *maid*; similarly the Aramaic *Bar-* in names like *Bar*abbas, *Bar*timeus, *Bar*tholomeus. Very commonly a mere suffix serves the purpose, as in the case of the Greek *-ides*, as *Peleides*, son of *Peleus*, *Philippides*, son of *Philippos*; or *-īon*, as *Kronīon*, son of *Kronos*. In Teutonic the suffix *-ingas* or *-ungas* is used similarly; thus O. Eng. *Hrēþling*, son of *Hrēþel*; also in tribal names, O. Eng. *Wylfingas*: M. H. Germ. *Wülfinge*. It survives in modern English family names and place-names like *Manning*, *Billings*, *Reading*, *Walsingham*, *Buckingham*; cf. Germ. names *Göttingen*. This suffix represents an Indo-Europ. *-enḱós*, or *-n̥ḱós*; cf. Gr. *-ακος* in *Ἵππακος* (: *Ἵππων*). B. I. W.

Patroons: those Dutch settlers in the colony of New Netherland (afterward New York), who on certain conditions as to colonizing enjoyed manorial rights over their lands. To obtain the privileges of a patroon it was necessary to plant a colony of fifty persons over fifteen years of age on lands selected for the purpose, and within four years after notice was given of intent to colonize. The rights of these proprietors, as enumerated in the charter of 1629 "to all such as shall plant colonies in New Netherland," were of a semi-feudal nature, and the colonies were governed by the same laws as the feudal manors of the United Provinces. Accused of encroachment on the rights of the West India Company, the patroons were involved in continual quarrels with the directors, and were more zealous in undertaking trade ventures for their own profit than in bringing in new colonists. The feudal tenures of these manorial lords were maintained after the Revolution, and although laws were passed in 1779 and 1785 abolishing them, the proprietors contrived a form of deed by which the tenant bound himself to perform services and pay rents and dues in the same manner as before the old system was abolished. From 1839 to 1847 there was considerable opposition to these burdens, and associations of so-called ANTI-RENTERS (*q. v.*) were organized to redress the grievances of tenants. F. M. COLBY.

Patten, SIMON NELSON, A. M., Ph. D.: economist; b. at Sandwich, Ill., May 1, 1852; educated at Northwestern University, Evanston, Ill., and at the University of Halle, Germany, where he received the degree of Ph. D. in 1878. He was elected Professor of Political Economy in the University of Pennsylvania 1888. He is author of *The Stability of Prices* (1888); *The Consumption of Wealth* (1889); *The Economic Basis of Protection* (1890); *Principles of Rational Taxation* (1890); *The Educational Value of Political Economy* (1891); *The Theory of Dynamic Economics* (1892); and many valuable papers on economic topics to the *Annals* of the American Academy of Political and Social Science, *The Political Science Quarterly*, *The Journal of Economics*, Conrad's *Jahrbücher*, and other periodicals. C. H. T.

Patterson, CARLILE POLLOCK: superintendent of civil survey; son of Daniel Tod Patterson; b. at Shieldsboro, Bay of St. Louis, Miss., Aug. 24, 1816; appointed midshipman Sept., 1830; joined the frigate Brandywine in October, and served in the Mediterranean squadron; in Feb., 1836, returned to the U. S. in the line-of-battle ship Delaware, carrying his father's flag as commodore; was passed midshipman June, 1836; graduated from Georgetown College, Ky., as civil engineer early in 1838; joined the U. S. Coast Survey, and served until 1841; as second lieutenant of the U. S. brig Boxer cruised in the West Indies until Jan., 1844; again in Coast Survey in 1845, and conducted a hydrographic party in the Gulf of Mexico; took command of Pacific mail steamship Oregon in Jan., 1850; resigned as lieutenant in the navy Sept., 1853, and remained on the Pacific coast until Mar., 1861. In May, 1861, he became hydrographic inspector U. S. Coast Survey, and so continued until Feb. 17, 1874, when he was appointed superintendent of that work. D. Aug. 15, 1881. See COAST AND GEODETIC SURVEY.

Patterson, DANIEL TOD: naval officer; b. on Long Island, N. Y., Mar. 6, 1786; appointed midshipman in the navy in 1800; attached to the frigate Philadelphia when that vessel ran on a reef near Tripoli in Oct., 1803, and surrendered to Tripolitan gunboats. Patterson remained a prisoner until peace was concluded in 1805; promoted to the rank of lieutenant in 1807, and of master-commandant in 1813. In 1814 he commanded naval forces at New Orleans, and for able co-operation with Gen. Jackson in defending that city received the thanks of Congress. He commanded the flotilla which captured and destroyed the forts and other defenses of Lafitte, the pirate, on the island of Barataria; was appointed captain in Feb., 1815; commanded the frigate Constitution 1826–28 in the Mediterranean; served as navy commissioner 1828–32; commanded the Mediterranean squadron 1832–36; and from 1836 was commandant at the navy-yard, Washington, where he died in 1839.

Patterson, Rev. GEORGE: See the Appendix.

Patterson, JOHN: b. at New Britain, Conn., 1744; graduated at Yale College 1762; became a lawyer; removed to Lenox, Mass., 1774; was a member of the first and second provincial congresses of Massachusetts 1774–75; raised a Berkshire regiment of minute-men and started for Cambridge within eighteen hours of receiving the news of the battle of Lexington; took part in the disastrous expedition against Canada and the battles of Trenton and Princeton; was appointed brigadier-general Feb. 21, 1777; rendered important services at the battle of Stillwater; was present at Burgoyne's surrender and at the battle of Monmouth; remained in service throughout the war; was engaged in the suppression of Shays's rebellion 1786; settled soon afterward at Lisle, Broome co., N. Y.; became a county judge, member of the State Legislature, of the constitutional convention of 1801, and of Congress 1803–05. D. at Lisle, July 19, 1808.

Patterson, ROBERT: military officer; b. in Tyrone County, Ireland, Jan. 12, 1792; at an early age came to the U. S., and subsequently became a very successful merchant of Philadelphia. On the outbreak of the war with Mexico he was appointed a major-general of volunteers in the service

of the U. S., and commanded a division under Gen. Scott, taking part in the battle of Cerro Gordo. On the breaking out of civil war in 1861 he was mustered into the service of the U. S. as major-general of Pennsylvania troops assembled under the President's first call on the States (Apr. 15, 1861) for 75,000 men for three months. Commanding the force on the Potomac in the neighborhood of Harper's Ferry, opposed to the Confederate force under Gen. J. E. Johnston, he was charged with neutralizing that force and preventing its junction with Beauregard at Manassas Junction; but Johnston succeeded in effecting a junction, his advance reaching Manassas on the 20th, the battle of Bull Run ensuing the next day. (See BULL RUN.) On the expiration of his commission (July 27, 1861) Gen. Patterson was mustered out of service. He from that time resided in the city of his adoption, Philadelphia, one of her most honored and influential citizens, and one of the largest mill-owners in the U. S. D. Aug. 7, 1881.

Patterson, ROBERT WILSON, D. D., LL. D.: minister; b. near Maryville, Tenn., Jan. 21, 1814; was educated at Illinois College and Lane Seminary; was tutor in Illinois College 1839–40; supplied several churches 1840–42; was pastor of the Second Presbyterian church, Chicago, from its organization, 1842–74; Professor of Evidences and Ethics in McCormick Seminary 1873–81; president of Lake Forest University 1876–78; and lecturer in Lane Seminary 1880–83. Dr. Patterson was moderator of the General Assembly (New School) at Wilmington, Del., in 1859. D. in Evanston, Ill., Feb. 28, 1894. C. K. HOYT.

Patteson, JOHN COLERIDGE, D. D.: missionary; b. in London, England, Apr. 1, 1827; educated at Merton and Baliol Colleges, Oxford; became a fellow of Merton 1852; curate of Alfington, Devonshire, 1853; went in 1855 with Bishop Selwyn to New Zealand; labored as a missionary until 1861, when he was made Bishop of the Melanesian islands; spent the remainder of his life visiting the islands under his episcopal charge, and endeavoring to suppress the kidnaping of the natives to be carried to Queensland; was killed on the island of Nukapu by the Melanesians, Sept. 20, 1871. His *Life* has been written by Miss C. M. Yonge (2 vols., London, 1874) and by Francis Awdry, *The Story of a Fellow-soldier* (1875).

Patti, ADELINA MARIA CLORINDA: singer; b. in Madrid, Spain, Feb. 19, 1843. Her father, Salvatore Patti, was a Sicilian, her mother a Roman, and both were operatic singers. In 1844 her parents removed to the U. S., and lived humbly in New York. At the age of four the child displayed wonderful talent. She received instruction on the piano from her sister Carlotta, who later became a singer of high reputation, and in vocalization from her step-brother Barili, and her brother-in-law, Maurice Strakosch. When about nine years of age Adelina appeared at a concert in New York, and achieved a remarkable success. In a series of concerts given in connection with Maurice Strakosch and Ole Bull, the infantile prima donna's share of the profits amounted to $10,000. On Nov. 24, 1859, she made her *début* in opera at the Academy of Music, New York, appearing as Lucia. She made professional visits to Boston, Philadelphia, and other cities, and went to Europe in 1861 under the management of Maurice Strakosch. The London managers would not give her an opportunity to sing, and she was on the point of returning to the U. S., when manager Gye, of Covent Garden theater, promised to allow her to sing three times, for which she was to receive no pay whatever. She appeared May 14, 1861, as Amina, in *La Sonnambula*, and her triumph was instantaneous. Since that time she has sung in all the capitals and the principal cities of France, Germany, Italy, Spain, Russia, Mexico, and South America. In 1868 she was married to the Marquis de Caux in London, but was divorced from him in 1878. She married, in Wales, Signor Nicolini, an opera-singer, June 9, 1886. Nicolini died in 1898, and in 1899 she married Baron Rolf Cedarstrom. She has a magnificent country-seat at Craig-y-Nos, Wales. Her repertory is chiefly confined to the Italian school.

Pattison, MARK: scholar: b. at Hornby, Yorkshire, England, 1813; was educated at Oriel College, Oxford, and was elected a fellow of Lincoln College, in that university, in 1840. In 1861 he became rector of his college. He published *Tendencies of Religious Thought in England from 1688 to 1750* (1860); *Report on Elementary Education in Protestant Germany* (1860; 2d ed. 1871); *Suggestions on Academical Organization, with Special Reference to Oxford* (1868); *Pope's Essay on Man*, with notes (1869; 6th ed. 1879); and *Pope's Satires and Epistles*, with notes (1872; 2d ed. 1874). He also wrote a biography of Milton, and a celebrated *Life of Casaubon* (2d ed. 1892), and published annotated editions of Milton's sonnets, etc. D. at Harrogate, July 30, 1884. A volume of his *Memoirs* was published in 1885; of collected *Sermons* in 1885; and of *Essays* in 1889. For a sketch of his wife, see DILKE, LADY EMILIA.

Revised by A. GUDEMAN.

Patton, FRANCIS LANDEY, D. D., LL. D.: clergyman; b. at Warwick, Bermuda, West Indies, Jan. 22, 1843; educated at University College, Toronto, Canada; studied theology at Knox College, Toronto, and at Princeton Theological Seminary, graduating at the latter institution in 1865; was ordained by the Presbytery of New York, and was pastor of Presbyterian churches in Eighty-fourth Street, New York, 1865–67, Nyack 1867–71, and Chicago 1874–81, and from 1871 to 1881 was Professor of Didactic and Polemical Theology in the Presbyterian Theological Seminary at Chicago. In 1873–76 he edited *The Interior* at Chicago; became Professor of the Relations of Philosophy and Science to Religion in Princeton Theological Seminary 1881; and in 1888 president of the College of New Jersey. He was moderator of the Presbyterian General Assembly in 1878.

Revised by S. M. JACKSON.

Patuxent River: a stream which rises 18 miles E. of Frederick, Md.; flows S. S. E. and S., and falls at last into Chesapeake Bay by a wide and deep estuary. Its valley is very narrow, and the river is for many miles a navigable tidal stream, abounding in oyster-beds of great value.

Patwin Indians: See COPEHAN INDIANS.

Patz'cuaro: a city near the central part of the state of Michoacan, Mexico; beautifully situated on the plateau, by a lake of the same name; 7,185 feet above the sea; pop. (1893) about 10,000 (see map of Mexico, ref. 7–G). It is said to have been a very ancient capital of the Tarascan Indians. The lake is about 30 miles in circumference, and contains several forest-covered islands. Patzcuaro is connected with Morelia and Mexico by rail, and, being the center of a rich agricultural region, is rapidly growing. Much of the beautiful feather-work sold in Mexico is made here. H. H. S.

Pau, pō: chief town of the department of Basses-Pyrénées, France; picturesquely situated on the Gave du Pau, at a height of over 600 feet above the sea; 143 miles S. S. E. of Bordeaux (see map of France, ref. 9–D). It has fine promenades, commanding magnificent views of the Pyrenees. It was formerly the capital of the kingdom of Béarn and Basse-Navarre, which was united to France in 1620. It has a remarkable old castle, built by Gaston de Foix in 1363, in which Henry IV. was born, several good educational institutions, linen, steel, leather, and chocolate manufactures, and an active trade in wine, hams, fruits, and flour; but the inhabitants chiefly depend upon their 4,000 winter visitors, of whom many come from England. Pop. (1896) 33,012.

Paul, SAINT: the apostle to the Gentiles; b. in Tarsus, in Cilicia, a province of Asia Minor, probably about 1 A. D. His name at first is Saul, but from Acts xiii. 9 Paul, without explanation of the change. He was a Benjamite and a Pharisee. He was also a free-born Roman citizen; his father must therefore have been enfranchised. As was the practice among the Jews, even those of independent condition, the lad was taught a trade. Hair-cloth for tents was one of the chief products of Cilicia, and the trade of tent-making was the one which this boy learned.

Education.—Doubtless he received such education as could be furnished in the synagogue schools of Tarsus; he was sent to Jerusalem, where he became a pupil of the great Gamaliel, grandson of Hillel, and one of the seven great Jewish Rabbans. Saul must have been studying in Jerusalem while Jesus was in seclusion at Nazareth; but it is unlikely that Jesus and Paul ever met. It is probable that after completing his study of the law with Gamaliel he returned to Tarsus, and was dwelling there during the term of Christ's public ministry.

Return to Jerusalem.—After the death of Christ we find Paul again in Jerusalem. The sect of the Nazarenes is growing rapidly, and Jewish conservatism is alarmed. One of the younger leaders of this sect, a deacon named Stephen, undertakes an active propagandism, and in the synagogues of "the Libertines and of the Cyrenians and of the Alexandrians and of them of Cilicia and of Asia" (Acts vi. 9) there is hot controversy between this zealous advocate of what the Jews called "The Way" and the orthodox Jews.

The Martyrdom of Stephen.—When, shortly after, Stephen was arrested and dragged before the Sanhedrin on a charge of blasphemy, Saul was undoubtedly present, for when Stephen was condemned to death by stoning Saul accompanied the mob of executioners to the place outside the gate where the deed was done, and the witnesses who hurled the missiles laid down their garments at his feet. The narrative in the Acts was written by one of Paul's traveling companions, and it is altogether probable that the report of the execution was gleaned from the apostle's own lips. That "Saul was consenting unto his death" is not an accusation but a confession, and the serene and triumphant faith of the first martyr made an impression on his mind which was never effaced. It has been supposed that either before or soon after the death of Stephen Saul was elected a member of the Sanhedrin; the principal evidence of this is his statement that he was not only active in the persecution of the Christians, but that when they were condemned to death he gave his vote against them (Acts xxvi. 10). This is the literal meaning of the Greek, but it may be used metaphorically. If Paul was a member of the Sanhedrin he must have been married and the father of a family, and the absence of all allusions to such relations, in those passages where a man of his mental habit would have been sure to refer to them, makes it seem highly improbable that he could have had a family.

Whatever may have been his official position, there is no doubt that he became about this time the leader of the persecution which was raging against the Christians. Not only in Jerusalem and its environs did he harry them to prison and to death, but by some strange confusion of jurisdiction or connivance of officials he received from the chief priests authority to proceed to Damascus, the capital of another province, five or six days' journey distant, that he might stamp out the heresy in that region.

It was on this journey that the remarkable event took place which changed the whole current of this impetuous life. Most truly has Dr. Harnack said that this event "has proved to be of transcendent importance for the religious history of mankind."

This man had been, as he testifies, a most conscientious observer and a most strenuous upholder of the Jewish law, but a hard, literal conformity to a merely external standard brought him no satisfaction, and his restless spirit sought in a still more intense devotion the peace which had always eluded him. The lonely journey to Damascus gave him time for meditation; doubtless the gentle and tolerant words of his old master Gamaliel came back to him with power, and in the midst of these mental overturnings a vision of the Nazarene appeared to him in the sky, and a voice in the Hebrew tongue cried: "Saul, Saul, why persecutest thou me?" Paul's own belief was that Jesus appeared to him. The one thing certain is that from this hour he ceased to be a persecutor of the Nazarenes and became, in due time, their foremost leader. At Damascus he was received and befriended by those whom he had come to destroy.

"Many days" passed, not less than three years, it would seem, before Paul ventured to return to Jerusalem. Part of this time was spent, as he tells us, in seclusion in Arabia. He felt that repose and meditation were needed that he might comprehend the nature of his vocation, and understand the relation between the old faith and the new. When, at last, he went back to the scene of his Pharisaic exploits, although the distrust of the disciples was overcome, the enmity of his former coreligionists was inflamed, and he was forced to flee to his home in Tarsus. Here he tarried, we know not how long, perhaps preaching Christ in the synagogues of Cilicia. After a while a remarkable interest in the story of the Gospel was awakened in Antioch, and Barnabas, who had been commissioned to take the superintendency at that place and who had great confidence in Paul, sought him out at Tarsus and entered into active association with him in this work. Here for more than a year these two wrought side by side in the great Syrian capital, and here it was that the disciples, who became a great multitude, were first called Christians.

Missionary Journeys.—From Antioch Barnabas and Saul set forth upon the first of those missionary journeys which were to occupy the remainder of his active life. These journeys took him by sea many times across the Eastern Mediterranean and the Ægean, and by land through Syria and the whole of Western Asia and Southern Europe; in nearly every prominent city of Asia Minor and of Greece he preached the Gospel and established churches; his activity during these missionary years must have been prodigious. In the first of these journeys he was accompanied by Barnabas and Mark, later by Silas and Timothy and Luke, the writer of the Acts of the Apostles. His practice on entering any city was to put himself first in communication with the synagogue of the Jews, and to impart to them his message; if they would not receive it he turned to the Gentiles. His success in gathering converts and establishing churches, when measured by the standards of modern missionaries, was certainly phenomenal. In Ephesus, in Thessalonica, in Athens, in Corinth he heralded the Gospel, sometimes to groups gathered in the market-places, sometimes to assemblies of philosophers, sometimes in little companies assembled in some hospitable home.

Arrest in Jerusalem.—On his return from his third missionary journey he was arrested in Jerusalem on the charge of profaning the temple, and was only saved by Roman officers from destruction by the mob. After a tedious imprisonment he appealed to the emperor's court, and so at last was forwarded as a prisoner to Rome, where for two years he awaited trial, dwelling in his own hired house, "receiving all that went in unto him, preaching the kingdom of God, and teaching the things concerning the Lord Jesus Christ with all boldness, none forbidding him" (Acts xxviii. 31). This is the end of all historical record concerning the apostle. There are many conjectures and traditions respecting his future career, and inferences from some of his epistles make it probable that his first trial resulted in an acquittal; tradition says that he then set forth upon another missionary journey, which was interrupted by his arrest and his second imprisonment at Rome, where he finally suffered martyrdom. All these rest upon very uncertain foundations.

The trustworthy records of Paul's life are found only in the Acts of the Apostles and in his epistles. (See Pauline Epistles, The.) Of the latter, thirteen in the New Testament are ascribed to him, not counting the Epistle to the Hebrews; nearly one-fourth of the bulk of the New Testament literature is supposed to have come from his pen. The authorship of some of these epistles is, however, in dispute. From the letters whose genuineness is unquestioned we may have the substance of his doctrine. Paul was the philosopher of the apostolic group; it is to him that we chiefly owe the reasoned statement of the principles of Christianity.

Doctrine.—Paul's doctrine is, moreover, largely the product of his own experience; what he teaches he has verified. He knows that neither perfection nor peace can be won by "the deeds of the law"; that neither in obedience to an external rule nor to the ethical imperative is the way of life revealed. The effort after self-perfection only emphasizes the self; when our thought is fixed upon our own performance, we miss, through our self-consciousness, the beauty of holiness. By the deeds of the law shall no flesh be justified. It is only when the soul goes out of itself in unselfish devotion to some worthy object that it finds life. When the man who has been struggling after perfection by obedience to the law learns that the struggle is hopeless, and surrenders himself to Him who in his own person reveals the law of the spirit of life, he passes from bondage to liberty, from death to life. Thus Christ is the end of the law for righteousness to every one who believeth; the perfection that we miss by aiming at it, we win by an unselfish trust in Him who is the revelation in human form of the divine perfection. It is impossible here to present, even in outline, the various analogies under which Paul seeks to express these sublime truths. His glowing metaphors have often been hardened into dogmas, but it has been impossible to suppress the life that pulsates through all his writings; after the Christ, in whom and for whom he lived, he is the one incomparable teacher of Christendom.

The First Reformer.—He is also the first of the Christian reformers; but for him the apostolic church would have been only a modified type of Judaism. The other apostles were strongly inclined to insist that no man could become a Christian without first becoming a Jew. It was Paul who demolished this barrier and opened the door of the Christian fellowship to the Gentile world. No more daring innovation was ever attempted. The victory which was won for Christian liberty in the council of Jerusalem, under the leadership of Paul, was one of the most illustrious and beneficent in Christian history. From this time his commission as the apostle to the Gentiles was unquestioned, and the truth "that the Gentiles are fellow heirs and fellow members of the body of Christ and fellow partakers of the

promise in Christ Jesus through the Gospel" was once for all established as the Christian doctrine.

LITERATURE.—Of books devoted to the life of Paul, a few of the most accessible are Conybeare and Howson's *The Life and Epistles of St. Paul*; Farrar's *The Life and Work of St. Paul*; Lewin's *The Life and Epistles of St. Paul*; and Stalker's *The Life of St. Paul*. Of books in foreign languages, some of the more important are Neander's *History of the Planting and Training of the Christian Church*; Baur's *Paul the Apostle of Jesus Christ*; and Renan's *The Apostles* and *St. Paul*. WASHINGTON GLADDEN.

Paul, Saint VINCENT, de: b. at Pony, Gascony, Apr. 24, 1577, in humble circumstances; received his first instruction from the Franciscan friars at Acqs; studied afterward at Toulouse: took holy orders in 1600, and was captured in 1605 by pirates on a voyage from Marseilles to Narbonne, and carried as a slave to Tunis. In 1607 he succeeded in making his escape; visited Rome and then Paris; was appointed chaplain to the ex-queen Margaret of Valois, and in 1622 chaplain to the galleys at Marseilles; repaired in 1627 to Paris, where he developed an extraordinary activity in the establishment and management of charitable institutions, hospitals, asylums, etc., and in the foundation of religious fraternities, the Lazarists, the Sisters of Charity; was a member of the "council of conscience," by which all ecclesiastical preferments were distributed. D. at St. Lazare, Sept. 27, 1660. He was a man not only of great religious and philanthropic zeal, but also of wonderful knowledge of human nature, great practical tact, and unflagging energy. His order of the Priests of the Mission, confirmed by Parliament in 1631 and settled in the house of St. Lazarus in 1632, was not immediately successful, but became eventually an institution of great importance. He was beatified by Benedict XIII. in 1729, and canonized by Clement XII. in 1737. His *Maxims and Counsels for Every Day in the Year* appeared in English translation (London, 1884). There are numerous *Lives* of the saint, e. g. in French by A. Loth (Paris, 1879) and Jean Morel (1884); in English by C. A. Jones (London, 1873).

Paul: the name of several popes. PAUL I., a Roman, succeeded his brother, Stephen III., in 757, and died at Rome, June 28, 767. He was an able prelate, and strengthened the papal authority in spite of its numerous enemies.—PAUL II. (*Pietro Barbo*), b. at Venice, Feb. 26, 1418; became a cardinal in 1440; was chosen in 1464 to succeed Pius II. He is especially noted for his hostility to the spirit of the Renaissance and his persecution of the humanists. He preached a crusade against George Podiebrad, King of Bohemia, who favored the Hussites. D. at Rome, July 28, 1471.—PAUL III. (*Alessandro Farnese*), b. at Canino, Feb. 29, 1468; succeeded Clement VII. as pope in 1534. He pursued with address and vigor his two chief aims in life, the aggrandizement of the Farnese family and the suppression of heresy. Among the prominent events of his important pontificate were the publication of a brief condemning slavery in 1537, the excommunication of Henry VIII. of England 1538, the approval of the order of Jesuits 1540, and the convocation of the Council of Trent 1545. D. at Rome, Nov. 10, 1549.—PAUL IV. (*Giovanni Pietro Caraffa*), b. at Capriglio, June 28, 1476; became Archbishop of Chieti 1507; was nuncio to London, and later had a high public office at Madrid; became Archbishop of Brindisi 1518; founded the Theatines 1524; became cardinal 1536; succeeded Marcellus II. as pope 1555; joined France in the war for the conquest of Naples from Spain 1555–57; strove for the elevation of his family, and his impolitic course regarding England and Germany strengthened the Protestant cause. He was bitterly hated by the common people of Rome on account of his austere rule. D. at Rome, Aug. 18, 1559.—PAUL V. (*Camillo Borghese*); b. at Rome, Sept. 17, 1552; became legate to Spain and cardinal 1596; succeeded Leo XI. as pope 1605. This pontificate was marked by the interdict laid upon Venice, the close of the Molinist controversy, the establishment of the Congregation of the Oratory and the orders of the Ursulines and the Visitation, and by great activity in the work of missions in heathen regions. D. at Rome, Jan. 28, 1621.

Paul: Czar of Russia; b. at St. Petersburg, Oct. 2, 1754; was the son of Peter III. and Catherine II.; succeeded to the throne on Catherine's death in 1796. He immediately set about to reverse her policy in every particular. His reign began well. Kosciusko and the other Polish prisoners were liberated and treated with generosity. In 1799–1800 his troops served in Italy and Switzerland against France; but in 1800 he changed sides, embraced the cause of Napoleon, and challenged to personal combat any prince who refused to join him in a league against Great Britain. Meanwhile the pucrilities and tyrannies of his rule begot a strong popular discontent, and he was murdered in his bed-chamber by his nobles, Mar. 24, 1801. Paul had some generous qualities. His own family he treated with a kindness before almost unknown in the Russian imperial house. He intended, it is said, to give Poland her freedom and autonomy; but his feeble intellect, his scanty education, and an absurd and almost insane self-conceit led him into many acts of tyranny.

Paul, powl, HERMANN, Ph. D.: philologist; b. at Salbke, Magdeburg, Prussia, Aug. 7, 1846: studied in Berlin and Leipzig; lectured in the University of Leipzig 1872–74; became professor at Freiburg, Baden, in 1874. He has published: *Ueber die ursprüngliche Anordnung von Freidanks Bescheidenheit* (1870); *Zur Kritik und Erklärung von Gottfrieds Tristan* (1872); *Gab es eine mittelhochdeutsche Schriftsprache?* (1872); *Zur Nibelungenfrage* (1877); *Untersuchungen über den germanischen Vocalismus* (1879); *Principien der Sprachgeschichte* (1880); *Mittelhochdeutsche Grammatik* (1881); an edition of *Gregorius*, by Hartmann von der Aue (1873); *Altdeutsche Textbibliothek* (1882, *sqq.*); *Beiträge zur Geschichte der deutschen Sprache und Literatur* (1874–91); *Grundriss der germanischen Philologie* (1889, *sqq.*).
BENJ. IDE WHEELER.

Paulding, JAMES KIRKE: author; b. in Pleasant Valley, Dutchess co., N. Y., Aug. 22, 1779. He received a scanty training in school, and in early life removed to New York, where his sister had married William, an elder brother of Washington Irving, with whom he became associated in the authorship of *Salmagundi* (1807), but the second series of *Salmagundi* (1819) was by Paulding alone; became in 1814 secretary of the board of navy commissioners; was navy agent at New York city from 1825 to 1838, and was Secretary of the U. S. Navy 1838–41; was a facile essayist and humorist, and author of numerous works, among which were novels, political pamphlets, poems, etc. The best of his writings are *The Dutchman's Fireside* (1831), a novel, and a *Life of Washington* (1835). D. at Hyde Park, N. Y., Apr. 6, 1860. Revised by H. A. BEERS.

Paulding, JOHN: b. in New York, 1758; served through the Revolutionary war, being three times taken prisoner; was one of the captors of Maj. André, for which service he received from Congress a silver medal, inscribed on one side "Fidelity" and on the other "Vincit Amor Patriæ," and was granted an annuity of $200. D. at Staatsburg, N. Y., Feb. 18, 1818. A monument to his memory was erected at Peekskill over his remains in 1827 by the corporation of the city of New York, and his name has been given to one of the northwest counties of Ohio, his companions, Van Wart and Williams, having been similarly honored.

Pauli, pow'lĕĕ, GEORG REINHOLD: b. in Berlin, Germany, May 25, 1823; studied philology and history at Berlin and Bonn; lived in Great Britain from 1847 to 1855, and was appointed Professor in History at Rostock in 1857, at Tübingen in 1859, at Marburg in 1867, and at Göttingen in 1870. Besides several minor essays on various subjects, and some larger works relating to the history of England, he wrote *König Alfred und seine Stellung in der Geschichte Englands* (Berlin, 1851; Eng. trans. by Thomas Wright, London, 1852) and *Bilder aus Alt-England* (Gotha, 1860; Eng. trans. by E. C. Otté, London, 1861). The sharp criticism to which he subjected the policy of the government of Würtemberg in a review in the *Preussische Jahrbücher* (1866) occasioned his removal from Tübingen to Marburg. D. June 3, 1882.

Pauli'cians: a dualistic sect of the Eastern Church, which originated in Armenia in the middle of the seventh century, in the village of Mananalis, near Samosata, where lived Constantine Silvanus, its founder, and preached in that locality from 657 till 684, when he was stoned for heresy. Our knowledge of the sect comes from their enemies, and is defective as well as vitiated by prejudice; but it seems to be proved that they were dualists; held that the soul proceeded from God but the body from the evil one; denied the perpetual virginity of Mary, and opposed Mariolatry, the doctrine of the atonement, and the Church view of the sacraments. Their founder had put an inordinate value upon the Pauline epistles, and so did his followers.

They also had in their canon the four Gospels, the Acts, the Epistles of James, John, and Jude; but they rejected the Epistles of Peter, because he had opposed Paul, the Revelation, and all the Old Testament. They were zealous for the Scriptures, and held in honor those among them who were their copyists and circulated these copies. They had no sacerdotal caste, but pastors and teachers, and were devout Bible students. After their founder their great man was Sergius, murdered for his faith's sake (835). After it had spread quietly in Armenia for about two centuries, though now and then persecuted by the Byzantine emperors, the Empress Theodora (842–857) undertook to suppress the sect. More than 100,000 are said to have been put to the sword, and the rest were exiled. Some fled to the Saracens, others to the Bulgarians, and in Bulgaria remnants of the sect were found as late as the sixteenth century. In the thirteenth century Paulician ideas were introduced into Europe by those who returned with the crusaders, and such sects as the Cathari and Bogomiles had Paulician elements.

SAMUEL MACAULEY JACKSON.

Pauline Congregation: See PIARISTS.

Pauline Epistles, The: letters written to churches and individuals by the apostle Paul.

1. *Number, Order, and Date.*—It is the common opinion that thirteen of these epistles have been preserved to us. From about the fifth century to the Reformation era the Epistle to the Hebrews was also reckoned as a Pauline epistle, making fourteen. This opinion arose in the Eastern Church, and at length became prevalent chiefly through the great influence of Jerome and Augustine. In the early centuries of the Christian era the epistle was not held to be Pauline by the Fathers of the Latin or Western Church. Clement of Rome quotes it, but does not refer it to Paul. Neither Irenæus nor Hippolytus quotes it as Paul's, and Tertullian ascribes it to Barnabas. Two considerations—one negative, the other positive—seem decisive against the Pauline authorship of Hebrews. (*a*) The epistle does not purport—as do all other alleged Paulines—to have been written by Paul. (*b*) The language, style, and modes of thought are characteristically different from Paul's.

The common view respecting the order and approximate dates of the epistles may be shown by the following grouping, which is not only chronological but according to their subject-matter: I. *The earlier or missionary epistles*, 1 and 2 Thessalonians, written at Corinth during A. D. 52 or 53. II. *The great doctrinal epistles*: Galatians, written at Ephesus within the period 54–57; 1 Corinthians, written at Ephesus in 57 or 58; 2 Corinthians, written in Macedonia in 57 or 58; Romans, written at Corinth, A. D. 58 or 59. III. *The epistles of the imprisonment*: Colossians, Philemon, Ephesians, Philippians, commonly believed to have been written during the apostle's Roman imprisonment during the years 62–63. IV. *The Pastoral Epistles*: 1 Timothy and Titus, written in Macedonia, and 2 Timothy, written during a second Roman imprisonment, shortly before the apostle's martyrdom. The date of this group is supposed to be 67 or 68.

Several points in this grouping have been called in question by competent scholars who accept the Pauline authorship of all thirteen letters. By some (as Bleek, Davidson, Conybeare and Howson, and Lightfoot) Galatians is placed third, instead of first, in the second group. On this view it was written in Corinth, probably during 57 or 58. Bishop Lightfoot gives as reasons for this view: (*a*) Galatians most closely resembles 2 Corinthians in its personal and apologetic elements and Romans in its doctrinal method and content, and thus naturally falls between them. (*b*) The development of Judaizing opposition to Paul best accords with this order. (*c*) This order corresponds to the development of doctrine. (See Lightfoot's introduction in his *Commentary on Galatians*, pp. 36–56.) While these arguments are not very cogent, they are perhaps as much so as that for the earlier date, which is based upon the rather indefinite expression in Gal. i. 6, "I marvel that ye are *so quickly* removing from him that called you," etc.

Many distinguished German scholars held that the first three epistles of the third group were written during Paul's imprisonment at Cæsarea (Acts xxiii. 23, xxvi. 32). The ingenious arguments by which this theory is supported may be found in full in Meyer's *Commentary on Ephesians*, Introduction, § 2. This view has found little favor with English scholars.

Bishop Lightfoot maintained that Philippians was the earliest of the *epistles of the imprisonment* on the following grounds: (*a*) Philippians stands apart from the other three in spirit and matter. (*b*) It reflects the state of Paul's mind which is illustrated in Romans and in 1 and 2 Corinthians. (*c*) Colossians and Ephesians are more nearly related to the *pastoral epistles* than is Philippians (see Lightfoot's dissertation, *Order of the Epistles of the Captivity*, in his *Commentary on Philippians*, pp. 30–46); but the progress of the Gospel at Rome, which had penetrated even the emperor's household (iv. 22), the Philippians' knowledge of Paul at Rome, the sending of Epaphroditus, his labors, sickness, etc., would point to a later time of writing, as would also the fact that Paul was more confident of release (ii. 24) than when Colossians and Ephesians were written, and so was, presumably, nearer to it.

Incidental allusions to lost epistles of Paul are found in 1 Cor. v. 9, and Col. iv. 16. These passages, according to their most natural interpretation, show that Paul wrote a letter to the Corinthians (antedating our 1 Corinthians), and that at the time when he wrote to Philemon and to the church at Colossæ he also wrote an epistle to the neighboring church at Laodicea. Some discern in passages like 2 Cor. ii. 4 and vii. 8, 9, allusions to a letter to the Corinthians intermediate between 1 and 2 Corinthians. General allusions to the frequency with which Paul wrote private letters, only one of which—that to Philemon—is extant, are found in 1 Cor. xvi. 3, 2 Cor. x. 10, and 2 Thess. iii. 17.

2. *Occasion and Aim.—1 Thessalonians.*—The narrative of the founding of the Church at Thessalonica is found in Acts xvii. 1–9. Some Jews, many women of noble birth, and many proselyte Greeks, accepted the Gospel, but Jewish opposition at length drove the apostle and his assistants from the city. Paul was eager to revisit his converts, and had twice purposed to do so, but had been hindered (ii. 18). When he could no longer restrain his anxiety to hear from them, he sent Timothy (from Athens, where they were at that time; cf. Acts xvii. 15) to encourage them and learn their state. Meanwhile Paul went on to Corinth. There Timothy joined him and brought his report concerning the Church. This report was the occasion of the epistle. Though faults and errors were to be corrected, their progress and patient endurance of persecution gave Paul great joy. The keynote of the letter is "Now we live, if ye stand fast in the Lord" (iii. 8).

2 Thessalonians.—In 1 Thessalonians Paul had encouraged his converts to endure their trials with patience by expressing the hope of the Lord's speedy return (iv. 16, v. 2). This expectation—fostered chiefly by a letter falsely purporting to have been written by Paul, ii. 2—became the occasion of developing a fanatical spirit among the Thessalonians. So near did they think the *parousia* to be that they abandoned their occupations (ii. 1–12, ii. 15, iii. 10–12). Paul wrote the epistle to rebuke this spirit, to urge them to resume their employment, and to divert their attention to certain events which should precede the *parousia* (see ii. 1–12).

Galatians.—The occasion of this epistle is found in the presence in the Galatian community of Jewish-Christian teachers who insisted that Gentiles who became Christians must also become Jews, that is, be circumcised and keep the Old Testament law as such. It is generally thought that these Judaizers had come from Palestine (so Meyer); others (as Neander) suppose that they were partly from Judea and partly native to Galatia, and still others (as Weiss) maintain that they were connected with Jewish-Christian congregations which had been gathered in Galatia previous to Paul's founding the Gentile-Christian churches in the province. No data exist for settling this question. Whoever these persons were, it is certain that they did not comprehend the newness and completeness of Christianity; it was to them but an appendix or supplement to the Old Testament system. Paul was the champion of the opposite view. For him Christianity was complete in itself and those who accepted it were not under the law. His opponents' position was contrary to the decision of the apostolic conference held at Jerusalem (Acts xv., Gal. ii.) at which the most conservative primitive apostles, Peter, James, and John, had approved his teaching and disclaimed any desire to supplement or change it.

1 Corinthians.—From v. 9 it appears that Paul had written to the Corinthians an earlier letter than 1 Corinthians. There are hints in v. 10, vii. 1, viii. 1, xii. 1, xvi. 1, and xvi. 12 of a letter from them to the apostle in return. The inquiries contained in this letter, and the condition of the

Corinthian church which they revealed, were the occasion of the epistle. An additional occasion lay in the report which Paul had received concerning divisions among them from the slaves of a certain Corinthian woman, Chloe (i. 11). These party rivalries seemed to the apostle more important than the inquiries contained in the letter of the Corinthians, for he takes up that subject first and devotes to it a large share of the epistle.

2 Corinthians.—It is impossible to determine with certainty the events which intervened between the two Corinthian epistles. It is certain, however, that opposition to Paul had increased in the Church. The Jewish-Christian portion—probably the Christ-party, especially—had accused him of fickleness, double-dealing, and cowardice, and had cast suspicion upon his character and apostleship. The aim of the epistle was to refute these calumnies, and to vindicate himself as a man and as an apostle. In chapters. i.–viii. Paul addresses himself more to the faithful majority, and in the latter part of the epistle turns more directly to the hostile Judaizers—the "false" or "exceeding apostles"—the extremists who had come to Corinth with letters of recommendation from Palestine.

Romans.—The occasion of this epistle is not clear, and many theories respecting it have been advanced. Baur regarded it as a polemic against Jewish Christianity; Schwegler as a defense of Paul's doctrine; Weizsäcker as intended to fortify Christians against attacks upon their faith in the future; Weiss as an attempt to draw up a statement of his doctrine of salvation, defending it on all sides against objections. Some combination of these views seems necessary. There are large polemic and apologetic elements in the epistle, and the protection of his converts against attacks upon their faith by Judaizers and the commendation of his doctrine to the favorable consideration of Jewish Christians may have been subordinate motives in writing. We may state his main object thus: To present a fuller exposition and defense than he had yet made of his "gospel" in contrast to Judaizing teaching and in its application to the Christian life. The growing importance of the Roman Church, by reason of its size and position, would furnish a sufficient reason why he should address the letter to them, although he had not founded the Church and had never even visited it.

Colossians.—This epistle was written to combat the errors which certain false teachers were introducing into the churches of the Lycus valley. The heresy appears to have been a sort of Jewish eclecticism which combined some of the tenets of the Essenes with Gnostic speculations. Its leading characteristics were: (*a*) Asceticism, a self-imposed subjection to ordinances and severity to the body (ii. 16–23). (*b*) Notions akin to the Gnostic doctrine of æons; theories of intermediate agents (angels) between God and the world (ii. 9. 10, 18). (*c*) An over-emphasis of an alleged knowledge on the part of its adherents (ii. 8–10, 18; cf. i. 9, 15, 16, 26, ii. 2, 10, 19). The tendency of this speculation was to degrade Christ to the rank of a creature, and to substitute ascetic rigors for trust in divine grace. In opposition to these false views Paul insists on the headship of Christ over the world and its powers, and upon the sole sufficiency for salvation of his person and work.

Philemon.—This is a private letter written at the same time as Colossians, and addressed to a Colossian Christian and friend of the apostle (Philemon). It is written to commend Onesimus, a slave of Philemon, who had stolen from his master and gone to Rome. There he met Paul and became a Christian. Paul sends him back to his master with a cordial commendation of his changed character. He reminds Philemon that he owes his own conversion to himself, and entreats him to receive his former servant as a Christian brother.

Ephesians.—No definite occasion for this epistle can be confidently assigned. By many critics it is regarded as an encyclical letter designed for a group of churches; by others it is believed to be the epistle to the Laodicean Church alluded to in Col. iv. 6. The omission of the phrase "in Ephesus" (i. 1) in the best MSS. strongly favor the first view, although it is not easy to explain satisfactorily the remaining words on the supposition of this omission. Perhaps a blank space was originally left in order that the name of the particular place where the letter was read might be inserted. The epistle resembles Colossians most nearly in scope and contents. Certain differences may, however, be noted: (*a*) Ephesians treats more of redemption in general (soteriology); Colossians of the Redeemer personally (Christology). (*b*) Ephesians aims at edification and education; Colossians at the refutation of heresy. (*c*) Ephesians treats more of the relation of Christ to the Church; Colossians of his relation to the universe. (*d*) In Ephesians the pre-eminence of Christ is made to depend more upon the divine will; in Colossians more upon his metaphysical nature.

Philippians.—When Paul was a Roman prisoner the Philippian Church, to which he was especially attached, sent one of their number, Epaphroditus, to supply his wants. This epistle is a letter of thanks for the gift, but it goes beyond its primary purpose and gives information concerning himself, adding warnings and advices for their benefit. It is the warmest and most affectionate of all Paul's letters.

The Pastorals.—These letters are addressed to the trusted helpers of the apostle, Timothy and Titus, to encourage and aid them in their work in Ephesus and Crete respectively. In them he has no occasion to deal with definitions or defenses of the Gospel. He urges the evangelists to adhere to "sound doctrine" and to avoid certain current speculations as unprofitable. These tendencies are characterized as a "different doctrine" (1 Tim. i. 3) from his own, and as dealing with Jewish fables, endless genealogies, and strivings about the law (Tit. 3, 9, 1 Tim. i. 4). We can not identify these speculations with the tenets of any particular sect.

3. *Criticism.*—F. C. Baur (1792–1860), the founder of the Tübingen school, admitted but four epistles (Galatians, 1 and 2 Corinthians, and Romans) as genuine. The others were rejected on grounds of internal evidence. The great doctrinal letters were made the standard of genuineness, and variations from these in style and contents were regarded as evidence of spuriousness. Since Baur's time, however, the tendency among the adherents of his school has been toward the admission of some of the discredited epistles as genuine. Holtzmann, Pfleiderer, and S. Davidson, for example, concede the genuineness of 1 Thessalonians and Philippians, and admit Pauline elements in 2 Thessalonians and Colossians. The pastoral epistles are most widely rejected on the following grounds: (*a*) There is no place for them in Paul's known life. (*b*) The errors combated in them belong to the post-apostolic age. (*c*) The church organization which they reflect is more highly developed than that found in the apostolic age. It is answered: (*a*) The Acts breaks off abruptly; Paul expected to be released from his imprisonment (Phil. ii. 24), and early tradition represents this to have been the fact. A place may thus be found for those letters in the apostle's last years. (*b*) The errors of the pastorals show no close affinity to the Gnosticism of the second century. (*c*) The only church officers in the pastorals are presbyter-bishops and deacons (as in Philippians).

In recent years a school has arisen which rejects even the four "undisputed" epistles. The chief representative of this type of criticism is Rudolf Steck, a Swiss professor. His theory of the history of the apostolic age is the opposite of that propounded by the Tübingen school. He maintains that the sharp opposition between the principles of faith and works, or grace and merit, which the doctrinal letters reflect, would develop only slowly and late, and therefore the writings in which this conflict of principles is presented must fall within the post-apostolic age. He places these writings in the second century. In opposition to this theory both the critical and the conservative schools agree in maintaining that the sharpest conflict of opposing principles is experienced in the early stages of a controversy, and that the development is toward adjustment and reconciliation. The extra-canonical literature of the second century shows no such contrast of Pauline and Judaizing Christianity as is illustrated in Galatians and Romans. Steck's theory reverses the common order of history, and is contrary to all the evidence which bears upon the progress of the controversies between the Gentile-Christian and the Jewish-Christian branches of the Church.

LITERATURE.—Only a select bibliography of recent literature can here be given. The works referred to are, in most instances, such as treat of the literary and historical questions connected with Paul's epistles rather than of his life in general or of his theology. F. C. Baur's *Paulus, u. s. w.* (Stuttgart, 1845; 2d ed. Leipzig, 1866–67), marks an epoch in the criticism of the Pauline epistles. More recent German treatises are largely taken up with the problems so boldly raised and discussed in this work. Many recent critics still follow Baur's method, and in part adopt his

arguments, while modifying more or less his premises and conclusions. S. Davidson's *Introduction to the New Testament* (3 vols., 1848–51; 3d ed. 2 vols., London, 1894) is conservative in the first edition; the second and third reproduce largely the Tübingen criticism. E. Renss's *Geschichte d. Heiligen Schriften d. Neuen Testament* (Halle, 1842; 6th ed. 1887; Eng. trans. Edinburgh, 1 vol., 1884; Boston, 2 vols., 1884) is a critical summary and history of opinion with ample references to the literature. P. J. Gloag's *Introduction to the Pautine Epistles* (Edinburgh, 1874) is a conservative summary and review of opinions. In H. A. W. Meyer's *Commentary on the New Testament* (various editions; Am. ed. New York, 1884–86) the introductions to the epistles are elaborate and conservative treatises. Those on the pastorals are written by Meyer's continuator, Huther, who maintains their genuineness, as Meyer did not. Meyer held to the genuineness of all the other epistles. J. B. Lightfoot's introductions and dissertations in his *Commentaries on Galatians* (8th ed. London, 1884), *Philippians* (8th ed. 1885), and *Colossians and Philemon* (9th ed. 1890), are of the highest value. The dissertations are published separately in a volume entitled *Dissertations on the Apostotic Age* (London, 1892). A. Sabatier, in *L'Apôtre Paut* (Paris, 1881; Eng. trans. New York, 1891), gives a vivacious treatment of Paul's letters in their historical setting, unfavorable to the pastorals. The English translation contains an essay *per contra* by the translator, G. G. Findlay. *Das Urchristenthum, u. s. w.* (Berlin, 1887,) and *Der Paulinismus* (Leipzig, 1873; 2d ed. 1890), by O. Pfleiderer, discuss the Pauline literature in the spirit and method of Baur, with important modifications, however, in detail. H. J. Holtzmann's *Einleitung in das Neue Testament* (Freiburg, 1885; 2d ed. 1886) is a history and summary of opinions from the standpoint of the "critical" school. B. Weiss's *Lehrbuch d. Einteitung in d. Neue Testament* (Berlin, 1886; 2d ed. 1889; Eng. trans. 2 vols., Edinburg, 1888, and New York, 1889), critical but conservative, is the best manual at present available in English. *An Introduction to the New Testament*, by M. Dods (New York, 1888), is a brief presentation of the main results of criticism. F. Godet's *Studies in the* (Pauline) *Epistles* (London, 1889) are popular essays, conservative in tone. *The Epistles of Paut the Apostle*, by G. G. Findlay (London, 1892), and J. R. Lumby's *Popular Introduction to the New Testament* (London, 1883) are both excellent manuals for popular use. In vols. ii. and iii. of the *Hand-Commentar zum Neuen Testament* (4 vols., Freiburg, 1891) are found elaborate introductions (by Schmiedel, Lipsius, and von Soden) on the Pauline letters. They are written from the critical point of view, and account is taken of the latest discussions. F. Godet's *Introduction au N. T.*, vol. i., *Les Épitres de S. Paul* (Paris, 1893), contains a history of the criticism of the Pauline epistles from the first century to the present time. The standard treatise of the modern radical criticism is *Der Galaterbrief nach seiner Echtheit untersucht* (Berlin, 1888), by R. Steck. The opinions of Steck are shared more or less fully by certain Dutch theologians, as Loman, van Manen, van Loon, and Völter. For a review and critique of these views, see Lipsius, *Hand-Commentar, Einleitung zu Gal.*, pp. 8, 9; Pfleiderer, *Der Pautinismus* (2d ed.), pp. 34–38; A. C. Zenos in the *Presbyterian Review* (Jan., 1891); and Knowling, *The Witness of the Epistles*, ch. iii. (London and New York, 1892). GEORGE B. STEVENS.

Pauli'nus, MEROPIUS PONTIUS ANICIUS: a Latin writer from Gaul; b. in Burdigala (Bordeaux) in 353; pupil of Ausonius, and through his influence made consul suffectus before 379. In 389 he was converted to Christianity, and in 409 made Bishop of Nola in Campania, which office he held until his death in 431. Hence he is commonly called Paulinus Nolanus. His extant works consist of some fifty letters and thirty-six poems in various meters, which show considerable culture and poetic feeling, with reminiscences of Horace, Vergil, Lucan, and Juvencus. The best account of his Christian poetry is given by Manitius, *Geschichte der Christlich-lat. Poesie*, pp. 261–297. See Migne, *Patrol.*, vol. lxi. A critical edition is promised by Hartel for the Vienna *Corpus Script. Eccles. lat.* M. WARREN.

Paulist Fathers, or **The Congregation of St. Paul the Apostle**: a missionary society of priests in the Roman Catholic Church, founded in 1858 by Rev. Isaac Thomas Hecker, and approved by Pope Pius IX. They are chiefly men who have abandoned Protestantism. The motherhouse is in New York.

Paullinia sorbilis: See GUARANA.

Paulo Affonso Cataract: See SÃO FRANCISCO RIVER.

Paulown'ia imperia'lis: scientific name of a fine tree of the family *Scrophulariaceæ*, a native of Japan. It has something the habit of a catalpa, the leaves being large and heart-shaped, the branches being crooked and nearly horizontal; the flowers are in large clusters of a pale-violet color, and precede the leaves. The tree rarely exceeds 40 feet in height, and its trunk is usually less than a foot in diameter. In the U. S. it is hardy as far N. as New York. The luxuriant growth and great heavy leaves make it a desirable tree for many effects in landscape-gardening.

Paulsen, powl'sen, FRIEDRICH, Ph. D.: professor of philosophy and pedagogy; b. in Langenborn, Schleswig, July 16, 1846; educated in the common schools of his native town, the gymnasium in Altona, and the Universities of Erlangen and Berlin; privat docent 1875–78, extraordinary professor 1878–93, and Professor of Philosophy since the autumn of 1893 in the University of Berlin. In philosophy Paulsen is classed with the new-school Kantians. His published works and numerous magazine articles give him a foremost rank among German philosophers, but no less important are his contributions to the history of pedagogy. In respect to secondary and higher education he is a recognized authority. His principal works are: *Versuch einer Entwicketungsgeschichte der Kantischen Erkenntnisstheorie* (1875); *Geschichte des gelehrten Unterrichts auf den deutschen Schulen und Universitäten, vom Ausgang des Mittetatters bis auf die Gegenwart* (1885); *System der Ethik* (1889; 3d ed. 1894); *Einteitung in die Philosophie* (1892; 3d ed. 1894); *Wesen und Geschichte der deutschen Universitäten* (in the work edited by Lexis, *Die deutschen Universitäten*, 1893). J. E. RUSSELL.

Paulus, pow'lōos, HEINRICH EBERHARD GOTTLOB: theologian; b. at Leonberg, near Stuttgart, Würtemberg, Sept. 1, 1761; studied Oriental languages and theology at Tübingen, Göttingen, London, and Paris, and was appointed Ordinary Professor of Oriental Languages in 1789 at Jena, in 1803 at Würzburg, director of the department of public worship and education in 1808 at Bamberg, in 1809 at Nuremberg, in 1811 at Ansbach, but moved in the same year as Professor of Exegesis and Ecclesiastical History to Heidelberg, where he died Aug. 10, 1851. He was one of the most prominent representatives of the rationalistic theology in its historico-critical phase. Among his numerous works are *Clavis über die Psalmen* (Jena, 1791, Heidelberg, 1815); *Clavis über Jesaias* (1793); *Kommentar über das Neue Testament* (but it only goes to John xi.; Lübeck, 4 vols., 1800–04; 2d ed. 1804–05); *Leben Jesu* (2 vols., 1828); *Exegetisches Handbuch über die drei ersten Evangelien* (3 vols., Heidelberg, 1830–33; 2d ed. 1841–42). He edited Schelling's *Vorlesungen über die Offenbarung* (1843), which implicated him in a lawsuit. He wrote a partial autobiography, *Skizzen aus meiner Bildungs- und Lebensgeschichte* (Heidelberg, 1839), and left materials for a full biography, which were utilized by Prof. Reichlin-Meldegg under the title *H. E. G. Paulus und seine Zeit* (2 vols., Stuttgart, 1853).

Pau'lus, JULIUS: a celebrated Roman jurist, contemporary with Ulpian, who held under Alexander Severus in 222 the office of præfectus prætorio. He was a voluminous writer, and more than 2,000 excerpts from his works are contained in the digests. His most important work, *Ad edictum*, embraced eighty books. An abridgment of his *Sententiarum ad filium libri V.*, is extant. See Huschke *Jurisprudentiæ Anteiustinianæ quæ supersunt*, pp. 450–561 (Leipzig, 1886). M. W.

Paulus, LUCIUS ÆMILIUS, surnamed **Macedonicus**: soldier; b. at Rome about 230 B.C.; a son of the consul of the same name, who fell at Cannæ 216; was prætor in 191; commanded afterward as pro-consul in the province of Further Spain, where he put down a formidable insurrection and defeated the Lusitanians; was consul the first time in 181, and a second time in 168; censor in 164. D. in 160. During his second consulship he finished the third Macedonian war by his brilliant victory over Perseus at Pydna. The Romans did not at once appropriate the territory of their vanquished enemy, but divided the Macedonian empire into four districts with oligarchical governments under the protection of Rome. Revised by G. L. HENDRICKSON.

Pau'lus Diac'onus, or **Levi'ta**: historian; b. at Cividale, in Friuli, about 725; educated at the Lombard court at

Pavia; he was ordained deacon not later than 763; at the instigation of Adelperga, wife of the Duke of Benevento, he composed about 770 his *Historia Romana*, a continuation of the *Breviarium* of Eutropius. (See edition by Droysen, Berlin, 1879.) He entered the monastery of Monte Casino, whence he addressed a poem to Charlemagne in 781, setting forth in a touching manner the sufferings of his family in consequence of Charlemagne's confiscation of their estates as a punishment for his brother's rebellion. Charlemagne was so much interested in the poet that he summoned him to his court. There Paulus lived till 787, and there he collected his *Homiliarius*, which was often reprinted in the fifteenth and sixteenth centuries and translated into German and Spanish, and wrote his *Gesta Episcoporum Mettensium*, printed in Pertz's *Monumenta Germaniæ Historica*, vol. ii. (Hanover, 1827); made an abridgment of Festus's *De Significatione Verborum* (see FESTUS); returned to Monte Cassino in 787. D. there about 797. His last and most important work was his *Historia Langobardorum Libri VI.*, which ends at 744, containing many valuable traditions. The best edition is by G. Waitz (Hanover, 1878) in the *Monumenta Germaniæ Historica*. See Felix Dahn, *Des Paulus Diaconus Leben und Schriften* (Leipzig, 1876). Revised by M. WARREN.

Paulus Ægineta: Greek physician and author; b. in Ægina at an unknown date, but Abulfaragius places him in the seventh century A. D., which is probably correct. His *De Re Medica Libri Septem* had great influence among European and Arabian physicians in the Middle Ages, and several Latin and Arabic versions were made. Of the Greek text the edition of 1528 (Venice) and 1538 (Basel) are complete. The Sydenham Society published (London, 1847) an improved edition of Francis Adams's complete translation, with abundant notes, in three volumes 8vo. Several other works of Paulus are mentioned by old writers. See SURGERY. Revised by J. R. S. STERRETT.

Paul Veronese: See VERONESE.

Pauncefote, Sir JULIAN: British jurist and statesman; b. at Munich, Germany, Sept. 13, 1828; educated at Paris, Geneva, and Marlborough College; called to the bar at the Inner Temple 1852; attorney-general of Hongkong 1865; chief justice of Supreme Court in Hongkong 1869; knighted 1874; Assistant Under-Secretary of State for the Colonies 1874; Assistant Under-Secretary of State for Foreign Affairs 1876; became permanent Under-Secretary of State for Foreign Affairs 1882; British minister at Washington 1889; ambassador to U. S. 1893. C. H. THURBER.

Pauperism [from Lat. *pauper*, poor (> O. Fr. *paure*, whence Eng. *poor*)]: in a general sense, the settled condition of large masses of people, who are more or less dependent on the alms of the community for their support. In earlier ages slavery, which was almost universal, rendered public assistance for paupers almost unnecessary, because the master was expected to provide for his aged and invalid slaves, as well as to assume the cost of rearing the young, which, in some modern communities, imposes the greater part of the public burden for the poor; but wherever slavery began to be abolished by individual emancipation, or by the result of war, or by other causes, pauperism, in the modern sense, began to take its place; and this process went on for centuries, from the earliest period of authentic Grecian history, until the present age, when the most general emancipations have taken place. Again, the reduction of large masses of the free population to a state of dependence, by the extension of landed estates and the effect of long-continued warfare, especially under the Roman rule, gave occasion for the greatest development of public charity which the world has seen, during the later years of the Roman republic and the first three centuries of the empire. When the rural inhabitants of Italy lost the land which they had cultivated, because great landlords absorbed the small *prædia* of their neighbors, they at once became dependent for support either on the rich, as clients, or on the public. It was to supply the needs of this class that the *leges frumentariæ* (corn-laws) were passed, at first cheapening the price of grain, and afterward providing for its distribution from the public granaries among the free-born poor of Rome and the provinces. These corn-laws were in fact poor-laws, and they laid the foundation of a pauper system of great extent, and very demoralizing in its influence, which prevailed from the time of Sulla through the flourishing period of the empire. It is said that in the reign of the Antonines 500,000 persons received this donation from the public—a proportion to the whole estimated population much larger than has usually prevailed under the pauper systems of Great Britain, France, or the U. S.

The pagan times give many examples of charity, and after Christianity began to influence the world the better adherents of the old religion exalted charity, both public and private, in emulation of the Christian practice. Cicero (*De Legibus*, xiv.) had proclaimed philanthropy as the basis of justice, and the Emperor Julian, following Cicero, regarded charity as the most sacred of duties. Similar sentiments were expressed by Plato, Xenophon, Seneca, and other ancient writers, whose works prove that the distribution of alms and the relief of the infirm and invalid were virtues well recognized by the followers of the older religions, but it was left for Christianity to make them its basis and rule. The introduction of Christianity may have checked in some degree the growth of pauperism in its Roman form, but the establishment of monasteries and religious houses, and even of churches, increased the number of persons who lived by begging; and vagrancy and mendicity were everywhere common when the legislation of Western Europe first began to take notice of the growing evil. The first poor-laws of England and France were decrees or statutes against vagrancy and mendicancy; and when at the Reformation many monasteries were broken up, and the administration of the church funds in the parishes was changed, a great number of paupers who had been relieved by the clergy or their servants were thrown upon the civil authorities for support, restraint, or relief. Economical changes going on at the same time in the century from 1520 to 1620 caused the number of poor people in England to increase greatly. Hence the increasing frequency of poor-law legislation in England from 1540 to 1601, when the famous statute (43 Elizabeth) which forms the basis of the pauper system both in England and the U. S. was enacted. An attempt had been made as early as the reign of Richard II. to repress vagrancy by severe statutes, and a law of Henry VII. sent beggars not able to work back to the parish of their last residence. The able-bodied beggar had been treated as a criminal much earlier, and in 1531 the law required him to be whipped and sent back to his birthplace. A few years later the local officers of each parish were required to support poor and vagrant persons, at the same time compelling them to labor; while almsgiving on the street or at the house-door was forbidden, on pain of forfeiting ten times the amount given. A "sturdy beggar" was to be whipped for the first offense, for the second his right ear was to be cropped, and for the third he was to be sent to jail, and if convicted, to suffer death, but legislation grew gradually milder against this evil from the experience gained that severe penalties did not diminish it. Licenses were now permitted for beggars on condition that they begged only in their own parish and for food alone, and in the manner directed by the churchwardens and overseers. In the time of Charles II. the more modern condition of settled pauperism had begun to take the place of mendicant vagrancy. The poor-law of Elizabeth did indeed succeed in diminishing mendicancy, but it again appeared in alarming proportions.

Legislation in France was quite as severe as in England against vagrancy, and the result was much the same. When the cruel French laws, enacted before 1550, failed to check vagrancy and begging, the authorities, gradually discovering how useless such legislation was, in the seventeenth century made trial of more humane methods of repression. In 1627 the law required beggars to be forced into the service of commercial companies or into the French naval service, and to embark for the Indies. At the same time there were ordered to be founded in the different provinces "hospital workshops" or workhouses, which were the beginnings of the French system of "dépôts of mendicity." Again, in 1688, an ordinance was passed expelling every pauper and beggar from Paris, under penalty of being sent to the galleys. Nothing, however, seemed to check mendicity in France, and in 1698 it was calculated that one-tenth of the whole population of the country was reduced to beggary. In the eighteenth century, although the progress of manufacturing, industry, and commerce checked the evil, yet in 1790 a decree was passed ordering the opening of workshops for able-bodied beggars. The poor who were impotent or sickly were to be sent to the hospitals, and strangers to the kingdom were to be expelled. Another law organized workhouses and almshouses for ordinary beggars, while those were sentenced to transportation who persisted in begging

after their punishment, or who committed other offenses. Under the First Empire the principle seems to have been recognized that before punishing mendicity as an offense work must be offered. A decree of 1808 ordered that a workhouse or "dépôt of mendicity" be established in every department. In four years eighty of these were founded. Many complaints against them, however, arose on account of their large expenditures and their industrial competition with non-pauper laborers. It was hoped that these establishments would nearly support themselves by the labor of the inmates, but this proved illusory, and they gradually became refuges of incurables. Under the Restoration they were nearly all suppressed, and at present there are very few "dépôts of mendicity" in France. Several workshops were substituted for the "dépôts," and some provinces founded houses of refuge for beggars, but none of these succeeded. Thus during five centuries every species of penalty and punishment has been tried in vain in France to suppress mendicity. Humane legislation has been equally a failure, and the sum of experience in that country is that all legal means fail to reach this great evil.

Poor-laws and Pauperism in France.—The English poor-law of Queen Elizabeth has never been formally introduced in France, but pauperism has long existed there, and has been met by a system of public relief, somewhat different from the English "workhouse test." An eminent French economist, Émil Levasseur, in his great work on *Population* (finished in 1892), has much to say of public charity in France. Malthus, in 1818, declared that the division of landed property which took place in France at the Revolution, and was further promoted by the laws of inheritance then adopted, would turn France into a rabbit-warren of paupers. Instead of verifying this prediction, Levasseur shows that pauperism is proportionately much less under the third republic than under the first. The statistics cited by him are confessedly imperfect, but they establish this fact beyond doubt. Since 1850 France has had a much smaller percentage of paupers in its population than England, but more than Germany, with the exception of Prussia, in which pauperism seems to have been greater before the Franco-German war than in France. After an examination of the statistics of pauperism, Levasseur concludes: "It can not be argued that pauperism has increased in Paris during the last hundred years; the contrary is true. The growth of population, the increasing emigration from country to city, the attractive force of a great city on the pauper class, have not, as some writers conjectured, resulted in the aggravation of pauperism." He calls attention, however, to what has been noticed in all other cities and countries since 1791, adding: "What has increased is the cost of relieving the poor. In 1804 the revenue accruing to hospitals, infirmaries, charity bureaus, and the support of foundlings was less than 8,500,000 francs in Paris; but in 1887 the public charities of the city expended 52,658,000 francs. The increase of wealth has allowed Paris to furnish more efficacious relief, to take care of the sick poor in their homes, to procure for them greater comforts in the hospitals, to establish sanitary measures which have decreased the death-rate, to watch with more solicitude over the education of neglected children, to ameliorate the management of infirmaries, and to give an easier existence to old people and chronic invalids." An earlier French writer, Baron, who in 1882 published an elaborate work on French pauperism (*Le Paupérisme, ses Causes et ses Remèdes*), lays great stress on inducing the workingmen to practice life-insurance, deposit in savings-banks, and in other ways raise themselves above the common level of poverty, from which he says it is but a step, in illness, old age, or vice, to the gulf of pauperism. Since then, in France, as well as in Great Britain, an agitation has begun in favor of giving to old people pensions drawn from a fund provided either by taxation or voluntary contribution, and administered by the Government. The cost of public charity has increased, especially in France, where the poor-law expenditure of cities greatly exceeds that of rural districts in France. Concerning the latter Levasseur says: "Wealth in general is less in the country than in the cities and large towns, but, in return, poverty also is less felt there, and pauperism, strictly speaking, rarely occurs in small country districts. Public relief is also much less abundant in such places; only about a third of the communes in France with less than 500 people keep up a charity bureau, while this form of relief exists in more than two-thirds of the communes which have 1,000 people or more."

France practically has a poor-law, and recognizes the duty of public aid, although it has never been carried so far, nor with such injurious results, as the poor-law system of England. In fact, the French system closely resembles in many particulars that which has grown up naturally and almost universally in the U. S. The first step in this system is the creation of a local board, called in France a charity bureau (*bureau de bienfaisance*) and in the U. S. a board of overseers, guardians, supervisors, etc., according to the usage in different parts of the country. These boards, both in France and the U. S., first distribute "family aid" (*secours à domicile*), which is what the English rather absurdly have termed "outdoor relief." They mean relief given outside the workhouse door—it having been a theory at one time in England that all the public poor, with a few exceptions, could be thrust into workhouses, but experience, in the British islands as well as in France, has shown that this theory is unfounded. Extending his observation from Paris to France as a whole, Levasseur says that increase of wealth has not aggravated pauperism in that country, although the cost of relieving the poor is so much greater than formerly. This is true in Great Britain, in the U. S., and in all civilized countries. Thus in Great Britain, where the cost in 1847 was only about $30,000,000, it is now (1894) considerably above $40,000,000, although the number of paupers is actually less than in 1847. Mr. Goschen, when president of what is now the Local Government Board, said in 1870: "It can not be denied that the more humane views which have prevailed during the last few years as to the treatment of the sick poor have added most materially to the poor-law expenditures. Workhouses, designed originally mainly as a test for the able-bodied, have, especially in the large towns, been of necessity gradually transferred into infirmaries for the sick; and the higher standard for hospital accommodations has had a material effect upon the expenditures." The process here mentioned has been going on more rapidly in Great Britain, in France, in Germany, and in the U. S. since 1870 than before; but previous to 1833 it had shown itself abundantly in France. In 1800 France expended less than 65,000,000 francs in public charity; in 1833 170,000,000; and since the latter date the cost of public charities has greatly increased. It is impossible to obtain in France such accurate returns of the poor as in England, where the paupers are counted twice a year; but there is reason to suppose that the number of paupers is now less, in proportion to the whole population, than it was in 1887. This is also true in England and Wales, where there has been a noticeable decrease both in indoor and outdoor relief since 1870, and still more since 1845, when pauperism was about at its maximum. In 1870 the number reported in a given day in England and Wales, both indoor and outdoor, was 1,047,662, but four years later it was only 784,006, and in 1894, although the whole population had increased to 30,000,000, the paupers enumerated on a given day were less than 840,000. The U. S. census of 1890, though far from accurate, indicates the same diminution of pauperism when compared with the whole population of the republic.

Indoor and Outdoor Relief.—This decrease of the public poor in England and Wales is due in part to the cutting off of "outdoor relief." Many British authorities attribute the pauperism now existing in the United Kingdom to the outdoor relief granted there still, and some hold that if outdoor relief were entirely cut off there would be a marvelous diminution of pauperism. This is a theoretical view which facts do not wholly sustain. The system followed in the U. S. is to mingle outdoor and indoor relief, since both are needful and their conjoint use is more judicious than the absolute exclusion of either. It often happens that a little relief given in a small community will keep a family from absolute dependence, while residence in an almshouse degrades and pauperizes. Outdoor relief in large communities by public authorities is, however, dangerous, because it is especially liable to misuse through want of vigilance or as a means of bribery or corruption. The principles which should govern almsgiving may be summed up in the words of Malthus: "It is in the highest degree important to the general happiness of the poor that no man should look to charity as a fund on which he may confidently depend." The application of this requires that outdoor relief should in no case be given to able-bodied men; that in cities it should be left as far as possible to organized private charity, lest the poor fall into the habit of believing in a right to relief at the hands of the public authorities; and that where given it should be bestowed in such a manner and under

such conditions as would tend to prevent future pauperism. The "workhouse test," however, to which Malthus was firmly attached, will not meet the exigencies of the case in Britain or anywhere else. The old-fashioned workhouse has been expanded since Malthus wrote, so that its door, originally but one, has become the manifold doors of infirmary, hospital, school for paupers, asylums for the blind, for the idiot, and for the insane, schools for the deaf, etc. "Indoor relief" now includes, or should include, support by the public in all establishments for the poor and suffering; while "outdoor relief" means "household aid" to those persons—much the larger number—who do not need the restraint or the special care of a public establishment, whether asylum, hospital, poorhouse, or by whatever other name. One reason why family aid has been carried, especially in cities, so far as to prove an abuse, was the desire to prevent the breaking-up of families, the corruption of the young, and the unspeakable distress of the old and virtuous by throwing them into forced association with the dregs of mankind in a so-called charitable establishment. This same desire counts for much in the present movement to pension the aged poor, which Charles Booth and other English writers strongly support, and which has already produced a pension-law, guarded by many restrictions, for the aged poor of Denmark. If experience can teach anything it is that both indoor relief and family aid (outdoor relief) properly practiced are indispensable in any complete system of public charity. Where to draw the line in individual cases is a matter only to be determined by the wise discretion of the poor-law officers. Indoor relief will generally be found more costly in proportion to the number relieved than family aid; and it will also, in general, apply to a much smaller number of cases, but so far as it can be rationally and humanely used it should be made to cover as many cases as possible. Family aid, on the other hand, should be restricted as much as possible, except for classes of the poor to whom indoor relief is (presently or prospectively) likely to be injurious. The public generally prefer, for reasons of sentiment and oftentimes of good sense, the use of "family aid" rather than the separation of households and the sequestration of persons in great establishments where individuality is lost in the mass.

Pauperism in the United States.—The national census chiefly takes account of the indoor poor of the U. S., but by no means includes them all in its tabulations, while it omits almost entirely the much more numerous class of the outdoor poor. The census of 1890 exhibits as the aggregate of paupers in almshouses in the whole republic 73,045; and this is probably less than 10,000 short of the actual number at any one time in 1890, which may be estimated at 80,000. The outdoor poor, which the census sets down as only 25,000, were in fact, upon careful estimates based on State returns, not less than 250,000 at any one date—that is, the average number. If we add to the almshouse poor the number of the insane poor supported by the public in hospitals, asylums, etc., which may be estimated at 30,000, and other classes of the indoor poor who are supported in establishments other than poorhouses and asylums for the insane, we shall probably find the whole number of the indoor poor of the U. S. rising toward 150,000. Assuming these estimates to be approximately correct, we should then have 400,000 as the constant or average number of paupers in a population of a little less than 63,000,000. At this rate the number of English paupers at any given date should be less than 200,000, for the population of England and Wales is less than half that of the U. S. The actual number of the English paupers in 1894 exceeded 800,000, so that, viewed in this proportion alone, pauperism is more than three times as common in England as in the U. S. There is, however, another consideration affecting this problem. How many paupers in the course of a year are represented by the single pauper who appears in the aggregate average number? Mr. Charles Booth, the most accurate calculator on this element of the question, finds that in England the total of pauperism during the year is to the average number as two and a half is to one. In the U. S. this proportion is no doubt smaller.

Settlement Laws and Poor-law Systems.—In the fifty States and Territories of the U. S. the poor-laws, including laws for the "settlement" or definite fixing of the pauper in a given locality, vary so much that no general statement can well be made. A poor-law may be said to exist almost everywhere in the U. S.—that is, the localities are everywhere expected to support their own poor by taxation; but the prevalence of the county system in many States, of the township system in others, and of a combination of township, county, and State systems in some localities, makes it extremely difficult to say what usages prevail in the republic as a whole. In the older Atlantic States the law of pauper settlement is derived from the English statutes of Charles II. and earlier reigns; yet the American laws all differ materially from the English statutes, and were never precisely the same, even in the provincial period. The period requisite for gaining a pauper settlement varies from one year to ten, or even more under some circumstances; but mere residence does not always confer this right without the payment of taxes or some other qualification. Marriage with a person who has a pauper settlement generally carries settlement with it for the wife and children; legitimate children follow the settlement of the father, if any, otherwise of the mother; illegitimate children follow the settlement of the mother; and this provision applies to women who have married a husband insufficiently divorced from a former wife. The complications which may arise from the article of marriage alone are numerous, and the whole body of settlement laws has given room for infinite litigation between towns, counties, and States; but an incidental advantage, springing even from obscure and complex pauper laws, has appeared in New England, and particularly in Massachusetts, where these laws have less simplicity, perhaps, than anywhere else. Their very complexity requires the official who acts under them to investigate every case of poverty brought to his notice, and in this way the condition of families, the existence of kindred, the nature of maladies, and all the numerous circumstances needing to be investigated are brought under examination. The formation in nearly a hundred cities of the U. S., since 1870, of charity organization societies (see CHARITY ORGANIZATION), has also promoted these inquiries into the state of the poor—guarding against much imposture, and bringing those truly in need under the eye of public or private charity. An important question arising under the immigration laws of the U. S. concerns "interstate migration," a subject which was brought before the national conference of charities in Denver, June 28, 1892. This national body passed a resolution to memorialize Congress for the regulation by national authority of the migration of poor, vagrant, insane, diseased, and criminal persons from one State to another. Such an exercise of the Federal authority, it was thought, would lead to a more systematic code of laws and a more uniform administration of public charity throughout the U. S. and would incidentally promote the collection of more exact statistics of pauperism.

F. B. SANBORN.

Paur, EMIL: See the Appendix.

Paurop'ida: name applied to a group of MYRIAPODA (*q. v.*), containing a few minute species, formerly placed between the Chilopods and Chilognaths, but shown by the researches of Schmidt (*Zoologischer Anzeiger*, 1894) to be degenerate members of the Chilognathous group. The genera *Pauropus* and *Eurypauropus* occur in the U. S.

Pausa'nias (in Gr. Παυσανίας): the Periegete or "conductor," of Magnesia in Asia Minor, who wrote toward the close of the second century A. D. a *Guide to Greece* (Περιήγησις τῆς Ἑλλάδος) in ten books. In this work, which is beyond price for archæology and mythology, especial attention is paid to monuments of art, in which the writers of the Greek Renaissance took great interest. The preference shown for temples and votive offerings is also explicable from the tendencies of the century. Pausanias doubtless compiled his manual from earlier guides, among whom POLEMON (*q. v.*), 150 B. C., is conspicuous; but this does not exclude personal vision any more than the free use of an old Murray or Baedeker would do to-day, and the absence of allusion to the great monuments of the period in which the compiler lived is of a piece with the antiquarian unreality of the age. The work has been edited by Siebelis (5 vols., Leipzig, 1822); Schubart and Walz (Leipzig, 1838; English translation by Thomas Taylor, 3 vols., London, 1793–94); and by Shilleto in Bohn's Library (2 vols., 1886). See also Kalkmann, *Pausanias der Perieget* (Berlin, 1886), and Gurlitt, *Pausanias* (Gratz, 1890).

B. L. GILDERSLEEVE.

Pausanias: a son of Cleombrotus and regent of Sparta during the minority of his cousin, Plistarchus, the son of Leonidas; commanded the confederate Greeks at Platæa 479 B. C., and achieved several brilliant victories during the following years; but, elated by these successes and led astray by an exorbitant ambition and vanity, he entered

into treasonous negotiations with the Persians. He desired to bring the whole of Greece under his sway, and he hoped to realize this plan by the aid of Xerxes, which he proposed to buy by placing his future kingdom under Persian authority. Meanwhile he assumed Persian dress, surrounded himself with a body-guard of Persian and Egyptian troops, and introduced Persian ceremony and Oriental luxury in his household. The Athenians denounced him and the Spartans suspected him. Twice he was recalled from the army and arraigned before the ephors, but no proofs could be presented and he was acquitted. He continued the negotiations with Xerxes, and even began to form a conspiracy with the Helots. At last a letter from him to Xerxes was delivered over to the ephors by the slave intrusted to carry it to the Persian camp, and when he learned that his treason was discovered and his plan frustrated, he took refuge in the temple of Athene Chalcioecus, where the people shut up the entrance by a pile of stones, to which his own mother carried the first, and he died of hunger about 468 B. C.—His grandson PAUSANIAS was King of Sparta from 444 to 394, when he fled the country to escape condemnation to death for treason. He died in Tegea in 385 B. C. The murderer of Philip, King of Macedonia, was still another person of the same name. Revised by J. R. S. STERRETT.

Pauw, pŏw, CORNELIS, or CORNELIUS, de: author; b. at Amsterdam, 1739. He was educated at Göttingen; entered the Franciscan order; became canon of Xanten, near Cleves, and for a time represented the Bishop of Liège, at Berlin; but most of his life was spent in literary labors. Like his celebrated nephew, Anacharsis Clootz, he was very eccentric, and he was insane before his death. De Pauw's writings were intended to explode the sentimental theories then in vogue respecting the American Indians and the Orientals; they show much research, and their spirit of criticism was valuable, though unduly violent, resulting in hot controversies. The principal ones are *Recherches Philosophiques sur les Américains* (Berlin, 1768–69; translated into English), and similar works on the Egyptians and Chinese (1774), and on the Greeks (1788); collected edition 1795. D. at Xanten, July 7, 1799. HERBERT H. SMITH.

Pavements: coverings of wood, stone, brick, or asphalt, laid firmly on a street in order to give a smooth and convenient surface for travel. The coverings of gravel and broken stone used for macadam roads in country and suburban districts, and also in small towns, are described under ROADS, while this article deals with the pavements for streets in larger towns and cities; such road surfaces, although well adapted to park drives, become so covered with mud and dust under the wear of heavy traffic, and require such a heavy expense for maintenance and renewal, that they can not be used in the thickly settled parts of cities. A street pavement should be durable, be readily cleaned and kept in repair, give a secure foothold for animals and easy traction, not become slippery from use, and be as noiseless as possible. It should also be of such material and construction that the original cost plus the expense of maintenance may be a minimum.

Foundation.—A good foundation is essential for the stability of a street pavement. The most common foundation is sand or gravel, laid in a thickness of from 3 to 6 inches upon a sub-grade surface, which is made nearly parallel to that of the pavement itself. Cobblestones set firmly in sand or gravel, rubblestones set on edge in contact, and rubblestones set on edge but not in contact with the voids filled with concrete, are also used. The best foundation is one of hydraulic concrete, 6 or 8 inches in thickness, but this is the most expensive, its cost being about $1.50 per square yard of surface. The surface of an old road sometimes makes a good foundation for a new pavement; for instance, in Brooklyn, N. Y., asphalt pavements have been laid on top of old cobble pavements, and in New York an asphalt pavement was laid in 1892 on the old macadam surface of the Boulevard.

Wooden Pavements.—The cheapest wooden pavement is made of round blocks sawed from small trees in lengths of 6 inches, the diameters of the blocks ranging from 2 to 12 inches. The earth is first excavated to the curve of the finished pavement and 2 or 3 inches of sand laid; on this boards are placed which are covered with hot coal-tar. The blocks are then set on end in contact, the interstices filled with sand, the surface coated with hot tar, and covered with a thin layer of sand. The cost of such a pavement is about $1.25 per square yard, and for a year or two it gives good satisfaction, being smooth, clean, and noiseless; it then begins to wear in ruts, and also to decay rapidly, so that renewal is necessary in a few years. The best wooden pavement is composed of rectangular blocks, 3 to 4 inches in width, 6 to 14 inches in length, and 6 inches deep, which are laid in courses across the street with an open joint three-quarters of an inch wide between the courses. This is also laid on a foundation of sand covered with boards, and the open joints are filled with coal-tar and gravel. The wooden blocks should be creosoted to prevent decay. There are many patented details of construction in wooden pavements, but experience indicates that none of them secures durability and economy. The rapid wear and decay necessitates a heavy expense for renewals; the odor arising from the noxious liquids, held in absorption by the wood or retained in the joints between the blocks, is sometimes offensive; and the dust resulting from wear and decay is often found to be injurious to health.

Stone Pavements.—The layer of cobblestones formerly in common use scarcely deserved the name of pavement; it was noisy, rough, hard to clean, and unpleasant for traffic, and it can now be said to be almost entirely abandoned. The best stone pavements are made of rectangular blocks set in contact in rows running across the street, and resting on a foundation of concrete. The Belgian pavement is formed of blocks nearly cubical in shape, the edge of the cube being from 5 to 7 inches long; trap-rock is generally employed on account of its toughness. The Gnidet pavement, which may be seen on Broadway, in New York, is formed of granite blocks from 4 to 5 inches wide, 10 to 15 inches long, and 8 to 10 inches in vertical depth. The blocks are set in close contact on the foundation, over which a layer of sand is laid, and are then rammed with heavy wooden rammers. The joints are filled with sand, or sometimes with asphalt. This pavement costs on a sand foundation from $4 to $5 per square yard. Stone pavements are durable, and when well made require little repair. They are open to the objection that they collect and retain the surface liquids between the joints, and in addition are noisy. Where the traffic is very heavy, however, stone seems to be the most advantageous material for a street pavement.

Brick Pavements.—The brick used for this purpose are hard burned, usually without being vitrified, and should be of uniform hardness and low porosity. A foundation of sand or gravel is first made and compacted by rolling, and upon this a course of brick is laid upon the flat side. A layer of sand an inch thick is next spread, and on this the top course of hardest and toughest bricks is laid, the bricks being set on edge with their longest dimension running across the street. This is covered with sand and well rolled until the pavement is brought to the assigned form of surface. Another method of construction is to omit the lower layer of bricks, using tarred boards instead, and sometimes the top layer has its courses laid diagonally across the streets. The first successful brick pavements were those built in Illinois and Ohio between 1875 and 1880, and they are now extensively used in the western parts of the U. S. With a good quality of brick and a traffic not heavy good results have been obtained, the pavement being clean, not noisy, durable, and the traction being easy. With brittle or soft bricks, however, cracking and wearing into ruts occurs. The cost of brick pavements has generally been between $1.50 and $2.50 per square yard on a sand foundation, and the construction of them is constantly increasing in large towns and smaller cities where the traffic is not severe.

Asphalt Pavements.—The bituminous limestone or asphalt rock of Switzerland, when heated, crumbles into a sandy powder, which, when spread on a good foundation in a sheet 2 or 3 inches thick and compacted by ramming with heated pestles, makes an excellent road covering. The bitumen from Trinidad mixed with heated sand makes a compound closely resembling that derived from the natural asphalt rock. It is also used in the form of rectangular blocks or bricks, which are made under heavy pressure. Such pavements when well made are very durable, the wear compacting the material instead of grinding it away. They are dustless, noiseless, smooth, and easy of traction, and do not absorb or retain noxious liquids. It does not become slippery from continual wear, although in wet weather it sometimes fails to give sufficient foothold to horses. It is adapted to all streets except those having steep grades and those crowded with traffic, and its use has become very extensive in the U. S., particularly for residence streets. The cost has usually ranged between $2.50 and $4 per square yard on a concrete foundation.

The comparative merits of the different kinds of pavements would be differently estimated, according to the character of the traffic. For a very heavy traffic nothing but stone blocks will prove satisfactory, while for lighter traffic brick or asphalt may be preferred. Stone is the most durable and wood the least, while asphalt and brick lie between the two. Wood is the cheapest in first cost, brick next, followed by asphalt, while stone is the dearest. Regarding maintenance and repairs probably asphalt stands first, stone second, and wood last. In the important matter of cleanliness and hygienic considerations asphalt stands first, brick second, and stone third, while wood is liable to many grave objections.

Statistics.—In a paper read in 1892 before the Commercial Club of Kansas City, Mo., Robert Gillham collected statistics of street-paving from fifty-one principal cities of the U. S. Stone pavements are divided into two classes—(1) dressed stone blocks of regular dimensions, and (2) cobblestone, rubblestone, or undressed irregular blocks. The number of miles of each kind of pavement for different groups of States is given in the following table:

STATES.	Stone. (1.)	Stone. (2.)	Brick.	Wood.	Asphalt.
New England States, 9 cities	177	20	..	...	5
Middle and Central States, 22 cities	879	1,079	56	480	323
Southern and Southwestern States, 9 cities	163	31	7	85	60
Northwestern States, 6 cities	38	....	25	170	29
Pacific States, 5 cities	31	2	..	1	4
Totals, 51 cities	1,288	1,132	88	736	421

New York had 321 miles of stone pavement of class (1) and only 3 miles of class (2), 16 miles of asphalt, less than 1 mile of wood, and none of brick. Philadelphia had 120 and 491 miles of the two kinds of stone pavement, 20 miles of brick, 43 of asphalt, and none of wood. Chicago had 23 miles of stone, 410 of wood, 9 of asphalt, and less than 1 mile of brick. It will be seen that the use of brick for street-paving is as yet limited in comparison with other materials. More than half of all the wood pavement in the U. S. is in Chicago. Buffalo, N. Y., takes the lead in regard to asphalt, having 125 miles, or more than one-fourth of the total, while Washington, D. C., stands next with 60 miles.

Planks, slag bricks, and gravel concrete are used to a very limited extent for street pavements. Granolithic paving is a kind of artificial stone, composed largely of hydraulic cement, which is made in place; the use of this, however, is mostly confined to sidewalks and court-yards. See Gillmore's *Roads, Streets, and Pavements* (1876); Love's *Pavements and Roads* (1889); and Byrne's *Highway Construction* (1892).

MANSFIELD MERRIMAN.

Pavia, pää-vee'ää (anc. *Ticinum*; med. *Papia*): city of Northern Italy; on the left bank of the Ticino, 2 miles above its junction with the Po; 21 miles by rail S. of Milan, with which it is also connected by a canal (see map of Italy, ref. 3–C). Pavia is still for the most part surrounded by walls, which form a circuit of 3½ miles. It was formerly called the city of the hundred towers. It is connected with the suburb of Ticino by a brick-built covered bridge which dates from the fourteenth century. The churches of Pavia are of great historic and architectural interest; among them are San Michele Maggiore, of the sixth or seventh century, perhaps the finest specimen of Lombard architecture existing; the cathedral of San Stefano (founded in 1488), containing the monument (fourteenth century) to St. Augustine and the remains of Boethius, which were brought thither from the ruined church San Pietro in Ciel d'Oro. Of the old castle, on the site of the ancient Lombard royal palace, little of interest is left except the half-ruined gateway. The University of Pavia, the *alma mater* of many illustrious men, is said to have been founded by Charlemagne, though not formally constituted until 1361. In 1891 there were 1,095 students and 56 teachers; attached to it are two colleges and a library with 185,000 volumes. The Museo Malespina contains some good pictures and a fine collection of engravings. Near Pavia is the picturesque old church Beato Lanfranco; but the great attraction of the neighborhood is the magnificent CERTOSA DI PAVIA (*q. v.*). Pavia is of very ancient, probably Ligurian, origin. It was of some importance under the Romans, and had a Christian church in 326. In 573 it became the Lombard capital, and for 200 years was a rich and great city. In 1524 Francis I. of France suffered a terrible defeat under the walls of Pavia, and was taken prisoner by the troops of Charles V. Three years later the town was barbarously sacked by the French, but it soon afterward fell into the hands of Austria. Bonaparte having taken Pavia (1796), at the prayers of the citizens limited his soldiers to a sack of three hours, so that the town was not totally destroyed. By the Peace of 1814 it returned to Austria, and after the battle of Solferino became a part of the kingdom of Italy. Pavia has some trade in rice, hemp, silk, wines, etc. Pop. (1893) 37,000.

Revised by R. A. ROBERTS.

Pavlov', NIKOLAÏ FILIPPOVICH: writer; b. in Moscow, Russia, in 1803; d. Mar. 29, 1865. He was brought up for the stage, but abandoned it two years after his *début*, and devoted himself to literature, although in order to acquire a better education he had first to prepare for the University of Moscow, and go through the courses there. He also was obliged to support himself by serving for some years as a government official. Some of the poems which he published in the newspapers were of merit, but he was more successful with his tales and essays, especially his *Four Letters to Gogol* (1847); *Vopros o Evreakh* (The Hebrew Question, 1858); *Mr. Chernyshevskiĭ and his Time* (1861). From 1860 to 1863 he was editor of the paper *Nashe Vremĭa* (Our Time) which was a failure.

A. C. COOLIDGE.

Pawcatuck' River: a stream formed in Washington co., R. I., by the union of the Charles and Wood rivers. It is navigable for small vessels for several miles, and forms the southern portion of the eastern boundary of Connecticut.

Pawn: See BETEL.

Pawnbroking [from O. Fr. *pan*, pledge, assurance, identical in form with *pan*, cloth, skirt (< Lat. *pannus*), but connected in meaning with *paner*, rob; Germ. *pfand* is probably a loan-word from O. Fr. *pan*]: the loaning of money upon the security of goods or chattels pledged by the borrower with the lender as security for the repayment of it. The word pawn is often applied in a broad sense to goods or chattels pledged as security for the performance of a contract, or the fulfillment of an obligation, or to the contract by which it is so pledged. The contract of pawn or pledge is a species of BAILMENT (*q. v.*), and differs from a hypothecation in that the latter does not require the actual delivery of the property, and from a chattel mortgage in that the mortgagee acquires the legal ownership. A pawnee has a larger right than a lienor, who does not have the right to sell on failure of payment.

The history of the practice of pawnbroking is lost in antiquity. The earliest records, however, of all civilized nations show that the practice existed among them, and that it was early regulated by laws which uniformly aimed to suppress extortion by the lender and to protect the borrower by strict regulations. Thus there is frequent mention in the Bible of laws among the ancient Hebrews forbidding lenders to keep or receive as security chattels the want of which exposes the borrower to great hardships or privations, as where it is forbidden to keep a man's coat over night or to take "nether or upper mill-stone to pledge," etc. See Exod. xxii. 26, 27; Deut. xxiv. 6, 11, 12, 13, 17.

Among the Chinese pawnbrokers are very numerous, and are kept under strict regulations, and any one acting without a license is severely punished. Pledges are usually redeemable for three years, and 3 per cent. per month is the highest rate of legal interest; and in the winter the monthly interest on pledges of wearing apparel may not exceed 2 per cent. These regulations have been enforced among the Chinese for at least 1,500 years. Interesting facts with regard to the practice are also found in the early records of the Hindus and Arabs and other nations of the East.

In modern times among European nations the first professional pawnbrokers were probably the Jews. The oppression and the hardships caused by the practice of the pawnbrokers early led to the passage of laws by which pawnbroking was exclusively intrusted to public institutions of a quasi-benevolent nature, now called *monts-de-piété*. The first of these was established at Padua, and from there the institutions were introduced into many states in Europe, and some of them still exist, as at Paris, Madrid, Brussels, Antwerp, etc. They were originally intended to be supplied with funds by contribution, and to loan upon with little or no interest; but this was found impracticable. Attempts have been made to introduce them into Great Britain, but they have met with no success; and several schemes that were started resulted in great loss of capital and the ruin of many interested. The *mont-de-piété*

at Paris may be described as giving a general idea of them all. It was opened in 1777, destroyed by the Revolution, opened again in 1797, and obtained a monopoly of pawnbroking in Paris in 1804, since which time it has continued with some minor changes. There is a central office and a number of commissioners who receive pledges in the various arrondissements. These commissioners make provisional loans on goods and then forward them to the central office, where they are appraised by the valuers of the *mont-de-piété*, the practice being to advance four-fifths on the value of gold and silver goods and two-thirds on that of other non-perishable goods. Since the *mont-de-piété* has a monopoly, the advances made are less liberal than where there is competition, so that the local commissioners make advances over the amount and recoup this by taking 2 per cent. of each pledge, 1 per cent. on redemption, and interest on the excess of advance. These charges have to be added to the 9 per cent. interest and ½ per cent. for valuation made by the central office. The trading capital of the *mont-de-piété* is obtained by the issue of promissory notes at 2½ per cent. for money deposited, by cash reserves, and by profit on the redemption and sale of pledges.

In England, as elsewhere in Europe, the first professional pawnbrokers were probably Jews, who, at and after the time of the Conquest, for more than two centuries charged from 45 to 65 per cent. per annum. This led to restrictive legislation, and in 1275 they were forbidden to take interest on pain of death, and in 1290 were expelled from the kingdom. Pawnbroking then fell into the hands of the Lombards, who throve upon it, although interest was unlawful until 1646, when it was fixed at 10 per cent. See USURY.

The taking of goods and chattels as security for the redemption of money lent thereon was first regulated by statute in England in 1757 (25 George III., c. 48, sec. 6). The provisions of this act were amended and re-enacted in several temporary statutes which were superseded by the Pawnbrokers' Act of 1800 (39 and 40 George III., c. 99). This act was also subsequently amended by various acts, but nevertheless grew unpopular, until in 1871 a committee was appointed by the House of Commons to investigate the matter of pawnbroking. In 1872, on their recommendation, a general act was passed regulating the business and repealing all previous laws. This act (35 and 36 Vict., c. 93) applies without qualification to every loan of a pawnbroker of not more than 40*s.*, and to loans of from 40*s.* to £10, unless the parties by special contract, in statutory form, agree to exclude the operation of the act as to profit and certain other particulars. Books of account of all transactions must be kept in a prescribed manner, and a pawn-ticket briefly stating the contract must be given with each pledge. The lawful profit is now a halfpenny per florin, or $2\frac{1}{12}$ per cent., per month, on loans up to 40*s.*, and a halfpenny per half-crown, or $1\frac{2}{3}$ per cent., on loans from 40*s.* to £10. The act also contains numerous other provisions, as for the liability in case of fire, for the prevention of the making of unlawful pawns, etc.

The system of pawnbroking as it exists in the U. S. is borrowed directly from that of England, and the subject is generally regulated by statutes or legal ordinances, the general effect of which is to restrict the interest that may be charged, and in other ways provide for the protection of the borrower, as by restricting the hours of business, requiring tickets to be given for each pledge, etc. See Jones on *Bailments*; Tyler on *Usury, Pawns, and Loans* (Albany, 1873); Turner's *Contract of Pawn* (London, 1883).

F. STURGES ALLEN.

Pawnee City: village (founded in 1856); capital of Pawnee co., Neb. (for location, see map of Nebraska, ref. 11–H); on the Burlington Route and the Chi., Rock Is. and Pac. railways: 75 miles S. of Lincoln. It is in an agricultural and stock-raising region, and has 6 churches, college, graded high school, 2 national banks with combined capital of $110,000, a State bank with capital of $15,000, and 2 weekly newspapers. Pop. (1890) 1,550; (1900) 1,969.

Pawnee Indians: See CADDOAN INDIANS.

Pawtucket: city; Providence co., R. I.; on both sides the Blackstone river and at head of navigation on the Pawtucket river; on the N. Y., N. H. and Hart. railway and leased lines; compact part of city 4 miles from compact part of Providence, which it abuts on the north; 39 miles S. S. W. of Boston (for location, see map of Rhode Island, ref. 7–H). It was the birthplace of the cotton manufacturing industry in the U. S., which was initiated in 1790 by SAMUEL SLATER (*q. v.*). The Blackstone river here has a fall of about 50 feet, furnishing abundant power for manufacturing, and is spanned by several bridges of iron and stone. The city, with an area of 9 sq. miles, presents a picturesque appearance, and has several public parks, system of waterworks introduced in 1878 at a cost of $1,333,000 and enlarged at a cost of $500,000, 23½ miles of electric street-railway, 46 miles of sewers, electric-light and gas plants, a public library (founded in 1876) containing over 19,500 volumes, public-school property valued at $597,000, 2 trust companies with a combined capital exceeding $1,000,000, 3 savings-banks with deposits in 1900 aggregating over $6,300,000, and 1 daily and 1 weekly periodical. It receives annually large quantities of coal, lumber, lath and shingles, brick, cement, lime, stone, and cotton. In 1900 the assessed valuations were: real property, $29,326,820; personal, $5,330,100—total, $34,656,920; and the net debt was $4,191,128.50, which included a water debt of $964,286.53. The census returns of 1890 showed that 371 manufacturing establishments (representing 73 industries) reported. These had a combined capital of $16,693,984, employed 9,508 persons, paid $4,079,579 for wages and $9,415,654 for materials, and had products valued at $16,303,729. The principal industry was the manufacture of cotton goods, which had 15 establishments, combined capital of $7,431,004, and products valued at $3,954,960. There were 7 hosiery and knit-goods mills, yielding a product valued at $745,712, and 9 textile dyeing and finishing factories, yielding a product valued at $1,417,971. Other important industries were the manufacture of foundry and machine-shop products, which had 13 establishments, $979,404 capital, and $1,110,852 receipts for products; and slaughtering and meat-packing, 3 establishments, $495,000 capital, and $2,895,191 receipts for products. Pawtucket was settled about 1655, was included in Bristol co., Mass., till 1861, and was incorporated as a city in 1885 (March 27). Pop. (1880) 19,030; (1890) 27,633; (1900) 39,231.

JOHN C. MINKINS.

Paxton: city (founded in 1858); capital of Ford co., Ill. (for location, see map of Illinois, ref. 5–F); on the Ill. Cent. and the Lake Erie and West. railways; 49 miles E. of Bloomington, 103 miles S. by W. of Chicago. It is in an agricultural region; contains 8 churches, Rice Collegiate Institute (founded in 1878), a national bank with capital of $50,000, and 2 weekly newspapers; and has water-works, electric-light plant, flour-mills, and various manufactories. Pop. (1890) 2,187; (1900) 3,036. EDITOR OF "RECORD."

Paxton, Sir JOSEPH: architect and horticulturist; b. at Milton-Bryant, Bedfordshire, England, Aug. 3, 1803, of humble parentage; educated in the free school at Woburn; obtained employment at Chiswick as a gardener in the service of the Duke of Devonshire, where he displayed such remarkable talent for landscape-gardening that the duke made him manager of his Derbyshire estates and commissioned him to remodel the grounds at Chatsworth. Under his care that mansion soon became the most renowned country-seat in Great Britain, the great conservatory especially being regarded as a wonderful triumph of art. This building became the germ of the idea which culminated in the plans for the Crystal Palace, the vast edifice of iron and glass erected from his designs for the great Universal Exposition of 1851. For this service he was knighted and received honors from several European sovereigns. He removed the buildings to Sydenham; erected a magnificent mansion for Baron James Rothschild; entered Parliament 1854; and published several works on botany, horticulture, and floriculture. D. at Sydenham, June 8, 1865.

Payment [from O. Fr. *payement*, deriv. of *payer*, pay < Lat. *paca're*, pacify, satisfy, deriv. of *pax*, *pa'cis*, peace]: a mode of discharging an obligation by the delivery and acceptance of money, or of something substituted for money by agreement of the parties. The original obligation may impose the liability to make payment. In such a case payment discharges it by performance. In other cases payment is made not in performance of the original obligation of the payer, but of one which the parties have substituted therefor—for example, one who is bound to transfer property or render services may prefer to pay a sum of money in lieu of performance. If the other assents to this, the original obligation is discharged by the substitution of the new agreement, and the latter is discharged by payment. A debtor often gives to his creditor a negotiable instrument instead of money. If the instrument is a genuine bill of a bank which has not failed, it will operate as money. A

forged bank bill, or, in most jurisdictions, the bill of a bank which has suspended payment, is treated as a nullity, and its delivery and acceptance are not payment. If the bill, note, or check of the debtor or of a third person be received by the creditor instead of money, it will have the effect of an absolute payment, provided the parties actually agree that such shall be its effect. In the absence of an actual agreement, however, the general rule is that it will operate as conditional payment only. If the condition is broken by the non-payment of the paper at maturity, the obligation is not discharged, but the creditor is remitted to all his original rights. See APPROPRIATION OF PAYMENTS and NEGOTIABLE INSTRUMENTS. FRANCIS M. BURDICK.

Payn, JAMES: novelist; b. at Cheltenham, England, in 1830. He was educated at Trinity College, Cambridge, and graduated in 1854; in 1858 became editor of *Chambers's Journal*, and in 1882 of *The Cornhill Magazine*. His published books, chiefly novels, are more than 100 in number, and include *Richard Arbour* (1861); *Lights and Shadows of London Life* (1867); *Won, not Wooed* (1871); *What he Cost her* (1877); *Under one Roof* (1879); and *The Eavesdropper* (1888). D. Mar. 25, 1898. H. A. BEERS.

Payne, CHARLES HENRY, D. D., LL. D.: minister and educator; b. at Taunton, Mass., Oct. 24, 1830. He was educated at East Greenwich Academy, Rhode Island, Wesleyan University, Middletown, Conn., and at the School of Theology of Boston University. He joined the Providence Conference in 1857; was pastor 1857–76, serving several of the leading churches in Brooklyn, Philadelphia, and Cincinnati; president of Ohio Wesleyan University 1876–88; elected corresponding secretary of the board of education 1888, and re-elected in 1892. He prepared a plan of federation of Methodist institutions of learning, which, with some modifications, was adopted by the General Conference of 1892. He published *The Social Glass and Christian Obligation* (1868); *Shall our American Sabbath be a Holiday or a Holy Day?* (1872); *Daniel, the Uncompromising Young Man* (1873); and *Guides and Guards in Character-building* (1884). D. in Clifton Springs, N. Y., May 5, 1899.

Payne, JOHN: poet; b. in London, 1842. He is a solicitor, and is known especially as a translator and a poet of the neo-romantic school, like Marzials and O'Shaughnessy, greatly influenced by Baudelaire and the French romanticists; author of *The Masque of Shadows* (1870); *Intaglios* (1871); *Songs of Life and Death* (1872); *Lautrec* (1878); *New Poems* (1880); *François Villon: a Biographical Study* (1881); and of the following translations: *The Poems of François Villon* (1881); *The Book of the Thousand Nights and One Night* (the first complete English version 1882–84, 9 vols.); *Tales from the Arabic* (1885); and *The Decameron of Boccaccio* (1886). H. A. BEERS.

Payne, JOHN HOWARD: dramatist and actor; b. in New York, June 9, 1792; began to edit a weekly paper, *The Thespian Mirror*, when thirteen years of age; two years later published twenty-five numbers of a periodical called *The Pastime*; made a successful *début* as an actor at the Park theater, New York, Feb. 26, 1809, in the character of Norval; appeared on the stage at Boston and other cities, also in London 1812–13, where he produced many new dramas, chiefly imitated from the French, for one of which, called *Clari, or the Maid of Milan*, he wrote the song *Home, Sweet Home*; published a volume of juvenile poems, *Lisping of the Muse* (1815); successfully produced his tragedy *Brutus* at Drury Lane 1818; was a friend and correspondent of Coleridge and Charles Lamb; edited in London a dramatic paper called *The Opera-glass* 1826–27; returned to the U. S. 1832; was U. S. consul at Tunis, Africa, 1841–45; again appointed 1851. D. there Apr. 10, 1852. Among his best writings were the plays *Virginius* and *Charles the Second*. His remains were removed from Tunis, Africa, to Washington, D. C., in 1883. A volume of his collected works, with a memoir, was published in 1875. See Brainard's *John Howard Payne*, a biographical sketch with narrative of removal of his remains to the U. S.

Payne, JOSEPH: See the Appendix.

Payne, WILLIAM HAROLD, A. M., Ph. D., LL. D.: educator; b. at Farmington, N. Y., May 12, 1836; educated in common schools in New York and at Macedon Academy; superintendent of public schools in Three Rivers, Niles, Ypsilanti, and Adrian, Mich., 1858–79; Professor of Science and Art of Teaching, University of Michigan, 1879–88; became chancellor University of Nashville and president Peabody Normal College, 1888; author of *School Supervision* (1875); *Outlines of Educational Doctrine* (1880); *Contributions to the Science of Education* (1887); translated and edited *Compayré's History of Pedagogy* (1884); *Compayré's Lectures on Teaching* (1888); *Compayré's Elements of Psychology* (1890); *Rousseau's Émile* (1892).

Payne, WILLIAM HENRY: See the Appendix.

Paysandú, pī-săn-doo′: a town of Western Uruguay, the third in size in the republic; on the river Uruguay; 214 miles N. W. of Montevideo; pop. about 14,000 (see map of South America, ref. 8–E). It is the center of a rich grazing region and has a large trade, by the river, in cattle and hides; above it, at Guaviyú, is an extensive meat-packing establishment. During the war of 1864–65 between Brazil and Uruguay, Paysandú was taken by the Brazilians, Jan. 2, 1865, after an engagement of fifty-two hours. It is the capital of the department of Paysandú, which has an area of 5,116 sq. miles, and a population (1887) of 28,417. HERBERT H. SMITH.

Payson, EDWARD, D. D.: clergyman; b. at Rindge, N. H., July 25, 1783; was a son of Rev. Dr. Seth Payson (1758–1820); graduated in 1803 at Harvard; was three years teacher of an academy at Portland, Me., where he was in 1807 ordained to the Congregational ministry and was colleague pastor with a Mr. Kellogg until 1811, when he became sole pastor. Here he remained till his death, Oct. 22, 1827. He was a man of great zeal and of saintly devotion. It is a curious misconception which generally prevails that he was a "hell-fire preacher." He was tenderness itself, and the hold he had upon the esteem of New England is shown by the number of children to whom his name was given in baptism. He was a faithful, considerate pastor, a zealous and impassioned preacher. He was at times melancholic, probably because dyspeptic, and morbid, but ordinarily he was a most agreeable companion. His sermons, etc. (3 vols., Portland, Me., 1846; new ed. Philadelphia, 1859), have been published, together with a *Life*, by Asa Cummings, D. D.—His uncle, PHILLIPS PAYSON, D. D. (1736–1801), for many years Congregational minister of Chelsea, Mass., was one of the most scholarly and influential divines of the Revolutionary period. Revised by S. M. JACKSON.

Pāzand: a form of language. See under PAHLAVĪ.

Paz Soldan, paath′sōl-daan′, MARIANO FELIPE: geographer, historian, and publicist; b. at Arequipa, Peru, Aug., 1821. He graduated in law at Arequipa 1847; took up his residence in Lima, held judicial positions, and was secretary of the Peruvian legation in Colombia; in 1853 he studied prison systems in the U. S., making an elaborate report. He was Minister of Foreign Affairs under Castilla, and of Justice under Balta; was long director of public works, and introduced important reforms in the Peruvian prisons. During the Chilian occupation of Peru he lived in exile at Buenos Ayres. His geographical and historical works are numerous, and are standard authorities. They include *Atlas geográfico del Perú* (1861); *Historia del Perú independiente* (1866); *Diccionario geográfico estadístico del Perú* (1877); *Diccionario de la República Argentina* (1884); and *Historia de la Guerra del Pacífico* (1884). D. at Lima, Dec. 31, 1886.—His brother, MATEO PAZ SOLDAN (b. 1814; d. about 1872), published several mathematical works and a *Geografía del Perú* (1861). HERBERT H. SMITH.

Pea [recently formed as sing. to *pease* (regarded as a plur.) < M. Eng. *pese*, from O. Fr. *peis* (> Mod. Fr. *pois*) < Lat. *pisum* = Gr. *πίσον*; the word appears also by direct borrowing from Lat. in O. Eng. as *pise*]: a plant of the family *Leguminosæ*, much prized in temperate countries for its seeds. The pea is known to botanists as *Pisum sativum*. It is native to Asia. The field pea, *P. arvense*, thought by de Candolle to be a native of Italy, is probably not specifically distinct. This latter is much grown in the northern parts of the U. S. and in Canada as a forage plant. The garden peas fall into two general categories, the common or shelling sorts and the sugar or edible-podded varieties. The shelling peas are those which are commonly grown in the U. S., the edible product being the seeds alone, which are shelled from the pod. In the U. S. these seeds are generally eaten when fresh and green, but dry peas are much used in parts of Europe. The edible-podded peas are those which possess a soft pod which does not burst open when the seeds are ripe. The pod, with the inclosed seeds, is eaten in the green state, much as "string" beans are used. Like the common peas,

the varieties are either dwarf or climbing. The common or shelling peas may be again divided into smooth-seeded and wrinkled-seeded varieties, the latter being considered of the better quality. Each of these classes is again divided into dwarf and climbing varieties. The peas now sold by the seedsmen of the U. S. number about 150 varieties, of which the Extra Early, or Philadelphia, strain includes the greater number of forms, strains, or sub-varieties. In the census year 1890 there were 56,162 acres devoted to peas upon the larger truck-farms of the U. S., and the aggregate of the plantations in smaller market gardens and home gardens must have been half as much more. In that year, 7,971 acres were used in growing peas for seed. The pea industry has increased rapidly because of the demand for the canned product. The plant thrives best in the Northern States and in the cooler months. It will endure light frost, and the seeds are therefore generally sown for the main crops just as soon as the soil can be worked in spring. The half-dwarf varieties are generally preferred for field culture, as they do not need poles or brush upon which to climb, and they are more productive than the very early and very dwarf varieties. The cow-pea, now much grown in the Southern States for forage, is *Vigna* (or *Dolichos*) *sinensis*. It is native to China and Japan. The black pea, gray pea, and others are varieties of it. L. H. Bailey.

Peabody: city; Marion co., Kan. (for location, see map of Kansas, ref. 6–H); on the Atch., Top. and S. Fé and the Chi., Rock Is. and Pac. railways; 36 miles N. of Wichita, 118 miles S. W. of Topeka. It is in an agricultural region: contains 6 churches, public library, a national bank with capital of $50,000, a State bank with capital of $50,000, several flour-mills, creamery, windmill-factory, and 2 weekly newspapers; and has a large business in exporting cattle, hogs, poultry, eggs, wheat, flour, butter, etc. Pop. (1880) 1,087; (1890) 1,474; (1900) 1,369. Editor of "Gazette."

Peabody: town (formerly South Danvers); Essex co., Mass. (for location, see map of Massachusetts, ref. 1–I); on the Boston and Maine Railroad; 2 miles W. of Salem, of which it was once a part. It contains 9 churches, 9 public-school buildings, public-school property valued at over $140,000, Peabody Institute (founded by George Peabody in 1852), 2 libraries (Peabody Institute and the Eben Dale Sutton Reference, founded in 1867), 2 national banks with combined capital of $400,000, a savings-bank, and 2 weekly newspapers. The principal industry is the manufacture of plain and morocco leather. The town was named after George Peabody, who was born there. Pop. (1880) 9,028; (1890) 10,158; (1900) 11,523. Editor of "Reporter."

Peabody, Andrew Preston, D. D., LL. D.: clergyman and author; b. at Beverly, Mass., Mar. 19, 1811; graduated at Harvard in 1826; was three years a teacher; studied divinity at Cambridge, Mass.; was tutor at Harvard College 1832–33; was minister of the South parish (Unitarian), Portsmouth, N. H., 1833–60, and was Plummer Professor of Christian Morals and preacher to Harvard University 1860–81; edited *The North American Review* 1852–61, and was long a leading contributor to the religious periodical press. Author of *Lectures on Christian Doctrine* (1844); *Sermons of Consolation* (1847); *Conversation* (1856); *Christianity the Religion of Nature* (1864); *Sermons for Children* (1866); a book of European travel (1868); *Christianity and Science* (1874), besides many published sermons, translations from classic authors, reviews, personal reminiscences, etc. One of the most conservative of his sect, he was equally admired and loved by all parties. D. in Boston, Mass., Mar. 10, 1893. Revised by J. W. Chadwick.

Peabody, Elizabeth Palmer: educator; b. at Billerica, Mass., May 16, 1804; spent her childhood in Salem; became a teacher at Boston 1822; wrote articles, chiefly on educational topics, for *The Journal of Education*, *The Christian Examiner*, *The Dial*, and *The Democratic Review*; translated de Gerando's *Moral Self-Education*; edited *Æsthetic Papers* (1849), *Crimes of the House of Austria against Mankind* (1850); published *R. G. Hazard's Essay on Language, and Other Papers* (1857), *Records of a School*, *First Steps to History* (1833), *Chronological History of the United States* (1856), *Letters to Kindergartners* (1886), *Last Evening with Allston, and Other Papers* (1887), and other works; and with her sister, Mrs. Mary (Peabody) Mann, published *Moral Culture of Infancy* and *The Kindergarten Guide* (1863). Her special service was in the promotion of the kindergarten in the U. S. D. at Jamaica Plain, Mass., Jan. 3, 1894. Revised by C. H. Thurber.

Peabody, Francis Greenwood, A. M., B. D., and D. D., Harvard University, and D. D., Yale: clergyman and theological professor; b. in Boston, Mass., Dec. 4, 1847; graduated at Harvard College in 1869, and from Harvard Divinity School in 1872; shortly became pastor of the first parish church in Cambridge, Mass., and after a brief ministry, remarkable for its high character and success, resigned on account of ill-health; has been for some years overseer and preacher of Harvard University, Parkman Professor of Theology, and Plummer Professor of Christian Morals. To connect the study of sociology with the study of ethics and religion has been his most characteristic aim. Both as a writer and speaker he is attractive and persuasive to a high degree. He is a frequent and valued writer for the reviews and magazines. John W. Chadwick.

Peabody, George, D. C. L.: philanthropist; b. at South Danvers, Mass., Feb. 18, 1795, of poor parents; received a scanty education; was a clerk in stores at Thetford, Vt., Newburyport, Mass., and at Georgetown, D. C., where he became partner with Elisha Riggs in the dry-goods business 1814; removed to Baltimore 1815; soon afterward opened branch houses at New York and Philadelphia; made several voyages to Europe on commercial business; became head of the firm 1829; removed to London, England, 1837; withdrew from the house of Peabody, Riggs & Co., and established a banking-house 1843; accumulated a large fortune; aided Mr. Grinnell in fitting out Dr. Kane's Arctic expedition 1852; founded in the same year the Peabody Institute in his native town, the endowment of which he subsequently increased to $200,000; visited the U. S. in 1857; gave $300,000 for the establishment at Baltimore of an institute of science, literature, and the fine arts; in 1862 gave $2,500,000 as a fund for building lodging-houses for the poor in London; gave in 1866, during another visit to the U. S., $150,000 to establish at Harvard College a museum and professorship of American archæology and ethnology, an equal sum for a department of physical science at Yale College, and created a Southern educational fund of $2,100,000, subsequently increased to $3,500,000, besides devoting $200,000 to various objects of public utility. In 1867 he gave $140,000 to trustees who established the Peabody Academy of Science at Salem, Mass. In recognition of his munificence, Queen Victoria offered him a baronetcy, which he declined, and gave him her portrait; the corporation of London conferred on him the freedom of the city, and the citizens ordered a statue by W. W. Story, which was unveiled in the Royal Exchange July 23, 1869, by the Prince of Wales, during Mr. Peabody's absence on a final visit to the U. S. On this occasion he raised the endowment of the institute at Baltimore to $1,000,000; gave $60,000 to Washington College, Virginia, $50,000 for a Peabody Institute at North Danvers, $30,000 to Phillips Academy, Andover, $25,000 to Kenyon College, Ohio, and $20,000 to the Maryland Historical Society, besides making large gifts to various charities. In the previous year he had endowed an art school at Rome. D. in London, Nov. 4, 1869, less than a month after returning from the U. S. His remains, after funeral honors in Westminster Abbey (Nov. 12), were taken to the U. S. in a British vessel of war and buried in his native town, now called Peabody. Several other bequests to objects of public utility were made by his will, in which his remaining fortune, about $5,000,000, was left to his relatives. See the *Life*, by Phebe A. Hanaford (Boston, 1882), and Cochrane's *Beneficent and Useful Lives* (1890).

Peabody, Gen. Nathaniel: soldier; b. at Topsfield, Mass., Mar. 1, 1741; settled at Plaistow, N. H., as a physician 1761; became lieutenant-colonel of militia; was one of the captors of Fort William and Mary at Newcastle, Dec., 1774; was an active and influential member of the legislature, of several conventions, and of the committee of safety during the Revolutionary war; became adjutant-general of the State militia 1777; delegate to the Continental Congress 1779–80; filled nearly every State office during a long course of public service, including those of Speaker of the House 1793 and major-general 1793–98, and was one of the founders of the New Hampshire Medical Society 1790. D. at Exeter, N. H., June 27, 1823.

Peabody, Oliver William Bourne: biographer and reviewer; b. at Exeter, N. H., July 9, 1799; graduated at Harvard College 1816; practiced law at Exeter 1819–30; edited *The Rockingham Gazette* and *Exeter News-Letter*; removed to Boston 1830; aided his brother-in-law, Alexander

H. Everett, in editing *The North American Review*; was for several years an editor of *The Daily Advertiser*; was Professor of English Literature at Jefferson College, Louisiana, 1842–43; wrote the *Lives* of Gens. Putnam and Sullivan in Sparks's *American Biography*; published an edition of Shakspeare, with a *Life* and notes (7 vols., 1844); became pastor of the Unitarian church at Burlington, Vt., in Aug., 1845. D. at Burlington, July 5, 1848.

Revised by H. A. Beers.

Peabody, William Bourne Oliver, D. D.: clergyman and scientist; twin-brother of O. W. B. Peabody; b. at Exeter, N. H., July 9, 1799; graduated at Harvard College 1816; was assistant instructor at Exeter Academy 1817; studied theology at the Cambridge Divinity School under Dr. Henry Ware; was licensed as a preacher 1819, and ordained in Oct., 1820, pastor of the Unitarian church at Springfield, Mass., where he remained through life. Dr. Peabody was a man of extensive knowledge, of gentle nature, and winning manners. He wrote much on various branches of natural history; was one of the commissioners of the Massachusetts zoölogical survey, for which he prepared a *Report on the Birds of the Commonwealth* (1839); wrote the *Lives* of Alexander Wilson, Cotton Mather, David Brainerd, and James Oglethorpe in Sparks's *American Biography*; was well versed in landscape-gardening, and was an able lecturer upon scientific topics. D. at Springfield, May 28, 1847. His sermons, with a prefatory memoir by his brother, were published in 1849, and his *Literary Remains* in 1850.

Peace [M. Eng. *pees*, from O. Fr. *pais*, *pes* (> Mod. Fr. *paix*) : Ital. *pace* : Provenç. *patz* : Span. *paz* < Lat. *pax*, *pacis*, peace]: a suspension of war and a return to a state of intercourse such as existed before war, and to *amnesty*, or the oblivion, the waiving, of all future claims on account of those particular acts of injury for which a war was initiated. For the existence of peace a treaty is necessary, unless, indeed, complete conquest and absorption of an entire country has taken place, when there would be no one to negotiate with. Such a treaty, if there be a number of belligerents, may be made by all the parties on one side with all on the other; or each on one side may make a treaty with every other. The great treaties, such as the Treaty of Westphalia and the final act of the Congress of Vienna, are complicated documents: the first combining in two separate treaties—one between France and the German powers, and the other between Sweden and the same powers—the results of negotiations in two separate places; while the other contains the results of a great number of special treaties with powers not properly parties to the congress, or of such powers with one another, as well as of treaties between the parties to the congress themselves. If any question of ownership is left unsettled by the treaty of peace, the rule of *uti possidetis* applies, i. e. property of every kind remains legally in the hands of that state which at the close of hostilities actually was master of it. The effects of a treaty of peace, in particular the cessation of all war operations, begin at once upon its signature, even if ratification still remains necessary, unless the contrary is specified.

Revised by T. S. Woolsey.

Peace is also good order among the members of a state. Blackstone declares that "the common law hath ever had a special care and regard for the conservation of the peace; for peace is the very end and foundation of civil society." The primitive state, however, makes little pretense to the maintenance of public peace. On the other hand, private war between its members is not only tolerated but legally sanctioned. In English legal history the first attempts by the state to keep the peace appear to have been confined to the citizen's homestead. "Every man was entitled to peace in his own house. The brawler or trespasser in another's homestead broke the owner's peace, and owed him special amends." The grade of the offense varied with the owner's rank. Breaking the peace of an earl, or of a church, was a serious matter, while the peace of the king's house was broken at the risk of the wrongdoer's life. The domain of the king's peace was extended as his power increased. Under the later Saxon kings it covered the four great roads of the realm and all waterways on which provisions were carried. It was also given by the king's hand as a special privilege to individuals, and was to be enforced throughout the kingdom during certain periods, such as Christmas, Easter, and Whitsuntide weeks. After the Norman conquest the king's peace soon became synonymous with the peace of the kingdom. It was proclaimed at his accession as extending to all his loyal subjects, and after the adoption of the fiction that the king never dies, in legal contemplation it was never suspended. Royal officers were appointed to maintain it, notably the justices of the peace, and forms of legal procedure were devised for its more effective enforcement. One who had reasonable fear of harm to his person or property was allowed a writ *de securitate pacis*, by which the person threatening could be made to give security to the complainant to keep "our strict peace according to the custom of England." With the institution of this writ the king's peace became a well-defined common-law right of every law-abiding citizen. Thereafter breaches of the peace included not only public assaults and riots, but all unlawful acts which tended directly to produce public disorder, such as challenges to fight and the publication of libels. Modern statutes carefully define criminal breaches of the peace and regulate their punishments. See Bill of Peace.

Francis M. Burdick.

Peace, Breach of: See Peace.

Peace River: a river of British America, which rises in the Coast Range Mountains N. of British Columbia, and flows N. E. through the Rocky Mountains to near Athabasca Lake, more than 600 miles, where it turns N., and under name of Slave river enters Great Slave Lake. It is navigable for most of its extent, and passes through a fertile valley.

Peach [from O. Fr. *pesche* > Fr. *pêche* < Late Lat. *persica* (whence Germ. *pfirsich*, peach), for Lat. *persicum* (sc. *ma'lum*, apple), Persian apple, peach, the peach having once been supposed to have come from Persia]: one of the most delicious of all fruits of temperate climates, a member of the rose family, and closely allied to the apricot and plum. Most botanists now agree in referring the peach to the genus *Prunus*, which includes the plum, and its botanical name is then *Prunus persica*. There are some writers, however, who prefer to retain the old genus *Persica*, and who call the peach *Persica vulgaris*. It is now considered that the peach is native to China, although it is not known to have been found truly wild. The opinion of Knight, cited by Darwin and others, that the peach is derived from the almond is not generally accepted. The species is a small tree, usually under 25 feet in height at maturity, with a brittle wood, and narrow, willow-like, lanceolate leaves. The tree is usually short-lived, rarely living beyond fifty years, and under the strain of high cultivation and heavy production it usually perishes or becomes unprofitable before the twentieth year. The flowers are sessile and borne singly upon the branches of the previous year's growth, and appear in early spring in advance of the leaves. They have a five-parted calyx, five pink or blush petals, about twenty stamens borne upon the throat of the calyx, and a single superior ovary containing a pair of ovules. When ripe the ovary becomes a fleshy drupe with a hard rough pit or stone, which, by suppression of one ovule, generally contains but a single seed, and a soft fuzzy skin. A type of peach has arisen, however, with a perfectly smooth plum-like skin, and this is known as the Nectarine (*q. v.*). The peaches proper, exclusive of the nectarines, fall into two general classes, the clingstones, or pavies, and the freestones, these terms referring to the manner in which the flesh joins the pit. These classes grade into each other, especially in the early peaches of the Hale Early type, which are pronounced clingstones in ordinary or dry seasons, but which may become nearly free in moist seasons. The clingstones are now little prized in the Eastern States because they are difficult to prepare for culinary uses, but they comprise the chief California peaches which are now shipped to the eastern markets. Each of these classes may be again divided into white-fleshed and yellow-fleshed peaches, of which the former are, in general, of the better quality, but the latter are much more popular in the market, and are therefore mostly grown in the U. S. There are also various red-fleshed or blood peaches, but they are little grown. The flat peaches, sometimes considered a distinct species (*Prunus platycarpa*), are really only modifications or varieties of the common peach. They are sometimes flattened to little more than the width of the stone. The Peen-to is the chief representative of this class in the U. S.

The peach thrives in those warm or mid-temperate climates which abound in warm days and bright suns. It is scarcely grown in England in the open air because of the cool and humid climate. There is no country in which the peach is cultivated so commonly and with such great success as in

the U. S. Its range is from the Gulf of Mexico to Southern New England and the shores of Lake Ontario, in both New York and Canada, and Lake Michigan, and upon the Pacific coast it again finds congenial climate over a wide extent of territory. In the Northern States the peach thrives only in favored localities, as in Southern Connecticut, along the western end of Lake Ontario and about the lakes of Central New York, along Lake Erie, and on the eastern shore of Lake Michigan. In the north only those areas within the influence of bodies of water are safe for peaches, because they there escape the late spring frosts which destroy the fruit-buds. Large areas in Southern Illinois, in Missouri, and other of the Mississippi and plains States are devoted to peach-culture. While the peach grows upon a variety of soils, it thrives best in a loose sand. Some of the best peach regions are those with even poor and leachy sandy soil. The trees are set from 16 to 20 feet apart in the orchard, and they should be given clean cultivation, and annual crops should not be grown among them after the third year. The trees may be expected to bear a crop the third year from planting. Peach-trees are always sold and planted when a year old or less, from the bud. That is, the seed is planted in the spring, and the resulting seedlings are budded the following August or September. These buds grow the next spring (see GRAFTING), or a year from the time the seeds were planted, and the trees are ready for sale the following fall, by which time the tree has grown from 4 to 7 feet tall. In the southern parts of the U. S. this process is sometimes hastened by "June budding," which consists in budding the stocks the June or July following the sowing of the seeds. The buds grow at once, and in the fall of the same year the trees are ready for sale. The varieties of peaches are very many. The Melocoton tribe is still the most popular in the northern parts of the U. S. The Red-cheek Melocoton was a famous peach of American origin, which is now scarcely, if at all, known in its original form. It was a firm, yellow-fleshed peach, with a red-splashed cheek and a prominent tip-like projection upon the apex. It is now represented by the Early and Late Crawford and many others of the same type; and the Elberta, which is now the leading peach of the Southern and Middle States, is undoubtedly an offshoot of the same type. The Hale Early type, represented in many varieties, is still prominent. This class is characterized by rather small or medium-sized fruits, with white flesh of indifferent quality and clinging more or less tenaciously to the stone. These are chiefly valuable for their earliness and productiveness. The best account of them is Stoll's *Amerikanische Frühpfirsiche* (Klosterneuburg, near Vienna, 1889). Other important varieties are Mountain Rose, Old Mixon, Hill's Chili, Stump, Smock, Salway, Stevens's Rareripe, Chinese Cling, Honey, the two last being chiefly grown in the Southern States. The leading peach shipped from California is the Lemon Cling or similar varieties.

There are many serious diseases and insect enemies of the peach. The chief of these is the yellows, a disease of unknown origin, which always terminates fatally. It is characterized by a red-spotted and usually prematurely ripening fruit, the putting forth of short stiff-leaved shoots from the tips or upper buds of growing twigs, the pushing out of slender and generally bunched growths from the larger limbs or trunk, and finally by the general sickening and death of the tree. It is now known that this disease is not due to any peculiarities of soil or climate, nor to injuries, insects, or parasitic fungi. It is communicable from tree to tree, although its method of spread is unknown. An affected tree lives from three to six years. There are laws for the suppression of the disease in many peach-growing States. Rosette is a somewhat similar but more virulent disease occurring in Georgia and Kansas.

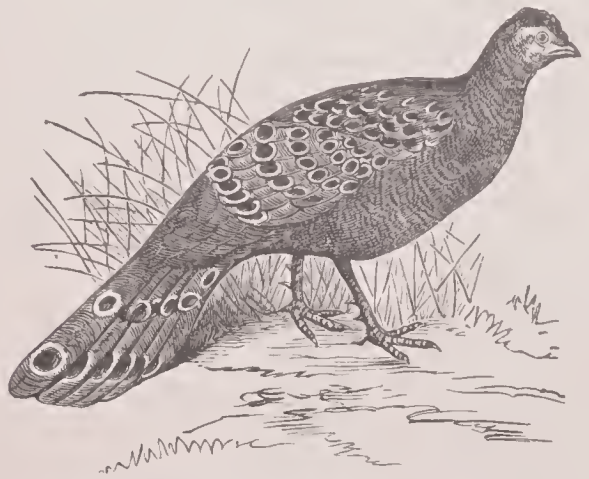
Fungous diseases of the peach are several, of which the most destructive is the twig-blight and fruit-rot, conditions caused by a fungus, *Monilia fructigena*. Spraying with Bordeaux mixture (see FUNGICIDE) in spring before the flowers appear is considered to be the best preventive. The curculio is the best known of the insect enemies of the peach. This beetle lays its eggs in the young fruit, and the larvæ are the "worms" of the stone fruits. The beetles are usually caught upon sheets or in a large canvas-covered hopper by jarring the trees in the morning before the insects begin to fly. Some success has been attained in spraying cherries with Paris green (see INSECTICIDE) to destroy the curculio, but the foliage of the peach is so tender that such treatment often injures it, and it is also doubtful if the practice is generally efficient. Borers are very troublesome in the trunks of peach-trees, especially near the base. These should be dug out in spring and fall. The stunted and yellow condition of trees injured by borers is often mistaken for the yellows. For fuller information on peaches in America, see the fruit manuals; also the special works of Fulton, Rutter, and Willcox. L. H. BAILEY.

Peach-curl: a fungous disease of peach leaves and twigs, in which they become somewhat swollen and much curled and deformed. It is caused by a minute parasitic fungus, *Exoascus deformans* (family *Gymnoascaceæ*), which penetrates the tissues of the leaf and finally produces spore-sacs upon the surface. In the latter eight or more spores are produced. Scribner recommends the early removal and destruction of all the diseased leaves and shoots, and suggests spraying the trees in early spring with a 30 to 40 per cent. solution of iron sulphate. C. E. BESSEY.

Spore-sacs of peach-curl. Highly magnified.

Peach-yellows: a contagious disease of peach-trees characterized by the yellowish-green foliage, dwarf shoots, and prematurely ripened, often reddish-stained fruits. A year or two after the first attack the trees die outright, or languish for several years, gradually dying from the extremities downward. It is common in most peach-growing districts in the eastern parts of the U. S. The cause of this disease is not certainly known, but is thought by some investigators to be due to the presence of bacteria. It is readily propagated by inoculation. No cure is known; all that can be done is to remove and burn the affected trees. CHARLES E. BESSEY.

Peacock [*pea-* < O. Eng. *pēa*, *pāwa*, peacock, from Lat. *pā'vō*, peacock, a loan-word, like Gr. *ταῶς*, from Semit.; cf. Arab. *tāwūs*]: any bird of the genus *Pavo* and family *Phasianidæ*. The several species are remarkable for the long and showy tail-coverts of the male. Three species are now recognized: 1, The common peacock (*Pavo cristatus*); 2, the black-shouldered peacock (*Pavo nigripennis*); and, 3, the Jason peacock (*Pavo muticus*). The common peacock is a native of Southern and Southeastern Asia, but is now naturalized in many parts of the world. Its flesh was formerly employed for food; but, except when young, it is scarcely palatable. The white peacock is an albino of the ordinary



Tibet peacock (*Polyplectron tibetanum*).

species. The name peacock is also sometimes applied to the species of the allied genera, *Polyplectron* and *Crossoptilon*. Revised by F. A. LUCAS.

Peacock, THOMAS BROWER: See the Appendix.

Peacock, THOMAS LOVE: author; b. at Weymouth, England, Oct. 18, 1785; entered the civil service of the East India Company 1818; was employed in the London office of that corporation until 1856; was a friend of Lamb and Shelley, and wrote a memoir of the latter. He was author of several volumes of poems and romances which met with favor at their first appearance, were forgotten for many years, and obtained a renewed popularity on their republication in 1875 by Lord Houghton, accompanied by a biographical sketch. Among his novels are *Headlong Hall* (1815); *Nightmare Abbey* (1818); *The Misfortunes of Elphin* (1829); and *Gryll Grange* (1860). His principal poems are *Palmyra* (1806); *The Genius of the Thames* (1810–12); and *Rhododaphne* (1818). D. in London, Jan. 23, 1866.

Peacock-pheasant: any pheasant of the genus *Polyplectron*; so called from the fact that the plumage, and especially the tail-feathers, of the males are adorned with large eye-like spots, suggesting those of the peacock. The generic name is given on account of the two or more spurs which arm the tarsus of the males. F. A. L.

Peale, Charles Willson: painter and inventor; b. at Chestertown, Md., Apr. 16, 1741; was successively a saddler, silversmith, watchmaker, and carver; studied painting under Copley at Boston and at the Royal Academy, London, under Benjamin West; painted the first portrait of Washington as a Virginia colonel 1772; commanded a company at the battles of Trenton and Germantown; was a member of the Pennsylvania convention of 1777; painted the portraits of the most prominent officers of the Revolution; was a leading promoter of the Pennsylvania Academy of Fine Arts; opened the first American museum; was the first American manufacturer of enamel teeth; invented a great variety of machines, and published a number of scientific essays. D. in Philadelphia, Feb. 22, 1827.
Revised by Russell Sturgis.

Peale, Rembrandt: artist; son of Charles W. Peale; b. in Bucks co., Pa., Feb. 22, 1778; received an artistic training from his father; painted a portrait of Washington Sept., 1795; studied under West at London 1801–04; spent several years at Paris; returned to Philadelphia 1809; achieved eminence as a portrait-painter; executed the well-known pictures *The Roman Daughter* and *The Court of Death* (the latter was profitably exhibited in the chief cities of the U. S. for a number of years); lectured on the portraits of Washington, and published a *Biography of Charles W. Peale*, *Notes on Italy* (1831), *Portfolio of an Artist* (1839), and other works on art. D. in Philadelphia, Oct. 3, 1860. Revised by Russell Sturgis.

Peanut: See Goober.

Pear [O. Eng. *peru*, from Lat. *pi'rum*, pear; cf. *pi'rus*, pear-tree, probably akin to Gr. ἄπιος, pear-tree]: a fruit of the rose family, widely cultivated in temperate climates. The common pear is *Pyrus communis*, and is native to Europe. In recent years the Chinese and Japanese pears, belonging to the species *Pyrus sinensis*, have been introduced into the U. S. in several varieties. This species is distinguished from *P. communis* by a more vigorous growth, larger and darker-colored leaves which are very sharply serrate, and especially by the long-stemmed apple-like fruits, which generally have a distinct depression about the stem. The fruits of this Oriental species are very much inferior to the common pears, being very hard and gritty, and lacking in agreeable flavor. The tree makes a good stock upon which to bud or graft other pears, however, and the hybrids with *P. communis*, like the Kieffer, Le Conte, and Garber, combine the vigor of the Chinese type with some of the edible qualities of the common type. *Pyrus nivalis*, the perry or snow-pear of Europe, is not grown in the U. S. The Russian pears recently introduced into the U. S. are simply very hardy and usually somewhat inferior types of the common *P. communis*. Dwarf pears are produced by grafting the common pears upon the quince-root. While all varieties of pears can be made to grow upon the quince, there are comparatively few which are considered to be profitable when so grown. Dwarf pear-trees are esteemed because they bear when young, and are usually very productive, and the small size of the tree renders the labor of picking and pruning easy. Pears can also be dwarfed by grafting them upon the thorn-trees (various species of *Cratægus*), but experience in this direction is so limited that the practice can not be recommended.

Pears are successfully grown over a wide territory in North America. In the southern parts of the U. S. derivatives of the Oriental stock, particularly the Le Conte, are now chiefly grown for commerce. Much of the Pacific slope is admirably adapted to pear-culture, and in that region the fruit attains a much greater size than it can be made to acquire in the older States. Of the Eastern States it is generally considered that New England and New York are best adapted to pears. The best pear lands are those which contain a liberal amount of clay. Standard pears—those grown upon pear-roots, in distinction from dwarfs—are commonly planted from 20 to 30 feet apart each way, and they are trained and pruned in essentially the same manner as apple-trees. The varieties of pears are very various in habit of growth, however, and the methods of pruning should be carefully adapted to the particular variety in hand. Dwarf pears are set about 12 to 15 feet apart, although the distance should be adjusted to the method of trimming. If the trees are kept in a narrow form and allowed to grow rather high they may be set as close as 10 feet, but if they are trimmed in the flat-topped fashion a rod apart each way is not too great. It is essential to success in the culture of dwarf pears that the trees be kept low. The tops should never rise above 10 or 12 feet. This is accomplished by shortening in the annual growth a third or half its length every winter. Trees kept to this stature do not become top-heavy and break off at the union with the quince, and they do not make greater demands than the quince-root can meet. It is also important that the point of union between the pear and quince should be placed from 3 to 6 inches in the ground, in order to prevent the breaking apart of the two, and to protect the quince-stock from borers. If attention is given to these essentials dwarf pear-trees, contrary to the general notion, will continue to thrive and bear for more than half a century. The pear, whether upon the roots of pear or quince, is budded in the nursery during the summer season. Nurserymen in the U. S. commonly import pear-stocks or seedlings from France, because seeds are more easily obtained there, the labor required in growing them can be procured more cheaply, and the leaf-blight, which is a serious disease in the U. S., is not present. These stocks are commonly imported when a year old—that is, in the fall succeeding the sowing of the seeds. These are set in nursery rows, and are budded the following summer, when the stocks are in their second year. These buds start the following spring in the North, and when they have grown two or three years the trees are ready for sale. Dwarf pears are propagated in much the same manner. About 3,000 varieties of pears are described, but the number in general cultivation in the U. S. will not greatly exceed fifty. The most popular of all pears in North America is the Bartlett, which originated in England about 1770, and which is there known as Williams's Bonchretien, from one Williams, a nurseryman of Turnham Green, who obtained it from Wheeler, who raised it. This is nearly always grown as a standard. Other leading sorts are Howell, Sheldon, Flemish Beauty, Anjou, Clairgeau, Lawrence, Summer Doyenne, Seckel, Louise Bonne. Kieffer is also gaining rapidly in favor, because of its vigor and productiveness, although the fruit is low in quality. Le Conte, of the same type, is the most popular pear of the southern parts of the U. S. For dwarfs, Duchesse d'Angoulême is the most popular, although several other varieties thrive upon the quince. Pears improve in quality if picked before full maturity—but when fully grown—and are ripened in a dry, cool room.

The most serious disease of pears is the pear-blight, or fire-blight. This is a germ disease, the microbes residing in the wood, usually of the smaller limbs, and breaking down the starch contents of the cells. The germs probably enter the tree through the growing or expanding tips, as the apex of a shoot or the flowers. They do not enter through the roots. The symptoms of the disease are a uniform browning and finally blackening of the leaves and young shoots, and the death of the bark along the branches where the injury has proceeded. The only treatment is to cut off the affected parts and burn them. Pear-blight is peculiar to North America. This disease must not be confounded with the pear-leaf blight, which causes the leaves to become spotted and to fall, and which, when it attacks the fruit, makes the pears crack. This leaf-blight is caused by a parasitic fungus (*Entomosporium maculatum*), and it can be readily overcome by the use of Bordeaux mixture. (See Fungicide.) The fungus which renders pears scabby is practically the same as that which produces the similar condition upon the apple, and the treatment is the spray of Bordeaux mixture. Among insects, the codlin-moth is probably best known. Its larva is the "worm" of apples and pears. This insect is combated by sprays of arsenites. (See Insecticide.) There are also various borers in pear-trees, which should be dug out as soon as discovered. There are other insects which occasionally do great damage in certain localities or in particular years. For further information, the reader should consult the fruit manuals; also Field's *Pear-culture*; Quinn's *Pear-culture for Profit*; Parry's *Forty Years' Experience in Pear-growing*; and Waite's *Pollination of Pear Flowers* (*Bull.* 5, Div. Vegetable Pathology, Dept. Agr., Washington). L. H. Bailey.

Pearce, Charles Sprague: figure and portrait painter; b. in Boston, Mass., Oct. 13, 1851; pupil of Bonnat in Paris;

member Society of American Artists 1886; received honorable mention, Paris Salon, 1881; third-class medal, Paris Salon, 1883; Temple gold medal, Pennsylvania Academy, Philadelphia, 1885; medal of honor, Ghent Exhibition, 1886; second-class medal, Munich Exhibition, 1888; member of the international jury of awards, Paris Exposition, 1889; grand diploma, Berlin Exhibition, 1891. His works are notable for fine drawing and cleverness of execution. His *Fantaisie* is in the Temple collection, Pennsylvania Academy, Philadelphia, and pictures by him are in the Art Institute, Chicago, Boston Art Club, and the Massachusetts Charitable Mechanics Association, Boston. Studio at Auvers-sur-Oise, France. WILLIAM A. COFFIN.

Pea Ridge: a range of hills in Benton co., Ark., near the northwest corner of the State, noted for the important battle fought there Mar. 6–8, 1862, between the Union forces under Gen. Curtis and the Confederates under Gen. Van Dorn, resulting in the defeat of the latter.

Pearlash: a term often applied to the commercial potassium bicarbonate. Pearlash, however, is properly the same substance as commercial potash, which has merely been subjected to a somewhat more careful preparation. The black salts, or crude black potash obtained by the boiling down of lye from wood-ashes, instead of being simply fused, is stirred for some time with an iron rod upon the hearth of a furnace in which a flame is made to play over the mass. The carbonaceous impurities are thus burned out, and the mass becomes of a more or less bluish-white color. See POTASSIUM.

Pear-leaf Blight: See BLIGHT.

Pearl-fisheries: the business or practice of taking shellfish which produce pearls, especially the pearl oyster, *Margaritiphora margaritifera*, Lam., a species widely distributed throughout tropical seas, and subject to considerable local variation, some authorities recognizing three species instead of one. While originally prosecuted for the pearls alone, pearl-fisheries are now carried on equally for the sake of the pearl oyster shells, from 12,000 to 15,000 tons of these being annually employed for the manufacture of various articles. The earliest recorded fisheries were those carried on in the Persian Gulf and on the coast of Ceylon. Later the Red Sea furnished pearls for the Egyptians, and after the discovery of America large numbers were taken from the Gulf of Panama and along the northern coast of South America. At present the most important fisheries are in the Persian Gulf, the Gulf of Manaar—between Ceylon and the mainland—the Gulf of California, the Sulu Archipelago, and on the tropical coasts of Australia. The Gulf of Manaar has always been a famous ground, and as early as 1330 8,000 boats were engaged there. The extensive Australian fisheries are carried on principally for the sake of the shells, and have their headquarters at Thursday island, in Torres Straits, where the best shells are found. Before the discovery of the Australian grounds the price of the best pearl shell had reached $2,000 per ton, but their immense yield has reduced the price to $900 per ton for the best, the value ranging from that down to $300. For a long time the only means of obtaining pearls was the primitive one of divers working from open boats without other equipment than a stone to aid them in their descent, and this method is still pursued. These divers stayed under from fifty to eighty seconds, gathering such shells as were at hand, and placing them in a basket to be pulled up by men in the boat above. A boat carried usually ten divers, who worked in pairs, the one above pulling up the sinkstone when his partner was at the bottom, and later on pulling him up also. At present the DIVING-DRESS (*q. v.*) is extensively employed, and by its aid the oysters can be taken in water 120 feet deep, although the majority are gathered in water from 40 to 50 feet deep. This apparatus necessitates the use of somewhat larger boats than were employed in the old style of fishery, and on the Australian coast the favorite boat is a lugger of about 10 tons burden. Dredging is also employed to gather shells in Australia. The use of the diving-dress temporarily increases the yield of pearl shells, but depletes the beds rapidly, and considerable attention is being given to the problems of regulating the fisheries and cultivating the pearl oyster. In Ceylon there has long been a close time, and the hours during which fishing may be carried on are also fixed by law. Information concerning the pearl-fisheries and statistics of their products are meager and not very reliable. The annual yield of the Gulf of California is said to be about $350,000, that of the Persian Gulf not far from $2,000,000. In 1887 30,947,905 shells, value not given, were taken in Ceylon, and the product of the shell-fishery of Queensland averages £69,000. Some gathering of unios for pearls has been done in the U. S., principally in Ohio, and there have been fisheries for these shells in Scotland. The industry is systematically carried on in parts of Europe, notably in Germany, and to a greater extent in China, where considerable attention is also given to the production of what may be termed sacred shells. This is done by introducing small figures of Buddha, or other divinity, stamped from tin or copper, between the shell and mantle. The mussel is then returned to the water, and in the course of from six months to two years retaken, when the figures are found coated with pearl uniform with the lining of the shell. F. A. L.

Pearl Harbor: See the Appendix.

Pearl River: a river formed by several head-streams which unite in Leake co., Miss. It flows in a general S. course for 250 miles into the Mississippi, and is for some distance the eastern boundary of Louisiana. Its navigation is impeded by snags and sand-bars.

Pearls: secretions of the "mantle" or lining membrane of various kinds of shellfish, consisting, like the shell itself, of carbonate of lime united with animal matter. They are of the same color as the interior of the shell in which they are found—white, black, pink, etc., but generally "pearly," or *nacreous*, as it is termed, i. e. with a play of delicate tints. The quality of a pearl is termed its orient. They are often attached to the inside of the shell, or are irregular or distorted in form, and have then but little value, only those of finely rounded shape or pear-shaped being employed in fine jewelry. The pearls of commerce come chiefly from a large shellfish known as the pearl-oyster (*Meleagrina*), and are procured mainly in the Persian Gulf and on the west coast of Mexico. The shells themselves yield "mother-of-pearl." Along the California coast the brilliant pearly green *abalone* shells (*Haliotis*) are gathered in like manner for inlaid work and ornaments, and in them are found green pearls. Pink pearls, not nacreous, are obtained from the large pink conchs (*Strombus*) of the West Indies. The river-shells, or "fresh-water mussels" (*Unios*), yield pearls also, and they abound in the rivers of the U. S. Some fine pink, cherry-colored, and other "fancy" pearls have been found in the rivers of Ohio and other States. GEORGE F. KUNZ.

Pearse, CARROLL GARDNER: See the Appendix.

Pearson, Sir CHARLES JOHN: See the Appendix.

Pearson, JOHN, D. D.: theologian; b. at Great Snoring, England, Feb. 28, 1613; educated at King's College, Cambridge, where he became fellow 1635; was afterward divinity professor and master of Trinity College (1662), and became in 1672 Bishop of Chester. D. at Chester, July 16, 1686. Author of *An Exposition of the Creed* (1659). His *Minor Theological Works* were published in 1844.

Peary, ROBERT E.: Arctic explorer; b. at Cresson Springs, Pa., May 6, 1856; educated at Bowdoin College; entered the civil engineer corps of the U. S. navy 1881. In 1886, with one companion, he penetrated the Greenland ice-cap for 100 miles in lat. 69° 30′ N.; went, with six companions, to McCormick Bay, N. W. Greenland, 1891, to study the Eskimos; in 1892, in a brilliant sledge journey of 1,300 miles, discovered Independence Bay on the N. E. coast (lat. 81° 37′ N.); partly outlined Peary Channel, supposed to be the northern limit of Greenland, which he proved to be an island; reached Independence Bay again in 1895 (after defeat by prolonged storms in 1894), but was unable, on account of failing supplies, etc., to explore the archipelago to the N. of Greenland. In 1898 he again went to Greenland, intending to ascend Smith Sound with his steamer. He described his Aretic work in his book *Northward Over the Great Ice* (1898).

Peary Land: See the Appendix.

Peasants' War: the revolutionary rising of the peasants of Southern and Central Germany in 1525. The Reformation was the immediate occasion of this movement, but not its real cause. Similar risings were frequent before the Reformation, and the real cause of all these risings was the miserable social condition of the peasants. They were serfs; that is to say, they belonged to the soil on which they were born, and through that to the lord who owned the soil. The latter often appropriated for his own use the common pasture-grounds of the village, forbade his tenants to fish in the streams and hunt in the woods, and increased the ground-rent, the tithe, and the socage service to an op-

pressive degree. While these were the causes of the revolt the Reformation, with its sudden enkindling of religious fanaticism in crude and ignorant minds, supplied the occasion. In spite of the warnings, and even denunciations of Luther and Melanchthon, several of the Reformers, such as Karlstadt, and many of their adherents among the nobility, aimed at once at a social and religious Reformation of the most radical nature. In 1524 a general fermentation spread among the German peasantry; and when, Jan. 1, 1525, the convent of Kempten was captured and plundered by a swarm of revolting peasants, this event became the signal for a general rising of the peasantry from the Alps to the Hartz and from the Rhine to the Bohemian frontier. With the exception of a few cases (as Thomas Münzer and Götz von Berlichingen) the peasants had no leaders and no organization. They gathered together in multitudes of from 8,000 to 30,000. Castles were burned, monasteries destroyed, cities plundered, and the most atrocious cruelties committed. As soon, however, as they fell in with regular armies—in the S. under Truchsess von Waldburg, in the N. under Philip of Hesse—they were routed or massacred in spite of their fierce resistance; and the revenge which the ruling classes took upon them was as cruel and as barbarous as their own behavior. Though the war lasted only a few months, it resulted in an enormous loss of life and property. The social position of the peasantry remained the same, or became even worse. See Oechsle, *Beiträge zur Geschichte des deutschen Bauernkriegs* (1829); Wachsmuth, *Der deutsche Bauernkrieg* (1834); Bensen, *Geschichte des Bauernkriegs in Ostfranken* (1840); Zimmermann, *Allgemeine Geschichte des grossen Bauernkriegs* (1841–43); Cornelius, *Studien zur Geschichte des Bauernkriegs* (1862); Schreiber, *Der deutsche Bauernkrieg* (1864).

Revised by F. M. Colby.

Peaslee, Edmund Randolph, M. D., LL. D.: gynæcologist; b. at Newton, N. H., Jan. 22, 1814; graduated at Dartmouth College in 1836, and in medicine at Yale in 1840; was appointed lecturer at Dartmouth in anatomy and physiology in 1841, and was professor of the same 1842–70; at Bowdoin College was lecturer on anatomy and surgery in 1843, and professor 1845–57, when he gave up anatomy, and remained Professor of Surgery till 1860; was Professor of Physiology and General Pathology in 1851 in New York Medical College, and Professor of Obstetrics 1858–60; was Professor of Gynæcology at Dartmouth in 1872, at the Bellevue Hospital Medical College in New York in 1874. In 1858 he took up his residence in New York. The degree of LL. D. was conferred upon him by his *alma mater* in 1859. He had been president of the New Hampshire State Medical Society and of several other medical associations, and was an honorary member of gynæcological or obstetrical societies in Boston, Berlin, Philadelphia, and Louisville. He published *Human Histology* (1857); *Ovarian Tumors and Ovariotomy* (1872); besides numerous articles in the medical journals. D. in New York, Jan. 21, 1878.

Revised by S. T. Armstrong.

Peat: See Fuel.

Peat-mosses: See Mossworts.

Pea-weevil, or **Pea-bug**: a small dark beetle (*Bruchus pisi*), well known for its ravages among dried peas. It may be destroyed by scalding the peas before planting. The insect lays her egg in the flower, and the grub passes into the pea while it is still growing.

Pebble [O. Eng. *papol-stān*, liter. (in form), *pebble-stone*, probably a loan-word from Latin *pa'pula*, pimple]: a small water-worn stone of any variety. Scotch pebble is simply agate. Brazilian pebble is a very transparent rock-crystal sometimes used by spectacle-makers as a material for their lenses. It is, however, much inferior to good glass. Most of the so-called pebble-spectacles are of common glass.

Pecan' (Fr. *pecane*): a tree, the *Carya olivæformis* (also known as *Hicoria pecan*), a species of hickory growing on river-banks from Indiana to Texas. The pecan is well known for its fine, delicious nuts, also called pecans, which constitute a considerable article of commerce. The tree is tall, slender, and has a hard timber. In the States bordering on the Gulf of Mexico it is planted in orchards for its nuts, and a score or more of named varieties are grown.

Revised by L. H. Bailey.

Pec'cary [from native S. Amer. name; cf. Fr. *pécari*, Span. *pecar*]: any one of certain swine-like, artiodactylate ungulates, composing the family *Dicotylidæ*. The peccaries are of two species, both American. The collared peccary (*Dicotyles tajacu*) ranges from Arkansas southwestward through Mexico and over a great part of South America. It is 3 feet long and sometimes weighs 60 lb. It is of a dark-gray color, and has a gland upon the loins which secretes a fetid substance. It is gregarious, and is a dangerous animal to attack, as the herd often assails the offending huntsman most vigorously and persistently with their strong tusks. The white-lipped peccary (*Dicotyles labiatus*) is a larger South American species. Both kinds are very destructive to growing crops, both are swine-like in habits and appearance. Their flesh is somewhat like pork, but not so good.

Revised by F. A. Lucas.

Pecchio, pek'ki-ō, Giuseppe, Count: publicist; b. at Milan, Italy, Nov. 15, 1785; d. at Brighton, England, June 4, 1835. After taking his degree in law at Pavia he returned to Milan, and in 1810 was given an important administrative post. In 1814 the overthrow of the old political conditions led to his retirement into private life. In 1819, however, he was elected to the provincial assembly; but he became implicated in the revolutionary movement, and the unhappy insurrection of Mar., 1821, caused him to flee to Switzerland. Thence he went to Spain, where he wrote down his impressions in his *Sei mesi in Ispagna nel 1821* (Madrid, 1821). Having made the acquaintance of the English Dr. Bowring, he went with him to Portugal, writing there his *Tre mesi in Portogallo* (Lisbon, 1822). Thence he went to England and became a teacher of Italian in Nottingham. In 1825 he and Count Gamba were intrusted by the friends of Greece with the delivery of £60,000 that had been raised to help the cause of Greek independence. This mission resulted in his book, *Relazione degli avvenimenti della Grecia nella primavera del 1825* (1826). Returning to England, Pecchio became Professor of Modern Languages at Manchester (1826); but in 1828 he married a wealthy lady and went to Brighton to live. Besides the works already mentioned, we have from him: *Saggio storico sull' Amministrazione finanziera dell' Ex-Regno d'Italia del 1802 al 1814* (1820; 2d ed. 1826); *L'anno 1826 dell' Inghilterra* (1827); *Storia dell' Economia Pubblica in Italia* (1829); *Vita di Ugo Foscolo* (1830); *Osservazioni semi-serie di un Esule sull' Inghilterra* (1831); *Storia critica della Poesia Inglese* (unfinished, 4 vols., 1833–35). See Ugoni, *Vita e Scritti di G. Pecchio* (Paris, 1836).

A. R. Marsh.

Pecht: See Bubastis.

Peck, George, D. D.: clergyman and author; b. in Middlefield, N. Y., Aug. 8, 1797; traveled and preached extensively; was principal of Oneida Conference Seminary 1835–39, then editor of *The Methodist Quarterly Review* (1840) and of *The Christian Advocate* (1848); wrote *Wyoming, its History*, etc. (1858); *Universalism Examined*; *History of the Apostles and Evangelists*; *Scripture Doctrine of Christian Perfection*; *Rule of Faith*; *History of Methodism within the Bounds of Old Genesee Conference*; and *Life and Times of George Peck* (1874). D. at Scranton, Pa., May 1, 1876.

Revised by A. Osborn.

Peck, Jesse Truesdell, D. D.: bishop; b. at Middlefield, N. Y., Aug. 4, 1811; joined the Oneida Conference in 1832; became principal of the Methodist seminary at Gouverneur, N. Y., in 1837, and of Troy Conference Academy at West Poultney, Vt., in 1841; in 1848 he was elected president of Dickinson College, Carlisle, Pa., but after four years' service returned to the pastorate. He occupied Foundry pulpit in Washington, D. C., 1852–54, and was secretary and editor of the tract society of his Church 1854–56. He subsequently served several years in pulpits in New York city and California, Peekskill, Albany, and in Syracuse, N. Y., where he was active in founding the Syracuse University. In 1872 he was elected bishop. He was author of *The Central Idea of Christianity* (New York, 1855); *The True Woman* (1857); *What must I do to be Saved?* (1858); and *The History of the Great Republic* (1868). D. at Syracuse, N. Y., May 17, 1883.

Revised by A. Osborn.

Peck, John Mason, D. D.: preacher; b. at Litchfield, Conn., Oct. 31, 1789; became a licensed Baptist preacher in Greene co., N. Y., in 1811; was ordained in 1813; removed in 1817 to St. Louis; was for forty years a successful pioneer preacher of Illinois and Missouri; organized in 1826 the first church of his denomination in St. Louis; was one of the founders of Shurtleff College, Upper Alton, Ill., and of the theological school at Covington, Ky.; received in 1852 the degree of D. D. from Harvard College. Author of

Guides for Emigrants (1831 and 1836); *Gazetteer of Illinois* (1834); *Life of Boone*, in Sparks's collection; *Father Clark, the Pioneer Preacher* (1855). D. Mar. 15, 1858.

Peck, Tracy, A. M.: classical scholar; b. at Bristol, Conn., May 24, 1838; graduated at Yale 1861, and Berlin University; Professor of Latin, Cornell University, 1871–80; became Professor of Latin in Yale College 1880; editor, with Prof. C. L. Smith, of Harvard, of a College Series of Latin Authors; author of philological and critical papers, especially in the line of restoring to Latin its ancient pronunciation; president American Philological Association 1885–86.

Peck, William Guy, LL. D., Ph. D.: soldier and mathematician; b. at Litchfield, Conn., Oct. 16, 1820; graduated at the U. S. Military Academy in 1844; was promoted to the U. S. Corps of Topographical Engineers, and served on the survey of Portsmouth harbor, in Western explorations under Fremont, and at the Military Academy as Assistant Professor of Philosophy, till the breaking out of the war with Mexico. He was then assigned to duty with the Army of the West under Gen. Kearny, and after the war became assistant instructor in mathematics at the Military Academy. He resigned his commission in Oct., 1855, and was for two years Professor of Physics and Civil Engineering in the University of Michigan. In 1857 he was called to Columbia College, New York, where he served as Professor of Mathematics, Mechanics, and Astronomy. He was engaged with Prof. Charles Davies in compiling a dictionary and encyclopædia of mathematics; he was the author of a treatise on mechanics, and the American editor of Ganot's popular *Physics*, besides which he wrote a course of mathematical text-books. D. Feb. 7, 1892.

Peck, William Henry: See the Appendix.

Peckham, Rufus William: See the Appendix.

Peckham, Stephen Farnum: See the Appendix.

Peckham, Wheeler H.: See the Appendix.

Pecos: See Tañoan Indians.

Pecos River: a stream of New Mexico and Texas; rises in San Miguel co., N. M., and flows in a general S. S. E. course, falling into the Rio Grande del Norte after a course of 800 miles. It flows through a broken country, and in summer is dry the greater part of its length.

Pecquet, pā'kā', Jean: anatomist; b. at Dieppe, France, about 1620; studied medicine, and especially anatomy, at Montpellier; discovered and demonstrated the course of the lacteal vessels in the body; wrote *Experimenta Nova Anatomica* (1651); *De Circulatione Sanguinis et Chyli Motu* and *De Thoracis Lacteis* (1651). Pecquet's discovery, which soon proved to be of the greatest practical importance, and has exercised a great influence on the development of physiology, immediately found many ardent adherents, but also many vehement opponents. D. in 1674.

Pectase: a substance of the class of ferments found in association with Pectose (*q. v.*) in the tissues of fruits and vegetables. The special function of pectase is to transform the pectose of unripe fruits, in the process of ripening, to Pectin (*q. v.*). Pectase is producible from the fresh juice of a plant—the carrot, for example—by precipitating with alcohol. This converts it into an insoluble modification, without, however, depriving it of its peculiar fermentive action upon pectosic substances. It has not been obtained in a crystalline form, being doubtless a colloid substance, like diastase, synaptase, and ferments generally.

Revised by Ira Remsen.

Pectic Acid: an insoluble gelatinous substance produced by the action of alkaline solutions upon the Pectin (*q. v.*) of ripe fruits and vegetables. Frémy calculates its composition as $C_{16}H_{22}O_{15}$, but this is not regarded as settled. The pectates of the alkalies are soluble, but all other bases form jelly-like insoluble masses, almost impossible to wash pure. Pectic acid, pectosic acid, and pectin are the principal constituents which give the gelatinous character to preserved fruits, fruit and vegetable jellies, etc.

Revised by Ira Remsen.

Pectin, or **Plant-jelly** [*pectin* is from Gr. πηκτός, curdled, congealed, deriv. of πηγνύναι, make fast or stiff]: a substance existing naturally in ripe fruits and vegetable juices generally, being a product, during the ripening, of the peculiar ferment called Pectase (*q. v.*) on the Pectose (*q. v.*) of unripe vegetables and fruits. It was obtained by Braconnot, its discoverer, by precipitating ripe-apple juice with alcohol, after boiling to coagulate the albumen, and filtering. Frémy improved upon this by first precipitating lime with oxalic acid. Pure pectin is white, amorphous, and soluble in water. The composition of pectin is somewhat uncertain. Frémy computes the formula $C_{16}H_{24}O_{16}$, but others have obtained figures differing a little from his.

Revised by Ira Remsen.

Pectinibranchia: See Monotocardia and Gasteropoda.

Pectoril'oquy [Lat. *pec'tus*, *pec'toris*, breast + *loqui*, speak]: in auscultation of the chest, a preternatural distinctness in the sound of the patient's speech, as propagated to the auscultator's ear through the air-passages and pulmonary tissues. Pectoriloquy is either cavernous or amphoric, according to the quality or timbre of its sound. It does not always, however, indicate a cavity in the lung, as was once supposed. It may arise from the solidification of a portion of the lung.

Pectose [deriv. of *pectin*]: a highly important proximate principle of vegetable bodies, from which proceed all the gelatinous constituents of fruits and vegetables. It exists largely in unripe fruits and roots, being, like cellulose, one of the "plastic" constituents, and giving, for instance, the hardness to green fruits. It is, however, a substance not only wholly insoluble, like cellulose, but, unlike the latter, extremely perishable or easily alterable. Therefore we have found no way of isolating and purifying it, so as to determine its composition. It is surmised to be a carbohydrate, like cellulose—that is, containing its hydrogen and oxygen in the proportions that form water. It exists in all parts of vegetable bodies, and is always accompanied by a peculiar ferment substance called Pectase (*q. v.*), which has the power to transform it, during the ripening of the fruit or maturation of the plant, into the plant-jelly or Pectin (*q. v.*). This substance and its derivatives are of great interest, and demand much further investigation—an investigation surrounded, however, with great difficulties, from the non-crystalline or colloid nature of these compounds.

Revised by Ira Remsen.

Pectosic Acid: an intermediate product of the action of the ferment pectase upon Pectose (*q. v.*). Like pectin, the principal product, it is highly gelatinous in its character, forming a frequent constituent of artificial fruit-jellies. Its composition is yet uncertain.

Peculiar, or **Peculiars**: the name given to a church or churches exempt from the jurisdiction of the bishop of the diocese in which the peculiar is situated: (1) as being subject to the jurisdiction of some other bishop, or (2) entirely exempt from episcopal jurisdiction. Chapels royal were exempt from episcopal jurisdiction. Battle Abbey, Bocking, Guernsey, Jersey, and Stamford are peculiars, and are entitled to their respective deans. Westminster Abbey and St. George's chapel, Windsor, are royal peculiars. W. S. P.

Pedagogics [from Gr. παιδαγωγός, a slave who acted as attendant and protector of a child, and instructed him in behavior and good manners; he attended him especially when he went to the school or palæstra. In Rome later the title was applied to the Greek slave who while acting as an attendant also taught the child Greek. Hence the transfer of signification]: the science of education; a body of educational doctrine pertaining to the mental and moral training of the young. Being a derived science, however, and depending mostly upon psychology for guidance as to ends and means, it is developed in various ways according to the psychological standpoint of the author. Some writers make much of what may be called the *a priori*, or rational, phase of psychology, deducing maxims for instruction and moral training from the original constitution of mind. Rosenkranz, in his *Philosophy of Education*, is perhaps the best exponent of this method of treatment. He deduces the laws or principles of education from a formal consideration of man as a self-realizing being in a process of development. The nature, form, and limits of education are all discussed from this standpoint, as are the special phases of physical, intellectual, and moral education. The subject-matter of the studies is assumed, but not discussed in detail. Dr. Harris, U. S. commissioner of education, points out the fact that there are five windows of the soul to be opened by these studies. In the elementary school arithmetic and physics open the soul to a quantitative knowledge of inorganic nature; geography and natural history to organic nature. History gives the mind an insight into the will of man as it has manifested itself in institutions: literature, drawing, and the like cultivate the æsthetic or emotional

sides of the soul; while grammar helps the mind to look within at its own processes, since in grammatical study the distinctions of thought are objectively examined. Thus three windows reveal what is within, viz., intellect, sensibilities, and will, while two reveal what is without, viz., organic and inorganic nature.

Another class of educational writers ignore largely the necessary and original laws of mind, as seen in rational psychology, adopting as their standpoint the *a posteriori* or concrete phase of mental life. They inquire, not what is the original equipment of the mind, but how does it grow? with what contents is it and ought it to be filled? In this view all the facts revealed by rational psychology and the self-realization of the mind are assumed but scarcely mentioned, attention being focused upon the concrete studies, their choice, sifting, sequence of topics, and co-ordination; also their treatment as to methods of presentation. Everything is examined from the empirical, or experience, side of psychology. There is little interest in the abstract terms arising from the refinement of psychological distinction, but a great deal of interest in the contents of children's minds, their natural interests and dispositions, their capacities in the acquisition of knowledge; in short, in the *growth* of their minds. Education, viewed from the standpoint of rational psychology, deals more with *static* relations of faculty and knowledge, whereas the same subject, seen from the standpoint of empirical psychology, concerns itself mostly with knowledge processes, hence is chiefly *dynamic* in its tendencies. *Apperception*, or mental assimilation, furnishes in this case the key to matter and methods for all departments of education.

A third standpoint from which to investigate educational questions is child-study upon a physiological basis. The senses are the medium through which the child gains his experience of the outer world, and the physical side in general is a constant factor in mind-growth. It follows, therefore, that a large number of important topics in education have a physiological aspect. The tonic and quantitative relations between external stimuli and the corresponding response of the mind in sensations are carefully investigated by hundreds of experiments in the domain of touch, taste, smell, hearing, and vision. The contents of children's minds are determined, as are also their fancies, falsehoods, tastes, ideas of justice, powers of graphic representation, conceptions of religion, and the like. Their capacities for apperception, association, memory are investigated by experimentation. Likewise, on the other hand, the conditions of health and disease for the various senses and the nervous system, as well as for digestion, circulation, and respiration, are carefully studied, and deductions made as to light, temperature, ventilation, size of type for books, bodily position, etc. It is chiefly from these three standpoints—rational psychology, the psychology of experience, and child-study upon a physiological basis—that the specific problems of education are examined. To some of the most important of these we may now turn our attention.

1. *What shall Constitute the Subject-matter of Education?*—This question is answered by each age and race according to the varying standard of civilization. The Persian taught his son to ride the horse, shoot with the bow, and tell the truth. The Greek taught his son literature and gymnastics; the Roman boy had to learn the tables of the law and how to swim. Education for gentlemen and for the professions may be quite different from the curriculum designed for the masses. Till late in the nineteenth century higher education was confined mostly to classic languages and mathematics. Herbert Spencer, however, in his *Education*, asks earnestly what knowledge is of most worth, and finds the answer in science. For the most part, American schools teach the studies that have become traditional, reading, writing, spelling, arithmetic, grammar, geography, and history, together with such branches as social or professional pressure may force upon them, such as scientific temperance and bookkeeping or stenography. Dr. Harris, as shown above, has sought to demonstrate that the standard studies now found in the common-school curriculum have a right to their place, because of their value in opening up the windows of the soul. It is only in recent times that any serious attempt has been made to determine upon rational grounds what subjects shall be selected and upon what principle the sequence of their various parts shall proceed. Concerning the latter topic Prof. Ziller, of Leipzig, pointed out the fact that there are two general methods of sequence for the parts of a study, one being the concentric method and the other the historical method, or progress according to *culture-epochs*. By the concentric method he means the selection of a few central facts of a subject, which are to be learned in the early grades, and then expanded like a series of concentric rings each succeeding year. Thus in Bible history a few facts about the life of Christ would be first taught, and this knowledge widened year by year by the addition of new facts. The other or historical method assumes that the child's mind in its development goes through in miniature substantially the same culture-epochs that the race passed through in its progress to the present stage of civilization, and that, consequently, if we would adjust the matter of our instruction most perfectly to the child's understanding and spontaneous interests, we must let him pass through ideally the stages that the world passed through really. For all subjects, therefore, having a human element, like Bible history, profane history, literature, art, languages, we must arrange our topics according to the important culture-epochs. The latter are sufficiently indicated by the great authors who have treated them. "Periods which no master has described, whose spirit no poet breathes, are of little value for education" (Herbart). Ziller claims that the concentric method sacrifices the interest of the pupils to a considerable degree, and that it produces educational waste, in that the same things have to be learned over again year after year in new combinations, whereas the historical method according to culture-epochs promotes natural interest through the freshness of material and its ideal adaptation to the growing mind of the child. Furthermore, he would avoid tediousness by presenting these topics as treated by masters, just as Greek boys were inspired by the writings of Homer. As for non-culture subjects, like the sciences, it may be pointed out that here we find two principles of advance, the first being that of the logical development of subjects as completed sciences, for instance, the order of evolution in biology from monera to man, and the psychological development as determined by the ability and knowledge of the child at any given stage. The latter order is the true one for the school, because knowledge exists for the child, not the child for knowledge.

2. *How shall Studies be Articulated or Co-ordinated?*—This question is supplementary to that of sequence of topics in the various subjects, for before studies can be intimately associated there must be some definite order of sequence established. This query, like the other, is a new one in American education. In the past it has hardly been raised, except perhaps in connection with the specific training of the "faculties." It has been assumed, for example, that "memory studies" precede "reason studies," but these faculties were not regarded as having any very intimate relations, so that the problem of the co-ordination of studies could hardly arise under these conditions. Each study developed its own independent line of ideas. Even history and geography, reading and spelling, were often taught as quite distinct and separate subjects, while efforts to find natural and easy associations between geography and science or history and literature were unheard of. Active interest, however, now exists for this phase of education, it being held that such associations as lead the studies to re-enforce one another enhance the pupil's interest in his work, promote his understanding, and develop his volitional power. The numerous plans for the co-ordination of studies may be reduced to three types, as follows: (1) The subordination of most branches to a few important ones. Ziller says that since the dominating ends of education are the moral ones we should select the culture studies, literature and history (profane and biblical), as the core of concentration around which the other studies should cluster like iron filings to a magnet. Others say that *real* knowledge as contained in the sciences is more important, and that these should be the central subjects for correlation. (2) The acceptance of universal scientific law, or philosophical unity of knowledge, as the guide to the concentration of studies. (*Talks on Pedagogics*, Col. I. W. Parker.) According to this plan the central, or knowledge, subjects are mineralogy, geology, geography, astronomy, meteorology, biology, zoölogy, anthropology, ethnology, and history. Out of these real studies all formal ones, like reading, writing, drawing, painting, modeling, number-work, and the like, are to grow. The central subjects being logically connected, and formal studies growing out of the concrete ones, it will be seen that there is a basis for weaving all series of ideas arising from the various branches into a connected whole. As may be seen, the emphasis falls upon the science studies, yet civilization developed without

science; it is, moreover, open to question whether the logical philosophical unity of the separate sciences is one that the teacher can see, or seeing teach. (3) The co-ordination of equal or independent branches through their natural relations. This plan grants to every important group of subjects its own principle of development. Thus culture subjects may follow the historical sequence where that seems advantageous without subordinating natural history to a principle of sequence not its own. Natural science, on the other hand, is free to develop according to its own laws, without dragging literature and history out of their natural channels. Dr. Frick (see *Herbart and the Herbartians*) presents a skeleton programme for a classical school with pupils ranging from ten to nineteen or twenty years of age. In this programme the historical interest is the backbone of the whole body of higher education, but not history as taught by the culture-epochs. This principle of Ziller is here modified on the ground that the environment of the pupil furnishes as good a bridge to his understanding and interest as the culture-epochs can furnish. Consequently, interest in national history comes first, and that in ancient history second. This is in accordance with the declaration of William II., that he wanted from the schools young Germans, not young Greeks and Romans. The reading-matter in the mother-tongue is depended upon to preserve the unity of the course through the studies touching the home environment of the child. There is the literature of culture and history (biography), and that of nature and occupation. Judicious selection will bind the studies together through close associations. In a similar manner these unions may be strengthened through art and music, which may emphasize now the natural, now the human elements. Geography touches three great realms, history, science, and economic occupation. It is the seat of history, the condition of animal and plant life, and in commercial geography the revelation of the modern commercial world. Frick agrees with Ziller and Herbart that only the important epochs of history should be studied. There are enough such to occupy the attention of children without wasting their time on non-essentials. Co-ordination is still further promoted by preserving within each important subject or group of subjects a unity of treatment. Thus, for instance, the whole of natural science is to be taught with its manifold relations clearly in view, a technical isolation of the various topics, like botany, zoölogy, geology, etc., being avoided. Furthermore, the search for and selection of organic bodies of knowledge pertaining to individuals, to communities, and states are to be constant; so, too, emphasis must be laid upon middle or turning points in the events pertaining to individuals or communities, to whole historical epochs, or to the development of important ideas.

3. *How shall Subjects be Taught?*—It may be well at the outset to make a distinction between that phase of method which can ignore the subjective or psychological element and proceed upon strictly logical lines to the exposition of knowledge, and that phase, mostly belonging to elementary education, which must take full account of limitations in knowledge, aptitude, and interest. The first method is seen in its perfection in the university, the latter in the primary school. Were the second phase of method not a real and necessary one the normal school would hardly have an excuse for existence. This is the department of method brought to view most clearly by empirical psychology and physiological child study. Here again we must distinguish between special and general methods—between devices for individual subjects or topics and the laws for all sound methods. The science of education can hardly busy itself with devices whose name is legion, but must content itself with an exposition of fundamental principles. With the apperception of the child in view (see Lange's *Apperception*) we may distinguish three grand phases in every sound method: (1) That of the assimilation of individual facts; (2) that of inductive approach to generalization, or rules and principles; and (3) the practical application of these principles, or the return from general principles to individual facts. This exposition gives rise to what the Herbartians call the *Formal Steps of Instruction*. (See McMurry, *General Method*, or De Garmo, *Essentials of Method*.) The term *formal* as here used signifies *universal*, since these steps must be recognized more or less clearly in all devices.

4. *How shall Moral Training be Effected?*—Some educators regard religious instruction as essential to this end; others try to engraft an ethical system more or less objectified upon the minds of the pupils, while Herbart advances the thought that through the school studies themselves, provided they are well selected, well articulated, and well taught, we may reveal to the child the moral order of the world, both as it will appeal to him as an individual and as a member of a social, family, civil, or business group. This thought is one of the most fruitful of modern pedagogics, and well worthy the closest attention of every teacher. (See *Herbart and the Herbartians*.)

The following-named works in English are of importance to the student of pedagogics: Lange, *Apperception* (Boston); Parker, *Theory of Concentration* (New York); Rosenkranz, *Philosophy of Education* (New York); Bain, *Education as a Science* (New York); Rein, *Outlines of Pedagogics* (Syracuse, N. Y.); Herbart, *Science of Education* (Boston); De Garmo, *Essentials of Method* (Boston); De Garmo, *Herbart and the Herbartians* (New York); Ufer, *Introduction to the Pedagogy of Herbart* (Boston); Rosmini, *Method in Education* (Boston); Spencer, *Education* (New York); McMurry, *General Method* (Bloomington, Ill.); Preyer, *The Development of the Intellect* and *The Senses and the Will* (New York); Pickard, *School Supervision* (New York); Froebel, *The Education of Men* (New York); Radestock, *Habit and Education* (Boston). CHARLES DE GARMO.

Pedee River: See GREAT PEDEE RIVER.

Pedersen, KRISTIERN: writer; b. in Svendborg, Denmark, about 1480; studied in Paris; returned (1517) and settled in Lund; became Christian II.'s secretary, and followed him into exile (1526). After the king's imprisonment he received permission (1532) to settle in Malmö, where he established a printing-office. Some time after this he joined the Lutheran Church. He is the first Danish prose-writer of prominence, and well deserves the title of father of Danish literature. His style is pure and direct, and all his writings are filled with a true national spirit. His translation of the New Testament (1529) and of the Psalms (1531) is superior to any then produced. His publication of *Saxo* (1514) undoubtedly saved that work from destruction, as no MS. has been preserved. His works, historical and religious, have been edited by C. J. Brandt and J. F. Fenger (5 vols., Copenhagen, 1850–56). D. Jan. 16, 1554. D. K. DODGE.

Pedianus: See ASCONIUS PEDIANUS.

Pedicula'ti [Mod. Lat., plur. of *pedicula'tus*, pedicled, deriv. of *pedi'culus*, stem, pedicle, from Lat. *pedi'culus*, dimin. of *pes*, *pe'dis*, foot]: an order of fishes whose representatives are distinguished by their grotesque forms. The skull is constructed in nearly the same manner as in the typical fishes; the epiotics united behind the supraoccipital; the intermaxillary and supramaxillary bones well developed and distinct; the first vertebra is united to the cranium by suture; the scapular arch is, as in ordinary fishes, composed of a great external bone (proscapula) and two internal bones (hypercoracoid and hypocoracoid), but coalescent with the proscapula; with these are articulated the actinosts, which are remarkable for their length; between the proscapula and the skull intervenes a post-temporal, which is not bifurcate, but connects by a squamous suture with the skull; the branchial aperture is thrown backward in or near the axilla of the pectoral fin; the ventral fins are more or less jugular; the dorsal fin is divided into a spinous and a soft portion; the latter is normal; the former modified, and in some of the representatives of the order represented by a filament in or near the nasal region. The order thus distinguished is composed of several families—viz., *Maltheidæ*, or the batfishes; *Lophiidæ*, or the anglers; *Ceratiidæ*; and *Antennariidæ*. Revised by F. A. LUCAS.

Pediment: See GABLE.

Pedipal'pi [Mod. Lat., from Lat. *pes*, *pedis*, foot + Mod. Lat. *palpus*, tactile organ, from Lat. *palpare*, to feel]: an order of Arachnida embracing a few tropical forms for which the common names of whip-scorpions and scorpion-spiders have been proposed. As these terms imply, they present general resemblances to both scorpions and spiders. Thus they have the second pair of appendages strong and sometimes furnished with pincers, the abdomen is plainly jointed, and in *Thelyphonus* is terminated with a many-jointed whip-like tail. In all the first pair of true legs terminates with a many-jointed whip-like portion. About thirty species are known. Comparatively little is known of their habits, but they have the reputation of being very poisonous; but a single species of *Thelyphonus* has been reported from the U. S. J. S. KINGSLEY.

Pedometer: See ODOMETER.

Pedra'rias: the name commonly given by historians to Pedro Arias Dávila or de Ávila; soldier and governor; b. in Spain about 1442. He was of good family, and served with distinction in the conquest of Granada and in Africa. In 1513 he was nominated governor of Castilla del Oro, on the coast of the Isthmus of Panama, including the colony of Darien, where Balboa had come into power. (See Balboa and Darien.) Pedrarias sailed from San Lucar Apr. 12, 1514, with a large fleet and 1,500 men. On his arrival at Darien (June 30), Balboa readily acknowledged his authority, but Pedrarias, a man of suspicious and violent character, imprisoned him on various charges. Subsequently, through the interposition of the bishop, the rivals were reconciled. Pedrarias promised Balboa his daughter in marriage, and lent his aid for the exploration of the South Sea; but on reports (probably false) of Balboa's treachery, he seized and executed him (1517). In 1519 he founded a new capital at Panama. Under his rule Spanish power was rapidly extended on the isthmus. He did all he could to prevent the exploration of Nicaragua by Gil Gonzalez Dávila (1522), and endeavored to forestall him by sending Córdoba to colonize that country. Córdoba rebelled, and Pedrarias captured and beheaded him (1526). In consequence of numerous complaints Pedrarias was superseded in 1526, but he was made governor of Nicaragua, where he died at Leon, Mar. 6, 1531. Herbert H. Smith.

Pedro I. (Dom Antonio Pedro de Alcantara Bourbon): first Emperor of Brazil; b. near Lisbon, Portugal, Oct. 12, 1798. He was the second son of Dom João, afterward John VI. of Portugal; was taken with the royal family to Brazil (1807), received a somewhat limited education there, and in 1818 was married to the Archduchess Leopoldina of Austria. His father was crowned King of Portugal at Rio de Janeiro in 1816, but returned to Lisbon in 1821, leaving Dom Pedro as regent. The prince was now heir to the throne, his elder brother having died. At this time the movement for the separation of Brazil from Portugal assumed active form, and the prince regent favored it more or less openly. He at length sent a refusal to the peremptory order of his father to return to Portugal, and on Sept. 7, 1822, he definitely declared for independence. He was proclaimed emperor in October, and crowned Dec. 1. The Portuguese authorities made little active resistance, except in the northern provinces, where they were soon driven out. At first the emperor was enthusiastically supported; but in 1823 he assumed a reactionary policy, dismissed and banished the liberal Andrada ministry, and forcibly dissolved the constituent assembly. In Mar., 1824, he promulgated the constitution (prepared by a council of state) which was in force during the empire. The empress died in 1826, and in 1829 he married Princess Amelia of Leuchtenberg. Uruguay, which had been attached to Brazil, became independent, after a rebellion of several years, in 1828. The opposition to the emperor increased when, in 1826, he fell heir to the Portuguese throne. In the impossibility of reuniting the two countries he transferred his claim to Portugal to his daughter, Donha Maria da Gloria, but the distrust continued, and at length broke out in popular tumults. To prevent bloodshed, the emperor abdicated in favor of his son on Apr. 7, 1831, and soon after sailed for England. On his arrival there he at once assumed the leadership of a movement for the restoration of his daughter, who had been deprived of the Portuguese throne by the usurpation of Dom Miguel. The latter was deposed after a civil war, and Donha Maria was crowned. Dom Pedro died two days after, in Lisbon, Sept. 24, 1834. Herbert H. Smith.

Pedro II. (Dom Pedro de Alcantara): son of Pedro I. and Emperor of Brazil; b. at Rio de Janeiro, Dec. 2, 1825. As he was a child when his father abdicated in his favor, Brazil was governed by regents until July 23, 1840, when his majority was proclaimed at the request of the parliament. He was crowned July 18, 1841, and in 1843 married Thereza Christina, sister of the King of the Sicilies. From the first he proved himself an intelligent, liberal, and humane ruler, and during his reign Brazil made great advances in civilization and material prosperity; he was the honored protector of science, the arts, and literature, for which he had marked tastes, and he was universally respected at home and abroad. On the other hand, important questions were sometimes neglected for minutiæ, and he showed, perhaps, a want of strength in great crises. He was strongly attached to constitutional forms, and governed entirely through his ministers. Rebellions in São Paulo and Minas Geraes, 1842, in Rio Grande do Sul, 1842–45, and in Pernambuco, 1849, were suppressed. In 1864–65 Brazil successfully supported the revolutionist Flores against the Government of Uruguay, which had refused satisfaction for injuries done to Brazilian subjects. Lopez, president of Paraguay, made war on Brazil, ostensibly on account of the Uruguayan question, Dec., 1864; this led to the Triple Alliance between Brazil, the Argentine Republic, and Uruguay, May 1, 1865, and a bloody war of five years. (See Lopez, Francisco Solano.) The emperor took a personal part in the first campaign. Traveling as a private gentleman, he visited Europe 1871–72, attended the Centennial Exposition in the U. S. 1876, going thence to Europe and the East, and in 1886–89 again went to Europe. By a law passed in Sept., 1871, children born of slave parents were freed under certain conditions, and an emancipation fund was established. Subsequently the abolition movement became a popular uprising, and culminated in the law of May 13, 1888, by which all slaves were freed. The emperor personally favored emancipation, and early freed the crown slaves, but he did not lead the movement nor greatly influence it; and it excited unfavorable comments that the laws of 1871 and 1888 were passed during his absence. Republican principles had been slowly but steadily gaining ground, and were fostered by the perfect freedom of the press; in 1885 republican deputies were first elected to parliament. The Princess Isabel was heir to the throne, and during her father's trips abroad had acted as regent; the republicans opposed her for alleged subserviency to the Church, and because she was married to a foreign prince, the Count d'Eu. It was generally supposed that a decided republican movement would be deferred until the emperor's death; but it was precipitated by discontented army officers, who excited a mutiny of the troops at Rio de Janeiro, and proclaimed a revolution Nov. 15, 1889. The emperor abdicated without resistance, and was at once sent with his family to Portugal; there the empress died from the effect of the excitement and shock, Dec. 28, 1889. The ex-emperor declined a pension which was offered to him by Brazil. D. in Paris, Dec. 5, 1891.
Herbert H. Smith.

Pee'blesshire: an inland county of Scotland; on both sides of the Tweed (hence sometimes called *Tweeddale*); consists mostly of low, well-wooded mountains. Area, 354 sq. miles. Pop. (1901) 15,066. Rearing of sheep and cattle is the chief occupation; coal is mined, and manufactures of woolens are carried on. The only royal burgh in the shire is Peebles, on a peninsula at the confluence of the Eddleston with the Tweed, 22 miles S. of Edinburgh, and the seat of a county administration (see map of Scotland, ref. 12–H). It is the birthplace of William Chambers, who in 1859 made a gift to the town of a spacious suite of buildings for educational purposes, the Chambers Institution. Pop. of town (1891) 4,704. The counties of Peebles and Selkirk send one member to Parliament.

Peekskill: village; Westchester co., N. Y. (for location, see map of New York, ref. 8–J); on the Hudson river, and the N. Y. Cent. and Hudson River Railroad; 43 miles N. of New York city. It contains 12 churches, 2 union public schools, St. Gabriel's boarding-school for young ladies (Protestant Episcopal), St. Joseph's Home and Franciscan Convent (Roman Catholic), a military academy, a House of the Good Shepherd (Roman Catholic), a free public library, several high-grade boarding-schools, a national bank with capital of $100,000, a savings-bank, and 4 weekly newspapers. There are water-works, electric-light and sewerage systems, and important manufactories, including iron-foundries, stove-works, cigar-factories, steam flour-mill, blank-book and book-binding establishment, and shirt-factories. The village has much scenic and historic interest. Pop. (1880) 6,893; (1890) 9,676; (1900) 10,358.
W. J. Charlton, board of trade.

Peel. Arthur Wellesley, D. C. L.: statesman; b. in 1829; youngest son of Sir Robert Peel (1788–1850): educated at Eton and Baliol College, Oxford; was secretary to the Poor Law Board 1868–71; secretary to the Board of Trade 1871–73: and secretary to the Treasury 1873–74. He was first elected Speaker of the House of Commons in 1884, and since then he has been re-elected three times. Retired Apr. 7, 1895. He was member for Warwick 1865–85, and since for Warwick and Leamington.

Peel, Sir Robert: statesman; b. near Bury, Lancashire, Feb. 5, 1788; was educated at Harrow and Christ Church, Oxford, where he passed B. A. as double first-class, the first

who ever had the distinction. In 1809 he entered Parliament for Cashel; was made Under-Secretary for the Colonies 1811, and was (1812–18) Chief Secretary for Ireland, where his Tory principles led to the most severe criticisms from the opposition. He established the Irish constabulary. Peel represented Oxford University in Parliament 1818–22; introduced and carried (1819) a bill to return to specie currency; was Home Secretary 1822–27, 1828–30; introduced and carried important reforms in the administration of criminal law; remodeled the London police; moved the bill for Catholic emancipation (1829), and thus broke with the Tory leaders. Previously Peel's name, with no special justice, had been associated with the leadership in the opposition to this cause, doubtless because he had held an important post in Ireland as a Tory. The University of Oxford rejected him in the new election; he re-entered Parliament for Westbury, and again represented Tamworth 1832–50; was First Lord of the Treasury and Chancellor of the Exchequer 1834–35, and afterward headed the Conservative opposition, having resisted the parliamentary reform of 1831–32 with all his power; was again Premier 1841–46, during which time his position drifted slowly from that of a protectionist and strict Conservative to that of a free-trader, and he at last supported the repeal of the corn-laws. He afterward acted generally with the Whigs. D. in London, July 2, 1850, in consequence of a fall from his horse. Peel was a man of thorough patriotism and high moral principle. His hereditary conservatism, although strengthened by a dislike of too hasty changes, was ever held subject to feelings of justice and humanity. He refused the Garter and the peerage, and was universally respected for honesty, truthfulness, and ability. See *Sir Robert Peel*, by Guizot (Paris, 1859), and *Sir Robert Peel*, by Henry Lord Dalling and Bulwer (London, 1874); and monographs by F. C. Montague (1888), Justin McCarthy (1891), and J. R. Thursfield (1891).

Peel, Sir ROBERT, G. C. B.: b. in London, May 4, 1822; was educated at Harrow and Christ Church, Oxford; was 1844–46 an *attaché* at Madrid; was secretary of legation 1846, and *chargé d'affaires* at Berne 1846–50; a lord of the admiralty 1855–57; Chief Secretary for Ireland 1861–65; was a Liberal member of Parliament for Tamworth 1850–80; was sworn of the Privy Council 1861; was made G. C. B. 1868; married in 1856 the eighth daughter of the Marquis of Tweeddale. D. at Brighton, May 8, 1895.

Peele, GEORGE: dramatist; b. in Devonshire, England, about 1553; graduated at Broadgate's Hall (now Pembroke College), Oxford, 1579; settled at London as a theatrical writer; was an associate of Nash, Marlowe, and Greene, and author of half a dozen plays, the best of which is *David and Bethsabe*. They were republished by Dyce, with his poems and miscellaneous writings (3 vols., 1828–39). D. about 1598.

Peele, JOHN THOMAS: See the Appendix.

Peepul: See BO-TREE.

Peerlkamp, PETER HOFMAN-: classical scholar; b. in Groningen, Holland, in 1786; professor at Leyden in 1822; retired in 1849. D. in Hilverzum, near Utrecht, Mar. 29, 1865. Peerlkamp may be called the father of a wanton method of textual criticism which rejects as spurious or emends whatever seems not to conform to a preconceived standard of poetic perfection and propriety. This perniciously subjective principle was rigorously applied by Peerlkamp particularly to the *Odes* of Horace, of which scarcely one remained intact. The ingenuity of his analysis, his fervor of conviction, and the brilliancy of his Latin style secured him many followers; but at the present time this athetizing mania possesses at best but a pathological interest. Among his writings may be mentioned: Horace, *Odes, Satires, Ars Poetica*; Tacitus, *Agricola*; Vergil, *Æneid*; Xenophon of Ephesus; and his own *De vita, doctrina et facultate Nederlandorum qui carmina composuerunt* (2d ed. 1838). ALFRED GUDEMAN.

Peers [Fr. *pair*, from the Latin *par*, equal]: noblemen having a special dignity or privilege. The meaning of the term has varied widely at different times. Thus in England the earlier usage, as in the phrase of Magna Charta, "judgment of his peers" (*judicium parium*), gives it merely the general meaning of equals, while at present it is used in a special sense to denote the members of the nobility and those prelates of the Church of England who are entitled to a seat in the House of Lords. The members of the nobility entitled to be called peers include dukes, marquises, earls, viscounts, and barons. In France Louis XVIII. created in 1814 a house of peers, but this peerage comprised only a very limited number of the whole class of the nobility. The attempt to make it hereditary failed, and in 1848 the Chamber of Peers ceased to exist.

Peet, STEPHEN DENISON, A. M., Ph. D.: anthropologist; b. at Euclid, O., Dec. 2, 1830. In 1837 the family removed to Green Bay, Wis., which was a center of trade for various Indian tribes. Young Peet entered Beloit College, and while a student had his curiosity awakened with respect to the mound-builders, whose mounds were numerous in Beloit and its vicinity. He studied theology at New Haven, Conn., and at Andover, Mass., where he graduated in 1851, and returned to Wisconsin, where he was a missionary for several years. Subsequently he took charge of important churches at Racine, Wis., and Ashtabula, O. From 1878 to 1888 he edited *The American Antiquarian*, and he was largely instrumental in organizing the Ohio Archæological Society and the American Anthropological Association. In 1878 he returned to Wisconsin, and held the pastorate at Clinton for eight years thereafter. His principal works are *The Ashtabula Disaster* (Chicago, 1879); *History of Ashtabula County, Ohio* (Cleveland, 1879); *Ancient Architecture in America* (Chicago, 1884); *Picture Writing* (1885); *History of Early Missions in Wisconsin* (Madison, 1886); *Primitive Symbolism* (Chicago, 1887); *The Effigy Mounds of Wisconsin* (1888).

Peewit: See LAPWING.

Peffer, WILLIAM ALFRED: See the Appendix.

Peg'asus (in Gr. Πήγασος): in Grecian mythology, a winged horse, who, together with Chrysaor, was begotten by Poseidon and the Gorgo Medusa at the sources of Oceanus, whence his name Pegasus (from πηγή, fountain). He sprang from the headless trunk of Medusa after she had been slain by Perseus. He first touched the earth on the Acropolis of Corinth, where Bellerophon caught him while he was drinking from the fountain Pirene. Mounted on his back Bellerophon performed many hazardous deeds (see CHIMÆRA), but when he attempted to fly to heaven he fell off and became lame and blind. Pegasus flew to heaven, where he thenceforward dwelt in the palace of Zeus. When Mt. Helicon, under the influence of the songs of the Muses, was soaring to heaven, its progress was stayed by a stamp of the hoof of Pegasus. On the smitten spot the spring Hippocrene (the fountain of the steed) burst forth, and hence he was called the horse of the Muses. J. R. S. STERRETT.

Pegmatite [from Gr. πῆγμα, anything fastened together]: a name originally suggested by Haüy for coarse-grained granitic rocks in which the quartz and feldspar are intergrown, each having a continuous crystallographic structure over considerable areas. The rocks have gradually come to be called *graphic granites* (Germ. *Schriftgranit*), although their characteristic structure, whether microscopic or macroscopic, is still called pegmatitic. The petrographical term *pegmatite* now includes all very coarse granites and granitic vein-stones. See GRANITE. G. H. WILLIAMS.

Pegu: a name of geographical and historical interest associated with the northwestern part of the Indo-Chinese peninsula, adjoining the Bay of Bengal, and especially about the Gulf of Martaban. It has sometimes been a separate kingdom, sometimes a dependency of Burma, and the territory covered has extended as far N. as Ava, sometimes as far S. as the Peninsula of Kra. It is now a British governmental division of Burma, occupying the lower valleys of the Irawadi and Salwen rivers from Tenasserim to Southern Arrakan. The town of PEGU, formerly a capital and important city, is now a small town and a railway station, 45 miles N. E. of Rangoon, on the Pegu river, an affluent of the Hlainy (see map of S. India, ref. 3–L).
MARK W. HARRINGTON.

Peh-chele, or **Pechili**: an old name for the province of China now known as CHIHLI (*q. v.*); also the shallow gulf which lies between Chihli and the Yellow Sea.

Peh-la, or **Pela** [Chinese; literally, white wax]: a kind of wax prepared by the Chinese from the secretions which an insect of the cochineal family (*Coccus sinensis*) deposits on the twigs of a species of ash (*Fraxinus chinensis*), called by the Chinese *lah-shoo*, or wax-tree. The insect resembles a louse, and is said to be taken indoors to be cared for during the winter, and put back on the trees in spring. The peculiar secretion which it voids about the end of summer is collected and melted by the natives, and forms a hard, white, translucent body, like spermaceti, which melts at a temper-

ature of 180° to 186° F., and is largely used for candle-making. It is extensively produced in Sze-chuen and in the northern provinces. R. Lilley.

Pehlavi Language: See Pahlavī.

Pei-ho, pī'hō, or pā'hō (literally, white river): the most important river of China N. of the Yellow River. It rises near the Great Wall, flows in a southeastern direction through the province of Chihli, and falls into the Gulf of Pechili at Taku. Its course is very tortuous, especially below Tien-tsin, which is 80 miles by water from its mouth, but only 35 by land. It is navigable for more than three-fourths of its course, but at its mouth there is a bar of stiff, tenacious clay, which makes the entrance very difficult.

Peine Forte et Dure [Fr. and O. Fr., hard and severe penalty], called also **Pressing to Death**: formerly, in England, the punishment of those who refused to plead or stood mute upon their arraignment for felony. The victim was stretched naked upon his back and had "iron laid upon him as much as he could bear and more," and he was so kept and fed on bread and stagnant water on alternate days (bread one day and water the next) until he yielded or died. The object in submitting to death by this penalty was not infrequently to avoid the forfeiture of lands consequent upon conviction for a felony. This punishment came into use about 1400, and is said to have been last employed in 1741. It was virtually abolished by 12 Geo. III., c. 20, which made standing mute in case of felony equivalent to a conviction. In 1827 (7 and 8 Geo. IV., c. 28, § 2) it was enacted that a plea of "not guilty" should be then entered. In 1692, at Salem, Mass., Giles Cory, a supposed witch, stood mute upon his trial, and was pressed to death. This is believed to be the only instance of the infliction of this penalty in America. See Stephen's *History of the Criminal Law of England*, and Pike's *History of Crime in England*.
Revised by F. Sturges Allen.

Pe'ipus: a large lake in Northwestern Russia, 87 miles long, 30 miles broad. It communicates with the Gulf of Finland through the Narova. It is deep, easy to navigate, and rich in fish, which are sent to the market of St. Petersburg. Its shores are low, marshy, or sandy, and in many places covered with forests. It occupies an area of about 1,500 sq. miles, and consists of two lakes connected with each other by a narrow strait. The southern lake is sometimes called Lake Pskow, after the city of Pskow, situated at its southeastern extremity.

Peirce, Benjamin, LL.D., F.R.S.: mathematician and astronomer; b. at Salem, Mass., Apr. 4, 1809; a son of Benjamin Peirce (1778–1831), librarian of Harvard University. The son was a pupil of Nathaniel Bowditch, and read the proof-sheets of the translation of Laplace's *Mécanique céleste* while yet a mere youth; graduated at Harvard in 1829; taught 1829–31 at Round Hill, Northampton, Mass.; became mathematical tutor in Harvard College 1831; Professor of Mathematics, etc., 1833–42; Professor of Astronomy, etc., 1842–67, and aided the construction and equipment of the observatory; superintendent of the U. S. Coast Survey 1867–74; became in 1849 consulting astronomer to the *Ephemeris and Nautical Almanac*; was a member of the leading American and foreign scientific societies; author of a series of mathematical text-books 1835–70, and of many scientific papers; prepared a volume of lunar tables in 1852 for the use of the American *Nautical Almanac*; published in 1857 his work *System of Analytical Mechanics*. His *Linear Associative Algebra* was reprinted in the *American Journal of Mathematics* in 1882. His work in pure and in applied mathematics is noteworthy for its novel, original, and remarkably direct and satisfactory methods. D. at Cambridge, Mass., Oct. 6, 1880. Revised by R. A. Roberts.

Peirce, Bradford Kinney, D.D.: author and journalist; b. at Royalton, Vt., Feb. 3, 1819; graduated at Wesleyan University 1841; entered the New England Conference 1842; was editor of *The Sunday-school Messenger* and the *Sunday-school Teacher*; was a State Senator for Norfolk County 1855–56; obtained the establishment of the State Industrial School for Girls at Lancaster, of which he became superintendent; was chaplain of the House of Refuge, Randall's island, N. Y., 1863–72, after which he returned to Boston, and was editor of *Zion's Herald* 1872–88. Author of Sunday-school question-books, a *Bible Scholar's Manual*, *The Eminent Dead*, *Notes on the Acts*, *The Word of God Opened* (1868); *A Half Century with Juvenile Delinquents* (1869); *Trials of an Inventor*, being an account of the career of Charles Goodyear, and *Audubon's Adventures* (1890). D. at Newton, Mass., Apr. 19, 1889. Revised by A. Osborn.

Peirce, Cyrus: educator; principal of the first normal school in the U. S.; b. at Waltham, Mass., Aug. 15, 1790; graduated at Harvard 1810; studied theology; pastor of Congregational church at North Reading 1819–27; turned from conviction to the work of teaching, and opened a school at North Andover; removed in 1831 to Nantucket, where his great achievement was the grading of the public schools. In June, 1839, he was engaged by Horace Mann as principal of the Normal School at Lexington, Mass., which had been established by the Massachusetts board of education Dec. 28, 1838. At the end of three years Mr. Peirce's health failed. He resigned, and was succeeded by Rev. Samuel J. May, who in turn resigned in 1844 to make way for the reappointment, Sept. 1, 1844, of Mr. Peirce, the school having meantime been moved to West Newton. Ill-health again led to his resignation in 1849. D. Apr. 5, 1860, at West Newton, Mass. To him more than to any one else is due the successful establishment of normal schools. See Barnard, *American Teachers and Educators* (New York, 1861); Gordy, *Rise and Growth of the Normal School Idea in the United States* (Washington, U. S. Bureau of Education, 1891). C. H. Thurber.

Peixoto, pā-shō'tō, Floriano: soldier and politician; b. in the province of Alagoas, Brazil, Apr. 30, 1842. He was one of the generals who supported Fonseca in the deposition of the emperor Nov. 15, 1889; was elected vice-president of the republic 1890; and by the resignation of Fonseca, Nov. 23, 1891, became president for the remainder of the term, or until Nov. 15, 1894. In 1893 he vetoed a bill which was intended to prevent his re-election; this, and the general opposition to a military president, caused much ill-feeling. A rebellion in Rio Grande do Sul gained ground, and a portion of the navy supported it, but was soon reduced to obedience. A more formidable revolt, involving the whole naval force, broke out in the Bay of Rio de Janeiro, Sept., 1893; the navy held the bay for many months and repeatedly bombarded Rio de Janeiro, besides taking Santa Catharina and other places on the coast. In this crisis President Peixoto showed much firmness; ships were ordered from Europe and North America, and on their arrival (Mar., 1894) the rebellion collapsed. Meanwhile the elections had resulted in the return of a civilian, Prudente Moraes, for the succeeding term. Marshal Peixoto died June 29, 1895.
Herbert H. Smith.

Peixoto, Ignacio José de Alvarenga: poet; b. in Rio de Janeiro about Dec., 1748. He graduated in canon law in Lisbon, and was appointed a judge in Minas Geraes, Brazil; there he was involved in the alleged revolutionary movement called the conspiracy of Tiradentes, was arrested in 1789, and in 1792 was condemned to death; the sentence was commuted to penal servitude at Angola, where he died Jan. 1, 1793. His odes and sonnets are esteemed among the finest in the Portuguese language. H. H. S.

Pekin': a form of the name *Peking*, derived from *Pékin*, the French spelling of the Chinese name.

Pekin: city; capital of Tazewell co., Ill. (for location, see map of Illinois, ref. 5–D); on the Illinois river, and the Atch., Top. and S. Fé, the Chi., Peoria and St. L., the Cleve., Cin., Chi. and St. L., the Peo. and Pekin Union, and the Peo., Decatur and Evansville railways; 10 miles S. of Peoria, 56 miles N. of Springfield. It is in an agricultural and coal-mining region, has large shipping interests by rail and water, and is an important grain-market. The city has a water front of over 3 miles, 2 national banks, with combined capital of $200,000, a private bank, and numerous industrial works, including 4 distilleries, 3 foundries and machine-shops, 2 grain elevators, 2 brick and tile works, organ-factory, 2 malt-houses, a roller-mill, marble-works, 3 lumber-yards, planing-mill, and header, wagon, plow, barrel, and soda-water factories. There are 13 churches, 4 public and several private schools, public library, and 2 daily, 4 weekly, and 2 monthly periodicals. Pop. (1880) 5,993; (1890) 6,347; (1900) 8,420. Editor of "Evening Post."

Pe'king', sometimes (but less correctly) **Pekin**, locally **Peiching** (literally, Northern Capital): the capital of China, and chief city of the department of *Shun-t'ien-foo*, in the province of Chih-li (but not within the jurisdiction of the Viceroy of Chih-li); in the basin of the Pei-ho river, but about 12 miles from that stream and 100 from Taku, at its mouth (see map of China, ref. 3–J). The latitude of the Russian ob-

servatory, near the northeast corner of the city, is 39° 56′ 48″ N., its longitude 116° 28′ 36″ E. On the eastern wall of the Northern or Manchu city is the ancient observatory, sometimes considered the origin for Chinese longitudes. It is 2′ 17″ S. and 12″ E. of the Russian observatory. The altitude of the latter is 121 feet above sea-level. The length of the city from N. to S. is 5·2 miles, and its average breadth a little over 4 miles. The area within the walls is 24·5 sq. miles, but much of this is occupied by public buildings, parks, ruins, and, in the Southern city, open fields. The suburbs are small and unimportant. The population is not given by census, and has been variously estimated. The old estimates were very high, and were either greatly exaggerated or the city has decreased—perhaps both. Conservative estimates by foreign residents now put the population at only 500,000.

The city consists of three distinct parts or cities, each with its own walls—viz., the Northern, Manchu, or Tartar city, within this the Imperial city, and adjacent to it the Southern or Chinese city. The first, though called the Tartar city, is now largely occupied by Chinese; the second contains the palaces, and public offices, and temples. The Southern city to a great extent consists of open fields, or is occupied by ruins.

The Tartar city is a regular rectangle (except that its northeast angle is somewhat depressed), about 4 miles N. and S. and 3 miles E. and W. The wall is 30 feet high, 25 feet thick at the base, 12 feet across at the top, and surmounted by a parapet. It is made of earth, faced with large brick laid in lime and clay, or, near the gates, with stone. Square buttresses, surmounted by towers, occur at frequent intervals, and there is always one on each side of each gate. There are nine gates, two for each side, except into the Chinese city to the S., where there are three. The gates are surmounted by small forts. This great structure was practically impregnable to native modes of warfare, but offers no serious resistance to modern artillery. The whole is surrounded by a ditch, fed by the waters of the Tung-hwei creek, a branch of the Pei-ho; but it is neglected, and is partly filled up, and often dry. The Tartar city is the finer of the two (Tartar and Chinese), has more and handsomer dwellings, is better cared for, and is the part in which foreigners live. It is crossed from side to side by several very broad streets, along which the shops are arranged. From these branch out innumerable alleys, along which are the dwellings. These are always surrounded by high walls and entered through closed gates, so that there is on the street little sign of the wealth or comfort to be found within. An old and imperfect system of sewerage has been allowed to go to decay. There are no public water-works, and the streets are not lighted at night. Sanitary arrangements, or others devoted to public comfort, are practically unknown. The city is on an alkaline plain, over which rain falls only two months in the year, and the climate is fairly healthful.

The inner or Imperial city is guarded by a wall almost as high and elaborate as that of the Tartar city. It is about 2 miles long by 1 broad; is entered by three gates, one each on the E. and W., and one on the S. The gates are carefully guarded, and no one is admitted except those having business within. The temples and palaces within are roofed with yellow tiles, and this city is consequently sometimes called the Yellow city. It contains considerable parks, and at its northern end is a high artificial hill surrounded by its own wall—an imperial pleasure-ground. Inside the Yellow city, and occupying perhaps a quarter of its space, is again an inclosure surrounded by a wall and containing the imperial residence. It is tiled with red, and is called the Red or Prohibited city.

The Southern or Chinese city abuts on the Tartar city on the S. It was originally a suburb, but was later surrounded by a wall, which is lower than that about the Tartar city. It has ten gates, three of them in common with the Tartar city. It is of a rectangular shape, about 6 miles E. and W. and 2½ N. and S. It contains the Temple of Heaven and that of Agriculture, representing the early and patriarchal religion of the empire. The emperor, representing his people, worships here with much ceremonial once every year.

Outside Peking, and but a short distance E. and W., are the temples of the Sun and Moon, and on the N. that of the Earth. About 8 miles N. W. is a very fine imperial park, called Yuen-ming-yuen, containing about 12 sq. miles and having many pleasure-houses; put in ruins by the allies in 1860. In the environs of the city are many temples, convents, and tombs, generally in ruins.

Peking is thoroughly policed, and is very safe under ordinary circumstances. Its industries are small and unimportant. The country immediately around it is relatively infertile, and its provisions come from some distance. The chief trade-route is by the Pei-ho to Tungchow, 12 miles distant, thence by cart or porter to the city. From the S. and W. carriage is largely by camels.

A city has occupied from time immemorial the present site of Peking, or one near by. The Chinese believe that it is the city *Ki*, known 1,000 years before the Christian era, and from time to time a royal or departmental capital until the fourth century A. D. From that time the name was frequently changed. In 1264–67 A. D. it was rebuilt about 3 *li* N. E. of its previous site, and the Mongol emperors used it as a capital. In the latter part of the thirteenth century it was well known to Marco Polo, who called it Cambaluc (improperly written *Cámbalú*). It continued an imperial residence until the fall of the Mongols (1368). The new (Ming) dynasty first took up their residence at Nanking (i. e. South Capital), but the second emperor of that dynasty returned to the northern capital, which was now called Peking. It was restored and reduced in size in 1409, and the part then constructed is the present Tartar city. The walls were completed in 1437, and the Southern city inclosed in 1544. There has been little change since then. In 1860 it was captured by the Anglo-French army. During the Boxer disturbances of 1900, the foreign legations were destroyed and the representatives of the foreign powers besieged by Boxers and imperial troops in the compound of the British legation from June 20 till Aug. 14, when the city was taken by the allied forces. The Chinese court fled to Singanfu and the city was under the military control of the powers during the peace negotiations and till the summer of 1901. See CHINA.

M. W. HARRINGTON.

Pela'gianism: a system of anthropological doctrine which takes its name from Pelagius, but owes its shape rather to bolder if not abler men. Pelagius is spoken of by several of his contemporaries as a Briton, which is likely enough in spite of his familiarity with Greek authors. In 409, to avoid Alaric's siege of Rome, he escaped with his convert and pupil, Cælestius, to Northern Africa, and had gone from there to Palestine before the meeting of the Council of Carthage in 411 (some say 412), which condemned Cælestius. In Palestine two councils (at Jerusalem and at Diospolis, the ancient Lydda, in 415) declared him orthodox. He is not heard of after 418, but there is a tradition that he was seventy years of age when he died in some obscure town of Palestine. In the controversy to which his peculiar views gave rise he may not have acted quite frankly, but otherwise he appears to have been a very good man, of more than common moral strictness and purity, if not a man of any great spiritual depth or intellectual grasp. The impulse to his alleged heresy was a practical one. He had been scandalized by hearing Christians plead human infirmity as an excuse for shortcomings in the religious life. He is said to have been greatly roused by hearing a bishop repeat the well-known prayer of Augustine, *Da quod jubes, et jube quod vis* (Give what Thou commandest, and command what Thou wilt). His convert, Cælestius, who appears to have been more of a Pelagian than Pelagius himself, had been an advocate in Rome, and was, perhaps, an Irishman by birth. He was younger and more impulsive than Pelagius. It was his application for ordination as a presbyter at Carthage (in 411 or 412) which led to the council already referred to. His application was denied, on the ground of these seven heretical opinions: (1) Adam would have died if he had not sinned; (2) Adam's sin injured himself only, not the race; (3) children are born as pure as Adam was before he fell; (4) men neither die because Adam fell, nor rise again in consequence of Christ's resurrection; (5) unbaptized, as well as baptized, infants are saved; (6) the law, as well as the gospel, leads to heaven; (7) even before Christ's advent there were sinless men. The answer of Cælestius, that these were matters merely of speculation, availed him nothing; he was excluded from the fellowship of the Church. He then went to Ephesus for ordination, and was a presbyter there from 412 to 417, when he returned to Rome, and for a time had the Bishop Sozimus (417–418) on his side, but fled from Rome in 418, Sozimus having turned against him; was banished from Constantinople in 429; appears in Rome again in 430; and is not heard of after 431, when he was condemned by the œcumenical Council of Ephesus. Meanwhile, a still younger man, of still greater boldness, Julian, Bishop of Eclanum, in Italy, comes

upon the stage. Deposed in 418, with eighteen other bishops, for sympathy with the opinions of Cælestius, he literally carried the war into Africa, assailing the Carthaginian anthropology with all his might. Augustine had already entered the lists on the other side. Julian went to Constantinople in 418, spent some years with Theodore of Mopsuestia, was in Constantinople again in 428, sought restoration to the Church in 439, but was refused, and died a schoolmaster in Sicily at some time between 440 and 453. Pelagianism, which was understood to be a denial both of original sin and of supernatural grace, was everywhere condemned. Semi-Pelagianism, 100 years later, shared the same fate. By a curious blunder the principal writings of Pelagius were attributed to Jerome, and are found among his printed works (ed. Vallarsius, vol. xi.). See *The Anti-Pelagian Writings of Augustine*, in English (New York, 1887), with historical introduction by Prof. B. B. Warfield; *Jerome's Dialogue against the Pelagians*, in Eng. trans. by W. H. Fremantle in *St. Jerome: Letters and Select Works* (New York, 1893). See G. F. Wiggers, *Versuch einer pragmatischen Darstellung des Augustinismus und Pelagianismus* (1831–33), vol. i. on *Pelagianism*, translated by Prof. Emerson of Andover (1840); J. L. Jacobi, *Die Lehre des Pelagius* (1842); A. Dorner, *Augustinus* (1873); W. G. T. Shedd, *History of Christian Doctrine* (1863); F. Wörter, *Der Pelagianismus* (1866; 2d ed. 1874). See ANTHROPOLOGY; also see CALVINISM and REGENERATION. Revised by S. M. JACKSON.

Pela'gius: See PELAGIANISM.

Pelagius I.: pope; of Roman birth; archdeacon and legate to Constantinople under Vigilius, his immediate predecessor, and, like him, a mere creature of the Byzantine emperor, Justinian. He was with Vigilius when he died at Syracuse on his way home from Constantinople (where he had been since 547), June 7, 555, and at once assumed the pontificate, as he had previously been authorized to do by Justinian. He was suspected of having hastened the death of Vigilius, and after his consecration at Rome, by two bishops and a presbyter, he thought it necessary solemnly and publicly to deny the charge. He had a troubled pontificate, owing to the refusal of many of his bishops to accept the decrees of the fifth œcumenical council, convened by Justinian in Constantinople 553, upon the Monophysite controversy, which sanctioned the formula, "God was crucified," or "One of the Trinity has suffered." D. in Rome, Mar. 3, 560. His literary remains are in Migne, *Pat. Lat.*, lxix.—PELAGIUS II., also of Roman birth, the immediate predecessor of Gregory the Great in the papal chair, and the first independently elected pontiff after the Byzantine conquest of Rome in 536. He was consecrated Nov. 27, 578; and, in consequence of a plague which followed an inundation of the Tiber, died about the middle of January, and was buried Feb. 8, 590. His literary remains are in Migne, *Pat. Lat.*, lxxii.
Revised by S. M. JACKSON.

Pelargonic Acid [from Mod. Lat. *Pelargo'nium*, a genus of geraniums in which this acid is found]: a member of the fatty acid series, of the composition $C_9H_{18}O_2$. It occurs naturally in the volatile oil of rose-geranium, *Pelargonium roseum*, whence its name, and is obtainable artificially by several methods, one being the oxidation of essential oil of *Ruta graveolens*, or rue. It is a colorless liquid, oily, and freezing by cold to a fatty mass, which melts at 12·5° C.; odor like that of butyric acid; boils at 253°–254°; slightly soluble in water and very soluble in alcohol. By keeping it becomes yellow. Revised by IRA REMSEN.

Pelargonic Ether: the ethyl ether of pelargonic acid. It is a colorless oil, boiling at 216°–219° C. Quinces owe their characteristic odor to the presence of this substance. It can be made by treating pelargonic acid with alcohol.

Pelargonium: See GERANIUM.

Pelas'gians: a people uniformly spoken of by all ancient Greek authors as the oldest inhabitants of Greece. The detailed information which has come down to us about them is vague and contradictory. Some authors, Homer and Herodotus, describe them as an extensive race, the parent-stock from which sprung the Hellenes, occupying not only Greece proper, but Asia Minor to the E., Macedonia, Thracia, and Illyria to the N., and Italy to the W. Others, Thucydides and Strabo, consider them only one of the many kindred tribes which inhabited Greece, like the Leleges and Dolopes. Of the Pelasgian language nothing has been preserved. Certain names, such as Larissa and Argos, are considered as pertaining to it. A Greek tradition designated the Albanian dialect as directly descended from it. Herodotus speaks of it as barbarous, but whether that means foreign or corrupted is not evident. Of architectural monuments found in Greece, certain constructions of an enormous massiveness and strength are ascribed to them. They consist of huge blocks of stone placed one above the other, and held together by their own weight, without any mortar; on account of their size these structures are called cyclopean. Of the history of the Pelasgians not one fact has as yet been ascertained, even that of the transition from the Pelasgian to the Hellenic period. Some modern Egyptologists, however, have described them as a seafaring people in frequent communication with Egypt. Of the stocks settled in Italy, the Japygians and Etruscans are generally considered as branches of the Pelasgian race, but the hypothesis is at once hazardous and barren. Revised by J. R. S. STERRETT.

Pelecan'idæ [Mod. Lat., named from *Peleca'nus*, the typical genus, from Lat. *peleca'nus* = Gr. πελέκανος, woodpecker, also pelican, liter., hewer, deriv. of πελεκᾶν, hew, deriv. of πέλεκυς, ax]: a family of birds of the order *Steganopodes*, whose species are familiarly known as pelicans. They are of large size; have a rather long flexible neck, moderate head, a long, nearly straight, and rather broad bill, whose culmen is rounded at the base, and at the end produced into a strong hook; the lower mandible is broader than the upper, and provided with a naked membrane, which extends backward on the throat and is capable of great extension; nostrils lacking; wings long and pointed; tarsi short and robust; toes four, connected together by a membrane, the three anterior largest, the fourth interno-posterior and smallest. Revised by F. A. LUCAS.

Pelecyp'oda (Mod. Lat.; Gr. πέλεκυς, hatchet + πούς, ποδός, foot]: a term used by a few writers for the group of molluscs, better called LAMELLIBRANCHIATA (*q. v.*), in allusion to the compressed "foot."

Pe'leus (in Gr. Πηλεύς): in Grecian mythology, son of Æacus, brother of Telamon and father of Achilles by Thetis, a daughter of Nereus, and therefore immortal. He was King of Phthia in Thessaly; took part in the Calydonian boar-hunt and the Argonautic expedition. At his marriage to Thetis in the cave of the centaur Chiron the gods appeared and brought goodly gifts, only Eris threw among the assembled guests the golden apple inscribed, "To the Fairest," a circumstance which gave rise to the Trojan war, in which the issue of this marriage (Achilles) was to be the leading figure. J. R. S. STERRETT.

Pelew' Islands: a group of twenty-six little islands W. of the Carolines in the Pacific; also called the Western Carolines. They belong to Spain, and are hilly and surrounded by coral reefs. The soil is fertile, and produces breadfruits, bananas, sugar-cane, and oranges. Pop. about 10,000, of the Malay race. See Semper, *Die Palau Inseln* (Leipzig, 1873). C. C. A.

Pelican [O. Eng. *pellican*, from Med. Lat. *pelecanus*, a pelican]: any one of several water-birds of the family *Pelecanidæ*, having all four toes connected by a web, and distinguishable at a glance by their extremely long bill, beneath which is a large skinny pouch. The tail is short, and consists of numerous (twenty or more) feathers; the wings very long; the bones are all permeated by air, and numerous air-sacs are present about the body. Pelicans are gregarious, and dwell both on the seacoast and by inland waters in temperate as well as tropical countries. They nest on the ground or on low trees and bushes, and lay from one to three eggs, like chalk in appearance. There are ten or a dozen species. The pouch is used for catching fish, on which these birds feed. They either plunge down upon the fish, like the brown pelican, or drive them into shallow water and scoop them up. It has been denied that the pelican carries fish to its young in its pouch, but it certainly does this occasionally. The common pelican of Europe (*Pelecanus onocrotalus*) has black primaries, the rest of the body being white suffused with a rosy or salmon tint; the young are grayish. This bird reaches a length of 5 feet, with a spread of wing of nearly 9. The

White pelican (*P. trachyrhynchus*).

white pelican of North America (*P. trachyrhynchus*), a bird of the size of the common pelican, is remarkable from the fact that during the breeding season a horny ridge or excrescence is developed on the upper mandible. This bird is found on the Gulf coast and extends inland to Great Salt Lake. The brown pelican of North America (*P. fuscus*) extends along the coast of the U. S. from Carolina to Texas, and a similar species (*P. californicus*) occurs on the Pacific coast. These birds are striped with black and white, while the neck of the male is of a rich reddish brown. F. A. Lucas.

Pelides: See Achilles.

Pe'lion (in Gr. τὸ Πήλιον ὄρος): the ancient name of the modern Plessidi, a mountain on the eastern coast of Thessaly, in the province of Magnesia. On the summit of its highest peak stood the temple of Jupiter Aetæus, and near this was the cave of Chiron. It is still celebrated for its magnificent forests of oak, chestnut, elm, and pine, and the deep impression which the ancients received of its lofty peaks found a fit expression in the myth of the giant sons of Aloeus, who in their wars against the gods placed Ossa on the top of Olympus and Pelion upon Ossa; or, as Vergil relates, piled Ossa on Pelion and rolled Olympus upon Ossa. See Mezières, *Sur le Pélion et l'Ossa* (Paris, 1853); Tozer, *Researches in the Highlands of Turkey* (London, 1869, vol. ii., pp. 98–139). Revised by J. R. S. Sterrett.

Pélissier, pā'lēĕ'si-ā', Jean Jacques Amable: Duke of Malakoff, marshal of France; b. at Maromme, near Rouen, Nov. 6, 1794; was educated at Brussels, afterward at the military schools of La Flêche and St.-Cyr; entered the artillery as sub-lieutenant in 1814; served in Spain in 1823, in the Morea in 1828, and in Algeria in 1830. Commanding in 1845 a corps as colonel, he entered the territory of the Ouled Riahs, defeated them, and shut them up in a cave. As they refused to surrender, and even fired at his messengers, he applied burning fagots to the mouth of the cave, and about 600 Arabs were suffocated. This atrocity excited general indignation, and he was saved only by the declaration of Marshal Bugeaud, commander-in-chief in Algeria, that he had simply obeyed a positive order. In 1855 he was made commander-in-chief of the army in the Crimea, and took the Malakoff. He was governor-general of Algeria from 1860 to his death May 22, 1864.

Pel'la (in Gr. Πέλλα): the ancient capital of the Macedonian empire and the birthplace of Alexander the Great. It was a large and magnificent city in the days of Philip and Alexander, but lost its importance under the Romans, and disappeared altogether during the Middle Ages. Some few remains of it are still traceable near Pel. It is said to have had over 80,000 inhabitants. See Tozer, *Researches in the Highlands of Turkey* (London, 1869, i.. p. 153); Heuzey and Daumet, *Mission archéologique de Macédoine* (Paris, 1876). J. R. S. Sterrett.

Pella: city; Marion co., Ia. (for location, see map of Iowa, ref. 6–H); on the Chi., Rock Is. and Pac. Railway; 47 miles E. S. E. of Des Moines, the State capital. It is in an agricultural and stock-raising region, is the seat of the Central University of Iowa (Baptist), and has stone quarries, vineyards, lime-kilns, flour-mills, grain elevators, and other industrial works, and a monthly and three weekly periodicals. Pop. (1880) 2,430; (1890) 2,408; (1900) 2,623.

Pella'gra [Ital., deriv. of *pelle*, skin; cf. Gr. ἄγρα, a catching]: a form of nervous disease with a peculiar skin eruption. It occurs in Italy, especially in Lombardy, in Spain, and in other parts of Europe, and sometimes becomes extremely prevalent. The symptoms refer to the stomach, the nervous system, and the skin. The disease is apt to be chronic, growing in severity with succeeding years. It is likely that poverty, hunger, overwork, and filth combined are the causes alike of the scaly eruption and of the other attendant evils. Revised by William Pepper.

Pelletier, pel'ti-ā', Charles Alphonse Pantaleon, C. M. G.: Senator; b. at Rivière Ouelle, Province of Quebec, Canada, Jan. 22, 1837; graduated B. C. L. at Laval University in 1858, and was admitted to the bar in 1860. He represented Kamouraska in the Dominion Parliament 1867–77; was Minister of Agriculture 1877–78; president of the Canadian commission for the Paris Universal Exhibition of 1878; for his services was made (1878) a Companion of the Order of St. Michael and St. George; was called to the Senate in 1877, and became its Speaker in July, 1896. As a major, he commanded a battalion of volunteers during the Fenian raid of 1866. Neil Macdonald.

Pellico, Silvio: poet and writer; b. at Saluzzo, province of Coni, Italy, June 24, 1789. He studied at Turin, and then spent four years at Lyons, chiefly studying French literature. In 1810, his family having removed to Milan, he became Professor of French in the Milanese Collegio degli Orfani Militari. Here he made the acquaintance of Monti and Foscolo (whose *Carmi de' Sepolcri* had deeply stirred him), and was soon in the midst of the best spirits of the city. During this period he wrote the first of his tragedies, *Laodicea* and *Francesca da Rimini*, the latter of which, acted in 1819, was a great success. In 1819, with a group of friends, among them Manzoni and Berchet, he established a periodical, *Il Conciliatore*, intended to represent the new romantic and patriotic tendencies they all felt so strongly. The Austrian administration looked with great disfavor upon this; and Pellico had difficulties also about his new tragedy, *Eufemio di Messina* (1820). In this same year the periodical had to be abandoned, and not long after Pellico, with several others, was arrested. He was confined first at Milan, then at Venice, but in 1822, on a false charge of Carbonarism, he was condemned to death. The sentence was commuted by the emperor to fifteen years of confinement at the Spielberg in Moravia. At last, in 1830, stirred by the July revolution in Paris, the Austrian Government released him, broken in health and impaired in mind. He went at once to Turin, and passed the remainder of his life in retirement as secretary and librarian to the Marchioness Barolo. His tragedies, *Iginia d'Asti* and *Ester d'Engaddi*, had been the fruit of his confinement in Venice, while at the Spielberg he composed *Leoniero da Dertona*. On his release he prepared the book chiefly associated with his name, *Le mie Prigioni: Memorie, etc.* (Turin, 1832), which first revealed to Europe the iniquities of the Austrian rule in Italy, and powerfully aided the movement for Italian independence. The book was speedily translated into all the cultivated European languages, as was also the little treatise *Dei Doveri degli Uomini, discorso ad un giovane* (1834). Besides the tragedies mentioned above, he composed three others—*Tommaso Moro*, *Erodiade*, and *Gismonda da Mendrisio*—as well as a number of briefer dramatic pieces. (See his *Rappresentazioni dramatiche inedite*, edited by G. Lanza, Turin, 1886.) His master in the drama was Alfieri, but there is little strength and too much sentimentality in his style. D. at Turin, Feb. 1, 1854. There is no good complete edition of Pellico's works. The chief are in the so-called *Opere Complete* (2 vols., Leipzig, 1834–48; 3 vols., Paris, 1836–37; 1 vol., Milan, 1857). Other editions of importance are his *Opere* (2 vols., Padua, 1831) and *Opere inedite* (2 vols., Turin, 1837). His *Epistolario* has been edited by G. Stefani (Florence, 1856). See P. Giuria, *Silvio Pellico e il suo tempo* (1854); and *Nel Centenario della Nascita di Silvio Pellico. Sua vita, memorie, e componimenti inediti* (Turin, 1889). A. R. Marsh.

Pel'litory [M. Eng. *paritorie*, from O. F. *paritoire* < Lat. *parieta'ria*, pellitory, deriv. of *parieta'rius*, belonging to walls, deriv. of *pa'ries*, *parie'tis*, wall]: common name of an urticaceous herb. (1) The *Parietaria officinalis*, or wall pellitory of the Old World, resembling outwardly the common nettle. It is used as a diuretic in domestic practice. *Parietaria pennsylvanica* is its North American representative. (2) More commonly this name is given to *Anacyclus pyrethrum*, a composite plant the root of which is brought from the Levant. It is much used by dentists to relieve toothache and benumb the nerves of the teeth, and is a valuable and powerful sialagogue and local stimulant in tic douloureux and facial paralysis; is often incorrectly called Spanish pellitory.

Pelop'idas (in Gr. Πελοπίδας): a man of great wealth and an intimate friend of Epaminondas; b. at Thebes; was expelled in 382 B. C. from his native city by an oligarchic party supported by Sparta, but returned in 379 B. C., slew the Spartan leader with his own hand, established a thoroughly democratic government, and broke the Spartan influence not only in Thebes, but in Greece. He distinguished himself in the battle of Leuctra, 371 B. C., and on a diplomatic mission to Susa he baffled the Spartan and Athenian intrigues at the Persian court, and Thebes was acknowledged as the first city of Greece. Sent in 368 B. C. as ambassador to Alexander of Pheræ, he was seized and imprisoned by the tyrant, but rescued by Epaminondas. In the year 364 B. C. he defeated Alexander at Cynoscephalæ in Thessaly, but was killed while pursuing the enemy.

Pelopium: See Columbium.

Peloponne'sus [= Lat. = Gr. Πελοπόννησος; Πέλοπος, of Pelops + νῆσος, island]: the ancient name for the southern division of Greeee, the peninsula, whieh now generally is called the Morea (*q. v.*). It was divided into six districts or states—namely, Achaia, in the N., along the Corinthian Gulf; Argolis, in the E., between the Saronic Gulf and the Gulf of Argolis; Laconia, in the S. E., between the Gulfs of Argolis, Laconia, or Colocythia, and Messenia or Koron; Messenia, in the S. W., on the Gulf of Messenia; Elis, in the W.; and Arcadia in the middle. See the artieles on Greece and its divisions; Curtius, *Peloponnesos* (Gotha, 1851–52); Clark, *Peloponnesus* (London, 1858); Beulé, *Études sur le Péloponèse* (Paris, 1875); Gell, *Itinerary of the Morea* (1827) and his *Journey in the Morea* (1823); Leake, *Travels in the Morea* (London, 1830) and his *Peloponnesiaca* (London, 1846); Blouet, *Expédition de Morée* (Paris, 1831–38); Ross, *Reisen im Peloponnes* (Berlin, 1841); Wyse, *Excursion in the Peloponnesus* (London, 1865); Bursian, *Geographie von Griechenland* (Leipzig, 1872, vol. ii., 1–343). For the Peloponnesian wars, sec Greece, History of Ancient.

Revised by J. R. S. Sterrett.

Pe'lops (in Gr. Πέλοψ): in Grecian mythology, the son of Tantalus (King of Phrygia), brother of Niobe and the father of Atreus and Thyestes; married Hippodamia, a daughter of King Œnomaus of Elis; became king after the death of his father-in-law; renewed the Olympian games, and gavc his name to the southern division of Greeee by sending a colony thither. Many and very different myths are eonnected with his name. Revised by J. R. S. Sterrett.

Pelo'tas: a town in the state of Rio Grande do Sul, Brazil; on the river São Gonçalo, which conneets the Lagoa dos Patos with the Lagoa Miri (see map of South America, ref. 8–F). It is built on flat ground, with wide, regular streets, and is one of the riehest and handsomest cities of Southern Brazil; railways connect it with Rio Grande do Sul and with the interior of the state, and vessels which can pass the Rio Grande bar ascend easily to this plaee. Pelotas is the principal cattle-market of the state and the center of the meat-drying industry, whence most of the states are supplied with jerked beef. The exports, besides jerked and salt beef, are hides, tallow, horns, ete. Pop. (1894) about 25,000. Herbert H. Smith.

Pels, Andries: Dutch poet and critic. Almost nothing is known of his life except that he lived at Amsterdam as a jurisconsult during the seeond half of the seventeenth century. He is, however, historieally a rather important figure in Dutch literature. The first production from his pen of which we know is his tragedy *Didoos dood* (1668). Soon after this he beeame the central figure of that group of men who undertook to regulate and diseipline the Dutch language and the forms of Dutch poetry. The group took for its motto the words *Nil volentibus arduum*, and is commonly known by this name. Its inspiration came from Franee, and it dreamed of a work like that of the recently established Aeadémie Française. The manifesto of the movement was written by Pels, and entitled *Horatius Dichtkunst op onze tijden en zeden gepast* (1677); and this was followed by a second treatise with a similar purpose, *Gebruik en misbruik des tooneels* (1681). The effect of the movement on Dutch letters was very unhappy. The would-be legislators had no real inspiration, and conceived of reform as a purely mechanical and exterior business. Henee their own works are now almost unreadable, as may be seen in Pels's *Minneliederen en Mengelzangen* (1684). A. R. Marsh.

Pelu'sium [= Lat. = Gr. Πηλούσιον; Egypt. *am*; probably identical with *Ha-uar*, Avaris or Abaris; Heb. *Sin*]: an Egyptian fortified city and outpost near the Mediterranean, on the Pelusiac branch of the Nile, at the northeast corner of the Delta region, on one of the main lines of travel to the East. Its history can not be traeed exeept in the geographical lists on temple walls, since the present remains are very few and much weatherbeaten. Avaris was the final stronghold of the Hyksos, from which they were driven by Ahmes I. (See Egypt.) It was also the scene of the overthrow of the native dynasty under Psammetichus III. by Cambyses. At present the site is nearly level with the surrounding marsh, the lowering of the mounds being due in part to denudation, but mainly to the gradual sinking of the northern portion of the isthmus. See Petrie, *Tanis* (part ii., p. 100 f.); Dümichen and Meyer, *Gesch. des alten Aegyptens*; Lipsius, *Letters from Egypt* (p. 429 ff.); Meyer; *Gesch. des Altertums*; Amélincau, *Géographie de l'Egypte* (p. 317 f.). Charles R. Gillett.

Pelvis [= Lat. *pel'vis*, basin, laver]: the lowest of the three great divisions of the trunk, or, more properly, the bony ring or framework, connecting the column of the spine with the lower extremities, and transferring the weight of the former to the latter. It consists of four bones. The front and sides are formed by the two *ossa innominata*, large irregular bones which have received their name from their not resembling any other body in form; behind, the circle is completed by the *sacrum* and *coccyx*. The pelvis varies somewhat in the male and female skeleton, and also in the skeletons of different races. See Osteology.

Pemberton, John Clifford: soldier; b. in Philadelphia, Pa., Aug. 10, 1814; graduated at the U. S. Military Aeademy, and became second lieutenant of artillery July, 1837; served in Florida against the Seminoles; in the war with Mexico on the staff of Gen. Worth, gaining the brevets of captain and major for Monterey and Molino del Rey; in Florida hostilities against the Seminole Indians, and in garrison principally in the Southern States until Apr. 29, 1861, when he resigned, being at the time a captain of artillery. Joining the Southern cause, he was appointed a colonel of cavalry, and attaehed to the staff of Gen. Joseph Johnston; rose to the rank of lieutenant-general, and in 1863 commanded in Mississippi, where he was defeated, May 16, at Champion Hills and Big Black (May 17); falling back on Vicksburg, he defended it against assault, but being besieged was compelled to surrender the city and garrison July 4, 1863. (See Vicksburg, Siege of.) He subsequently served as inspector of artillery; after the war farmed at Warrenton, Va., but in 1876 removed to Philadelphia. D. at Penllyn, near Philadelphia, July 13, 1881.

Revised by James Mercur.

Pembroke: town; in Pembrokeshire, South Wales; on an inlet of Milford Haven; 9 miles W. of Tenby (see map of England, ref. 12–C). At Pembroke Dock or Pater, 2½ miles N. W. of Pembroke, is a fortified dock-yard and arsenal. Pop. of Pembroke proper (1891) 14,978.

Pembroke: town; capital of Renfrew co., Ontario, Canada; on Allumette Lake, a part of Ottawa river; 100 miles above Ottawa (see map of Ontario, ref. 1–G). It is a great center of the lumber business. Water-power is furnished by the falls of Muskrat river. Beside the county buildings, Pembroke has several branch banks and mills. There are two weekly newspapers. Pop. (1890) 4,401.

Pembrokeshire: county of Wales; bounded N. and W. by the Irish Sea and S. by the Bristol Channel. Area, 617 sq. miles. The coast is rugged, but inland the surface is undulating, valleys alternating with hills, whieh reach a height of 1,754 feet in Cwm-Crwyn in the Precelly range. The prineipal rivers are the Teifi, the two branches of the Cleddan, and the Nevern. Mines of anthracite coal and lead are worked. In the southern part the soil is fertile, and barley, oats, and potatoes are raised; while in the more northerly regions more attention is given to cattle-rearing and dairy-farming. Over more than half its area English is spoken, though it is the farthest Welsh county from England. Pembrokeshire returns one member to Parliament. Pop. (1901) 87,856.

Pem'mican [the Cree Indian name]: a kind of concentrated food, originally made by the North American Indians by drying and powdering the lean meat of the buffalo or deer, mixing it with serviee-berries, stirring all into boiling fat, and making it into cakes. The name is also given to a very different form of meat-biscuit used by Arctic voyagers.

Pemphi'gus [Mod. Lat., from Gr. πέμφιξ, πέμφιγος, bubble]: a skin disease in which successive crops of watery or turbid blisters appear upon the patient. Two varieties are described: *P. vulgaris*, which may be acute or chronic, and *P. foliaceus*, which is always chronic. In the former the blebs are well distended, at first with clear serum, later with pus; in the latter, the vesicles are large, only partly filled, and purulent from the first. Moreover, they rupture early and leave a rough, red surface. Pemphigus often comes on suddenly, with chills and fever and great constitutional depression. It may be epidemic in certain localities, especially the form occurring in the new-born, *P. neonatorum*. The acute form lasts from two to six weeks, and may occasion severe constitutional symptoms, with the local heat or itching common to all forms. The chronic form

lasts from six months to a year or more, consisting, as a rule, of several distinct attacks, separated by an interval. The treatment consists in the internal administration of arsenic and of remedies to restore the general systemic tone, such as strychnia, quinine, and iron. Local treatment with dusting-powders or alkaline sedative lotions gives great relief, and in very severe cases patients have been kept in warm baths continuously for months. WILLIAM PEPPER.

Pen [viâ O. Fr. from Lat. *pen'na*, feather]: an instrument for writing. Among the earliest references to pens are those found in Judges v. 14, Psalms xlv. 1, Isaiah viii. 1, chiefly referring, no doubt, to the iron stylus which cut out characters in the tablets of limestone or soapstone. These may have been made of other metals, and were in some instances pointed with diamonds, as referred to in Jeremiah xvii. 1. Another reference is made in Jeremiah viii. 8, and if taken in connection with the mention of a penknife—xxxvi. 23—it would seem to imply that a reed was in use at that period. Later, tablets were made of the plastic clays of Central Asia, which, after receiving inscriptions, were dried in the sun or baked in ovens. The *style* used in Persia, Greece, and Syria was sharp at one end for writing and flattened at the other for the purpose of making erasures on the tablets, which were covered with wax, and were made of metal, bone, or ivory.

In the Third Epistle of John, 13th verse, written about A. D. 85, mention is made of "ink and pen," probably alluding to the custom of writing upon skins or other flexible material. Although the first reference in the Bible was made about B. C. 1296, Mariette discovered an inscription in one of the crypts of the Temple of Denderah in Upper Egypt which says that the great fundamental ordinance of Denderah was found written upon goat-skin in the inside of a brick wall during the reign of King Pepi (about B. C. 3650), and in the same crypt was another inscription stating that the restoration of the great fundamental ordinance of Denderah was made in accordance with what was found *written* in ancient writing of the time of King Khufu (about B. C. 3766).

At Bubastis, in Lower Egypt, Naville discovered on the walls of the Hall of Festival, among the processional subjects, the sacred scribe with *pen and palette*, and in the tombs of Gizeh, which are contemporaneous with the pyramids, the reed pen and inkstand, and scribes employed in writing, appear among the sculptures. In the supposed tomb of Aristotle, in Greece, a metal pen about 2 inches long was found, cut and slit like a quill pen, and a bronze one of undoubted Roman origin, made from sheet-metal bent and forged on a mandril, and with its point neatly cut and slit like a quill pen, was excavated in a field at Pré-Saint-Didier at a depth of 10 feet.

After the stylus, pens were doubtless made in tubular forms from sheet-metal of a required length for holding in the hand, the point being formed by filing away a portion of the tube or barrel; later, holders of many materials were introduced, and the metal part was of only sufficient length to give a flexibility to the point and to slip over the holder about 1½ inches. Metallic pens resembling modern patterns were generally supposed to have been unknown before the early part of the eighteenth century, but that theory was exploded when in excavating at Pompeii a pear or almond shaped one was found with a sort of ring at the stem, now preserved in the Museum at Naples, that certainly must be older than A. D. 79, when the city was buried by the eruption of Vesuvius.

Dr. Martin Lister, in 1698, in his *Journey to Paris*, describes an ancient writing implement of thick silver wound up like a screw, with both ends pointing one way and at a distance so that a man might easily put his forefinger betwixt the two points, one of which was sharp to write on wax tablets, the other shaped like the upper beak of a cock; the point was divided like that of our steel pens.

Quill Pens, etc.—In the far East, and perhaps in Egypt, the camel's-hair pencil was substituted for metal implements, and characters were painted on the bark of trees and skins of animals, very much as the Chinese draw them on paper, but the quills of geese and crows were discovered to be more useful than either the reed or brush, and were introduced, it is thought, about A. D. 56. For centuries the quill was the favorite instrument of the rapid writer, and continued to be so until the steel pen superseded it. Quills were most successfully prepared in Russia and Holland by clarifying them in hot sand and by dipping them in boiling alum-water or diluted nitric acid. Many writers made their own pens from these prepared quills, but the art was an acquired one after much instruction and practice. Every teacher was expected to be proficient in this part of his profession. Early in the nineteenth century they were made for sale, and boxes of them, also nibs for fastening upon holders, were vended by all stationers.

Notwithstanding the impression that the quill pen produces only coarse writing, as beautiful specimens of penmanship have been produced by it as by any other instrument in use, not excepting the engraver's tool. The demand for something more durable than quills led to a variety of experiments with horn, tortoise-shell, glass, steel, silver, and gold, resulting in the almost exclusive use of steel. The glass pen was more of a stylus than a pen, it being merely a ground stick. The horn and shell ones softened under the action of the ink and were no improvement on the quill, though they were pointed with diamonds and rubies. Silver pens, because of their elasticity and ductility, were thought to be a success, but their susceptibility to wear at the point and a failure to temper them properly caused them to be finally abandoned.

Steel Pens.—The invention of making steel pens from sheet-metal has so many claimants that it is difficult to decide to whom belongs the honor. The first manufacturer of steel pens is unknown. Arnoux, a French mechanic, made metallic pens with side slits in 1750. A New York city jeweler, working in Baltimore in 1800, made for his own use a steel pen with three slits. The Shakers, in 1819, made silver pens with one slit. Joseph Gillott, Sir Josiah Mason, John Mitchell, and James Perry, all Englishmen, began to manufacture by machinery about the same time. Patents were granted to Perry in 1830 and to Gillott in 1831, and the evidence of Perry's precedence seems to be cumulative.

The manufacture of steel pens is a delicate and laborious process. The raw material is produced in sheets 6 feet long, 17 inches in length, 23 wire-gauge thickness, which is cut into strips of convenient width and placed in air-tight iron boxes which are put in a muffle, where they remain until they gradually attain a dull-red heat, when the muffle is allowed to cool gradually. To rid the strips of an excrescence they are immersed in a vat of diluted sulphuric acid to loosen the scales, and then tumbled in a revolving barrel with pebbles and water. The steel is then rolled until reduced to the required gauge with such exactness that a variation of the one-thousandth part of an inch is not permitted. These strips are now punched into blanks of the same shape of the patterns of the pens desired, two-thirds of the material being used, one-third being scrap. Marking the blanks singly, with the name and number, by a stamp is the next process, and so dexterously are they handled that one girl can stamp 250 gross in a day. To obtain elasticity and to devise a method which shall cause the ink to attach itself to the smooth surface, the blanks are pierced by a delicate punch in a fly-press.

Before the blanks are shaped the dust and grease are removed by tumbling again; then to anneal or soften the metal the blanks are heated in a muffler once more to a dull red, and when cool moulded by a die into form, and then hardened by heating them to a bright-red heat in round pans, after which they are put into perforated buckets to be plunged into vats of oil, which drains from the buckets as they are raised. The oil is removed by rapid revolving in perforated, centrifugal cylinders, but as the pens are still greasy and as brittle as glass, they are cleansed in a bath of boiling soda-water and tempered by being rolled in cylinders over a charcoal fire. Another bath in a pickle of diluted sulphuric acid frees them from any extraneous substance, and another tumble for from five to eight hours in a revolving barrel with ground iron, followed by a tumble in a barrel of dry sawdust, gives them a bright silver color and points nicely rounded. They are then ground on leather buffs, dressed with emery, and made ready for slitting with a tool having the delicacy of the cutting edge of a razor. After slitting they are tumbled again with powdered iron for six hours to smooth the inside edges of the slit, then polished in sawdust and, after being colored, are varnished to prevent rust. First quality pens undergo a rigid examination, one at a time, by expert girls, who reject every pen that shows an imperfection; afterward the pens are counted and boxed, generally in one gross packages.

Pens are manufactured chiefly in Birmingham, England, thirteen firms, employing 4,600 persons, using about 56,000 lb. of steel per week, producing a weekly average of 250,000

gross. There are four or five manufacturers in France and Germany, and but six recognized manufaeturers in the U. S., situated in New Jersey, Pennsylvania, New York, and Connecticut, and employing about 400 people. The average weekly production is about 20,000 gross. The many names given by the venders of steel pens to the material from which they are made are but fancy names and do not indicate the quality of metal. The demand for steel pens is almost confined to Europe and Ameriea. The great Asiatie nations still write with pens made from reeds or with eamel's-hair pencils.

The first gross of pens sold in England in 1820 brought at wholesale about seven guineas or $36 in U. S. money. In 1825 they were sold at 31 cents, and in recent years pens as good as those sold in 1820 were disposed of at 10 cents per gross.

Gold Pens.—Although the U. S. has failed to eompete successfully with Great Britain in the manufacture of steel pens as to quality of metal and workmanship, the reverse may be said of gold ones. In this manufacture, requiring a higher degree of skill, the U. S. has for some years been foremost, and the product is now sold largely in Great Britain, Franee, and Germany. The first attempt at making gold pens was made in England about 1825. The metal, though alloyed, is too soft to make a durable point, therefore it beeame necessary to protect the points with diamonds or rubies; but John Isaac Hawkins, a eitizen of the U. S. residing in England, was led by aceident to use the native alloy of iridium and osmium, one of the hardest and most refractory of all metallic alloys. Hawkins's rights were purchased by a clergyman, who in 1835 indueed a watchmaker in Detroit to engage in the manufacture of gold pens. These were first made by hand, and were very poor substitutes for the quill. In 1840 he removed to New York and enlarged his business. One of the men in his employ, John Rendell, invented a number of maehines for the making and tempering of the pens, giving them the elasticity of the quill and the permaneney of the metal. About 1850 it was discovered that by bedding the iridium points in the gold instead of soldering them the eorrosive influenee of the ink on the two metals, the solder and the gold, was avoided and a firmer hold on the pen was given to the points. The elastieity was inereased and the temper regulated by a series of rolls and other processes. The cost of gold pens makes it absolutely neeessary that every one should be perfeet and durable, therefore only experts are allowed to inspeet and test them before they are offered for sale. The rejection of at least four in a dozen is a result of this severe serutiny and test. About 150 persons are employed in the manufaeture of gold pens in the U. S. by fourteen makers; the annual product has a value of about $500,000.

Fountain or Stylographic Pens.—These pens have a reservoir handle, earrying a supply of ink of sufficient quantity to last several days or, if eonstantly used, for several hours' eontinuous writing. A removable eap is usually provided to cover the point, so that the instrument may be carried about like an ordinary lead-peneil. In 1860 an attempt was made to produee fountain pens, but not until 1879 were they construeted to operate sueeessfully. The early attempts at making reservoir pens were generally confined to contrivances embraeed in the use of internal tubes, ducts, valves, or springs operated upon by the action of the nibs, which foreed the ink from a feeding-pipe upon the pen, assisted by air admitted at the top of the holder, to take the place of the exhausted ink. This mechanism was very erratic in its work, the ink flowing either too slow or too fast. The best results were obtained by providing a tubular holder tightly closed at its upper end, while at the lower end is inserted, usually, an ordinary nib pen made of gold, with an ink-feeder lying adjacent to the pen to attract the ink from the reservoir. Air is admitted at the lower end of the reservoir, whereby a constant automatic feeding is secured by capillary action between the feed-plate and the pen. As the ink is withdrawn air enters at the lower end of the eolumn and ascends in globules through the column of ink to fill the spaee made vaeant by the use of the ink. There are many patents for fountain pens, whieh were invented in the U. S., but the principle involved seems to be the retention of the ink by atmospheric pressure and the furnishing of a supply ready for use for hours of continuous writing without the necessity of dipping constantly into an ink-well.

THEODORE E. SMITH.

Penalty [from Fr. *pénalité*, punishment, from Lat *pœnalis*, pertaining to punishment, deriv. of *pœna*, punishment, loan-word from Gr. ποινή, fine, and represented by Fr. *peine*, Eng. *pain*]: the imposition of the payment of a sum of money or of some personal suffering. It may be imposed by the law, as in criminal or punitive cases, or by contract. The eighth amendment of the U. S. Constitution forbids the imposition of excessive fines or pecuniary penalties and the infliction of eruel and unusual punishments by the Federal Government. In the absenee of constitutional restraint the infliction of penalties and the disposition of the proceeds are matters of legislative discretion. A statutory penalty must be clearly imposed; it will not be implied. The legislative imposition of a penalty on a specific aet or omission is treated generally as equivalent to its prohibition. It may appear, however, from the entire statute that the legislature intended not to render the act or omission absolutely illegal, but to punish the offending party. *De Mers* vs. *Daniels*, 39 Northwestern Reporter 98; 39 Minn. 158.

A party may subject himself to a penalty by contract, as in the ease of an ordinary bond or of an agreement not to engage in a partieular business or profession. At common law the penal sum named in such a eontract was recoverable in case the contract was broken, but equity intervened early and redueed the recovery to the actual damages caused by the breach. This beneficent policy received the approval of Parliament in 1697 (8 and 9 William III., c. 11, § 8), and soon became the prevailing rule in common-law courts. In many eases, however, the parties to a contract are allowed to stipulate the amount to be paid by either upon his breaeh of its provisions as liquidated damages. If such a stipulation is made beeause of the uncertainty of the damages, it will be sustained; but if it is resorted to for the purpose of securing the performance of the contract by the threat of a punishment for its breaeh, it will be treated as a penalty, and the injured party will be allowed to reeover sueh damages only as he can prove the breach has caused him. The language of the contraet is not treated by the courts as conclusive of the intention of the parties. They may deelare the sum stipulated for to be liquidated damages, while the court, looking at all of the eontraet provisions, will declare it a penalty. On the other hand, they may refer to the sum as a penalty, while the entire transaetion discloses that they intended to agree upon and abide by it as their rating of damages instead of leaving them to be assessed or guessed at by a jury or a court.

FRANCIS M. BURDICK.

Penance [from O. Fr. *penance* < Lat. *pœniten'tia*, repentanee (whenee Eng. *penitence*), deriv. of *pœ'nitet*, makes repent]: in general, the atonement for sin. Roman Catholie theology treats penance both as a virtue and as a sacrament. The virtue of penanee includes sorrow for sin, amendment, and the performanee of expiatory works. The sacrament of penanee is that in which the forgiveness of sins eommitted after baptism is granted, by the absolution of a duly authorized priest, to those who repent, confess, and perform satisfaction. This sacrament was instituted by our Saviour in the words, "Receive ye the Holy Ghost; whose sins ye shall forgive they are forgiven them, and whose sins ye shall retain they are retained" (John xx. 22). The power thus eonferred is double; the priest, acting as God's minister, may grant absolution or withhold it. Also it is a judicial power: the priest must know what the sins are before he can remit them or retain them. Hence the necessity of confession. The mere fact, however, of declaring one's sins does not procure their pardon. The ehief condition on the part of the penitent is sincere contrition. If this be wanting, the absolution is null, and the confession, instead of removing guilt, adds to it the crime of sacrilege. Nor does the penitent's obligation, when he is properly disposed, end with the priest's absolution. For though this releases him from sin and, in case of grievous offenses, from their eternal punishment, it does not always caneel the temporal reparation required by divine justice. This satisfaction, as it is termed, the priest imposes in the form of prayer, almsdeed, fasting, or other good works to be done by the penitent. In no case does the sacrament of penance imply a "permission to commit sin."

This is the teaching not only of the Latin Church, but also of the Eastern Churches, of those even which at an early period severed their connection with Rome. The sacramental character of penance was acknowledged moreover by those sectarians who held peculiar views regarding the power of forgiving sins. Though the Novatians and Montanists excepted certain grievous sins from this power, few of them denied it absolutely. The Donatists claimed

that it could be exercised only by worthy ministers; the Waldenses, that it belonged to the laity as well as to the priesthood; Huss and Wycliffe, that its efficacy depended upon the worthiness of those who exercised it, and that perfect contrition rendered the sacrament unnecessary. The Reformers spoke, it is true, of an *absolutio*; but as they considered this a mere declaration of forgiveness, and forgiveness itself a revival of baptismal grace—*regressus ad baptismum*—they virtually rejected the sacrament of penance.

The *practice* of the Church in administering the sacrament and in dealing with penitents has varied from time to time. During the first four centuries auricular confession was often followed by a public confession when it was thought that this would be edifying. As, however, the opposite effect was sometimes produced, the public confession was abandoned toward the middle of the fifth century. Similar vicissitudes appear in the history of the *penitential discipline* or process by which the sinner after due reparation was reconciled to the Church. The offenses for which public penance was enjoined—*peccata capitalia*—were adultery, idolatry, and murder. The penalty was excommunication, and this in the latter half of the second century was perpetual. Later on it was limited to a period longer or shorter according to the nature of the offense. In the East the penitents were divided into four class. The Προσκλαίοντες, *flentes*, or weepers, remained outside the church during divine service and implored the prayers of the faithful. The Ἀκροώμενοι, *audientes*, or hearers, entered the church but remained behind the catechumens, and like them left when the more solemn part of the service began. The Ὑποπίπτοντες, *substrati*, were dismissed after the bishop's blessing, which they received kneeling or prostrate. The Συστάντες, *consistentes*, were present during the whole service, but did not communicate. This classification was not in vogue in the West, where penitents were treated in the same way as catechumens, but were obliged to wear a peculiar dress, to abstain from all luxuries, and to practice various austerities. The nature of the penance and its duration were decided by the bishop, who also presided at the public reconciliation.

In the East this discipline disappeared along with public confession at the close of the fourth century. The Western Church relaxed its discipline gradually from the seventh century until the thirteenth or fourteenth. As a substitute for public penance fasts, almsdeeds, and pilgrimages were enjoined. The crusades, especially, served to relax the penitential rigor. In the sixteenth century efforts were made to restore the ancient practice, but these had neither a widespread nor a lasting success. At the present day, though excommunication is the penalty for certain crimes, the performance of public penance is rare.

Literature.—Bingham's *Christian Antiquities*, bk. xvii. f. (Oxford, 1855); Pelliccia, *De Christianæ Ecclesiæ Politia* (Cologne, 1829); Probst, *Sakramente und Sakramentalien* (Tübingen, 1872). J. J. Keane.

Penang': an island in the Strait of Malacca, forming a part of the Straits Settlements, a crown colony of Great Britain. Area, 107 sq. miles. The ground is high and mountainous, but the soil is very fertile, and eminently well adapted to the cultivation of pepper, cloves, nutmegs, and other spices, which are largely exported. Sugar, coffee, indigo, and cotton are also raised, and tin is one of the chief exports. Province Wellesley, a narrow, very fertile coast strip on the mainland opposite the island is a part of Penang Settlement. The chief town is George Town, with a good harbor and considerable trade. Revised by C. C. Adams.

Pena'tes [= Lat.; cf. *pe'nus*, store, closet, *pe'nitus*, inwardly, prepos. *penes*, with]: in Roman mythology, the gods of the household, originally the guardians of the storeroom, i. e. those who care for the daily bread of the family. They were gods of the hearth, and were worshiped by offerings of food and drink at the daily meals in a manner similar to the worship of the Lares (*q. v.*). The designation Penates is often used in a loose way, and may include, as Servius says, all gods who are worshiped in the home. Their name was to the Roman synonymous with home; they were the gods of his fathers and of his race, and, in short, formed the point about which religious conceptions concerning the family centered. The community, as being but an extension of the family, had also its Penates, associated with the cult of Vesta, by whose priests, the Vestal virgins, they were worshiped in much the same manner as the Penates of the household. G. L. Hendrickson.

Pencil [from O. Fr. *pincel* > Fr. *pinceau*, painter's pencil, brush (with *i* on analogy of *pingere*, paint) < Lat. *penicil'lus*, collateral form of *peni'culus*, brush, painter's brush, liter., dimin. of *pe'nis*, tail]: an instrument for painting, drawing, or writing. The oldest pictures were no doubt produced simply by lumps of colored earth or chalk cut in forms convenient for holding in the hand; but in the fourth century B. C. Greek artists began to use wet colors, which were laid on with fine hair brushes. For such brushes or pencils the hairs of camels, badgers, sables, minks, kolinskis, fitches, goats, and the bristles of hogs are used. They are tied up in bundles terminating in a perfectly smooth cone, well pointed, and either drawn through goose-quills or fastened in metallic holders provided with wooden handles. The manufacture of such a pencil, especially of the finest kinds used by artists, requires great skill and care.

Ancient writers mention the use of lead for ruling on papyrus, as well as documents ruled with graphite, and probably fragments of different colored minerals were used previous to all historic mention. Even as late as the nineteenth century pencils made of soft lead hammered into convenient forms were used and known as "plummets." Now graphite, sometimes called plumbago or blacklead, mixed with a soft gritless clay, has superseded all other materials.

Graphite is one of the three principal forms of carbon, and is obtained in innumerable localities. (See Graphite.) In the sixteenth century a mine of very pure graphite was discovered in Cumberland, England, and became famous as the Borrowdale mine. The graphite was so soft and pure that it was readily sawed into thin strips which were glued into slabs of wood, properly grooved, and then sawed into pencils. After the exhaustion of the Borrowdale mine powdered graphite mixed with clay was used. This method was the invention of the Comte de Paris. The mixture of graphite and clay while in the soft state was placed in grooved wood, and, after hardening, a thin veneer of wood was glued on and the slabs sawed into pencil form.

The present practice is briefly as follows: Powdered graphite freed from all grit and impurities is mixed with clay, the quantity of clay depending upon the degree of hardness required. The harder leads can be made in smaller diameter than the soft leads. The mass, made thoroughly homogeneous, is then spun through dies by pressure, and the leads cut into lengths desired. Afterward the leads are baked to make them strong, and then placed in grooved cedar slabs. The slabs are formed by machinery into pencils and finished into various styles. Red, blue, and other colored leads are made of colored pigments and wax. They can not be subjected to the toughening process of baking on account of the nature of the materials, but in other respects the method of manufacture is the same.

Lead-pencils are manufactured in France, Bavaria, Austria, and the U. S. The wood used is obtained chiefly from the forests of Bohemia and Florida. George E. Long.

Pendentive: a piece of masonry which supports a cupola or dome, and rests in its turn on arches below. Each pendentive is somewhat triangular in shape, for it is bounded on each side by the curving extrados of an arch, and at top by the lowest ring of the cupola. Pendentives may be either parts of a larger cupola which is penetrated by the great arches, or may be composed of small arches built across from one great arch to another, or of a system of corbels. R. S.

Pendleton: city (laid out in 1869, named after George H. Pendleton); capital of Umatilla co., Ore. (for location, see map of Oregon, ref. 1–H); on the Umatilla river, and the Union Pac. and the Wash. and Col. River railways; 231 miles E. of Portland. The limits of the city were enlarged in 1884 under a special act of Congress by the addition of 640 acres of the Umatilla Indian reservation. The city is on both sides of the river, which is here spanned by three bridges and affords good power for manufacturing. A levee nearly 2 miles long has been constructed on the south bank of the river at a cost of $40,000. Pendleton has a court-house, built in 1889 at a cost of $90,000, a graded public-school building built in 1886 at a cost of $20,000, St. Joseph's Academy (Roman Catholic), Pendleton Academy, 7 churches, 2 national banks, a savings-bank, 4 hotels, electric-light plant, flour-mills, machine-shops, and other manufactories, and 2 daily and 2 weekly newspapers. Pop. (1880) 730; (1890) 2,506; (1900) 4,406. Editor of "East Oregonian."

Pendleton, Edmund: statesman; b. in Caroline co., Va., Sept. 9, 1721; became a lawyer when twenty-one years old;

was one of the leaders of the Virginia Legislature, and often its Speaker; as a conservative he was the politieal antagonist of Patrick Henry; was in the first Continental Congress 1774–75; drew up the resolutions by which Virginia instructed her delegates to propose the Declaration of Independence; though maimed for life by an accident in 1777, he continued to take an important part in public affairs, and afterward presided over the courts of chancery and of appeals, and over the convention of 1788, by which Virginia indorsed the U. S. Constitution. He was distinguished as a debater. D. at Richmond, Va., Oct. 23, 1803.

Pendleton, William Kimbrough, LL. D.: edueator; b. in Louisa co., Va., Sept. 8, 1817; educated in the University of Virginia, where he graduated from the law school and was admitted to the bar. In 1841 he married a daughter of Alexander Campbell, and, moving to Bethany, took part in the founding of Bethany College, in whieh institution he was professor until Mr. Campbell's death, when he succeeded him as president. He was a member of the West Virginia constitutional eonvention, and was four years State superintendent of public sehools. J. H. Garrison.

Pendleton, William Nelson: soldier; b. in Richmond, Va., Dec. 26, 1809; graduated at West Point in 1830; promoted brevet second lieutenant of artillery, served a year in the Augusta arsenal and as Assistant Professor of Mathematics at West Point 1831–32. Resigned Oct. 31, 1833, and became Professor of Mathematics at Bristol College, Pennsylvania, and subsequently at Delaware College, Delaware. Having been ordained a minister in the Episeopal Church in 1837, he became rector of the Episcopal dioeesan school of Virginia, in Alexandria, in 1839. At the outbreak of the war he returned to his former military occupation, and was chief of artillery in the army of Northern Virginia. He was with Gen. Lee's command when the latter surrendered in 1865. After the war he was made rector of Grace Memorial Protestant Episcopal church in Lexington, Va., where he died Jan. 17, 1883. He was author of *Science a Witness for the Bible* (London, 1860). Revised by James Mercur.

Pendulum [Mod. Lat., liter., neut. of Lat. *pen'dulus*, hanging, swinging, deriv. of *pen'dere*, hang]: a suspended body oscillating under the action of gravity. In order to investigate the laws of its motions we abstract from its material qualities, and consider a heavy point suspended by a right line without weight from a fixed point, about which it is free to move. This is ealled a *simple pendulum*; by an *oscillation* is meant its motion from one extreme of the arc to the other extreme on the opposite side of the vertieal. When the are of vibration is small, the following relation is found to obtain between the length l of the pendulum and the time t of one vibration, viz., $t^2 = \frac{\pi^2}{g} l$, g denoting the foree of gravity, or *the squares of the times are proportional to the lengths*. Henee a pendulum making one oscillation in two seconds must have four times the length of one that oscillates once in one second of time. By g is meant the veloeity aequired in one second by a heavy particle falling from rest by the aetion of the earth's gravity, the space fallen through being $= \frac{1}{2}g$. Henee we see also by putting $t = 1$ in the above equation, that $g = \pi^2 l$, or that the velocity aequired in one second is $\pi^2 \times$ the length of a simple seconds pendulum. That length having been found to be, at New York, 39·10 inches, it follows that $g = 32{\cdot}16$ feet at that place. This is the most accurate way of measuring the force of gravity at any plaee.

It thus appears that the time of vibration is independent of the length of the arc, so long as the arc is very small—an important property in the applieation of the pendulum to the regulation of time-keepers which was first made use of for that purpose by Huyghens. (See Clocks.) When a simple pendulum, being at the extremity of its arc of vibration, receives an impulse at right angles to the plane of its vibration, the heavy point will describe a curved path about the vertical, and it is then ealled a *conical pendulum*. Its path will be eireular, with a certain impulse; a greater or less impulse will cause it to deseribe elliptic arcs. This property is made use of in regulators for steam-engines and other machinery.

When instead of a simple pendulum we have a material or *compound pendulum*—consisting, for instanee, of a rod with a disk or ball attaehed to its lower extremity—the same laws ean be applied by eoneeiving the whole mass of the pendulum united in one point, called the *center of oscillation*, whose distance from the line of suspension is equal to the length of a simple pendulum vibrating in the same time as the given eompound pendulum. When the line of suspension has a considerable length, and bears a very small proportion to the suspended mass, the center of oscillation is very near the center of gravity of the latter.

When we desire to ascertain the absolute length of a seconds pendulum, it becomes necessary to measure the distance between its point of suspension and its center of oscillation. Aecurate experiments to this end were first made in 1790 at Paris by Borda, who employed a spherical platinum ball suspended by fine wire 12 feet in length, and found, after applying all due corrections, 3 feet 8·5593 lines (old French measure). The method devised by Huyghens and first employed by Kater is, however, that which affords the simplest means of ascertaining the length of an equivalent simple pendulum. It consists in using a *reversible* pendulum; that is, a rod with opposite knife-edges near either end, and so weighted with two *unequal* weights that the time of vibration is the same whiehever of the two knife-edges the pendulum is suspended from. In sueh case each knife-edge is in the center of oscillation of the other, and the time of vibration is therefore the same as that of a simple pendulum whose length is equal to the distance between the two. When the times of vibration are not exaetly, but very nearly, equal, the requisite reduction can be dedueed from the relative distances of the two knife-edges from the eenter of gravity. By having the two weights of equal size, one of them being hollow and plaeed at equal distanees from the nearest knife-edge, the resistances and other variable circumstances affect the vibrations alike in both positions of the pendulum. Such is the form of the reversible pendulum used by Plantamour in Switzerland, which has also been adopted by the European Geodesic Assoeiation. The times of oscillation are observed by means of a telescope, and are compared by the eleetrochronographic method with a standard cloek regulated by astronomieal observations. The knife-edges rest on agate planes supported by a firm frame, and about 3,000 consecutive oscillations are observed in each of the four positions in which the pendulum ean be suspended. From the combination of a great number of observations at various latitudes, Helmert found that, at a place in latitude B, the length of a seconds pendulum in meters is $0{\cdot}990918\ (1 + 0{\cdot}00531 \sin^2 B)$. Revised by S. Newcomb.

Penel'ope [in Gr. Πηνελόπη]: in the Greek legend, the daughter of Iearius, the wife of Odysseus (Ulysses), and the mother of Telemachus. When Odysseus was in Sparta as one of the suitors of Helen, he fell in love with Penelope, Helen's first cousin. In return for Odysseus's advice with regard to the suitors of Helen, Tyndareos agreed to prevail upon his brother Iearius to give Penelope in marriage to Odysseus. While Odysseus was absent at Troy Penelope was beset by numerous and eager suitors, whom she put off by declaring that she must first finish weaving the shroud of Laërtes. Aecordingly, she wove by day and unwove by night, and thus prolonged the work. Detected in her noble deceit, she was hard pressed by the villains, but was relieved by her husband's return after an absence of twenty years.

Penelop'idæ [Mod. Lat., named from *Penelope*, the typical genus, from Gr. Πηνελόπη, wife of Odysseus]: a family of gallinaceous birds (also ealled *Cracidæ*), including the eurassows and guans of South America. The bill is moderate; the wings moderate and round; tail elongated and broad; tarsi robust, with the toes three before, eonnected together by a basal web, and a long hinder one on the same plane as the front ones. The sternum has its lateral elements (*Metostea*) united by a broad margin with the central part (*Lophosteon*). The species are "strictly confined to the forests of the New World, and extend from the Rio Grande of Texas on the N. to the wooded region of Paraguay on the S. They do not oeeur in the Antilles, with the exception of Trinidad and Tobago, and on the western side of the Andes do not pass southward of the Gulf of Guayaquil." See also Curassow and Guan. Revised by F. A. Lucas.

Penguin [said to be a corruption of pinwing]: a name originally applied to the great auk (*Alca impennis*) from the fact that it was as flightless as if pinwinged or pinioned, i. e. had its wings locked over its baek. At an early date the name was transferred to the flightless birds of the southern seas, and is now used as a popular name for any

member of the family *Spheniscidæ*, a group of birds peculiar to the southern hemisphere, incapable of flight, and having the wings modified as swimming paddles. The body and wings are evenly covered with short, scale-like feathers, the feet are stout and but little used in swimming. These birds sit erect, resting on their tarsi, and in this attitude walk, or rather waddle, although when hurried they frequently lie flat and scramble with feet and wings. They are wonderful swimmers, and some species progress at times by a series of leaps much like those of a porpoise. There are about a dozen species, ranging in size from the great king penguin (*Aptenodytes forsteri*), which is over 3 feet in length, to the little *Eudyptila minor*, which is about half that length.

King penguin.

Penguins feed on fishes, shellfish, and small crustaceans. They dwell in communities, and the females, according to the species, lay one or two white eggs in a burrow, or in a slight depression of the ground. Most of them inhabit the colder regions of the southern hemisphere, and species have been found in the Antarctic seas as far S. as vessels have penetrated. The Falkland islands appear to be their center of distribution, half the known species occurring there.

The upper part of the plumage in nearly all species is dark bluish, or bluish gray, lower parts white. The king penguin has a band of yellow under the neck, and the members of the genus *Eudyptes* are decorated with a tuft of flowing yellow feathers on either side of the head.

Penn, William: founder and first legislator of the State of Pennsylvania; b. in London, Oct. 14, 1644. He was a son of Admiral Sir William Penn, and received a very careful education. He studied at Christ Church, Oxford, but having met here with Thomas Loe, he was converted to Quakerism, and shortly after expelled from the university. His father sent him on travels in Holland and France, and on his return in 1666 he was ordered to manage the estates of the family in the county of Cork, Ireland. He fulfilled this task with great success, but in Cork he met for the second time with Thomas Loe. He was imprisoned for attending a Quaker meeting, and although he was very soon liberated he had to leave Ireland. On his return to London he began to preach and work in different ways for the society to which he belonged, and after the publication of *The Sandy Foundation Shaken* (in 1668) he was thrown into the Tower. Here he wrote *No Cross, no Crown*, and *Innocency with her Open Face*, but by the interference of the Duke of York he soon obtained his freedom. The good relations between father and son were several times disturbed on account of the religious views of the latter, but after every rupture a reconciliation soon followed; and when the admiral died (in 1670) he left his estates and all his property to his son. Penn continued to preach and work for what he considered to be the highest truth, and in 1671 he was once more thrown into prison. As he would not take an oath at his trial, he was sent to Newgate for six months, and while here he wrote the celebrated defense for toleration, *The Great Cause of Liberty of Conscience*. Having been liberated, he made a tour to Holland and Germany, and on his return in 1672 he married Gulielma Maria Springett. From his father he had inherited a claim on the Government for £16,000. In settlement of this claim the Government granted him large territories in North America, the present State of Pennsylvania, with right to found a colony or society with such laws and institutions as expressed his views and principles. In 1682 he went over to America. A great number of settlers, not only Quakers, but members of all denominations, Englishmen, Swedes, and Germans, gathered together; a charter of liberties was issued, and a democratic government instituted; the city of Philadelphia was planned, and the colony soon came into a most flourishing condition. Penn returned to England toward the close of the reign of Charles II., intent on bettering the social position of the Quakers in that kingdom, in which plan he partly succeeded. During the reign of James II. his connection with the court became very intimate—so much so that he was suspected of being implicated in certain disgraceful measures of the king. After the overthrow of James he was twice accused of entertaining treasonable communications with the exiled king, and an order of council (Mar. 14, 1692) deprived him of his title to the Pennsylvania government. After a most searching trial he was fully acquitted in 1693, and another order of council restored his title to him in 1694. After the death in 1693 of his first wife, he married (in 1695) Hannah Callowhill, and went in 1699, for the second time, to Pennsylvania (Philadelphia), where he stayed till 1701. His return to England was chiefly caused by the deranged state of his affairs there. The mismanagement and villainy of his agent had brought him to the verge of bankruptcy. He was even thrown into the Fleet for some time in 1708. These vexations affected his health; in 1712 he was struck with apoplexy, and although he recovered, his mental faculties were greatly impaired after that time. D. at Ruscombe in Berkshire, July 30, 1718. His contemporaries, even such as were not his friends, testify to the correctness and justice of his character, and although he was savagely attacked by Macaulay in the *History of England*—the charges being modified, but not withdrawn in later editions—Penn's vindication at the hands of Paget (*Paradoxes and Puzzles*, Edinburgh, 1874) and W. E. Forster (*Reply to Macaulay*, reprinted in Philadelphia, 1850) has been recognized as completely successful. For Penn's own life, see biographies by S. M. Janney (Philadelphia, often reprinted) and J. Stoughton (London, 1882). A less ambitious but entertaining work is Maria Webb's *The Penns and Peningtons* (London, 1867). For Penn's part in the founding of Pennsylvania, see Winsor's *Narrative and Critical History of America*, iii., 469 ff. Penn was a voluminous writer; for a list of his works, see Joseph Smith, *Descriptive Catalogue of Friends' Books* (2 vols., London, 1867). Revised by F. B. Gummere.

Pennacook Indians: See Algonquian Indians.

Pennant: See Flag.

Pennant, Thomas, LL. D., F. R. S.: zoölogist and archæologist; b. at Downing, Flintshire, Wales, June 14, 1726; studied at Queen's and Oriel Colleges, Oxford, but did not take a degree; produced a large number of folio and quarto volumes containing his travels in various parts of the British islands, which possess few graces of style and little scientific accuracy, but have preserved from oblivion some valuable facts. D. at Downing, Dec. 16, 1798. Among the more important of his works are *British Zoölogy* (4 vols., 1765–77); *History of Quadrupeds* (2 vols., 1771); *Tours in Scotland* (3 vols., 1771–75); *Tours in Wales* (2 vols., 1778–81; new ed. 3 vols., 1883); *Arctic Zoölogy* (3 vols., 1784–87); *Antiquarian and Historical Account of London* (1790), of which many editions have been published, and his autobiography, *The Literary Life of the Late Thomas Pennant, Esq.* (1793).

Penn College: See the Appendix.

Pennsylvania: one of the U. S. of North America (North Atlantic group); the second of the original thirteen States that ratified the Federal Constitution; popularly known as the Keystone State.

Location and Area.—It lies between lat. 39° 43′ and 42° 15′ N., and lon. 74° 43′ 36″ and 80° 31′ 36″ W.; is bounded on the N. by Lake Erie and the State of New York, on the E. by Chautauqua and Delaware cos., N. Y., and the Delaware river, on the S. by Delaware, Maryland, and West Virginia, on the W. by West Virginia, Ohio, and Lake Erie; extreme length from E. to W., 302·34 miles; extreme breadth from N. to S., 175·6 miles; area, 45,215 sq. miles (28,937,600 acres), of which 230 sq. miles are water surface; capital,

Harrisburg. According to the census of 1900 the State ranked second in population. In 1890 it was first in mineral production and second in manufactures.

Physical Features.—The surface falls into three divisions—viz.: (1) The southeastern section or district extending from Delaware river to the Blue or Kittatinny Mountains; near the river a narrow plain of level land, but a few miles inland a rolling or undulating tract with gently rounded hills. This region, while containing much mineral wealth, is admirably adapted for the growth of cereals. (2) The mountain district adjoining this, which crosses the State in a belt varying in width from 75 to 160 miles, and trending from N. E. to S. W. All the mountain chains which go to make up the Appalachian system are here in their full breadth, though not attaining a great altitude. The mountains of the Appalachian system in the State, aside from their general division in two great ranges, the Blue or Kittatinny and the Alleghany range, are subdivided into a host of minor chains, intersected by numerous valleys, broad and fertile, with the precipitous east face of the Alleghany range overhanging them. (3) The western tableland, which occupies about half the area of the State, is a broad, rolling plateau, with occasional ranges of hills, but sloping N. and W. toward New York, Lake Erie, and Ohio river. It extends from the summits of the Alleghanies W. to the northwestern and western boundaries of the State. The northwestern portion has several isolated summits. It is the region of pine and hemlock lands, and furnishes vast amounts of lumber to Eastern markets.

Rivers.—There are six distinct water-basins, which, with their tributaries, drain the entire State—viz.: the Delaware and its affluents, the Susquehanna and its tributaries, the Genesee, the Potomac, Lake Erie, and the Ohio with its large and numerous affluents. The Ohio is formed by the union of two large rivers, the Alleghany and Monongahela, at Pittsburg. Both have numerous tributaries. The Monongahela receives the Youghiogheny and several smaller streams. Aside from Lake Erie there are no lakes of importance. There are several islands in the Delaware, and two or three in Lake Erie, belonging to Pennsylvania.

Obverse. Reverse.

Seal of Pennsylvania.

Soil and Productions.—The soil of the valleys and plains is generally fertile, and some of it very rich, yielding large crops for a succession of years. There is a large area in forests. The trees include several species of pine, hemlock, spruce, fir, and cedar, as well as some other coniferous trees: six or seven species of oak and four of hickory, the black walnut and butternut, three or four species of maple, the chestnut, chinquapin, beech, buckeye, linden, tulip-tree, dogwood, hornbeam, birch, ash, willow, elm, aspen, sycamore, American poplar, mulberry, persimmon, gum, sassafras, locust, wild cherry, papaw, catalpa, magnolia, crab-apple, etc. The flora is varied. The number of wild animals is quite large—bears, panthers, wildcats, lynxes, wolves, otters, the red and the gray fox, the raccoon, marten, mink, weasel, skunk, opossum, musk-rat, porcupine, woodchuck or groundhog, and occasionally the beaver; the flying, red, striped, and gray squirrel, the hare or rabbit, and among the larger game the Virginian deer, and rarely the elk. Birds are numerous—of prey, the bald and the golden eagle, the turkey-buzzard, fish and other varieties of hawk, owls, the whippoorwill, the night-hawk, the swallow, etc.; these and the reptiles are the same as those of New York and New Jersey.

The following summary from the census reports of 1880 and 1890 shows the extent of farm operations in the State:

FARMS, ETC.	1880.	1890.	Per cent.*
Total number of farms	213,542	211,557	0·9
Total acreage of farms	19,791,341	18,364,370	7·2
Total value of farms, including buildings and fences	$975,689,410	$922,240,233	5·5

* Decrease.

The following table shows the acreage, yield, and value of the principal crops in the calendar year 1900:

CROPS.	Acreage.	Yield.	Value.
Corn	1,308,316	32,707,900 bush.	$14,718,555
Wheat	1,502,321	20,281,334 "	14,602,560
Oats	1,221,893	38,000,872 "	11,400,262
Rye	288,647	4,416,299 "	2,340,638
Barley	7,793	148,067 "	74,034
Buckwheat	227,743	3,188,402 "	1,753,621
Tobacco (1896)	13,884	16,244,280 lb.	1,299,542
Potatoes	188,306	10,921,748 bush.	5,788,526
Hay	2,429,601	2,672,561 tons	37,148,598
Totals	7,178,504	.....	$89,126,336

On Jan. 1, 1900, the farm animals comprised 559,722 horses, value $33,243,571; 37,794 mules, value $2,878,355; 970,473 milch cows, value $32,171,180; 523,653 oxen and other cattle, value $14,314,840; 814,322 sheep, value $2,928,302; and about 1,000,000 swine, value $8,000,000—total head, 3,905,964; total value, $93,536,248.

Minerals.—Gold, silver, copper, tin, and sulphur in a native state have been discovered in Pennsylvania, but none of them in quantities to make their working profitable. Iron does not exist in a native state, but the iron ores embrace every known ore and many not found elsewhere. The most valuable mineral, economically, is coal, bituminous and anthracite. Of bituminous, the production in 1899 was 74,150,175 short tons, valued at $56,247,791. Of the total product, 53,671,963 tons were loaded at the mines for shipment, 1,525,772 tons were sold in local trade and used by employees, 972,692 tons were used at the mines for steam and heat, and 17,979,748 tons were made into coke. The production of anthracite was 53,944,647 short tons, valued at $88,142,130, of which 47,823,241 tons were loaded at the mines for shipment, 1,144,609 tons were sold in local trade and used by employees, and 4,976,797 tons were used at the mines for steam and heat. The total production of both kinds was 128,094,822 short tons, valued at $144,389,921. The State produced 14,743,214 bbls. of petroleum, valued at $13,608,002, ranking second to Ohio. In the production of iron ores the State ranked fourth in 1899 with 38,331 long tons of red hematite, 152,468 tons of brown hematite, 815,771 tons of magnetite, and 2,757 tons of carbonate—total product, 1,009,327 long tons, valued at $1,991,772. In 1883 natural gas began to be used extensively for fuel, and the value of the amount so consumed reached its highest point in 1888 ($19,282,375). The value of the consumption steadily decreased till 1896, since when it has shown a slight increase, being in 1899 $8,337,210. The consumption in Pennsylvania alone in 1888 was about equal to the entire consumption in the U. S. in 1899. The productions of the quarrying industries in 1899 were valued as follows: Granite, $385,101 ($237,780 in 1898); slate, $2,537,022 ($2,491,756 in 1898); marble, $139,506 ($39,373 in 1898); sandstone, $717,053 ($478,451 in 1898); limestone, $3,088,583 ($2,746,256 in 1898); cement, $4,546,322 ($3,392,689 in 1898); and metallic paint, 18,680 short tons, value $212,734 (16,232 tons, value $220,637 in 1898). There are numerous mineral springs, some of them of great medicinal value. The bottled product in 1899 was valued at $340,254. Of the minerals possessing only scientific value the number is very great, embracing almost every mineral of note in the largest catalogues.

Climate.—There are considerable differences in the climate of different portions of the State. The mean annual

* Reference for location of counties, see map of Pennsylvania.

Principal Cities and Towns.—Philadelphia, 1,293,697; Pittsburg, 321,616; Alleghany, 129,896; Scranton, 102,026; Reading, 78,961; Erie, 52,733; Wilkesbarre, 51,721; Harrisburg, 50,167; Lancaster, 41,459; Altoona, 38,973; Johnstown, 35,936; Allentown, 35,416; McKeesport, 34,227; Chester, 33,988; York, 33,708; Williamsport, 28,757; Newcastle, 28,339; Easton, 25,238; Morristown, 22,265; Shenandoah, 20,321; Shamokin, 18,202; Lebanon, 17,628; Pottsville, 15,710; Braddock, 15,654; Bradford, 15,029.

Population and Races.—1860, 2,906,215; 1870, 3,521,951; 1880, 4,282,891; 1890, 5,258,014 (native, 4,412,294; foreign, 845,720; males, 2,666,331; females, 2,591,683; white, 5,148,257; colored, 109,757, of whom 107,596 were Negroes, 1,146 Chinese, 32 Japanese, and 983 civilized Indians).

Industries and Business Interests.—In 1890 the census returns showed that 39,336 manufacturing establishments reported. These had a combined capital of $990,999,375; investment in plants, $505,400,180, including value of machinery, tools, and implements, $258,427,613; persons employed, 620,484; paid for wages $40,788,793, for materials used $773,530,105, for miscellaneous expenses $74,833,862; and had products valued at $1,331,523,101. The principal industry reported was the manufacture of iron and steel, which had 417 establishments, employed 103,976 persons, paid $57,435,000 for wages and $180,803,312 for materials, and had products valued at $295,358,622. Other leading industries, with the value of their products, were: Machinery, $67,587,025; sugar and molasses, $46,599,754; lumber and its products, $46,171,522; clothing, $42,552,794; flour and grist mill products, $39,478,076; leather, $39,011,518; carpets, $22,886,416; and cotton goods, $18,431,773. No census report was issued on the ship-building industry. In 1893 the iron and steel industry had 199 furnaces, of which 109 were anthracite, 76 bituminous, and 14 charcoal; 221 rolling-mills; 90 steel-works, of which 20 were Bessemer, 2 Clapp-Griffiths, 1 Robert-Bessemer, 42 open-hearth, and 25 crucible; 25 tin-plate works; 10 forges and bloomeries; 1,392 cut-nail machines; and 9 wire-nail works. The production of pig-iron in 1899 aggregated 6,558,878 long tons; Bessemer-steel ingots, 3,968,779 tons; Bessemer-steel rails, 1,227,258 tons; open-hearth and other steel about 2,500,000 tons. There were 150 coking establishments, which had 27,591 ovens, burned 19,930,419 short tons of coal, and produced 13,577,870 short tons of coke, valued at $22,881,910.

Finance.—The revenue of the State is mostly derived from special taxes on corporations, including bank stock, foreign insurance companies, corporation stock, gross receipts, incomes, commutation of tonnage, licenses, etc., and in 1900 aggregated $17,494,211.78. The total public debt Dec. 1, 1900, was $6,815,299.02; sinking funds, $6,021,402.12—net debt, $783,896.90. The assessed valuation of real estate was $3,027,649,299; of this $299,485,963 is exempt. The total amount of taxes collected was $55,808,585.32.

Banking.—On Sept. 5, 1900, there were 469 national banks with capital of $76,206,321.41, surplus and profits of $66,534,160.85, and deposits of $380,756,230.37. On May 17 of the same year 95 State banks, capital $8,422,014, surplus and profits $8,390,120, and deposits $73,345,813; and 14 mutual savings-banks, surplus and profits $9,717,364, and $105,416,854 in savings deposits from 361,220 depositors. On June 30 the private banks numbered 28, capital $965,005, surplus and profits $304,301, and deposits $7,406,101; and there were 97 loan and trust companies, capital $39,809,778, surplus and profits $31,160,623, and deposits $160,259,761.

Building and Loan Associations.—The numerous building and loan associations have been an agency of immense value in enabling the people to provide themselves with homes. In June, 1894, the State bureau of statistics presented the following estimates for 1,239 such associations: Assets, $103,943,364; cash income, one year, $44,432,686.57; matured shares and withdrawals, one year, $12,933,970.56; average assets per association, $83,892.14; total expenses, one year, $381,636.78; salaries, one year, $328,636.78; total membership, 272,580; total borrowers, 81,658; and total shares, 1,651,814.

Post-offices and Periodicals.—On Jan. 1, 1901, there were 5,216 post-offices in the State, of which 322 were presidential (15 first-class, 88 second-class, 219 third-class) and 4,894 fourth-class, with 2,311 money-order offices, and 219 money-order stations. There were 1,393 newspapers and periodicals, of which 197 were daily, 6 tri-weekly, 35 semi-weekly, 908 weekly, 3 bi-weekly, 9 semi-monthly, 219 monthly, 8 bi-monthly, and 13 quarterly publications.

Means of Communication.—On June 30, 1892, there were in operation 9,022·87 miles of direct railway, with a total of 16,177·31 miles of track. The five companies (operating wholly or partly within the State) that showed the greatest earnings from freight traffic were the Pennsylvania, $47,619,280.40; Philadelphia and Reading, $26,792,121.20; New York, Lake Erie and Western, $24,895,983.96; Lake Shore and Michigan Southern, $14,884,871.53; and the Pittsburg, Cincinnati, Chicago and St. Louis, $10,950,876.38—making a total of $125,143,133.47. The five companies showing the greatest passenger earnings were the Pennsylvania, $19,636,075.77; Lake Shore and Michigan Southern, $7,421,844.48; Philadelphia and Reading, $5,866,711.24; New York, Lake Erie and Western, $6,530,134.27; and Philadelphia, Wilmington and Baltimore, $4,591,661.68. There are in the State 9 canal and navigation companies, with a capital of $58,114,258, and a funded and floating debt of $39,851,005.56. The cost of canals and fixtures was $30,125,578.21; gross receipts of the year, $2,803,953.82; expenses, $607,416. In

1899 there were 10,181·43 miles of railway, and the total earnings were $498,012,493; operating expenses, $428,837,899; and dividends, $37,823,306.

The number of street-railway companies reporting in 1892 was 221, with a capital of $45,462,262, and a funded and floating debt of $22,091,385. The cost of roads and equipment was $41,636,011; mileage of road, 819,015; cars in use, 3,050, horses and mules, 10,878; cars propelled by electricity, 660, by cable, 324: passengers carried, 260,655,224; total receipts, $14,629,704; expenses, $8,188,745; and value of real estate, $2,849,578. The number of telegraph and telephone companies was 23, with a capital of $99,578,652, and a funded and floating debt of $19,327,469. The cost of lines and equipments was $4,920,327; length of lines in Pennsylvania, 13,538·87 miles; receipts in Pennsylvania, $1,355,914; expenses in Pennsylvania, $424,143.

Churches.—The census of 1890 gave the following statistics of the religious bodies having a membership of 5,000 and upward in the State:

DENOMINATIONS.	Organizations.	Churches and halls.	Members.	Value of church property.
Roman Catholic	654	660	551,577	$10,068,770
Methodist Episcopal	2,042	2,041	222,886	12,642,104
Presb. in the U. S. of America	939	1,101	161,386	15,491,680
Lutheran, General Council	616	515	124,163	4,993,355
Reformed in the U. S.	754	624	122,944	5,121,328
Baptists, Regular	634	690	83,122	5,984,322
Lutheran, General Synod	596	562	78,938	3,672,650
Protestant Episcopal	369	446	54,720	10,854,131
Evangelical Association	662	660	42,379	1,590,605
United Presb. of N. A.	281	290	39,204	2,552,450
United Brethren in Christ	526	520	33,951	1,086,135
Dunkard, Conservative	101	251	14,194	354,008
Disciples of Christ	125	116	12,007	533,147
African Methodist Episcopal	87	117	11,613	605,000
Methodist Protestant	172	169	10,081	641,575
Mennonite	114	113	10,077	221,100
Friends, Hicksite	65	74	10,001	546,700
Congregational	108	108	9,818	672,588
Church of God	162	156	9,344	375,185
African Meth. Epis., Zion	62	62	8,689	256,150
Lutheran Synod. Conference	26	26	6,559	284,915
Cumberland Presb.	52	50	6,210	257,500
Jews, Reformed	18	18	5,582	552,500
Lutheran, Joint Syn. of Ohio, etc.	32	32	5,552	206,100
German Evan. Synod of N. A.	12	12	5,293	132,150

Schools.—In the year ending the first Monday of June, 1900, the whole number of teachers was 29,390—men, 9,394, women, 19,996; the total enrollment was 1,151,880, the total receipts for schools and buildings were $24,916,668.69, and the total expenditures were $21,476,994.90. The number of school districts in the State is 2,510; number of schools, 28,330; number of graded schools, 15,720; number of superintendents, 140; average salaries of male teachers per month, $44.25; of female, $37.74; average length of school term in months, 8·33; average number of pupils in daily attendance, 854,640; teachers' wages, $11,205,482.61; cost of school text-books, $806,148.30; cost of school supplies other than text-books, $422,696.87; fuel, contingencies, fees of collectors, and other expenses, $4,978,540.36. The State appropriation for the school year ending June 5, 1899, was $5,500,000, and the estimated value of school property was $54,797,506.32. There were 14 normal schools, maintained partly by the State and partly by fees. Text-books in all public schools are free. There are 34 colleges and universities, including 6 business colleges and 40 to 50 seminaries, academies, institutes, and other secondary schools. The State was a pioneer in providing soldiers' orphans' schools, and three such schools are still maintained.

Libraries.—According to a U. S. Government report in 1891 on public libraries of 1,000 volumes and upward each Pennsylvania had 351 libraries, which contained 2,318,456 bound volumes and 387,511 pamphlets.

Charitable, Reformatory, and Penal Institutions.—The State supports a great number of charitable institutions, including five hospitals for the insane, a newly erected special hospital for the chronic insane, and institutions for the blind, for the deaf and dumb, and for the feeble-minded. There are two penitentiaries, the Eastern and the Western, two reform schools for wayward youth, and an industrial reformatory for persons convicted of first offenses. An effort is made in all the penal and reformatory institutions to provide educational and industrial training.

Political Organization.—The Legislature is called a General Assembly, and consists of a Senate of 50 members, chosen for four years (one-half every two years), and a House of Representatives of about 200 members (in 1895, 204), chosen for two years. The membership of both is based on population, and the State is divided into districts after each U. S. census. Senators must be twenty-four years of age and representatives twenty-one years; both must have been citizens of the State four years and of their districts one year next before election, and must reside in their districts during term of service. All laws must be passed by bill, and no bill save the appropriation bill can contain more than one subject, which must be clearly expressed in its title. The purpose of a bill can not be changed during its passage. Each bill must be referred to a committee, be reported therefrom, and printed for the use of the members before it can be considered. It must be read at length on three different days in each house, and on its final passage must receive the affirmative votes of a majority of all the members elected to each house. Amendments made by either house must be concurred in by a majority of all the members of the other, and reports of conference committees must be adopted by a majority of the members of each house. All bills for raising revenue must originate in the House of Representatives, but the Senate may amend such bills. All bills and resolutions passed must be signed by the presiding officer of each house, in its presence, after the titles have been publicly read, and the fact of signing must be publicly entered on the journals. The chief executive is the Governor, elected for four years; salary, $10,000 per annum. Besides exercising the usual administrative powers he may veto any bill (or, in an appropriation bill, any separate item), which to become operative must be re-enacted by a vote of two-thirds of the members of each house. He appoints (with the advice and consent of the Senate) a secretary of the commonwealth, attorney-general, and adjutant-general, to serve at his pleasure; a superintendent of public instruction for four years, a commissioner of insurance for three years, a superintendent of public printing for four years, and a State librarian for three years. Other administrative officers are elected—viz.: a State treasurer for two years, auditor-general for three years, and secretary of internal affairs for three years. The treasurer and auditor-general can not serve two successive terms. A Lieutenant-Governor is elected at the same time and for the same term as the Governor. He presides over the Senate, has a vote only in case of a tie, and succeeds to a vacancy in the office of Governor, in which event the president *pro tem.* of the Senate becomes Lieutenant-Governor. The judicial power is vested in a Supreme Court, courts of common pleas, oyer and terminer, general jail delivery, quarter sessions of the peace, orphans' courts, magistrates' courts, and such others as the Legislature may establish, and in aldermen and justices of the peace. The Supreme Court is the highest court of both original and appellate jurisdiction. It consists of seven judges, elected for twenty-one years, and ineligible to reelection, the oldest in commission sitting as chief justice; salary, $8,000 per annum. The State is divided into judicial districts, varying in number according to population, for the courts of common pleas. Each county containing 40,000 or more inhabitants forms a separate district; those containing less are combined. Districts are fixed by the Legislature within limits prescribed by the constitution. The judges are elected for a term of ten years. Special provisions exist for the two most populous counties, Allegheny and Philadelphia.

The right to vote at all elections is possessed by every male citizen, twenty-one years of age, who has been a citizen of the U. S. at least one month, has resided in the State one year (six months if, having previously been a qualified elector, or native-born citizen of the State, he shall have removed therefrom and returned), immediately preceding the election; has resided in the election district where he shall offer to vote at least two months immediately preceding the election; and, if twenty-two years of age or upward, has paid within two years a State or county tax, which shall have been assessed at least two months and paid at least one month before the election. Women twenty-one years of age and over are eligible to every office of control or management under the school laws of the State. General elections are held on the Tuesday next following the first Monday in November. All regular municipal elections (for city, ward, borough, and township officers) are held annually on the third Tuesday in February.

History.—The first settlement within the bounds of Pennsylvania was at Tinicum island by Swedish colonists, under

John Printz's administration. In 1655 the Dutch from New Amsterdam marched upon these Swedish settlements and took formal possession of the country. In 1660 a Dutch settlement was planted at the Minisinks, the settlers being colonists from New Amsterdam. When the English captured New Amsterdam, in 1664, the colony on the Delaware followed its fortunes, and remained under the government of New York (except for a part of 1673–74, when the Dutch recaptured it) until Mar. 4, 1681, when Charles II. granted to William Penn the "tract of land in America lying N. of Maryland, on the E. bounded with Delaware river, on the W. limited as Maryland, and northward to extend as far as plantable." Penn landed at New Castle (now in Delaware) Oct. 27 (o. s.), 1682. During 1683 he organized his new government and provided places for the many immigrants (mostly Friends) who began to flock thither. He returned to England in 1684 for the settlement of the boundary between Pennsylvania and Maryland. In 1699 he again visited his province, remaining till 1701, and gave the colonists a new constitution and Philadelphia a charter. From this time to 1720 emigration to Pennsylvania constantly increased. Penn died in 1718, and his heirs succeeded him as proprietaries. The war between France and Great Britain in 1744 led to apprehensions of trouble with the Indians, whom the French were stimulating to hostility against the English colonists. Great efforts were made to retain the friendship of the Indians, but all in vain. The Shawanese were the first to break faith with the colonists. The French, having secured them as allies, constantly increased their aggressions. The boundary between Pennsylvania and Maryland was run in 1766–67 by Charles Mason and Jeremiah Dixon. In 1768, by a treaty with the Six Nations, a large tract of land, called the New Purchase, embracing most of the counties of Northern and Northwestern Pennsylvania, was conveyed to the proprietaries, and at once induced an enlarged immigration. Pennsylvania took an active part in the movement for independence. (See PHILADELPHIA.) The massacre of the Wyoming settlers by British soldiers, Tories, and Indians occurred in July, 1778, and was summarily avenged by the McIntosh and the Sullivan expeditions. In 1778 the royal charter was annulled, and the Penns were allowed £130,000 for their unsettled lands in the State. Pennsylvania furnished more than her full quota of troops for the Revolutionary war. Slavery was abolished in 1780. The "Whisky Insurrection" in the western counties occurred in 1794; it occasioned great excitement, but was put down without bloodshed. A less considerable insurrection was attempted four years later, but was promptly suppressed. In 1799 the State capital was removed to Lancaster, and in 1812 to Harrisburg. After the war of 1812 the State was largely engaged in colossal enterprises of internal improvement—canals and railways—which for some years embarrassed her finances. In 1859 the petroleum discoveries were made. The State was three times invaded by the Confederates—first on Oct. 10, 1862, when Chambersburg was captured and military stores burned; second, by Gen. Lee, when the battle of Gettysburg was fought on her territory; third, in July, 1864, when Chambersburg was burned. The State furnished nearly 400,000 soldiers for the civil war (1861–65).

The constitution of 1776 was framed on the advice of the Continental Congress. A convention, called on the recommendation of a conference of county committees (ignoring the Assembly of the province then in session), drew up a constitution and provided for setting it in operation. It was not submitted to vote of the people. It provided for a single legislative assembly and a plural executive (president and council). It also provided for a council of censors, two from each county, to meet every seven years, with authority to investigate breaches of the constitution and recommend changes in it; and it contained the germ of the modern *referendum* by requiring all public bills to be printed for the consideration of the people before their final passage, which, except on occasions of public emergency, was to be deferred till a succeeding session. On Sept. 15, 1789, the Assembly provided for a convention to amend the constitution. The convention met Nov. 24, completed its work Feb. 20, 1790, voted that the new constitution be published, adjourned till Aug. 9, and on Sept. 2 adopted it with some modifications. It was not submitted to the popular vote. By this constitution the number of representatives was to be not less than 60 nor more than 100, distributed among the counties in proportion to taxable inhabitants. A senate was created to consist of not more than one-third nor less than one-fourth the number of the lower house. The executive power was vested in a Governor, to be elected for a term of three years. Judges were to be appointed to serve during good behavior (seven years having been the previous term), and to receive a fixed compensation. This constitution introduced a highly important change of the old English law of libel, by providing that "in prosecutions for the publication of papers investigating the official conduct of officers or men in a public capacity, or where the matter published is proper for public information, the truth thereof may [might] be given in evidence." In 1837 and 1838 another convention was held which reduced the patronage of the Governor, gave the election of all county officers to the people, and limited the term of judges to fifteen, ten, and five years. Amendments to this constitution were proposed by the Legislature and adopted by the people—one in 1850, four in 1857, three in 1864, and one in 1872. In 1872 and 1873 another convention framed the present constitution, which introduced many important changes, and was ratified Dec. 16, 1873. Under this constitution a Governor can not be elected his own successor.

GOVERNORS OF PENNSYLVANIA.

COLONIAL.

Under the Swedes.

Peter Minuit	1638
Peter Hollandaer	1641
John Printz	1643
John Pappegoya	1653
Johan C. Rysingh	1654

Under the Dutch.

John Paul Jacquet	1655
Colony divided into city and company	1657–62
Jacob Alricks (city)	1657
Alex. d'Hinoyossa (city)	1659
Goeran Van Dyke (company)	1657
Wm. Beekman (company)	1658
Colony united	1662
Wm. Beekman	1662
Alexander d'Hinoyossa	1663
Captured by the English	1664

Under the English.

Col. Richard Nicolls (gov.)	1664
Robert Carr (deputy gov.)	1664
Col. Francis Lovelace	1667

Under the Dutch.

Anthony Colve (gov.)	1673
Peter Alricks (deputy gov.)	1673

Under the English.

Sir Edmund Andros	1674

The Proprietary Government.

Wm. Markham (dep. gov.)	1681
Wm. Penn (proprietary)	1682
The Council (Thos. Lloyd, president)	1684
Commissioners appointed by Penn	1688
John Blackwell (dep. gov.)	1688
The Council (Thos. Lloyd, president)	1690
Thos. Lloyd (d. g. of prov.)	1691
Wm. Markham (deputy governor lower counties)	1691

Under the Crown.

Benj. Fletcher, Goveruor of New York (governor)	1693
Wm. Markham (lieut.-gov.)	1693

Proprietary Government.

Wm. Markham (gov.)	1695
Wm. Penn (proprietary)	1699
Andrew Hamilton (gov.)	1701
Council (E. Shippen, pres.)	1703
John Evans (gov.)	1704
Charles Gookin (lieut.-gov.)	1709
Sir Wm. Keith (lieut.-gov.)	1717
Patrick Gordon (lieut.-gov.)	1726
Council (J. Logan, pres.)	1736
Geo. Thomas (lieut.-gov.)	1738
Council (A. Palmer, pres.)	1747
Jas. Hamilton (lieut.-gov.)	1748
Robt. Hunter Morris (lt.-gov.)	1754
William Denny (lieut.-gov.)	1756
Jas. Hamilton (lieut.-gov.)	1759
John Penn (gov.)	1763
Council (J. Hamilton, pres.)	1771
Richard Penn (gov.)	1771
John Penn (lieut.-gov.)	1776

In the Revolution.

Com. of Safety (B. Franklin, chairman)	Sept., 1776–Mar., 1777

Pres. of Supreme Ex. Council.

Thos. Wharton, Jr.	Mar. 5, 1777
George Bryan (v.-p.), acting	May 23, 1778
Joseph Reed	Dec. 22, 1778
William Moore	Nov. 15, 1781
John Dickinson	Nov. 7, 1782
Benj. Franklin	Oct. 18, 1785
Thomas Mifflin	Nov. 5, 1788

STATE.

Thomas Mifflin	1790
Thomas McKean	1799
Simon Snyder	1808
William Findlay	1817
Joseph Heister	1820
John Andrew Shulze	1823
George Wolf	1829
Joseph Ritner	1835
David R. Porter	1839
Francis R. Shunk	1845

torical Society, 1888); *The Pennsylvania Magazine of History and Biography*, 18 vols.; and numerous county and local histories. GEORGE W. ATHERTON.

Pennsylvania College: an institution at Gettysburg, Pa.; founded in 1832, under the auspices of the Lutheran Church. In 1834 the State of Pennsylvania appropriated $18,000 to the institution, and, for a number of years, annually $1,000. By an act of the Legislature in 1850 one-third of the value of the funds of Franklin College of Lancaster, Pa., was transferred to Pennsylvania College, to establish in it a professorship known as the "Franklin professorship." A preparatory department has been from the first connected with the institution. The control is in the hands of a board of thirty-six trustees, six of whom are nominated by the alumni association, but all of whom are elected by the board itself as vacancies occur. The president (1901) is Rev. Harvey W. McKnight, elected in 1884. There are professorships of the German language and literature, of the English language and literature, of the natural sciences, of hygiene and physical culture, and of the English Bible. The institution possesses chemical and philosophical apparatus, a laboratory for practical chemistry, a cabinet of mineralogy, and an astronomical observatory. Its libraries and those of its literary societies contain over 24,000 volumes. Since 1888 a large recitation and library hall has been erected at a cost of $91,000, also Bena Chapel, and Pennsylvania and Linnæan halls and the chemical laboratory have been remodeled and improved at a cost of about $40,000. The number of students was 249 in 1899–1900. H. W. MCKNIGHT.

Pennsylvania Dutch (more correctly *Pennsylvania German*): a South-German dialect, due to the fusion of forms existing on the upper Rhine in Rhenish Bavaria, Baden, Darmstadt, Würtemberg, German Switzerland, and Alsace, and taking up in the U. S. (chiefly in Pennsylvania) an English element, as English itself took up native words like *hickory*, or French forms like *prairie*, *bayou*, and *ville*. The characteristics of the dialect may be learned from the excellent poems in it by the late H. Harbaugh, D. D. (1870), and in Haldeman's *Pennsylvania Dutch* (1872). It is a mistake to suppose that it is a corrupt dialect of German, or in any way akin to such broken English as Leland in his *Hans Breitmann's Ballads* attributes to European German. Careless speakers of English unconsciously corrupt their language with Germanic idioms, as in the use of "dumb" for *dull* or *stupid*, and "red beet" for *beet*, translating *die rothe Rübe*, because in German a "white" beet (*weisse Rübe*) is a turnip.

Pennsylvania, University of: an institution which originated as a charity school in 1740; was founded as an academy in 1749; incorporated as a college in 1755; erected into a university, the first in the U. S., in 1779. The medical department, the oldest in America, was founded in 1765, and the law department in 1789. In 1872 the institution was removed to its present site in West Philadelphia, Pa., where it has above 52 acres. The twelve departments of the university occupy twenty-three buildings. The college embraces the courses in arts and science; the Towne Scientific School, including the courses in civil, mechanical, and electrical engineering, chemistry, etc.; the School of Architecture; the School of Biology; the School of American History; and the Wharton School of Finance and Economy. These are all four-year courses, with the exception of the two-year courses in history. In the science courses the degree of B. S. is given after four years, and the technical degree after prescribed post-graduate work. The college offers altogether 450 courses. The department of medicine had a three years' course up to the fall of 1893, when it was made four years. Closely connected with it are the University Hospital, with accommodations for over 200 patients; the auxiliary department of medicine, which makes provision for advanced study in medical science; and the recently endowed Wistar Institute of Anatomy and Biology. The Dental School has a three years' course, and is thoroughly equipped, the students using, with the medical students, the largest chemical instruction laboratory building in the world. The veterinary department occupies four buildings erected for its use, two of these being devoted to the Veterinary Hospital. The course of instruction lasts three years. The department of law has a course of three years, with additional post-graduate instruction where desired. The method of instruction is partly by lectures and partly by moot-courts. The department of hygiene, opened in 1892, is situated in a large building, with ample facilities for the study of hygiene and bacteriology, and for special research. The university's courses leading to the post-graduate degrees of M. A., M. S., and Ph. D. are under the supervision of the department of philosophy. Allied with this is the graduate department for women, which makes free provision for a certain number of students. The university museums are very large, and the libraries contain more than 140,000 bound volumes and a larger number of unbound volumes and pamphlets. In 1900 there were 258 professors and other teachers, and 2,790 students.

Pennsylvania, Western University of: See Appendix.

Penny [M. Eng. *peni* < O. Eng. *penig*, *pening*, *pending*. For ending, cf. *shilling* and *farthing*. Etymology obscure]: an English coin, first mentioned in the laws of Ina, King of Wessex, about 695 A. D. It was at first of silver, and at one time weighed 22½ grains troy, but its value and weight slowly declined. The first copper pence were introduced in 1797. At present the British penny is of bronze. It is the twelfth part of a shilling, and is designated by the letter *d*, the initial of the Lat. *denarius*. The name is sometimes also applied to the U. S. cent.

Penn Yan: village; capital of Yates co., N. Y. (for location, see map of New York, ref. 5–E); at the foot of Keuka Lake; on the Fall Brook and the North. Cent. railways; 43 miles N. by W. of Elmira, 53 miles S. E. of Rochester. It is the distributing center of the largest grape-growing region E. of California, being surrounded by 16,000 acres of vineyard. It has daily steamboat connection with Hammondsport, at the head of the lake, and derives good power for manufacturing from the lake. There are 2 national banks with combined capital of $100,000, a State bank with capital of $50,000, an academy, and a monthly and 3 weekly newspapers. Pop. (1880) 3,475; (1890) 4,254; (1900) 4,650. EDITOR OF "CHRONICLE."

Pennyroyal [(by attraction to *penny*) < O. Eng. *puliall royal*, transl. of Lat. *pulegium regium*; *pule'gium*, fleabane, pennyroyal (deriv. of *pulex*, flea), whence Eng. *puliall* + *regium*, royal]: a fragrant labiate herb of the Old World (*Mentha pulegium*) growing wild or cultivated in gardens, and used in Europe in domestic medicine as a stimulant and carminative. It is a perennial herb, very common in Southern Europe, and still hardy in the northern part of Germany. Its odor is quite distinct from that of other mints, having in its sweetness something sour which at first is found very refreshing, but soon becomes nauseous. In the U. S. the name is given to *Hedeoma pulegioides* (low pennyroyal) and *Mentha canadensis* (high pennyroyal), both having very nearly the odor of the English pennyroyal. They are found all over the U. S., from Mexico to Canada, mostly in barren and arid places. They are valuable as deobstruents, carminatives, and diaphoretics.

Pennyweight: See WEIGHTS AND MEASURES.

Penobscot Bay: an inlet of the Atlantic Ocean penetrating the coast of Maine for 30 miles, having Waldo and Knox Counties on the W. and Hancock County on the E. Its deep waters abound in islands and good harbors; principal tributary, Penobscot river.

Penobscot Indians: See ALGONQUIAN INDIANS.

Penobscot River: the longest and largest river of Maine, and the most important navigable stream in the New England States. It rises in Somerset County, near the Canada line, flows E. into Chesuncook Lake, thence S. E. to its union with the Mattawamkeag, having 12 miles above united in the town of Medway with the Seboois or east branch of the Penobscot. Afterward its course is S. by W. to Penobscot Bay; its total length is 300 miles. It is navigable for large ships to Bangor, 60 miles, where the tide rises 17 feet. Above this point small steamers run for many miles. Its upper waters afford valuable motive power, and great numbers of logs are floated from the forests of Northern Maine to Bangor, and then sawed for lumber. The valley of the Penobscot has an area of 8,200 sq. miles. The mean outflow of water is given as 146,250 cubic feet per minute, but this enormous motive power is only in small part utilized.

Penology: See PRISON DISCIPLINE.

Penrith: town; in the county of Cumberland, England; 18 miles S. S. E. of Carlisle (see map of England, ref. 4–F). It is well built, and has a ruined castle in which Richard III. is said to have lived before he came to the throne. There are tanneries, breweries, and sawmills. Pop. (1891) 8,981.

Pensacola: city, port of entry, and capital of Escambia co., Fla. (for location, see map of Florida, ref. 2–B); on Pensacola Bay, and the Louisv. and Nashv. and the Pensacola and Perdido railways; 6 miles N. of the Gulf of Mexico, 48 miles E. of Mobile. It has an excellent landlocked harbor with from 31 to 33 feet of water on the bar; was a place of much importance during the Spanish and English government of Florida; and is the site of a U. S. navy-yard, of Forts Pensacola, McRee, Barrancas, and Pickens, and of the ruins of the old Spanish fortresses of San Miguel and San Bernardo. The city has gas, electric-light, water, and street-railway plants, and contains 11 public-school buildings, public-school property valued at over $65,000, U. S. Government building (cost $250,000), opera-house (cost $75,000), court-house (cost $45,000), State armory, several public parks, 3 national banks with combined capital of $400,000, and 2 daily and 5 weekly newspapers. It has a large foreign and domestic trade in lumber, timber, shingles, phosphate, cotton, fresh fish, and coal. The climate is generally healthful, the sanitary and quarantine regulations of the port being of a character to preclude the possibility of further introductions of yellow fever. In 1899 the city had an assessed valuation of $3,159,096, and a net debt of $279,754. Pop. (1890) 11,750; (1900) 17,750.

EDITOR OF "NEWS."

Pensacola Bay: an inlet of the Gulf of Mexico: at the western extremity of Florida, extending inland N. E. about 35 miles, affording a deep, capacious, and commodious harbor. It is divided into Escambia Bay on the W. and the Bay of Santa Maria de Galvez on the E., and receives Escambia, Black Water, and Yellow Water rivers. The entrance is a mile wide between Santa Rosa island, on the E. defended by Fort Pickens, and the entrance point of the mainland on the W., on which stands Fort McRae. Less than 2 miles N. of the latter stands the old Spanish fort of San Carlos de Barrancas, and in its immediate vicinity a naval hospital, extensive barracks, and a lighthouse, while a short distance N. E. is the navy-yard, which was surrendered to the Florida militia Jan. 12, 1861, not long before the outbreak of the civil war, but recovered by the Federal forces, after sharp engagements, early in 1862.

Pensions [from Lat. *pen'sio*, payment, deriv. of *pen'dere*, *pen'sum*, weigh, weigh out, pay]: allowances of money, generally in fixed amounts and annual payments, made by the government to certain individuals or to their families and representatives, in consideration of some public services performed or supposed to have been performed by them. In Great Britain, besides large sums devoted to pensioning army and navy men, pensions are conferred upon the judges of the higher courts and upon many other civil officers who have performed their duties for a specified number of years and then resigned their active functions. They are also frequently granted to distinguished and meritorious authors, artists, scientific men, inventors, and the like, or to their widows or families, for the purpose of rewarding personal merit and of encouraging literature, art, and science. The policy of the U. S. Government has confined the bestowment of pensions to the officers and privates who have served in the army or navy during the wars in which the republic has been engaged, or who have been wounded or otherwise disabled while in active service, and to their widows, children, and other dependent relatives. The provisions of the existing laws relating to pensions in the U. S. are contained in the Revised Statutes of the U. S. (§§ 4692–4791, and later).

Pentacrinus [Mod. Lat., from Gr. πέντε, five + κρίνον, lily]: a genus of Crinoids (see CRINOIDEA) containing nine living and many fossil species, most abundant in the Jurassic. The living species are inhabitants of the deeper portions of the Atlantic and Pacific Oceans.

Pentam'eter [from Gr. πενταμετρος, of five measures; πέντε, five + μέτρον, measure]: properly, a verse of five feet, but the name is usually given to the syncopated dactylic hexameter of Greek and Latin elegiac poetry. (See ELEGIAC DISTICH.) It consists of two cola (like the masculine first colon of a hexameter) with invariable cæsura between, the entire feet of the second colon always being pure dactyls:

– ⏑ ⏑ | – ⏑ ⏑ | – ‖ – ⏑ ⏑ | – ⏑ ⏑ | – ×

αὐτὰς ἀναιδείη γαῖαν ἐπιστρέφεται.

Panditur ad nullas ianua nigra preces.

Never is death's dark door opened at human appeal.

The third foot is often to be read with a pause instead of prolongation of the syllable.

The name originated from the absurd assumption that the verse was – ⏑ ⏑ | – ⏑ ⏑ | – – | ⏑ ⏑ – | ⏑ ⏑ –, though the correct reading is explicitly taught by ancient authors.

MILTON W. HUMPHREYS.

Pentateuch [from Lat. *pentateu'chus* = Gr. πενταteυχος; πέντε, five + τεῦχος, implement, book, deriv. of τεύχειν, prepare]: the collective name of the first five books of the Old Testament—Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. It originated from the Greek translators and Fathers; the Jews themselves called this division of their sacred book *Torah*, the Law. These and the book of Joshua form the HEXATEUCH (*q. v.* for authenticity, etc.). See also the article BIBLE.

Pentathion'ic Acid: an acid of the composition $H_2S_5O_6$, prepared by the action of hydrogen sulphide, H_2S, on a solution of sulphur dioxide, SO_2, in water. It is unstable, and very little is known about it.

Pentecost [from Lat. *pentecos'te* = Gr. πεντηκοστή, the fiftieth (sc. ἡμέρα, day), deriv. of πεντήκοντα, fifty]: one of the three principal festivals of the Jews, celebrated on the fiftieth day after the 16th Nisan, the second day of the Passover (Lev. xxiii. 15, 16), whence the name. It was originally called the "Feast of Weeks" (took place at the beginning of harvest-time, hence also its other name, "Feast of Harvest"), was characterized by the offering, as "first fruits," of two loaves of leavened bread made from new grain, and was a period of liberality to the poor. In modern times the Jewish festival of the Pentecost lasts two days, and the anniversary of the giving of the Law on Sinai has been combined with the earlier festival. In the Christian churches the word Pentecost has a different meaning, derived from the occurrences related in Acts ii.—viz., the descent of the Holy Spirit upon the infant Church ten days after the Ascension, the gift of tongues, and the conversion of 3,000 persons. In the English Church, Penteeost is known as Whitsunday or Whitsuntide, from the white garments formerly worn by candidates for baptism.

Revised by S. M. JACKSON.

Pentecost, GEORGE FREDERICK, D. D.: clergyman and author; b. at Albion, Ill., Sept. 23, 1842; learned the trade of a printer, then studied law. He became a member of Georgetown College, Kentueky, whieh he left in 1862 to serve in the Union army. He was the pastor sueeessively of five Baptist churches, but from 1881 to 1890 he was pastor of a Congregational ehurch in Brooklyn, N. Y. For many years he has been engaged in evangelistic work in the U. S., in India, and in Great Britain. He has written *Bible Studies for 1889* (1888); *The Gospel of Luke* (1889); and several religious books, besides traets. In 1885 he became the editor of *Words and Weapons for Christian Workers*.

G. P. FISHER.

Pentland Firth: a channel connecting the Atlantic with the German Ocean, and separating the Orkney islands from Scotland; is 17 miles long, from 6 to 8 miles broad, and annually passed through by about 4,000 vessels, though it is very difficult to navigate.

Penum'bra: See ECLIPSE.

Pen'za: government of European Russia; lying around the rivers Moksha and Soora (see map of Russia, ref. 8–F). Area, 14,997 sq. miles. The ground is mostly level and somewhat elevated, and the soil fertile. Wheat, flax, hemp, tobacco, hops, and beetroots are raised; forests of oak-trees cover nearly one-third of the country. Besides agriculture, the prineipal branch of industry, manufactures of linen stuffs, spirits, glass, and beetroot-sugar are carried on. Pop. (1897) 1,483,948. The capital, Penza, on the Soora, has a cathedral, a large park, and manufactures of paper, soap, spirits, beetroot-sugar, etc. Pop. (1897) 55,680.

Penzance': town; in the county of Cornwall, England; at the head of Mount's Bay; 80 miles S. by W. of Plymouth and the terminus of the Great Western Railway (see map of England, ref. 15–B). It has an esplanade commanding picturesque land and sea views, a harbor, forming a tidal basin of 21 acres, with doeks and two piers. The chief buildings, principally constructed of granite, include the public rooms in the Italian Renaissance style and the market-house in the Grecian style. The churches of St. Mary and St. Paul are built of cut granite in the Perpendieular and thirteenth century styles, respectively. The most important industries are the mackerel and pilchard fisheries and market gardening. The mild climate and the beauty of the surroundings attract a great number of visitors. Pop. (1891) 12,448.

Pe'ony [from O. Fr. *pione* > Fr. *pivoine* < Lat. *pæo'nia* = Gr. *παιωνία*, deriv. of *Παίων*, *Παιάν*, the god of healing. See PÆAN]: any herb or shrub of the genus *Pæonia*, family *Ranunculaceæ*. The U. S. has but one native species, *P. brownii*, of the Pacific States and British America. It has small purple flowers. The various Old World species are cultivated as ornamental plants. The flowers are generally showy. Of the many artificial varieties some are fragrant. All have a poisonous principle, and some species were once employed in medicine, but none are much used at present. The seeds and roots of some species are used as food by wild tribes in Asia and America. The finest varieties in garden-culture belong to *P. officinalis*, *albifolia*, *tenuiflora*, *paradoxa*, etc. The tree-peony of Japan (*P. moutan*) affords some very fine varieties. Revised by L. H. BAILEY.

People's Party: a political party in the U. S. whose leading principle is opposition to the control exerted by wealth. The idea prevails, especially in the West and South, that the laws are largely framed and executed in a manner to give undue advantage to those who are unscrupulous in the use of money, and that this is the prime reason for the great inequality in the distribution of property. According to the estimate of special census agent G. K. Holmes, 9 per cent. of the people own 71 per cent. of the national wealth, while Thomas G. Shearman estimated that less than 50,000 people own half.

Principles and Arguments.—The great increase in the proportion of business done by corporations, with the resulting concentration of capital into the hands of a few managers and the temptation to use it to protect or procure valuable franchises or trade advantages, together with the preservation of monopolies and the expense of securing elections (which appears to be from $7,000 to $13,000 for a Congressman, the salary of whose term is only $10,000), have introduced an era of official venality unparalleled since the days of Walpole. To such an extent do rich men find their way into the Senate that the average income of a Senator is estimated to be above that of a British peer, stated by London *Truth* at $135,000 per annum. This condition excites attention in Europe and leads to comments like that of Leroy Beaulieu, that money seems to be the legitimate sovereign of democracies.

Of the laws and lack of laws through which the rich are aggrandized, the chief attention of the Populists has been given to those creating or permitting (1) unequal taxation; (2) trusts and monopolies; (3) the single gold standard, excluding silver.

The burden of local taxation caused by the escape or unjust exemption of notes, stocks, and bonds—the peculiar property of the wealthy—is rapidly increasing. Though personal property increases much faster than real, its assessment relatively declines. This is roughly seen in the census data, which show an increase from 1870 to 1890 in the real estate taxed from 9,914 millions of dollars to 18,933, while the increase for the same time in personalty was from 4,264 millions to 5,718. The comptroller of the State of New York, in his report for 1890, gave his official opinion that in that State more than 2,500 millions of personal property unjustly escaped taxation. In Massachusetts it is the opinion of men versed in the subject that the people are defrauded of more than $15,000,000 a year in taxes, a sum which at legal interest compounded for a generation would equal the whole valuation by the assessors. The taxes shirked by the wealthy fall over largely on the farmers, whose property is visible and can not escape, and, through rents, on to the working classes. The Populist calls for equal taxation of property, sometimes for doomage laws, and always for an income-tax.

As to monopolies, the substance of the Populist doctrine is that as the Government recognizes its duty to protect the citizen against the man who by superior physical strength wrongfully seizes his pocketbook, it is equally bound to protect him against the man who by superior financial strength or special privilege does the same. Therefore it calls for adequate control of such, and, where necessary for this purpose, for Government ownership and operation of monopolistic properties. As this is the first step in the plan of Edward Bellamy, the Nationalists are generally Populists.

The leading question, however, has been that of honest money, whose proper function is to buy always the same average amount of commodities. When A buys of B 1,000 bush. of wheat for $1,000, payable in five years with interest, the money should give B, when the debt is paid, not the same amount of wheat, for that may have fallen or risen, but the same average amount of all exchangeable commodities which it would buy when the debt was made. It need not give the same amount of labor, for that may have risen or fallen, and B has no more right to claim that than he has to claim the same wheat, though given by him in time of plenty and paid in time of famine. Neither can he justly claim more commodities if improved modes of production may have cheapened them. He gave to A a certain amount of commodities or capital for a rent called interest, and he has no better claim to be made whole for such a depreciation than he would have had he rented a house, to be made whole for a reduction in its value caused by the introduction during the tenancy of some improved mode of building. He would have suffered that loss had he kept his house or capital himself. All economists agree that there has been since 1873 a great increase in the purchasing power of gold. If the foregoing reasoning is correct, debtors have thereby been defrauded. Most economists agree that this is due to the demonetization of silver in 1873, and the smallness of the annual increment of gold since going into the money volume compared with the increase of demand; but the cause is immaterial. The extent of this appreciation of gold since 1873 is shown by various price-tables which substantially agree. Those of Augustus Sauerbeck show a decline in prices of 38·3 per cent. up to Nov. 1, 1892, and the financial depression of 1893 probably increased this to 44 or 45, which represents an increase in the purchasing power of money of about 80 per cent.

A conception of the hardship to debtors may be had by a rough estimate. The debts of the world are supposed to reach 150 billions of dollars. Suppose the volume since 1873 to have been 100 billions, and the average increase in the purchasing power of money has been 30 per cent., the unjust exaction from debtors will reach 30 billions in commodities, while the whole assessed value of the property, real and personal, of the U. S. in 1890 was only 24 billions. Declining prices also involve business stagnation. The Populists generally, restless at the great increase in the burden of their debts, propose fresh issues of paper and the free coinage of silver. Those in Massachusetts have proposed multiple standard money, involving the demonetization of gold and silver, and the substitution of a volume of irredeemable legal-tender treasury notes, issued only by the Government, and receivable for all its dues, the volume to be expanded or contracted according as it shall be found that the dollar will buy more or less in a given market than a predetermined average amount of a large number of commodities (say 100) selected as best representing all commodities. The purchasing power of the dollar would thus always be kept uniform.

The Farmers' Alliance.—The farmers, pinched by such conditions as rendered it very hard to pay their debts, bled by railroads and middlemen who sold them goods and made advances on their crops, began to organize societies for mutual advantage, education, and defense. The chief of these has been the Farmers' Alliance. Its effective beginning was in a small body organized at Poolville, Tex., July 28, 1879. The order, having extended into a few counties, formed, and obtained a charter for, a State alliance in Texas, Oct. 6, 1880. By 1882 120 sub-alliances had been organized. This order was consolidated with another of like purpose, the Farmers' Union of Louisiana. A national organization, the National Farmers' Alliance and Co-operative Union of America, was established at Waco, Tex., in Jan., 1887. The Agricultural Wheel, another like order, was also joined, subject to ratification of the subordinate bodies, and a constitution was adopted at a meeting of both orders at Meridian, Miss., Dec. 5, 1888. The Agricultural Wheel originated Feb. 15, 1882, at a meeting held in a log cabin near Des Arc, Ark. It was chartered in Aug., 1882, organized a State Wheel Apr. 7, 1883, and a National Wheel in 1886. In 1888 it reached 1,947 subordinate bodies, and had 75,000 members in Arkansas alone. The name given the consolidated order at Meridian was The Farmers' and Laborers' Union of America. The union was after ratification proclaimed as of Oct. 1, 1889. The order contained fully 1,000,000 members, and extended into eighteen States and Territories. The next national meeting was held at St. Louis, Dec. 3, 1889. The constitution was amended, and the name National Farmers' Alliance and Industrial Union adopted. These orders had been largely educational and social, and did not admit colored persons. They had established co-operative stores and united in various ways to promote agricultural interests. They were strictly non-partisan,

but were free to formulate political demands, and active within the old party organizations. Great interest had begun to be felt in all the kindred organizations representing the industrial masses to agree upon common political principles and unite to secure just legislation. Accordingly, the National Farmers' Alliance of the Northwest and the National Colored Farmers' Alliance met also at St. Louis at the same time. The Knights of Labor sent also their president, with other officers. Demands were formulated with the express concurrence of the latter, which were adopted, with those of later conventions, with some modifications by the People's Party in their national convention at Omaha in 1892. The next annual meeting of the National Farmers' Alliance and Industrial Union was held at Ocala, Fla., Dec. 2, 1890. Additional demands were made, and it was voted "that a free ballot and a fair count will be insisted upon and had for colored and white alike by every true Alliance man in America."

The Formation of the People's Party.—By this time, failure to secure favorable results through the old parties being apparent, a strong pressure existed for separate political action. The Alliance and its sympathizers had made in 1890 energetic contests in many sections in the South, mainly through the primaries, but in the Northwest at the polls. The results were greatest in Georgia and Kansas. In the latter State a Republican plurality of 80,000 was cut down to 8,000, the Legislature was carried (securing a U. S. Senator), and five Congressmen out of seven elected. The chairman of the executive committee at Ocala, stating that a third party was opposed in the South but favored in the West and Northwest, suggested a meeting of "delegates from all the organizations of producers" to decide the question. A committee was chosen to carry this into effect, and the St. Louis conference of Feb. 22, 1892, was the result. Another conference, to provide for a national ticket in 1892, if the St. Louis conference should fail to do so, was arranged for by individual delegates at Ocala, and held at Cincinnati on May 19, 1891. At St. Louis the third-party men gained control. The opponents were mainly from the South, and some of the leaders bolted afterward. A vote was passed requesting Alliance Congressmen to stay out of old-party caucuses. An address was adopted denouncing the old parties and declaring that a party representing the principles then agreed was necessary. Action which might be held to contravene the organic law of the order was taken by the delegates as individuals remaining in their seats after adjournment.

The national convention of the People's Party provided for by these conferences was held at Omaha, July 4, 1892, with 1,347 regularly elected delegates. A platform was adopted, of which the demands may be thus epitomized:

A national legal-tender currency, safe, sound, and flexible, issued by the Government only without the use of banks, direct distribution to the people at a tax not to exceed 2 per cent. per annum, to be provided as set forth in the Alliance sub-treasury plan or a better system, and by payments in discharge of obligations for public improvements. Free coinage of silver and gold at the ratio of 16 to 1. Increase of the circulating medium to $50 per capita. A graduated income-tax. Limitation of State and national revenues to the necessary expenses of government economically and honestly administered. Government ownership and operation of railroads, telegraphs, and telephones. That land and natural sources of wealth should not be monopolized for speculation, and alien ownership of land should be prohibited. That land owned by railroads and corporations in excess of needs and land of aliens should be reclaimed by the Government and held for settlers.

Resolutions were adopted for a free ballot and a fair count, to be secured by the unperverted Australian secret-ballot system. For the application of the revenue of the graduated income tax to relieve the taxes on domestic industries; for fair and liberal pensions; for further restriction of undesirable immigration; for enforcement of the eight-hour law on Government work, with penalties; against the Pinkertons; for the initiative and referendum; for limiting the offices of President and Vice-President to one term; and against subsidies and private corporations.

On this platform James B. Weaver, of Iowa, was nominated for President, and James G. Field, of Virginia, for Vice-President. The vote for Weaver reached 1,041,028. He carried the States of Colorado, Idaho, Kansas, Nevada, and North Dakota, receiving twenty-two electoral votes. Five U. S. Senators and eleven Representatives were elected.

At the meeting at Memphis, Nov. 9, 1892, a new subordinate organization was formed in aid of the People's Party. It was called the Industrial Legion and was indorsed by the national executive committee. In 1894 1,000 subordinate legions were in existence. HENRY WINN.

Peoria: city (settled in 1779); capital of Peoria co., Ill. (for location, see map of Illinois, ref. 4–D); on the Illinois river, and eleven main lines of railway; 45 miles W. N. W. of Bloomington, 160 miles S. W. of Chicago. It is at the foot of an expansion of the river known as Peoria Lake, has a water frontage of about 4 miles, and covers an elevated plateau extending back three-quarters of a mile to a bluff rising 120 feet above tide-water. On the bluff are many fine residences, and from it may be had many attractive views of the river valley and the adjacent country. An elaborate system of parks and driveways has been established. There are 35 miles of paved streets. The city is in a corn and coal region, is noted for its manufactures of spirits, and is the eighth grain-market in the U. S. It has an extensive commerce by rail and water with Chicago, St. Louis, and other large centers. There are 16 public-school buildings, public-school property valued at over $500,000, court-house (cost $300,000), U. S. Government building (cost $250,000), cathedral (cost $225,000), high-school building (cost $75,000), new system of water-works, 3 libraries (High School, Law, and Public) containing over 55,000 volumes, 7 national banks with combined capital of $1,400,000, 4 State banks with capital of $700,000, 5 savings-banks, 2 private banks, 6 electric street-railways, gas and electric light plants, and a monthly, 6 daily, and 11 weekly periodicals. The census returns of 1890 showed that 554 manufacturing establishments (representing 90 industries) reported. These combined had a capital of $15,072,567, employed 7,696 persons, paid $4,327,637 for wages and $9,979,907 for materials, and had products valued at $55,504,523. The principal industries reported were, in the order of capital investment, the manufacture of agricultural implements, 7 establishments and $967,366 capital; malt liquors, 4 establishments and $874,496 capital; cooperage, 8 establishments and $388,200 capital; foundry and machine-shop products, 14 establishments and $372,072 capital; printing and publishing, 19 establishments and $359,520 capital; planing-mill products, 5 establishments and $343,132 capital; and flour and grist mill products, 8 establishments and $280,100 capital. There are 14 distilleries, 5 grain elevators with a total capacity of 2,400,000 bush., 2 large glucose-factories, using 30,000 bush. of corn per day, an extensive chemical laboratory, flour-mills, straw-board mill, rolling mill, white lead works, stock-yards, and several meat-packing houses. The city expenditures during 1893 were $338,785; bank clearings, $82,836,982; grain receipts, 33,670,870 bush.; and internal revenue collection, $13,389,736. In 1894 the city had an assessed valuation of $8,869,644, and a net debt of $614,500. Pop. (1880) 29,259; (1890) 41,024; (1900) 56,100.

Peoria Indians: See ALGONQUIAN INDIANS.

Pepe, GUGLIELMO: revolutionist; b. at Squillace, Italy, in 1783; served in the army of the Parthenopean republic, fought on the side of the French in Spain, and afterward under Murat. By the year 1815 he had risen to the rank of lieutenant-general. Sympathizing with the aspirations of the liberal party in Naples he joined the Carbonari, and in 1820 placed himself at the head of a military revolt. This was at first successful; Pepe entered Naples in triumph, and the king was forced to accept the constitution, but Austrian intervention, under the sanction of the Holy Alliance, soon restored the Bourbon tyranny. Pepe was defeated at Rieti Mar. 7, 1821, and fled to London, later to Paris. Having returned in 1848, he commanded the Neapolitan contingent against the Austrians, and distinguished himself by his brilliant defense of Venice. He afterward lived in Turin, where he died Aug. 9, 1855. His principal works are *Relation des Évènements Politiques et Militaires qui ont eu lieu à Naples en 1820 et 1821* (Paris, 1822; Italian and French); *Histoire des Révolutions et Guerres d'Italie en 1847–49* (Paris, 1850).

Pepin, Lake: an expansion of the Mississippi river; 27 miles long and from 2 to 3 miles wide, having Pierce and Pepin cos., Wis., on the N. E., and Goodhue and Wabashaw cos., Minn., on the S. W. It is surrounded by rocky ramparts of picturesque and inspiring appearance. The lake is not very deep.

Pepin (or **Pippin**) **le Bref** [Fr., Pepin the Short]: the first Carlovingian king of the Franks; b. in 714; son of

Charles Martel and father of Charlemagne; became in 741 major-domus of Neustria and Burgundy under Childeric III., one of the *rois fainéants*, and in 747 succeeded his brother Carloman as major-domus of Austrasia and the Rhine country, including Thuringia and Suabia. In 749 he defeated the Bavarians, and in 752 was crowned King of the Franks by St. Boniface by authority of Pope Zachary; conquered Septimania from the Saracens 752–760; was again crowned by Pope Stephen III. 754; broke the power of the Lombards in Italy 754–756, and gave the exarchate of Ravenna and the Pentapolis to the holy see, the origin of the temporal power of the popes; overcame the Saxons 757; took Narbonne from the Saracens 759; waged a stubborn war with Guaifar, Duke of Aquitania, 760–768, and in the latter year procured the assassination of his valorous enemy. D. Sept. 18 or 24, 768. See FRANKS, THE.

Pepin of Héristal: founder of the Carlovingian line of Frankish kings; a grandson of Pepin von Landen, mayor of the palace in Austrasia; became Duke of the Austrasian Franks 680, and in 687, by the battle of Testry, conquered Burgundy and Neustria, and afterward subdued the Frisians and ravaged Suabia. D. Dec. 16, 714 A. D. He never assumed the royal title, but exercised sovereign power in the name of four successive Merovingian *fainéant* kings. Charles Martel was his natural son.

Pepper [M. Eng. *peper* < O. Eng. *pipor*, from Lat. *piper* from Gr. *πίπερι*, *πέπερι*; cf. Sanskr. *pippala*, a kind of pepper, Pers. *pulpul*, pepper]: a name applied to the pungent fruits of certain plants and to the condiment prepared therefrom. Black pepper is the product of a climbing shrub belonging to the family PIPERACEÆ (*q. v.*), with a smooth, woody stem from 12 to 20 feet long, with leathery, ovate, cordate leaves, and, opposite to each leaf, a solitary spike with hermaphrodite flowers, and fruits of the size of a pea and bright red when ripe. The plant is a native of the East Indies, but now extensively cultivated in most tropical countries. It was known to the Romans, and highly appreciated during the Middle Ages, when a pound of pepper was considered a royal present. It is now one of the most common spices. The white pepper of commerce is the same product with the outer covering removed. Red pepper is the product of a species of *Capsicum*, a genus of the Nightshade family especially *C. annuum* and *C. frutescens*, natives of South America, but now widely dispersed in warm countries. From these the Chili and Cayenne peppers are made. The commercial product is prepared by grinding the dried ripe fruits, adding flour to the powder, and baking the whole into cakes. These cakes are then ground into commercial pepper. In temperate climates many varieties of red peppers are grown for home use and as an ingredient of mixed pickles. These kitchen-garden peppers, while immensely variable, are no doubt all offspring of *Capsicum annuum*. Over thirty varieties are now in cultivation in the U. S. The most pungent of these are the so-called Cayenne and Chili varieties, which bear very long and slender finger-like fruits. The mild varieties, or so-called "sweet peppers," are fruits of great size and are somewhat hollow and furrowed. The Bull Nose, Sweet Mountain, and Grossum are common sorts of this type. Red peppers need a warm, quick soil and a forward exposure. As they continue to bear until cut off by frost, the largest product is obtained when the plants are started under glass. Jamaica pepper is the product of a species of *Eugenia* of the family *Myrtaceæ*, and various other species of *Piper*, as *P. longum*, *P. officinarum*, *P. methysticum*, *and P. betle*, yield pepper or pepper-like products. Both pepper and capsicum are useful gastric stimulants and carminatives. Cubebs, used in medicine, are the product of *P. cubeba* (*Cubeba officinalis*). L. H. BAILEY.

Pepper, WILLIAM, M. D., LL. D.: eleventh provost of the University of Pennsylvania; specialist in medicine; b. in Philadelphia, Aug. 21, 1843; son of Dr. William Pepper (Professor of Theory and Practice of Medicine, University of Pennsylvania, 1860–64); graduated at the University of Pennsylvania 1862; from the medical department 1864; lecturer on morbid anatomy 1868–70, on clinical medicine 1870–76; Professor of Clinical Medicine 1876–87; Professor of Theory and Practice of Medicine, succeeding Dr. Stillé, 1887; unanimously elected provost of the university 1881; resigned in 1894. During his administration the material equipment of the institution increased in value not less than $2,500,000, and the Wharton School of Finance and Economy, the department of veterinary medicine, the School of Philosophy, the School of Biology, the School of American History, the department of archæology and palæontology, and the department of hygiene were added. He attended to his professional practice while organizing and moulding the university. He was medical director of the Centennial Exposition 1876, and for his services received from the King of Sweden the decoration of Knight Commander of the Order of St. Olaf. He was elected president of the Association of American Physicians 1891, and of the first Pan-American Medical Congress in Washington (1893). He founded *The Medical Times*, and was its editor 1870–71. His principal literary work was the editing of the *System of Medicine*, by American authors (1885–86). Among his contributions to journals or the transactions of societies are *Trephining in Cerebral Disease* (1871); *Local Treatment of Pulmonary Cavities* (1874); *Catarrhal Irritation* (1881); *Report on the Mineral Springs of America* (1881); *Epilepsy* (1883); *Phthisis in Pennsylvania* (1886). Other publications of less technical character are *Sanitary Relations of Hospitals* (1875); *Higher Medical Education: the True Interest of the Public and the Profession* (1877); *Report* of the Medical Department of the Centennial Exposition (1877). He was associate editor in charge of the department of medicine, surgery, and collateral sciences, *Johnson's Universal Cyclopædia*. D. in Pleasanton, Cal., July 28, 1898. C. H. THURBER.

Pepperell, Sir WILLIAM: b. at Kittery Point, Me., June 27, 1696, of Welsh descent; the son of a fisherman; became a merchant and a distinguished Indian fighter; was a member of the Massachusetts council 1727–59; became chief justice of the common pleas court 1730; captured Louisburg 1745; was made a baronet 1746; a colonel of the British army 1749; major-general 1755; lieutenant-general 1759; was acting Governor of Massachusetts 1756–58. D. at Kittery, Me., July 6, 1759.—WILLIAM PEPPERELL SPARHAWK, his grandson, took his name, title, and his great estates in 1774, but lost everything in consequence of his Tory principles in 1778. D. in London, Dec. 17, 1816.

Pepper Family: the PIPERACEÆ (*q. v.*).

Pepperidge: See BLACK-GUM.

Peppermint: a well-known labiate herb, the *Mentha piperita*, a native of the Old World, but completely naturalized in the New. This plant and its essential oil are extensively used in confectionery, and in medicine as a carminative and to conceal the flavor of nauseous drugs. Peppermint is extensively cultivated in Kalamazoo, St. Joseph, and Wayne cos., Mich., and in Wayne co., N. Y.

Pepsin [from Gr. *πέψις*, cooking, digesting, deriv. of *πέσσειν*, cook]: an active ferment of the gastric juice, secreted by the cells lining the "peptic" glands, and may be precipitated by alcohol or lead acetate. It has never yet been perfectly isolated, but is known to be one of the albuminoids or nitrogenous organic substances. Pepsin possesses the power of converting proteids into peptones in the presence of an acid and heat. It does not digest starches. Substances called pepsin, usually containing some of the active principle, are often prescribed in dyspepsia for the relief of the irritated stomach. Recently so pure a pepsin has been isolated that it will digest 25,000 times its own weight of albumen. Pepsin is usually derived from the stomach of the pig. Revised by H. A. HARE.

Peptonized Food: food prepared, through the action of pancreatin upon proteid substances, for the purpose of supplanting natural digestion in persons whose digestive apparatus is too feeble to carry out its function properly. This process of peptonization (see FERMENTATION) has become an exceedingly important one in dietetics, and is constantly resorted to. The method of peptonizing milk is as follows: From 5 to 20 grains of pancreatin and 5 grains of bicarbonate of sodium are added to a pint of milk at a temperature of 100°, and the process of peptonization is permitted to go on for varying lengths of time, according to the degree of digestion which is desired; 5, 10, or 20 minutes is the period generally allowed. After this time, if the digestive process is not stopped, the formation of a large amount of peptone gives such a bitter taste to the milk that most patients refuse to take it. Most of the pancreatin used for peptonizing foods is put up by manufacturing chemists in small glass tubes containing the proper quantities and ingredients for one process, or in compressed tablets containing the same quantity.

Peptonized beef is made in the same way by taking a quarter of a pound of finely minced lean beef, adding to it a pint of warm water, mixing it in a saucepan, and then

keeping the mixture at the temperature of the body, or a little above, for a few minutes. In the case of both the milk and the beef the process of peptonizing may be stopped in one or two ways, either by bringing the liquid to the boiling-point, which destroys the ferment, or by placing it upon ice, where it will rapidly cool. If it is desirable to stop the process absolutely, it is safer to bring the liquid to the boiling-point than to cool it. H. A. Hare.

Pepys, pep'is, or peps, Samuel: diarist; b. Feb. 23, 1633; the son of a London tailor; was educated at Huntingdon, and at Magdalene College, Cambridge; became a Roundhead, but turned Royalist under Monk; held various positions in the navy and was secretary to the admiralty under James II. He was imprisoned 1679–80 for alleged complicity in the popish plot; president of the Royal Society 1684–86, and was in 1690 imprisoned for a time as a Jacobite. D. in London, May 26, 1703. Pepys's *Diary*, kept in shorthand (1660–69), has been often imperfectly reprinted since 1825, when Lord Braybrooke's incomplete edition appeared. Bohn's edition, by H. B. Wheatley (8 vols.), gives the complete annotated text as rendered from the MS. by Rev. Mynors Bright, with the exception of some details of his and wife's ailments, and some coarse expressions and stories, all such omissions being indicated by dots. This work is instructive and entertaining, giving us a valuable insight into the everyday life of the times of the later Stuarts. His *Memoirs of the Royal Navy* (1690), *Portugal History* (1677), and other writings, are of some value. He was an industrious collector of ballads, prints, maps, and music, a dabbler in the various sciences and the fine arts, and founder of the Pepysian Library at Magdalene College, Cambridge. See H. B. Wheatley, *Samuel Pepys and the World he lived in* (London, 1880). Revised by H. A. Beers.

Pequod or Pequot Indians: See Algonquian Indians.

Pe'ra [from Gr. *πέραν*, beyond]: a suburb of Constantinople. The term has been applied since the sixth century to the formerly waste plateau N. of the Golden Horn and beyond Galata. This region began to be inhabited after the Ottoman Conquest (1453), and has become the diplomatic quarter of the metropolis and the chief residence of the foreign Christians. In the great fire of 1870 more than 1,000 persons lost their lives, and over 6,000 houses were consumed, but the suburb has been entirely rebuilt. E. A. G.

Peræ'a [= Lat. = Gr. *περαία* (sc. *γῆ*, land, or *χώρα*, region), liter., the farther country, the country beyond, fem. of *περαῖος*, lying farther, beyond, deriv. of *πέραν*, beyond]: any one of several districts lying beyond a river, strait, or sea, but used especially of that part of Trans-Jordanic Palestine which extended from Pella on the N. to Machærus on the S., and from Philadelphia on the E. to the Jordan on the W. These were its boundaries as given by Josephus in his *De Bello Judaico*, iii., 3, 3. It is there described as generally wild and rugged, though well watered by streams and fountains, and in some parts of it very fertile. The name has also been applied to the whole of Palestine beyond the Jordan. Peræa constituted one of the four provinces into which Herod, and later the Romans, divided Palestine.

Per Capita: See Descent.

Perception [from Lat. *percep'tio*, deriv. of *perci'pere*, *percep'tum*, seize, perceive, liter., take or get completely; *per-*, through, thoroughly + *ca'pere*, take]: the act of obtaining knowledge of external objects through or by means of the organs of sense, or of internal states and conditions by means of consciousness or intuition. It also signifies the result of such act. Application has been made of this term to signify cognition or thinking in general, including all the theoretical powers—sensation, representation, inference, and intuition. In this sense perception and volition would include all the powers of the mind. It is limited by many writers to external perception by means of the senses, and the higher activities of reason and reflection are regarded as modified sensation. The presence of inference or judgment in each act of sense-perception has been pointed out by Reid, Kant, Fichte, Hegel, Plato, and others. Erasmus Darwin made volition an essential element of higher perception—the association of ideas. In so far as attention underlies perception, the modifying influence of the will is obvious.

Historical.—The doctrine of the intervention of images arising from effluxes from sense-objects has played a great *rôle* in the history of philosophy. Empedocles (500 B. C.) first advanced this theory, explaining sense-perception through effluxes and pores, interpenetration and mixture of elements arising through the same; effluxes of fire and water to and from the eyes constituting sight; of air into the ears, producing sound; smell and taste being similarly caused. Cognition of the elements of things was held to be by means of corresponding elements in ourselves. Anaxagoras (500 B. C.) noted the principle of contrast in perception, and held that like is not known by like, but by unlike, thus repudiating the principle of identity as set up by Empedocles, and explaining perception through difference. The atomists Leucippus and Democritus (460 B. C.) taught the doctrine of effluxes modified to suit their doctrine of atoms. Atoms impinge on our senses and produce images. These thinkers also distinguished between obscure perception (*σκοτία*)—i. e. through the organs of sense—and clear perception (*γνησία*), through investigation. The doctrine of effluxes appears again with Epicurus (341–270 B. C.); sense-perceptions are mental images coming from the surfaces of things by efflux. Plato (427–347) pointed out the existence of inference in all sense-perception, and showed it to be necessary to reconcile the contradictory predicates which inhere in sense-objects by reason of their relativity. He found a higher form of perception in the cognition of ideas, which constitute the true in and for itself; sense-perception deals with the changing and variable. Aristotle (384–322 B. C.) held that sense-perception (*αἴσθησις*) is the result of qualities which exist potentially in the objects perceived, and actually in the perceiving subject. The seeing of colors, for example, depends on the activity of the medium of vision (air or water). In the active reason (*νοῦς ποιητικός*), which is the highest phase of the soul, will and perception are one; it is creative and cognitive in one. The Peripatetic Strato (288 B. C.) made this higher perception to be only a modification of the lower, and in this direction the Stoics tended, their prevalent doctrine being that sense-perception is the origin and criterion of all perception. St. Augustine, Thomas Aquinas, and Meister Eckhart held the doctrine of effluxes and images which were taken up into the soul through the senses; but with Aristotle, they distinguished from this the higher perception through the active reason, which gives us knowledge of divine truth. Descartes (1596–1650) laid great stress on the distinction between clear and obscure perceptions, making the former cognizant of eternal truths existing only in the mind, and the latter cognizant of external things and their affections. He separated soul from body so sharply that he was forced to explain their connection (in volition and sense-perception) by divine interference. Geulincx tried to explain the same by the doctrine of occasionalism, holding that through God's power our psychical activity is transmuted into corporeal, and the latter into the former. Malebranche unfolded this into the mystical doctrine that we perceive all things by participation in God's perception. Spinoza, however, abandoned the Cartesian dualism altogether for the doctrine of the unity of substance, which makes perception explicable. Leibnitz denied the theory of effluxes as a mere mechanical explanation, and set forth the more spiritual one of monads as perceiving-substances which reflect or represent within themselves, each, the entire universe. Obscure or insensible perceptions are those which are unaccompanied with consciousness or memory. The myriad of perceptions to which we do not direct our attention are of this order. The whole universe is latent, as it were, in each monad, existing in this form of insensible perception, which needs only to be aroused to consciousness to become actual knowledge. Thus even the lowest state of the monad—that simply of heavy matter—contains in its weight an obscure representation of the universe of matter, for the weight of each body depends upon the mass of all other bodies in space. Thus the entire history of each being and of all beings is contained in a dormant state in each being; and it is the activity of the soul which brings them to consciousness in the various grades of perception. The aggregate of these obscure or insensible perceptions makes up the instinct of animals, and the disposition, impulses, and emotions of man. Herbart (1776–1841) and Beneke (1798–1854) have pursued this thought of Leibnitz, and have made many valuable discoveries in psychology. The mutual arrest of opposing ideas in consciousness, and the power which one idea has of intensifying or obscuring and rendering latent another, as well as of combining, when latent, with other latent ideas and reappearing in consciousness in a new guise—the investigation of these phases of perception forms one of the most interesting chapters in modern psychology. Kant (1732–

1804) made time and space the *a priori* forms of sense-perception, and denied the objective validity of higher perception, limiting it to subjective forms. Reid (1710–96) taught that mind is active in sense-perception, every act being an act of judgment or inference. Common sense or higher perception cognizes necessary truths of inherence, causation, and design—truths which Kant had pronounced merely subjective. Sir William Hamilton agrees on the one hand with Reid in repudiating the intervention of images and material effluxes, but holds with Kant that we do not cognize things in themselves, thus rejecting Reid's common-sense theory. WILLIAM T. HARRIS.

Current Theories of Perception.—Leaving the general problems of the theory of knowledge to metaphysics, current psychological theories have to do only with the process of perception, considered as an operation of mind in attaining knowledge of the external world. That is, we have to answer the simple question, "How do we arrive at the knowledge of individual objects localized in space and time?" In view of the terms of this question and of the analysis which follows, we may define perception in a general way as *the process of the construction of our representation of the external world.*

A little reflection leads to the conclusion that our perception of the external world is a matter of mental construction. All advance into the region of mind must be through mental states. The characteristic of mind is consciousness, and nothing can enter the domain of mind except through the mediation of consciousness. This is seen in the fact that our images play in consciousness in such a way as sometimes to deceive us in regard to the external world. (See ILLUSION.) Many pathological facts show this. When the eye is deranged the mind is deceived in regard to colors and distances. When we have a cold our taste is impaired. When the hand is amputated, irritation of the nerve ends is still localized in the hand. This amounts to saying that the mental picture, which in every case is necessary to the perception of the object, is impaired or dissipated. The nervous system also intervenes between the mind and the world, and the proper activity of mind in representation depends upon the normal functioning of this system. This fact, that the mind deals with its images primarily and with external realities only through these images, is best seen when we consider that all mental states are modifications of consciousness itself, and that the perception of the external world, however real that world be, with its conditions of space and time, is possible only by some process of mind whereby these conditions can be mentally reconstructed and the data of experience cast in the forms of this reconstruction.

The construction of the representation of the external world is generally analyzed into three stages, which we may call *Discrimination*, *Localization*, and *Sense-intuition.*

Discrimination.—The beginning of all life experience is probably a state of general undifferentiated feeling. There are, at this beginning of sensation, no distinct forms for the different senses, no notion of externality, no perception either of one's own body or of things. It is easy to imagine one's self in that condition. All physical feeling is then vague, like the internal sensations which we can not localize or trace to their causes. It is probable that the muscular sense, with touch, constitutes almost the whole of this experience. The earliest transition from this state of general sensation is also probably due to touch and the muscular sense, through differences of intensity in feelings of resistance, and through the sense of locality in the body. The special organs of the other senses are more complex and must be adapted to their function of reporting impressions from without. Yet no step toward a real differentiation of sensations can take place till a reaction of consciousness is possible in the shape of *attention.* Definite sensations as such are not distinguished without attention. At first this attention is called "primary" or reflex; but by it the unordered and chaotic mass of sensation, which is thrown upon the helpless individual, is divided and distinguished. As this differentiation proceeds, each sense becomes a distinct source of experience, somewhat in the following order of development: muscular sense, touch, temperature, light, sound, taste, smell, color. The mere fact of differentiation, however, can give us no sense of difference between our own body and a foreign body. This distinction can arise only after we begin to localize our states; and even then all these states are located first in the bodily organs.

Localization.—By this is meant the mental reference of sensations to a locality in space. "Things," as we perceive them, are always in space. Whence does the perception of space arise, and to what factor in the perceiving process is it due? This is the question of the origin of the idea of space, one of the problems most discussed in general philosophy, and one to which contemporary psychology is fully alive.

In the perception of space relations by the muscular sense, touch, and sight, the senses through which it is accomplished, two classes of data seem to be involved. These data are of a physical kind, and serve as basis for a mental reaction. They are *muscular movements* and *local signs.*

Muscular Movement.—In the discussions of muscular sense, sensations of "effort" are usually distinguished from sensations of "resistance." Both of these seem necessary to the finished feeling of movement, though feelings of resistance play a predominating *rôle.* We learn from pathological cases that if the feeling of resistance be destroyed, a limb may be moved voluntarily, but there may be no knowledge of the actual movement, and, consequently, no indication of space position; but, on the other hand, the movement of a limb mechanically is felt as movement when there is no voluntary motor discharge. Hence, whether we hold that space is a succession of resistances, or that space is an original element in the muscular experience, we still find the element of muscular resistance in our first sensations of locality. The same influence of movement is found in the appreciation of space relations by the eye.

The muscular movements of the eye are of extreme delicacy and variety. There is for every point of the retina a fixed amount and direction of movement necessary to bring the center of clearest vision to that point; and when such a point, right, left, above, below, is excited there is at once a tendency to revolve the ball of the eye in such a way as to bring the line of vision through this point. This represents a given degree of central nervous discharge to bring about the muscular strain. Since movement of the eyes precedes vision, there are no means whereby such movement can be ruled out; and further, the influence it exerts in localization is seen in the fact that if one of the muscles of the eye be destroyed, so that no movement follows its stimulation, objects are localized as if this movement had taken place.

Local Signs.—The second kind of data required by modern theories is the local sign, by which is meant some character in each position on the skin and retina by which its peculiar location is reported. The doctrine was first propounded by Lotze.

Perception of Foreign Body.—The distinction between our own and a foreign body arises very early in child life, and is not subsequent to the completed idea of our own body. As we have seen, the perception of our own body as extended involves both distance or movement, and resistance. In the primary feeling of resistance we have the beginning of the perception of foreign body. The amount of movement or distance, measured in muscular sensation, indicates roughly, at first, but with great precision later, the localities of objects around us in reference to our own body. This is greatly aided by active touch and by sight. We feel round a body and give it the third dimension, which we have already found to be an attribute of our own body. The distinction between our own members and other objects is further assisted by the phenomenon of double touch; that is, the two sensations of touching and being touched, when we come in contact with our own skin. In paralysis our own limbs are to us as foreign bodies, inasmuch as the sensation of active touch is present alone. Another important series of double sensations arises when the child sees and also feels his own movements.

Sense-intuition.—The final factor in perception is the gathering up of all the data of sense, time, and place in the finished objects of the external world. This is sense-intuition. It is largely due to association, as is shown again by pathological cases. Injuries to the brain, either accidental (in man) or intended (in animals), may leave the creature with all his senses intact, but with no power to distinguish things, their uses, their nature, their relationships. This faculty probably demands the association in the brain of many centers bound together by the so-called "association fibers." On the side of consciousness it demands healthy and concentrated attention. See ASSOCIATION OF IDEAS, SUGGESTION, SENSATION, PSYCHOLOGY, ILLUSION, and INSANITY.

LITERATURE.—See the *Psychologies* of James, Höffding, Sully, Ladd, Baldwin; Hume, *Treatise on Human Nature*; Berkeley, *Principles of Knowledge*; Mill, *Examination of Hamilton*; Pikler, *Belief in Objective Existence*; articles

by Stout, Robertson, Baldwin, on *External Reality* in *Mind* (1890–91); Royce, *The External World and the Social Consciousness* (*Philos. Review*, Sept., 1894). J. M. Baldwin.

Per'ceval, Spencer: statesman; b. in London, England, Nov. 1, 1762; was the second son of John, Earl of Egmont; educated at Harrow and Cambridge; studied law at Lincoln's Inn; was called to the bar 1786; entered Parliament for Northampton 1796; became intimate with Pitt, through whose influence he was made solicitor-general in the Addington ministry 1801; was promoted to attorney-general 1802; conducted the prosecution in the celebrated Peltier case; was an active partisan of war with France and an opponent of Catholic emancipation; resigned office on the death of Pitt; became chancellor of the exchequer in the Portland cabinet Apr., 1807: succeeded the Duke of Portland as premier Oct., 1809; and was assassinated by John Bellingham in the lobby of the House of Commons May 11, 1812.

Perch [viâ O. Fr. from Lat. *per'ca* = Gr. *πέρκη*, perch; cf. *περκνός*, dark-colored: Sanskr. *pṛ̂çni*, spotted. The Teutonic cognate appears in Germ. *forelle*]: a name originally applied to the species of *Perca* or yellow perches (*Perca fluviatilis* of Europe (see Fishes for illustration), and the related American *Perca flavescens*). In the U. S., especially southward and westward, where the yellow perch is not found, the name is applied loosely to various spiny-rayed fishes. See Percidæ. Revised by D. S. Jordan.

Perchlo'rates: See Perchloric Acid.

Perchlo'ric Acid: a compound of chlorine, hydrogen, and oxygen. When potassium chlorate is heated for the purpose of making oxygen it first undergoes a change represented in the following equation, the products being oxygen, potassium chloride, and potassium perchlorate:

$$2\ KClO_3 = KCl + KClO_4 + O_2.$$

By treating potassium chlorate with sulphuric acid and heating, perchloric acid distills over in solution in water. When pure it is a colorless, fuming liquid of the composition $HClO_4$. It acts very energetically upon combustible substances, causing explosions in consequence of the ease with which it gives up its oxygen. *Perchlorates* are salts formed by the action of perchloric acid on bases. The potassium perchlorate formed when potassium chlorate is heated, as stated above, is a good example. Ira Remsen.

Per'cidæ [Mod. Lat., named from *per'ca*, the typical genus, from Lat. *per'ca*. See Perch]: a family of fishes typified by the common yellow perches of Europe and the U. S. The body is elongated; covered with ctenoid scales, and the head conic and more or less compressed; the mouth variable in size; teeth villiform, on the jaws as well as palate; branchial apertures ample; branchiostegal rays seven; dorsals two, the anterior with many spinous rays, the posterior with soft ones; anal small, far behind; ventrals thoracic, each with one spine and five rays. The skeleton has numerous vertebræ (in the perch 21 + 20 — 21); the stomach is cæcal, and pyloric cæca are developed. The family, as now limited, embraces only fresh-water fishes distinguished by the increased number of vertebræ and other associated characters. To it are to be referred, besides the large and familiar species of the group, numerous small fishes distributed among the fresh waters of the U. S., commonly known as Darters, and composing the genus *Etheostoma*. These small fishes, some seventy species in all, are confined to the eastern waters of the U. S., and are remarkable for their brilliancy of coloration, some of them surpassing in this respect all other fresh-water fishes whatsoever. These are concentrated perches fitted to a life on the rocky bottoms of swift streams. All the *Percidæ* are confined to the north temperate zone. The best-known genera are *Perca*, including the common yellow perches; *Lucioperca*, including the pike-perches; *Accrina*, represented by the ruffles of Europe; *Aspro*, confined to the Old World; *Etheostoma*, confined to the New World. Revised by D. S. Jordan.

Percop'sidæ [Mod. Lat., named from *Percop'sis*, the typical genus; *Perca*, perch + Gr. *ὄψις*, appearance]: a family of fishes represented by two genera, *Percopsis* and *Columbia*, confined to North America. The form is perch-like, with the mouth and the rough scales of the perch associated with the fins of a trout. The body is covered by moderate scales with comb-like margins; lateral line well defined and nearly straight, but somewhat concurrent with the back; head conical, compressed; opercular apparatus with all the bones present and unarmed; mouth small, but with a lateral cleft; upper jaw with its margin formed by the intermaxillary bones alone; teeth villiform on the jaws, but none on the palate; branchial apertures ample; branchiostegal rays six; one true dorsal fin, with mostly branched rays; an adipose fin also developed as in the Salmonids; the anal small; ventrals thoracic. The family was considered by Prof. Agassiz, who first described its type, as one of the most remarkable of living fishes, and was referred by him either to the vicinity of the *Percidæ*, or considered as perhaps the type of a peculiar order; it is now, however, generally admitted to be most closely related to certain South American forms (*Haplochitonidæ*, etc.), and more distantly to the *Salmonidæ*. Two species are known, the sand-roller (*Percopsis guttatus*), from the Great Lakes and the Western rivers, and *Columbia transmontana*, from the Columbia river.

Revised by D. S. Jordan.

Percussion [from Lat. *percus'sio*, deriv. of *percu'tere*, strike through or thoroughly; *per*, through, thoroughly + *qua'tere*, shake, strike]: in medicine, a peculiar branch of auscultation, by which the presence or absence of air and fluid in certain internal organs is ascertained by the aid of artificial sounds. These sounds are produced either directly by tapping with the fingers or a small hammer tipped with India-rubber on the surface of the body just above the place to be investigated, or mediately by the aid of a plexímeter, and struck either with the fingers or with a hammer. See Auscultation.

Percussion-caps: See Fulminates.

Percy: a noted family of England, descended from William de Percy, who was a companion of William the Conqueror, and derived his name from the village of Percy in Normandy. The barony of Alnwick was acquired by Henry de Percy in the reign of Edward I. His grandson having married into the royal Lancastrian family, Henry Percy, father of the celebrated Hotspur, was created Earl of Northumberland in 1377 by Richard II. The first four earls of this family took prominent parts in the wars of the Roses, and all perished in battle or by assassination. The title became extinct in 1537, but was revived in 1557 in favor of Thomas Percy, who was beheaded at York 1572 for conspiring against Elizabeth. His brother Henry, eighth earl, was charged with conspiring in favor of Mary, Queen of Scots, and was murdered in the Tower of London June 21, 1585; Henry, the ninth earl, was imprisoned many years in the Tower for alleged participation in the Gunpowder Plot of 1605. The title having again become extinct in 1670, it was revived in 1749 in favor of Seymour, Duke of Somerset, a grandson of the last earl. His son-in-law, Sir Hugh Smithson, took the name of Percy, succeeded by permission of Parliament to the earldom in 1750, and was made first Duke of Northumberland 1766. His son, Hugh (known as Earl Percy), was engaged in the battle of Lexington, suceeeded to the dukedom June 6, 1786, and died July 10, 1817. The career of his son, Algernon Percy, fourth duke, has been given under the title Northumberland, Duke of.—The present representative of the family is Algernon George Percy, LL. D., sixth duke, b. May 2, 1810, who succeeded to the title Aug. 22, 1867, and became Lord of the Admiralty 1858. Northumberland House, Charing Cross, the London residence of the Percies for many generations, was sold to the board of public works in 1873 for £500,000, to be pulled down for the opening of a new street, and the duke employed a considerable part of that sum in the improvement of Trafalgar Square.

Percy, Henry (surnamed Hotspur): son of the first Earl of Northumberland; b. in England May 20, 1364; became famous in the wars of France and of the Scottish border; defeated and killed Douglas at Otterburn (Chevy Chase) 1388; joined Henry of Lancaster 1399, aiding him to obtain the English throne; was rewarded with the wardenship of the East Marches and the gift of the Isle of Man; was distinguished at the battle of Homildon Hill 1402; took up arms with his father to place Mortimer, Earl of March, on the throne, and was killed at the battle of Shrewsbury, July 21, 1403. He is immortalized in Shakspeare's *Henry IV.*

Percy, Thomas: clergyman and author; b. at Bridgenorth, Shropshire, England, Apr. 13, 1728; was educated at Christ Church, Oxford, where he took his master's degree 1753; became vicar of Easton Maudit and rector of Wilby 1756; and Bishop of Dromore, Ireland, 1782. D. at Dromore, Sept. 30, 1811. His best-known work, *The Reliques of Ancient English Poetry* (1765), had a wide influence in develop-

ing a taste for ballad literature and antiquities. It has been repeatedly published, e. g. edited by H. B. Wheatley (3 vols., London, 1891); by R. A. Willmott (1893): and the folio MS. reprinted by J. W. Hales and F. J. Furnivall (3 vols., 1868), with *Life* by J. Pickford. He translated Mallet's *Northern Antiquities* (1770, now in Bohn's Library), and collected a mass of ancient tales and poetry which were not printed until 1868. Among his other works is a *Key to the New Testament.* Revised by H. A. Beers.

Perdic'cas (in Gr. Περδίκκας): the name of several kings of Macedonia—(1) the founder of the dynasty, an Argive, who became king about 700 B. C.; (2) Perdiccas II. reigned from 454–413 B. C.; (3) Perdiccas III. reigned from 365–360 B. C.: (4) a prince of the royal blood and general of Alexander the Great. When on his death-bed Alexander gave him his ring, the symbol of the royal power; he held the empire together for a short time by his superior energy and talents, but when it became evident that he himself aspired to the crown, a coalition was formed against him by Antipater, Craterus, and Ptolemy, and on his expedition against Ptolemy he was assassinated in 321 B. C., near Memphis, by his own soldiers. Revised by J. R. S. Sterrett.

Pereda, pā-rā'dăa, José María, de: novelist; b. at Santander, Spain, in 1833. His first repute as a writer came from his remarkable knowledge of all the peculiarities of the life of his native region—*La Montaña*, as it is commonly called in Spain. With almost photographic accuracy, but with great literary skill, he reproduced this life in the sketches which about 1859 began to appear in the journal called *La Abeja Montañesa*, of Santander. In 1864 he collected these sketches in his first book, entitled *Escenas montañesas.* For some years he continued to produce only such brief pictures of the land and people he was familiar with—*Tipos y paisajes* (1871); *Bocetos al temple* (1876); *Tipos trashumantes* (1877). In 1877 began a new period in his literary career, with the story *El Buey Suelto*, of ampler dimensions, though still a picture of manners rather than a novel. In 1878 came the study of political intrigue, *Don Gonzalo González de la Gonzalera*, though this also had had a predecessor in the story *Los hombres de pró*, written in 1872, but published in the volume *Bocetos al temple.* In 1879 appeared *De tal palo, tal astilla*, in which at last there is something of both the amplitude and the repose of a complete work of art. This was followed in 1881 by another volume of sketches, *Esbozos y rasguños*, and by the novel *El sabor de la tierruca.* Since these Pereda has published the stories *Pedro Sánchez* (1883); *Sotileza* (a study of Galician fisher-life, 1884); *La Montálvez* (1887); *La Puchera* (1888); *Nubes de estío* (1891); and *Al primer vuelo: Idilio vulgar* (1891). Pereda is one of the greatest masters in Spain of the novel of description or manners. Not a "naturalist," or realist, by theory, he yet is primarily an observer of fact, not an imaginative creator. So rich and powerful is his style, however, that his work rises into the domain of art. The *Obras completas de D. José M. de Pereda* began to appear in Madrid in 1889, and up to 1891 fifteen volumes had been issued. A. R. Marsh.

Per'egrine Falcon [*peregrine* is from Lat. *peregri'nus* (whence Eng. *pilgrim*), migratory, coming from foreign parts, deriv. of *peregre*, "in the country"; *per* + *ager*, field]: a hawk formerly much used in falconry; the *Falco peregrinus* of ornithologists. It is bold, graceful, swift, docile, strong, and destructive, and was the favorite among the noble falcons, though less powerful than the lanner and the jerfalcon. The female peregrine is the bird which is, *par excellence*, called falcon; the male is the tercel, and is smaller than his mate. See also Falcon.

Perei'ra, Jonathan, M. D., F. R. S.: pharmacologist and therapeutist; b. in Shoreditch, London, May 22, 1804; studied at Finsbury for four years; received a medical education; was licensed by the apothecaries 1823; became fellow of the Royal College of Surgeons 1825; apothecary and chemical lecturer to the Aldersgate Street Dispensary 1823: Professor of Materia Medica in the same school 1832; in 1833 Professor of Chemistry in London Hospital; took the doctor's degree at Erlangen 1840; became a fellow of the Royal College of Physicians 1845; physician to the London Hospital 1851: was one of the examiners of London University. D. in London, Jan. 20, 1853. His great work was the *Elements of Materia Medica and Therapeutics* (1839–40), still a standard authority; also published a *Treatise on Diet* (1843), *Lectures on Polarized Light* (1843), and other works.
Revised by S. T. Armstrong.

Perei'ra da Sil'va, João Manoel: historian; b. at Rio de Janeiro, Brazil, Aug. 30, 1817. He graduated in law at Paris, and settled at Rio de Janeiro where, after 1844, he was somewhat prominent in politics. His works are voluminous, and deal mainly with modern Brazilian history and biography. They include: *Plutarco Brasileiro* (1847), enlarged and republished as *Varões illustres do Brasil* (1858); *Historia da fundação do Imperio Brasileiro* (7 vols., 1864–68); *Segundo periodo do reinado de D. Pedro I.* (1871); and *Historia do Brasil de 1831 á 1840* (1878). H. H. S.

Perekop: town in the government of Taurida, European Russia; on the isthmus of the same name, which connects the Crimea with the mainland (see map of Russia, ref. 10–D). The town, which was formerly strongly fortified, is still of great strategical and commercial importance, as it is situated at a point where all the roads leading from Southern Russia into the Crimea connect. The preliminary works for a ship-canal through the isthmus were completed in 1889. Pop. about 5,000.

Pe'rez (Sp. pron. pā'reth), Antonio: b. at Monreal de Ariza, Aragon, Spain, in 1541; natural son of Gonzalo Perez, who was long a secretary of Charles V. and Philip II.; educated at the University of Louvain, studying also at Venice and at Madrid; became Secretary of State to Philip II. on the death of his father in 1567; was the chief agent of that treacherous monarch in many of his secret crimes, especially in the assassination of Juan de Escovedo 1578; was tried for that crime, imprisoned, and exiled from the court; was again arrested for the same crime in 1590, when, being put to the torture, he confessed the act, but accused the king of complicity; escaped to Aragon in April, where he placed himself under the protection of the *fueros* or privileges of that kingdom; was twice seized by royal command and handed over to the Inquisition, but on both occasions released by the people, thus giving rise to a rebellion which ended in the suppression of the *fueros* of Aragon. Perez escaped to France Nov., 1591; resided in England as secret agent of Henry IV. 1593–95; published in London his *Relaciones*, giving his own account of his romantic adventures (1594), and was the author of *Cartas Familiares* and several other works, elegantly written. D. in Paris, Nov. 3, 1611. See Mignet's *Antoine Perez et Philippe II.* (1845).

Pérez de Hita, Ginés: Spanish romancer and historian, the dates of whose birth and death are alike unknown. The one assured fact of his biography is that he took part as a soldier in the cruel campaign against the revolted Spanish Moors (1568–71). He was probably a citizen of Murcia, though there are reasons for thinking that his birthplace was the town of Mula, some 20 miles W. of Murcia. The fame of Pérez de Hita comes from the work, in two parts, commonly known as the *Guerras civiles de Granada.* The first of these, purporting to be a history, was published in Saragossa in 1595. (An edition of Alcalá (1588) is mentioned in some bibliographies, but seems uncertain.) The work is not a history, but an historical romance based upon popular tradition, and as a work of fiction is very notable. The second part, published in Barcelona in 1619 (written, however, and perhaps published, in 1604), deals with events seventy years later than those of the first part—in fact, the events of that very campaign against the Moors in which Pérez de Hita had himself taken part. Here there is much of historical fact, but here also the author has added romantic embellishments. Numerous editions of the work as a whole have appeared even down to the present day. Calderón took the story of Tuzani (*Guerras de Granada*, 2a parte, cap. xxii., xxiii., xxiv.) for the theme of one of the finest of his plays, *Amor después de la Muerte.* In France Mme. de Scudéry founded upon the work of Pérez de Hita her romance, *L'Almahide*, which in its turn gave rise to a long series of romances and plays. Later we have also in France the *Gonsalve de Cordoue* of Florian, and *L'Abencerrage* of Chateaubriand, both based on the same material. Finally, we have in the U. S. the famous *Conquest of Granada* of Washington Irving, which reproduces both in its affectation of historical accuracy and its romantic coloring its original. The best edition of the *Guerras de Granada* is in volume iii. of Rivadeneyra's *Biblioteca de Autores Españoles* (Madrid, 1876). A. R. Marsh.

Pérez de Montalván, Juan: See Montalván, Juan Pérez, de.

Pérez Galdós, Benito: Spanish novelist: b. at Las Palmas, Canary islands, May 10, 1845. In 1863 he went to

Madrid to study law, but with little affection for the profession. He already inclined toward letters, and soon tried his hand at writing pieces for the stage, none of which had sufficient merit to be actually produced. In 1867 he had the happy inspiration to write a novel, *La Fontana de Oro*, on which he worked for several years, finally publishing it in 1871. The success of this encouraged him to write a second story, *El Audaz*, published in 1872. Both these tales were essentially historical romances, dealing with events in Spanish history of the years 1820–23 and 1804 respectively. Through them Pérez Galdós entered upon his two long series of historical novels, called by him *Episodios Nacionales*, dealing either with the period of struggle against Napoleon, or with the agitation of the contest of Spanish liberalism against the tyranny of Ferdinand VII. The first of these works was *Trafalgar*, written in 1873, and it has been succeeded by the following volumes of the first series: *La Corte de Carlos IV.*; *El 19 de Marzo y el 2 de Mayo*; *Bailén*; *Napoleón en Chamartín*; *Zaragoza*; *Gerona*; *Cádiz*; *Juan Martín el Empecinado*; *La batalla de los Arapiles.* To the second series belong *El Equipaje del Rey José*; *Memorias de un Cortesano de 1815*; *La segunda casaca*; *El Grande Oriente*; *7 de Julio*; *Los cien mil hijos de San Luis*; *El Terror de 1824*; *Un voluntario realista*; *Los Apostólicos*; *Un faccioso más y algunos frailes menos.* In these works Pérez Galdós shows clearly the influences of Erckmann-Chatrian, but at the same time he tells his story always with a force and purity of style peculiar to himself, and notable enough to give him a foremost place among living novelists. More original in matter and more interesting to others than Spaniards are the novels called by their author *Novelas españolas contemporáneas.* Among these are *Doña Perfecta*; *Gloria*; *Marianela*; *La familia de León Roch*; *La Desheredada*; *El Amigo Manso*; *El Doctor Centeno*; *Tormento*; *La de Bringas*; *Lo Prohibido*; *Fortunata y Jacinta*; *Miau*; *La Incógnita.* In all these works are to be found both truth to social fact and imaginative rendering of that fact in a very unusual degree. This results perhaps from the circumstance that while Pérez Galdós has felt deeply the so-called realistic tendencies of recent literature, he has not blindly accepted the theories of the French school of realists. His chief admiration is the English, not the French, novel; and certainly both his style and his matter show a happy combination of manliness and uprightness of feeling with desire to state the truth as it is. Of late years Pérez Galdós has lived chiefly in Madrid, varying his literary labors with those of a deputy, representing Puerto Rico. He has also been long the editor of the best Spanish periodical, the *Revista de España.* In politics he is an ardent upholder of the liberal-monarchical—i. e. constitutional—party. There are numerous editions of all Pérez Galdós's novels. See Leopoldo Alas (Clarín), *Benito Pérez Galdós, estudio crítico-biográfico* (Madrid, 1889).

A. R. Marsh.

Perfectionism: the doctrine held by many, both Roman Catholics and Protestants, that it is possible to lead a sinless life. The former maintain that the law of God may be and frequently is perfectly obeyed, yet that no man is entirely free from venial sins—i. e. those which do not send the soul to perdition. They claim that as a matter of fact many do lead perfect lives, and even accumulate a fund of supererogatory merit. The commonest teaching on the subject among Protestants proceeds from the Methodists, who assert that it is possible to live in complete conformity to God's law; yet not so that one is entirely free from errors and infirmities. There is, however, no inward disposition to sin, and no outward commission of it, so there is what is called "Christian perfection." President Asa Mahan, of Oberlin University, Ohio, and Prof. Charles G. Finney, both Congregationalists, taught that one could attain that state of devotedness to God which is required by the moral law. So among the Society of Friends it has been held that the justified may be free from actual sin; but the Lutheran and Reformed creeds agree in maintaining that "sanctification is never perfected in this life; that sin is not in any case entirely subdued; so that the most advanced believer has need so long as he continues in the flesh daily to pray for the forgiveness of sins" (C. Hodge). Those who accept these creeds agree also that perfection with those who claim it is a relative term; that it is based upon a comparatively shallow conception of the holiness of God and the deceitfulness of sin. They assert that the godly who lay no claim to perfection do live as holily as those who do, but both are faulty, and that the claim to be perfect is one which no one can make without great risk of spiritual pride.

Samuel Macauley Jackson.

Perfumery: See the Appendix.

Pergamus, or **Pergamum**: an ancient city of Mysia, Asia Minor; founded by Greek colonists on the northern bank of the river Caïcus, 120 stadia (less than 15 miles) from the sea. In the confusion which reigned after the death of Alexander the Great, the city became important as the stronghold of Lysimachus. His governor, Philetærus, made himself independent, and Attalus I. (241–197 B. C.) succeeded in establishing a kingdom, of which Pergamus became the capital. The Romans favored this new state as a useful ally against Macedonia and Syria, and at different times Phrygia, Lydia, Pisidia, Lycaonia, and Pamphylia were added to it. Meanwhile the capital became one of the greatest and most magnificent cities of Asia Minor, celebrated for its architectural monuments, its splendid library, its grammar school, its invention of parchment, etc. King Attalus III. (133 B. C.) bequeathed his possessions to the Romans, and they made Pergamus the focus of all the great military and commercial routes of Asia Minor. Under the Byzantine rule it rapidly declined, but extensive ruins around the modern Bergama (*q. v.*) testify to its former importance.

Periander: See Corinth.

Perianth: See Flower.

Pericarditis: See Heart Disease.

Pericar'dium [Mod. Lat., from Gr. *περικάρδιον*; *περί*, around + *καρδία*, heart]: the fibro-serous sac which surrounds the heart. Its outer fibrous part is very dense and strong; its inner or serous lining membrane is continuous with that which covers the heart. It secretes a thin lubricating serous fluid which facilitates the motions of the heart. See Heart.

Per'icles [= Lat. = Gr. *Περικλῆς*, *Περικλέης*, liter., far-famed: *περί*, around + *κλέος*, fame]: statesman; b. at Athens about 495 B. C., descended on the father's side from the Pisistratidæ, on the mother's from the Alcmæonidæ; received the instruction of Zeno and Anaxagoras; served with distinction in the army, and entered, about 469 B. C., on his political career as a member of the democratic party. He proposed laws according to which the funds of the public treasury were employed for the benefit of the poorer classes. It became the law that citizens should be paid when serving in the army, on a jury, or when performing any other public duty, even when attending the religious festivals; and thereby it became possible for the poorer classes to take part more actively in public life. By these laws Pericles gained the attention and favor of his party, and soon he attained the absolute leadership of it by his eminent talents, his irresistible eloquence, his adroitness in party manœuvring, and his wise plans. A great victory was achieved over the aristocratic party in 461 B. C.; its position was undermined and its leader was crushed. The Areopagus, which was the principal political organ of the Athenian oligarchy, lost almost entirely its influence as a party organ by the introduction of a new jury system; and after his unsuccessful campaign against Mt. Ithome, Cimon was impeached, and shortly after banished by ostracism. Pericles was now in reality the ruler of the state. Cimon was recalled in 454 B. C., but on the proposition of Pericles, and it was said that there existed an agreement between them, according to which Cimon should command the army on its foreign expeditions and Pericles govern at home. After the death of Cimon, in 449 B. C., the aristocratic party was reorganized by one Thucydides, and once more arrayed against Pericles. In 444 B. C. Pericles was accused of squandering the public money or employing it for inappropriate purposes, but the attempt to overthrow him failed. Thucydides was banished by ostracism, and henceforth there existed in Athens no really effective opposition to Pericles. He was arraigned once more for embezzling some of the gold destined for the statue of Athene in the Parthenon; his friends were repeatedly attacked; Phidias died in prison, Anaxagoras was banished, and Aspasia was saved only by great exertions; but these and other similar events were nothing more than the outbursts of a desperate envy and maliciousness. There is no instance in which any important measure of Pericles was frustrated by an internal opposition. It was the great aim of his policy to make Athens the brilliant and magnificent political center of a united Greece. He opposed his countrymen's extravagant plans of conquest in Egypt, Car-

thage, or Sicily, and concentrated his whole energy on the affairs of Greece herself. Athens stood at the head of a confederacy of several Greek states for defense against a possible Persian invasion. This confederacy held its meetings and kept its treasury at Delos. By Pericles's dexterous negotiations both the meetings and the treasury were transferred to Athens; furthermore, the contributions of the allies were commuted from actual service to a sum of money, for which Athens alone undertook to furnish the whole military armament. Thus the supremacy of Athens was established, and it was further developed by the successful settlement of new colonies, by supporting the democratic parties in the Greek states, etc. Of great influence too in this respect were the magnificence of the city and the splendor of the life led in it. It was the time of Phidias, Socrates, Sophocles. The Parthenon, the first Odeon, and the Propylæa were built. Commerce flourished, and many branches of industry were carried to perfection; but Athens had an unrelenting rival in the Spartan aristocracy. The Peloponnesian war drew nearer and nearer, and, although Pericles warded it off for several years by bribery, at last it became inevitable. In the same year that it broke out the city was fearfully devastated by the plague. Next year Pericles died (429 B. C.), and with his death began the decline of Athens.

Revised by J. R. S. Sterrett.

Pericles, Age of: See Architecture.

Peridot: See Chrysolite.

Peridotite [from *peridot*, French name for chrysolite or olivine]: an important group of very basic, ferro-magnesian, igneous rocks, free from feldspar, and having as their essential constituent the mineral olivine. Peridotites are subdivided according to the minerals which they contain beside olivine as follows: *picrite* (+ augite), *harzburgite* (+ enstatite), *buchnerite* (+ augite + enstatite), *wehrlite* (+ diallage), *lherzolite* (+ diallage + enstatite), *cortlandtite* (+ enstatite + hornblende), *scyelite* (+ biotite), *dunite* (+ chromite).

The peridotites are holocrystalline rocks usually with an evenly granular structure. They are generally considered to be of igneous origin, and have been definitely proved to be so in some cases. Their component minerals so readily change to serpentine that rocks of this class may be regarded as having given rise to many of the masses of serpentine so common in the older geological formations of the globe. Some of the types of peridotite find their equivalents among the meteoric stones.

Another group of ferro-magnesian rocks closely allied to the peridotites is called by the collective name *pyroxenite*. These rocks contain too little alumina to allow of the formation of feldspar, and also too much silica to permit the crystallization of olivine. They are composed essentially of pyroxene in different varieties, and may be subdivided, like the peridotites, into bronzitite, diallagite, websterite (bronzite + diallage), etc.

G. H. Williams.

Perier, pe-ri-ā′, Casimir: politician; b. at Grenoble, department of Isère, France, Oct. 21, 1777; was educated at Lyons; served for a short time in the army; engaged then in the large and prosperous banking business established at Paris by his father and elder brother; was elected a member of the Chamber of Deputies in 1817, and became one of the leaders of the opposition under Charles X. After the Revolution of July, 1830, he was prime minister to Louis Philippe, from Mar. 13, 1831, to his death, May 16, 1832, and as such he occupied a distinctly defined standpoint, the so-called *juste-milieu*, which he vindicated with great vigor, and also with partial success. Attempts at insurrection were speedily put down, and his resistance to the differently colored tendencies of anarchy, ultramontane and radical, which showed themselves in France after 1830, was very effective. Guizot, who in several respects was his political disciple and heir, has given a very vivid and impressive picture of him in his *Mémoires*. His speeches, etc., were published, with a biographical notice by Charles de Rémusat, as *Opinions et discours* (4 vols., Paris, 1834).

Revised by A. G. Canfield.

Periers, pe-ri-ā′, Jean Bonaventure, des: author: b. in Burgundy, France, at the end of the fifteenth century; though poor, had a liberal education, and found a protector in Marguerite of Navarre. From 1531 to 1537 he was engaged upon the translation of the *Lysis* of Plato, in aiding Étienne Dolet on his *Commentarii linguæ latinæ*, and other scholarly labors. In 1537 he published the *Cymbalum mundi*, a veiled attack on religion, which was burned by the *parlement*, lost him the patronage of Marguerite, and drew to him such universal suspicion that he committed suicide about 1544. His best-known work is his *Nouvelles récréations et joyeux devis*, a collection of short stories reviving somewhat the matter and the spirit of the old *fableaux*. His works have been edited by Lacour (2 vols., Paris, 1866); the *Cymbalum mundi*, with a valuable commentary, by F. Frank (Paris, 1874).

A. G. Canfield.

Per'igee [Gr. περί, around, near + γῆ, earth]: in astronomy, that point of the moon's orbit which is nearest to the earth. Anciently, when the sun and planets were supposed to circulate around the earth, the term was also applied to them.

Périgueux, pā′rĕĕ′gö′ (anc. *Vesunna*): town; in the department of Dordogne, France; on the right bank of the Isle, a tributary of the Dordogne, 95 miles by rail N. E. of Bordeaux (see map of France, ref. 7–D). The old part of the city, containing the magnificent cathedral and many interesting Roman remains, consists of narrow and gloomy streets, but it is encircled by new and elegant boulevards occupying the site of the old walls and ramparts. A large trade in liqueurs, truffles, partridges, and wine, and some manufactures of paper and woolens are carried on. Pop. (1896) 31,313.

Perihe'lion [Gr. περί, around, near + ἥλιος, sun]: in astronomy, that point in the orbit of a planet or comet which is nearest to the sun. Its position or longitude is one of the elements by which the orbit is determined.

Perim, pā-reem′: a small island belonging to Great Britain, in the Strait of Bab-el-Mandeb, at the entrance of the Red Sea, 19 miles from the African coast and 1½ mile from the Arabian. Area, 7 sq. miles. It rises about 230 feet from the sea, is rocky, nearly destitute of vegetation, and without water, but it has a good harbor on its southern coast, and its fortifications command the strait on both sides. Perim was first occupied by the British in 1799, while Napoleon was in Egypt. It was given up in 1801, but again occupied and fortified in 1857, on account of the cutting of the Suez Canal. In 1883 it was made a coaling station. The island is under the jurisdiction of the governor of Bombay Presidency. Pop. about 400.

Perimeter: See Recording Apparatus, Psychological, in the Appendix.

Periodical: any publication appearing at stated intervals. In current usage the word is applied only to publications composed of miscellaneous articles, appearing less often than once a week and more frequently than once a year, thus excluding the daily and weekly newspapers on the one hand, and annual publications, such as almanacs, directories, etc., on the other. Using the word in this restricted sense, periodicals may be roughly divided into three main groups: (1) Magazines and reviews devoted to general literature and science; (2) what may be termed class periodicals, devoted to particular branches of science, art, or industry; (3) publications of academies and societies, though in this group it is often difficult to determine what is and what is not entitled to be called a periodical. As regards form, by far the greater number of periodicals in the English language are monthly publications, and the same may be said of continental European periodicals as a whole, though in France and Italy the fortnightly is a favorite form, and in Germany a large and constantly increasing number of periodicals are issued at irregular intervals.

The earliest representative of the modern periodical is generally considered to be the still flourishing *Journal des Savants*, which began its career in Jan., 1665, as a weekly review of literary events, but, after the thirteenth number, was issued at irregular intervals down to 1723, when it suspended publication, to reappear as a monthly in 1724; after several subsequent interruptions it was finally re-established in 1816 as the organ of the French Academy, and is now edited by a committee of scholars under the auspices of the Minister of Public Instruction. Though the origin of the modern periodical may thus be traced back to the seventeenth century, its development was slow, and the periodicals of the seventeenth and eighteenth centuries were neither numerous nor of great importance. Thus we find that of the 5,100 scientific and technical periodicals recorded in Bolton's catalogue as published during the period from 1665 to 1882, apparently not more than eighty were in existence before 1800, and of the 232 literary periodicals important

enough to be included in Poole's *Index to English Literature*, only three date back to 1800. The foundation of *The Edinburgh Review* in 1802 may be taken as the starting-point of this remarkable development of English periodical literature, and in tracing its course we find that the decade from 1840 to 1850 was notably prolific in new periodicals, as was also the decade from 1860 to 1870, which was marked by the rise of the shilling magazines. In the U. S. the periodicals of the eighteenth century were few, and, as a rule, had but a brief existence. It was not till about the middle of the nineteenth century that what we now regard as the distinctively American type of monthly magazine began to appear. The illustrations which form one of the characteristic features of this type, at first crude and coarse in execution, have now been brought to a high degree of perfection.

It is almost impossible to obtain accurate statistics of the number of periodicals now appearing throughout the world, but taking the best available statistics for the U. S. alone we find that in 1892 the total number of all kinds of periodicals published in the U. S., excluding newspapers and annuals, was 3,309. Of these, 307 appeared fortnightly, 2,754 monthly, 56 bi-monthly, and 192 quarterly. These figures may give some idea of the enormous number of periodicals now published. In every country of the civilized world each science, art, and industry has its own special journals.

The few really valuable and important papers which see the light in periodicals would soon lie buried in the mass of forgotten or neglected journals were it not for the existence of indexes and special bibliographies which furnish a clew to this labyrinth of literature. Among the more important of these indexes are the following: Poole and Fletcher's *Index to Periodical Literature* (from 1800 to 1882), with its two supplements (1883–87 and 1887–92); it includes only periodicals in the English language, and purely professional and scientific journals are generally omitted. A continuation of this is *The Annual Literary Index* (1892–93). An annual *Index to Periodical Literature* is also published by *The Review of Reviews*. The *Catalogue of Scientific Papers* (1800–63), compiled and published by the Royal Society of London, with its two supplements (1863–73 and 1873–83), is an alphabetical index, by authors, of scientific papers contained in the transactions of societies, journals, and other periodical works which have been published throughout the world since the beginning of the nineteenth century, excluding such papers as are purely literary, technical, or professional. For technical literature an admirable guide is provided by the *Repertorium der technischen Journal-Litteratur*, now published annually in Berlin under the auspices of the German Patent Office. This index, begun by Schubarth, with an index covering the period from 1823 to 1853, and continued by Kerl and Rieth, gives under subject-headings the contents of all the important technical periodicals of the world. The *Index Medicus*, edited by Billings and Fletcher and published monthly, supplies a classified subject-index of the current medical literature of the world. A very full list of special bibliographies and of indexes to periodicals is given in the *Handbook for Readers*, issued by the Boston Public Library.

Of periodicals themselves there exists no universal catalogue. Probably the volumes of the British Museum *Catalogue* devoted to *Academies* and *Periodicals* give the largest and fullest general list of periodicals to be found anywhere. For scientific periodicals we have Bolton's *Catalogue of Scientific and Technical Periodicals, 1665–1882*, published by the Smithsonian Institution; this was intended to contain the principal independent periodicals of any branch of pure and applied science published in all countries down to 1882, but medical periodicals and serials published by scientific societies are not included. This is supplemented by Scudder's *Catalogue of Scientific Serials of all Countries, including the Transactions of Learned Societies in the Natural, Physical, and Mathematical Sciences, 1633–1876*, published by Harvard University.

For the current periodicals of different countries, reference must be made to such annual publications as the *American Newspaper Directory* for the U. S., May's *British and Irish Press Guide* for Great Britain, *Annuaire de la Presse française* for France, *Deutscher Journal-Katalog* for Germany, etc. The growth of the periodical press in the U. S. is well described in North's *History and Present Condition of the Newspaper and Periodical Press of the United States, with a Catalogue of the Publications of the Census Year*, in vol. viii. of the tenth census of the U. S.

G. W. Harris.

Periodic Law: See Chemistry.

Periœ'ci [= Lat. = Gr. *περίοικοι*, plur. of *περίοικος*, dwelling around; *περί*, around + *οἶκος*, house, dwelling]: in Laconia and other ancient Dorian lands, the descendants of the more ancient inhabitants of the country. The Periœci were freemen, and not strictly vassals, much less serfs like the Helots, but they were inferior in social rank and political rights to the Spartiatæ. They occupied the inferior kind of lands, were artisans, merchants, and sailors, and had at times a share in the government. They might, at least at some periods, intermarry with the Dorians, and they served in war even as hoplites, though not in the same corps with Dorians. They were in many cases people of wealth and refinement.

Revised by J. R. S. Sterrett.

Perios'teum [Mod. Lat., from Gr. *περιόστεος*, surrounding bones; *περί*, around + *ὀστέον*, bone]: the strong fibrous membrane which surrounds the bones, excepting only the parts covered with cartilage. It is found also around the roots of the teeth, and lines the sockets in which the teeth are fixed. That which covers the outside of the skull is the *pericranium*, and that within the skull is the *dura mater*; but the *dura mater* of the spinal cord is distinct from the periosteum. The periosteal membrane is called *endosteum* when it lines the medullary cavity of a bone. The periosteum is continuous with the tendons and ligaments. It is very vascular, and plays an important part in the growth and nutrition of bone. Thus, in operations for the removal of diseased bone the periosteum should be carefully peeled off and left *in situ*, and in many cases new and healthy bone will be developed from it, especially if the patient be young. See Histology (*Bone*). Revised by W. Pepper.

Periosti'tis [Mod. Lat.; *perios'teum* (which see) + suffix *-itis*, denoting a disease of]: the inflammation of the periosteum; sometimes caused by a syphilitic, scrofulous, or perhaps rheumatic dyscrasia, or by injury; it is also very commonly induced in boys and young men by a sudden exposure to severe cold, as by bathing in very cold water after violent exercise, by standing long in cold water, and the like. It is a very painful disease, and is best treated by local poultices, by opiates, and by free incisions. Cases due to any specific cause will require special constitutional treatment.

Revised by W. Pepper.

Peripatetic Philosophy: See Aristotle.

Peripatus: See Onychophora.

Perissodac'tyla [Mod. Lat.; Gr. *περισσός*, odd, liter., extra, over, superfluous (deriv. of *περί*, around, over, beyond) + *δάκτυλος*, finger, toe]: a sub-order—or, according to some authors, an order—of the hoofed animals (Ungulata), so named because the digits are unpaired or unequal. These are unpaired or uneven, the third being the largest and most exserted, the fourth nearly coequal in size and position with the second, and the fifth on the hind foot at least atrophied; the astragalus has the anterior or inferior articulate surface divided into two very unequal facets; the femur is provided with a third trochanter; the dorso-lumbar vertebræ are in increased number—i. e. not less than twenty-two (d. 18 — 19 + 1, 1·3 — 6). The skull has the intermaxillary bones tectiform or shelving in a roof-like manner above, and united at the symphyses, and the incisors, when present, are implanted nearly vertically, and are parallel to their roots; the stomach is cæcal; the cæcum very much enlarged and sacculated. The sub-order thus distinguished includes three families represented by living forms: the tapirs (*Tapiridæ*), rhinoceroses (*Rhinocerotidæ*), and horses (*Equidæ*). In previous geological ages numerous others, more or less related to them, flourished. The affinities of these forms were, to some extent, recognized by Cuvier, and still more by de Blainville, but the sub-order was first distinctly introduced with formal characters by Prof. Owen.

Peristaltic Motions [*peristaltic* is from Gr. *περισταλτικός*, clasping and compressing, deriv. of *περιστέλλειν*, wrap up, wrap around; *περί*, around + *στέλλειν*, send]: certain movements which take place in the alimentary canal, the term being generally restricted to the worm-like action by means of which the food is carried to and fro over the mucous membrane of stomach and intestines. The walls of both stomach and intestines are made up of two layers of involuntary muscular tissue, which are arranged as an external longitudinal and an internal circular; the outermost layer of the intestine is serous, and is simply a reflexion of the peritoneum. The internal coat consists of a mucous tissue, varying in structure in different parts. From the anatomy of the parts it is

easy to perceive how, by the simple action of its muscular walls, the food after its entrance into the stomach is first moved about in this organ, and then, having passed into the small intestine, is carried onward by the gradual contraction and relaxation, which, starting from above, is continued downward. During the processes of digestion this movement is readily observed by opening the abdomen of a living animal, and it will be seen that the movement continues for a short time, then ceases, to be renewed. Not only does the muscular wall carry the food toward the outlet of the canal, but often after the mass has been pushed, or rather squeezed, for a certain distance downward, it is carried back again in the opposite direction (antiperistaltic movement). There is probably little if any peristaltic action while the intestine is empty, it being the stimulus of food which causes it. The alimentary mass, coming in contact with the periphery of the nerves situated in the mucous membrane, imparts a certain amount of irritation, which is followed by muscular movement—i. e. contraction and relaxation—probably through the agency of the *ganglionic plexus*, situated in the walls of the intestine; and this slow, gradual passage of the food backward and forward is required for the processes of digestion. Various other theories are entertained in regard to the causation of peristalsis. The bile does probably aid by stimulating activity, but the direct irritation by food and effete products is the important agency. Revised by WILLIAM PEPPER.

Peristerop'odes [from Gr. περιστερά, pigeon + πούς, ποδός, foot]: a division, or sub-order, of the *Gallinæ*, including the curassows and mound-builders, distinguished by having the hind toe long and on a level with the others as in pigeons; contrasted with *Alectoropodes*, or true fowls, which have the hind toe short and elevated. F. A. L.

Perithecia: See FUNGI.

Peritoneum: See PERITONITIS.

Peritoni'tis [Mod. Lat., deriv. of *peritone'um* (cf. PERIOSTITIS), = Gr. περιτόναιον, liter., neut. of περιτόναιος, stretched or stretching over or all around, peritoneum; περί, around + τείνειν, stretch]: inflammation of the peritoneum, a serous membrane investing the viscera of the abdomen; popularly designated "inflammation of the bowels." The peritoneum has two layers, and constitutes a closed sac; the external layer lines the abdominal walls; the internal is reflected over the stomach and intestines, liver, spleen, ovaries, uterus, and bladder. These opposed surfaces are smooth and lubricated by secreted serum, permitting the free movements of the viscera, their ascent and descent in respiration, and the peristaltic movements of the bowels.

Peritonitis, or inflammation of the peritoneum, may be due to traumatism, to cold, to extension of inflammation from other organs, to general disorder of the blood, or infection. Traumatic peritonitis is the result of bruises, wounds, and surgical operations. Idiopathic peritonitis is a primary inflammation resulting from perverted conditions of the blood, or from exposure to cold. Local peritonitis from extension of inflammation is a frequent occurrence, the inflammatory process being limited to the peritoneal investment of a single organ, as the liver, uterus, or ovary. A very important source of localized peritonitis is the diseased vermiform appendix. Very many cases of so-called idiopathic peritonitis really begin as appendicitis. Puerperal peritonitis is inflammation of the uterus and peritoneum following confinement. (See PUERPERAL FEVER.) Tubercular peritonitis is an infective form due to the action of the same bacillus as that of pulmonary tuberculosis, which gains access to the peritoneum through the food, or through the blood from a primary tuberculosis of the lungs, intestines, etc. It is usually chronic, and consists in the deposition of inflammatory lymph and miliary tubercles, with interspersed masses of caseous matter, or yellow tubercle; tubercle usually coexists in the lungs and other organs. Acute peritonitis, as a rule, is of sudden onset. Abdominal pain is its prominent symptom, at first localized, but quickly diffused over the entire abdomen. The pain is increased by pressure, by the movements of respiration, and by tension of the abdominal muscles. The breathing is therefore chiefly thoracic, the diaphragm fixed to prevent abdominal movement, and the respiration is correspondingly shallow, restrained, and rapid. The limbs are retracted upon the body to relax tension of the abdominal surface. There is temporary paralysis of the muscular coat of the bowel; constipation results, also extreme flatulent distension of the intestines, and general tumefaction of the abdomen. The inflamed surface is so extensive, invests so many important organs, producing extensive peripheral nerve-irritation as well as impressions on the plexuses of the sympathetic nerve, that the constitutional depression is very marked. The face is pale, haggard, and anxious, wearing an expression of great suffering. The teeth are set, the lips tightly drawn, the eye set and sunken, the cheeks collapsed—in extreme cases constituting the *Hippocratic facies*, or *facies griffé* of the French. Peritonitis is always a dangerous disease, but its termination depends upon early diagnosis and a correct treatment, conducted with vigor and persistence. When incipient, it may be aborted or limited by local use of ice or cold water, local dry cupping, cardiac sedatives, as veratrum, and a single prompt saline purge. If fully developed, opium is the supreme remedy to allay pain and secure absolute rest of the intestines from their physiological peristaltic action. In peritonitis the tolerance of opium is very great. In some forms of peritonitis, particularly in the puerperal, small doses of saline purges, given at short intervals to produce gentle looseness of the bowels, act with better success than opium. The cold water or ice pack, if judiciously used, will be of value during the acute period of the disease, but later warm and anodyne applications are preferable. Curiously enough, chronic tuberculous peritonitis is sometimes curable by simple opening of the abdomen (cœliotomy or laparotomy) and flushing out the cavity with an antiseptic solution. Revised by WILLIAM PEPPER.

Periwinkle: any one of various half-shrubby and herbaceous erect or trailing plants of the genus *Vinca* and family *Apocynaceæ*. The *V. major*, *V. minor*, and *V. herbacea* of the gardens are hardy European plants. *V. rosea*, a fine greenhouse evergreen shrub, grows wild in most tropical regions, and also in Florida.

Periwinkle: the popular name for several small gasteropodous molluses of the genus *Littorina* and allied genera, and particularly *Littorina littorea*, a species much used for food in Europe, several hundred tons being eaten yearly. The species has become quite abundant on the eastern coast of the U. S. The name is also applied in the U. S. to several large molluses, *Busycon carica*, *Sycotypus canaliculatus*, and species of *Purpura* which do great damage to the oyster beds of the eastern coast. F. A. L.

Perizo'nius, JACOB (*Voorbroek*): historian and philologian; b. at Dam, in Holland, in 1651; studied under Græ vius at Leyden; Professor of Ancient History at Franeker in 1681, at Leyden in 1693; d. Apr. 6, 1715. His principal works are editions of *Ælian*, *Dictys Cretensis et Dares Phrygius*, *Q. Curtius*, *Animadversiones historicæ* (1685; 2d ed. by Harles, with biography, 1771); *Origines Babylon. et Ægypt.* (2 vols., 1711; 2d ed. 1736); *Adnotationes in Suetonium*, *Observationes in Valerium Maximum*. See W. Kramer, *Elogium Perizonii* (1822); Hofman-Peerlkamp in *Bibl. critica nova* (v., pp. 545–552), and *Ersch und Gruber* (iii., pt. 17, pp. 108–113). ALFRED GUDEMAN.

Perjury [viâ O. Fr. from Lat. *perju'rium*, a forswearing, a false oath, deriv. of *perjura're*, swear falsely, perjure; *per*, through + *jura're*, swear]: at common law, the crime of willfully giving false material testimony under a lawful oath in any judicial proceeding. Modern statutes have extended its scope. For example, § 5392 of the U. S. Revised Statutes provides that "every person who, having taken an oath before a competent tribunal, officer, or person, in any case in which a law of the U. S. authorizes an oath to be administered, that he will testify, declare, depose, or certify truly, or that any written testimony, declaration, deposition, or certificate by him subscribed is true, willfully and contrary to such oath states or subscribes any material matter which he does not believe to be true, is guilty of perjury, and shall be punished by fine of not more than $2,000, and by imprisonment at hard labor not more than five years." See OATH.

Whether the false testimony was material is a question for the court. If it was material, it does not matter that the witness was incompetent, or that his testimony was erroneously admitted, or that it was not believed. The essence of the crime is not the harm actually inflicted upon a particular litigant, but the false swearing with the intention to pervert justice. Hence one commits perjury who swears to something of which he is conscious he has no knowledge, although it turns out to be true. If the opinion of a witness is material, he commits perjury by a willfully false expression of it.

As perjury in a judicial proceeding is peculiarly an of-

fense against the system of laws under which the court is organized, it has been held in the U. S. that perjury committed in a Federal court is not punishable in a State court. In some cases, however, a State officer is authorized by Federal law to administer an oath in matters of Federal jurisdiction, and perjury before such an officer is a crime against the U. S.

The punishment for perjury has always been severe. Anciently it was death; then banishment or the cutting out of the tongue; later, the forfeiture of goods, while at present it is generally a fine or imprisonment and incapacity to be a witness. Formerly the evidence of two witnesses was necessary to convict one of perjury, on the theory that the oath of the witness for the prosecution was no weightier than that of the prisoner. The present rule is that the evidence of the prosecution must be sufficient to counterbalance the prisoner's oath, and the presumption of his innocence. See *U. S.* vs. *Wood*, 14 Peters 430.

FRANCIS M. BURDICK.

Perkins, ELISHA: physician; b. in Norwich, Conn., Jan. 16, 1741; established an academy in Plainfield, where he practiced medicine. In 1796 he announced the invention of metallic tractors for the cure of rheumatism, gout, and the like. His son went to Europe with the tractors, where, as well as in the U. S., the new cure, called Perkinism, was favorably received even by physicians. Lord Rivers presided over a Perkinian institution in which many marvelous cures were wrought solely by the power of imagination, for the tractors were simply pins of iron and brass which were drawn over the affected part. In Copenhagen the medical faculty published a voluminous report in favor of Perkinism; and when in 1803 the British physicians had begun to see through the imposture, Thomas G. Fessenden produced his *Terrible Tractoration* as a defense of Perkins and a satire on the doctors. Perkins afterward invented a remedy of great alleged value in the cure of fevers, and during a yellow-fever season in New York went there to test its value, but fell a victim to the disease, Sept. 6, 1799.

Perkins, FREDERIC BEECHER: See the Appendix.

Perkins, GEORGE HENRY: See the Appendix.

Perkins, JACOB: inventor; b. at Newburyport, Mass., July 9, 1766; was in childhood apprenticed to a goldsmith; invented a new method of plating shoe-buckles; was employed in 1797 to make dies for the State coinage; invented soon afterward a machine for cutting and heading nails at a single operation, and was the originator of the use of steel instead of copper plates for engraving bank-notes. After residing some years in Boston and New York he engaged in business in Philadelphia in 1814 as a bank-note engraver; went to England in 1818; obtained a contract for supplying plates to the Bank of Ireland; was the inventor of the steam-gun, of the bathometer for measuring the depth of water, of the pleometer for registering the speed of vessels, and largely aided in perfecting the manufacture of the steam-engine. D. in London, July 30, 1849.

Perlidæ: See ENTOMOLOGY.

Perm: the easternmost government of European Russia. Area, 128,211 sq. miles (see map of Russia, ref. 6–H). The larger, central part of the country is covered by the Ural Mountains, which attain a height of 5,360 feet. The chief branch of industry is mining. Gold, silver, platinum, iron, salt, coal, alabaster, marble, and diamonds are found, and some of the mines are very rich. The platinum mines (see PLATINUM) are the richest in the world. The western part of the government, situated on the European side of the mountains, has some good agricultural land where rye, oats, barley, and potatoes are grown; on the Siberian side the country is fit only for pastures. Pop. (1897) 3,002,655. The capital, Perm, on the Kama, carries on an extensive transit trade between European and Asiatic Russia, and has a cathedral, distilleries, flour-mills, and a cannon-foundry. Pop. (1897) 45,403.

Permanent Way: in railway engineering, the road-bed, track, bridges, and buildings of a line of railway, as distinguished from the rolling-stock, which consists of the locomotives and cars.

Permanganates: See MANGANESE.

Permangan'ic Acid: See MANGANESE.

Permeability and **Permeance**: See MAGNETISM OF IRON.

Permian Series: in geology, a group of rocks occurring in the province of Perm, Russia. Formations of various other countries have been recognized as their equivalents, and by some taxonomists the corresponding portion of geologic time is styled the Permian period, and made co-ordinate with the Carboniferous and other great divisions of the Palæozoic era. A more prevalent usage recognizes the Permian epoch as the closing part of the Carboniferous period. In the U. S. approximate equivalents of the Russian beds have been noted in West Virginia, Kansas, and Utah. See CARBONIFEROUS PERIOD, and consult Bulletin No. 80, U. S. Geological Survey.

G. K. G.

Permutations [from Lat. *permuta'tio*, deriv. of *permuta're*, change throughout, interchange; *per*, through, thoroughly + *muta're*, change]: the results obtained by writing a certain number of letters or factors in every possible order, so that all the letters shall enter each result, and each letter but once. Thus the letters *a*, *b*, and *c* may be written *abc*, *acb*, *bac*, *bca*, *cab*, and *cba*. Here there are three letters and $1 \times 2 \times 3$, or 6, permutations. To determine the number of permutations of n letters, n being any whole number, let us denote the number of permutations of $n - 1$ letters by Q; if we now introduce a new letter, it is obvious that it may have n places in each of the Q permutations of $n - 1$ letters; that is, it may be written before the first letter of each, between each two letters, and after the last letter of each; hence the whole number of permutations of n letters is $Q \times n$. Now, the number of permutations of 3 letters is $1 \times 2 \times 3$; hence the number of permutations of 4 letters is $1 \times 2 \times 3 \times 4$. Proceeding from this conclusion, we infer that the number of permutations of 5 letters is $1 \times 2 \times 3 \times 4 \times 5$, and so on indefinitely. Hence the number of permutations of n letters is the continued product of the natural numbers from 1 to n, inclusive, n being any whole number. If the actual product indicated by each permutation is found, it will be equal to a fixed quantity in each case. The theory of permutations finds an important application in the deduction of formulas for combinations and arrangements, and these in turn are used in developing the theory of probabilities. See Newcomb's *College Algebra*, or Oliver Wait and Jones's *Algebra*.

Revised by S. NEWCOMB.

Pernambu'co: a state in the eastern part of Brazil; bounded N. by Ceará and Parahyba, E. by the Atlantic, S. by Alagoas and Bahia, and W. by Piauhy. Area, 49,560 sq. miles. A sandstone reef follows nearly the whole coast, and the only harbors are formed by openings through it, as at the city of Pernambuco. A strip extending from the coast about 40 miles inland is low and partly flat land, originally covered with forest, well watered, and very fertile; this is known as the *Matta*. Beyond it the surface rises abruptly or gradually to the *Sertão*, or "desert"; this is properly a part of the Brazilian plateau, but much varied with hills and valleys and with a general southwest slope to the river São Francisco. Most of the *Sertão* is open land, resembling the neighboring parts of Ceará in its parched dry season (September to February) and its occasional destructive droughts. Most of the population is gathered in the *Matta* belt, where the prominent industry is sugar-planting; cotton is raised farther inland, and the *Sertão* supports large herds of cattle in favored places. There are considerable manufactures, and the state is one of the richest and most progressive in Brazil. Estimated pop. (1894) 1,254,159. The most important exports are sugar, rum, and cotton. The coast region was occupied by the Dutch 1630 to 1654.

HERBERT H. SMITH.

Pernambuco (officially *Recife*): capital and chief city and port of the state of the same name; on the coast at the mouths of the little rivers Caparibe and Beberibe (see map of South America, ref. 4–H). It consists of three parts—Recife proper and Santo Antonio, on narrow islands, one behind the other, and Boa Vista, on the neighboring mainland. These are all on flat ground, and are connected by bridges. Recife, nearest the sea, is the oldest, and its narrow streets and ancient houses, some of the Dutch period, are very interesting; it contains the principal wholesale commercial houses. The other divisions have wide streets, with many handsome buildings, and the beautiful suburbs are ornamented with stately old trees and extensive gardens. The harbor proper is formed by a sandstone reef, which has been artificially extended; it will not admit vessels of more than 17 feet draught, and large ships must anchor in the open roadstead, whence landing is often difficult. Pernambuco is nearer Europe than any other important Brazilian port, and it is almost the only commercial outlet of the state; several railways run to the interior. In population and com-

merce it is the third city in Brazil; sugar, rum, cotton, hides, tobacco, cigars, coffee, etc., are exported. The climate is generally salubrious; the heat is modified by regular trade-winds, and epidemics are infrequent. Under the Dutch (1630–54) Recife was a mere village; in the eighteenth century it supplanted the original capital and port, Olinda (*q. v.*). Pop. (1894) about 150,000. Herbert H. Smith.

Peronospora'ceæ [Mod. Lat.; Gr. περόνη, brooch, pin + σπόρος, seed]: a family of fungi, including the Downy Mildews and White Rusts. See Mildews and Rusts.

Perosi, Lorenzo: See the Appendix.

Perowne, John J. S.: See the Appendix.

Peroxide of Hydrogen: See Hydrogen Peroxide.

Perpetual Apparition, Circle of: See Circle of Perpetual Apparition.

Perpetual Motion: a term applied to a mechanism which is assumed to put itself in motion and to possess sufficient inherent power not only to continue such motion indefinitely (or until the mechanism is worn out), but to have a surplus which can be used in doing useful work. The absurdity of such an idea is evident to most well-informed minds the moment it is clearly stated, but since the first recorded scheme for a mechanical perpetual motion (by Willars de Honecort, an architect of the thirteenth century) numbers of persons have pursued this *ignis fatuus* of mechanics. In the nineteenth century there have been upward of 180 patents (the large majority of them English) granted for machines intended to move perpetually, and during that and the preceding century there have been printed descriptions of nearly 300 other schemes for perpetual motion that were not patented. The searchers for perpetual motion have employed every force in nature, but the majority employ the force of gravity in some way, a favorite contrivance being a wheel provided with movable weights intended to descend on one side at a distance from the center of rotation, and to be raised on the other side through a path much nearer that center.

The planets are examples of perpetual motion on a grand scale in that they revolve unceasingly, but even they do not fulfill the requirements of the problem of perpetual motion, inasmuch as their movements involve a perfect equilibrium of forces, and there is no surplus power for work outside of that required for their own rotations and stability in their orbits. See Force. W. F. Durfee.
