Pownall, Thomas, LL. D.: statesman; b. at Lincoln, England, in 1722; graduated at Cambridge 1743; became secretary to the commissioners for trade and plantations 1745; went to New Jersey as secretary of that province 1753; became lieutenant-governor 1755; was a member of the colonial congress which met at Albany in 1754 to devise measures of defense against the French; was Governor of Massachusetts 1757–60, of South Carolina 1760–61, after which he became director-general of the office of control; sat in Parliament, where he opposed in many well-considered speeches the rash policy of the crown toward the American colonies; published *The Administration of the Colonies* (1766); *A Topographical Description of the Middle British Colonies* (1775); and many other works on archæology and politics. D. at Bath, England, Feb. 25, 1805.

Poynter, Edward John: historical painter; b. in Paris, of English parents, Mar. 20, 1836; studied at the Royal Academy, London, and under Gleyre in Paris; Royal Academician 1876; Slade Professor of Fine Arts at University College, London, 1870–75; director of the art schools at South Kensington Museum 1875. One of his most celebrated works is *Atalanta's Race* (1876), and he has executed noteworthy frescoes in St. Stephen's church, Dulwich, and mosaics in the Houses of Parliament. Studio in London.
W. A. C.

Pozzi, pŏt'sĕe, Samuel Jean, M. D.: gynæcologist; b. at Bergerac, Dordogne, France, Oct. 3, 1846; studied medicine in Paris, graduating M. D. in 1873; in 1875 became associate professor in the faculty, and in 1877 surgeon to the hospitals; paid special attention to gynæcology, and is one of the most prominent of European specialists. His most important work is *Traité de gynécologie clinique et opératoire* (Paris, 1890).
S. T. Armstrong.

Pozzo di Borgo, pot'sō-dĕe-bōr'gō, Carlo Andrea: diplomat; b. at Alata, in Corsica, Mar. 8, 1764; studied law at the University of Pisa, and settled as an advocate at Ajaccio, where he lived in great intimacy with Joseph and Napoleon Bonaparte. This friendship soon cooled, however, and the relation between the former friends assumed a very bitter character when Pozzo di Borgo espoused the cause of Paoli, who showed great confidence in him. In 1791 he represented Ajaccio in the National Assembly, and sided with the Girondists, but returned to Corsica in 1792; held a high position in the government of the island during its occupation by the British, and fled, after their expulsion, to London. Here he became the agent of the French *émigrés*, and began his flying missions from one court to another to form plots and coalitions against France. In 1803 he entered the Russian diplomatic service, and the interest which Alexander I. took in him gave an opportunity of gratifying his hatred of the Bonapartes. The intimacy which sprang up between Napoleon and Alexander after the Peace of Tilsit brought him for a moment into great danger, and he went first to Austria and then to England, never ceasing to work for the downfall of Napoleon. In 1812 the Czar recalled him to St. Petersburg. He induced Alexander to continue the war in 1813, and he persuaded the allies to reject Napoleon's offers of peace. He wrote the famous proclamation which preceded the entrance of the allies into France—that they waged war against Napoleon, not against the French people—and he had at last the triumph of signing the Treaty of Paris in 1815 as Russian ambassador. After the fall of Napoleon he remained in the Russian service, and enjoyed great esteem from the Russian court, though perhaps not always full confidence. In 1825 the Emperor Nicholas made him a count. He was for several years ambassador in Paris, where he was the oracle of the doctrinaires and detested by the radicals. In 1834 he was appointed ambassador in London, but retired from public life in 1835. D. in Paris, Feb. 15, 1842. See Vuhrer, *Notice biographique sur le Comte Pozzo di Borgo* (Paris, 1842).

Pozzuolana, pŏt-soo-ō-laa'nă: a rock possessing the properties of hydraulic lime or cement, so called from the village of Pozzuola, near the base of Mt. Vesuvius, where it was first discovered. The word is applied to the pozzuolanas proper, tras or terras, the arènes, some of the ocherous earths, and the sands of certain graywackes, granites, basalts, etc. Their principal ingredients are silica and alumina, the former largely preponderating, and most of them contain small quantities of soda and potash, and the oxides of iron and manganese. When finely pulverized, even without previous roasting, and combined with a paste of common lime, a hydraulic mixture is produced which will compare favorably with the mortars of hydraulic lime and sand. Pozzuolana itself was known to both Vitruvius and Pliny, and it was extensively used by the Romans before their day. Vitruvius gives a formula which, with slight variations, has been followed in Italy ever since: 12 parts of pozzuolana, well pulverized; 6 parts of quartzose sand, well washed; and 9 parts of rich lime, recently slaked. This constitutes the mortar. To this is added 6 parts of broken stone, porous and angular, when it is intended for concrete or monolithic masonry.

Tras closely resembles pozzuolana, and is employed substantially in the same way. It is found on the Rhine between Mayence and Cologne, and in various localities in Holland. The arènes are a species of ocherous sand, containing so large a proportion of clay that they can be mixed into a paste with water without the addition of lime, and used in that state for pisé work, as well as for common mortar. Mixed with rich lime, they yield hydraulic mortars of considerable energy. Many of the natural pozzuolanas are improved by a slight roasting, and an artificial pozzuolana may be produced by subjecting clay to a slight calcination. Brick-dust mixed with common lime gives a feebly hydraulic mortar. Forge scales from the smith's anvil, the slags from iron-foundries, and the ashes from lime-kilns, containing cinders, coal, and lime, are artificial pozzuolanas.
Revised by Mansfield Merriman.

Pozzuoli, pŏt-soo-ō'lĕe (Gr. Δικαιαρχία; Lat. *Puteoli*): town in the province of Naples, Italy; on the northern shore of the Bay of Pozzuoli, about 6 miles W. of the city of Naples (see map of Italy, ref. 7–F). The streets are narrow and irregular, and many of them very steep. Among the buildings there is little of interest except the cathedral of St. Proculus, which occupies the site of a temple erected to Augustus by L. Calpurnius. The neighborhood of Pozzuoli, however, abounds in interest for the archæologist. The famous temple of Serapis consisted of a rectangular court inclosed by forty-eight massive columns, and having in the center a round temple with sixteen Corinthian pillars of African marble. The statue of Serapis is now in the National Museum of Naples. The amphitheater erected in the time of the Flavian dynasty accommodated 30,000 spectators. There are besides minor ruins, among which are a temple of Neptune and a temple in honor of Hadrian, which was built on the site of Cicero's villa. In 194 B. C. Puteoli was colonized from Rome, and afterward became the most important commercial port in Italy. Later it was sacked by Alaric (410), Genseric (455), Totila (545), and the Turks (1550), and ruined by earthquakes in 1198 and 1538. In 1888–90 military engineering works, a branch of the Armstrong works at Newcastle, were established here. Agriculture, fishing, soap-making, etc., are carried on. Pop. 11,967.

Practice: in law, the form and manner of conducting suits or prosecutions (whether legal or equitable, civil or criminal) through the necessary steps according to the principles and rules governing in the several courts. The scope of the meaning of the term is not definitely settled, but it is generally used as excluding the principles and rules of both pleading and evidence, and referring rather to the formal method and course of bringing matters pleaded to trial and proof, and of enforcing judgment. The jurisprudence of every civilized country, ancient or modern, has established certain formal modes in which proceedings before public tribunals must be conducted, as being in general promotive of public justice, and contributing to private convenience. The rules of practice are to a large extent fixed by custom or statute, but the judges of the different courts are very generally intrusted with a large discretionary power of changing them. See the general treatises of Chitty and Daniell (Chitty, common practice law; Daniel, chancery, or equity, practice) and the numerous special treatises on the practice of the various courts.
F. Sturges Allen.

Pradier, James: sculptor; b. at Geneva, Switzerland, May 23, 1792. In 1809 he entered the studio of Baron Lemot, and by special favor was exempted from the conscription even in the height of Napoleon's demands upon his empire. In 1813 he won the Grand Prix de Rome by his bas-relief of *Philoctetes and Ulysses in Lemnos*. He then spent the usual time of five years in Rome, and on his return exhibited a *Nymph*, now in the Museum of Rouen, and other works. During another stay in Italy, before 1823, he produced three statues, which were bought by the Government for the Luxembourg Museum—a *Venus*, a *Psyche*, and a *Son of Niobe*. Then came a number of important works

for the churches of Paris and Versailles, a *Venus* now in the Museum of Orleans, a group of the *Three Graces* which stands in the Museum of Versailles, the colossal allegorical statues of *Strassburg* and *Lille* on the Place de la Concorde in Paris, several statues for the fountain of Molière near the great National Library, the *Twelve Victories* of the tomb of Napoleon in the Church of Les Invalides, statues for the funeral chapel of the royal family at Dreux, four bas-reliefs, *Fame* for the Arc de Triomphe, and a great number of smaller works in public and private collections. He was always as classical as he knew how to be, but his work has a feminine grace which he did not find in his Græco-Roman models. D. at Bougival, near Paris, June 14, 1852.

RUSSELL STURGIS.

Pradier-Fodéré, PAUL LOUIS ERNEST: publicist; b. at Strassburg, July 11, 1827; studied law in Strassburg, and was admitted to the bar of Paris in 1857, and made Professor of Public Law in the Armenian College of Moorat; appointed in 1874 by the Peruvian Government to organize the instruction in the studies of political and administrative sciences in the University of Lima. At the end of the war with Chili he returned to France and was made *conseiller* (judge) of the court of appeal of Lyons June 3, 1882; Chevalier of the Legion of Honor. He has published, besides other works, *La Question de l'Alabama et le Droit des Gens*; *Commentaire sur le Code de Justice Militaire*; *Traité de Droit International Public, Européen et Américain*; *Droit de la Guerre et de la Paix* (translation of the work by Grotius); *Précis de Droit Administratif*; *Traité de Droit Commercial*.

F. STURGES ALLEN.

Pradon, prăă'dōñ', NICOLAS: dramatic poet; b. at Rouen, France, 1632; went early to Paris and devoted himself to literature. Of very mediocre poetic gifts, he was yet able to enjoy a great temporary reputation as a tragic poet, profiting by the jealousies excited by the popularity of Racine. His *Phèdre et Hippolyte* (1677), played a few days after the *Phèdre* of Racine, appeared, by an intrigue of Racine's enemies, to have a striking triumph over it, which led Racine to renounce the drama. D. in Jan., 1698. A. G. C.

Praed, prād, WINTHROP MACKWORTH: poet; b. in London, July 26, 1802; educated at Eton; was the associate of John Moultrie and H. N. Coleridge in editing *The Etonian*; entered Trinity College, Cambridge, and graduated 1825; contributed to Knight's *Quarterly Magazine*; was called to the bar 1829; sat in Parliament as a Conservative for St. Germain, and subsequently for Great Yarmouth and Aylesbury; became secretary of the board of control 1834, and afterward recorder of Barnstaple and deputy high steward for the University of Cambridge. He wrote essays and graceful *vers de société* for the magazines. D. in London, July 15, 1839. His *Poems* were edited in New York by R. W. Griswold (1844), and, with a *Memoir*, by W. H. Whitmore (2 vols., 1859), and a complete edition, with a memoir by Rev. Derwent Coleridge, was issued by his sister, Lady Young (2 vols., 1864). His prose essays were published in 1887 and an edition of his political poems in 1888.

Præraphaelites: See PRERAPHAELITES.

Præ'tor [= Lat., for **præitor*, one who goes before, deriv. of *præire*, go before; *præ*, before + *ire*, go]: in ancient Rome, a magistrate created by the Licinian law of 367 B. C. as "lesser colleague" of the two consuls. In practice, however, the functions of the prætor were quite exclusively judicial. He was obliged to remain in the city, and from this fact was called the *prætor urbanus*. About the middle of the third century B. C., with the increase of the city's population, an additional prætor was named and given jurisdiction over the foreigners resident at Rome, and hence called the *prætor peregrinus*. With the expansion of Roman territory new prætors were added until in the reign of Claudius (41–54 A. D.) there were eighteen, though not all of them exercised judicial functions. In the early part of the first century B. C. the custom was inaugurated of practically extending a prætor's term of office by sending him out as governor of a province on the expiration of his year of service in the city. By their decisions as judges, and especially by their edicts or official announcements of the principles on which jurisdiction would be based, the prætors became most important agents in the development of the Roman law.

G. L. HENDRICKSON.

Prætorians [from Lat. *prætō'rium*, or *cohors prætō'ria*, prætorium, prætorian cohort, orig. the body-guard of a general (Lat. *prætor*, prætor, general), later of the emperor]: the personal guard of the Roman emperors. During the time of the republic the general in command had a guard, a *cohors prætoria*, which consisted of picked soldiers from the legions, whose only mark of distinction from the common soldiers was the bravery or devotion which had commended their selection. At the end of a campaign this guard was always dissolved and its members returned to the legions. Augustus, however, transformed (in 27 B. C.) his *cohors prætoria* into a standing body of troops, consisting of ten cohorts, each numbering 1,000 men (horse and foot), of which he kept three in Rome for service in the palace, while the rest were stationed in the neighborhood of the metropolis. Tiberius gathered all the cohorts to Rome for the sake of maintaining a better discipline, and built them a fortified camp in the northeastern corner of the city, and Vitellius increased their number to sixteen cohorts. Originally, only Italians were employed in this guard, but later others were admitted from regions which had become thoroughly Romanized. The term of service was sixteen years; the pay double that of the legions; the rank of a private of the guard equal to that of a centurion in the legions; and when the time of service expired each soldier received 20,000 sesterces. In the hands of ambitious and unscrupulous prefects their political influence was often superior to that of emperor or senate. They were the murderers of many of the emperors, none of whom could maintain themselves without their aid, and their voice was often the controlling one in determining the imperial succession. In the remodeling of the Roman military system by Constantine the prætorian guard was abolished.

Revised by G. L. HENDRICKSON.

Pragmatic Sanction: a diplomatic term which originated with the Byzantine court, and denoted the highest and most solemn state ordinances issued by the emperor. It was early introduced into France, and has become historical as applied to four important instruments—namely, (1) that by which Charles VII. and the States-General of France, assembled at Bourges in 1438, adopted those decrees of the Council of Basel which authorized the election of bishops by cathedral chapters, and which were condemned by the pope. (See GALLICAN CHURCH.) (2) That by which the same decrees were adopted by the German Diet, assembled at Mentz in 1439. (3) That by which Charles VI., Emperor of Germany, who had no male issue, settled the right of succession to his Austrian dominions on his daughter, Maria Theresa. It was accepted by the various peoples over which he ruled, consented to by the different members of his family, guaranteed by all the European states, but immediately after his death (Oct. 20, 1740) the war of the Austrian Succession (see SUCCESSION WARS) broke out. (4) That by which Charles III. of Spain in 1759 settled the right of succession to the kingdom of the Two Sicilies on his third son, Ferdinand.

Prague (Germ. *Prag*: Czech, *Praha*): the capital of Bohemia, Austria; in lat. 50° 5′ N., lon. 14° 25′ E.; on both sides of the Moldau, 217 miles by rail N. N. W. of Vienna (see map of Austria-Hungary, ref. 3–D). It presents a picturesque and imposing aspect on account of the diversity of the surface on which it stands and its numerous towers, spires, and domes. It was surrounded by a wall 12 miles in circumference, which, since 1866, has been to a great extent removed; outside this line extend the suburbs of Karolinenthal, Wyscherad, Weinberg, and Smichow. The city proper consists of five parts—the Altstadt, Neustadt, and Josephstadt on the right bank of the Moldau, and the Hradschin and Kleinseite on the left—connected with each other by several bridges, of which the most remarkable is the Karlsbrücke, built 1358–1503 of stone, 31½ feet broad, 1,572 feet long, resting on sixteen arches and adorned with statues. The Altstadt, consisting of narrow, crooked streets lined with tall, quaint old houses, the Neustadt, of a more modern and elegant appearance, and the Josephstadt, the Jewish city, form the business part of Prague; the Hradschin and Kleinseite consist almost exclusively of palaces and public buildings. Here is the imperial castle, one of the largest royal residences in Europe. The Hradschin Place, formed by the immense palaces of the primate, the ex-Emperor Ferdinand, and Prince Schwarzenberg, extends in front of the castle. On the terrace in the rear of the castle stands the cathedral of St. Vitus, a Gothic structure built 1343–85, and containing the tomb of St. Nepomuk, the patron saint of the country, with his monument of solid

silver weighing 30 ewt., and a mausoleum of Carrara marble erected by Rudolph II. over the Bohemian kings. Among the most prominent buildings of the Kleinseite are the so-called Sachsenhaus, built in the thirteenth century; the gorgeous Church of St. Nicolai, erected in 1628 by the Jesuits; the palaces of Waldstein with beautiful gardens, of Fürstenberg with a large library and a picture-gallery, of Nostitz with a collection of coins, a library, and an art gallery, etc. In the Altstadt is the church Am Teyn, the old Hussite church, founded in 1407, containing the monuments of the two Bohemian martyrs, Cyrillus and Methodius, and of the Danish astronomer Tycho Brahe. The university has a library containing 195,000 volumes and 3,800 MSS., a botanical garden, a laboratory, an observatory, and the faculties of theology, law, medicine, philosophy (which comprises also languages and history), and the exact sciences. It was founded in 1348 by Charles IV., and was frequented in the fifteenth century by about 10,000 students, but subsequently its importance decreased. It was reorganized in 1881 and now has two sides, one German and the other Czech. In 1892 the former had 152 teachers and 1,248 students, and the latter 152 teachers and 2,354 students. There is also a technical high school of engineering and chemistry with (1892) 117 teachers and 569 students. The suburb of Karolinenthal, which is of modern growth, has numerous fine buildings, public gardens, and manufacturing establishments; farther N. there are public walks on the Moldau and a great botanical garden. The commerce and industry of the city are considerable. Leather, glass, liqueurs, beer, spirits, chemicals, woolens, linens, metal ware, and machinery are manufactured. Prague was founded in the eighth century, and has ever since formed the leading center of the Czech community. After the connection with Austria, Bohemia was often dragged into wars entirely foreign to its interests, and Prague, as its capital and a strong fortress, has several times suffered severely from sieges and bombardments. In 1866 it was occupied by the Prussians without bloodshed, and a treaty was concluded here. About four-fifths of the inhabitants are Czech. Pop. (1890) of the town proper, 184,-109; with the suburbs (1893) 327,953.

Revised by R. A. Roberts.

Prairie [= Fr. < Late Lat. *prata'ria*, an extensive meadow, deriv. of *pra'tum*, meadow > Fr. *pré*, meadow]: a word applied by the early explorers of North America to the fertile, grassy plains of the Mississippi basin. Prairies are level or gently rolling, and free from trees. The origin of their even surface has been described under Plain (*q. v.*) as sheets of fine glacial drift, or beds of former lakes, or swamps, or deeply weathered plains of denudation. The absence of trees has been much discussed. It can not be ascribed to deficiency of rainfall, as is the case on the treeless Western plains, for over the prairies the rainfall is sufficient and well distributed through the year. It can not be ascribed to excess of heat or cold, for trees grow abundantly in forests farther S. and N., as well as along watercourses and on hilly interruptions of the prairies. Moreover, trees will flourish on prairies if they are artificially planted and cared for. The absence of trees is more plausibly ascribed to the prevailingly fine and close texture of the prairie soil, this explanation being particularly applicable to those smaller prairies formed by the gradual filling of swampy lakes with peaty growth and fine silt, and to those broader prairies that represent the bottom of glacial lakes. There is reason to think that the former prevalence of prairie fires, while the country was occupied by Indians, may have had much to do with retarding the invasion of trees into districts where they would naturally spread; for trees are invading certain prairies, now that the settlement of the region prevents the frequent recurrence of fires.

The prairie region of the upper Mississippi valley is of extraordinary richness agriculturally, and has tempted rapid settlement by emigration from Europe and from the older Eastern States; it is in this respect strongly contrasted with the semi-arid, treeless plains farther W.

The prairies need no clearing of trees or rocks, and they yield abundant crops. Their disadvantages are insufficient local supply of timber for building and fuel, scarcity of building stone and road metal, and generally a want of sufficient slope for good drainage. W. M. Davis.

Prairie-dog: any rodent of the genus *Cynomys*, which forms a part of the great squirrel family, whose members are closely related to the ground or prairie squirrels (*Spermophilus*). Why they were called *dogs* it is difficult to see, for they neither look, act, nor bark like those animals. They are considerably larger than the squirrels, being generally about a foot in length, exclusive of the tail, which is short and from about 2 to nearly 5 inches in length, according to the species. They inhabit the prairies of Western North America, congregate in large numbers, and form communities designated as "villages." They burrow to a considerable distance in the ground, throwing up around the mouths of the burrows hillocks on which they are wont to mount and from thence survey the doings of the community. Horses are sometimes thrown by stumbling into such burrows. Four species of *Cynomys* are recognized, the best known being *C. ludovicianus*, abundant on the plains from Kansas to the Rocky Mountains, and from Western Texas to 49° N. The fable still clings to this species that it lives in harmony with the burrowing owl (*Speotyto*) and rattlesnake, but when any two of the above-named animals are found together it is either due to accident or bodes ill to the young "dogs" or owls. *Cynomys mexicanus* is a more southern species, while *C. gunnisoni* and *leucurus* inhabit uplands.

Revised by F. A. Lucas.

Prairie du Chien, prā'rĕe-doo-sheen': city; capital of Crawford co., Wis.; on the Mississippi river, 3 miles from its junction with the Wisconsin, and the Burlington Route and the Chi., Mil. and St. P. railways; 70 miles N. by W. of Dubuque, Ia., 194 miles W. of Milwaukee (for location, see map of Wisconsin, ref. 7–C). It has a large river trade, numerous artesian mineral wells, several mills, machine-shops, and other manufactories, St. Mary's Institute, St. John's College, a State bank, and two weekly newspapers. Pop. (1880) 2,777; (1890) 3,131; (1900) 3,232.

Prairie-hen, or **Pinnated Grouse**: a peculiar form of the grouse family, the *Tympanuchus americanus*, restricted to the U. S. and found chiefly on comparatively open plains and prairies. The species is at once recognizable by the extension of feathers to the lower end of the tarsus, the air-bladders, and the long and lanceolate feathers of the sides of the neck, and the short, subtruncate tail; the former generic name (*Cupidonia*) alludes to the long neck-feathers, which have recalled to the imagination of some the wings of the fabled Cupid; beneath these feathers on each side is a bare and distensible air-sac developed in the male, and connected with the organs of voice. During the love season the male inflates the bladders, which then resemble small oranges, lowers his head to the ground, and opening his bill gives utterance to a single sound, produced partly by means of the air contained in these bladders, which are alternately filled and emptied as he makes his booming noise. If these sacs are punctured they are no longer resonant. The prairie-hen feeds chiefly upon berries of various plants, as well as upon the buds, and in some places encroaches considerably upon the domains of the farmer. This species ranges from Illinois westward to the foot-hills of the Rocky Mountains, and formerly abounded, but has been decimated by market gunners. It is replaced in the Southwest by *T. pallidicincta*. A very closely related species, *Tympanuchus cupido*, formerly inhabited portions of the eastern parts of the U. S., and in comparatively recent times was common on Long Island, but has now been almost exterminated, only a few individuals being left on Martha's Vineyard and Naushon. This bird was for a long time confounded with the Western species, and much confusion of names has arisen in consequence.

Revised by F. A. Lucas.

Prairie-squirrel: any member of the genus *Spermophilus*, of the family *Sciuridæ*, found in various parts of the U. S. These are simply squirrels frequenting the ground rather than the trees, and having a shorter tail than the tree-squirrels, and also provided with cheek-pouches. They live on the prairie-lands of the Western States and Territories, make burrows, and generally associate in considerable communities. Eleven species are now recognized as inhabitants of various parts of the U. S.; the best known are the *Spermophilus 13-lineatus* (striped gopher and prairie-squirrel of Illinois, Iowa, and adjacent States), and the *Spermophilus franklini* (great gopher of Illinois and corresponding latitudes upward to the Saskatchewan region). See also Sciuridæ.

Prairie-wolf: See Wolf.

Prâkrit Languages [*Prâkrit* is from Sanskr. *Prākṛta*, liter., natural, common, vulgar, vernacular, deriv. of *prakṛti*, origin]: in Hindu usage, all languages derived from San-

skrit as their common source (*prakṛti*); Sanskritists and linguists, however, restrict the connotation of this term to the languages immediately derived from Sanskrit, while they call those more remotely connected with it *bhâshâ*, vernaculars, or modern Prâkrits. This article refers to the Prâkrit dialects in the narrower signification of the word.

The source of the Prâkrit languages is not the literary Sanskrit which has been cultivated by the Brahmans as their sacred language, but popular idioms of perhaps equal antiquity, which may be regarded as constituting, together with literary Sanskrit, the Aryan dialects of ancient India. The Prâkrits are lineal descendants from them. There have been brought forward some very interesting speculations on the distribution of these old Indian dialects (see Hoernle's *Comparative Grammar of the Gaudian Languages*, London, 1880, p. xxxi. ff.), but no certainty is yet attainable.

Though the root of the Prâkrits is fixed in the ancient Indian dialects, they developed under the continued influence of the Sanskrit. Their constant dependence on it is more visible in the literary Prâkrits than it would have been in the popular language, but of the latter we know little or nothing. The development of the Prâkrits differs considerably from that of languages which were entirely left to themselves. Nearly all crude forms of Sanskrit words could at all times be borrowed by Prâkrit writers, provided that they were made to agree with the phonetic laws of the dialect; such words are called *tatsamas* when they are identical with their Sanskrit prototypes, and *tadbhavas* when their difference from them is caused by a phonetic change only. On their account all Prâkrits look more archaic than their long separation in time from their parent language would lead us to expect. This appearance, however, is deceptive, for many words of common use, as some verbs (called *thâtvâdeças*), numerals, pronouns, etc., which could not be borrowed from the sacred language, present forms which can not be brought under the well-known phonetic laws of Prâkrit. The same remark applies to the so-called *deçîs*—i. e. words used in the Prâkrits, which can not be derived from Sanskrit, or have a meaning different from their meaning in Sanskrit. The *Deçînâmamâlâ* of Hemachandra (ed. by Prof. Pischel in the Bombay Sanskrit Series, 1880) contains about 3,000 *deçî* words, most of which are, as would seem at present, without corresponding originals in Sanskrit. They are probably derived from such Sanskrit prototypes as belonged to the vocabulary of the common people, and were therefore beyond the remodeling influence of learned authors.

The oldest Prâkrits are the Pâli, the nearly cognate idioms of the inscriptions, ranging from about 250 B. C. to 200 A. D. The Prâkrits proper, which represent a more advanced phase in the development of the language, come next in time. Among them Paiçâcî seems to have preserved the most archaic character. In this language was composed the *Brhatkathâ* by Guṇâdhya, probably in the first century A. D. It has not yet been recovered, and we have but scant materials to form an idea of its language. Younger than it from a linguistic point of view, but older from a literary one, is the Jaina Prâkrit, or the language in which the canonical books of the Jains were written; but as these works were brought into their present shape many centuries after their composition, their language may have undergone alterations. As it is, it resembles the Mâhârâshṭrî dialect in most points, but it has many forms which may be older or be derived from other sources. The writer believes that the Jaina Prâkrit represents faithfully, on the whole, an old literary Prâkrit, and that the Mâhârâshṭrî is but a more modern and refined variety of it, which assumed its present form in order to be suitable for songs. The oldest work extant, written in Mâhârâshṭrî, is the *Saptaçatakam*, or collection of 700 stanzas by various older poets, edited by Prof. A. Weber (Leipzig, 1881), and in the *Kâvyamâlâ* (Bombay, 1889). Its reputed collector is King Sâtavâhana or Hâla, who lived probably about the second century A. D. Mâhârâshṭrî is considered by the Prâkrit grammarians as the standard Prâkrit; in it are composed all Prâkrit poems such as the *Sétubandha*, *Gaüḍavaha*, etc., and it has been used by Jaina writers in many non-canonical works in verse and prose. There is, indeed, a large literature extant in Mâhârâshṭrî. The other dialects are chiefly used in dramas in which nearly all women and some men, not of the highest rank, speak various Prâkrit dialects. The one most frequently employed is the Çaurasênî, but its use is almost entirely restricted to prose, while the same persons use Mâhârâshṭrî in their songs or verses. The remaining dialects, among which Mâgadhî, Ardhamâgadhî, Paiçâcî, Âvantikî are the most conspicuous, are reserved for persons of the lowest social, moral, or intellectual status, or to denote their local extraction. Most of these dialects are named after countries, probably after those where they were spoken. A third group of Prâkrit dialects which has undergone the greatest changes is collectively called Apabhraṃça, and is said to have been the language of *abhîras* or cowherds. These idioms seem to have been the forerunners of the modern vernaculars of India, and to have gradually merged into them. Yet they are apparently as old as the other Prâkrits, since they are used in one of Kâlidâsa's plays, and some Apabhraṃça peculiarities occur in metrical works of the Jaina canon.

All Prâkrits, Pâli included, differ from Sanskrit in the following points: (1) They have lost (*a*) the Sanskrit vowels *ṛ*; *ḷ*; *ai*; *au*, replacing them by *a*, *i*, *u*, *ri*; *ili*; *é* or *aï*; *ô* or *aü*; (*b*) the Visarga. (2) They have but one sibilant (rarely two), usually *s*, instead of the three sibilants in Sanskrit. (3) They do not admit groups of more than two consonants, which, besides, must never be dissimilar. (4) They shorten long vowels before two consonants (few exceptions in Pâli), and occasionally lengthen a short vowel when an original group has been reduced to one consonant. (5) At the end of words they allow only vowels and the *anusvâra*. (6) They have lost the dual number. Besides these special changes, the inflection, especially that of the verb, has been gradually simplified till in the most modern Prâkrits only few original forms are left.

In Prâkrit proper single consonants between vowels, which are generally retained in Pâli, are variously modified. In Mâhârâshṭrî the following consonants are dropped between vowels: *k*, *g*, *c*, *j*, *t*, *d*, *y*; they either disappear entirely or with the Jainas are replaced by a scarcely audible *y*. The aspirates *kh*, *gh*, *th*, *dh*, *ph*, *bh* become *h*. The cerebral surds become soft, *ḍ* becomes *l*; *ç* and *sh*, *s*; *p* and *b*, *v*; *n*, *ṇ*. The same changes occur in Çaurasênî except that the soft consonants, which are dropped or replaced by *h* in Mâhârâshṭrî, remain unchanged, and the surds become soft. This also applies to Mâgadhî which, besides, changes *r* to *l*, and the sibilants to *ç*. Paiçâcî as taught by the grammarians totally differs in this respect from Mâhârâshṭrî and the other dialects, as it retains all single consonants between vowels, and only changes *d* to *t*, *ṇ* to *n*. Except these two changes Paiçâcî scarcely differs from the Prâkrit of the inscriptions; its difference from Pâli consists in the grammatical structure of the language which is more like that of Prâkrit proper. In the subdialect Cûlikapaiçacî every soft consonant is changed to the corresponding surd. Jaina Prâkrit has an intermediate position between Paiçâcî and the standard Prâkrit, at least as regards single consonants; for it optionally retains them. It may be mentioned that it admits the dental *n* when it is initial or doubled or joined with *h*.

Initial single consonants undergo no change except *y*, which in Mâhârâshṭrî and Çaurasênî becomes *j*, while in Mâgadhî it retains its sound and even *j* is changed to *y*.

Conjunct consonants are treated in very much the same way as in Pâli (see the article on PÂLI); even those conjunct consonants which are admitted in Pâli, as *jv*, *lv*, *vy*, *yh*, *vh*, *tr*, *br*, *tv*, *sv*, *kv*, *sm*, are assimilated in Prâkrit to *jj*, *ll*, *vv*, *jjh*, *bbh*, *tt*, *bb*, *tt*, *ss*, *kk*, *mh*. In some points the dialects differ from one another. Thus Çaurasênî admits *yy* for *ry*, which in Mâhârâshṭrî is changed into *jj*, and Mâgadhî always has *yy* for the *jj* of the common Prâkrit. Mâgadhî retains *s* before other consonants and substitutes *st* for *tt* and *shṭh*, *st* for *sth* and *rth*, *çch* for *chchh*, the *jihvâmûlîya* and *k* for *ksh*; it shares with the Paiçâcî and the older Prâkrits the change of *ny*, *ṇy*, *jñ*, *ñj* to *ññ*, which corresponds to *nn* in the other dialects.

As regards the inflection of nouns and adjectives, stems ending in consonants generally drop the consonant or add a vowel, so that they practically become stems ending in vowels; but some stems in *n* and *r* have retained a few original inflected forms. Thus we have only three declensions: (1) stems in *a*; (2) stems in *i* or *u*; (3) the feminine stems in *â*, *î*, *û*. Following are the paradigms of the masculine in *a* and the feminines in *â*: Singular nom. *dêvô*; voc. *dêva*; acc. *dêvaṃ*; instr. *dêvêṇa(ṃ)*; dat. *dêvâê* (very rare); abl. *dêvâô*, *dêvâ*: gen. *dêvassa*; loc. *dêvê*, *devammi*. Plural nom. voc. *dêvâ*; acc. *dêvê*; instr. *dêvêhi(ṃ)*; gen. *dêvâṇa(ṃ)*; loc. *dêvêsu*; abl. *dêvêhiṃto*, *dêvêsuṃto* (not frequent). Sing. nom. *mahilâ*; voc. *mahilê*; acc. *mahilaṃ*; abl. *mahilâo*; instr. gen. loc. *mahilâe*. Plural nom. voc.

acc. *mahilâo*, etc. Nom. acc. plural of neuters *vaṇâiṃ* or *vaṇâṇi*. In Çaurasênî the abl. is *dêvâdô*; loc. only *dêvê*; acc. plur. *dêvâ*. The pronouns differ only in the gen. plur., which may be *têsiṃ*, *tâsiṃ*, or *tâṇaṃ*. The personal pronouns have developed many new forms, most of which can be accounted for by the principle of analogy.

Prâkrit has suffered the greatest loss of forms in the conjugation of verbs. Of original tenses it possesses but the present with its modes (indicative, optative, and imperative) and the future. The present or, more usually, the past passive participle is substituted for the original past tenses—the imperfect, perfect, and aorist. The Âtmanêpadam is lost, except the third person singular and plural, which are occasionally met with. There is but one set of endings: *mi*, *si*, *i*; *mo*, *ha*, *nti* (in Çaurasênî, *mi*, *si*, *di*; *mha*, *dha*, *nti*). The imperative has peculiar endings in the second person singular: *hi*, *su* (Çaurasênî, *ssa*); third sing. *u* (Çaurasênî, *du*); third plural *ntu*.

The original variety of stems has given way to great simplicity: all stems of the present end in *a* or *ê*, few in *â* or *ô*. From this stem the modes and tenses are derived. Following are the Mâhârâshṭrî forms of the third person singular of a verb in *a*: Present, *bhaṇai*; imperative, *bhaṇau*; optative, *bhaṇejjâ*; future, *bhaṇissai* or *bhaṇihii*. The participle of the present is *bhaṇanta*, *bhaṇamâṇa*; of the future, *bhaṇissanta*, *bhaṇissamâṇa*; the infinitive is *bhaṇiuṃ*; the gerund, *bhaṇiuṃ*, *bhaṇiya*, *bhaṇittâ*; the future pass. part., *bhaṇiyavva*, *bhaṇaṇijja*; the perfect pass. part., *bhaṇiya*. There are, however, many irregular forms which in truth are generally the regular Sanskrit forms. Besides the active, Prâkrit has a regular passive verb, *bhaṇijjai*, or one directly derived from Sanskrit, *bhaṇṇai*, and a causative verb, *bhaṇâvei*. Both active and causative may be conjugated in all tenses and modes.

For details of Prakrit grammar, the student is referred to the following works: Chr. Lassen, *Institutiones linguæ Pracriticæ* (Bonn, 1837); H. Jacobi, *Ausgewählte Erzählungen in Mâhârâshṭrî* (Leipzig, 1886); E. Müller, *Beiträge zur Grammatik des Jaina Prâkrit* (Leipzig, 1876); and to the native grammarians: Vararuchi, *Prâkrita Prakâśa*, ed. E. B. Cowell (London, 1868); Hemachandra, *Grammatik der Prâkrit Sprachen*, ed. R. Pischel (Halle, 1877–80); Chaṇḍa, *Prâkrita Lakshaṇa*, ed. R. Hoernle (Calcutta, 1880).

HERMANN JACOBI.

Pram. KRISTEN HENRIKSEN: Danish poet and critic; b. in Norway of Danish parents, 1756. He was the author of a vast number of poems and plays of slight value, the best of the former being *Emilies Kilde* (Emilia's Spring). As one of the founders and editors of the critical journal *Minerva*, he exerted great and beneficial influence on public taste in the north. D. at St. Thomas, 1821. His works were edited by K. L. Rahbek (6 vols., Copenhagen, 1824–29). D. K. D.

Prase: See QUARTZ.

Pratinas (Gr. Πρατίνας) of Phlius in the Peloponnesus: Greek poet; flourished toward the end of the sixth century B. C., and is said to have introduced the satyr drama into Athens. Interesting fragments of his lyrics are given in Bergk, *Poetæ Lyrici Græci*, vol. iii., 557 foll. (4th ed.).

Prato (sometimes called *Prato in Toscana*): town; in the province of Florence, Italy; on the right bank of the Bisenzio; 11 miles N. W. of Florence (see map of Italy, ref. 4–D). It is situated in a plain surrounded by hills; has a citadel and a cathedral with frescoes by Filippo Lippi, and manufactures of cloth, paper, and straw hats; the water of the Bisenzio is largely used to work machinery. The chief domestic industry is straw-plaiting. Pop. 15,510.

Pratt, CHARLES: See CAMDEN, CHARLES PRATT, EARL OF.

Pratt, ORSON: Mormon apostle and author; b. at Hartford, Washington co., N. Y., Sept. 19, 1811; was educated in common schools in Columbia County; became a member of the Mormon Church, in which he was one of the "twelve apostles"; traveled extensively as a preacher; was also Professor of Mathematics in Deseret University, and Church historian, and was for several sessions Speaker of the Utah House of Representatives; author of *Divine Authenticity of the Book of Mormon*; *Cubic and Bi-Quadratic Equations* (London, 1866); *The Great First Cause*; *The Absurdities of Immaterialism*; and many religious pamphlets; had in MS. *Lectures on Astronomy* and *Differential Calculus*, and was engaged in the preparation of a work to be entitled *A New System of the Universe*. D. at Salt Lake City, Oct. 3, 1881.

Pratt, PARLEY PARKER: Mormon apostle; b. at Burlington, N. Y., Apr. 12, 1807; joined the Mormon Church in 1830, and was a member in 1835 of the first quorum of the twelve apostles; traveled widely in the U. S. in his efforts to make converts; visited England in 1840, where he established and edited at Manchester *The Millennial Star*; revisited England in 1846; explored parts of what is now Utah in 1847 and 1849; made a proselyting tour to the Pacific coast in 1851 and 1854; on a similar tour eastward was assassinated near Van Buren, Ark., May 13, 1857. He was the author of numerous pamphlets, and of the works *Voice of Warning and Instruction to all People* (New York, 1837); *History of the Persecutions in Missouri* (Detroit, 1839); and *Key to the Science of Theology* (Liverpool, 1854).

Pratt, ZADOCK: manufacturer; b. at Stephentown, Rensselaer co., N. Y., Oct. 30, 1790; began business 1811 as a saddler and harness-maker; located a tannery in 1824 among the Catskill Mountains on Schoharie Kill, Greene County, which became the nucleus of the town of Prattsville; was elected to Congress 1836, and again 1842; became noted for his advocacy of cheap postage; procured the establishment of the National Bureau of Statistics, and prepared the plans for the new post-office building at Washington; became colonel of militia 1823, State Senator 1830, presidential elector 1836 and 1852; was an active Democratic politician, a delegate to the Baltimore convention of 1852 and president of many industrial and benevolent institutions. D. at Bergen, N. J., Apr. 6, 1871.

Pratt Institute: an educational institution in Brooklyn, N. Y.; founded in 1887, and endowed by Charles Pratt (1830–1891), and administered by his sons, who constitute a board of trustees. Its work is on four general lines: (1) Educational, pure and simple, aiming to develop the faculties harmoniously, as in the high-school department, where art and manual training play a large part in fitting youth for life; (2) normal—the preparation of teachers; (3) technical—special training for skill in handicraft, applied science, household science, domestic art, library economy, etc.; (4) philanthropic and social—designed to exert a pronounced influence on the community for industry, thrift, self-culture, good-citizenship, etc.; illustrated in free lecture courses on social science and on art, in a savings-bank, a free library, and a "neighborship association," for Pratt Institute extension.

The departments, each administered by a director, are high school, with classes in language, history, politics, mathematics, science, drawing and manual training, and music; department of fine art, including freehand drawing and drawing from life, painting, designing, modeling, normal training, wood-carving, art needlework; of domestic art, including sewing, dressmaking, study of textiles, millinery, physical culture; of domestic science, including household economy, cookery, laundry-work, hygiene, and home nursing; of science and technology, including mechanical drawing, machine design, mathematics, mechanism, strength of materials, theory of steam-engine, trade-school work; of commerce, including phonography, typewriting, bookkeeping, and commercial arithmetic; of kindergarten, including theory and practice; of libraries, including library economy and management, a circulating department of 45,000 volumes, large reading and reference rooms, with branches; the thrift, including investments, deposits, loans; of museums, including art and industrial collections. There are classes for morning, afternoon, and evening. The average number of students is about 3,000. C. M. PRATT.

Pratz, LE PAGE, du: colonizer and explorer; b. in Holland about 1690; entered the French army in early youth; was engaged in campaigns in Germany; became a member of a French Western Land Company, which obtained the grant of a tract of land near New Orleans, La.; conducted an expedition thither 1718; made fruitless efforts at colonization; ascended the Mississippi 1720, and settled among the Natchez; explored Missouri and Arkansas rivers; was for several years treasurer of the land company at New Orleans; returned to France 1734; published a valuable *History of Louisiana* (3 vols., 1758). D. in 1775.

Prawn [M. Eng. *prane*, probably from a deriv. of Lat *perna*, mussel]: a name applied to many of the smaller long-tailed decapod crustaceans, chiefly to those of the *Palæmonidæ* and *Peneidæ*. In Europe and in the tropics they are used as food, but in the U. S., except in the Southern States, they are little used. Some of the species which inhabit the seas of warm climates reach a large size.

Praxit'eles: a Greek sculptor; head of the Attic school; b., it is thought, at Athens about 392 B. C. Of his life nothing is known; of his works we have an idea through tradition, descriptions, images on coins, copies, and fragments. His favorite material was marble, though he wrought also in bronze. The *Cnidian Venus*, celebrated in antiquity, which travelers went to Cnidus expressly to see, which King Nicomedes is said to have offered in vain to buy at the price of the whole debt of the island, we know by copies, one of the most famous being in the Vatican Museum, partly concealed by metal drapery. Another famous Venus was at Cos. The *Cupid* of the Vatican, the *Satyr* in the Capitol, the *Apollo Sauroktonos* in Florence and the Louvre, the *Narcissus* in Naples, familiar to visitors at the galleries and to lovers of art, are thought to be reproductions, replicas, or copies of works of his. One statue only is known which is certainly his own work, the famous *Hermes* at Olympia in Greece. Praxiteles has been called the sculptor of the beautiful, as Phidias was of the sublime.

Pray, Isaac Clark: journalist and actor; b. in Boston, Mass., May 15, 1813; graduated at Amherst College 1833; became a journalist at Boston and New York, and subsequently a successful theatrical manager and actor, and both in the U. S. and in England aided in the professional training of several theatrical celebrities, including Charlotte Cushman; published *Prose and Verse* (1835), *Poems* (1837), *Book of the Drama* (1851), *Memoirs of James G. Bennett* (1855); was author of several burlesques and other plays, including a tragedy, *Virginius*; edited several magazines and other periodicals, and conducted the Philadelphia *Inquirer* 1859–60. D. in New York, Nov. 28, 1869.

Revised by B. B. Vallentine.

Prayer [from O. Fr. *preiere* (> Fr. *prière*) < Lat. *preca'rius*, pertaining to prayer, deriv. of *preca'ri*, entreat, pray > O. Fr. *preier*, whence Eng. *pray*]: the communion of the soul with God. It is the necessary result of the recognition of the dependent relation of the creature to the Creator. It may be exceedingly various in form, "uttered or unexpressed," but in its most perfect form it is the expression of thought, feeling, or purpose to God in language. Such prayer will consist in adoration, thanksgiving, confession, petition, and intercession. Adoration expresses a sense of the excellence, glory, majesty, and holiness of God, and delight in his works of providence and redemption. It is the natural utterance of every heart in which there is a true love for him, which must delight in his excellences. The prayers of the Bible, specially the Psalms, are full of it. Thanksgiving recognizes with gratitude the special goodness of God, as it has been manifested in particular benefits conferred. Confession recognizes sinfulness, general or explicit, with the expression of penitence, the promise of reformation, and the request for pardon and for grace. Its language is: "Forgive us our debts as we forgive our debtors." All approach to God partakes of that original repentance by which man gives himself to God in conversion, and all prayer is the repetition of the cry of the publican (Luke xviii. 13), especially when sins have long been persisted in, and when prayer is the resumption of long neglected duty (Ezra ix. 6–15, x. 11). Petition may properly embrace our daily physical wants, "our daily bread," the general course of our life, its great affairs, our work and career, success in our efforts to perform all the ordinary and extraordinary duties of our lot and station (Romans i. 10), our special necessities also, whether in times of crisis, in sickness, and want, or in more common times (Isaiah xxxviii. 3; Matt. xxvi. 36 ff.; Heb. v. 7; Psalms xxxv., xxxviii., xl., etc.); but particularly it should include spiritual gifts of every sort, which constitute the burden of the biblical prayers (Eph. i. 16, iii. 14–19; John xvii.), and prayer for which is never denied since it is "according to the will of God" (1 John v. 14; Luke xi. 13); and it reaches its culmination in the great petition, embodying substantially all others: "Thy kingdom come, thy will be done on earth as it is in heaven." Intercession is both recommended by the example of our Lord, who completes therein his sacerdotal office (Heb. vii. 25, ix. 23–28), and commanded by the apostle (1 Tim. ii. 1), and should embrace every person and every cause with which the suppliant has a natural connection, even his enemies (Matt. v. 44).

Prayer is founded upon the belief that it constitutes a real transaction between the soul and God, leading to real and definite consequences. Its effects may be subjective, preparing the soul to receive the gifts of God, exerting a soothing, purifying, and elevating influence upon it; or objective, in the consequent communication to the soul of gifts of grace or the conferment of outward benefits. It has its *conditions*, however. The suppliant must come in the spirit of true submission and reconciliation to God, else there is no communion (Psalms lxvi. 18). Every prayer must contain implicitly or explicitly the petition "Thy will be done" (Matt. vi. 10, xxvi. 42). Hence it can not be dictation; nor the substitution in the intent of the petitioner of the will of man for that of God, which would make prayer, if it were thus answered, a calamity to the universe; nor the substitution of the wisdom of man for that of God; but it is the petition of a child, and must have the childlike spirit of a subject, and must have the loyal spirit of one who recognizes both limitations and shortcomings. Faith is also a condition (Heb. xi. 6). It lays hold of God with confidence in him, and it may at times rise into the realm of moral certainty, as was the case in the faith that wrought miracles (Matt. xxi. 22), or as when perfect obedience has brought perfect union with Christ (John xv. 7), when perfect sympathy with God brings the knowledge that petitions are in accord with his will (1 John v. 14, 15), and when the spirit inspireth the petition (Romans viii. 26). Prayer must also be offered in the name of Christ (John xiv. 13, 14, xvi. 23, 24, 26), that is, upon the ground of his person and work, and by a believer in him, pleading his intercession.

The *objections* to the possibility or the reality of prayer are mostly evacuated by the true understanding of its nature. If it be said that God is too great to answer prayer, the reply is that he may, and as it seems actually does, call man into a co-operation with him in his greatest works through prayer. The existence of general laws in the universe which, it is said, do not permit of exceptions in answer to prayers, may be so viewed as to imply that there is back of these laws no conscious Spirit, in which case the reply is the whole argument of theism. Or these laws may be viewed merely as an observed fact, so invariable as to leave no place for the supposition of their continual interruption. But if there is a personal God, the laws of the universe are modes of his operation, and not forces superior to him which he can not administer. Nor does the answer of prayer necessarily involve the suspension of laws, except in the sense that one suspends the law of gravitation when he lifts a stone. So far as man can say, every ordinary answer to prayer may be in the strictest accord with natural law. Certainly no law is violated when a widow prays for bread, and when the thought is suggested to the mind of some prosperous friend to send her just then an abundance of food. It is the "just then" which shows the hand of God; but law is not violated. Neither does the divine predetermination destroy the reality of prayer. Let all things be foreknown and foredetermined, including both my prayer and its answer; still I have a free will, and can pray or decline to pray, and hence my prayer is a real act; and the answer is just as real as if it never entered into the thought of God till I had already prayed. The whole difficulty about prayer being answered or not answered resolves itself into one of the manner in which the divine and human agencies co-operate. The objection that as a fact many prayers are not answered is met by the consideration that, if an answer is not given in the precise form in which it was put, it is because of the higher wisdom of the Giver, which was invoked in and with the petition, and by the affirmation that no true petitioner ever fails to find some form of answer to his request.

The *forms of prayer* have been quite various. The ancient Greeks offered prayers and vows together. The worshiper raised his eyes and hands toward heaven or toward the images of the gods. He stood, or if in deeper earnest he and at times all the assembly knelt. Suppliants wore garlands on their heads or necks, and carried boughs of olive or laurel twined with wool, with which they touched the knees or cheeks of the images. Libations of wine, water, or oil were poured out. The Romans covered their heads, bowed to the ground, moved completely round from right to left, as if to meet the god from whatever direction he might approach; then, with the right hand on the mouth, looked toward the east or toward the altars or images. In higher devotion they knelt or were prostrate, and laid hold on the altar. Public prayers were offered by the priest or magistrate. The Mosaic law took prayer for granted; the temple was "the house of prayer" where public prayer accompanied the sacrifices and where private prayer was offered. Those who were absent from the temple prayed toward it. The chief

hours for the duty were 9 A. M., 12 M., and 3 P. M. To these were added the beginning and end of night and the time of eating. According to the degree of his fervor, the Jew stood, bowed, knelt, or prostrated himself. Free prayers were constantly offered, though forms were used with tithe-offerings and certain blessings, but Solomon's prayer at the dedication of the temple seems to have been the beginning of a litnrgy, which at the time of Christ had developed into a set service before, during, and after the sacrifice. A similar liturgy was used in the synagogue, from which the petitions of the Lord's Prayer were probably drawn. Prayer was accompanied by almsgiving and fasting, and was made in conspicuous places, with many vain repetitions, by formalists who loved display. Among the early Christians prayer was the chief service, and was counted the main bond of unity. In their methods they followed Jewish customs largely. The pastor led the congregation, using both free prayer and forms. A strong liturgical tendency appears early in both the East and the West. Worship was first simple, then intricate, then regulated, then liturgical. Liturgies were made first by the bishops, then by the metropolitans. Early Christians knelt in ordinary prayer, but stood on the Lord's Day and from Easter to Whitsunday, in honor of Christ's resurrection. Prayer at all times and in all places was commended, though the temple and other places of meeting, the Lord's Days, occasional appointed days, morning and night, times of eating, times of success or distress, and crises of every kind were deemed peculiarly appropriate.

Pre-Adamites: men living before the time of Adam. This term has been adopted by various writers to designate the tribes or nations which they believe existed on the earth before the date assigned by the usual scriptural chronology to the appearance of Adam and Eve. Before the investigations of geologists and archæologists in the nineteenth century there was no positive reason for imputing a greater antiquity to the human race than that given in the book of Genesis. This itself was not definitely fixed, as the chronological data of the Pentateuch differ widely in the three authoritative ancient versions known as the Masoretic Hebrew text, the Septuagint (which is the early Greek translation), and the Samaritan Pentateuch. The usual date for the creation of Adam given in English works is that derived by Archbishop Usher (about 1660) from the Hebrew text, and places it 4,004 years before the birth of Christ. The calculations of William Hales (about 1810) founded upon the Septuagint assigned the creation of Adam to 5411 B. C. Still wider variations have been advanced by other competent orthodox scholars, so that it is stated in a publication by the University of Oxford (*Chronological Tables*, 1835) that "not less than 300 different dates have been assigned as the era of the creation, varying in the extremes no less than 3,000 years." The decided tendency among the ripest scholars of all Christian denominations is to regard the account of the Pentateuch, in respect to time, as symbolical, indicative of the relation of the primitive human race to their Creator, and not as an historical narration. The same is true in regard to the location of Adam's creation. It was long supposed to have been somewhere in the valley of the river Euphrates, and many attempts have been made to discover the precise spot once occupied there by the Garden of Eden; but a closer examination of the text shows that Eden lay eastward from the scene of Adam's first existence as described, and that the river Nile (Gihon) was its western boundary. From these exegetical considerations, the term "pre-Adamites" means simply those members of the human race who lived previous to the beginning of the chronological records in the book of Genesis. That there were such, and in considerable numbers, is distinctly implied by that book itself, for there would have been no necessity for placing a mark on Cain to prevent him being killed if there had been no one living but members of his own family; nor could he have built a city if there had been none to live in it. It is entirely consistent, therefore, with faith in the scriptural narrative to recognize an antiquity of the human race indefinitely greater than that attributed to it in the chronology of Archbishop Usher. The necessity of so doing became apparent when geologists and archæologists discovered in undisturbed deposits of vast antiquity the fragments of human bones and the relics of human industry. These have been exhumed in every continent, showing that at a very remote epoch man was not only living upon the earth, but had already wandered widely over its surface. The scene of his first home can only approximately be defined, and the term of his existence as a species can not from such data be established with accuracy; but in the opinion of most competent observers it must be estimated by tens of thousands of years. Furthermore, investigations on the sites of the oldest known cities of the valleys of the Nile and the Euphrates prove beyond question that several of them were founded and were the scenes of a developed civilization long antecedent to the remotest date above mentioned as that of the creation of Adam. Prof. Norman Lockyer has demonstrated from astronomic data that some of the temples of Philæ in Egypt were constructed not later than 6400 B. C.; and the explorations of Niffir in Babylonia show it to have been a city already old in age at Usher's alleged date of the creation of the world. Even in America, usually considered to have been the latest of the continents to have received its human population, relics have been found, both in the northern and southern continents, which indicate that its extensive area was at least sparsely inhabited by tribes of low culture when many animals were living which are now extinct, and when the climate and the distribution of land and water were widely different from those now prevailing. This means a lapse of many thousand years since the earliest men reached its shores.

It may be said in conclusion that the term "pre-Adamites" is no longer regarded as sufficiently accurate for the language of science. It is better to employ the phrase "prehistoric men," meaning those who lived before the recorded dates of any authentic historical narratives. This avoids the impossible effort to frame a correspondence between the scriptural account of creation, which was certainly not intended to be a treatise on geology, and the results of modern scientific research, which, upon this subject, have by no means reached harmonious conclusions among themselves.

D. G. BRINTON.

Preble, preb'l, EDWARD: naval officer; b. at Falmouth (now Portland), Me., Aug. 15, 1761; in 1777 embarked in a privateer, and in 1779 entered as midshipman in the provincial navy; was taken prisoner in New York harbor, and upon his release served as first lieutenant on board the sloop of war Winthrop, with which he remained until 1782, greatly distinguishing himself by boarding with four men an armed British brig off Castine, Me., and capturing her under fire. In 1799 he was appointed to the command of the Essex, and in 1803 he commanded the squadron sent against Tripoli. Arriving at Tangier, he concluded peaceful negotiations with the Sultan of Morocco, after which he proceeded to blockade Tripoli, which he subjected to repeated vigorous bombardments, interrupted by several sharp engagements with the Tripolitan gunboats. In Sept., 1804, having been relieved by Com. Barron, he returned home, and received the thanks of Congress and a gold medal. D. at Portland, Aug. 21, 1807.

Preble, GEORGE HENRY: naval officer; b. at Portland, Me., Feb. 25, 1816; entered the navy as a midshipman Oct. 10, 1835. Served in Florida against the Seminoles, and in the Mexican war participated in the capture of Alvarado and Tampico; was in several actions with Chinese pirates in 1854–55; commanded the Katahdin at the taking of New Orleans in 1862, and the fleet brigade in the battles of Honey Hill and De Vaux's Neck in 1864. He was promoted to the rank of rear admiral Sept. 30, 1876; retired Feb. 25, 1878. D. in Boston, Mass., Mar. 1, 1885. He was the author of *History of the American Flag* (Albany, 1872); *History of Steam Navigation* (Philadelphia, 1883); and other historical works. Revised by C. BELKNAP.

Preble, WILLIAM PITT, LL. D.: jurist; b. at York, Me., Nov. 27, 1783; graduated at Harvard College 1806; was tutor in mathematics there 1809–11; became a lawyer and a leader of the Democratic party; was U. S. district attorney 1813; settled at Portland 1818; was a leading member of the convention which formed the State constitution of Maine 1819; on the inauguration of the new State government was appointed a judge of the State Supreme Court 1820; was minister to the Netherlands 1829; held many other public offices; was the first president of the Atlantic and St. Lawrence Railroad 1847. D. at Portland, Me., Oct. 11, 1857.

Precambrian Flora: See PLANTS, FOSSIL.

Prec'edents [from Lat. *præce'dens*, pres. partic. of *præce'dere*, go before, precede; *præ*, before + *ce'dere*, go]: (1) forms of procedure, of conveyancing, and the like, which have been approved by usage or judicial authority, and therefore may be followed safely; (2) decisions of the courts which declare a rule of law susceptible of application to other cases.

Legal precedents have a place in every system of jurisprudence, but English law is peculiar in the limits and the value which it puts upon them. It confines them to the judicial decisions of actually litigated cases. The opinions of distinguished lawyers and text-writers are not precedents, and British judges frequently condemn the practice of citing such opinions even upon the argument of a cause. (*Union Bank* vs. *Munster*, 37 Chancery Division 51.) In the U. S., however, such practice is not discouraged by the courts, but the opinion of a text-writer is never treated as a precedent.

The value of a judicial precedent varies with the questions involved and with the rank of the court from which it emanates. If the question is one of procedure, and especially if it is decided without serious contest, the court will not consider itself bound by its prior decision. (*Cross* vs. *Burke*, 146 U. S. 82.) The declaration of a rule of substantive law by a court of last resort is binding on all inferior tribunals within that jurisdiction, and will not be overruled by the same court unless it is convinced that the principle laid down is erroneous and works serious hardship. The strongest argument in favor of this practice is that of convenience. It has been stated in the following terms by Chancellor Kent: "It would therefore be extremely inconvenient to the public if precedents were not duly regarded and implicitly followed. It is by the notoriety and stability of such rules that professional men can give safe advice to those who consult them, and people in general can venture with confidence to buy and trust, and to deal with each other. If judicial decisions were to be lightly disregarded, we should disturb and unsettle the great landmarks of property." This "sort of consecration," to use Sir Henry Maine's expression, which English law gives to judicial precedents, exercises a most conservative influence in legal development. At times it has conserved error and barred legal progress. This is especially notable in international law, where the rules evolved by the courts based on early precedents are frequently less enlightened and benignant than those formulated by military commanders, who are not bound by the precedents of an earlier and less humane age.

After a decision of the court of last resort has been overruled it is treated not as having been bad law, but as not having been law at all. It still concludes the parties to the case in which it was rendered, but it does not affect the rights of other parties depending on the question erroneously decided.

In the U. S. the decisions of State courts are binding precedents upon the Federal tribunals when they decide questions dependent upon local statutes or local usages of a fixed and permanent operation, such as the rights and titles to immovables, but not when they decide questions of general commercial law. *Baltimore Railway* vs. *Baugh*, 149 U. S. 368. FRANCIS M. BURDICK.

Precession of the Equinoxes [*precession* is from Lat. *præce'dere*, go before or ahead; *præ*, before + *ce'dere*, go]: a slow change in the position of the equinox among the stars, of such a nature that the pole of the equator moves around the pole of the ecliptic in a period of about 25,000 years. It was first discovered through a difference in the length of the year as determined by the passage of the sun through the equinox, and by its angular distance from a bright star. The distance of the sun from the star Spica or α Virginis was determined from time to time by Hipparchus and other ancient astronomers by measuring the distance between the sun and the moon shortly before sunset, and between the moon and star after sunset. This double measure was necessary, because the star and the sun could never be seen at the same time. At the end of a year, when the earth had made a revolution around the sun, the same distance could again be measured. By repeating the measures at an interval of one or two centuries the true time of the revolution of the earth, or the sidereal year, could thus be determined. In this way it was found by Hipparchus and Ptolemy that the length of the sidereal year was a few minutes more than 365¼ days; but the interval between two passages of the sun over the equator was found to be a few minutes less than 365¼ days. This showed the point at which the sun crossed the equator. This point was called the equinox, and was subject to a continual motion from E. toward W. among the stars. According to the ancient astronomers the motion was a degree in a hundred years, so that a complete revolution would have required 36,000 years. Modern astronomy, however, shows it to be greater, about 50·25″ in a year, and therefore a degree in about seventy-one years; but the amount varies with the obliquity of the ecliptic, and will increase for several centuries to come.

When the motion of the earth around the sun was understood, it was seen that precession meant simply a gradual change in the direction of the earth's axis. Newton showed that this change was due to the action of the sun and moon upon the slight protuberance of the earth around the equator. The effect of the moon is about twice that of the sun. Were the earth perfectly spherical, there never could be any change in the direction of its axis; but owing to the centrifugal force generated by its rotation on its axis, the equatorial parts are slightly expanded, and the figure is changed into that of a spheroid, flattened at the poles, and bulging at the equator. In consequence of this bulging, there is a certain excess of attraction upon those parts of the equator nearest the sun or moon, and a deficiency in those parts farthest from it. This slight effect causes the unceasing change which has been described. The action is somewhat analogous to that which makes a top in rapid rotation perform a slow motion round and round, so as to describe the surface of a cone. If the sun and moon were always in the plane of the earth's equator—that is, if there were no obliquity of the ecliptic—the attraction of these bodies upon the northern and southern hemispheres would be symmetrical, and there would be no such motion as has been described, and therefore no precession. The latter arises from and varies with the sun's declination. At the time of the equinoxes the sun is on the earth's equator, and farthest from it at the solstices. The result is that the force which produces precession is not a uniform one, but takes place in a series of small cycloids, two in each year. This inequality of motion is called *nutation*.

Nutation, as here described, is produced not only by the action of the sun, but also by that of the moon; but in the case of the latter action there is also another inequality due to the fact that, owing to the revolution of the moon's nodes in a period of eighteen and a half years, the action of the moon in producing precession is more powerful at some epochs than it is at others. Again the result is an inequality, having a period equal to that of the revolution of the moon's nodes. This is called *lunar nutation*. The semi-annual term produced by the sun is called *solar nutation*. In addition to these principal inequalities there are a number of minuter ones, depending on the eccentricity of the sun's orbit, and on the inclination of the lunar orbit to the ecliptic. The formulas for these terms are given in astronomical ephemerides, to which reference may be made. S. NEWCOMB.

Précieuses, prā'si-öz': name given in France in the seventeenth century to a group of women who cultivated an extreme refinement in speech and manners. They carried to excess the concern for propriety and elegance of expression and of the forms of social intercourse which, centering in the Hôtel de Rambouillet, was doing much to refine French language and society. With the *précieuses* this elegance became affectation. Such common words as mirror or chair were held vulgar; they were to be replaced by "counselor of the graces" and "convenience of conversation." For a moment the *précieuses* were conspicuous in the salons that imitated the Hôtel de Rambouillet, and even invaded that salon itself, and threatened to impose their jargon on the French language; but good sense, aided materially by the pungent satire of Molière's *Précieuses ridicules*, turned them into ridicule. Cf. Livet, *Précieux et Précieuses* (Paris, 1859); V. Cousin, *La Société française au XVII^e siècle* (2 vols., Paris, 1858). A. G. CANFIELD.

Precious Stones: mineral substances possessing such beauty and brilliancy of color, hardness, and rarity, as to fit them for use in jewelry or for ornamental purposes. Strictly speaking, the only precious stones are the diamond, ruby, sapphire, and emerald, though the term is often extended to the opal, notwithstanding its lack of hardness, and to the pearl, which is strictly an animal product.

There are other minerals hard enough to scratch quartz,

without metallic luster, but generally brilliant and beautiful, such as the chrysoberyl, alexandrite, tourmaline, spinel, zircon, andalusite, aquamarine, and topaz, which are known as semi-precious or "fancy" stones (called *pierres de fantaisie* by the French). Minerals of both these classes, especially when cut and polished, are popularly called gems, but mineralogically only the semi-precious stones are so called, while archæologically the term gem is restricted to engraved stones, such as intaglios and cameos. See GEM.

The diamond, although the hardest and the most brilliant of the precious stones, does not command the highest price unless it be of a fine red, blue, or green color, all of exceptional rarity. Fine rubies command from five to ten times the price of fine white diamonds. Emeralds rank next in value, and frequently sell for as much as or more than fine diamonds; sapphires for somewhat less; fine cat's-eyes and the alexandrite variety frequently sell for as much as sapphires. The finest Hungarian opals frequently command one-half the value of diamonds, but little increase in price with size. The New South Wales, Queensland, and Washington opals sell for less. Ruby spinels of deep ruby-like color frequently command a price nearly as great as that of the diamond. The diamond is 10 in hardness; sapphire, 8·9; chrysoberyl or cat's-eye, 8·5; spinel, 8; topaz and aquamarine, 8; emerald and zircon, 7·8; tourmaline, 7·5; garnet, agate-chalcedony, and bloodstone, 7·3; rock-crystal, smoky cairngorm, smoky quartz, amethyst, 7; turquoise and opal, 6. The beauty of the precious stones is brought out by cutting and polishing, or the correct form of cutting and the angle of the various facets. To produce the greatest brilliancy the brilliant form of cutting is the best. The most perfect brilliant cut has fifty-eight facets. To heighten the color in a stone the step, degree, or trap cutting is the best.

The terms "artificial" and "imitation" must not be confounded in speaking of gems or precious stones, the former being of the true material, but produced by art, while the latter are imitations in other materials. Nearly all gems, with the exception of the diamond, have been artificially produced, but, with the exception of the ruby, only in small examples. Rubies have been made, but the chamber of commerce of precious stones of Paris has decreed that all gems of this kind shall be sold as artificial and not as precious stones. Imitation gems comprise (1) what are known as doublets, in which the upper part of the gem is made of garnet, quartz, or other hard stone, below which is cemented glass the color of the stone to be imitated; for instance, an imitation emerald may have its top of garnet or quartz, and the back a green glass. Other kinds are (2) those which are made by heating rock-crystal and plunging it in a solution the color of the gem to be imitated; and (3) those made entirely of glass, for which purpose a brilliant glass is employed containing oxide of lead, and known as *paste* or strass. This is colored by small amounts of metallic oxides, according to the tint desired—e. g. oxide of cobalt for blue, oxide of manganese for violet, etc.

Pearls are imitated by lining tiny hollow glass beads with the scale of the bleakfish, called *essence d'orient*, and then filling them with wax. Another imitation is made by silvering beads made of mother-of-pearl. GEORGE F. KUNZ.

Precocity [from Lat. *præ'cox*, *præ'cocis*, cooked or ripened too soon; *præ*, before + *co'quere*, cook]: a rapid and abnormally early development of the mental powers, sometimes associated with a correspondingly early ripening of the functions of the body. The popular belief that precocious infants are usually destined to early decay of mental and physical powers, resulting in speedy death, idiocy, or at the best in mediocrity, is well founded, as can be established by abundant proofs; but there are exceptions to the rule. No doubt precocity is often associated with diseases of the nervous system, with scrofulous symptoms, and with rickets, but not a few instances can be adduced of precocity associated with apparently good health. There is a double relationship between ill-health and precocity. The former by restraining a child leads to habits of reading and association with older people, and thus to precocity. The latter by causing a taste for reading and indoor life tends to engender ill-health or disease. Precocious children should be restrained from following their intellectual bent, and their physical culture encouraged. Revised by W. PEPPER.

Predestination [from Lat. *prædestina're*, predestine, foreordain; *præ*, before + *destina're*, establish, determine]: in theology, the doctrine according to which God has foreordained from eternity and unchangeably whatever takes place. It was first defined and debated during the controversy between Pelagius (see PELAGIANISM) and ST. AUGUSTINE (*q. v.*). In the Roman Catholic Church the Jansenists (see JANSENISM) became the champions of predestination. It was generally adopted by the earliest Reformers, but while in the Reformed Church it received a very strict and explicit development by Calvin (see CALVINISM), to which the Arminians (see ARMINIUS AND ARMINIANISM) opposed a milder explanation, it was for some time entirely given up by the Lutheran Church until Schleiermacher revived it in a mitigated and somewhat mystical form. The doctrine is distinct from various theories of the method by which events are governed; and it is in every form intended to be totally different from the idea of fate. All the chief points of the idea will be found expanded in Forbes's *Predestination* (Edinburgh, 1878). See also MOHAMMEDANISM.

Revised by F. H. FOSTER.

Predicate (in logic): the second term in a proposition; that which is asserted or predicated of the subject. See LOGIC.

Preece, WILLIAM HENRY: electrician; b. near Caernarvon, North Wales, Feb. 15, 1834; was educated at King's College, London; received practical training in the telegraph and cable service. In 1870 he entered the service of the Post-office as divisional engineer, was appointed electrician in 1877, and chief electrician in 1892. He is the author of many important papers in electro-technics, particularly in the fields of submarine telegraphy and telephony. He is also the author (with Sir James Sivewright) of a well-known *Text-book of Telegraphy*, and (in collaboration with Julius Maier) of a volume on the telephone. Mr. Preece is a fellow of the Royal Society and a member of numerous other learned scientific associations. E. L. NICHOLS.

Pre-emption [Lat. *præ*, before + *e'mere*, *emp'tum*, buy, obtain, (in compounds) take]: the act of one belligerent in seizing upon the sea, and taking at a price, certain kinds of neutral property not strictly contraband intended for importation within the territory of his foe; a forced purchase instead of confiscation. It was a relaxation of the harshness of the doctrine of *occasional contraband*. See CONTRABAND. T. S. W.

Prefect [from Lat. *præfec'tus*, prefect; *præ*, before + *fac'tus*, made]: the title of many officers and magistrates of ancient Rome. The *præfectus urbi* was the warden of the city, and was anciently an officer of great dignity and importance, but his duties varied much at different periods, and at times were almost nominal. The prætorian prefects commanded the imperial body-guard. The *præfectus annonæ* was an extraordinary magistrate of great importance who presided over the corn-market and the distribution of public charity. In modern France a prefect is an important official, the chief of police in each department, and a kind of justice of the peace.

Prefixes: significant particles joined to the beginning of words. In the Indo-European languages the prefixes are generally adverbial or prepositional in character, and their use with nouns appears to have been originally due to a connection with verbs either in meaning or by direct derivation; thus Eng. *belief* owes its existence to *believe*. In primitive Teutonic these prepositional prefixes were accented in the nouns but unaccented in the verbs. Traces of this appear in modern German—as *ant'wort*, but *entspre'chen*; *ur'theil*, but *erthei'len*; *urlaub*, but *erlau'ben*. In English the native Teutonic prefixes are relatively few—e. g. *a-* in *arise*, *be-* in *begin*, *for-* in *forget*, *mis-* in *misdeed*, *of-* in *offspring*, *un-* (Germ. *ant-*, *ent-*) in *untie*, *un-* (: Gr. ἀ-: Lat. *in-*) in *unwise*. The Latin prefixes are the most common; some of them come with Latin words directly from the Latin, as *ab-* in *abscond*, *ad-* in *adapt*, *amb-* in *ambition*, *ante-* in *antecedent*, *bi-* in *bisect*, *circum-* in *circumvent*, *con-* in *conduct*, *contra-* in *contradict*, *de-* in *delegate*, *dis-* in *dissolve*, *ex-* in *express*, *extra-* in *extravagant*, *in-* in *invade*, *in-* (: Gr. ἀ-: Germ. *un-*) in *insane*, *inter-* in *interference*, *intro-* in *introduce*, *ob-* in *obviate*, *per-* in *pervade*, *post-* in *postpone*, *præ-* in *precept*, *pro-* in *produce*, *retro-* in *retrograde*, *se-* in *seduce*, *semi-* in *semicolon*, *sub-* in *subscribe*, *super-* in *superimpose*, *trans-* in *transpose*; others come from Latin viâ the French, as *counter-* (< Lat. *contra-*) in *counterpart*, *es-* (< Lat. *ex-*) in *escape*, *en-* (< Lat. *in-*) in *enjoin*, *enter-* (< Lat. *inter-*) in *entertain*, *par-* (< Lat. *per-*) in *pardon*, *sur-* (< Lat. *super-*) in *surface*. The Greek has

also furnished a number of important prefixes, as *anti-* in *antithesis*, *apo-* in *apology*, *cata-* in *catalogue*, *di-* in *digraph*, *dia-* in *diameter*, *en-* in *energy*, *endo-* in *endogamous*, *epi-* in *epitaph*, *exo-* in *exogamous*, *hyper-* in *hypercritical*, *hypo-* in *hypodermic*, *meta-* in *metathesis*, *para-* in *parody*, *syn-* in *synthesis*. In the strictest sense, however, none of these alien prefixes can be regarded as having acquired a position as English prefixes, unless they have proven their vitality by contributing to the formation of new words. The Greek *en-* of *enthusiasm* is only from the Greek point of view a prefix. In English it is merely a syllable of a loan-word. It shows no vitality. Contrast *anti-* in *anti-fat*, *anti-snapper*. Pregnancy: See OBSTETRICS.

Prejevalsky, Col. NICOLAI MICHAELOVITCH: See PRJEVALSKY.

Prel'ate [from Lat. *præla'tus*, preferred, or placed before; partic. of *præferre*, prefer]: a term applicable to all ecclesiastics of high rank, as well as some of the inferior dignitaries of the papal court. Prelates of the Great Mantle are the lowest in rank; those of the Small Mantle, of higher rank. In the Roman Catholic Church they have mostly the title of "monsignore."

Premium: See INSURANCE.

Premonstratensians [by analogy of Lat. *præmonstra're*, show beforehand, point out the way, from Fr. *Prémontré* < Lat. *pratum monstra'tum*, liter., shown meadow], or **Norbertines**: a religious order established at Prémontré, near Laon, in France, in 1120, by St. Norbert (1080–1134). Norbert was a relative of the Emperor Henry V., and held several rich benefices, when suddenly he was converted, and retired from the world to found a new monastic order, which followed the rule of St. Augustine and were in part canons regular. He became Archbishop of Magdeburg in 1127. The order (which had become very powerful and widespread) kept up the primitive vigor of the rule for about 120 years, but began to decline toward the end of the fifteenth century. It was divided about 1573 into two congregations, the Spanish abbeys having a stricter observance. In 1630 the whole order received the stricter rule. It is not very large, but has convents both of monks and nuns, especially in Austria, Belgium, and Holland. The habit is white. See *Hugonis Annales Ordinis P.* (Nancy, 1734); Winter, *Die Premonstratensen d. 12ten Jahrhunderts* (Berlin, 1865); and Currier, *History of Religious Orders* (New York, 1894). Revised by J. J. KEANE.

Prence, or **Prince**, THOMAS: governor of Plymouth, Mass.; b. in England in 1601: was one of the Leyden Pilgrims; arrived at Plymouth, Mass., in 1621; was one of the first settlers at Nansett or Eastham; was chosen governor in 1634, 1638, and continuously from 1657 to his death; was assistant 1635–37 and 1639–57; was distinguished for religious zeal and the promotion of education. D. at Plymouth, Mar. 29, 1673.

Prentice, GEORGE DENISON; journalist; b. at Preston, Conn., Dec. 18, 1802; graduated at Brown University 1823; was admitted to the bar in 1829; edited *The Weekly Review*, Hartford, Conn., 1828–30; from 1830 to his death was editor of the Louisville, Ky., *Journal*, which he made one of the leading Whig newspapers of the country; author of many fugitive poems and of a *Life* of Henry Clay (1831): *Prenticeana* (1859), a collection of his witticisms, has gone through several enlarged editions. D. at Louisville, Ky., Jan. 22, 1870. His *Life* has been written by G. W. Griffin, and a posthumous edition of his *Poems* was issued in 1876.
Revised by H. A. BEERS.

Prentiss, GEORGE LEWIS, D. D.: minister and professor; b. in Gorham, Me., May 12, 1816; was educated at Bowdoin College; studied theology in Halle and Berlin 1839–41; was pastor of the South Trinitarian church, New Bedford, Mass., 1845–51, of Mercer Street Presbyterian church, New York, 1851–58; traveled abroad 1858–60; in 1860 organized the Church of the Covenant in New York, of which he was pastor till 1873; since 1873 he has been Professor of Pastoral Theology, Church Polity, and Missionary Work in Union Seminary. Besides sermons, addresses, and contributions to periodicals, Dr. Prentiss has published *Memoir of Sergeant Smith Prentiss* (2 vols., New York, 1855; new edition 1879); *Discourse in Memory of Thomas Harvey Skinner, D D., LL. D.* (1871); *Our National Bane* (1877); *Life and Letters of Elizabeth Prentiss* (1882; new edition 1887); *The Union Theological Seminary* (1889); *The Agreement between Union Seminary and the General Assembly* (1891); and *The Problem of the Veto Power and How to Solve It* (1892). —His wife, ELIZABETH (*Payson*) PRENTISS (b. at Portland, Me., Oct. 26, 1818; d. at Dorset, Vt., Aug. 13, 1878), was married in 1845; published a number of very popular works, including *Little Susy's Six Birthdays* (1853); *The Flower of the Family* (1856); *Fred and Maria and Me* (1868); *Stepping Heavenward* (1869), translated into several foreign languages; *The Percys* (1870); *Aunt Jane's Hero* (1871); *Urbane and His Friends* (1874); *The Home at Greylock* (1876); and *Gentleman Jim* (1879). C. K. HOYT.

Prentiss, SEARGEANT SMITH: lawyer; b. in Portland, Me., Sept. 30, 1808; graduated at Bowdoin College 1826. He practiced law at Vicksburg, Miss., but losing much property by legal process, and partly also because he regarded that State as "disgraced and degraded" by its repudiation of its bonded debt, he removed to New Orleans in 1845, and died at Longwood, near Natchez, Miss., July 1, 1850. He was eminent as a lawyer, and still more so as an orator. In the opinion of such judges as Daniel Webster and Edward Everett he was a peer of the statesmen of the period so prolific in eloquent men. See his *Life*, by his brother, George Lewis Prentiss.

Prepositions [from Lat. *præpositio* (*præ*, before + *po'nere*, place), a translation of the Greek term *πρόθεσις*; *πρό*, before + *θεῖναι*, set, referring to the usual position of these words before the noun]: a class of words which serve the purpose of defining the relation of a noun-word to its governing word in the sentence. Thus in the sentences *he went to it*, *he went from it*, *he went for it*, the prepositions *to*, *from*, *for* set forth the relation existing between the act of *going* and the thing *it*; similarly in the case of relations between nouns or adjectives and nouns, as *the son of John*, *ready for use*. In the primitive Indo-European, which was a highly inflected language, these relations were expressed chiefly by the case-endings, and prepositions were used only where these relations were not clearly or definitely enough expressed by the case-endings. Such is also approximately the condition in the classical Greek and Latin. The group of words which afterward became prepositions were in Indo-European chiefly, and in their origin probably entirely used as preverbs—i. e. they were closely attached to the verb, and served to define more clearly the nature of the action; cf. Gr. *κατ' ἄρ' ἕζετο*, he sat down; Sanskr. *tíṣṭhā rátham ádhi tám*, step upon this car. In the last example the preverb *adhi*, upon, serves so directly to suggest the aspect of the action toward the governed object that it may be regarded as a preposition. It represents the transition from preverb to preposition. In the English, *to pass by the house*, *what were you thinking of*, it is also difficult to determine whether *by* and *of* are preverbs or prepositions—i. e. whether their connection is closer with verb or noun. The fact that *pass-by* and *think-of* can be inflected in the passive voice, *it can not be passed by*, *it must not be thought of*, points, however, to the conclusion that *pass-by* and *think-of* are compound verbs in nearly the same sense as Gr. *παραλείπειν*, or Lat. *deliberare*. BENJ. IDE WHEELER.

Preraphaelites, or **Præraphaelites**, or **Pre-Raphaelites**: a very small body of artists and lovers of fine art, called by themselves the Pre-Raphaelite Brotherhood, and formed in London in 1849; less properly, all those artists and others in England or elsewhere who executed or admired artistic work done in supposed sympathy with the aims of the brotherhood—that is, those who painted minutely and with attention to detail; those who sought an unaccustomed reality of gesture or pose in painting or sculpture; or those who took religious and mystical subjects and tried to give them new interpretations; thus the school of Cornelius was called the German Pre-Raphaelites. The name given in this way was often inappropriate and misplaced.

The Pre-Raphaelite Brotherhood, or P. R. B., consisted of Dante Gabriel Rossetti, William Michael Rossetti, William Holman Hunt, John Everett Millais, James Collinson, Frederick George Stephens, and Thomas Woolner. According to the latest writers on the subject and biographers of Rossetti, no other persons ever became members of the brotherhood. They were all very young men; Woolner and Hunt, apparently the oldest, were twenty-seven and twenty-five years of age, the Rossettis much younger. They saw in paintings of the fifteenth century a religious enthusiasm and a simplicity of artistic aim which they longed to re-

call, and they thought that Raphael's early work in Rome marked the change from that purer art to later and less single-minded designing. One of their first objects was to publish a journal, in which their ideas about fine art should be expressed in prose and verse, and embodied in etchings, and *The Germ* was begun in 1850, had its name changed to *Art and Poetry* after the second issue, and never appeared after the fourth number. This little magazine contains Thomas Woolner's poem, *My Beautiful Lady*, and several poems by Dante Rossetti and Christina Rossetti which are contained (often altered) in their collected works.

The avowed purposes of the brotherhood were the encouragement of perfect sincerity and a lofty purpose in the practice of art. Some of their rules or maxims seem now excessively strict, and even fettering, but the fine art of the day in England seemed to young and high-minded men extremely meaningless and feeble, and that of all Europe, so far as they knew it, devoid of any true purpose, and they stated their principles in a dogmatic form by way of protest and counter-action. Thus it was laid down as a principle that a figure should be painted from one and only one person serving as a model. It is evident from the pictures themselves that the painter allowed himself to impart as much of feeling to the expression of the face as he wished and could achieve. Probably, too, he felt at liberty to make stiff movements more easy, or else he did so unconsciously. The one man or woman in the costume desired, with the color and light actually seen in it, he painted just as it seemed to him. Even gesture was to be stiff and awkward if thereby it became natural and dramatic; thus in Millais's picture, taken from Keats's poem *Isabella, or the Pot of Basil*, a painting of *Isabella and Lorenzo* at the supper-table, where Isabella's brothers and their household are seated, one of the brothers reaches out his right leg with energetic kick at the hound whose head lies in Isabella's lap, and the other bites his nails and grins savagely at Lorenzo, who is speaking to Isabella tenderly and handing her fruit. There was also a disposition, like that of the recent impressionists, to paint effects of light and color, generally seen by artists only. There was also a very free use of suggestive and illustrative imagery, aiding the main purpose of the composition.

Artists not included in the original brotherhood, but who were considered Pre-Raphaelites among Englishmen of the years from 1850 and 1860, were Arthur Hughes, Ford Madox Brown, and Edward Burne-Jones. The architects most interested in the Gothic revival were also considered as more or less allied with the Pre-Raphaelites, especially Sir Thomas Woodward and William Burges, and perhaps Philip Webb. John Ruskin was looked upon as the most ardent and influential advocate of Pre-Raphaelite doctrines and practice.

Bibliography.—*The Fortnightly Review*, vol. xlix., contains Holman Hunt's paper on the brotherhood, and *The Portfolio*, new series, May, 1894, consists of a monograph on D. G. Rossetti by Frederick G. Stephens. Also see Esther Wood, *Dante Gabriel Rossetti and the Pre-Raphaelite Movement*; William Sharp, *Dante Gabriel Rossetti, a Record and a Study*; Harry Quilter, *Preferences in Art, Life, and Literature*; Ruskin's pamphlet, *Pre-Raphaelitism*, and passages in other works. The large-paper edition of the last-named work contains many photographic copies of pictures, and Mrs. Wood's book and Stephens's essay each give several illustrations. The Moxon *Tennyson's Poems* of 1856 contains several wood-cuts after designs by Rossetti, Hunt, and Millais. Russell Sturgis.

Presburg: See Pressburg.

Presbyter [= Lat. = Gr. πρεσβύτερος, elder, deriv. (liter., compar.) of πρέσβυς, old]: the title of an officer in the Christian Church, given at first on account of age, length of service, or dignity. It was a Jewish-Christian name, and came from the synagogue. In the New Testament the words "presbyter" and "bishop" are interchangeable. In each early church there was a board of presbyters. Their duties were to superintend the church order, discipline, and doctrine, to teach, preach, visit the sick, receive strangers, and preside at the meetings. They were appointed by the apostles or their representatives, or may have been elected or nominated by the people. They were ordained with prayer and the laying on of hands. See J. A. Hodge, *What is Presbyterian Law?* (Philadelphia, 1882); A. T. McGill, *Church Government* (Philadelphia, 1890). See Presbyterian Church.

Presbyterian Church [*Presbyterian* is from Gr. πρεσβύτερος, elder, and πρεσβυτέριον, a body of elders. See Presbyter]: a distinctive title descriptive of one division of the Church of God. I. *Name.*—The Greek word is used in both the Septuagint and the New Testament to designate a body of officers to whom was committed the government of the Church. In the Septuagint (e. g. Lev. iv. 14, 15) the term synagogue is used for the congregation of Israel, and "the elders (presbyters) of the synagogue" are the representatives of the whole people. In the New Testament the synagogue is a parish church, but the elders of the Jews are members of the Sanhedrin and representatives of the whole people, though possibly they are sometimes local, e. g. Luke vii. 3. In some later writings the elders are the officers of the local synagogue. The title and the duties it implies were retained under the new dispensation, as the Christian Church was the outgrowth of the Jewish. Hence the name is the key to the system.

II. *Constitution.*—The visible Church is held to be the aggregate of those who are known as the people of God. It exists in the form of organized associations. Every such association must have its official representatives; and, since an ecclesiastical organization is of necessity widespread, it must provide both for particular congregations and for the relations of these to each other. In the following description of the Presbyterian Church, as it now exists, the Presbyterian Church in the United States of America is taken as a type, though the features indicated are mainly those that are common to most Presbyterian churches. A particular congregation is generally organized by some recognized authority, but is complete in itself. It elects its own officers, who are—(1) a pastor, (2) a bench of elders, (3) a board of deacons. A pastor, once elected, is installed by the ecclesiastical body, called presbytery, with which the congregation is connected. In case no pastor is installed, an ordained minister may have charge of the congregation, subject to the oversight of the presbytery. The elders are elected by the people and "set apart" by the presiding minister or by the presbytery. To them is committed the spiritual oversight and government of the congregation. Their number is determined by the wishes of the people; it is seldom less than three or greater than twelve. The *office* is for life, but in some congregations the term of active service is limited by vote. The board of deacons is also elected by the congregation, and its members are "set apart" by solemn ceremony, as are the elders. Their duty is to care for the poor of the congregation and for such temporal interests as may be committed to them. They have no governmental control. In most parts of the U. S. there is a civil corporation, created by State law, technically differing from the ecclesiastical "congregation," though practically consisting of the same persons, which owns and manages the property, through trustees chosen for that purpose. In Scotland and in some parts of the U. S. the duties of trustees are discharged by the deacons.

Governmentally, there are in the Presbyterian body four "judicatures," styled in order the session, the presbytery, the synod, and the general assembly. The *session* consists of the bench of elders above described. Of this judicatory the pastor is *ex officio* a member and its moderator. The *presbytery* consists of all the ministers or "teaching elders" (as they are sometimes distinctively called) and one "ruling elder" from each congregation in a limited district. Each minister in that district is, if received by vote, a permanent member of the presbytery. The ruling elders act at particular meetings, being elected by the sessions for that purpose. The duties of this body are "to receive and issue appeals from church sessions, and references brought before them in an orderly manner; to examine and license candidates for the holy ministry; to ordain, install, remove, and judge ministers; to examine and approve or censure the records of church sessions; to resolve questions of doctrine or discipline seriously and reasonably proposed; to condemn erroneous opinions which injure the purity or peace of the Church; to visit particular churches for the purpose of inquiring into their state and redressing the evils that may have arisen in them; to unite or divide congregations at the request of the people, or to form or receive new congregations; and in general to order whatever pertains to the spiritual welfare of the churches under their care" (*Form of Government*). The *synod* originally consisted of all the ministers and one elder from each congregation within a larger district, which must embrace at least three presbyteries. At present, however, in some of the Presbyterian

churches, the synod is a body of delegates. It stands to the presbyteries within its bounds in the same relation in which each presbytery stands to its churches. It is empowered to receive and issue appeals from the presbyteries, to examine their records, to form or divide or unite these lower bodies, and generally to take proper oversight of presbyteries, sessions, and people under their care. The *general assembly* consists of an equal delegation of ministers and elders from each presbytery. For the proportion and the functions of this judicatory, see GENERAL ASSEMBLY.

III. *Essential Principles of Church Polity.*—Three things are essential in Presbyterian polity. First, there must be a presbyter ministry, that is, a body of ordained ministers, equal in order. In this Presbyterians agree with the other churches that hold to the parity of the ministry. They differ, on the one hand, with those who recognize other orders in the ministry (bishops or deacons, for instance), either above or below the order of elders; and, on the other hand, with those who do not set their ministers apart by ordination. Second, there must be ruling elders, distinct from ordained ministers, and co-ordinate with them in the government of the church. Properly speaking, the Presbyterian elder (presbyter) is not the ruling elder, but is the minister, though the opposite use of the term is very prevalent, leading to some confusion concerning the two offices. The setting apart of the ruling elder is often called ordination, like the setting apart of the minister, but the standards of the Presbyterian churches do not teach that the two are equivalent. Third, there is the principle of review and control by the higher judicatories. These are not, as among Congregationalists, merely advisory or arbitrating bodies, but have an actual right of jurisdiction. Connected with these three points are others of less importance. In particular the office of deacon, as above described, is quite different from the office of deacon in other churches.

IV. *Doctrines.*—A church with Presbyterian polity is Presbyterian irrespective of all questions of doctrine; but, as a matter of fact, the Presbyterian churches mainly hold to the type of theology that is called Calvinistic. Several different theological symbols are accepted among the different Presbyterian bodies. Probably those that come nearest to being typical are the Confession of Faith and the Catechisms adopted by the famous Westminster Assembly, and then by the Parliament of England and by the Church of Scotland, 1646–48. These plant themselves first of all upon the fundamental Protestant principle that the books of the Old and New Testaments were given by inspiration, and are the only infallible rule of faith and conduct. From the Scriptures they deduce a system of doctrine controlled at every point by the idea of the sovereignty of God. Human freedom and divine love are affirmed, and all deep ethical and spiritual truths and experiences are either affirmed or taken for granted, but the thing that is everywhere made conspicuous is that God controls beforehand all his creatures and all their actions. Among the principal doctrines held are: First, God in three persons, Father, Son, and Holy Ghost, these three "the same in substance, equal in power and glory." Second, man morally depraved by nature. Third, Jesus Christ an atoning Saviour. Fourth, justification by faith in the Redeemer. Fifth, regeneration and sanctification by the Holy Ghost. Sixth, eternal happiness in the other world for believers, and eternal punishment for the finally impenitent. To the articles of the "Confessions" of the different branches of the Church the officers are required to subscribe at their ordination; but the only usual requirements for membership are repentance from sin, faith in the Lord Jesus Christ, and an unreserved consecration to God. See CHRISTIANITY, CALVINISM, and the articles on the various specific religious doctrines.

V. *History.*—Presbyterians claim that their history begins even before the apostolic age; that the analogy between the constitution of the Presbyterian church and that of the Jewish church is evident, being much closer than that of flower to seed; that the synagogue had its rabbi, its bench of elders, its appeal to a higher ecclesiastical court at Jerusalem; that the Christian church, very naturally, adopted the principal ideas of that church order to which it succeeded. Further, according to their view, the congregations of the apostolic Church were organized associations of the people of God, now assuming the title of Christians. The officers of these congregations were ordained elders. Appeals went up from one body of ecclesiastical rulers to another. Ordinations to the ministry, as in the case of Timothy, were performed by the "laying on of the hands of the presbytery." The whole visible Church was regarded as one body, and the decrees of the assembled apostles and elders at Jerusalem were, when sent down to the congregations, received as authoritative. It is claimed but by few that the present order of the Presbyterian church is *precisely* that of the apostolic age; few claim a *jure divino* authority for the system; yet its principles are believed to have undergone little change. After the apostolic age presbyterian government in the Church gradually gave way to prelatical. It is claimed that there are traces of Presbyterianism in all the centuries, but, at best, they are not very distinct. Among the Culdees and other earliest Christians in different parts of Great Britain; among the Albigenses and, later, among the Vaudois or Waldenses, in France and Piedmont; among the Hussites in Bohemia and their successors the Taborites, the Bohemian Brethren, the older Moravian Brethren; among the English Lollards and other early Protestants from Wycliffe to Cranmer and Hooper, from the fourteenth century to the sixteenth—among these, and elsewhere, elements may be distinguished affiliated with Presbyterianism as it now exists, but also other elements not so affiliated. When, however, the Reformers of the sixteenth century broke with the Church of Rome, they found themselves in need of a polity by which to organize the churches of the Reformation. They looked into the New Testament for such a polity, with the pretty uniform result of finding there, each of them, some elements of what we now know as Presbyterianism; though, when it is said that "all the Reformed churches in France, Germany, Holland, Hungary, Geneva, and Scotland were thorough Presbyterians, not only in principle but also in practice," the statement is misleading if we understand by it that all these churches were at once organized into congregations, each choosing ruling elders for itself, with relations of appeal and review and control between each and a higher judicatory. The changes that actually occurred were affected by complications concerning church and state, by the retaining of ideas and usages that had prevailed under Roman supremacy, and, on the other hand, in some quarters by ideas of independency in church government that sprang up along with Presbyterian ideas. In some cases ruling elders were for a city or for a district, and not for a particular congregation. In John Calvin's church at Geneva the ruling elders were appointed not by the people, but by the civil authorities. A Presbyterian polity of some sort, however, came to be very prevalent among the churches of the Reformation. See REFORMATION, GENEVA, CALVIN, HUSS, HUSSITES, HUGUENOTS, etc.

These churches became classified as Lutheran and Reformed. Though the Lutheran churches have always retained certain elements of Presbyterianism in their polity, they are not regarded as Presbyterian churches. The distinctive symbols of the Reformed churches, on the other hand, are regarded as monuments of Presbyterian orthodoxy. This is especially true of the Gallican Confession, adopted by the first national synod of France in 1559; the Belgic Confession, written in 1561, and afterward adopted in Belgium and Holland; the Second Helvetic Confession, written by Bullinger in 1562, and afterward adopted in Switzerland, Scotland, Hungary, France, Poland, and other countries; the Heidelberg Catechism, prepared in 1562; the Canons of Dort, made for the Netherlands in 1619; and various symbols of the British churches.

At present, however, the established Reformed churches on the Continent are hardly to be counted as in sympathy with Presbyterianism. The Churches of Switzerland and of Hungary, of the Helvetic Confession, and the Church of the Netherlands come nearest to being exceptions to this rule. In different localities, more perhaps in France than elsewhere, the churches that now combine a genuine Presbyterian polity with an evangelical Calvinistic theology maintain some sort of continuity with the Reformed churches of the sixteenth century; but, in the main, these churches are relatively small, and are in an attitude of practical dissent from the established churches of the countries where they exist.

In Great Britain the case is somewhat different. The first Scottish General Assembly was organized by John Knox and others in 1560. A presbytery was formed at Wandsworth, England, in 1572, and such Englishmen as Thomas Cartwright (1535–1603) and Walter Travers advocated Presbyterian principles. In 1592 the Scottish church was formally established by act of Parliament. (See the article SCOTLAND, CHURCH OF.) Then followed the anti-Presbyterian policy of King James and King Charles and

the Covenant movements of 1638 and 1643. (See COVENANTERS and COVENANT, NATIONAL.) Meanwhile Puritanism, which at that stage was strongly Presbyterian, made great progress in England. In 1643 the Westminster Assembly of English divines, with four assessors from Scotland, was convened in London by act of Parliament. In 1647 and 1648 the various parts of the doctrinal standards framed by them were adopted by the English and Scottish Parliaments. Till the death of Cromwell the Presbyterianism thus defined was nominally (though not actually) the established religion of England. At the restoration of the Stuarts Episcopacy was re-established in both countries. On their overthrow the Presbyterian polity was restored in Scotland. In Ireland Presbyterianism appeared at the beginning of the seventeenth century, was firmly established there by the middle of the century, and has maintained itself with vicissitudes somewhat like those through which the Scottish churches have passed. On the history of Presbyterianism, in addition to articles already referred to, see HENDERSON, ALEXANDER; KNOX, JOHN; WESTMINSTER STANDARDS, etc.

VI. *Some of the existing Presbyterian Churches.*—Presbyterians in America are descended from those of every part of Europe, but in their organized churches only those of Germany, Holland, England, and Scotland are perpetuated. The Reformed Church in Germany is represented by the REFORMED CHURCH IN THE UNITED STATES (*q. v.*), popularly known as the German Reformed Church. Its standard is the Heidelberg Catechism. German immigration began as early as 1684. Churches were organized soon after, and a synod in 1747. Statistics of this and the other churches named are given at the end of this article.

The Reformed Church of the Netherlands took for its standards the Belgic Confession and the Heidelberg Catechism, and later the Canons of Dort; but, notwithstanding its abundant confessional bulwarks, it changed in doctrine and discipline, and in 1835, in protest against the alleged growing laxity, a number of ministers and people separated from it, and are now known as the Christian Reformed Church. In America the oldest church of the Presbyterian order is the daughter of the Reformed Church of Holland, the Reformed Church in America, popularly called the Dutch Reformed Church. It adopts the three standards of the Holland church, and in addition the Nicene and Athanasian creeds. Its earliest congregation was organized in New Amsterdam (now New York) in 1628. Negotiations were in progress for organic union between this church and the German Reformed Church, but the action taken in 1892 was adverse. In 1822 the Rev. Sol Froeligh and others separated from this church and formed the True Reformed Dutch Church. At one time this body had attained to some importance, but it dwindled to a few congregations, and in 1889 these were absorbed into the Christian Reformed Church of the United States. This is a branch of the church of the same name in Holland, and is a comparatively recent body. In 1882 it received a considerable accession from members of the Dutch Reformed synod of Chicago, who were dissatisfied with the refusal of that church to make Freemasonry a subject of church discipline. It now exists in the form of one synod, with nine classes, and about 100 churches, about half of its strength being in Michigan.

The changes in the British Presbyterian churches and their American progeny are more complicated. The Presbyterian churches in Scotland are the Reformed Church of Scotland, the Reformed Presbyterian Church, the Synod of United Original Seceders, the Free Church of Scotland, and the United Presbyterian Church. The origin of the Church of Scotland has already been noticed. During the interval between 1660 and 1689, and especially during the last ten years of that time, many Scotchmen, among whom Richard Cameron was prominent, abjured the sovereignty of King Charles II. and King James II. on account of their tyranny, and especially their violation of the Solemn League and Covenant. These people formed societies, and were known as Cameronians and Covenanters. At the accession of William and Mary, Presbyterianism in Scotland was restored on the basis of the old establishment of 1592, and of the Westminster standards, the Covenant not being re-enacted. For this reason many members of the societies stood aloof from the established church. In 1706 Rev. John Macmillan joined them, and in 1743 the Rev. Mr. Nairn. They then constituted the "Reformed Presbytery." This was the beginning of the Reformed Presbyterian Church of Scotland, whose members are popularly known as Covenanters, or Cameronians. About 1863 a large majority in the Scotch synod of this Church held that it was consistent with their principles so far to countenance existing political institutions as to vote for a member of Parliament. A minority thought otherwise, and a disruption took place. In 1876 the larger body joined the Free Church of Scotland. The smaller still maintains its existence.

In 1718 Edward Fisher's book, *The Marrow of Modern Divinity*, was republished in Scotland. The General Assembly of 1720 condemned the book. Twelve ministers, of whom Ebenezer Erskine was one, sent to the Assembly a representation to the effect that some of the propositions they had condemned were identical with statements in the Scriptures and in the church standards. In 1722 the Assembly rebuked them for this. They are known as Marrow Men and Representers. In 1731 the Assembly approved the calling of ministers to a congregation by the patrons and elders, without the consent of the congregation. Erskine rebuked this in two sermons preached in 1733. Being admonished for so doing, he and three others protested. They were suspended. In December of that year they organized the Associate Presbytery. In 1745 the number of congregations had increased to forty-five, and the Associate Synod was formed. Two years later a controversy culminated respecting the oath taken by the burgesses of Edinburgh and other towns, which included a profession of "the true religion presently professed within this realm." The Antiburghers held that the swearing of this oath was a sin, to be punished by excommunication, and went through the form of deposing and excommunicating Erskine and the others who held the opposite view, and who were known as Burghers. Both Burghers and Antiburghers increased rapidly, and each claimed to be the Associate Synod; but in 1788 the Antiburghers divided into four provincial synods, and from that time were called the General Associate Synod.

Meanwhile, in 1752, Thomas Gillespie was deposed by the Church of Scotland for refusing to take part in the installation of a minister whom he regarded as thrust upon an unwilling congregation. In 1761 he, with two others, formed the Relief Presbytery. This grew in time into the Relief Church, with a synod and seven presbyteries.

For more than fifty years the Burgher and Antiburgher synods grew side by side, with no intercourse between them. Then controversies arose in each in regard to the power of the civil magistrate in matters of religion. In each the more liberal party was largely in the majority, and was called New Light, while the other party was called Old Light. In 1799 the Old Light Burghers seceded, taking the name Associate Presbytery, which became in 1805 the Associate Synod, or Original Burgher Synod. In 1804 McCrie and three others (Old Lights) withdrew from the Antiburgher Synod and formed the Constitutional Associate Presbytery.

Thus, in 1820, there were in existence in Scotland five little denominations of seceders from the national church. In that year 129 of the congregations of the New Light Antiburgher Synod united with the 154 congregations of the New Light Burgher Synod, forming the United Secession Church. The remaining eight of the Antiburgher congregations united in 1827 with the Old Light Antiburghers, forming the Associate Synod of Original Seceders. In 1839 a majority of the Old Light Burgher Synod joined the Church of Scotland. The remainder, in 1842, joined the Associate Synod of Original Seceders, taking the name of United Original Seceders. A small majority of these, twenty-seven ministers in all, joined the Free Church in 1852. The remainder constitute the present synod of this name. In 1841 James Morrison, minister of the United Secession Church, was deposed for holding, *inter alia*, that the spirit strives with all the unregenerate, and that the atonement is universal; and he and others formed the EVANGELICAL UNION (*q. v.*). In 1847 the United Secession Church joined with the Relief Church, forming the United Presbyterian Church of Scotland, which thus became a large and important body.

In 1843 the FREE CHURCH OF SCOTLAND (*q. v.*) came out from the established church. The question at stake was measurably the same as in the times of Erskine, namely, the right of a congregation to choose its pastor. In 1852 and 1876 it absorbed majorities of the Original Seceders and of the Reformed Presbyterians. Negotiations for a union between the United Presbyterian and the Free churches were brought to a successful conclusion in October, 1900, when the resultant body was constituted as the United Free Church of Scotland. A small minority of the Free Church, however, deny the validity of the union, and claim that their organization is the lawful Free Church.

In England the Presbyterianism established in 1647–48 failed to take permanent root. Many of the Puritans emigrated and others conformed to the established church. Some of the Presbyterian churches lapsed from orthodoxy, but during the second half of the nineteenth century a new Presbyterianism has grown up in England. Previous to 1876 there was in England a branch of the Scottish United Presbyterian Church and an English Presbyterian church. In that year the two united, taking the name of the English body, the Presbyterian Church of England. There is also in England a synod connected with the Church of Scotland. There is a strong Welsh Church, sometimes called the Presbyterian Church in Wales, but oftener the Welsh Calvinistic Methodist Church. (See METHODISTS.) In Ireland are the Presbyterian Church in Ireland, the Reformed Presbyterian Church of Ireland, the Eastern Reformed Presbyterian Church of Ireland, and the Secession Church of Ireland. The second and fourth of these are in connection with the Scottish churches of the same names.

We have already noticed the German and Dutch Presbyterian bodies in America. Had the early Dutch ascendency been maintained, the Dutch type of Presbyterianism would perhaps have remained dominant. As affairs turned out, the mould of the principal type of Presbyterianism in the U. S. was formed by the fusion of English Puritans with people from the churches of Scotland and Ireland. Into this mould Presbyterians of other types became assimilated, among these very prominently the French Huguenots. Into this main body were absorbed a large proportion even of the German and Dutch Presbyterians, and, probably, a majority of the immigrants who belonged to the Reformed Presbyterian and the Secession churches of Scotland. Many of these last, however, adhered to their old-country preferences and organized churches of their own, and we will briefly follow their history before taking up that of the larger bodies.

The Seceders (Antiburghers mainly) organized the Associate Presbytery of Pennsylvania about 1753 and that of New York in 1776. The Covenanters organized a Reformed Presbytery in 1774. In 1782 the three presbyteries united, forming the Associate Reformed Synod of North America; but some members of each body refused to go into the union, and before 1800 an additional body had been organized, so that the century opened with four of these organizations—an Associate Presbytery or Presbyteries, a Reformed Presbytery, an Associate Reformed Synod, and the Reformed Dissenting Presbytery. Of the last there seems to be no further trace.

The Reformed Presbyterians organized a synod in 1809 and a general synod in 1823. In 1833 a division occurred similar to that which came thirty years later in Scotland, the New Light party holding that it was right to vote and hold office under the Government of the U. S., and the Old Light party holding the contrary. This caused a division. The New Light body has ever since been known as the Reformed Presbyterian Church in North America (General Synod). The other is the Reformed Presbyterian Church in the United States of America (Synod). In 1840 the Reformed Presbyterian Covenanted Church withdrew from the Synod on account of the alleged lack of strictness in that body. In 1883 the Reformed Presbyterian Church in the United States and Canada was formed by separation from the General Synod.

The Associate Presbyterians in 1801 organized the Associate Synod of North America, otherwise known as the Associate Church of North America. In 1858 the number of congregations had become nearly 300. It was then merged into the UNITED PRESBYTERIAN CHURCH OF NORTH AMERICA (*q. v.*), though a small minority continued their separate existence and perpetuate the name of the Associate Church.

The Associate Reformed Presbyterians in 1802 formed a general synod, including the synods of New York, Pennsylvania, Scioto, and the Carolinas. In 1820 the Synod of Scioto withdrew. About the same time an unsuccessful attempt was made to unite the Associate Reformed and Reformed Dutch churches under the name of the Reformed Protestant Church of North America. In 1821 the Synod of the Carolinas became an independent body, which still exists as the Associate Reformed Synod of the South. The same year a union was made illegally between the Associate Reformed body and the General Assembly of the Presbyterian Church. In this attempt the Pennsylvania Synod was practically merged into the General Assembly. The Scioto Synod grew, became a general synod, and after several unsuccessful attempts united again with the New York Synod in 1855, forming a body of 367 congregations. This body three years later consolidated with the Associate Presbyterians into the United Presbyterian Church. There still remained, however, a separate body named the Associate Reformed Synod of New York. By 1894 all the congregations of this body save two were absorbed into other churches.

The first presbytery in the American colonies was that of Philadelphia, formed in 1705. In 1716 the Synod of Philadelphia was constituted. In 1729 it adopted the Westminster Confession of Faith. In 1745 the presbyteries of New Brunswick, New York, and a part of that of Newcastle withdrew and formed the independent Synod of New York. This was called the New Side Synod, and the old Synod of Philadelphia the Old Side. The Old Side stood aloof from Whitefield and revivals, and insisted on a full course of scholastic study for ministers; the New Side affiliated with Whitefield and judged of ministers by their qualifications and not by their scholastic studies only. The synod came together again in 1758 as the Synod of New York and Philadelphia. The Old Side ministers were in the majority at the disruption; at the reunion the New Side outnumbered them three to one.

Four ministers withdrew in 1779 and formed the Presbytery of Morris County. Three other affiliated presbyteries were formed within the next eighteen years. They were known as the Associated Presbyteries. In no very long time they were absorbed by other bodies.

In 1788 the Synod of New York and Philadelphia had increased to sixteen presbyteries. In 1789 these were distributed into four synods, and the General Assembly of the Presbyterian Church in the United States of America was organized. Very soon after, as the effect of a plan of united work with the Congregationalists of New England, the churches of the assembly multiplied greatly in the new settlements of New York and Ohio. In the first decade of the nineteenth century differences arose among the Scotch-Irish Presbyterians in the Cumberland valley, and these resulted in the formation of the CUMBERLAND PRESBYTERIAN CHURCH (*q. v.*). In the following decades arose the division into Old School and New School. The New School men were charged at the time with laxity in doctrine and discipline. This they denied, and they certainly made good their denial. As the Old School party was strong in the Southern States, the party was charged with proslavery sympathies; but it does not appear that this was true in such a sense as to affect their ecclesiastical conduct. The difference was partly a difference of race and temperament, English blood being relatively more prominent among the New School men, and Scotch-Irish blood among the Old School men. The Old School men magnified the prerogatives of church government and church office, were ambitious of power in the church courts, were very ready to bring men before church courts for trial, were impatient of any restrictions that should prevent a majority in a church court doing as it pleased. The New School men were not ambitious to distinguish themselves as ecclesiastical leaders, insisted on constitutional restrictions as limiting the power of majorities in church courts, preferred to deal with innovations rather by study and argument than by prosecution. In 1837 the Old School men, finding themselves in a majority in the General Assembly, passed a vote exscinding several of the synods in which the New School men were most numerous. The New School men denied the constitutionality of this, but accepted the situation under protest, and were soon in good working order as a church by themselves. In 1858 the Southern presbyteries of the New School church withdrew and formed the United Synod of the Presbyterian Church. In 1862 the Southern constituency of the Old School church withdrew and formed the General Assembly of the Confederate States of America, a name which at the close of the civil war was changed to the Presbyterian Church in the United States. The following year this body formed an organic union with the United Synod of the south, and a few years later incorporated the synods of Missouri and Kentucky, which had been practically exscinded by the Old School General Assembly in 1866. In 1869 the Old School and New School General Assemblies after thirty-two years of separation were reunited.

With the addition of the Welsh Calvinistic Methodist Church in the U. S. the list is substantially complete.

In Canada, Presbyterianism was planted in nearly as many different forms as in the U. S., and passed through somewhat similar stages. The several movements for union culminated in 1875, when practically all the Canadian Pres-

byterian churches were consolidated into one church bearing the name The Presbyterian Church in Canada. In Australia, New Zealand, and other British dependencies, and in South Africa, are vigorous Presbyterian bodies.

A federative assembly of the Presbyterian churches in Australia was formed in 1896; and the necessary legal steps to their union were completed in 1901, when the first United General Assembly was to meet at Sydney July 24.

VII. *Church Institutions.*—The Presbyterian churches commonly manage their missionary work, domestic and foreign, and other special forms of church work, through permanent boards or permanent committees. For example, the Presbyterian Church in the United States of America has the following organizations of this sort: The trustees of the assembly, the boards of home missions, of foreign missions, of education, of publication and Sabbath-school work, of church erection, of ministerial relief, of freedmen, of aid for colleges and academies, and the permanent committee on temperance. The other Presbyterian churches have similar arrangements. In addition, many particular synods and presbyteries are incorporated, having boards of trustees of their own, authorized to hold and use property for church purposes. The Presbyterian churches also have a large number of educational institutions. (See COLLEGE, and the names of particular institutions.) Further, they have hospitals and asylums in many parts of the earth, and also historical societies, houses of publication, clubs, family papers, reviews, etc. The Young Men's Christian Association and the Young People's Society of Christian Endeavor have been especially fruitful in their work among Presbyterians.

VIII. *Present Condition of Presbyterianism.*—The various evangelical Presbyterian churches number about 4,852,500 communicants, representing a population of about five times that number—nearly one-fifth of the Protestant population of the world. In order to give an account of the different Presbyterian bodies by name it has been necessary to describe the series of disruptions and reunions that have characterized Presbyterian history. It should be remembered that this phase has never had more than a small relative importance as compared with the Christian work done in these churches, which have always been distinguished for the number and character of their educational institutions, for the extent of their foreign missionary operations, for their liberal contributions for religious and educational purposes, and for thoughtful preaching.

As the result of a movement begun in the U. S. in 1812 to bring the Presbyterian churches into closer union, a council was held in London in July, 1815, at which a constitution for a federation to be called "The Alliance of the Reformed Churches holding the Presbyterian System" was agreed upon. The first general council of the confederation was held at Edinburgh July, 1877; and six others have been held—viz.: at Philadelphia, Sept., 1880; Belfast, June, 1884; London, July, 1888; Toronto, Sept., 1892; Glasgow, June, 1896; and Washington, Sept., 1899. The union is popularly known as the Pan-Presbyterian Council.

In the different branches of the Presbyterian church there is more or less of movement toward creed revision. Several of the British churches have adopted changes in the Westminster standards, or explanatory declarations, or both. In the largest American Presbyterian church a special committee was appointed in 1901 to consider the subject. The formulation of a creed which shall express the consensus of doctrine in all the churches of the alliance is also proposed.

IX. *Statistics.*—The following general summary of the Presbyterian and Reformed churches of the world, and the statistics for Great Britain, taken from the volume of the Washington Council of 1899, with fuller statistics for North America, will show the present condition of these bodies:

GENERAL SUMMARY.

COUNTRIES.	Congregations.	Ministers.	Communicants.
European continent	5,164	5,467	926,184
United Kingdom	5,375	5,186	1,474,225
Asia	189	255	50,726
Africa	328	214	195,028
North America	17,935	14,522	2,110,431
South America	93	61	12,986
West Indies	33	30	11,133
Australia	457	460	42,965
New Zealand	172	201	25,338
Melonesia	.....	25	3,050
Total	29,746	26,421	4,852,066

*General Assembly or General Synod reports of 1901.

A summary of Presbyterian and Reformed foreign missions, reported at the meeting of the Council of the Alliance in 1899, gave the following numbers: of European agents of all kinds, 2,098; of native agents, 4,574; of communicants, 147,135; of pupils in the schools, 158,648.

X. LITERATURE.—The literature of Presbyterianism is extensive. First. It has its place in many general historical works, particularly those that treat of religious and missionary movements in the Reformation and post-Reformation period. A valuable bibliography of this period is contained in Fisher's *History of the Reformation.* Second. Presbyterian statistics and other information are to be found in the census reports and other archives of the U. S. and other nations. Such material in compendious form is given in such works as *The Census of the Churches* (1894) and *The Religious Forces of the United States*, vol. i. in the American Church History Series (1893), by H. K. Carroll; *Our Country* (revised edition 1891), by Josiah Strong; *Problem of Religious Progress* (1881), by Daniel Dorchester; and *The Churches and Churchless of Scotland*, by Robert Howie. Third. Sessions, presbyteries, synods, general assemblies, and the Alliance are record-keeping bodies, and their records and archives, either in manuscript or published, are the true sources of information. The prominent churches publish their minutes annually, and some publish an additional volume of reports and documents. Collections of these are accessible in libraries. Among the publications of this kind that have an interdenominational value may be mentioned the *Scottish Church and University Almanac*, Nevin's *Presbyterian Year-book*, and the quadrennial volumes of the Alliance of the Reformed Churches. For the earliest period, see *Introduction to the Records of the General Assembly, 1646–47*, *Minutes of the General Assembly, 1644–49* (Edinburgh, 1874), and *The Westminster Assembly, its History and Standards* (London, 1883), by A. F. Mitchell; *History of the Westminster Assembly of Divines* (4th ed., revised, Edinburgh, 1878), by W. M. Hetherington; and *Documentary History of the Westminster Assembly* (*Presbyterian Review*, Jan., 1880), by C. A. Briggs. Fourth. A unique work, of importance to those interested in the creed-revision movements of 1887–92, is the scrap-book entitled *Confessional Revision*, made by Winthrop S. Gilman, of which complete copies exist in the libraries of Union, Auburn, and Princeton Theological Seminaries. Fifth. The doctrinal position of the Presbyterians is defined in the published standards of each Church. The well-known *Confession of Faith* of the Scottish and American churches is the most prominent example. A good account may be found in *Creeds of Christendom*, by Philip Schaff (5th ed. 1890). Of Presbyterian theological works the following are a few among many: *History of Christian Doctrines* (1889) and *Dogmatic Theology* (2d ed. 1889), by W. G. T. Shedd; *Christian Dogmatics* (1887), by J. J. Van Oosterzee; *Systematic Theology* (1873), by C. Hodge; *Outlines of Theology* (1862, and later editions), by A. A. Hodge; *Sys-*

tem of Christian Theology (4th ed. 1890), by H. B. Smith; *Present Day Theology* (1893), by L. F. Stearns; *Systematic Theology* (Nashville, 1870), by R. Beard; *The Doctrine of the Covenants in Reformed Theology* (1891), by G. Vos; and *The Institutes of the Christian Religion* (1891–95), by E. V. Gerhart. Sixth. Works on Church polity: *The Books of Discipline* of the several churches; *The Law of Creeds in Scotland* (1867), by A. T. Innes; MacPherson's *Presbyterianism* (Scottish); Levi's *Digest of the Presbyterian Church of England*; *Digest of Deliverances in the United Presbyterian Church*, by A. G. Wallace; *Assembly Digest*, by S. J. Baird (1856, rev. ed. 1858); *The Presbyterian Digest of 1886*, by W. E. Moore; *Digest of the Presbyterian Church (South) to 1887*, by W. A. Alexander; *Manual of Church Polity* (1878), by S. M. Hopkins; *What is Presbyterian Law?* (1884), by J. A. Hodge; *Relations of Civil Law to Church Polity* (1875), by Justice William Strong; and *Manual of Law and Usage* (1888), by B. F. Bittinger. Eighth. Works on the history of Presbyterianism: Knox's *History of the Reformation in Scotland*; Burton's *History of Scotland*; McCrie's *Vindication of the Scottish Covenanters*; *History of the Puritans*, by Stowell, Hetherington, and Neal; Plumley's *The Presbyterian Church throughout the World* (1875); Stoughton's *History of Religions in England* (1884); and Blaekie's *History of Presbyterianism in New England* (1881). Church of Scotland: The histories of Calderwood, Spotiswood, Row, and Woodrow, among the older authorities; those of Hetherington (1853), Stanley (1872), Walker (1882), Moffat (1884), P. M. Muir (1893); and *St. Giles Lectures*, first series (1881). Reformed Church in the U. S.: *Tercentenary Monument, Chambersburg* (1863); *History of the Reformed Church*, by L. Mayer (1851), by E. V. Gerhart (1863), by J. H. Dubbs, in American Church History Series, vol. vii. (1895), and *Historic Manual* (1885), by J. H. Dubbs. Reformed Church in America: *Manual* (3d ed. 1879), *Centennial Discourses* (1876), *Centennial Volume of the New Brunswick Seminary* (1884), and *The Reformed Church in America* in the American Church History Series, vol. vii. (1895), by E. T. Corwin; *History of Rutgers College* (1879), by T. S. Doolittle; *The Huguenots on the Hackensack* (1886) and *The Reformed Church in America* (1856; 3d ed. 1889), by D. D. Demarest. Reformed Presbyterian Church of Scotland: Naismith's *Historical Sketch* (1887). United Presbyterian Church of Scotland: M'Kerrow's *History of the United Secession Church* (1841); Struther's *History of the Relief Church* (1843); and Mackelvie's *Annals and Statutes of the United Presbyterian Church* (1873). Free Church of Scotland: Hanna's *Life of Dr. Chalmers*; Rainy's *Life of William Cunningham*; Walker's *Life of Buchanan*; Buchanan's *Ten Years' Conflict* (1849); Bryce's *Ten Years of the Church of Scotland* (1859); *Our Church Heritage* (1874), *Religious History of Scotland* (1882), and *Scottish Church History* (1880), by N. L. Walker; *The Free Church of Scotland* (1893), by Peter Bayne; and (in one volume) *Scotland's Free Church*, by G. B. Ryley, with the *Summary of Free Church Progress*, by J. M. McCandlish (1893). Presbyterian Church of England: T. McCrie's *Annals of the English Presbytery from the Earliest Period to the Present Time* (1872); Skeats's *History of Free Churches in England, A. D. 1688–1851* (1869); Drysdale's *The Presbyterians in England* (1889); Black's *Presbyterianism in England in the Eighteenth and Nineteenth Centuries*; and D. Fraser's *Presbyterian Church in England* (1892). Welsh Calvinistic Church: *Encyclopædia Cambrensis* (10 vols., in Welsh, Denbigh, 1882). Presbyterian Church in Ireland: *Ecclesiastical History of Ireland* (1875), by W. D. Killen; *The Presbyterian Church in Ireland*, by P. Adair (1866), by J. S. Reid (1867), and by W. Cleland (1892). Reformed Presbyterian: Glasgow's *History of the Reformed Presbyterian Church*; *Reformation Principles as Testimony*. United Presbyterian Church: *United Presbyterianism* (2d ed. 1883), by W. J. Reid; *The United Presbyterian Church*, by A. G. Wallace, in Hay's *Presbyterians* (1892), and by J. B. Scouller, in vol. ii. of the American Church History Series (1894). Cumberland Presbyterian Church: *The Presbyterian Church in Kentucky* (1847), by R. Davidson; *The Cumberland Presbyterian Church*, by B. W. McDonnold (1888), and by R. V. Foster in vol. ii. of the American Church History Series (1894). Presbyterian Church in the United States of America: Hotchkin's *History of Western New York* (1848); *The Presbyterian Church in America* (1857), by R. Webster; *Sketch of Presbyterianism in Central New York* (1877), by P. H. Fowler; *History of the Division in the Presbyterian Church* (1852), by G. N. Judd; Brown's *Historical Vindication of the Abrogation of the Plan of Union* (1855); *History of the New School* (1868), by S. J. Baird; *Presbyterian Reunion* (1870); *Centennial Historical Discourses* 1876); *Historical Almanac* (10 vols., 1858–68), by T. M. Wilson; *Constitutional History of the Presbyterian Church* (1840), by C. Hodge; *The Presbyterian Church* (revised ed. 1873), by E. H. Gillett; *Presbyterians* (1892), by G. P. Hays; *American Presbyterianism* (1885), by C. A. Briggs; and *Presbyterians*, by R. E. Thompson, in the American Church History Series, vol. vi. (1895). Presbyterian Church in the U. S.: Howe's *Presbyterian Church in South Carolina* (vol. i., 1870; vol. ii., 1883); *James H. Thornwell's Collected Writings* (Richmond, 1881–86), his *Life and Letters* (1875), by B. M. Palmer; and *The Southern Presbyterian Church*, by T. C. Johnson, in vol. ii. of the American Church History Series (1894). Welsh Calvinistic Methodist: *Welsh Methodism* (in Welsh, 3 vols., Wrexham, Wales, 1850-56), by J. Hughes; *The Welsh Calvinistic Methodists* (Rome, N. Y., 1854), by W. Roland; *Welsh Calvinistic Methodism* (London, 1872), by W. Williams; and *The Welsh in America* (in Welsh, 1872), by R. D. Thomas. The Presbyterian Church in Canada: *History of the Presbyterian Church in Canada*, by G. Bryce (1875), by W. Cleland (1890), by W. Gregg (1890); and *Short History of the Presbyterian Church in Canada from the Earliest to the Present Times* (1892), by W. Gregg.

Revised by W. J. Beecher and William H. Larrabee.

Prescott, William: soldier; b. at Groton, Mass., Feb. 20, 1726; served in the expeditions against Cape Breton (1754) and Acadia (1756), attaining the rank of captain; became a farmer in the town of Pepperell, where he inherited a considerable landed estate; commanded a regiment of minutemen 1775; took part in the battle of Lexington, and commanded in that of Bunker Hill (according to the usual account); resigned from the army 1777, but took part as a volunteer in the campaign against Burgoyne in the same year; and sat in the Massachusetts Legislature for several years. D. Oct. 13, 1795.

Prescott, William Hickling: historian; b. at Salem, Mass., May 4, 1796. He entered Harvard College as a sophomore in 1811. Not long after he received injuries which eventually resulted in total blindness in one eye and partial loss of sight in the other. Owing to this misfortune he was forced to employ a reader for his historical investigations, and in writing he used an ingeniously contrived frame, the "noctograph." He graduated at Harvard in 1814 with high honors in classics and literature; traveled in the Azores, England, France, and Italy 1815–17, and settled in Boston, where he was married in 1820. He chose as his special field of literary work modern Spain and the Spanish conquests in America. In the course of his researches he procured from Spain copies of a large number of valuable manuscripts. His first book, *History of the Reign of Ferdinand and Isabella* (3 vols., Boston, 1837), was the result of ten years of labor. It was recognized in Europe as the most meritorious historical work which had yet appeared in America, and was translated into French, Spanish, Italian, German, and Dutch; yet it is stated that Prescott himself, with characteristic modesty, refused to give it to the world until urged to do so by his friends. In 1843 appeared his most brilliant work, *History of the Conquest of Mexico*; it was followed by *Biographical and Critical Miscellanies* (1845); *Conquest of Peru* (1847); and *History of the Reign of Philip the Second* (3 vols., 1857–58, incomplete). In 1858 he edited Robertson's *Charles the Fifth*, with a supplement on the life of the emperor after his abdication, and he was the author of historical and critical articles in *The North American Review* and other periodicals. His relations with Irving, Motley, and Ticknor were particularly cordial, and their mutual confessions honored them all. Irving, who had begun a work on the conquest of Mexico, resigned the field to Prescott as soon as he heard that the latter had taken it up, and Prescott aided and encouraged Motley to write his *Dutch Republic*, though the subject was partly covered by his own *Philip the Second*. Prescott, like Irving, was a brilliant writer and a painstaking investigator, but his tendency to hero-worship and to picturesque coloring often produces a false impression. He himself was aware of this, and tried to counterbalance it by occasional rigid condemnation of such men as Cortés and Pizarro, but his evident sympathy and his gorgeous descriptions blind us to the cruelty and injustice of the conquer-

ors. His works are among the American classics and have had numerous editions. D. in Boston, Jan. 28, 1859. See Ticknor, *Life of W. H. Prescott* (1864), and for critical estimates Allibone's *Dictionary of Authors* and Bancroft's *Mexico*, vol. i., pp. 7, 17, 701–702. HERBERT H. SMITH.

Prescription [from Lat. *præscrip'tio*, liter., a writing before or in front of; in Roman procedure, a defense which, if proven, renders unnecessary the examination of the plaintiff's allegations, and which was therefore put at the top of the formula sent to the referee; deriv. of *præscri'bere*, write before; *præ*, before + *scribere*, write]: the conversion of an actual into a legal state of things by lapse of time. It is evident that prescription, in this sense, plays a very important part in public law. In the relations of state to state, and of class to class within the same state, power actually asserted is constantly transforming itself into right, and rights left unexercised are sooner or later lost.

In private relations, lapse of time seems to have had equally great and equally general results in early society. Originally, rights of all kinds appear to have been created by successful force and extinguished by the failure to exercise them. In civilized states, however, the law does not give prescription so wide an effect. Certain rights only are established by the exercise of the corresponding power, and certain rights only are lost by non-user. To the former category belong, regularly, rights over things. To the latter category belong certain rights *in re*, and nearly all rights of action, or claims, whether *in rem* or *in personam*. For the Roman and modern European law governing the prescriptive extinction of claims, see LIMITATION OF ACTIONS; what remains to be noted is the law governing the prescriptive establishment and extinction of rights over things.

1. *The Roman law* started with the rule that all corporeal objects capable of private ownership passed, in relatively short terms, into the ownership of the possessor; movables in one year, immovables in two years. This method of acquiring property right was called "taking by use" (*usucapio*). In the provinces, where usucaption, as an institution of the civil law, was held to be inapplicable, an analogous protection was given to the possessor of realty by the "prescription of long time." The rules of usucaption and of prescription were subjected, partly by legislation and partly by interpretation, to certain qualifications, and the two institutions were fused into one by Justinian. According to the rules laid down by him, the possessor of movables acquired ownership in three years; the possessor of immovables in ten years *inter præsentes* (i. e. when both the prior and the present possessor resided in the same province), and in twenty years *inter absentes*. In order to ripen into ownership the possession had to be "juristic" and must have been acquired *bona fide*, which regularly implied color of title. In calculating the term of possession the possessor was permitted to reckon the possession of him from whom he obtained possession (*accessio possessionis*), provided the latter also had acquired *bona fide*. Things incapable of ownership (*res extra commercium*) were, of course, incapable of prescription; also, by the rule of the Twelve Tables, things which had been stolen, and by a later enactment things of which the possession had been acquired originally by force.

This "ordinary" prescription was supplemented in the codification of Justinian by a much more sweeping *præscriptio longissimi temporis*. By virtue of this so-called "extraordinary" prescription, possession, if acquired *bona fide*, was converted into ownership whenever the previous owner's actions were lost by limitation. The period in this case was thirty or forty years.

Lesser rights over things, e. g., the servitudes or easements upon realty, were capable of being acquired by prescription in ten or twenty years.

As to the loss of rights over things by non-user, distinctions were drawn. Ownership was not lost by non-user, but only in consequence of the creation of a new adverse ownership. Real or "prædial" servitudes were extinguished by non-user whenever the exercise of the right involved positive acts on the part of its holder (as, for example, in the case of a right of way). When the servitude merely imposed upon the owner of the servient estate the duty of not doing certain things (which was regularly the case with the so-called "town servitudes") the servitude was extinguished only by "usucaption of liberty," i. e. the owner of the servient estate must do that which he was forbidden to do and must maintain this attitude of opposition for the legal period (ten or twenty years). The so-called "personal" servitudes were not extinguished by non-user.

All the shorter prescriptions of the Roman law were suspended during the minority of the true owner, and in certain other cases where he was unable to press his claim. No such suspension was recognized in the case of the prescriptions of thirty or forty years.

2. *Mediæval Developments.*—Teutonic custom recognized, as regarded immovables, no acquisition of ownership by lapse of time, but only a strengthened claim of the possessor to legal protection. This protection was given through the rules of procedure and particularly of evidence. He who had possessed for a "year and day," however vicious his original possession, had at least the advantage of the defensive position; and if his possession was based on a colorable title, like inheritance or conveyance in folk-moot, he might either ignore opposing claims or defend himself by proving, with the aid of compurgators, his possession, and by his "sole oath" the manner in which he acquired possession. This protection was obviously based rather on the extinction of opposing claims than on the acquisition of prescriptive right.

As regarded movables, Teutonic custom treated possession as ownership except in the case of things lost or stolen; but here again the protection of the possessor was based, originally, on the fact that the owner of movables who had parted with possession of his free will was allowed no action of recovery against other persons than his bailee.

The Church accepted the Roman rules of prescription, but with one important modification. The Roman law required that possession should be obtained *bona fide*, but did not demand the continuance of *bona fides*. In other words, the fact that the possessor discovered, after prescriptive possession had been established, that his title was bad, did not interfere with the completion of the prescription. The Church made such a discovery fatal to the completion of prescription (*mala fides superveniens nocet*). This rule was generally recognized and enforced by the secular courts.

3. *Modern legislations* generally recognize, in some form and to some extent, the Roman theories of prescription (Fr. *prescription*, Germ. *Ersitzung*). According to the analogy of the Roman extraordinary prescription, the European codes generally treat the extinction of the previous owner's action of recovery as establishing the ownership of the honest possessor. The Code Napoléon goes further and discards the Roman requirement of *bona fides*. The rules of ordinary prescription are substantially Roman, but in some legislations the character of the title on which prescription can be based has been modified. The Roman law permitted prescription when the possessor erroneously imagined that he had color of title; so, for example, when he acquired possession through a representative or agent and erroneously supposed that the agent had acquired by some legal method of transfer (so-called "putative" title). The Roman law, again, permitted the heir to prescribe, although his ancestor had held possession for another as bailee or lessee, etc., provided the heir was ignorant of this fact (title *pro herede*). In the latter case prescription is excluded by the French law; in the former case it is excluded by the Austrian law, which admits prescription only when the possessor has at least a color of title.

The whole doctrine, however, has lost or is losing much of its importance in modern European law, by reason of changes in the law concerning acquisition of ownership. As regards movables, the tendency is to give further protection to the honest possessor than was given as Roman law. In a large number of cases honest possession carries with it a perfect title, exception being made only in the case of lost and stolen property. The Code Napoléon, which goes furthest in the protection of the honest possessor, lays down no rules at all concerning the prescriptive acquisition of movables. The matter is regulated by treating honest possession as equivalent to ownership, except in the case of things lost or stolen, and by limiting the action for the recovery of lost or stolen things to three years.

In the German law there is a tendency to exclude prescription of realty. This tendency is due to the development of the "land-book" system (see RECORDING) and to the *publica fides* which entries in the land-book enjoy. In Prussia and in a large number of minor German states prescription is absolutely excluded as against a registered title; and in some of these states, in which registration is made

essential to title, preseription of unregistered land gives only a right to demand registration. The German draft code excludes real property from preseription.

The Austrian code, whieh does not go so far in the protection of the registered title, makes the entry in the land-book a basis for a peeuliar preseription of perfeet title without aetual possession. The person registered as owner obtains "full right" against all the world in three years.

4. *Theory.*—Preseriptive aequisition is defended on the same grounds whieh are held to justify the LIMITATION OF ACTIONS (*q. v.*). Statutes of preseription are also "statutes of rest." The wrong apparently done to him who loses his right in eonsequenee of the establishment of an adverse right disappears when it is eonsidered that he has only himself to blame, that he is the vietim of his own negligenee. An independent reason for reeognizing preseriptive aequisition is found in the faet that it not merely transforms imperfeet into perfeet titles, but that it also transforms derivative into original titles, and frees owners from the neeessity of proving the titles of their predeeessors. The former result of preseription is oeeasional, the latter is constant. This eonstant eonversion of derivative into original titles is really the most important funetion diseharged by laws of preseription; and it is beeause the same end is gained, as regards realty, by the German registration laws, and as regards movables, by the proteetion given to the honest possessor as sueh, that preseription is losing its importanee in modern European law.

IMMEMORIAL PRESCRIPTION.—Ordinary preseription and the so-ealled extraordinary preseription of thirty or forty years ereate and extinguish only eertain kinds of property rights. It is commonly asserted by European jurists that by virtue of the so-ealled "immemorial preseription" any sort of status may beeome a legal status; and that, in particular, private rights whieh ean not be established by any other sort of prescription (e. g. obligations) may be established by the faet that they have been exercised "time out of mind." Aeeording to one theory, immemorial preseription absolutely ereates rights; aeeording to another, it creates a presumption that the powers actually exercised are rightful —a presumption that can be overturned only by showing that their origin was unlawful. The doctrine is not based wholly upon the Roman law, which reeognized immemorial preseription only in a very limited class of eases (viz., rights of way, water rights, etc., *quorum memoria non extat*), but upon certain provisions of the canon law and the rules of old German eustom. The canon law, however, recognized immemorial preseription only as establishing rights of eeclesiastieal supervision, rights to tithes, and rights to eertain tolls and tributes, all of which are properly publie, not private rights; and while old German custom upheld as presumably rightful a state of things which had existed for at least two generations, provided the older members of the community had neither known nor heard of a contrary state of things, the rights thus established were either quasi-publie rights or rights capable of what the Romans called quasi-possession. Those who, nevertheless, affirm the general recognition of immemorial prescription in old German law not infrequently confuse the establishment of legal rules by immemorial eustom with the establishment of rights by preseription. The doctrine of immemorial prescription seems to have no place in modern private law. It is ignored by all the European eodes.

MUNROE SMITH.

Prescription: *English and U. S. Law.*—In the eommon-law system the term *prescription*, though borrowed from the civil law and embodying the same legal eoneeption, is used in a much narrower sense. Here it describes the aequisition by lapse of time only of those rights over the land of others whieh the Roman law described as *servitudes*—sueh as easements and profits (see EASEMENT and HEREDITAMENTS, *Incorporeal*)—and it has no referenee to the aequisition of title to lands or goods by long occupation. The theory of the eommon law as to the title to lands by *adverse possession* was that the property in the land was at once transferred by the disseisin and oeeupancy to the wrongful taker, and that the lapse of time operated not to confer any additional right upon the latter, but only to make him more seeure by depriving the former owner of his remedies against the wrongful transfer of title. (See LIMITATION OF ACTIONS, *Real Property.*) The theory of *prescription*, on the other hand, is that long and uninterrupted enjoyment of a use or profit in another's land is of itself conclusive evidence of a *right* lawfully aequired at some remote period in the past.

It is in the highest degree probable that many of these preseriptive rights go back to a time when the land over whieh they are asserted was common land, and when the use in question was merely the exercise of a eommon right, and that the private ownership of the land affeeted was imposed upon these original rights of enjoyment and was exercised in subordination to them. This is espeeially true of that extensive elass of rights known as "rights of eommon" (see HEREDITAMENTS, *Incorporeal*), as well as of those eustomary rights whieh are hereinafter deseribed. This historical view of the origin of preseriptive rights, however true in faet, eould not long withstand the feudalization of the eommon law of property. In a system under whieh all lands were held, direetly or indirectly, of the king, as lord paramount, there was no room for any theory of original ownership of lands in eommon. (See ESTATES, FEUDAL SYSTEM, and PROPERTY.) Aeeordingly a support for these preseriptive rights was found in the doetrine of a "lost grant." This doetrine was expressed in terms of a legal presumption, that uninterrupted, notorious, and adverse enjoyment of the right asserted, from time immemorial (i. e. for so long a time "that the memory of man ran not to the eontrary"), was evidenee of a grant of sueh right in the remote past by the then owner of the "servient tenement" to the aneestor or predeeessor (as the ease might be) of the person now elaiming the right. This theory of a lost grant was, of eourse, a fietion, pure and simple, and was invented in order to give a eolor of legality to the preseriptive elaim, there being in English law no eountenanee for the doetrine of the eivil law that mere persistenee for any length of time in a wrongful state of affairs converts it into a right and lawful state of affairs. Originally, however, the fietion was taken very seriously by the judges, and the question as to whether there had in faet been sueh a grant as was alleged was submitted to the jury for their determination. At a later period the doctrine took its plaee as a true presumption of law (see PRESUMPTIONS), the existenee of the grant being arbitrarily assumed by the law from the fact of use and enjoyment for the required term and under the proper conditions. It was still possible, however, to rebut this presumption by showing that such a grant as the one alleged eould in faet never have been made. This appears to be the state of the law in England at present in eases not covered by the statute hereinafter referred to. (See 3 *Harv. Law Rev.* 183.) In the U. S., however, the fictitious character of the doctrine of a lost grant has, as a general thing, been fully reeognized and evidence is not admitted to rebut the allegation. This result is commonly expressed by saying that the presumption of a grant has beeome "conclusive," but the true view of the matter would seem to be that the law no longer indulges in any presumption regarding the origin of the right in question, but arbitrarily holds that due and proper enjoyment thereof shall be eonclusive evidenee of the existenee of the right.

The length of time requisite to answer the description of "immemorial" enjoyment has varied greatly from time to time, the period of limitation of real actions (see *Real Property*, under LIMITATION OF ACTIONS) having usually been adopted by the eourts as the measure of the prescriptive term. This rule formerly required the tenant to show that his possession or enjoyment dated back to the aceession of Riehard I. (A. D. 1189), but, when the lapse of centuries rendered this an inconvenient measure of the right claimed, it was shortened by statute (32 Hen. VIII., c. 2, A. D. 1540) to sixty years, and finally to twenty years, at which it now stands in England and most of the U. S. The eourts having taken over this period of limitation as the measure of the preseriptive term, it follows that a right in the nature of an easement or profit over the land of another may now generally be aequired by enjoyment of the right for twenty years, though different periods, varying from fifteen to thirty years, have been adopted in a few of the States. A disability existing at the time the prescriptive period began to run will be allowed in computing the latter, as in the case of the limitation of aetions for the reeovery of real estate. In England the whole subject is now for the most part regulated and the length of the preseriptive term fixed by a Prescription Aet (2 and 3 Wm. IV., ch. 71, A. D. 1832), but in the U. S. the doctrine eontinues to be governed by the eommon law as above set forth.

Not all easements or rights in the nature of easements may be aequired by preseription. The use or enjoyment relied upon as the foundation of the right must be of sueh a character that it is a visible and notorious infringement

upon another's property rights. It is wholly immaterial whether the person against whom the right is claimed has actual knowledge of the infringement or not, but the acts relied upon must be of such a character that he might or should have known of them. In all cases of *positive* easement—such as rights of way, of drainage, and the like—and in all profits, the notoriety of the enjoyment is conclusively presumed; but where the easement is of the kind described as *negative*—such as lateral support, light, etc.—and where the user is unobtrusive and of such a nature that it can not be conveniently interrupted, the courts have been loath to recognize a right founded upon mere prescriptive enjoyment. As applied to the easement of light the principle has long been established in England under the name of "ancient lights," and the English courts have lately applied it to an easement of the support of one house by another (*Angus* vs. *Dalton*, 3 Q. B. D. 85; 4 Q. B. D. 162; 6 App. Cas. 740), but they have refused to extend it so as to include a right to the flow of air to a windmill or to legalize a nuisance arising from the vibration of a wall in consequence of the operation of a pestle and mortar. In the U. S. the courts have generally refused to recognize the validity of prescriptive claims to negative easements on the ground of the unsuitability of the doctrine to the conditions of life and property in a new country.

Prescriptive rights as here described should be carefully distinguished from similar rights existing by local or special custom, with which they are often confounded. In England (though not, it would seem, in the U. S.; see *Ackerman* vs. *Shelp*, 3 Halsted [N. J.] 125) all persons residing in a certain community or belonging to a certain calling may have common rights, in the nature of easements, over the land of an individual by virtue of a local custom of great antiquity. What distinguishes these customary rights from prescriptive rights proper is the fact that they attach to the persons belonging to the group in question by virtue merely of their domicile or calling, as the case may be, and that a person who has newly become a member of the community or guild in question is entitled to the right equally with all other members thereof, whereas in the case of prescription proper the person asserting the right must show that it has descended to him from his ancestors or predecessors in title, as the case may be, or at least that it has been enjoyed by himself for the prescriptive period.

In addition to the authorities cited in the course of this article, see Gale on *Easements* and Washburne on *Easements and Servitudes*. GEORGE W. KIRCHWEY.

Prescription: in international law, a founding of good title to territory which without a treaty of cession or any well-defined right has for a considerable length of time been held in possession by a state. The objections to it are (1) its indefiniteness, since no fixed limit of time exists to constitute prescriptive possession; (2) the false resemblance to the common law doctrine, inasmuch as a dispossessed state can not be bound to declare war in order to prevent prescription from running against it; (3) its frequent violation at the dictate of national policy.

In spite of such arguments, the principle of a prescriptive title to territory has obtained in international law to quiet an originally doubtful title and to remove the uncertainty which would result if ownership of territory, though wrongfully acquired, after years of uninterrupted enjoyment could be called in question. Thus Wheaton believes this doctrine to be founded upon the general consent of mankind and man's sense of its mutual utility, and that it tends to promote the general welfare.

Phillimore asserts that "the peace of the world, the highest and best interests of humanity, the fulfillment of the ends for which states exist, require that this doctrine be firmly incorporated in the code of international law."

Hall declares that "the object of prescription as between states is mainly to assist in creating a stability of international order, which is of more practical advantage than the bare possibility of an ultimate victory of right," at the same time pointing out the defects of the theory. These opinions are shared by nearly all publicists. In accordance with this principle, Poland, divided between three states under no pretext of legality, has now lost its identity, and legally belongs to them. Among the proofs of prescriptive possession may be mentioned publicity, long continued (though not necessarily immemorial) occupancy, absence of interruption, and the use of the state's resources upon the land. THEODORE S. WOOLSEY.

Prescription: a written formula for the compounding and dispensing of medicines. Previous to the nineteenth century physicians dispensed their remedies, and the prescription was chiefly a record for the guidance of an assistant, who performed the manual work, and for the preservation of valuable or standard curative combinations; but with the separation of the vocations of physician and apothecary the prescription has become the medium of communication between them, the written instructions of the former to the latter. The ingredients of a prescription are commonly designated in Latin; the nomenclature of botany and of chemistry determines the names of vegetable and mineral remedies, and their technical names are the only ones by which they can be definitely known and correctly prepared. The enumeration of the several articles is preceded by the symbol ℞, an abbreviation of Lat. *recipe* (take). This symbol has also been regarded as a modification of the sign ♃, the symbol of Jupiter, with which the ancients prefaced their prescriptions to propitiate the gods and insure a favorable action of their drugs. The several component parts of a prescription should be enumerated in the order—(1) of their chemical relation and pharmaceutical combination; (2) with reference to the object sought by each. The chief therapeutic or remedial agent should be prominent; co-operating remedies and those producing other and secondary effects, termed *adjuvantia*, receive the second position; articles intended to modify or correct the action of the preceding, termed *corrigentia*, come next; and, lastly, substances, liquid or solid, intended to secure definite quantity or consistency, to insure solubility and uniform subdivision of doses, and variously known as the *vehicle*, *excipient*, or *menstruum*. The latter term arose from the superstition of ancient chemists and alchemists that dissolvents acted best at the time of the lunar changes. The quantities of the components are expressed by symbols. The prescription terminates with the abbreviation M. of Lat. *misce* (mix). Appended to the prescription the physician usually adds instructions of the dose and time and method of taking. These are usually in Latin, which the apothecary translates and transcribes on the label of the dispensed medicine; but the custom is growing of restricting the use of Latin to the prescription proper, and stating the direction for use plainly in English.

Revised by H. A. HARE.

Presentment: in criminal law, strictly, the act of a grand jury which of its own motion and from its own knowledge, or from evidence placed before it, and without a bill of indictment, makes a written accusation charging some person or persons with the commission of some public offense. At the common law, before criminal proceeding can be instituted against the accused upon this accusation, an INDICTMENT (*q. v.*) must be framed, but in some of the U. S. this rule is modified, and a trial may be had upon the presentment. Sometimes in the U. S. grand juries make general charges of public evils or offenses for the purpose of calling the attention of the public or the proper officers to them, without intending that they shall be a basis for an indictment or information. See GRAND JURY. F. S. ALLEN.

Preservation of Food: the art of treating articles of food so as to prevent their deterioration and loss through lapse of time. Although applicable to all perishable foods, it is of especial importance in relation to fruit. The value of fruits in the diet of human beings can hardly be overestimated. Their juices regulate the biliary secretions and the action of the digestive organs, and purify the blood. Grapes, peaches, strawberries, blackberries, and, pre-eminently, apples, if partaken of freely when at their ripest and best, go far toward obviating the need of cathartics and astringents.

Desiccation.—Even a partial appreciation of the nutritive, alterative, and curative properties of fruits, roots, and other vegetable edibles at an early age begot the desire to preserve them during the seasons when fresh supplies were not procurable. Succulence made them valuable, yet for a long time desiccation was the only method of preventing them from decaying into worthlessness. Dried dates, packed in bags, under powerful pressure, were as essential to the Arab in his desert wanderings as jerked buffalo, dried in the sun or smoked over the fire, was to the North American Indian. Delicious juices during this process became granulated sugar, and much of sweetness and distinctive flavor were lost. The antiseptic effect of desiccation upon flesh and fish was aided by salt, and certain fruits and green cereals were packed down in this, the saline taste being ex-

tracted by soaking in several waters before eating. Peaches, figs, apricots, limes, prunes, cherries, and grapes boiled in sirup and then desiccated were known as candied sweetmeats. They are popular still under the name of crystallized fruits. Ginger and other medicinal roots are sometimes preserved by mere desiccation, natural or artificial, or are cooked in sirup and then dried. Fruits, vegetables, meat, and fish are now dried in kilns far more rapidly and effectually than by the heat of the sun, the waste by shrinkage being reduced to a minimum, and the very form of the juice-cells remaining almost unchanged.

Method of Canning.—In canning the chief agent is heat: the object is to retain as far as practicable the natural character of the article subjected to the process, and to arrest at a given point agencies which would, in the natural course of events, cause decay. To effect this air must be absolutely excluded. The minutest flaw in the can or in the rubber padding the tightly screwed top will admit bacteria, the presence of which means putrescence. It is requisite, also, that the substance to be preserved should be made hot through and through. The heart of the fruit or vegetable, or the center of the lump of flesh or fish to be canned, must be of the same high temperature with the outside, or the germs which cause decomposition will not be destroyed.

The larger fruits are prepared for canning by paring and removing hard portions that would resist the action of heat, and decayed parts that would mar the flavor and color. As the fruit is pared it is dropped into cold water, lest it should "rust," that is, darken with exposure to the air, with consequent injury to the flavor. When ready for heating the prepared peaches, pears, or apples are packed in a kettle of clean bell-metal, of agate ironware, or of iron lined with porcelain. Sugar, in the proportion of one tablespoonful to each pound of fruit, is scattered between the layers, and the whole is brought slowly to the boiling-point. This reached, the contents of the kettle are cooked gently three minutes, to insure a thorough and even temperature. There must be no diminution of heat throughout the operation. The glass jars or tin cans designed to receive the fruit must be made hot, filled to overflowing directly from the kettle, and sealed instantly. The fruit and liquor in cooling will leave a vacuum between the cover and the contents. Were space left while the fruit is hot it would be filled with germ-laden air, and the process be imperfect. Small fruits are canned in the same way, with the omission of the prefatory paring. Vegetables of every kind are put up in accordance with the leading principles of thorough heating and hermetical sealing. When the work is done skillfully the preserved fruit is good for two years, often for ten.

Meats of various sorts, and such fleshy fish as salmon and sturgeon, are cut into neat pieces, boiled for a longer time than fruits and vegetables, and sealed hot. Chicken and tongue are sometimes cooked tender, packed into glass or metal cases, and the interstices between the pieces filled with well-seasoned meat-jelly or "aspic." This is a hot liquid when the cans are sealed, but congeals in cooling and tends to preserve the meat, while adding much to the palatableness and elegance of the dish when served. Sardines, anchovies, and other small fish are cooked in oil, pressed into tin boxes or glass jars, covered with boiling oil, and sealed. *Pâtés* and potted meats are made of well-cooked meats highly seasoned, ground into a paste, and pressed hard into cases. The surface is covered with melted butter or lard, scalding hot, and the cover is air-tight.

Somewhat similar in principle to canning is the use of dry sand, sawdust, ground cork, and desiccated earth in packing grapes, apples, and pears for long keeping—the intent in each case being exclusion of the outer air. Whenever this can be accomplished the integrity of the article to be preserved is tolerably sure. Other approved agents are tin-foil and raw cotton.

Pickles.—Almost every variety of esculent known to man is prepared and stored for table use by means of spiced vinegar. Green vegetables, liable to spoil by reason of the succulence that is their chief recommendation, must first be made firm. This is done by steeping them in strong brine for a number of days. Several times during the process the pickling substances are taken out, cleansed, and picked over, all doubtful specimens being rejected and the sound returned to freshly made brine. When sufficiently hard they are transferred to a vessel containing pure, soft water, and left thus for twenty-four hours. A kettle is lined with green vine-leaves, the cucumbers, mangoes, green peppers, melon-rind, gherkins, or whatever other articles are on hand, are packed into it with alternate layers of vine-leaves, and covered thickly with the same. Powdered alum is sprinkled between the layers and over the topmost stratum, and cold water poured in until the kettle is full, after which the contents are slowly cooked, or steamed, for a couple of hours, or until the vegetables are of a fine green. They are then thrown into ice-cold water, and lie in it for an hour or more. Finally, they are packed in a jar and scalding vinegar, highly spiced, is poured over them. The vinegar is strained off, heated, and returned to the pickles every two or three days for a fortnight. The jars are then covered and set away in the cellar or other cool place for the pickles to ripen. Thus prepared they keep good for years.

Meats and every variety of fish, oysters, clams, lobsters, shrimps, etc., are pickled by being partially cooked in clear water, and while lukewarm treated with boiling vinegar seasoned with whole spices, red pepper, and a little salt. These must be sealed boiling hot. Pickled oysters and clams, if put up in glass vessels, should be kept in a dark place, as the light darkens, and even has a tendency to decompose them.

Raw meats and fish are preserved from decomposition by plunging them into and keeping them below the surface of a solution of salt and water strong enough to float an egg. This process is technically known as corning. While it prevents decay, it hardens fiber and grain and renders the food more undigestible than when fresh. Beef and the legs and shoulders of pork are often treated with a mixture of saltpeter, sugar, and salt, rubbed well into them before they are covered with brine—treatment repeated at stated intervals for two or three weeks, until the corning or pickling is complete.

Olives, young limes, and anchovies are preserved by scalding them in salt and water, then filling the bottles in which they are packed with the same. Cucumbers, mangoes, and the like can be kept in simple brine for months, but deteriorate in tenderness and flavor.

Curing is done by suspending flesh or fish that has already undergone pickling in the smoke of smoldering wood, usually hickory or oak, and leaving it thus for an indefinite time, seldom for less than a month. A blackish crust, that tastes and smells of the creosote which is the antiseptic agent here, while it supplements the work of the brine and saltpeter, is not always proof against the invading host of bacteria and other invisible enemies. Unless hams, shoulders, and rounds are further defended by stout linen cases, which, in turn, are fortified by whitewash or paint, they can not be reckoned upon with safety. Some housewives envelop bacon in thick paper and bury it in sifted ashes. Buffalo-meat and salted fish hang all winter from the ceiling of wigwam and hut; the flitch of bacon of "ye olden time" hung in the cotter's wide-mouthed chimney. The Greenlanders and Lapps dry and then smoke reindeer venison and seal-meat. In Labrador and other regions where herring abound tens of thousands of barrels of these fish are salted, smoked, and pickled annually for the home and foreign market. The Yarmouth bloaters of England hold a high place in this class of staple provisions.

Eggs may be preserved good for two months by washing them all over with a solution of gum tragacanth and water, letting them dry in the shade, and packing them, the small ends downward, in bran, meal, flour, or salt. Another way is to arrange them, small ends downward, in a crock and cover them with lime-water. This is made by mixing a pound of lime, 2 oz. of salt, and half an ounce of saltpeter in a gallon of boiling water, stirring it until all are dissolved, and letting it get perfectly cold before it is added to the eggs. Still another more expensive method of keeping eggs is to pack them as above directed and pour over them half-congealed lard as cool as it can be and yet flow, and letting it harden about the eggs. Some housewives grease eggs with lard or oil and pack them in bran or salt.

Charcoal is a potent antiseptic. Butter may be kept sweet for a long time by fitting into the bottom of crock or firkin a linen bag of powdered charcoal. A bag of coarse charcoal is often kept in the barrel of pickled meat, and bits, wrapped in thin cloths, introduced into the inside of fish and fowl after they are cleaned, will ward off decomposition for a day or two.

Preserves.—This term is popularly applied to fruits cooked in sirup in the proportion of a pound of sugar to one of fruit. Our great-grandmothers called them "conserves," and gave them honorable place among their stored delicacies. Under the head of preserves come jams and marma-

lades, the only difference between these and the conserve proper being that less sugar is needed for jams, and that they and marmalades are stewed down to a smooth paste. In the regular preserve care is taken to retain, as far as may be, the form of the fruit. Clearness of sirup and agreeable color in the conserve are much esteemed by housewives. The process is delicate and tedious, and for some years the quicker and more economical method of canning threatened to supersede it entirely.

Fruit jellies are made by pressing and straining the juice from the pulp, boiling it clear, and adding a pound of sugar for each pint of scalding liquid, stirring the mixture over the fire until the sugar is dissolved, and filling heated glasses or china jars with it. When the jelly is cold and firm the surface is covered with tissue-paper, saturated with spirits, before metal or paper tops are fitted upon the glasses.

Alcoholic liquors are efficient agents in the preservation of fruits. A rich sirup is made in which the fruit, pared or with the skins on, is gently stewed until tender and clear; the liquor is added an instant before the kettle leaves the fire. When this preliminary stage is neglected the substance immersed in the spirits becomes tough and acrid.

Condensed Milk.—See MILK.

Extreme cold, by suspending natural processes which would induce decay, has long been recognized as a valuable accessory in preserving food. Food of every description, including the most delicate fruits, is transported from one side of the continent to the other in refrigerator-cars. Summer hotels have immense store-rooms, constructed upon the refrigerator principle, in which fish, poultry, and what is sold as "butcher's meat" may be kept for long periods. The beef killed upon the Texas plantation finds a market in New York and Boston. Adirondack trout and salmon from the Kennebec river set forth tables in New Orleans and San Francisco.

MARION HARLAND.

Preservation of Timber: the act or process of rendering timber more durable. Methods which accomplish this end are important as positive aids in arresting the progress of the exhaustion of the timber-supply. The extent to which the various practical methods of preserving timber are used depends upon the cost of timber, the nature of the structure, etc.

Decay of wood proceeds from agencies both internal and external. *Cellulose*, which constitutes the great bulk of woody tissue, is by itself an exceedingly imperishable substance, but appears, when in contact with fermenting or putrefying nitrogenous matters, to be capable of entering into decomposition like its isomers and congeners sugar and starch, forming humus-like substances, devoid of coherence. Fermentation or putrefaction can not take place in the absence of moisture, and hence perfect seasoning of the wood is a powerful preservative. This process, however, is exceedingly consumptive of time and expensive; being nugatory, moreover, in case the wood is to be exposed to moisture. It has been thought that this internal destructive agency is best antagonized by the use of chemical agents. Other internal destructive agencies arise from the eggs of insects deposited in the wood or under the bark. This may be sometimes, though not always, remedied by stripping off the bark; impregnation with agents poisonous to the developing larvæ is surer. External destroying agencies are many, and are most powerful when the wood is exposed to simultaneous action of air and moisture, which engender and foster a number of destructive processes. Under seawater, and between high and low tide, the teredo is another destructive agent. In tropical countries ants are enemies of timber structures. Contact with iron also destroys cellulose rapidly, through a slow combustion set up between the carbon of the cellulose and the oxygen of ferric oxide. A species of disintegration called DRY ROT (*q. v.*) is also caused by the action of some fungi. See also ROT.

The following are a few of the more prominent methods of treatment for rendering wood durable that have been practiced and have met with approval.

The Method of Kyan.—Impregnation with a solution of *corrosive sublimate*, bichloride of mercury. This was the first method experimented with in the U. S., and great expectations were entertained regarding it. It is founded on the known property of corrosive sublimate to form insoluble compounds with albuminoid bodies.

The Methods of Boucherie.—Impregnation with *sulphate of copper*, also with *chloride of calcium*. Sulphate of copper has much preservative power, and is cheaper and far less dangerous to handle than corrosive sublimate. It is, however, removed gradually from the wood by moisture. Chloride of calcium renders the wood fire-proof, adding also great strength and toughness. The latter substance has never been sufficiently or fairly experimented with, considering its cheapness and the enormous advantages it holds out. Dr. Boucherie was also the inventor of a method of making the preservative liquids penetrate the tree while still standing. Notches are cut in the trunk near the roots, and caoutchouc bags holding the solutions bound on. The tree sucks up the liquid through the evaporation from the leaves above.

The Method of Burnett.—A solution of *chloride of zinc*. This agent, like *corrosive sublimate*, operates by combining with the fermentable albuminoids, but is much cheaper and not noxious. For many uses burnettized timber is no doubt very valuable.

The Method of Bethell.—The impregnation of the wood with heavy oils of coal-tar, called in Great Britain "creosote oil"—in the U. S. "dead oil." This method has been largely used in Europe, and apparently with much success, even against the salt-water teredo, which other methods do not resist. The oil was forced into the pores of the timber in a strong receiver by a pressure of 13 or 14 atmospheres.

The Method of Seeley.—This is an improvement on that of Bethell. The wood is immersed in the oil—a crude carbolic acid being used, which is believed to be much more efficient than the common dead oil—in a closed tank, and the temperature raised to 300° F. The air and moisture are thus expelled from the timber, which is then suddenly introduced into a bath of *cold* carbolic acid. By this ingenious process an absolute impregnation is accomplished.

Revised by IRA REMSEN.

Preserves: See PRESERVATION OF FOOD.

President: in the U. S., the chief magistrate of the nation, chosen by a college of electors elected by the voters of the several States. The term of office is four years, after which the President may be a candidate for re-election, but custom and precedent are against electing him for a third term. The office, which was established by the Constitution of 1787, imposes upon the incumbent the obligation to see that the laws are faithfully executed, authorizes him to grant pardons and reprieves, to conclude treaties with the concurrence of the Senate, to veto unwise legislative measures, which can then be passed only by a vote of two-thirds of each house of Congress, and to appoint officers to administer the laws. He is commander-in-chief of the army and navy of the U. S., and of the militia of the several States, when called into the service of the U. S. Upon the death, removal, or resignation of the President, the Vice-President succeeds him in office. If, for any reason, both the President and the Vice-President are unable to serve, a member of the cabinet, in the following order, acts as President until the disability is removed or a President is elected: the Secretary of State, Secretary of the Treasury, Secretary of War, Attorney-General, Postmaster-General, Secretary of the Navy, Secretary of the Interior, and Secretary of Agriculture.

Presidential Electoral Commission: a board appointed during the second session of the Forty-fourth Congress of the U. S. to determine questions arising out of the presentation of two or more discordant certificates of the votes of the electoral colleges of certain States in which the election of presidential electors had been contested. The result of the election depended on the voice of three States, Florida, Louisiana, and South Carolina, in which both parties claimed the victory; and of a fourth, Oregon, in which one elector was claimed to have been elected by a minority, in consequence of a constitutional disqualification affecting one of the candidates of the majority. From Louisiana, Oregon, and South Carolina, the certificates presented were in each case twofold, and from Florida threefold. The electoral congress was so divided between the opposing parties that the choice of the Democratic electors in any one of the contested States would have given the majority to the Democrats, while the choice of the Republicans in all would give that party a majority of one. An angry controversy arose as to the constitutional mode of deciding between these competing certificates. The dispute assumed proportions which even threatened the peace of the republic. For the purpose of averting the impending danger a joint committee of fourteen members from the two houses was appointed early in Jan., 1877, to devise, if possible, some

means satisfactory to all of ascertaining the legal result of the election. The bill reported by this committee on Jan. 18 and passed by both houses in the following week provided for the creation of a tribunal to be composed of five Senators, five Representatives, and five associate justices of the Supreme Court of the U. S., four of the latter being designated by their districts in the bill itself, the fifth to be subsequently chosen by these four; to which tribunal should be referred the conflicting certificates, with the authority to ascertain the legal vote of each State in which the election was contested. The bill further provided that the decisions of such tribunal in every case should stand, unless rejected by the concurrent vote of both houses.

On Jan. 31 the commission was elected, three Republicans and two Democrats being taken by agreement from the Senate, and three Democrats and two Republicans from the House. The four justices having chosen a Republican, the relative strength of the two parties in the commission was eight Republicans to seven Democrats. When the subject had been argued by the ablest legal counsel that could be engaged on both sides, the vote in favor of the respective certificates was eight Republicans against seven Democrats, the eight Republicans voting in favor of the Republican electors in each of the contested States, thus giving to their party the majority of 185 to 184 in the electoral congress. The decision was communicated to the joint convention of the houses of Congress on Thursday, Mar. 1, and on Mar. 2 the president of the convention announced that Rutherford B. Hayes, of Ohio, had been duly elected President of the U. S. Revised by C. K. Adams.

Presidio of San Francisco: a military post in the northwest suburbs of San Francisco, Cal. It takes its name from the Spanish *presidio*, a garrison or fortress, the Spanish garrison defending San Francisco having been located near this site. The post is arranged for the accommodation of sixteen companies, but usually the garrison is much smaller. It is distant 4½ miles from the railway station in San Francisco, with which it is connected by a city railway. The reservation is large—1,540 acres—affording sites for gun and mortar batteries for harbor defense. J. M.

Presque Isle, presk'eel': town; Aroostook co., Me.; on the Aroostook river, and the Canadian Pacific Railway; 42 miles N. by W. of Houlton, the county-seat (for location, see map of Maine, ref. 3–F). The river affords abundant power for manufacturing, in which the town has large interest. There are a number of saw and grist mills, starch-factories, and machine-shops, a national bank with capital of $50,000, a trust and banking-house with capital of $50,000. Pop. (1890) 3,046; (1900) 3,804; village, 1,256.

Press: See Printing-presses.

Pressburg (Hun. *Pozsony*; Lat. *Posonium*): town; one of the finest of Hungary; on the north bank of the Danube, near the frontier of Lower Austria (see map of Austria-Hungary, ref. 5–F). It was the Hungarian capital from 1541 till 1784, when Joseph II. restored that dignity to its former possessor—Buda. It has a stately cathedral and a city-hall, begun in 1090 and 1288 respectively, an academy, museums of antiquity and natural history, and numerous other excellent educational and philanthropic institutions. Ruins of its magnificent royal castle, destroyed by fire in 1811, crown the neighboring hill 277 feet above the river. It manufactures chemicals, leather, and gold and silver ware, and carries on a large trade in grain and wine. Pop. (1890) 52,411, of whom less than a fourth are Hungarians, the majority being Germans. E. A. Grosvenor.

Pressensé, prā'sāañ'sā', Edmond (Dehault), dc, D. D.: clergyman and author; b. in Paris, Jan. 24, 1824; was educated in Paris, Lausanne, Halle, and Berlin; was pastor of the Chapelle Taitbout, Paris (Evangelical or Independent Protestant), 1847–70; received the degree of D. D. from Breslau 1869, from Montauban 1876, and from Edinburgh 1884; an eloquent and earnest preacher, his whole energies were devoted to the maintenance of the freedom of the Church from state interference and from dependence upon state aid, and to the presentation of Christianity as the means of solving the important moral and social questions of the day. After the proclamation of the republic he was elected a member of the French Assembly, and a life senator Nov. 13, 1883. Among his principal works are *Conférences sur le Christianisme dans son Application aux Questions sociales* (Paris, 1849); *Histoire des trois premiers siècles de l'Église Chrétienne* (1858–77, 6 vols.; 2d ed. 1889, *seq.*; Eng. trans. 1869–77; introduction to new edition separately trans. under title *Ancient World and Christianity*, Eng. trans. 1888); *L'Église et la Révolution française* (1864; 2d ed. 1867; Eng. trans. *The Church and the French Revolution*, London, 1869); *Jésus-Christ, son Temps, sa Vie, etc.* (1866; 7th ed. 1884; trans. into English by Annie Harwood, London, 1866; 4th ed. 1871); *Le Concile du Vatican* (1872); *Études contemporaines* (1880; Eng. trans. *Contemporary Portraits*, 1880); *Les Origines* (1882; Eng. trans. *Study of Origins*, 1883). D. in Paris, Apr. 8, 1891.
Revised by S. M. Jackson.

Pressing to Death: See Peine Forte et Dure.

Pressure-sense: the apparatus in the skin, muscles, etc., and its nervous connections, which gives sensations of weight or pressure. Such a sense, apart from touch and muscular-movement sensation, is claimed by expert investigators, and very delicate determinations have been made upon the minimum perceptible pressure, the pressure giving pain, the smallest perceptible difference of pressures, etc. See Psycho-physics and Sensation. J. M. B.

Prester John (*Priest John*): a semi-mythical character who figured largely in the geographical romances of the Middle Ages, whose true country and period are difficult to be fixed with certainty. According to general belief, there was somewhere in the interior of Asia or Africa a kingdom which had been converted from Islam to Christianity, governed by a priest-king named John, who was exceedingly anxious to open friendly intercourse with the Church of Rome. During two centuries numerous embassies were sent to Central Asia, and even to Abyssinia (1481–95), in search of the lost Christian nation, but the search proved fruitless. The origin of the legend appears to date from the Nestorian missions which in the eleventh and twelfth centuries penetrated to Karakorum in Turkestan, and converted the khan of that district, named Ung, who was overthrown and killed by Genghis Khan in 1202. He appears to have authorized the Nestorians to make in his name certain requests of the pope, and to their glowing narratives, sent to the Greek emperor and to the Kings of France and Portugal, Europe was indebted for a favorite cycle of legends which may be read in Assemani's *Bibliotheca Orientalis*. Father Rubruquis, sent by St. Louis, King of France (1253), in search of Prester John, penetrated to Karakorum. (See his interesting narrative in Purchas's *Pilgrims*.) There are extant letters from Prester John to the Greek emperor Manuel (1165) and one to him by Pope Alexander III. (1177). See G. Oppert, *Der Presbyter Johannes in Sage und Geschichte* (Berlin, 1864; 2d ed. 1870); F. Zamke, *Der Priester Johannes* (Leipzig, 1876–79, 2 parts); and note in Col. Yule's edition of the *Travels of Marco Polo* (London, 1871; 2d ed. 1875).
Revised by S. M. Jackson.

Preston: town; in Lancashire, England; on the Ribble, at the head of its estuary; 28 miles N. N. E. of Liverpool (see map of England, ref. 7–F). It is substantially built, principally of brick, at a height of about 120 feet above the river. The town-hall, designed by Sir Gilbert Scott, is a French Gothic structure with a spire. The Roman Catholic church, St. Walburge's, has the highest spire (306 feet) built in England since the Reformation. Three public parks were laid out in 1867. Preston was constituted a port in 1843, and since 1885 the channel has been deepened and a dock of 40 acres constructed. It is one of the chief seats of the Lancashire cotton industry. (See Lancashire, *Industries*). There are also iron and brass foundries, tanneries, rope-walks, glass-works, ship-building yards, engineering and machine shops, breweries, and distilleries. As capital of a district which was granted to the cathedral church of York, the place came to be known as Priests' town, afterward Preston. Near Preston, Aug. 17, 1648, Cromwell totally routed the royalists. Preston returns two members to Parliament. Pop. (1901) 120,860.

Preston, Harriet Waters: author; b. at Danvers, Mass., about 1843. She has spent much time abroad, and is known especially as a translator from French and Provençal. In 1873 she published a translation of the *Mireio* of the Provençal poet Mistral, and in 1881 a spirited rendering of Vergil's *Georgics*. She is also the author of *Aspendale* (1872); *Love in the Nineteenth Century* (1874); *Troubadours and Trouvères* (1876); *A Year in Eden* (1886); and other works. H. A. Beers.

Preston, Margaret Junkin: author; b. in Philadelphia about 1835; daughter of Rev. George Junkin, who became

in 1848, president of Washington and Lee University, and wife (1857) of Col. J. T. L. Preston, professor in the Virginia Military Institute; author of *Silver Wood, a Book of Memories* (1856); *Beechenbrook, a Rhyme of the War* (1866); *The Young Ruler's Question* (1869); *Old Songs and New* (1870); *Cartoons* (1875); *Colonial Ballads* (1887); and other writings in prose and verse, chiefly upon topics connected with the civil war. Her translation of the *Dies Iræ*, which appeared in 1855, has been highly commended. D. in Baltimore, Md., Mar. 28, 1897. Revised by H. A. Beers.

Preston, Right Rev. Thomas Scott, V. G.: prelate; b. at Hartford, Conn., July 23, 1824; graduated at Trinity College, Hartford, 1843; entered the Protestant Episcopal ministry 1846; assistant rector Church of the Ascension, New York, and later of St. Luke's; became a Roman Catholic 1849; studied at St. Joseph's Theological Seminary, Fordham, N. Y.; ordained a priest 1850; assistant at the cathedral, New York; subsequently pastor St. Mary's, Yonkers, N. Y.; appointed parish priest of St. Ann's, New York, 1861; appointed chancellor of the diocese of New York 1853, and vicar-general 1873; appointed domestic prelate in the pope's household, with title of monsignore, 1881; promoted prothonotary apostolic 1888; author of *Ark of the Covenant* (1860); *Life of St. Mary Magdalene* (1861); *Sermons for the Seasons* (1864); *Life of St. Vincent de Paul* (1866); *Christian Unity* (1866); *Purgatorian Manual* (1867); *Reason and Revelation* (1868); *Christ and the Church*, etc. D. in New York, Nov. 4, 1891. Revised by J. J. Keane.

Prestwich, Joseph, F. R. S.: geologist; b. at Clapham, London, England, Mar. 12, 1812; educated at University College, London; received medals from the Geological Society 1849, the Royal Society 1865, and the Institute of Civil Engineers for his contributions to science; has been repeatedly appointed by the Government on scientific commissions; Professor of Geology at Oxford University 1874–88; president of the Geological Society of London 1870–72; vice-president of the Royal Society 1870–71; and president of the international congress of geologists in London 1888. Prestwich's more important researches relate to Pleistocene submergences of the land and the evidences of prehistoric man. In 1886–88 he published a manual of geology in two volumes. D. at Darent Hulme, Shoreham, Kent, June 23, 1896. Revised by G. K. Gilbert.

Presum'ptions [from Lat. *præsump'tio*, a taking beforehand, a supposing beforehand, presumption: *præ*, before + *su'mere*, take]: assumptions of fact made by the law and embodied in legal rules (*presumptions of law*). The term has been involved in much ambiguity, owing, on the one hand, to its familiar use to describe mere inferences of fact (*presumptions of fact*), as well as to its employment, on the other hand, to cover a class of legal fictions whereby new rules of substantive law are introduced under the guise of assumptions of fact (*conclusive presumptions of law*).

All presumptions are originally presumptions of fact of varying weight according to the strength of the inference in a given case. The law, for its own purposes, selects certain of the strongest of these presumptions of fact, and adopts them, gives them a weight beyond that which logic and reason attach to them, and arbitrarily *assumes* that the inference is the correct one unless and until evidence is produced to prove that it is not. Here, then, we have the "presumption" proper, the "presumption of law."

Every fact which tends, however slightly, to support the fact sought to be established by evidence raises a "presumption of fact." Suppose it be required to prove that X is dead. It is proven that he has been missing for a year; that he was last seen embarking on a long voyage; that the vessel in which he embarked has never been heard from. Each of these facts, as a matter of logic and reason, suggests more or less strongly the probable fate of X. They all "raise a presumption," i. e. suggest the inference that X has lost his life by drowning. But this presumption of fact has no legal sanction. Its appeal is to logic, to the reasoning faculty, and its force is no greater in a court of law than in the forum of logic and reason outside.

But the inference from the facts proven may in a given case be so obvious or so clearly demanded by the policy of the law that it would be mischievous to leave it to be drawn by the untrustworthy reason of a jury or even of a particular judge. Hence the law, distrustful of individual judgment, prescribes in advance what inferences shall be drawn from certain facts. Thus if a man has been absent from home for seven years, and unheard of during that time, the law will not in a particular case allow the court or jury to draw the inference that he is probably alive, but arbitrarily directs the inference that he is dead. Hence we have the familiar presumption of law that seven years' unexplained absence is presumptive evidence of death.

A presumption, then, is a rule which fixes the legal value of a fact or facts in evidence, and this legal value may be exactly the same as the logical value of the fact, but is more likely to be in excess of its logical value. As, for example, there may be cases where the absence of a person for seven years would not logically demand the conclusion that he is dead, but the law draws that conclusion in all cases, nevertheless. Of course this presumption may (like all true presumptions) be rebutted by showing that the man is actually alive. The presumption has in that case performed the usual office of presumptions of law in shifting the burden of proof from the party in whose favor the presumption was drawn to the party who seeks to rebut it.

It has already been intimated that what is known as a conclusive presumption of law is not properly speaking a presumption at all, but a rule of substantive law which has in the process of legal evolution lost its inferential or presumptive character, though continuing to be expressed in terms of presumption. It is obvious that whenever a presumption becomes conclusive it can only be by discarding as immaterial the fact which is assumed. In other words, the facts in evidence now have consequences attached to them which are entirely independent of the intermediate facts "presumed" to exist. This process is well illustrated in the development of the doctrine of a "lost grant," as the foundation of rights claimed by prescription. (See Prescription.) In the present state of that doctrine, as it obtains in the U. S., at least, twenty years' enjoyment under the proper conditions of the right claimed is said to raise a "conclusive presumption" that the right had a lawful origin. But this is only a more awkward and roundabout way of saying that twenty years' enjoyment of itself confers the right claimed. The law no longer indulges in any presumptions on the subject, but it continues to veil the new rule behind the legal fiction of a presumption.

The number of presumptions of law is very large, and is constantly being augmented by the process of judicial legislation above described, as well as by direct legislative act. They play an important part in the due and orderly administration of justice, and furnish the best existing means for the modification and amelioration of the law by the process of adjudication.

See Greenleaf on *Evidence*, Best on *Evidence* (Chamberlayne's edition), and Prof. J. B. Thayer's article, *Presumptions and the Law of Evidence*, 3 *Harv. Law Rev.* 141.

George W. Kirchwey.

Pretender: a name frequently applied to the Stuart claimant to the British throne after the death of the exiled James II. The Pretenders were the son and grandson of that monarch, the lineal heirs to the throne, which they respectively attempted to recover by means of the "Jacobite" insurrections in Scotland in 1715 and 1745. See the articles James Francis Edward Stuart and Charles Edward.

Pretoria: capital of the South African Republic (now Transvaal Colony); on the Apies, a head-stream of the Limpopo; 1,040 miles by rail N. E. of Cape Town. Railways connect Pretoria with Lourenço Marques on Delagoa Bay and with Durban and Cape Town. The town lies at an elevation of 4,500 feet in a plain surrounded by hills. New public buildings, including a parliament-house, have been constructed. It was captured by Lord Roberts June 5, 1900. (See Africa.) Pop. 12,000, of whom about three-fourths are whites.

Previous Question: in parliamentary law, the question whether the main issue shall now be voted on. In the U. S. the motion is made and seconded by supporters of the issue for the purpose of shutting off further debate; they therefore, of course, vote in the affirmative on the previous question itself. In the British Parliament the previous question is brought forward and seconded by opponents of the main issue, who vote against the motion when put for the purpose of preventing the putting of the main question. See Parliamentary Law and Cloture.

Previtale, prā-vē̆e-taa'lā, Andrea: painter; b. at Bergamo, Italy, in the latter part of the fifteenth century. He probably studied under Giovanni Bellini in Venice, as his earliest known work, an altar-piece at Borgo Sant' Antonio,

bears the inscription *Andreas Bergomensis dissipulus* (*sic*) *Jo Bellini*. The altar-piece of St. John the Baptist in Sto. Spirito at Bergamo is considered his finest work. D. of the plague at Bergamo in 1528. Many of his pictures are at Bergamo. The National Gallery in London possesses a *Madonna and Child* by him. W. J. STILLMAN.

Prévost d'Exiles, prā′vō′dāg′zeel′, Abbé ANTOINE FRANÇOIS: novelist; b. at Hesdin, Artois, France, Apr. 1, 1697. After a good education he vibrated for a time between the army and the order of the Jesuits. In 1719 he entered the order of Benedictine monks of Saint-Maur, and for several years gave himself to serious study. He left the order somewhat irregularly (1727 or 1728), fled to Holland, and devoted himself to letters. His first work, *Mémoires d'un homme de qualité* (8 vols., 1728–32), revealed his gifts as a story-teller, and was very successful. He went to England in 1733, and in 1734 was permitted to return to Paris. D. Nov. 23, 1763. Among his works are *L'Histoire de M. Cléveland* (8 vols., 1732–39); *Le Doyen de Killerine* (6 vols., 1735); translations of Richardson's *Pamela* and *Clarissa*; and above all the *Histoire du chevalier des Grieux et de Manon Lescaut* (1731), one of the masterpieces of the French novel of all times. It has often been republished. His *Œuvres choisies* were published in 1783 and in 1810–16. A. G. CANFIELD.

Prévost-Paradol′, -pāā′rāā′dōl′, LUCIEN ANATOLE: author; b. in Paris, France, Aug. 8, 1829; became Professor of French Literature in Aix in 1855; was a frequent contributor to Parisian journals, and wrote *Revue de l'Histoire universelle* (1854); *Du Rôle de la Famille dans l'Éducation* (1857); *Essais* (3 vols., 1859–63); *Quelques pages d'Histoire contemporaine* (4 vols., 1862–66); and *La France nouvelle* (1868). In 1870 he went as ambassador to Washington, D. C. He arrived in July, but on Aug. 11 committed suicide.

Preyer, THIERRY WILLIAM, M. D., Ph. D.: psychologist and physiologist; b. in Manchester, England, July 4, 1841; educated in Manchester, London, Duisburg, Bonn, and at the Universities of Bonn, Berlin, Heidelberg, Vienna, and Paris; became privat docent at Bonn in 1865, Professor of Physiology at Jena in 1869, and privat docent at Berlin in 1888. His principal works are *Die Grenzen des Empfindungsvermögens und des Wollens* (Bonn, 1868); *Ueber Empfindungen* (Berlin, 1867); *Elemente der reinen Empfindungslehre* (Jena, 1877); *Die Kataplexie und der thierische Hypnotismus* (Jena, 1878); *Die Entdeckung des Hypnotismus* (Berlin, 1881); *Ueber den Farben- und Temperatursinn* (Bonn, 1881); *Ueber die Grenzen der Tonwahrnehmung* (Jena, 1876); *Akustische Untersuchungen* (Jena, 1879); *Die Seele des Kindes* (Leipzig, 1881; 3d ed. 1890); *Specielle Physiologie des Embryo* (Leipzig, 1883–84); *Elemente der allgemeinen Physiologie* (Leipzig, 1883); *Die Erklärung des Gedankenlesens* (Leipzig, 1885); *Die Bewegungen der Seesterne* (Berlin, 1887); and *Der Hypnotismus* (Vienna, 1890). D. in Wiesbaden, July 15, 1897. J. MARK BALDWIN.

Priacanth'idæ [Mod. Lat., named from *Priacan'thus*, the typical genus; Gr. πρίων, saw + ἄκανθα, spine]: a family of fishes of the sub-order *Acanthopteri*, distinguished by their very large eyes and small rough scales, which extend on the snout and jaws. Over twenty species are known from different tropical seas, in all of which some species are found. They are generally of a reddish color.

Revised by F. A. LUCAS.

Pri'am (in Gr. Πρίαμος): son of Laomedon and Strymo, and the last King of Troy. His original name was Podarces, but he received the name of Priam because he was ransomed (πρίασθαι) by his sister Hesione from Heracles. He was the husband of Hecuba, the father of Hector, Paris, Polyxena, Cassandra, Deiphobus, Helenus, Troilus, and others. During his reign fell the Trojan war, which ended with the destruction of Troy and the extinction of his race. The matchless words of the *Iliad* of Homer narrate a small portion of the events of the Trojan war. J. R. S. STERRETT.

Pribilof or **Pribyloff Islands**: a group of small volcanic islands in Bering Sea; 192 miles N. of Unalaska, 200 miles S. of St. Matthew, and about the same distance W. of Cape Newenham, on the mainland. The climate is disagreeable; but the perfect isolation of these islands, and the mist and fog which prevail, cause the fur-seal to select these grounds for the purpose of breeding. The great seal-producing island is St. Paúl, with a shore-line of 42 miles, of which 16½ miles are frequented by the fur-seals. See SEAL-FISHERIES.

Revised by G. K. GILBERT.

Price: See POLITICAL ECONOMY.

Price: town; capital of Carbon co. (organized from the northern part of Emery County in 1894), Utah; on the Price river, and the Rio Grande Western Railway; 78 miles S. E. of Provo City, 122 miles S. E. of Salt Lake City (for location, see map of Utah, ref. 5–N). It is in an agricultural, stock-raising, and mining region, is the immediate starting-point for Fort Duchesne and the Uintah and Uncompahgre Indian reservations, and is the shipping-point for a mine of remarkably pure asphaltum. The town has a church, two public schools, and a weekly newspaper. Pop. (1900) 655.

Price, BONAMY: economist; b. in the island of Guernsey, May 22, 1807; graduated at Oxford, 1829; soon afterward became assistant master at Rugby School, where he remained as teacher till 1850, and Professor of Political Economy at Oxford University 1868. Prof. Price was a distinguished representative of free-trade doctrines, which he presented to the public of the U. S. in 1874 in a series of lectures. He was the author of *The Principles of Currency* (1869); *Of Currency and Banking* (1876); *Practical Political Economy* (1878); and of many articles in reviews and magazines. D. in London, Jan. 8, 1888.

Price, IRA MAURICE, B. D., Ph. D.: educator; b. near Newark, O., Apr. 29, 1856; graduated at Denison University 1879; Professor of Greek and Modern Languages, University of Des Moines (now Des Moines College), Iowa, 1879–80; instructor in French and German, Morgan Park Military Academy, 1880–83; instructor in correspondence, School of the American Institute of Hebrew, 1882–84; Ph. D., University of Leipzig, 1887; instructor in Hebrew and cognate languages, Baptist Union Theological Seminary, 1886–88; professor of same department 1888–92; Associate Professor of the Semitic Languages and Literatures in the Graduate School of the University of Chicago. He is author of *An Introduction into the Inscriptions discovered by Mons. E. de Sarzec* (Munich, 1887); *Syllabus of Old Testament History* (1891; 3d ed. 1892); associate editor of new edition of Gesenius's *Hebrew Grammar* (Boston, 1892); member editorial staff of the *Standard Dictionary of the English Language* (New York, 1893–95).

Price, RICHARD, D. D., LL. D., F. R. S.: philosopher; b. at Tynton, Glamorganshire, Wales, Feb. 22, 1723; educated at Talgarth and Coward's Academy in London; became a Presbyterian minister; was chaplain to a Mr. Streatfield at Stoke Newington 1743–56, and pastor of churches at Hackney and Newington Green for the remainder of his life. D. in London, Apr. 19, 1791. Author of many papers in the *Philosophical Transactions*, and of numerous theological, economical, and political publications, among which were *A Review of the Principal Questions and Difficulties in Morals* (1758); *Observations on Reversionary Payments, Annuities, etc.* (1769); *An Appeal to the Public on the Subject of the National Debt* (1771); *The Nature and Dignity of the Human Soul* (1776); *Observations on the Nature of Civil Liberty, Principles of Government, and the Justice and Policy of the War with America* (1776); *Additional Observations, etc.* (1777); *An Essay on the Present State of Population in England and Wales* (1779); and *Observations on the Importance of the American Revolution* (1784). The pamphlets on American affairs forcibly and eloquently advocated the claims of the colonists to an ample redress of grievances, and 60,000 copies of the first pamphlet on this subject were sold in a few months. Dr. Price's various writings on the doctrine of chances, annuities, and the duration of life entitle him to a high place among the founders of the science of vital statistics, and his financial publications give him similar rank in regard to political economy. In religious opinions he was a precursor of the Unitarian movement, agreeing in many things with his friend Dr. Priestley. See his *Memoirs*, by his nephew, William Morgan, F. R. S. (1815).

Price, STERLING: soldier; b. in Prince Edward co., Va., Sept. 11, 1809; settled in Charlton co., Mo., 1830; served in the Legislature; was member of Congress 1845–47; colonel of Missouri volunteers in the Mexican war; captured Taos, N. M.; commanded at the battle of Canada, N. M., Jan. 24, 1847; was made brigadier-general July 20, 1847, and appointed military governor of Chihuahua; gained the battle of Santa Cruz de Rosales Mar. 16, 1848. He was Governor of Missouri 1853–57; presided over the State convention of Feb., 1861; was appointed major-general of the State forces by Gov. Claiborne F. Jackson, and endeavored to pre-

cipitate the withdrawal of Missouri from the Union, but was foiled in his purpose by the promptness of F. P. Blair and Nathaniel Lyon in compelling the surrender of the State guard at St. Louis, and defeating the militia at Boonville. In the South, however, the Governor and Price reeruited an army of about 8,000 men, and, being joined by McCullough with 3,000 from Arkansas, defeated Lyon and Sigel at Springfield Aug. 7. Price quarreled with McCullough, who withdrew his forces; captured Lexington, with 3,000 prisoners, after a four days' siege, Sept. 20, for which he was thanked by the Confederate Congress; was soon forced to retreat into Arkansas; was appointed major-general in the Confederate service Mar., 1862; took part in the battles of Pea Ridge, Iuka, and Corinth; was in command of the department of Arkansas 1863–64, when he entered into a combination with Clement Vallandigham, of Ohio, and other Northern sympathizers with the Confederacy, founding the secret organization known as Knights of the Golden Circle, of which he was "grand commander," and which nearly 25,000 Missourians joined. He invaded Missouri Sept., 1864, advancing with nearly 20,000 men as far as Pilot Knob, but failed to rally the Knights to his standard on account of the measures taken by Gen. Rosecrans in the discovery and repression of the plot; presented himself before Jefferson City and pushed westward to the Kansas border, but being pursued by Pleasonton and Curtis, had to retreat to Arkansas, thereby terminating in disaster a movement which had been expected to result in the conquest of Illinois and other States. After the war Gen. Price went to Mexico and founded a colony of ex-Confederate officers near Córdova; but the downfall of Maximilian involved that of the colony, and he returned to Missouri early in 1867 in poverty and broken health. D. in St. Louis, Sept. 29, 1867.

Price, Thomas Randolph, A. M., LL. D.: professor of Greek and English; b. in Richmond, Va., Mar. 18, 1839; educated at University of Virginia (1856–59), Universities of Berlin and Kiel (1859–61); served in the Confederate army; Professor of Latin and Greek at Randolph College 1867–70, Greek and English 1870–76; Professor of Greek in the University of Virginia 1876–82; became Professor of English Language and Literature, Columbia College, 1882; author of *The Teaching of the Mother-Tongue* (1877); *Shakespeare's Verse Construction* (1889); editor of *Othello*, Bankside edition of Shakspeare (1890). C. H. Thurber.

Prich'ard, James Cowles, M. D.: ethnologist; b. at Ross, Herefordshire, England, Feb. 11, 1786; resided in youth at Bristol; studied medicine at Bristol, London, and Edinburgh; began practice as a physician at Bristol in 1810, and received medical appointments at the Clifton Dispensary, St. Peter's Hospital, and the Bristol Infirmary. In 1813 he published his chief work, *Researches into the Physical History of Mankind* (4th ed. 1841–51). Dr. Prichard then applied himself to philology, and produced his standard treatise on *The Eastern Origin of the Celtic Nations* (1831; 2d ed. 1857). In 1843 he issued his *Natural History of Man* (4th ed. 1855); became 1845 commissioner in lunacy; was for many years president of the Ethnological Society, and published several works on medical subjects. D. in London, Dec. 22, 1848.

Prickly-ash, or **Toothache-tree**: the *Xanthoxylum americanum*; a large prickly shrub, belonging to the *Rutaceæ*; found in most parts of the U. S. The leaves have the smell of lemons. The bark is aromatic and stimulant, and is used as a remedy for toothache, for rheumatism, and other diseases. *X. carolinianum*, the Southern prickly ash, has a more southern range. It becomes quite a large tree. Its bark is extremely pungent, and is armed with curious prickly warts. *X. floridanum* and *X. pterota* grow also in Florida. China, Japan, South America, and the West Indies abound in species of this genus, nearly or quite all aromatic, pungent, and medicinal.

Prickly Heat: a popular name for eruptive skin diseases, occurring in hot weather and characterized by itching and sensations of stinging. Disordered digestion, constipation, and abnormal perspiration are causes. The disease is known as "miliaria" in technical language. In India there is quite a formidable variety of lichen called by this name. A popular treatment is the use of saline cathartics, which doubtless are sometimes advantageous. Soothing lotions containing carbolic acid, camphor, and similar sedatives are useful, and the disease is often avoided by susceptible persons by frequent bathing and protection from the sun's rays. W. Pepper.

Prickly-pear: any cactus of the genus *Opuntia*, especially *O. vulgaris*, a native of many places in the U. S. from Massachusetts southward and westward. It is naturalized extensively in the Old World. Its fruit is smooth and eatable, but not so good as that of *O. ficus indicus*, which is prickly. Some of the numerous species are used for forage in Mexico. The erect kinds are serviceable hedge-plants. One species is the official emblem of Mexico. Some prickly-pears afford food to the cochineal insect.

Prideaux, prid'ō, Humphrey, D. D.: b. at Padstow, Cornwall, England, May 2, 1648; educated at Westminster School; educated at Christ Church, Oxford, and graduated 1672; published a Latin account of the Arundelian marbles, *Marmora Oxoniensia* (1676); became rector of St. Clement's, Oxford (1679); prebendary of Norwich 1681, archdeacon of Suffolk 1688, and dean of Norwich 1702. D. at Norwich, Nov. 1, 1724. Author of a *Life of Mahomet* (1697), once very popular, and of *The Connection of the History of the Old and New Testaments* (4 vols., 1715–18), which is frequently reprinted.

Pride's Purge: See Cromwell, Oliver.

Priess'nitz, Vincent: hydropathist; b. at Gräfenberg, Austrian Silesia, Oct. 5, 1799, of peasant parents; became the inventor of hydropathy, and in 1822, by special authority from the Austrian Government, the founder of the Gräfenberg water-cure, which he administered till his death Nov. 28, 1851. See Hydropathy.

Priest [O. Eng. *prēost*, like Germ. *priester*, an early loan-word from Lat. *pres'byter*, in a Vulg. Lat. form of **prebister*. In Rom. languages the word appears as Ital. *prete*: Fr. *prêtre*, Provenç. *preste-s*. Lat. *presbyter* = Gr. πρεσβύτερος, elder]: one authorized to perform certain public religious acts, particularly religious sacrifices; in hierarchical churches, one of the second order of the ministry. In all nations of antiquity among whom a system of worship received any considerable development there existed also a system of priesthood. The priest stood in a sort of mediatorial relation between God and man, and under the Hebrew legislation this was divinely recognized and received the emphatic sanction of divine appointment. In earliest times the functions of the priest appear to have been discharged by the head of the family, who, as the recognized superior of all its members, was the fittest person to appear for them before God. Hence came what is called the "patriarchal priesthood." As the family multiplied into the tribe the duties of its head became too numerous for the proper discharge of the priesthood, as well as often incongruous, and persons were specially selected to fill the office, as in the case of Jethro, "the priest of Midian." When the tribe became a nation a class of men was set aside for the same purpose, although the monarch often remained at the nominal head of the priesthood thus established, as was the case in Egypt. Among the most ancient nations, India, Egypt, and the Hebrews, the priesthood was hereditary, and in the two former constituted a class distinctly separated in their whole life from the rest of the nation, and in Egypt endowed with large landed estates and great wealth. Among the Hebrews, on the contrary, the priests were only allowed cities necessary for their residence, and were cut off from other inheritance in land among the tribes of Israel. They were only in so far a caste as was necessary for the discharge of their duties, and in all other respects were on the same footing as their fellow citizens, it being specially noteworthy that all were entirely equal before the law. Their support was provided for by a tithe from the Levites of the tithes received by them from the whole body of the people, and also by assigned portions of most of the sacrifices. As there was no provision in the Hebrew law for the enforcement of the payment of the tithes, their income was dependent upon the general fidelity of the people. The special function of the Aaronic priesthood was to come near to God—themselves of the people, yet specially sanctified on their behalf to approach God and obtain from him pardon and blessings for their brethren. Hence their chief characteristic must be holiness, which was set forth in the Levitical law in every possible symbolical way, as well as directly commanded. The first of all their duties was the offering of sacrifice, thus "making atonement for the people." No sacrifice could be offered or incense burned without their intervention. They had also, as naturally connected with this, the general care of the sanctuary and the multitudinous duties flowing from this; and, as being themselves specially trained in the

Law, to them was assigned the duty of teaching it to the people. They had, however, little or nothing of the *pastoral* relation toward the people; their duties were almost wholly official. Their qualifications were Aaronic descent, perfect physical formation, and, during their ministrations, freedom from legal uncleanness and abstinence from wine and intoxicating drinks. There was no limitation of age. In marriage they were only restricted to virgins or widows of one of the tribes of Israel. When largely multiplied, in the time of David and Solomon, they were divided into twenty-four courses, which were placed on duty each one week in turn. When on duty, like the Egyptian priests, they wore linen robes and were unshod. The whole order culminated in the high priest, whose office was also hereditary, and who by the magnificence of his official robes was marked as very much elevated above his brethren. He was peculiarly the appointed mediator as a type of the promised Redeemer to come, and alone once in every year entered the Holy of holies. He could marry only a virgin within the priestly family. Later there was a "second priest," or vice high priest. The whole Hebrew priesthood, having its main function in the "making of atonement," necessarily ceased with the coming of Christ. By Canon 34 of the Anglican Church one must be twenty-four years of age before he can be admitted to the priesthood; anciently thirty years was required. Still by dispensation for sufficient cause it may be, and has occasionally been, conferred at an earlier age. In the Protestant Episcopal Church the person priested must be twenty-four years old, and usually the interval of a year is required between ordination to the diaconate and admission to the priesthood. Consult Kalisch, *Preliminary Essay to Lev. viii.*; Küper, *Das Priesterthum des alten Bundes.*

Revised by W. S. Perry.

Catholic theology teaches that Christ, "a high priest according to the order of Melchisedech" (Heb. v. 10), instituted at the Last Supper not only a sacrament, but a sacrifice also, and by commanding the apostles to do what he had done for a commemoration of him (Luke xxii. 19), established the priesthood of the new Law. The offering of the eucharistic sacrifice in the Mass, the clean oblation identical with that of the cross, is the principal function of the Christian priest. Also by his ministration the faithful partake of the fruits of this sacrifice, chiefly in Holy Communion, and, according to their various needs, in the sacraments of baptism, penance, and extreme unction. Confirmation and holy orders are administered by the bishop, while in matrimony, as theologians generally hold, the contracting parties are the ministers and the priest or bishop is the official witness. The priest, moreover, is charged with the preaching of the Gospel, and with the religious instruction and spiritual direction of those committed to his care. The jurisdiction necessary for exercising sacerdotal functions is given by the bishop of the diocese in which the priest permanently or temporarily resides, and the priesthood itself is conferred by the bishop at ordination. It imparts to the worthy recipient those graces or supernatural helps which he needs for the faithful discharge of his duties, and imprints upon his soul a character which can never be effaced. Once ordained, the priest, though he may be deprived of the right to exercise his office, always retains the essential power of consecrating the body and blood of Christ. See Lambrecht, *De S^mo^ Missæ Sacrificio* (Louvain, 1875); Probst, *Sakramente und Sakramentalien* (Tübingen, 1872); Cardinal Manning, *The Eternal Priesthood* (1883).

J. J. Keane.

Priestley, Joseph: physicist and writer on theology; b. at Birstal-Fieldhead, near Leeds, England, Mar. 24, 1733 (N. S.); was son of a cloth-dresser; was placed at a free grammar school, and at a Presbyterian academy at Daventry; obtained by private study a knowledge of the classics and modern languages, to which he added Hebrew and the rudiments of Chaldaic, Syriac, and Arabic; rejected some points of the Calvinistic theology before entering college, but was ordained in 1755 assistant minister to an Independent congregation at Needham-Market, Suffolk; left that post in 1758 on account of having adopted Unitarian views; taught a private school at Nantwich, Cheshire, 1758–61, making there numerous experiments in physics, and writing his first published work, *The Scripture Doctrine of Remission* (1761); was teacher of languages and literature in an academy at Warrington 1761–67, during which period he made the acquaintance of Dr. Richard Price and of Dr. Franklin, and prepared, at the instance of the latter, his *History and Present State of Electricity, with Original Experiments* (1767), which procured him the degree of LL. D. from the University of Edinburgh and election as fellow of the Royal Society; was pastor of Mill Hill Chapel, Leeds, 1767–73; made there important researches in pneumatics and chemistry, which he gave to the world in his *Directions for Impregnating Water with Fixed Air* (1772), and *History and Present State of Discoveries relating to Vision, Light, and Colors* (2 vols. 4to, 1772); published his *Institutes of Natural and Revealed Religion* (3 vols., 1772–74), which he had begun eighteen years before; was from 1773 to 1780 librarian and literary companion to the Earl of Shelburne, whom he attended in 1774 in a tour on the Continent; made in that year the discovery of oxygen (called by him dephlogisticated air; see Chemistry), soon followed by that of other gases, besides contributions to theoretical chemistry set forth in his *Experiments and Observations on Different Kinds of Air* (3 vols., 1774–77); published (1774–78) *Disquisition relating to Matter and Spirit*, and other philosophical works which excited much controversy. In 1780 Priestley retired from the service of Lord Shelburne with a life-pension of £150, became minister to the principal Independent congregation at Birmingham, and addressed to an eminent Frenchman his *Letters to a Philosophical Unbeliever*, in which he contended strongly for the doctrines of a revelation and a resurrection. This was followed by his *History of the Corruptions of Christianity* (2 vols., 1782); *History of Early Opinions concerning Jesus Christ, compiled from Original Writers, proving that the Christian Church was at first Unitarian* (4 vols., 1786), and other works, including *Letters to Burke, occasioned by his Reflections on the Revolution in France* (1791). The last treatise procured him an honorary citizenship in the French republic, and was the cause of a riot at Birmingham (July 15, 1791), in which Priestley's house was pillaged and his library, manuscripts, and scientific apparatus scattered through the streets, he himself escaping personal violence by flight. For three years he resided at Hackney as the successor of Dr. Price, instituted a suit for compensation for his losses, in which he was successful after nine years' delay, and in 1794 removed to the U. S., where his sons already resided. He settled on his son's farm at Northumberland, Pa., where he passed the remainder of his life; wrote replies to Volney and Paine, and several other works of little comparative importance, the most elaborate being *Notes on all the Books of Scripture* (Northumberland, 4 vols., 1803). He declined a professorship in the University of Pennsylvania, but occasionally preached at Philadelphia, and delivered there two series of *Discourses relating to the Evidences of Revealed Religion* (1796–97). D. at Northumberland, Pa., Feb. 6, 1804. His autobiographical *Memoirs*, with a continuation by his son, appeared in 1806, and a collection of his *Theological and Miscellaneous Works* (26 vols., Hackney, 1817–32) was edited by John Towell Rutt, vols. i. and ii. being composed of his *Life and Correspondence.* A bibliography of Dr. Priestley's productions, prepared at Washington (1875), gives the titles of more than 300 separate publications.

Revised by R. A. Roberts.

Priestley, Sir William Overend, M. D., LL. D., F. R. C. P.: obstetrician; b. near Leeds, Yorkshire, June 24, 1829; grand-nephew of Joseph Priestley; educated at the University of Edinburgh and took the degree of M. D. in 1853; received the senate gold medal for original research at graduation; settled in London as a physician in 1856; became lecturer on midwifery at the Middlesex Hospital; Professor of Obstetric Medicine in King's College, London, and physician to King's College Hospital 1862; and later consulting physician to King's College Hospital. He is a fellow of several colleges, and member of various learned societies; has been examiner in the University of London, Royal College of Physicians, Royal College of Surgeons, University of Cambridge, and Victoria University; in 1875 and 1876 was president of the Obstetrical Society of London. He has published *On the Development of the Gravid Uterus*; *On the Pathology of Intrauterine Death*; and was joint editor of Sir J. Y. Simpson's *Obstetric Works.* He was knighted in 1893.

Prieto, prĕĕ-ā'tō, Joaquin: general and politician; b. at Concepcion, Chili, Aug. 20, 1786. After serving in the Spanish militia he joined the patriots in 1811; took part in all the revolutionary struggles, holding high military offices; was prominent in congress from 1823 as a leader of the conservative party; joined in the conservative revolt of

1829–30, deciding its success by his victory over Freire at Lircay Apr. 17, 1830, and on the death of Ovalle was made provisional president by congress Mar. 22, 1831. He was confirmed in the post by a regular election, holding it by re-election until Sept., 1841. With him began the prosperous though somewhat reactionary rule of the conservative party in Chili. A constitution (still in force, though somewhat amended) was adopted in May, 1833; there was an unsuccessful revolt in 1836, and Chili aided Peruvian malcontents to overthrow the Peru-Bolivian confederation 1837–38. After retiring from the presidency Gen. Prieto was councilor of state, senator, and commandant at Valparaiso, where he died Nov. 22, 1854. HERBERT H. SMITH.

Prim, JUAN: Count of Reus and Marquis of Castillejos; b. in Reus, Catalonia, Spain, Dec. 6, 1814; entered the Spanish army in boyhood; obtained rapid promotion during the first Carlist war; became colonel in 1837; was soon afterward elected to the Cortes, plotted against the government of Espartero, and in 1843 placed himself at the head of a revolt in Catalonia. He aided materially in effecting the return of Christina, but, falling under suspicion of treason, was tried and sentenced to death. He was pardoned, however, and appointed governor of Puerto Rico. He was commander of the reserve division in the war against Morocco 1859–60, gaining a great military reputation and the title of marquis. As commander of the Spanish contingent in the allied intervention in Mexico 1861, he was instrumental in bringing about the convention of Soledad, Feb. 19, 1862, in which assurance was given that the independence of the Mexican republic would not be disturbed. On his return to Spain he successfully defended his conduct in the Cortes, denouncing the ambitious plans of the French emperor; was banished from Madrid Aug., 1864; devoted himself thenceforth to the overthrow of Isabella, for which object he entered into various combinations and headed several unsuccessful insurrections, especially that of Jan., 1866, in Aragon and Catalonia, but ultimately succeeded in organizing the movement which in Sept., 1868, through the aid of Serrano and Topete, resulted in the flight of the queen to France; was welcomed with enthusiasm at Madrid; became Minister of War and head of the cabinet in the new provisional government; conducted several negotiations for founding a new dynasty in Spain; furnished the pretext for the Franco-German war of 1870–71 by his offer of the crown of Spain to Prince Leopold of Hohenzollern, and in the autumn of 1870 obtained from the Cortes the election of the Italian prince Amadeus, Duke of Aosta. On the day that the new king landed at Barcelona (Dec. 28) Prim was attacked by assassins in a street of Madrid, and received eight balls in his body, and died two days later (Dec. 30, 1870).
Revised by F. M. COLBY.

Primary Elections: in U. S. politics, a term usually applied to the preliminary meetings of the voters of any political party to nominate candidates for offices to be filled by the people at a subsequent election, or to choose delegates to a convention that will make such nominations. The word caucus is sometimes used with reference to a meeting of certain members of a legislature or other deliberative body to decide upon harmonious action with reference to pending business. (See CAUCUS.) It will be seen that the primary election is the source of all nominations, from that of the village constable or pathmaster (unless these officers are both nominated and elected in town meeting) to that of President, although this has not been true throughout the history of the country. From 1800 till 1824 the presidential candidates of one party at least, and often of both, were designated by the members of Congress in a congressional caucus, though in the later years some of the State Legislatures also made nominations. In 1828 the presidential candidates were nominated by the State Legislatures, and in 1832 the present system of nomination by convention founded upon the primaries was started.

In rural districts, or in smaller towns where the voters of each political party are personally known to one another, the ordinary primary election is not generally seriously abused. The local political leaders are likely to pack the meetings in the interest of their favorites; but this can be successfully done, with rare exceptions, only when there is apathy on the part of many voters. In the larger cities, owing to the lack of acquaintance among the voters, there are many opportunities for fraud, and many abuses. The necessity of some means of identifying voters has led in New York and other large cities to the formation of local political associations; and from these associations have come the worst abuses. A check list of names of voters is of course necessary, no person being allowed to vote whose name does not appear on the list. This machinery of registration, and the necessity of having some authority to call meetings, make the appointment of a committee imperative. These committees, often reappointed, soon know their districts so well that they can manage them better than any one else; hence they have much influence with higher party officials. In New York each assembly district has had its local association in the nature of a permanent club, and its committee, associated with a central committee, which has had the general direction of affairs in the city. The two leading parties have had, under somewhat different forms, practically the same method of working. The direction of affairs has been held, in the main, in the hands of the central committee; and as membership in the local associations has been limited by pledges of support of regular candidates selected by the committee, pledges that many men could not give, the control has been retained. This rigid control has at times permitted not more than one-sixth, or even not more than one-tenth, of the voters to take part in nominations, and even these were compelled to follow the dictates of the small central executive committee. In such circumstances nominations could be made by the "boss" at will.

Much thought has been given to finding remedies for these evils in making nominations, but none that have been suggested are entirely satisfactory. The system of proportional representation, as found in three cantons of Switzerland, by lessening the strength of parties and party feeling is said to have had a marked influence toward purifying nominations and elections. (See REPRESENTATION.) Under the present system of party government in the U. S., probably more has been accomplished than in any other way by what are called "Primary Election Laws" in several States. By these laws—found in more or less complete form in Ohio, Kentucky, Missouri, California, Illinois, Kansas, West Virginia, Wyoming, Wisconsin, Oregon, Washington, etc.—primary elections are no longer to be considered entirely as voluntary meetings. The most complete laws provide regulations for duly calling and publishing notices of meeting, for registration of voters, for inspectors, challenging, voting, etc., with severe penalties against fraud, as well as against bribery or undue influence of any kind. Late practice in some districts in New York shows that a good system of minority representation in the primary election itself has had excellent results. JEREMIAH W. JENKS.

Primary Schools: See COMMON SCHOOLS.

Primate [viâ O. Fr. from Lat. *pri'mas, prima'tis*, one of the first, chief, (in Mediæv. Lat.) a primate, deriv. of *primus*, first]: originally, in the ecclesiastical system of the Roman Catholic Church and the Church of England, the first in rank of the archbishops in a country. Thus in England the Archbishop of Canterbury was long primate, but at present the Archbishop of York is styled "Primate of England," while Canterbury takes the higher title of "Primate of all England." The Church of Ireland Archbishop of Dublin has the title "Primate of Ireland," and the Church of Ireland and Roman Catholic Archbishops of Armagh are each called "Primate of all Ireland." Five or six French prelates are called primates, but the Archbishop of Lyons is "Primate of primates." Again, the Archbishop of Braga is Primate of Portugal, although inferior in rank to the Patriarch of Lisbon. These facts indicate that the office of primate has to some extent and in certain cases become a titular one, or at least a mere indication of a comparatively unimportant precedence. Revised by W. S. PERRY.

Primates [Mod. Lat., from Lat. *pri'mas, prima'tis*, of the first, chief, excellent, deriv. of *pri'mus*, first]: an order of monodelph mammals including man, the monkeys, and the lemurs. These are all externally distinguished by the fore as well as hind limbs being completely or almost entirely exserted outside of the common integument, and thus distinguished from the ordinary quadrupeds, in which the proximal joints are inclosed therein; the members have also generally five digits, developed on the hands as well as feet; the innermost or first of the hand or fore foot being the thumb, which is, however, frequently suppressed, and the corresponding and innermost digit of the foot being thickened and generally opposable like the thumb to the other digits, only in man assuming parallelism with them; this great toe is always furnished with a depressed nail; the teeth are not distinctive, being modified according to

several types; they are, however, at least in one stage, incisors, canines, and molars; of the incisors there are in each jaw generally four, and never more, although they may be reduced to two, or all in the upper jaw may be suppressed; the clavicles are always completely developed and co-ordinated with the development of distinct shoulders and their distance from each other; the brain has a large cerebrum which completely overlaps the olfactory lobes in front, and behind more or less covers the cerebellum; on the interior surface of each hemisphere behind a peculiar sulcus (the so-called calcarine) exists, which is co-ordinated with the development of a raised portion (the hippocampus minor) within the posterior corner of the ventricle by which the posterior lobe of the cerebrum is traversed. The order as thus distinguished includes two sub-orders—(1) *Anthropoidea*, comprising the families *Hominidæ* (man), *Simiidæ* (the large tailless apes), *Cercopithecidæ* (the Old World monkeys, baboons, etc.), *Cebidæ* (the common New World monkeys), and *Midídæ* (the marmosets, etc.); and (2) *Prosimiæ*, with the families *Lemuridæ*, *Tarsidæ*, and *Daubentonidæ*. The order, as thus limited and defined, is the result of studies of recent zoölogists. Linnæus, who framed the name, embraced under it in addition to the forms above indicated, all the *Cheiroptera* and *Galeopithecus*. By Cuvier and his numerous followers the true *Primates* were differentiated into two orders—*Bimana* (including man) and *Quadrumana* (including the monkeys and lemurs). The naturalness of the association of man with the monkeys is now almost universally conceded, and the main question in dispute at the present time is whether those forms (the anthropoids) should be associated with the lemuroids in a single order, or the two distinguished as independent orders. The differences between them are certainly great, and the discovery by Alphonse Milne-Edwards of the peculiarities of the lemuroid placentas adds to the arguments in favor of their separation, and the question is a very evenly balanced one. See, further, the names of the sub-orders and families.

Revised by F. A. Lucas.

Primaticcio, prĕē-maă-tĕē'tchō, Francesco: painter; b. at Bologna, 1490, of a noble family. Innocenzio da Imola and Bagnacavallo were his first masters, but it was at Mantua, where he studied under Giulio Romano, that he learned the art of color and modeling in stucco as a means of decoration. He gave proof of his talents in this line by the two pieces in the Palazzo del Te. He painted also several subjects after Giulio Romano's designs, so that when Francis I. of France asked Duke Gonzaga to send him a painter capable of directing the decoration of Fontainebleau, Primaticcio was sent as the best of Romano's followers. After nine years, during which time his work gave much satisfaction, he became the superintendent of the king's buildings, succeeding in this post the Florentine Rosso, who had died, and of whom Primaticcio had always been extremely jealous. After the death of Francis I. he continued to hold the same post under Henry II., and Francis II. made him commissary-in-general of all the buildings in the kingdom. He gave the designs for all statues, decorations, fountains, goldsmiths' work, and of all court pageants. He built the first château at Meudon for the Cardinal de Lorraine, and adorned it with sculpture and paintings. He became the artist in highest renown, and was a protector of art, except when touched by jealousy of any extraordinary talent. He was an implacable enemy of Benvenuto Cellini, whom he tried to deprive of commissions by conspiring against him together with the king's mistress, Madame d'Estampes. The Gallery of Ulysses at Fontainebleau was considered one of the finest works of the kind in France. The painting is utterly ruined by time, so that the designs are known to us only through engravings. Primaticcio died in Paris in 1570. The Louvre contains two of his works, which are very rare in Italy; in Bologna the most remarkable is that in the Zambeccari Gallery, representing a concert of three women.

W. J. Stillman.

Prime, Samuel Irenæus: editor and author; son of Dr. Nathaniel S. Prime; b. at Ballston, N. Y., Nov. 6, 1812; graduated at Williams College 1829; studied theology at Princeton; was ordained to the ministry of the Presbyterian Church, and preached several years, but on account of ill-health withdrew from the pulpit in 1840, when he became editor of *The New York Observer*, the leading religious paper of his denomination—a post he retained till his death; several times visited Europe, and published some forty volumes, chiefly anonymous. Among his books are *Travels in Europe and the East* (2 vols., 1855); *Letters from Switzerland* (1860); *The Bible in the Levant* (1859); *Memoirs of Rev. Nicholas Murray* (1862); *The Alhambra and the Kremlin* (1873); and a *Life of Samuel F. B. Morse* (1874). D. at Manchester, Vt., July 18, 1885. His autobiography appeared, ed. by W. Prime, in 1886.

Prime, William Cowper: journalist; b. at Cambridge, N. Y., Oct. 31, 1825. Graduated at Princeton College, and practiced law in New York till 1861. He was afterward editor of the New York *Journal of Commerce*; traveled in Egypt and Palestine; was made Professor of the History of Art at Princeton in 1884. His published writings include *The Owl Creek Letters* (1848); *Boat Life in Egypt* (1857); *Tent Life in the Holy Land* (1857); *Coins, Medals, and Seals* (1860); *I Go A-fishing* (1878); *Pottery and Porcelain* (1878); *Holy Cross* (1879); and other works; edited *McClellan's Own Story* (1886), and wrote a biography of Gen. McClellan for that volume. H. A. Beers.

Prime Mover: the term employed to designate a machine, the office of which is to transform the energy expended in some natural source of power into available work. For example, a quantity of water falling from one level to another represents an expenditure of energy due to the force of gravity, equivalent in foot-pounds to the product of the weight of the water multiplied by the height of fall in feet. In falling without obstruction or resistance the velocity of the water continually increases, and the energy is usually dissipated in the shock at the bottom of the fall. To render this source of power available, a water-wheel may be introduced, which, receiving the impulses of the falling particles, causes a portion of the work to be transformed into useful work, and the water reaches the bottom of the fall with its energy diminished by precisely the quantity which has been so transferred or transmuted into the work absorbed by the water-wheel.

While prime movers generally have the characteristics of other machines in many respects, yet only a few machines can be classed as prime movers. In prime movers the construction and arrangement of their parts depend on the nature or source of the energy which is to be utilized, and demand the application of a wide range of the physical sciences. Questions of *economy of power* should receive first consideration. See Machines and Machinery.

The sources of energy in nature which are made available for useful purposes by the aid of prime movers are heat, the energy of falling water, the motions of the atmosphere, and electricity or magnetism. The latter being, however, regarded as referable to heat, and the second and third sources mentioned being manifestations of the force of gravity, the ultimate sources of available energy may be considered to be *heat* and *gravitation*. As regards *muscular* energy, men and animals may be regarded as prime movers—perfect exhibitions, in this respect, of the imperfect results of human efforts in artificial constructions.

The heat-engine, under the form of the steam-engine, holds the first place in importance among all the prime movers. In the investigations and experiments connected with economy in its use and its adaptation to various purposes, especially to the propulsion of steamships, it has engaged the attention of scientific men, practical engineers, and artisans to a greater extent than all others combined; and the developments arising from its use have given rise to a special branch of engineering science. The use of the water-wheel in the form of the turbine, the second prime mover in importance, has been greatly extended through the new facilities afforded for its construction by steam machinery and the arts and industries developed by it. Hot-air engines, gas-engines, and electro-dynamic engines are prime movers more restricted in their applications, but they possess respectively peculiarities which render them advantageous under certain conditions. The windmill is another prime mover which in favorable localities is of great value. See Dynamo-electric Machine, Gas-engine, Hot-air Engine, Steam-engine, Water-power, and Windmills.

Revised by R. A. Roberts.

Prime Numbers [*prime* is liter. first, i. e. in any series of multiples into which a prime number can enter, from Lat. *prī'mus*, first]: those whole numbers which can not be exactly divided by any other whole number except 1. Two numbers are prime with respect to each other when they can not both be divided by any whole number except 1. Thus 2, 3, 5, etc., are prime numbers; 6 and 25 are prime with respect to each other. No rule has been found for discover-

ing prime numbers by a direct process. A method of sifting out numbers not prime was described by Eratosthenes, and for that reason is generally known as Eratosthenes's sieve. The method is as follows: Since every even number is divisible by 2, we may omit or sift out all such numbers, and remembering that 2 itself is prime, we write down the series of odd numbers up to any limit, say up to 99: 1, 3, 5, 7, 9, 11, 13, 15, etc. We begin with the first prime number after 2, which is 3, and counting from it, we strike out every third number, because all such numbers are divisible by 3, and therefore are not prime. We then begin with 5, and counting from it we strike out every fifth number, because all such numbers are divisible by 5. We then begin with 7, and counting from it, we strike out every seventh number. The remaining numbers, up to the square of the next prime number whose multiples are to be struck out, are prime. In this way we find that the prime numbers less than 100 are 1, 2, 3, 5, 7, 11, 13, 17, 19. 23, 29. 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, and 97. The operation of sifting may be extended to any series of whole numbers, but beyond a certain limit the operation becomes tedious. In applying the method just described it is to be remembered that if a number can not be divided by a prime number less than its own square root, that number must be prime. Thus in the case supposed we need not go farther than 7, because 7 is the greatest prime number less than $\sqrt{100}$. From the nature of the process of Eratosthenes it is evident that the number of prime numbers in a given interval will be less the higher that interval commences. The number of prime numbers up to 10,000 is 1,230; the number between 10,000 and 20,000 is 1,033; between 20,000 and 30,000 it is 985, and so on. Many tables of prime numbers have been published of greater or less extent: those of Burckhardt extend to the number 3,036,000; Glaisher's tables extend from 3,000,000 to 6,000,000; Dase's from 6,000,000 to 9,000,000. The highest number that has been shown to be prime is $2^{31}-1=2,147,483,647$; this was found by Euler.

Primogen'iture [Lat. *pri'mus*, first + *genitu'ra*, a begetting, being born, but in meaning deriv. of *primoge'nitus*, first-born; *pri'mus*, first + *gig'ni*, *genitus*, be born]: the preference in inheritance which the law accords to the eldest born. The sole and exclusive heirship of the eldest son in the English rule of primogeniture dates back directly only to the complete establishment of the feudal system of land tenure in England after the Norman conquest. On the Continent, however, in the feudal states which were erected on the ruins of the Roman empire, the principle had already completely triumphed over the Teutonic as well as the Roman ideas of succession. Its obscure origin and the rapidity with which it overran Western Europe at this time constitute one of the puzzles of legal history. In the multitude of different customary rules of descent which a study of primitive society discloses, it is seldom that the student comes upon any traces of it. The right of the eldest son prevails, indeed, but it is as a right of political succession, and not of succession to property. In this latter form it was unknown either to the Greek or to the Roman jurisprudence, and the "birthright" of the Hebrew and of the Hindu law, which is sometimes confounded with the rule of primogeniture, was at the most only a recognition of the claim of one of several sons (not necessarily the eldest) to a double portion of the inheritance.

The general acceptance of the doctrine of primogeniture in the Middle Ages would seem to indicate that it was peculiarly adapted to the necessities of that mixture of political, social, and property relations which we call the feudal system. With the well-nigh complete disappearance of that system, however, the rule of primogeniture has generally been swept away, surviving only, on the Continent, as a rule regulating succession to the crown. In England only has it been preserved in full force and virtue. There it still prevails, as a rule or canon of descent of real property, "that," to use Blackstone's statement of the rule, "the male issue shall be admitted before the female," and, "where there are two or more males in equal degree, the eldest only shall inherit; but the females all together." Of course, under a system of law in which the landowner may freely alienate his estate by will, it is really optional with him whether he will, by dying intestate, subject his real property to the rule of primogeniture or not. The system has been persistently attacked of late, but it has become too closely bound up with the habits and traditions of the English people to be easily dislodged.

The rule of primogeniture was introduced, along with the rest of the common law, into the English colonies in America, but the principle has long since been repudiated, by statute or constitutional inhibition, in all of the States as being unsuited to the spirit of their institutions. In the U. S., as also in Canada and the English colonies generally, all descendants of the same degree inherit the real property of their ancestor equally as tenants in common. See Maine's *Ancient Law* and *Early History of Institutions* and the *Commentaries* of Blackstone and Kent.

George W. Kirchwey.

Primrose [(by confusion with *rose*) < M. Eng. *primerole*, viâ O. Fr. from Lat. *pri'mula*, primrose, deriv. of *pri'mus*, first, named from its early flowering]: any plant of the genus *Primula*, although many have separate names. They are handsome flowering herbs, largely European. The true primrose is *P. grandiflora* of Europe. *P. officinalis* is the cowslip, of which the polyanthus is a cultivated form, all of these running into many varieties. The birdseye primrose (*P. farinosa*) belongs to a humbler division of the genus. This and the related *P. mistassinica* are indigenous to the northern parts of North America. *P. auricula*, the parent of the auriculas of the gardens, is a native of Southern Europe. The oxlip is *P. elatior*. The Chinese primrose (*P. sinensis*), now one of the commonest house-plants, represents a different section of the genus, to which *P. cortusoides*, a choice Siberian species, also belongs. *P. obconica*, from China, is a species much prized for greenhouse culture. It has pungent hairs which are irritating-poisonous to some persons. The evening primroses are species of *Œnothera*, of a wholly different family, and took the name from a very superficial likeness of the corolla to that of the true primrose.

Revised by L. H. Bailey.

Primrose Family: the *Primula'ceæ* (from *Primula*, the typical genus); a family of gamopetalous, dicotyledonous herbs, widely distributed over the world, but chiefly in the cooler parts of the northern hemisphere. Plants of this family are characterized by having stamens of the same number as the lobes of the corolla, and opposite them, on the tube or throat, a single style and stigma, and a one-celled ovary with a free central placenta, bearing several or numerous ovules. To this must be added the herbaceous character, to distinguish them from the *Myrtinaceæ*, tropical trees or shrubs which have a similar floral structure. Except a slight acridity, *Primulaceæ* are nearly inert plants, of no economic importance beyond the beauty of their blossoms. Besides the Primrose (*q. v.*) and its near allies, the cyclamen, the beautiful dodecatheon of the U. S., popularly known as American cowslip and shooting-star, and one species of *Anagallis*, are familiar in ornamental cultivation.

Revised by Charles E. Bessey.

Prince [viâ O. Fr. from Lat. *prin'ceps*, *prin'cipis*, one who is first, leader, chief, ruler, sovereign; *pri'mus*, first + *ca'pere*, take]: a title which sprang from that of the Roman *princeps senatus*, which became a title of the Roman emperors, and from them passed to mediæval and modern sovereigns. There are also sovereign rulers who have no higher title than prince. Nobles of the blood are in general called princes, whether they officially bear this or some inferior title. In continental Europe there are also princes who are not related to sovereign families (called in Germany *Fürst*, and not *Prinz*). Strictly, all English nobles of higher rank than viscount are entitled to be styled princes, but in practical use princes of the blood are the only ones so designated.

Prince, Thomas: clergyman and author; b. at Sandwich, Mass., May 15, 1687; graduated at Harvard 1707; went to England 1709; attended lectures at Gresham College, London; preached at Combs, Suffolk, 1712–16, and elsewhere in England; returned to Massachusetts 1717; was ordained colleague of Rev. Dr. Joseph Sewall, pastor of the Old South church, Boston, Oct. 1, 1718; devoted many years to the collection of materials for the civil and religious history of New England, and gathered a valuable library, which he bequeathed to the Old South church. D. in Boston, Oct. 22, 1758. When the Old South church was desecrated by British soldiery during the war of the Revolution, manuscript documents in the Prince library were stolen or destroyed. The books, tracts, and MSS. remaining, 1,500 in number, were deposited in the Boston Public Library in 1860. Prince

published, in addition to sermons, many occasional writings, including *An Account of the First Aurora Borealis* (1717); *Earthquakes of New England* (1755); and a revision of the *New England Psalm-book* (1758); and undertook a work valuable from its extreme accuracy of detail, *New England Chronology*, of which, however, only vol. i. (1736) and part of vol. ii. (1755) appeared, extending only to 1633 (new ed. 1826).

Prince Edward Island [named in 1798 in honor of Edward, Duke of Kent, father of Queen Victoria]: an island in the Gulf of St. Lawrence, constituting, since 1873, the smallest province of the Dominion of Canada (see map of Province of Quebec, Prince Edward Island, etc.). Area, 2,133 sq. miles. Pop. (1891) 109,088. Twenty-four minor islands belong to the province. There are numerous bays, harbors, and promontories. Northumberland Strait, on the S. and W., separates it from the mainland of Nova Scotia and New Brunswick. The soil is very fertile. The surface is generally level, with some low hills. The climate is insular and therefore not severe. The forests are greatly reduced. They consist of birch, elm, maple, ash, beech, pine, spruce, fir, hemlock, cedar, juniper or tamarack, poplar, and willow. Vast quantities of sea-manure are everywhere accessible. The waters teem with fish—mackerel, herring, cod, and many other species—and the north shore is one of the best fishing-grounds in North America. The manufacturing interests are not extensive, but ship-building is an important industry. A railway extends the whole length of the island. Wheat, oats, barley, rye, potatoes, buckwheat, and garden vegetables are raised. Cattle, horses, swine, sheep, and poultry are bred extensively. The island is divided into three counties—King's, Queen's, and Prince—each of which elects ten representatives to the Legislative Assembly. There has been a system of free public schools since 1821. The system includes grammar or higher schools, secondary schools, and normal schools for the training of teachers. There are three denominational colleges—Roman Catholic, Anglican, and Wesleyan—all at Charlottetown, the capital. During the summer the island is visited by regular lines of steamers and by thousands of fishing-vessels. In winter the island was formerly almost inaccessible, but this disadvantage has been partly remedied by a steamship owned by the Government, and specially designed for winter navigation. There is a submarine telegraph.

History.—The island (the Île St. Jean of the French) was discovered by the Cabots in 1497. It began to be settled by the French (1715), who increased rapidly for many years. In 1764, having come under British rule, it was abandoned by many of the French, and it was then parceled out among sixty-seven grantees, who agreed to furnish a numerous colony of Protestant settlers (not English) for the colony. Though these conditions were never fulfilled, the great estates were not broken up until 1875, when their absentee landlords were finally bought out under the Land Purchase Act of that year. The Roman Catholic religion was never fully tolerated till 1830. There is a Roman Catholic bishop of Charlottetown, and that body is more numerous than any other denomination. Revised by C. C. Adams.

Prince of the Peace: See Godoy, Manuel, de.

Prince of Wales, Cape: See Cape Prince of Wales.

Prin'ceps [Lat., the first man]: the civil title of the Roman emperors, as *imperator* was their military title. How the word first came to be used in this sense is a matter of dispute, many holding (with Mommsen) that it was a new designation, created to comprehend the various powers concentrated in the hands of Augustus, in 27 B. C., by virtue of which he became the "first citizen"; while others, with apparently better reason, maintain that it was nothing more than a continuation of the ancient title of *princeps senatus*, and that from its absolute use in the first instance by the senators (as *princeps noster*) it was gradually extended, until Augustus himself made official use of it in this way, and thus established the title as the imperial designation. It should be understood, however, that this dispute has regard only to the origin of the designation, and that in any case the word *princeps*, as applied to Augustus and the succeeding emperors, has a significance entirely new. For while no unprecedented powers had been lodged in the hands of Augustus, he was the first to unite in one person military authority, in the provinces and at home, with several of the most important civil offices, such as the tribunitian power, the censorship, and the supreme pontificate.

G. L. Hendrickson.

Prince Rupert's Drops: glass drops with an elongated, tapering form, made by throwing melted glass into water. A smart blow upon the large end makes no impression, but if the smallest part be picked off the small end, the whole falls into powder. They derive their name from the fact that Prince Rupert, a nephew of Charles I., introduced them into England.

Prince's Feathers: See Amaranth.

Prince's Islands: eight islands in the Marmora at the entrance of the Gulf of Nicomedia. Prinkipo, Chalki, Antigone, and Proti are the chief. Most enchanting in climate and natural scenery, in all ages they have been the favorite resort of the wealthy and luxurious classes of Constantinople. Many emperors and members of the Byzantine imperial families have resided there. Also they have been occupied by numerous monasteries, some of which still exist. At Chalki is the chief theological seminary of the Orthodox Church, manned by an able and learned corps of professors. The disastrous earthquake of July, 1894, wrecked many buildings and caused great loss of life. E. A. G.

Prince's Metal: See Brass.

Princeton: city; capital of Bureau co., Ill.; on the Chi., Burl. and Quincy Railroad; 22 miles W. S. W. of Mendota, 105 miles W. S. W. of Chicago (for location, see map of Illinois, ref. 3–D). It is in an agricultural and coal-mining region, and contains flour-mills, grain-warehouses, agricultural-implement works, foundry and machine-shop, 2 libraries (High School, founded 1867. Matson, founded 1879), 3 national banks with combined capital of $315,000, and 3 weekly newspapers. Pop. (1890) 3,396; (1900) 4,023.

Princeton: city; capital of Gibson co., Ind.; on the Evansv. and Terre Haute and the Louisv., Evansv. and St. L. Consolidated railways; 24 miles S. of Vincennes, 27 miles N. of Evansville (for location, see map of Indiana, ref. 11–B). It is in an agricultural region, and contains flour-, woolen-, and planing-mills, grain-elevator, carriage-factories, a public library (founded in 1879), a national bank with capital of $75,000, a State bank with capital of $100,000, and three weekly papers. Pop. (1890) 3,076; (1900) 6,041.

Princeton: borough; Mercer co., N. J.; on the Delaware and Raritan Canal; 10 miles N. E. of Trenton, 50 miles S. W. of New York city (for location, see map of New Jersey, ref. 4–C). It is on a high ridge, 3 miles from the main line of the Penn. Railroad, with which it is connected by a branch line, and commands an extensive view of the surrounding country. The borough is laid out with wide streets, beautifully shaded and ornamented with broad lawns, and contains some quaint colonial houses and many fine modern residences. The old graveyard has been called "the Westminster of America" because of the eminent persons buried there. There are 8 churches, Evelyn College for young women, a national bank with capital of $50,000, a State bank with capital of $100,000, a savings-bank, 2 weekly newspapers, and 4 college periodicals. Princeton is most widely noted as the seat of Princeton University (*q. v.* in the Appendix), and of the Theological Seminary of the Presbyterian Church in the United States of America (founded in 1812; now has about 300 students). It is also noted as the scene of a battle in the Revolutionary war, which proved the initiative of operations by which the British were driven from the greater part of the two Jerseys. Washington surprised and captured Trenton on Dec. 26, 1776, and concentrated his army there a few days afterward. Cornwallis, resuming command of the British in the Jerseys after the surrender of Trenton, made his headquarters at Princeton. On Jan. 2, 1777, Cornwallis advanced the greater part of his army toward Trenton, intending to attack the Americans on the following day. Washington, learning that only a small force remained at Princeton, made a night march thither, surprised the British at daybreak on Jan. 3 near the college, and routed and dispersed them within thirty minutes, inflicting a loss of 100 killed and wounded and of 230 prisoners, and sustaining a loss of less than 30. Though the forces engaged were small, the result was of great value in encouraging the colonists, who had become disheartened by many reverses. Pop. (1900) 3,899.

Princeton University: See the Appendix.

Pringle, Thomas: poet; b. at Blaiklaw, Teviotdale, Scotland, Jan. 5, 1789; graduated at Edinburgh University; became clerk to the commissioners on the public records of Scotland; began in 1811 to publish occasional poems; became in 1817 co-editor with James Cleghorn of the Edin-

burgh *Monthly Magazine*; was at the same time editor of the *Star*, a semi-weekly newspaper, and of *Constable's Magazine*; emigrated to South Africa 1820; taught school at Cape Town; became librarian to the colonial Government, and successively edited two newspapers; returned to England 1826; became secretary of the Anti-Slavery Society 1827; published *African Sketches* (1834), etc., and left a posthumous *Narrative of a Residence in South Africa* (1835). D. Dec. 5, 1834. See *Poetical Works of Thomas Pringle, with a Sketch of his Life*, by Leitch Ritchie (1838).

Printing [deriv. of *print*, shortened from *imprint*, from O. Fr. *empreindre* < Lat. *impri'mere*, impress; *in*, in, on + *pre'mere*, *pres'sum*, press]: the processes which are involved in making copies, generally in ink and by pressure, of letter-press or of designs engraved, etched, or drawn upon a solid surface. In its most restricted sense, and that in which it is used in this article, it is synonymous with typography (in its widest sense), and includes typesetting, electrotyping, stereotyping, etc., and the taking of impressions from the inked surface of the type thus set up, or of plates made from them on presses specially constructed for the purpose; but in a wider sense lithography, engraving, zincography, and embossing books in raised letters for the blind, as well as the reproduction of photographic images by the action of the sun on specially prepared paper, etc., are all included.

History.—From the earliest historic period some mode of engraving and producing impressions or devices has been known, but it seems not to have advanced beyond the form of seals until the time of the Babylonians and Assyrians. Their buildings were generally built of burnt brick, which were stamped with an inscription according to the character of the edifice, and bore the name of the reigning monarch. In many instances these impressions show clearly that the stamp was engraved in relief and applied to the plastic clay. The Assyrians, unlike any other nation of antiquity, employed terra-cotta prisms, cylinders, and tablets for all the purposes of writing and the preservation of their literature. (See Assyrian Literature.) The Egyptians also used stamps to impress the bricks used for their buildings. The stamps appear to have been used to mark the destination of the bricks. The Chinese have used a simple mode of printing from an early date. A work supposed to have been written during the reign of Wu Wang (in the twelfth century B. C.) mentions the blackening of engraved characters, but this is probably an allusion to some mode of making inscriptions more legible by blackening the letters. According to their chronicles, the early attempts of their present mode of printing were made about 50 B. C., but no great advance was made till the reign of Ming-Tsung (927–934 A. D.), when Fung-Taou made copies of the classical books by taking impressions from stone plates, into which the letters had been cut; in the impression therefore the letters were white on a field of black. Fung-Taou then printed an edition of the nine *King*, or classical books, for the imperial college at Peking, from wooden blocks engraved in relief: this work was completed in 952. In 1041 a Chinese blacksmith cut the most frequently used characters upon cubes of porcelain paste, which he then baked until hardened. These, being of different heights and thicknesses, were placed in a kind of cement, pressed down evenly, and printed from; but this process seems not to have extended after his time. Various attempts have been made to substitute separate characters for the engraved blocks, but it is rendered difficult because every word in Chinese requires a separate character, instead of each word being composed of elements resolvable into the simple alphabet of Western nations. It is estimated that there are about 80,000 of these characters, though not more than 14,000 to 15,000 are in regular use. Movable type, both of wood and of copper, have long been in use in China, and some large works have been printed from them. (See Encyclopædia.) The *Peking Gazette* is printed from movable wooden type (see Newspapers), and millions of pages of books and periodicals in Chinese are annually printed from movable type at the mission presses and elsewhere. The Greeks were early acquainted with engraving on metal, their maps being cut with lines below the surface, but it does not appear that they multiplied copies from them. The ancient Romans made use of metal stamps, with characters engraved in relief, to mark their articles of commerce and brand cattle. The old Roman potters appear to have possessed separate stamps for letters, as some of their clay lamps show that the inscriptions were made by impressing each letter separately. The British Museum contains several Roman stamps with the letters engraved in relief, which seem to have been used to print the owner's signature on documents. Although the Romans had no mechanical mode of multiplying literature, they had a well-organized system of slave-labor, which enabled books to be written cheaply, and nearly every one could boast of having one or more volumes. With the decline of Roman civilization literature was despised by all ranks of society. During the following centuries the taste for literature was cultivated by a few; the Church through her scribes fostered the transcription of the Bible, the classics were multiplied, and gradually the people acquired a thirst for knowledge which was but poorly supplied. With the introduction of the art of paper-making, about the beginning of the eighth century, epistolary correspondence increased, books were multiplied more rapidly, and with the endeavor to supply the people more cheaply with religious reading wood-engraving was invented, first to disseminate scriptural scenes, and afterward to make illustrations and texts for books in imitation of the manuscripts of the period.

Block-printing and Block-books.—Toward the beginning of the thirteenth century wood was engraved upon in Italy, Sicily, and Spain to produce designs with the aid of ink on fabrics of linen and silk. Playing-cards were produced by the same method, and afterward colored by hand or by means of stencil-plates. Old manuscripts of this time are in existence which have initial letters, and sometimes pictures printed, while the text is in handwriting. There is in the library of Upsala, Sweden, a curious volume known as the *Codex Argenteus*, or *Silvered Book*, a translation of the four Gospels, so called because the letters are in silver on leaves of purple vellum, supposed to have been made not later than the sixth century. From the indentation on the other side of the leaf, and the turned letters found occasionally, it seems to have been made by the separate stamping of each letter upon the leaf. About the beginning of the fifteenth century single prints of a religious character appeared, from Germany and Holland. These pictures, or image-prints, were made of many sizes, generally engraved in outline, and highly colored. The earliest known with date is that of St. Christopher carrying the infant Saviour upon his back across a river. It has a legend of two lines at the foot, with the date 1423. Three copies are known to be in existence. It is about 8 by 11 inches in size, printed on paper, and in ink almost black, differing thus from other image-prints, which are generally in a dull or faded brown ink. There are many other image-prints which are referred to about the same date. Manuals of devotion followed, of a limited number of pages, generally containing pictures with a few words beneath or in the interior, some having the pictures on one leaf and the explanation or text on the other. The most notable of these were the *Biblia Pauperum*, or *Bibles for the Poor*, or rather books for indigent preachers, consisting of a series of rude engravings, each occupying a page, on one side of the leaf only, and divided into compartments having pictorial illustrations of the most remarkable incidents mentioned in the Pentateuch, the Gospels, and the Apocalypse, and accompanied with explanations in Gothic characters. The two pages facing each other were engraved on one block of wood, and the book put together in sections of two leaves, two pages of illustrations being followed by two blank pages. It was a folio, printed on paper, in ink of a dull or rusty-brown color, and contained forty pages, each engraving being 10 inches long and 7½ inches wide, without folios; but the first twenty pages were marked in alphabetical order from *a* to *v*, and the last twenty with the same letters having a dot before and after, as *.a.* to *.v.* Its date is referred to about 1420. At least four distinct editions from wood, two Latin and two German, have been discovered. Of the first edition there are known to be fifteen copies, varying in slight particulars, but tending to prove a common origin. The workmanship of the *Biblia Pauperum* is like that of other block-books, of which notable examples of an early date are the *Apocalypsis Johannis*, three works on the *Virgin Mary*, the *Ennditkrist* or *Antichrist*, *Ars Memorandi*, *Ars Moriendi*, and *Speculum Humanæ Salvationis*. Sotheby, in his *Principia Typographica* (1858), describes twenty-one block-books, all distinct works.

Introduction of Typography.—There is no exact and entirely acceptable account of the invention of typography from the pen of any eye-witness or contemporary chronicler. Our knowledge of the subject has been gathered from the imprints of the first books; from casual and often inexact

notices of early writers, who relate hearsay testimony; and from legal records, sometimes of doubtful authority. All the notices are deficient in necessary details. They show that the invention was not fully appreciated, either by the printers or by the public. When the eye-witnesses were dead, and the merit of the invention was acknowledged, explicit and positive testimony began to appear, but this testimony was usually colored by family or national pride. The claimant of earliest date is Laurens Janszoon Koster, of Haarlem, whose name was first mentioned in print in 1588. It is said that Koster invented types of wood about 1428, and types of metal at a later date, that with these he printed the *Speculum Salutis* and other little books, and that about 1440 one John (by implication John Fust or Faust), then a workman in Koster's employ, stole his types and his secret, carried them to Mentz, and there introduced typography. Koster died soon after, leaving no known successor nor any school or process of printing that can be claimed as his. Dr. Van der Linde, in his *Haarlem Legend*, has proved the falsity of the Koster legend, but William Blades, in his *Pentateuch of Printing*, holds that even if the Koster legend be proved untrue, there is evidence of a petty but unsuccessful practice of typography in Holland before 1450. This evidence is indirect, inferential, and unsatisfactory. Other claimants for the honor of the invention are Albert Pfister, of Bamberg, Germany, an engraver on wood, whose first dated book is of the year 1461; Pamphilo Castaldi, of Feltre, Italy (to whom a statue was erected there in 1868), who is said to have taught Fust how to make types before 1454; John Mentel, of Strassburg, who is said to have been a printer as early as 1440; and Procope Valdfoghel, a goldsmith of Prague, who taught "artificial writing" by means of metal letters at Avignon, France, in 1444. The testimony in favor of these and of other claimants of minor importance has not withstood critical investigation. John Gutenberg is the only claimant who is known to have received honor as the true inventor during his lifetime. He did not put his name on any of his books; he did not personally make any claim to be the inventor; he did not clearly describe his invention. Most of our knowledge of him and his work is derived from legal documents and the testimony of friends, who meagerly and often inexactly described his processes. The records of a suit at law in which judgment was recorded Dec. 12, 1439, show that he was then at variance with his copartners, Dritzehen, Riffe, and Heilmann. It appears from the written testimony that he had been engaged in the development of a secret process, from which all the partners hoped to get great profit at the fair of Aix-la-Chapelle to be held in 1440. Only one of the witnesses testified that the work was printing. It does not appear that Gutenberg was then successful as a printer, for there is no book that can be even plausibly claimed as the result of his work in Strassburg. The genuineness of this legal record has been challenged by Dr. Hessels, but it has been accepted as trustworthy by most bibliographers. Unfortunately, it was destroyed by the Prussian army in the siege of Strassburg in 1870. In 1448 Gutenberg was a resident of Mentz, with a printing-office in the house of his uncle. In 1455 he appears as defendant in a suit brought by John Fust or Faust for the recovery of 1,550 guilders, lent for the purpose of "making tools" for "vellum, paper, and ink," and for the "work on the books." Fust won the suit and took possession of the printed work and types of Gutenberg. This did not prevent Gutenberg from establishing a new printing-office, which he is supposed to have managed until his death in 1468. As Fust and his son-in-law, Peter Schoeffer, continued to print after 1455, and as there is some reason to believe that there was a third unknown and unnamed printing-house in Mentz before 1455, it is difficult to specify the books made by Gutenberg. The *Letters of Indulgence of 1454*, *1455*, and *1461*, and six small pamphlets have been attributed to him, on account of the similarity of their types with the types of his books, but the evidence is not sufficient. The *Bible of 42 lines*, usually bound in three volumes, folio, two columns to the page, published before 1456; the *Bible of 36 lines*, three volumes, folio, two columns to the page, of unknown date (certainly before 1460, and possibly before 1450); and the *Catholicon of 1460*, a Latin dictionary of 748 pages folio, two columns to the page, are the best specimens of the work reasonably accredited to his press—all of them unmistakable productions of a master. In 1465 Gutenberg was appointed by the elector as one of his courtiers, in recognition of his services. When he died the elector forbade his printing-office to be removed from Mentz. Gutenberg's neglect to assert himself as the inventor of printing was incompletely remedied by his friends and successors, but it was generally admitted before the year 1500, by printers everywhere, in France, Germany, Italy, and the Netherlands, that Gutenberg was the inventor of typography. A tablet certifying his right as an inventor was put up soon after his death in the church at Mentz, and another in 1509 in a law school of that city. Statues have been erected to him in Mentz, Frankfort, and Strassburg. The merit of Gutenberg's invention was largely in his superior method of making types by means of punch, matrix, and mould. When he began his experiments he found already in common use paper, printing-ink, engraving in relief, some form of printing-press, and the art of printing playing-cards and block-books. Possibly isolated types were then in use, but they could not be used to profit, because they were not scientifically made and sufficiently exact. That Gutenberg derived advantage from the successful experiments of earlier block-book printers is probable, but he must have added to the common stock of knowledge much more than he found. Gutenberg's method of type-making was the only key to the invention of practical typography. It was so considered by him when he speaks in the *Catholicon of 1460* of the new art as dependent on "the admirable proportion, harmony, and connection of the punches and matrices." Fust and Schoeffer further say in the *Psalter of 1457* that the book was made by the "masterly invention of printing and also of type-making." The printing-press is never mentioned by any early writer as an important factor in the development of the invention. Gutenberg's process of type-making has been improved in details, but its elementary principles have not been found susceptible of any improvement.

A few years after the sacking of Mentz (1462) the pupils and the workmen of Fust and Schoeffer were dispersed, the discovery was made public, and the art spread over Europe. From Mentz the art was transplanted to Rome in 1467 by Sweynheym and Pannartz; to Paris in 1469; to England in 1477; and to Spain in 1474. Hawkins, in his *Titles of the First Books* (New York, 1884), gives a chronological table of 236 places where the art was practiced during the fifteenth century, with the names of the printers when known, and of the first productions of their presses. Of the various editions of books published in the sixteenth century, one-half were Italian, of which one-half were Venetian; one-seventeenth were English.

Printing in America.—The date of the introduction of printing into America is uncertain, but from the record of three early Spanish authorities it is believed that the art was introduced into Mexico by Viceroy Antonio de Mendoza, who arrived in that country in Oct., 1535. The first printer's name was Juan Pablos, and the first work printed the *Escala espiritual para llegar al Cielo* of San Juan Climaco, a translation from the Latin into Castilian by the printer himself. No copy of the work exists. The first book with date establishes the fact that a press was working in the city of Mexico in 1540. It is called *Manual de Adultos*, dated Dec. 13, 1540, a quarto in Gothic letter, printed by Juan Cromberger, whose imprint is also on several other books printed from 1540 to 1544. This Cromberger was a celebrated printer of Seville, and books bearing his imprint at this place also appeared both before and after the dates of the Mexican works. It is suggested, to reconcile all the statements brought to light, that Juan Pablos may have been at Seville in the employ of Cromberger, who was charged by Mendoza with the establishment of a printing-press in the city of Mexico, and who sent Juan Pablos over to conduct the business in the name and for the benefit of his master; that after Cromberger's death Pablos became the owner of the establishment, and was in this way, although not the first owner of a printing-press, entitled to the honor of calling himself the first printer of Mexico. The next press established in the New World was at Lima, Peru, about 1584, the earliest known book printed there being the *Doctrina Christiana*, a quarto in the Quichua and Aymara languages, printed by Antonio Ricardo in 1584. Several other religious works by the same printer in 1585 and 1586 are in existence. Between 1540 and 1600 there is recorded the issue of ninety-three works in the city of Mexico and seven in Lima. In 1639 the first press in North America was erected at Cambridge, Mass., in the house of the president of Harvard College, Rev. Henry Dunster, through the efforts of Rev. Joseph Glover, who died while bringing the press and materials to this place. It was

placed under the direction of Stephen Daye, by whom the first work issued was *The Freeman's Oath*, followed by *An Almanack* in the same year. Daye was succeeded about 1649 by Samuel Green, under whom, in 1660–63, was printed the celebrated Indian Bible of Eliot, and other of his works in the Indian language. This press is still active, and known as the "University Press." The next press was established in Boston in 1676, after which printing gradually extended throughout the colonies. In 1775 the whole number of printing-houses in the British colonies was fifty.

Early Printed Books.—It is interesting to note the peculiarities of the first printed works. An edition consisted of a limited number, for 200 or 300 was then esteemed a large issue. The size was either large or small folio, sometimes quarto. The leaves were without running title, direction-word, folios, or paragraphs. The words were printed close together; abbreviations were numerous; the orthography was arbitrary; the sentences were distinguished only by the single or the double point, but subsequently the virgule / was used for the simple pause, answering to our comma. The initial letters at the beginning of a chapter or important division were left blank to be filled in by hand. In some works the embellishments surrounding the text were illuminated in colors, even gold and silver, and charged with saints, birds, flowers, etc. The printer's name, residence, etc., were either omitted or put at the end. The date was often omitted, sometimes obscurely indicated, or printed either at full length or by numerical letters, and sometimes in several ways together, as, "One Thousand cccc. and lxiiii.," etc., but always at the end. A variety of characters was uncommon; as a rule a Gothic letter of the same size was used through the work.

Type.—These are the letters or characters used in typography. A type is a thin metallic bar, like Fig. 1, which represents the letter M, and has the following characteristics: *c* is the face; *f*, the body; *g*, the nick; *a* to *b*, the width or set; *b* to *d* the height of the printed character; *c* to *e*, the height to paper; *d*, the shoulder; from *d* to the face is called the beard; *h*, the groove left in dressing by cutting off the superfluous metal left by the mould, which leaves two parts for the bottom of the type, called the feet; the thicker stroke of a letter is called the stem or body-mark; the fine lines at the top and the bottom of a letter are the serifs; a projection over the body, as the top and the bottom of *f*, is a kern. Types are made of type-metal, a composition of which the principal ingredient is lead. The type-founders of the present day use alloys which are generally trade-secrets. The alloy most approved is composed of certain proportions of lead, antimony, tin, and copper, so that the metal shall be hard, yet not brittle; ductile, yet tough; flowing freely, yet hardening quickly. This composition on solidifying contracts but very slightly and insures the sharpness of the lines of the face; the antimony gives hardness, the tin toughness, and the copper tenacity. Different sizes of type are made of varying qualities of metal, designated ordinary metal, hard metal, and extra-hard metal. Comparatively soft metal is used for spaces and large type, while small type is composed of hard metal. Type is made more durable by a process which deposits a thin film of copper over the face. Roman and Italic type are most commonly employed in printing books in Europe and America, and these have undergone every change in form that taste or fancy could suggest, as may be noticed in the multitude of sizes, shades, and ornamentation exhibited in the display-lines of books, papers, circulars, and posters.

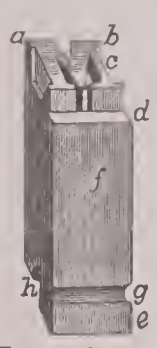

FIG. 1.—Type.

Wood Type.—The large letters used in handbills and posters are made of wood, usually maple or bay mahogany, which is prepared as for wood-engraving. By the old method the outline of the character was first carefully cut upon the face of the block, and this was afterward put under a revolving drill, which cut away the superfluous wood, when it was finished by an engraver. William Leavenworth, of Allentown, N. J., in 1834 applied the pantograph to the cutting of wood type. In this a tracing-point at one end follows the outline of a large model letter, and is repeated at the other end by a revolving cutter, which cuts the letter from a block of wood, after which it is dressed with a graver.

Sizes of Type.—The various sizes of type have grown gradually into use, as the requirements of books and newspapers have dictated, or the pride of punch-cutters has accomplished. The names given to them are arbitrary and unmeaning. The following are the old names of the sizes most used in books and newspapers: 1. Brilliant; 2. Diamond; 3. Pearl; 4. Agate or ruby; 5. Nonpareil; 6. Minion; 7. Brevier; 8. Bourgeois; 9. Long primer; 10. Small pica; 11. Pica; 12. English; 13. Great primer.

The following is a specimen of the sizes of type up to great primer, the numbers corresponding to the numbers and names above.

1.—abcdefghijklmnopqrstuvwxyz
2.—abcdefghijklmnopqrstuvwxyz
3.—abcdefghijklmnopqrstuvwxyz
4.—abcdefghijklmnopqrstuvwxyz
5.—abcdefghijklmnopqrstuvwxyz
6.—abcdefghijklmnopqrstuvwxyz
7.—abcdefghijklmnopqrstuvwxyz
8.—abcdefghijklmnopqrstuvwxyz
9.—abcdefghijklmnopqrstuvwxyz
10.—abcdefghijklmnopqrstuvwxyz
11.—abcdefghijklmnopqrstuvwxyz
12.—abcdefghijklmnopqrstuvwxyz
13.—abcdefghijklmnopqrstuvwx

These alphabets show clearly the difference in the height of face and the thickness of the letters of the various fonts. Larger sizes, with a few exceptions, are named according to the number of pica lines in depth, as four-line pica, five-line pica, etc. Between nonpareil and minion there is a size in Great Britain known as emerald. Newspapers use minion, nonpareil, and agate extensively. Diamond is seldom used for entire works. The Oxford University Press issued in 1875 the "smallest Bible in the world," in English, printed on India paper, from diamond type; it contained 984 pages, each 72 lines long, including the head, and 37 ems wide. The bound volume is $2\frac{6}{8}$ inches wide, $4\frac{5}{8}$ inches long, and half an inch thick. The American Bible Society issued in 1857 a diamond Bible, containing 882 pages, each 72 lines long, and 41 ems wide, which has the usual thin paper and leather binding. If presented in the English dress, it would be about a quarter inch wider and longer, but 100 pages thinner. Brilliant is rarely employed, except for references or side-notes to Bibles, etc. Small as this type is, a type-cutter of Berlin has formed a type so minute as to be scarcely readable without a good magnifying-glass. More surprising still, as early as 1828 Henri Didot, of Paris, had cut characters of almost microscopic fineness, 25 lines to the English inch, with which he printed an elegant edition of Horace in 64mo.

The names here given to types are those of the old system, which is steadily falling into disuse in Europe and America. The U. S. Type Founders' Association in 1886 changed the names and dimensions of all bodies, as is shown in the following table:

New name.	Fraction of an inch.	Old name.
3-point	0·0415	Excelsior.
$3\frac{1}{2}$ "	0·0484	
4 "	0·0553	Brilliant.
$4\frac{1}{2}$ "	0·0622	Diamond.
5 "	0·0692	Pearl.
$5\frac{1}{2}$ "	0·0761	Agate.
6 "	0·083	Nonpareil.
7 "	0·0968	Minion.
8 "	0·1107	Brevier.
9 "	0·1245	Bourgeois.
10 "	0·1383	Long primer.
11 "	0·1522	Small pica.
12 "	0·166	Pica.

These numerical names define the size of each body and its relation to all other bodies. The French system of points, from which the American system was copied, has its point of larger size—·0376 + cm., which is too large for the nicer subdivisions of bodies made by type-founders in the U. S. Eleven points French are nearly as large as twelve points American. The French system has been adopted in Germany, Spain, Belgium, Switzerland, and Italy.

Height, Measurement, and Standard.—The height to paper, or the distance from the face to the feet of type, varies in the type made by the foundries of Europe and America. The standard English height is ·9166 inch; the U. S. new

standard is ·9186 inch; the French standard is higher; the Russian standard is more than 1 inch. There is no generally accepted standard of width for the alphabet of twenty-six letters, which must vary with the fashion of the face and the size of the body. As types decrease in size below bourgeois they must be made of steadily increasing width. Different fonts will vary from twelve ems to sixteen ems to the alphabet. Book-compositors require fonts from pica to bourgeois to measure not less than thirteen ems, and below bourgeois not less than fourteen ems; for smaller sizes a greater width is exacted. For very thin types that fall below the standard extra compensation is allowed. The earliest exact standard is the French, in general use on the Continent, which divides pica, one-sixth of an inch deep, into twelve parts, called points, and conforms each size to a certain number of these points. The standards vary in Great Britain and the U. S., though generally, a pica being about one-sixth of an inch, two nonpareils are equal to one pica, two pearls to one long primer, two diamonds to one bourgeois. The following table will give an idea of the proportions of types to space, etc., taking Bruce's standard of length, in which 201·58 lines of diamond are contained in a foot, and every size is made 12·2462 per cent. smaller than the size following it:

SIZE.	Lines in a foot.	Ems in a pound.	Square inches in 1,000 ems.
Pearl	179·59	800	4·55
Agate	160	690	5·29
Nonpareil	142·54	520	6·93
Minion	126·99	360	10·10
Brevier	113·13	290	12·60
Bourgeois	100·79	270	13·86
Long primer	89·79	200	18·20
Small pica	80	170	21·16
Pica	71·27	130	27·72

Types made by the point system will show slight variations from the figures of this table.

One pound of composed type occupies 3·5 sq. inches. For the various processes in making type, see TYPE-FOUNDING.

Fonts.—A complete assortment of type of any one face or size is called a *font* or *fount*, which may be varied to any extent. Type-founders have a scheme for the proportional quantity of every letter required for a font, and a peculiar scale is necessary for every language. In Great Britain founders select a scale having 3,000 of the small letter *m* for its basis. In the U. S. the founders adopt nearly the same scheme by weight, and proportion all fonts, large or small, accordingly, a font of 500 lb. containing 20 lb. 8 oz. of *a* and 28 lb. 4 oz. of *e*. The following table shows the relative proportion of every character required in a font of 800 lb. of pica for ordinary work in the English language:

A FONT OF PICA, WEIGHING 800 LB.

Small letters.		Points, etc.		Capitals.		Small capitals.	
a	8,500	,	4,500	A	600	A	300
b	1,600	;	800	B	400	B	200
c	3,000	:	600	C	500	C	250
d	4,400	.	2,000	D	500	D	250
e	12,000	-	1,000	E	600	E	300

v	1,200	4	1,000	V	300	V	150
w	2,000	5	1,000	W	400	W	200
x	400	6	1,000	X	180	X	90
y	2,000	7	1,000	Y	300	Y	150
z	200	8	1,000	Z	80	Z	40
&	200	9	1,000	Æ	40	Æ	20
ff	400	0	1,300	Œ	30	Œ	15
fi	500						
fl	200	Accents.		Spaces.			
ffi	150	6	200	3-em spaces	18,000		
ffl	100	à	200	4-em “	12,000		
æ	100	â	200	5-em “	8,000		
œ	60	ô	200	Hair “	3,000		
—	150	All other accents, 100 each.		Em quads	2,500		
——	90			En “	5,000		
———	60			Large quadrats, 80 lb.			

This is the proportion for Roman letters, etc. An Italic font to accompany this would be in the proportion of one-tenth of the Roman, not including spaces and small capitals. To give an idea of the number of pages this will set, suppose the page of pica type to be 8¾ inches long by 5¼ inches wide, or 53 lines long by 35 lines or ems wide. This will give 1,855 ems in a page; there being 130 ems in a pound, this will make the page weigh nearly 14¼ lb., which, divided into 800 lb., gives about 56 pages. This calculation shows only how many pages could be set if every character were used, but copy always exhausts the characters unequally. Fonts of book-type vary from 50 lb. to 20,000 lb.

Arrangement of the Type in Cases.—The type when received from the founder are arranged in a case containing

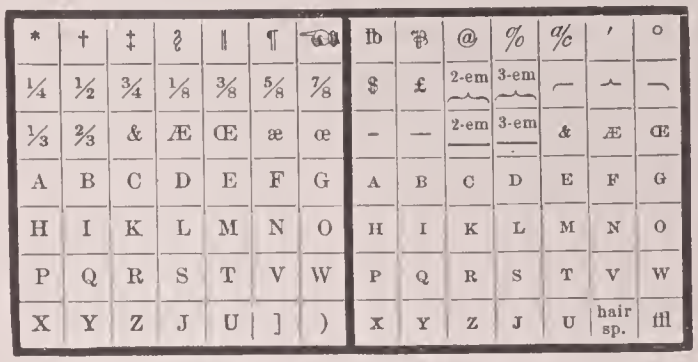

FIG. 2.—Upper case.

boxes of various sizes for the different characters. The lower case has remained nearly the same as it was 200 years ago. It is a tray of wood, about 1¼ inches deep, 32½ inches long, and 16¾ inches wide. Cases go in pairs, the upper case (Fig. 2) containing 98 boxes for capitals, etc., and the lower case (Fig. 3) containing 54 boxes for small letters, figures, and

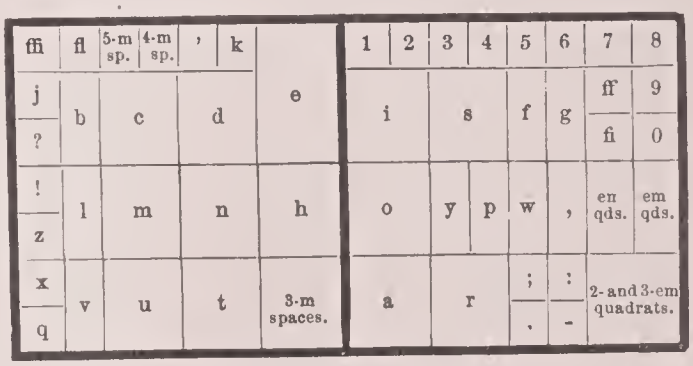

FIG. 3.—Lower case.

spaces. Fig. 2 shows the case adopted by the book-compositors of the U. S., having the capitals on the left side and the small capitals on the right. Newspaper compositors prefer the capitals on the right side and the small capitals on the left. The lower case is so arranged that the letters most frequently used are placed in large boxes toward the middle and in front of the compositor. These cases are placed on a frame or stand about the height of the breast, and in a sloping position from the top to the bottom of the case, the capital case on the upper part of the frame, whence called upper case, and the case containing the small letters on the lower part of the frame, hence called lower case. These cases contain only Roman letters. Italics and all other varieties are kept separately in similar cases. The spaces noticed in the cases are of different widths, so made to equalize the spacing. The *em* is a square space; *en*, 2 to an em; 3-em, 3 to an em; 4-em, 4 to an em; 5-em, 5 to an em; and hair-spaces, 6 to 13 to an em; 2- and 3-em quadrats are double or triple *ems*.

Composition or Typesetting.—The compositor in setting up type uses a small frame of steel, having three sides and a bottom, called the composing-stick (Fig. 4). It is usually from 6 to 12 inches long, 2 inches wide, and ⅝ inch deep, and will hold about 20 lines of minion. Larger sizes are occasionally used for wide measures. Two sides are immovable, the third side being movable to be adjusted to the width of the page, and then clasped, as in the Grover patent (Fig. 4), or secured with a screw. A setting-rule, type high, and of the required measure, is also used with the stick; it is made of a strip of steel or brass, having a short pointed projection at the top of the right end or on both

FIG. 4.—Composing-stick.

ends. It enables the type to be put quickly in its place, and is used in emptying matter from the stick, in lifting matter, and to support matter in the left hand while distributing with the right. Having received a "take" or small portion of the copy of a work, which is placed conveniently on the upper case, the compositor holds in his left hand the stick, made up to the required measure, like a small trough, the rule resting against the back, and stands in front of the frame or the left of the middle of the case. Observing and remembering a few words of the copy, he looks to the proper box for the first letter, picks it up with the right hand so that the nick (Fig. 1, *g*) shall be outward and from him, and lays it in the stick with the nick looking toward the opening, which brings the letter right side up. While putting the first letter in the stick, his eye at the same time looks toward the next box, and, his hand following immediately, he again picks up a letter with the nick from him, and places it by the side of the other. He does not look at the face of the letter, but glances at the nick (Fig. 1, *g*), and takes it for granted that if it come from the right box it must be the right letter. He secures every letter successively with the thumb of the left hand as the type are placed side by side in line from left to right. As nearly as the letters will allow in print, the type are set in the stick thus: ⊥ʎdoƃɹɐdɥʎ. The compositor always reads the type in this manner, and does so as quickly as the ordinary reader comprehends the printed page. When he comes to the end of his line, and finds that he has a syllable or word which is either too long or too short to fill out the measure, he has to perform an operation which requires care and judgment. This is called *justification.* The first and the last letter must be at the extremities of the line; and the distances between the words must be made as nearly as possible uniform by changing the spaces, already described, and thus getting in or driving out the whole of the syllable or word. The first line being justified, the rule is lifted to the front, and the compositor proceeds with the next line, and so on till the stick is full. If the matter is open, thin strips of metal (called "leads") are placed between the lines. Placing the rule at the front, he clasps the stickful with the thumbs on each upper corner, the forefingers on each lower corner, and the side of the first and second joints of each middle finger at the left and right sides of the type, presses the corners and the sides toward the center, and thus readily lifts the mass of separate letters; but it requires some practice to do this neatly. The stickful is placed on a galley, or oblong tray of wood or brass, having a raised edge of half an inch on two, three, or four sides, but generally on the left side and top. Having completed his portion, the matter, as it is now called, is ready to be made up.

Distribution of the Type.—When the compositor has set most of the type out of the case, he distributes *dead* matter. The matter is first wet with water to hold the type slightly together. Placing twenty lines or so on the rule, held in the left hand and resting against the inside of the thumb and on the side of the third finger, he takes a few words between the thumb and middle finger of the right hand, separates the letters by the pressure of the forefinger, and, when his hand is over the proper box, lets the letter fall. This he continues till the case is full.

Composing and Distributing Machines.—Much labor and ingenuity have been expended in efforts to substitute machinery for hand-labor in setting type, and though about 100 patents have been granted, but few machines are in use. The only typesetting machines now doing practical work in the U. S. (1894) are the Mergenthaler or Linotype, the Thorne, the MacMillan, and the Burr. The Mergenthaler is also a type-making machine. It produces lines of newspaper type in solid bars, at the rate of three or four lines a minute. The Lanston machine makes single types and composes them. The Thorne machine makes use of the type of type-founders, composing and distributing them at the rate of 4,000 ems or more an hour. The MacMillan also makes use of founded type, which it composes at the same rate of speed, but its distribution has to be done on a separate machine. The Paige machine uses type already founded, which it composes, distributes, and justifies at a very high rate of speed. The Burr machine makes use of founded type, which it composes rapidly, but it requires a separate machine for distribution. Every machine, however fast or accurate, has disadvantages. Most of the typesetting of the world is still done by hand.

Unit of Measurement.—In the U. S. the compositor is paid according to the number of ems he sets (in Great Britain by the number of ens), without compensation for filling his case or for correcting errors. Difficult manuscript or intricate composition, however, is generally done at a certain price per week. In Continental Europe matter is measured generally by the number of letters, a more equitable method, as modern newspaper type varies from 12 to 18 ems to the alphabet. The em of measurement is the square of the body of type to be measured; the en of measurement is one-half of that square. In measuring the width of columns or pages, the letter m is placed sidewise in the stick, thus,

mmmmmmmmmmmmmmmmmmmmmmmmmmm;

and the number of these, multiplied by the number of lines in length, gives the number of ems; for instance, this cyclopædia is set in brevier type, 27 ems wide in a column, 84 lines long (not counting head and foot lines), and two columns in a page—$27 \times 84 \times 2$, making 4,536 ems in a page. The average number of pieces of metal, spaces and letters, is 2·25 to an em, so that 1,000 ems contain about 2,250 pieces. In an average page of this cyclopædia there are 1,680 words, 10 words to a line, 5 letters to a word; in addition, the spaces average 2·25 ems in a line, and 409 ems in a page. Words, therefore, in the English language average 5 letters, and in type 2·5 ems each. The number of ems the average compositor will set in an hour is 800. Many compositors are reported to have set from 1,500 to 2,000 ems per hour, and a large number average over 1,300 ems.

Make-up.—In newspaper-work or work requiring many corrections, or for other reasons, a proof is taken of the matter secured in a galley in long pieces, read, and corrected, sent to the author, and then made up, read, corrected, and sent to press or stereotyped. Usually, it is placed in the hands of the "maker-up," who, having set the appropriate headings, places a head-line at the top of the matter, containing the running-title of the book or the appropriate subdivisions of the work, divides the matter into pages with a gauge, affixes the foot-line—a blank line put at the bottom of a page—containing sometimes the signature or folio, and binds the page with cord. A proof, termed the "first proof," is taken, given to the proof-reader, who carefully compares it with the author's copy by the aid of a copy-holder, who reads aloud, and the errors noted are corrected by the compositor. A second proof, or "revise," is compared with the first, and sent to the author for his revision. His corrections are made, and the third or "press proof" is carefully read, generally by a more skillful proof-reader than the first, when the corrections are made, and the matter is ready for the press or for stereotyping or electrotyping. See STEREOTYPING.

Imposition is the method of so arranging the pages that they will be in consecutive order when the sheet or section of a book is folded. When the pages are to be stereotyped or electrotyped, only a few pages in their regular order are secured together and cast; yet these cast pages are afterward imposed on the press in the same manner as described below. For over 400 years imposition remained merely a trial process, the few early modes having been handed down to the present time without any attempt at systematic explanation. The pages are laid upon a marble or iron table, called the *stone.* Any number of pages may be imposed in one form, from 2 to 128, according to the size. The first page in simple forms is placed in the left-hand corner, with the foot of the page toward the imposer, and when completed the last page is found at its side. The second page and the next to the last are together; the third and the third from the last, and so on, advancing one from the first folio and receding one from the last, until the two middle pages are reached, which are in the 4to the 2d and 3d; in the 8vo. the 4th and 5th; in the 12mo. the 6th and 7th; in the 16mo, the 8th and 9th; in the 24mo. the 12th and 13th, and so on. (The terms 4to, 8vo, etc., here refer to the number of pages in a form, the usual designation of printers.) The imposition of the octavo, Fig. 5, and

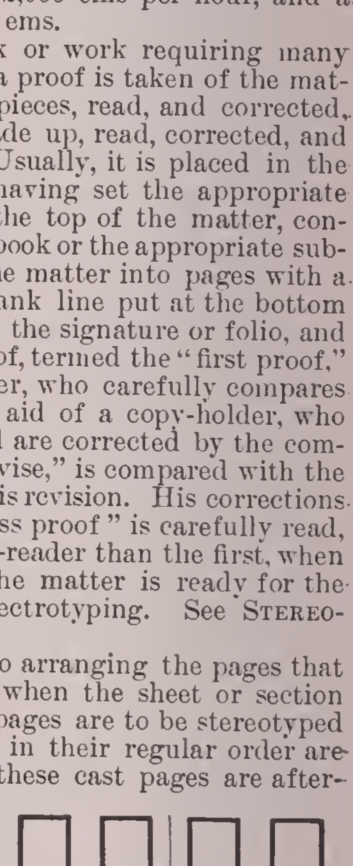

FIG. 5.—Imposition of the octavo.

of the duodecimo, Fig. 6, will illustrate the principle, the folio at one end of the page representing the head.

The pages are adjusted to the required distance apart according to the size of the paper, an iron "chase" or frame is placed around them, and wood or metal furniture, half an inch high, of various thicknesses, is placed, some at the head of the pages, called "head-sticks," some between the pages,

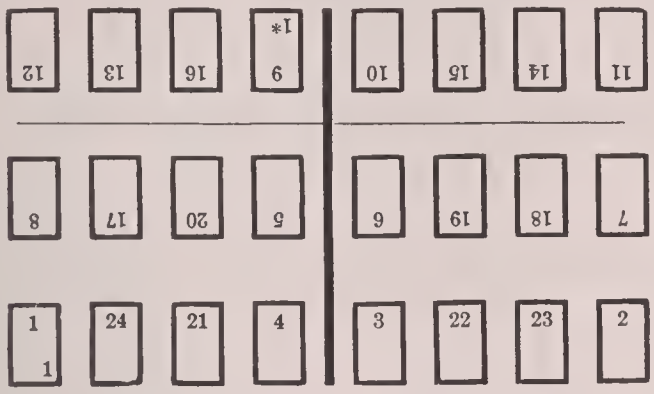

FIG. 6.—Imposition of the duodecimo.

called "gutters," and others at the sides and feet, called "side" and "foot sticks." The latter are larger at one end than the other, so that small wedges of wood or metal, called "quoins," may be driven tightly between them and the sides of the chase, locking the type firmly, making it like a solid piece, which may be lifted and placed on the press. The general practice up to recent date was to place the pages which would appear on the outside of a sheet in a single chase, and the inside pages in another chase, requiring every sheet to be printed from two forms for one copy. All the pages of a single sheet are now usually placed in one chase, and the paper turned over on the press, making two copies at two impressions. The chase is crossed by two iron bars, represented by the long lines across Fig. 5 and Fig. 6, which support and keep the chase from springing.

Signatures.—The signature is a figure or a letter of the alphabet placed at the foot of the first page of every form, or a section or sub-section of a form, to denote the order of the sheets, and serves as a guide to the binder. In an edition of *Terence*, printed by Antonio Zarot at Milan in 1470, signatures were used, and it is the first printed book known to have them. Catch-words were once extensively used, placed at the foot of the page, to show the connecting word on the next page, and are said to have been first used by Vindelius de Spira in Venice; but the Assyrians used catchwords. The English generally use for signatures the alphabetical letters, omitting J, V, W, which were not used in the Gothic letters of the early printers; and if the sheets extend beyond Z, the letters are doubled or preceded by a figure. The practice in the U. S., and in most European nations, is to use figures, a section to be inset being distinguished by a star after the signature figure. The star shows that that part of the sheet is cut off and placed inside the first part when folded. This is the simplest and readiest for the binder.

Sizes of Books.—The descriptive names of the sizes of books refer to the size of the leaves, and originated from the number of leaves into which a sheet of paper was folded after printing. The facility of paper manufacture has placed within the reach of printers any size of sheet, so that the size of the page of a book now depends only on the wish of the publisher. The book when bound is termed according to the nearest size of the regular sheets.

SIZE OF BOOK.	Pages in a sheet.	Size of leaf, untrimmed, in inches.
Royal 4to	8	11×14
Medium 4to	8	9½×12
Imperial 8vo	16	8×11½
Super-royal 8vo	16	7×10½
Medium 8vo	16	6×9½
Crown 8vo	16	5½×8½
Medium 12mo	24	5½×7½
" 16mo	32	4½×6½
" 18mo	36	4×6½
" 24mo	48	3½×5½
" 32mo	64	3×4½

The size of paper called medium, 19 by 24 inches, is the standard by which all sizes of books, not otherwise specifically described, are classified; and quarto, octavo, duodecimo, etc., mean that the leaves of books of these sizes are nearly the fourth, eighth, twelfth, etc., of the medium sheet.

Printing-ink is a mechanical mixture of prepared oil and smoke-black or other coloring-matter. News ink has more of oil, and book ink more of black. When properly made it "distributes" or freely spreads out in a very thin film on the inking rollers and the types, is readily transferred to paper by impression, and adheres to it when dry without smearing or fading.

Printing-rollers.—In the early days of printing the ink was applied to the type by large leather-coated balls. Each ball was fitted to a handle of wood. The interior of the ball was stuffed with wool or hair to make it elastic. One of these the pressman took in each hand, and, applying them to the ink-table, daubed and knocked them together to distribute the ink equally, and then blacked the form by beating the balls upon the face of the type. Rollers wound with cloth and covered with soft leather were next introduced, but to B. Forster, of England, is due the invention (about 1820) of the present roller. These rollers consist of a composition of glue and molasses, boiled together, and moulded upon a cylinder of wood encasing an iron rod, which works in a handle or in a proper frame for large presses. This cylindrical inking roller is rolled over the type, and applies the ink in a quick and even manner. Other compositions have been tried for rollers, but this was preferred for many years on account of its peculiar softness, even retention of the ink, and cheapness. The composition now most approved for its greater durability is a combination of glue, glycerin, and sugar.

Paper.—The paper used in newspaper-printing is always dampened before use, as wet paper takes the ink better than dry, and is now generally wet by a wetting-press. Paper is usually supplied by the ream of 20 quires of 24 sheets, or 480 sheets per ream. For the perfecting press paper is supplied from 3 to 5 miles long, a single web containing from 5,000 to 10,000 sheets. After printing, for book-work the sheets are hung up to dry, placed between sheets of thin smooth mill-board, placed in an hydraulic press, and subjected to great pressure, which smooths and restores the brilliant appearance of the paper. The sheets are afterward forwarded by the binder. See BOOKBINDING.

BIBLIOGRAPHY.—The bibliography of printing is voluminous; but a few of the prominent treatises are mentioned below. The origin of typography has been treated by Dr. A. Van der Linde in *The Haarlem Legend* (translated by J. H. Hessels, London, 1871) and in *Gutenberg* (Stuttgart, 1878); by J. H. Hessels in *Gutenberg* (London, 1882); A. F. Didot, *Essai sur la Typographie* (Paris, 1851); A. Bernard, *De l'origine et des Débuts de l'Imprimerie en Europe* (2 vols., Paris, 1853); Karl Faullman, *Geschichte der Buchdruckerkunst* (Leipzig, 1882); T. L. De Vinne, *The Invention of Printing* (New York, 1878). The development of typography among English-speaking peoples has been treated of by Ames in his *Typographical Antiquities* of various editions, of which Herbert's is best; C. H. Timperley, *Dictionary of Printers and Printing* (London, 1839); W. Blades, *William Caxton* (London, 1861–63); Talbot B. Reed, *Old English Letter Founderies* (London, 1887); Isaiah Thomas, *History of Printing in America* (2 vols., Worcester, 1810). The practice of typography has been explained by T. C. Hansard, *Typographia* (London, 1825); Ringwalt, *Encyclopædia of Printing* (Philadelphia, 1871); A. Marahrens, *Handbuch der Typographie* (Leipzig, 1870); T. Lefèvre, *Guide Pratique du Compositeur* (Paris, 1855); and *The Dictionary of Printing and Bookmaking* (New York, 1893). Good facsimile plates of early books have been published by Sotheby, *Principia Typographia* (3 vols., London, 1858); J. W. Holtrop, *Monuments Typographiques* (The Hague, 1868); Weigel and Zestermann, *Die Anfänge der Druckerkunst in Bild und Schrift* (2 vols., Leipzig, 1866). Bigmore and Wymans's *Bibliography of Printing* (3 vols., London, 1880) is a useful catalogue of all the authorities.

Revised by THEODORE L. DE VINNE.

Printing-presses: machines for taking impressions from an inked surface upon paper, used for books, newspapers, handbills, etc.

The Earliest Form.—Gutenberg's printing-press consisted of two upright timbers with crosspieces of wood to stay them together at the top and bottom, and two intermediate cross-timbers. On one of these the type was supported, and through the other a wooden screw passed, its lower point resting on the center of a wooden "platen," which was thus screwed down upon the type after it had been inked and the paper spread over it. The mechanical principle embodied

in this machine is found in the old cheese and linen presses.

This simple form of press continued in use for about 150 years, or until the early part of the seventeenth century, without any material change. The forms of type were placed upon wood or stone beds, incased in frames called "coffins," moved in and out laboriously by hand, and after each impression the platen had to be screwed up with the bar, so that the paper which had been printed might be removed and hung up to dry.

Blaeuw's Press.—The first recorded improvements in this press were made by William Janson Blaeuw, a printer of Amsterdam, about 1620. He passed the spindle of the screw through a square block which was guided in the wooden frame, and suspended the platen from this block. He also placed a device upon the press for rolling the bed in and out, and added a new form of iron hand-lever for turning the screw. Blaeuw's press was introduced into England, and used there as well as on the Continent, being substantially the same as that Benjamin Franklin worked upon when in London in 1725.

FIG. 1.—The Franklin screw-lever press.

Introduction of Iron Printing-presses.—Little further improvement was made in the printing-press before the year 1798, when the Earl of Stanhope caused one to be made, the frame of which, instead of being of wood, was one piece of cast iron. A necessity had arisen for greater power in giving the impression, especially in the printing of wood-cuts, and the tendency was naturally toward larger forms of type, requiring greater exertion on the part of the printer. The Earl of Stanhope retained the screw, but added a combination of levers to assist the pressman in gaining greater power with less expenditure of energy. These machines, although very heavy and cumbersome, came into use to some extent.

The next practical improvement was made by George Clymer, of Philadelphia, who, about 1816, devised an iron machine, entirely dispensing with the screw. A long, heavy cast-iron lever was placed over the platen, one end attached to one of the uprights of the cast-iron frame and the other capable of being raised and lowered by a combination of smaller levers, worked by the pressman after the manner of the ordinary hand-press. The impression was given and the platen raised and lowered by a spindle or pin attached to the center of the large cross lever at the top. Clymer carried his invention to England, where it was introduced to some extent, and was known as the Columbian press. In England Rutheven, Brown, and others made iron hand-presses, all improving upon the Stanhope. In 1822 Peter Smith devised a machine with a cast-iron frame, in which a toggle-joint, at once simple and effective, took the place of the screw with levers.

The Washington Press.—In 1827 Samuel Rust, of New York, perfected an invention which was a great improvement on the Smith press. The frame, instead of being all of cast iron, had the uprights at the sides hollowed for the admission of wrought-iron bars, which were securely riveted at the top and bottom of the casting. This gave not only additional strength, but greatly diminished the amount of metal used in the construction. The toggle motion was also a great improvement over that in the Smith press. This patent was purchased by R. Hoe & Co., who improved upon it. The new invention was known as the Washington press, and in principle and construction has never been surpassed by any hand printing-machine.

The bed slides on a track and is run in and out from under the platen by turning a crank which has belts attached to a pulley upon its shaft. The impression of the platen is given by means of a bent lever acting on a toggle-joint, and the platen is lifted by springs on either side. Attached to the bed is a tympan-frame covered with cloth, and standing inclined to receive the sheet to be printed. Another frame, called the frisket, is attached to the tympan, and covered with a sheet of paper, having the parts that would be printed upon cut away, so as to prevent the chase and furniture from blacking or soiling the sheet. The frisket

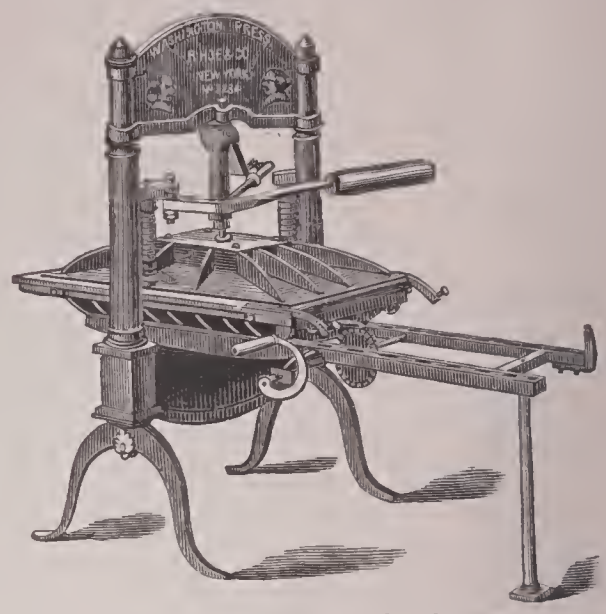

FIG. 2.—The Washington hand-press.

is turned down over the sheet and tympan and all are folded down when the impression is taken. Automatic inking-rollers were attached to this machine.

The bed-and-platen system of printing was up to the middle of the nineteenth century the favorite method for fine books and illustrations, and it is still used to a great extent. The first "power" or steam press upon this principle was made by Daniel Treadwell, of Boston, in 1822. The frames were of wood, but probably only three or four were ever constructed. The best press of this description is that devised and patented by Isaac Adams, of Boston, in 1830 and 1836,

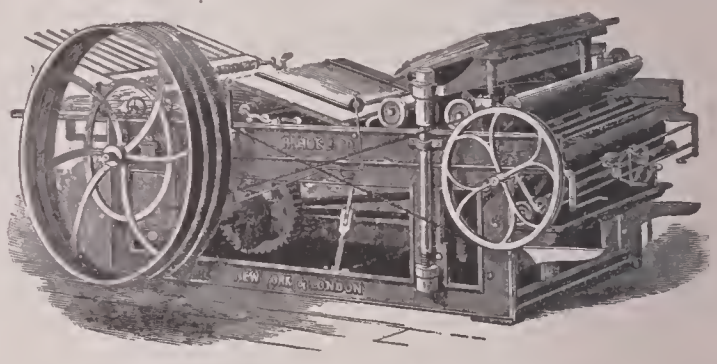

FIG. 3.—The Adams bed-and-platen press.

and by Otis Tufts, of the same place, in 1834. This was first made with a wooden and afterward with an iron frame. In 1858 Adams's business became the property of Hoe & Co., who continued to manufacture these presses, with added improvements. In these machines the type is placed upon an iron bed, after the usual manner of the hand-press, and this bed is raised and lowered by straightening a toggle-joint by means of cams, thus giving the impression upon the iron platen fixed above it, and firmly held in position by upright iron rods secured to the foundation of the machine. The ink-fountain is at one end of the press; the inking-rollers travel twice over the form, in a movable frisket-frame, while the bed is down; the paper is taken in by grippers on the frisket and carried over the form, when the bed rises and the impression is given; finally, the sheets pass forward from the frisket by tapes to a sheet-flier, which delivers them on the fly-board. One thousand sheets per hour is the maximum speed of the larger sizes of the Adams press.

Job-presses.—Many different kinds of small presses on the bed-and-platen principle are made; a typical one is the Gordon, illustrated on the next page. This can print over 1,000 cards or small sheets per hour. Special presses are also made for printing cards or tickets and numbering or lettering them consecutively.

Cylinder Presses.—The method of printing from plates or forms carried upon a flat bed backward and forward beneath a cylinder had been employed in a rude form by printers of copperplate engravings in the fifteenth century. With the re-introduction of this system began an entirely new era in the history of the printing-press. It should be understood,

however, that the vast number of patents granted for printing-machines in which the cylinder is connected with the bed, or by the operation of two cylinders together, one holding the form and the other giving the impression, are almost all

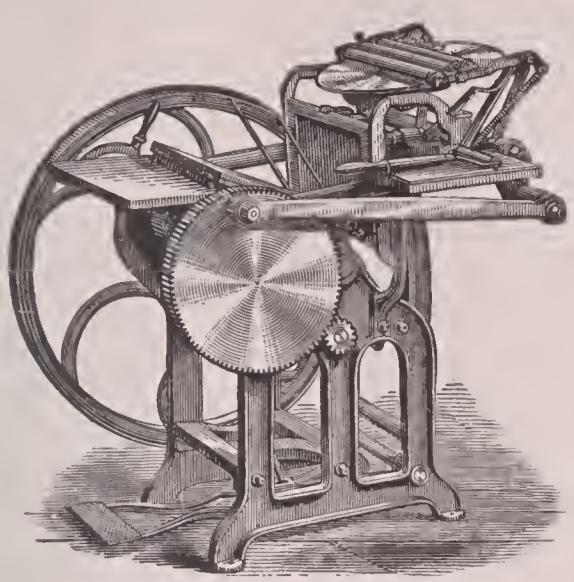

Fig. 4.—The Gordon press.

for improvements and devices of detail, the radical principles upon which they are founded remaining the same. There will be here described only those presses which have been in use as practical improvements.

The Flat-bed Cylinder Press.—The credit of actually introducing into use a flat-bed cylinder press is due to a Saxon named Friederich Koenig, who visited England in 1806, and through the assistance of Thomas Bensley, a printer in London, devised a machine which in 1812–13 was used by him, and printed, among other publications, a part of Clarkson's *Life of William Penn.* Koenig was assisted also by a mechanic named Andrew Bauer, a fellow countryman. The form of type was placed on a flat bed, the cylinder above it having a threefold motion, or stopping three times, the first third of the turn receiving the sheet upon one of the tympans and securing it by the frisket; the second giving the impression, and allowing the sheet to be removed by hand; and the third returning the tympan empty to receive another sheet. He also devised what has proved, even to this day, to be the best mechanism for producing reciprocating motion of the type-bed. This consists of a pinion carried on the inner end of a long shaft which is turned by gearing from the side of the press-frame, and has in its length a universal joint, allowing an up-and-down motion of the pinion. Underneath the bed and fastened to it is a "rack," or double row of teeth set back to back, with a crescent-shaped segment of hard metal at each end. The shaft being set in motion revolves the pinion, which moves the bed by engaging the teeth in this rack. On reaching the end of the rack, the pinion turns around over a pin or stud against the segment at the end of the rack, and immediately re-engages its teeth in the opposite side, so carrying the bed back again. This motion is repeated at the opposite end of the rack, and the bed again stopped and returned.

The Continuously Revolving Cylinder Press.—In 1814 Koenig patented a continuously revolving cylinder press. The part of the periphery of the cylinder not used for giving the impression is slightly reduced in diameter, so as to allow the form to return under it freely after giving an impression. He showed designs adapting it for use as a single-cylinder press, and also as a two-cylinder press, both for printing one side of the paper at a time; likewise a two-cylinder press for printing both sides of the paper at one operation. In this latter press the two forms were placed one at each end of a long bed, and the paper after being printed on one side by one cylinder was carried by tapes over a registering roller to the other cylinder, where it was printed upon the opposite side. This press, termed a "perfecting" press, was afterward improved by Applegath and Cowper, so as to be considered at the time a very efficient machine.

Koenig erected in the office of the London *Times* in 1814 two of the two-cylinder presses mentioned above, which printed on one side of the paper only, at the rate of 800 sheets per hour. He was not alone in his efforts to perfect a cylinder press. Various patents were gotten out by Bacon and Donkin in 1813; by Cowper in 1816, and again in 1818; and by Applegath in 1818.

Napier's Improvements.—The most ingenious and practical device in connection with the movements of a flat bed and a cylinder for printing-machines was patented by Napier in 1828 and 1830. He was the first who introduced "grippers" or "fingers" for the conveyance of the sheets around the cylinder during the impression, and for delivering them after printing. Tapes or strings had previously been used. He was also the first to construct presses in which the impression-cylinders are of small size, and make two or more revolutions to each sheet printed; and he devised the toggles for bringing the cylinders down to print on the form and then raising them to let the form run back without touching.

The Single Large Cylinder Press.—About 1832 Robert Hoe made the first cylinder press ever used in the U. S. It was the pattern known as the single large cylinder, the cylinder making one revolution for each impression in print-

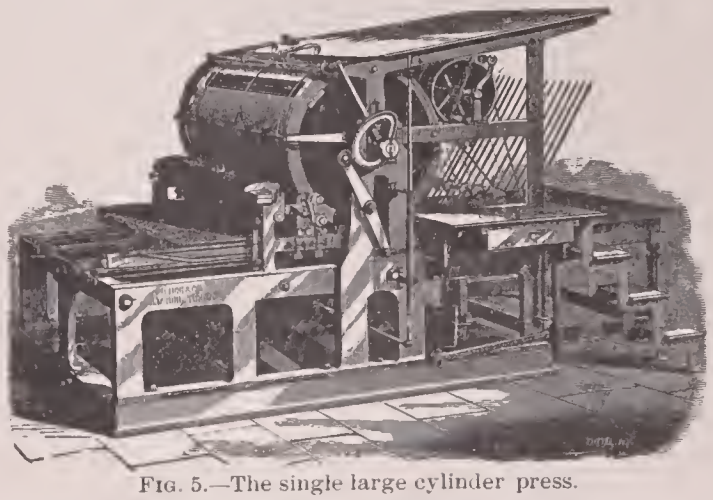

Fig. 5.—The single large cylinder press.

ing, and never stopping. Only a portion of the cylinder was employed to take the impression, the remainder of its circumference being turned down small enough to allow the type on the bed to pass back under it without touching. Similar presses were made later by other manufacturers, and this form of press is still in use, with patented automatic sheet-fliers, and other improvements.

The Stop Cylinder Press.—The press upon which the finest letterpress and wood-cut work is turned off is known as the Stop Cylinder. This was devised and patented by a Frenchman named Dutartre in 1852, and was later introduced into the U. S., and improved in many respects. The type is secured upon an iron bed, which moves back and forth upon friction-rollers of steel by a simple crank motion,

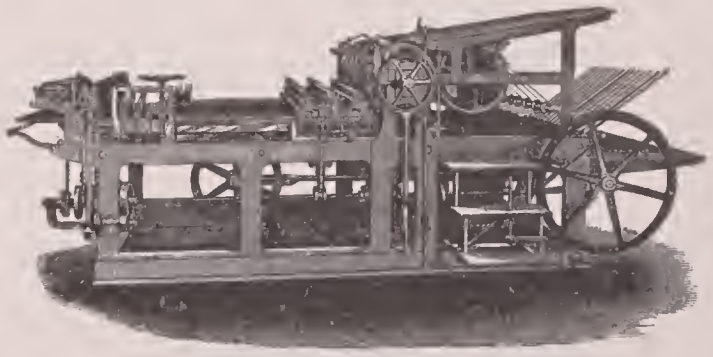

Fig. 6.—The stop cylinder press.

stopping and starting without noise or jar. The cylinder is stopped and started by a cam motion pending the backward travel of the bed, and during the interval of rest the sheet is fed down against the guides and the grippers close upon it before the cylinder starts, thus insuring the utmost accuracy of register. After the impression the sheet is transferred to a skeleton cylinder, also containing grippers, which receive and deliver it over fine cords upon the sheet-flier, which in turn deposits it upon the table. The distribution of the ink is effected partly by a vibrating polished steel cylinder, and partly upon a flat table at the end of the traveling bed, the number of inking-rollers varying from four to six. The average output of one of these presses with a bed 36 by 54 inches is from 1,000 to 1,500 impressions per hour. The very finest engraving, or cut-work, such as would be done with the greatest deliberation upon the Washington hand-press, is printed upon it at a speed of 700 impressions per hour.

Up to 1847 American newspapers were printed upon single small-cylinder and double-cylinder machines. The output of one of the single-cylinder presses reached 2,000 impressions per hour, or about as fast as the feeder could lay down the sheets. With the double-cylinder press the travel of the bed was of such length that the form of type passed backward and forward under both cylinders. Two feeders accordingly put in the sheets, the maximum speed obtained from each cylinder being about 2,000, or 4,000 per hour for the two cylinders, printed upon one side. The growing demand for papers containing the latest news, however, necessitated faster machines. The presses of Middleton, Dryden & Ford, and others in England failed to meet the requirements there, as did the single cylinder and double cylinder in the U. S.

The Type-revolving Machine.—Experiments made in 1845 and 1846 resulted in the construction of a press known as the Hoe type-revolving machine. The first of these machines was placed in *The Public Ledger* office in Philadelphia in 1846. The basis of these inventions consisted in an apparatus for securely fastening the forms of type on a central cylinder placed in a horizontal position. This was accomplished by the construction of cast-iron or brass beds, one for each page of the newspaper. The column rules were made "V"-shaped, i. e. tapering toward the feet of the type. It was found that, with proper arrangement for locking up or securing the type upon these beds, it could be held firmly in position, the surface forming a true circle, and the cylinder revolved at any speed required without danger of the type falling out. Around this central cylinder from four to ten impression-cylinders, according to the output required, were grouped. The sheets were fed in by boys, and taken from the feed-board by automatic grippers, or fingers, operated by cams in the impression-cylinders, which conveyed them

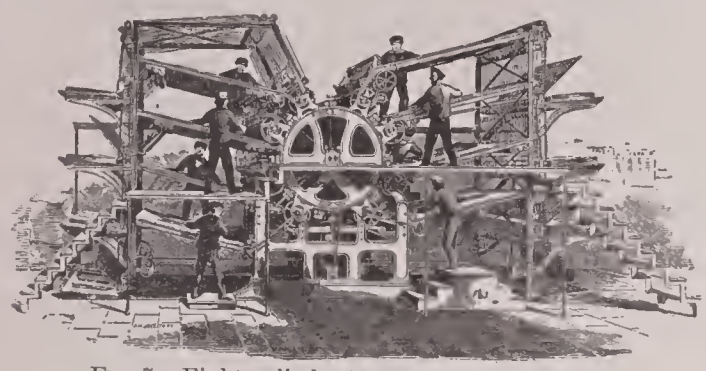

Fig. 7.—Eight-cylinder type-revolving machine.

around against the revolving form of the central cylinder. Here, again, a great advantage was gained by the use of the patented sheet-flier, consisting of a row of long wooden fingers fastened to a shaft, and operated by a cam and springs, the sheet after printing being conducted out underneath each feed-board by means of tapes to the sheet-fliers, which laid them in piles on tables, the number of fliers and tables corresponding to the number of impression-cylinders. The inking was accomplished by the use of composition-rollers placed between each of the impression-cylinders, the fountain being below, underneath the main type-cylinder. The portion of the surface of this type-cylinder not occupied by the type itself was utilized as a distributing-table, its surface being lower than that of the type, and the inking-rollers rising and falling alternately to place the ink on the type and receive a new supply from the distributing-surface. The speed obtained was about 2,000 sheets to each feeder per hour, thus giving, with what was called a four-feeder or four-cylinder machine, a running capacity of about 8,000 papers per hour printed upon one side. As the demands of the newspapers increased more impression-cylinders were added, until these machines were made with as many as ten grouped around the central cylinder, giving an aggregate speed of about 20,000 papers per hour printed upon one side. A revolution in newspaper-printing took place. Journals which before had been limited in their circulation by their inability to furnish the papers rapidly increased their issues, and many new ones were started. The first one put up abroad was erected in 1848, in the office of *La Patrie* in Paris. In 1856 Edward Lloyd, of *Lloyd's Weekly London Newspaper*, ordered a six-cylinder machine, and later the London *Times* ordered two ten-cylinder presses to replace an Applegath machine.

In the meantime experiments had demonstrated the possibility of casting stereotype plates on a curve. The process was brought to perfection by the use of flexible paper matrices, upon which the metal was cast in curved moulds to any circle desired, and these plates were placed upon the type-revolving machine upon beds adapted to receive them instead of the type-forms. The newspaper publishers were thus enabled to duplicate the forms, and run several machines at the same time.

Improvements by Applegath and Cowper.—After the return of Koenig to Germany an Englishman named Applegath, in connection with a machinist named Cowper, made various improvements, mostly in the way of simplifying Koenig's presses, and in 1848 constructed for the London *Times* an elaborate machine, entirely upon the cylindrical principle. All of the cylinders of this machine were vertical. The type was placed upon a large upright central cylinder, but the circumference, instead of presenting a complete circle, represented as many flat surfaces as there were columns in the newspaper, the forms thus being polygonal. Around this central or form cylinder were placed eight smaller vertical cylinders for taking the impression, rollers being introduced to ink the type as it passed alternately from one of these impression-cylinders to another. The sheets were fed down by hand from eight flat horizontal feed-boards through tapes, then grasped by another set of tapes and passed sideways between the impression-cylinder and the type-cylinder, thus obtaining sheets printed upon one side. The impression-cylinder delivered them, still in a vertical position, into the hands of boys, one stationed at each cylinder to receive them. The results obtained from this machine were in a measure satisfactory, as the number of papers printed per hour upon one side, from one form of type, was increased to 8,000. The press used in the London *Times* office was the only one of this kind ever made.

Use of a Continuous Web.—In 1835 Sir Rowland Hill suggested the possibilities of a machine which should print both sides at once from a roll of paper. Cotton cloths had long been printed in this way, the cylinders being engraved and the cloth after printing being reeled up again. William

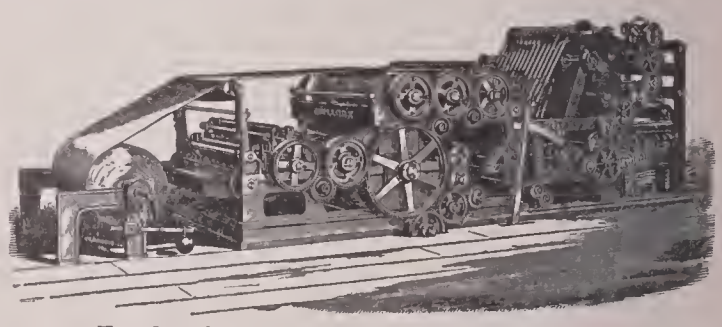

Fig. 8.—The Bullock stereotype perfecting press.

Bullock, of Philadelphia, constructed in 1865 the first machine to print from a continuous web or roll of paper. It consisted of two pairs of cylinders—i. e. two form or plate cylinders and two impression-cylinders. The second impression-cylinder was made of large size to provide additional tympan-surface, to lessen the offset from the first printed side of the paper. The stereotype plates were not made to fill the whole circumference of each of the form-cylinders, since by means of knives in cylinders the sheets were cut before printing. The sheets were carried through the press by tapes and fingers, and delivery sought to be accomplished by means of a series of automatic metal nippers placed upon endless leather belts at such distance apart as to grasp each sheet successively as it came from the last printing-cylinders. This machine was unreliable, especially in the delivery of the papers, but it was finally so far perfected that it came into use to a considerable extent.

Introduction of the Rotary Perfecting Press.—Meanwhile the proprietors of the London *Times* had begun experiments with the view of making a rotary perfecting press, and started the first one in their office about 1868. It was similar in construction to the Bullock press so far as the printing apparatus was concerned, excepting that the cylinders were all of one size and placed one above the other. The sheets were severed after printing, brought up by tapes, and carried down to a sheet-flier which moved back and forth and "flirted" the sheets alternately into the hands of two boys seated opposite one another on either side of the sheet-flier.

Marinoni, of Paris, also devised a machine on a similar principle, making the impression and the form cylinders of one size and placed them one above the other, but having separate fly-boards for the delivery of the sheets.

In 1871 R. Hoe & Co. also turned their attention to the construction of a rotary perfecting press to print from a continuous web of paper. The greatest difficulties were—1. The set-off of the first side. Devices were used to overcome this, and the ink-makers were induced to pay special attention to the manufacture of rapid-drying inks. 2. The need of paper in the roll of uniform perfection and strength. The paper-makers were led to produce large rolls of paper meeting these requirements. 3. The necessity of a rapid severing of the sheets after printing. 4. The need of a reliable and accurate delivery.

These last two operations were not accomplished satisfactorily until the appearance of the Hoe machine. In this press the sheets were not entirely severed by the cutters, but simply perforated after the printing. They were then drawn on by accelerating tapes, which completely separated them, to a gathering cylinder so constructed that six perfect papers, or any other desired number, could be gathered one over the other. These, by means of a switch, were at the proper moment turned off to one sheet-flier which deposited them on the receiving-board. The first of these machines was placed in the office of *Lloyd's Weekly London Newspaper*, and the first one used in the U. S. in the *Tribune* office in New York. There was no limit to their capacity for printing excepting the ability of the paper to stand the strain of passing through the press, which could produce from a single set of stereotype plates 18,000 perfect papers an hour, delivered accurately on one feed-board. The average speed, however, in printing-offices was 12,000 per hour.

The Walter press, made by the London *Times*, was used by it, and also by the London *Daily News* and by *The New York Times*. Further than that it made no progress. Meantime the Hoe machine was adopted by most of the large newspapers in the U. S. and Great Britain. These new methods of course entirely superseded the type-revolving machine, which had held the field in the newspaper world for over twenty years and of which 175 had been made.

Introduction of Automatic Folders.—It was desirable that the presses should deliver the papers folded. The first apparatus to accomplish this was similar in design to the hand folding-machines in common use in printing-offices. The sheets, fed by hand into these machines, were carried by tapes running upon pulleys under striking blades, which forced them between pairs of folding rollers. After the first fold they were again carried in a similar manner under striking blades, placed at right angles to the first, and again struck down between rollers to receive a second fold. This action was continued until the desired number of folds had been secured. Folders of this description were attached to the fast presses, but none made could be worked faster than about 8,000 per hour, until in 1875 Hoe & Co. patented a rotating folding cylinder which folded the papers at the rate of 15,000 per hour. The first of these folding-machines were put upon presses made for the Philadelphia *Times*, and operated in the Centennial Exhibition in 1876.

Striking blade folders were used in the Bullock press, and in machines made by C. Potter, Jr., & Co., and others. Andrew Campbell, a printing-press manufacturer, also constructed a rotary perfecting press, but his devices were not original. Four or five machines were made by him, and these soon went out of use.

Further Advances in Fast Printing.—About 1876 Messrs. Anthony and Taylor, of England, took out patents for devices by which the webs of paper could be turned over after printing on one side and the opposite or reverse side presented to the printing cylinder. Edward L. Ford, engaged in the publication of a newspaper in New York, patented the uniting of the product of two or more printing mechanisms, thus producing (in restricted form) a multiple number of pages at one time. He was unable, however, to develop his plans to any practical result, but deserves the credit of being the first to patent, if not to conceive, the idea of the association of printed sheets for this purpose.

The Double-supplement Press.—Further experiments upon the manipulation of webs of paper resulted in the production of the Hoe double-supplement press, the first specimen of which was purchased by James Gordon Bennett, of *The New York Herald*. For a third time a complete revolution of the methods of fast newspaper printing took place. The most remarkable features of this machine are its extreme simplicity, considering the work it performs, and its great speed, accuracy, and efficiency. It turns out either four, six, eight, ten, or twelve page papers at 24,000 per hour, and sixteen-page papers at 12,000 per hour, the odd pages being in every case accurately inserted and pasted in, and the papers cut at the top and delivered folded. This machine is constructed in two parts, in one portion the cylinders being twice the length of those in the other, the shortest cylinders being used for the supplements of the paper when it is desired to print more than eight pages. The plates being secured on the cylinders, the paper enters from the two rolls into the two portions of the machine, through each of which it is carried between the two pairs of type and impression cylinders, and printed on both sides, after which the two broad ribbons or "webs" pass over turning-bars and other devices, by which they are laid evenly one over the other, and pasted together. The webs of paper then pass down upon a triangular "former," which folds them along the center margin. They are then taken over a cylinder, from which they receive the final folds, a revolving blade within this cylinder projecting and thrusting the paper between folding rollers, while at the same moment a knife in the same cylinder severs the sheet, and a rapidly revolving mechanism, resembling in its motion human fingers, causes their accurate disposal upon traveling belts, conveying them on for final removal.

Previous to the introduction of the double-supplement press, Hoe & Co. had made what is known as their double perfecting machine. This embraces substantially the printing and folding devices embodied in the double-supplement machine, and is the connecting link between it and the ordinary "single" or two-page-wide press.

The Quadruple Newspaper Press.—The next improvement in fast presses was the construction of the quadruple newspaper press. The first one was constructed by R. Hoe & Co. in 1887 and placed in the office of *The New York World*. The same principles were embraced in this as

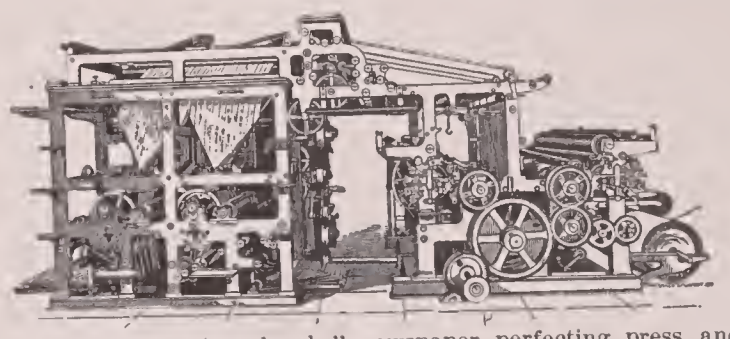

FIG. 9.—The Hoe "quadruple" newspaper perfecting press and folders.

in the double supplement, but developed to a greater extent. The supplement portion of the press was increased in width. By means of ingenious arrangements of the turning-bars and manipulation of the webs of paper this press was made to produce eight-page papers at a running speed of 48,000 per hour; also 24,000 per hour of either ten, twelve, fourteen, or sixteen page papers, all delivered in perfect form, cut at the top, pasted, and folded ready for the carrier or the mails. This press, together with the double-supplement press, superseded almost all others in the large offices of the U. S., as well as in Great Britain and Australia.

The Sextuple Press.—In 1889 the same firm undertook the task of constructing a machine for *The New York Herald*, which would even eclipse the quadruple machine. It is known as the sextuple machine, and occupied about eighteen months in construction. It is composed of about 16,000 pieces, and weighs about 58 tons. The form and impression cylinders are all placed parallel, instead of any being at right angles, as in the quadruple and double-supplement presses. The press is fed from three rolls, and can print, cut, paste, fold, count, and deliver complete in an hour 24,000 *Heralds* of fourteen, twenty, or twenty-four pages each, 36,000 of sixteen pages each, 48,000 of ten or twelve pages each, or 72,000 (20 per second) of eight pages each. It has six plate-cylinders, each carrying eight stereotype plates a page in size, and making at full speed 200 revolutions per minute.

Type-revolving Perfecting Presses.—About 1871 a machine called the Prestonian was made by Foster, a machinist of Preston, England, and several were set to work, but did not enjoy any great degree of favor. They embodied a combination of the Hoe type-revolving machine with the endless sheet perfecting press. The form of type for one side of the paper was placed upon one cylinder, with impression-cylinders around it, in the manner of the Hoe press, and the form for the other side on another cylinder, and the paper passed from one set of impression-cylinders to the

other. The objection to this machine was its lack of speed. The same principle, however, had been developed years before in the type-revolving perfecting presses, having two sets of type-forms on separate large cylinders, and feeding

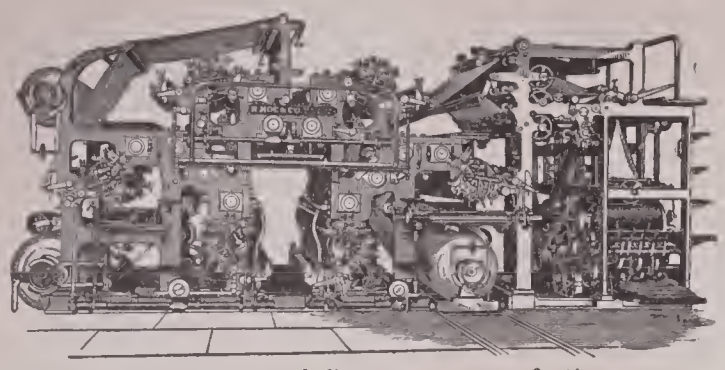

Fig. 10.—The Hoe "sextuple" newspaper perfecting press and folders.

the sheets in by hand, conveying them from one impression-cylinder to the other and against the forms by means of fingers or grippers. The sheets were then delivered on a sheet-flier. These presses were especially designed for printing books of which large numbers were required, such as text-books and spelling-books. The contents of a whole book could be placed on these cylinders and printed and delivered at one impression. One of these machines, built in 1852, is still (1895) in operation at Messrs. D. Appleton & Co.'s printing-office in Brooklyn.

The Rotary Type Endless Sheet Perfecting Press.—In 1881 Hoe & Co. turned their attention to the making of a machine which should print from one form of type at a greater speed than had ever yet been attained. The result was the rotary type endless sheet perfecting press. The principle of this machine was in a measure that of their type-revolving press. The forms of type for both sides of the paper were placed on a central cylinder, which was surrounded by impression-cylinders and inking-rollers. The roll of paper was placed at the end of the press, passed around the impression-cylinders arranged at one side of the form cylinder, and then turned upside down at the lower part of the machine, thence being carried upward. The opposite or unprinted side was presented in turn between each impression-cylinder and the forms. If four impression-cylinders were placed around the central cylinder, then at each revolution of the latter four perfect papers were printed. If eight impression-cylinders were placed around the central cylinder, then eight perfect papers were printed at one revolution of the main or form cylinder. The speed attained by this machine with four impression-cylinders was about 12,000 per hour, and from machines with eight impression-cylinders 24,000 copies per hour were printed all folded.

The Prudential Perfecting Machine.—In 1889 a patented perfecting machine called the Prudential was made, in which the plates, or forms, for both sides are placed upon one cylinder, one side of the form of matter being placed upon one end, or half, of the cylinder, and the other side upon the opposite portion of the cylinder. One impression-cylinder only is used, and the inking apparatus is greatly extended. This machine is remarkable for the great variety of work it will do. At a high rate of speed, sheets of 8, 16, 24, and so on up to 96 or 128 pages may be printed and delivered folded in either 12mo, 8vo, 4to, or folio sizes, ready for the binder. The press does the work of ten flat-bed cylinder presses and ten hand-feed folding-machines. Curved electrotypes are now made successfully, and this press is the first to bring the printing of the average book and catalogue within the range of web-press work. While in general principles the press is similar to the large newspaper perfecting presses, though very much smaller in bulk, it has increased facilities for distribution, and finer adjustments throughout. The plates admit of underlays and overlays the same as on a flat-bed press. There are no tapes, the folding being done on rollers and small cylinders without smutting the printing. In the folding-machine there are knives which cut the sheet into the right size for folding, after which they are automatically delivered counted in lots of fifty each. The speed on a thirty-two-page form is about 16,000 copies per hour.

The Century Magazine's Press.—In 1886 Hoe & Co. made an advance toward perfection in the rotary system of printing, and constructed for Theodore L. De Vinne, the printer of *The Century Magazine*, a perfecting press to do the plain forms of that periodical.

This press prints from curved electrotype plates, and the product at every revolution of the cylinder is sixty-four pages, neatly printed, truly cut, and accurately registered and folded, ready for the binder. This web press is not so fast as the web press of daily newspapers, but it performs more operations and does more accurate work. It is not large or noisy, but the paper goes through the cylinders at the rate of nearly 200 feet a minute. It does the work of ten presses of the stop cylinder or two-revolution type.

The Rotary Art Press.—The success of this perfecting press induced the makers to devise a machine on the rotary principle adapted for the finest kind of illustrations; in short, to make a press which should do work as fine as it was possible to do on the hand-press, or the stop cylinder. The result was the setting up, in 1890, at the De Vinne Press, of a machine known as the rotary art press. This machine is described in the *Century* of Nov., 1890, as follows: "Sixty-four plates of the *Century*, truly bent to the proper curve, are firmly fastened on one cylinder 60 inches long and about 30 inches in diameter; sixteen inking-rollers, supplied with ink from two fountains, successfully ink these sixty-four plates with a delicacy and yet with a fullness of color never before attained. The shafts of the impression-cylinder and the plate-cylinders, 4½ inches in diameter, do not give or spring under the strongest impression. Although rigid in every part, in the hands of an expert pressman it can be made responsive to the slightest overlay. This machine is fed by four feeders from single sheets in the usual manner, and does the work of four stop cylinders in superior style."

The Once-a-Week Press.—Another rotary perfecting machine for fine cut-work was made in 1891 by the same manufacturers, and is known as the Once-a-Week press. In this machine the apparatus for printing the first side is placed at right angles with that for the second side. The paper, after being taken from the roll through the first pair of cylinders, printing the inside or type side of the periodical, takes a half turn over obliquely placed turning-bars, passing the paper reversed into the other portion of the printing apparatus. This second portion of the machine, being intended to do the finest quality of cut-work, is supplied with a more elaborate inking apparatus, and eight form-rollers, which distribute the ink in thin layers over the plates. In the folding apparatus tapes are entirely dispensed with, and the sheets of heavy cut-work are folded and delivered fresh from the press, without any smutting or set-off of the ink.

Ingenious devices are found in a machine which was constructed in 1892, and put up in the office of the Hartford, Conn., *Courant*. From a single set of stereotype plates this machine produces either four, six, eight, ten, twelve, fourteen, or sixteen page papers at a speed of 12,000 per hour, all cut at the top, pasted and folded, and the supplements inserted in their proper places. With duplicate sets of plates it will print four, six, or eight page papers at 24,000 per hour. Two narrow rolls are placed nearly end to end at the back of the machine. The paper from one of these goes through the machine and is printed, then over the "former," and on to the final cutting cylinders without interruption. The peculiarity of the invention consists in taking the paper from the other roll, which is run at half the speed of the first, conveying it into the printing mechanism of the cylinders by accelerating its motion, and presenting the small sheet which has been severed for the two-page supplement between the cylinders in such a way that it receives the impression from the two supplement plates. This machine covers a floor-space of only 18 feet by 8½ feet, and is 8 feet high.

Color-printing.—It has been found that a combination of three primary colors properly printed will produce any picture required. To these black is sometimes added, making four printings for a complete colored picture. Taking advantage of this the daily newspapers have attempted to meet the popular taste for colored pictures, and to that end presses have been constructed for some of the leading New York newspapers. In the presses for printing in colors the forms for the different colors are placed upon separate cylinders, opposite to each of which are attached impression-cylinders. The paper passing through this series of cylinders receives in perfect register the different colors, having first been printed in black upon one side. These colored supplements are delivered from the machines folded, without smutting. The art of simultaneous color-printing on the rotary principle is still in its infancy.

Robert Hoe.

Prior, Matthew: poet and diplomatist; b. at Wimborne-Minster, Dorsetshire, England, July 21, 1664. He was educated at St. John's College, Cambridge, where he formed an intimacy with Charles Montagu, afterward Earl of Halifax, and with him wrote a poem, *The City Mouse and Country Mouse* (1687), intended as a travesty upon Dryden's *Hind and Panther*. Introduced at court by his patron, Prior became a favorite with William III.; was secretary of the commissioners who concluded the Treaty of Ryswick 1697; secretary of embassy at Paris 1698; Under-Secretary of State 1699; commissioner of trade 1700, in which year he published his *Carmen Seculare*, in praise of King William; entered Parliament 1701; became soon afterward a vehement Tory; was sent to Paris with Bolingbroke 1711 to make private proposals for peace; was charged with treason for his conduct in this negotiation on the accession of the Whigs to power in 1714; and was imprisoned two years in his own house, during which time he wrote *Alma, or the Progress of the Mind*. D. at Wimpole, Cambridgeshire, Sept. 18, 1721, and was buried in Westminster Abbey. His collected poems were first published in 1709, and in a sumptuous folio in 1718, a subscription edition which brought him £4,000. He excelled in epigram, society verse, and the short humorous fable. A selection of his poetry was edited by Austin Dobson in 1889.

Priscian, surnamed Cæsariensis, probably because he was born at Cæsarea: the most celebrated Latin grammarian; flourished about 500 A. D., and was a teacher of Latin at Constantinople, where he received a salary from the court. His *Commentariorum Grammaticorum Libri XVIII.*, of which the first sixteen books treat upon the eight parts of speech recognized by the ancient grammarians, and the last two on syntax, were edited by Krehl (Leipzig, 1819) and Hertz (Leipzig, 1855–59, 2 vols.). Other works extant are a grammatical catechism on parts of the *Æneid*, a treatise on the symbols used to denote numbers and weights, an essay on accents, another on the meters of Terence, etc., edited by Lindemann (Leyden, 1818) and by Keil (Leipzig, 1860). Two poems, *De Laude Anastasii imperatoris*, written about 512, and *Periegesis*, both in hexameters, are printed in Baehrens's *Poetæ Lat. Minores* (vol. v., pp. 264–312).

Priscia'nus, Theodorus: physician; a pupil of Vindicianus. He lived at the court of Constantinople in the fourth century A. D., and is the author of a work, *Rerum Medicarum Libri Quatuor*, first printed in 1532 at Strassburg, in which he tries to combine the ideas of the methodical and dogmatical schools with those of the empirical.

Priscil'lian: Bishop of Avila, in Spain; belonged to a noble Spanish family; founded a sect whose doctrines were a blending of Manichæism and Gnosticism. In 379 the existence of the sect became known, and in 380 the Council of Saragossa condemned its doctrines and excommunicated its founder. The influence of Priscillian was too powerful, however, and his most zealous adversary, Bishop Ithacius of Ossonoba, was compelled to fly. He sought refuge with the usurper Maximus, who had Priscillian brought to trial before the Council of Treves, condemned, and put to death in 385. It was the first instance of a Christian being put to death for heresy, and it aroused the indignation of St. Martin of Tours, St. Ambrose, and others. The sect spread subsequently from Northern Spain to Languedoc, and even into Northern Italy, but disappeared entirely in the sixth century, after the second synod of Braga in 563. See Lübkert, *De Hæresi Priscilliani* (Copenhagen, 1840), and Mandernach, *Geschichte des Priscillianismus* (Treves, 1851). Up to 1885 it was supposed that no works of Priscillian had been preserved, but in that year G. Schepss discovered in a Würzburg MS. eleven tractates, which he proved to be by Priscillian, and edited in the *Corpus Eccl. Lat.*, vol. xviii. (Vienna, 1889). See also by the same writer *Archiv. für Lat. Lexicographie* (iii., 309–328), and *Priscillian ein neuaufgefundener Lat. Schriftsteller* (Würzburg, 1886).

Revised by M. Warren.

Prism [from Lat. *pris'ma* = Gr. πρίσμα, prism, liter., something sawed out, deriv. of πρίειν, πρίζειν, saw]: a polyhedron two of whose faces are equal polygons, having their sides parallel and all the remaining faces parallelograms. The first-named faces are called bases, and the remaining ones make up what is called the lateral surface of the prism. The distance between the bases is the altitude of the prism. For the Nicol prism, see Polarization.

Prismoid [Gr. πρίσμα, prism + suffix *-oid*, having the form of, Gr. εἶδος, form]: a polyhedron resembling a prism. It is a frustum of a wedge. The volume of a prismoid is equal to the sum of its parallel bases plus four times the section midway between the bases multiplied by one-sixth of the altitude.

Prismoidal Formula: a formula for computing the volumes of certain solids, mainly used by civil engineers for earthwork calculations. Let L be the length of any prism, A the area of one end, B the area of the other, and M the area of a section half way between the two ends. Then the volume of the prism is

$$V = \tfrac{1}{6}L(A + 4M + B).$$

This formula applies not only to prisms, pyramids, and solids bounded by planes, but also to those bounded by warped surfaces, and to those inclosed by surfaces which are generated by conic sections.

The two-term prismoidal formula, due to Halsted, is

$$V = \tfrac{1}{4}L(A + 3N),$$

in which N is the area of a section at two-thirds the altitude from the base A.

Mansfield Merriman.

Prison [from O. Fr. *prison*: Ital. *prigione*: Span. *prisión* < Lat. *prēn'sio, -o'nis* (or *prehensio*), seizure, confinement, deriv. of *prendere* (*prehendere*), seize]: primarily, a place of detention for debtors or persons charged with political or other crimes until they were tried or adjudged guilty or innocent of the offenses for which they were committed; later, the prison has become, to some extent, the place and instrument of punishment. The idea of punishment by imprisonment itself does not seem to have entered into the minds of the rulers of ancient times, though the prison was often, from its crowded and filthy condition, its want of ventilation, the foul fevers and plagues engendered there, and the starvation inflicted on its hapless inmates, a place of cruel torture and often of speedy death; but the ancient idea of punishment was embodied in the stocks, scourging, beating with rods, the bastinado, the knout, the wheel, the rack, the thumb-screw, the iron boot, mutilation of the eye, the ear, the nose, the hand, the foot, etc.; the crown of thorns, walking over hot irons or coals, branding, whipping at the whipping-post or the tail of a cart, the pillory, the ball and chain, the treadmill, or the galleys; or, where the punishment was intended to be death, the stake, the terrible death by crucifixion, beheading, stoning, the administration of poison, or, in more modern times, hanging, the guillotine, or the garrote.

Prisons of Egypt and Palestine.—Detention of debtors and of political and other offenders was very early an admitted necessity. The earliest instances of its use are found among the Egyptians, whose superior civilization led them to devise measures of police of which other nations, less advanced, had not yet felt the want. Thus we find in Gen. xxxix. 20 that "Joseph's master took him and put him into the prison, a place where the king's prisoners were bound; and he was there in the prison." This was primarily a place of confinement for political prisoners. There are numerous references to prisons in the Old Testament, as well as among profane writers contemporary with its later books, but always as a place of detention simply, though in the case of Jeremiah the dungeon connected with the prison (Jer. xxxviii. 6), from the depth of its miry bottom and its filthiness, seems to have been intended for the destruction of the prisoners who were cast into it. All the Oriental monarchies had their prisons; but though these were, as they are still, wretched, ill-ventilated, and filthy dens, in which it would seem to be impossible to support life, and where the poor culprit who had no money or friends was welcome to die of starvation and foul air as soon as he liked, yet the only theory of the prison was that it was simply a place of detention, and no length of endurance of its horrors was allowed to mitigate in any way the severity of the physical tortures or punishments inflicted on him if he was found guilty of the offense with which he was charged.

Greek and Roman Prisons.—Among the Greeks and Romans the prison, though more cleanly, was generally only a place of detention, though the "inner prison," low, close, and hardly ventilated at all, was occasionally made a place of temporary torture. By the laws of Rome, a Roman citizen could not be cast into prison except by the direct command of the emperor and for some very grave offense; and the violation of this law was severely punished. The usual method of detention for a Roman citizen was to chain his right arm

to the left arm of a soldier, who was made responsible for his safe-keeping; sometimes each arm was chained to a soldier: this guard was changed every twelve hours. In the first century after Christ there was at Rome one prison, and possibly more, intended for the confinement of prisoners condemned to death or awaiting a final hearing before the emperor. This was the Mamertine prison, consisting of two (possibly three) distinct vaults, one below the other. The upper was 16 feet in height, 30 in length, and 22 in breadth; the lower was smaller and lower, and the only access to it was by a hole in the middle of the ceiling, through which the prisoners were let down. This was originally the case also with the upper vault, called the dungeon of Ancus Martius. There were houses of detention in Rome which were used for the safe keeping of slaves. Even at a later period the Code Justinian has very little to say of prisons; its penalties were scourgings, tortures, mutilations, and death.

Mediæval Prisons.—With the downfall of the Roman empire, and the assumption of power over small districts of territory by the feudal barons, there came a change. The great tower of every castle, the *donjon*, had its *keep* or strong-room, often underground, to which foe or rival was forthwith consigned. They were utterly unfit for the confinement of human beings, and the names *oubliettes* (little places of the forgotten) or *vade-in-pace* (go in peace) by which they were designated in grim jest by their builders or owners indicated but too truly their murderous purpose. Of a somewhat better character, though still cheerless and almost hopeless prisons, were those isolated fortresses where chiefs, nobles, and kings in the Middle Ages were often incarcerated. The Tower of London belonged to the same class.

Prisons of the Inquisition.—The prisons of the Inquisition in Italy, Spain, Portugal, France, Belgium, and Austria, though not in the main intended so much for punishment as for detention—the punishment (often within the prison-walls) consisting mainly in the racks, wheels, boots, thumb-screws, and other instruments of torture which a fiendish ingenuity exhausted itself in contriving, and in the *autos-de-fé* and other modes of inflicting the death-penalty—were yet, in some cases, places of protracted and cruel punishment, in which every idea of horror and apprehension which could torture the mind of the victim was suggested, to aggravate the distress of confinement. Even during the nineteenth century the victims of this cruel imprisonment have died by slow torture.

Prisons of the Eighteenth Century.—On the Continent, and even in Great Britain, the idea that imprisonment, except in the case of political offenders, constitutes any part of the punishment of crime does not seem to have dawned upon the minds of statesmen, political economists, or penologists—if the latter class could be said to have existed—until well into the eighteenth century. There were jails, houses of detention, prisons—if they might be called such—both in Great Britain and on the Continent, but they were filled with debtors, persons arrested for crime and awaiting trial, and those who had been sentenced to banishment or transportation, to slavery, to the galleys, or to execution. The jails and prisons were so filthy and ill-ventilated that deadly fevers, the plague, and the black death would occur in them, and frequently spread over the adjacent country. At what was known as the "Black Assize" in England, in the seventeenth century, over 300 persons, including judges, jury, lawyers, and spectators, fell victims to a malignant jail-fever which was communicated by the prisoners brought out of the jail for trial. The moral pollution of these jails was as great as the physical: the grossest intemperance and licentiousness prevailed in all of them, and the fee for the prostitution of the female prisoners was a recognized perquisite of the keepers.

John Howard and his Associates.—Attempts were made to reform and improve the jails in England, as well as on the the Continent, by John Howard in the latter part of the eighteenth century; they were attended with some success, though not so great as his philanthropic efforts and the final sacrifice of his life to the cause warranted. Beccaria in Italy, and Sir William Blackstone, Jeremy Bentham, and Mr. Eden (afterward Lord Auckland) in Great Britain, took up the work and went forward with it. At this time, however, Great Britain was largely engaged in schemes of transportation, which her statesmen believed would rid them of her vicious population, and they were not inclined to give much heed to measures of prison reform. They had sent convicts to Virginia from 1619 to 1770, until they would no longer be received, and, after the beginning of settlements in Australia and the adjacent islands, had forwarded thousands to Botany Bay, Sydney, Tasmania, North and West Australia, and to British Guiana, till about 1850; but, contrary to their expectations, the number of criminals at home did not decrease. Most of the continental states had tried the same experiment of transportation, and with about the same success. France, while sending off large numbers of criminals, consigned very many to the galleys, where they learned only evil, and at their discharge became leaders in crime. Russia sent the greater part of her criminals, as well as her political offenders, to the mines in Siberia, and most of the other powers rid themselves of their criminals by transportation wherever they could find the opportunity, sometimes sending them to the territories of the U. S., to Mexico, and to South America. These efforts did not lessen the number of actual criminals. As yet the possibility of the reformation of criminals was not conceded.

Prison Reform in Great Britain.—All efforts to keep down the number by transportation having failed, and the benevolent labors of John Howard, of Mrs. Elizabeth Fry, and of the aldermanic committee of London having proved ineffectual to remedy the evil, Sir T. Fowell Buxton, a member of Parliament, published in 1818 an *Inquiry whether Crime and Misery are produced or prevented by the Present System of Discipline.* After a conflict of nearly thirty years the prisons and prison-systems of Great Britain and Ireland were very thoroughly reformed; transportation ceased, and the convict prisons, though more expensive than they should be, are well managed, and many of their prisoners are reformed. Many of the convicts are employed in the great naval shipyards at Dartmouth and Portsmouth. The jails are cleanly, well-ventilated, and for the most part have some employment for the prisoners, which keeps them from mischief and contributes a small sum toward the expense of their support. The reformatories for young offenders have, by reforming the young criminals, prevented the increase of the criminal class, and greatly diminished the number and magnitude of crimes in the kingdom. In Scotland and Ireland, by a different application of the same principles, a still greater measure of success has been attained. What is known as the Crofton or Irish system of prison discipline has proved very successful in Ireland.

Prisons in the United States.—In the U. S. transportation has never been attempted as a means of ridding the community of the dangerous classes. Before the Revolutionary war the criminal code was very severe; death was the penalty of a great number of crimes; in one of the States 115 crimes punishable by death were enumerated; in other States the number was from 80 to 100. Burglary, horse-stealing, highway robbery, and even grand larceny, as well as forgery, counterfeiting, and many other crimes now punishable by a moderate term of imprisonment, subjected the criminal to the death-penalty. At the same time the prisons were in a wretched condition, hardly better than those of Great Britain. In 1786 Pennsylvania made the first effort at improvement of her prisons by the adoption of the *solitary* plan of discipline. Reforms were accomplished in Boston by the Prison Discipline Society, which existed from 1824 to 1844. The Prison Association of New York was organized in 1844. The "separate plan" in operation at the Eastern penitentiary at Philadelphia is very expensive; the work is unprofitable, the proceeds of it not defraying more than one-sixth of the expenses of the prison; and, though there is not so much insanity or fatuity as under the solitary system, the prisoners fail in self-reliance, and are very seldom of any service to the community after their discharge. In 1821–23 the "congregated or silent system" (now known as the Auburn system), was adopted at Auburn, N. Y., and soon attained such a reputation that it was adopted by other States, and with various modifications is now the prevalent system in the U. S. See PRISON DISCIPLINE.

In many of the congregate prisons the labor of the prisoners is let to contractors at a given sum per day; in several of the States the whole expenses of the prison are thus defrayed, and in some a surplus is paid into the State treasury. In some cases the State employs the convicts and disposes of the products of their labor, but these generally fail to defray the entire expenses. Many objections have been made to the contracting of the labor of prisoners, and in several States it has been superseded by what is known as the "piece price," and "State account" systems.

County Jails.—Of all the prisons in the U. S., county jails

are the most unsatisfactory. With rare exceptions, prisoners of all grades and of all ages are herded together in a common hall, and the contaminating influences of association are so injurious that all penologists are agreed in the conclusion that no large progress can be made in reducing crime until this evil is corrected. The remedy clearly consists in such a separation of prisoners awaiting trial as will not permit any prisoner to associate with any other prisoner. This rule has been enforced in England for many years, and its violation by any jailer is made a penal offense by act of Parliament. In the U. S. this system was first adopted in Massachusetts, in the Suffolk County jail in Boston about 1860, and the results have been so satisfactory that it has been extended to all other jails in the State where the construction of the jail will permit. In Ohio a similar requirement has been made by legislative enactment, and in several Western States new jails have been constructed with a view to confining prisoners in separate cells. See IMPRISONMENT.

Revised by R. BRINKERHOFF.

Prison Discipline: the proper care and regulation of persons suffering detention or punishment by incarceration. Three systems of prison discipline divide the study and the suffrages of the civilized world—viz., the Auburn, or congregate silent system; the Philadelphia, or separate cell system; and the system of progressive classification—sometimes called the Irish system, because first applied in Ireland—sometimes the Crofton system, from the name of the man who devised and applied it in the form it has there, although Capt. Alexander Maconochie, of the British navy, was the real author of the system. The essential principle of the Auburn system is that of absolute separation of the prisoners by night and associated silent labor by day. This system is almost universal in the U. S., and has also a foothold in various European countries, where, too, the old system of common dormitories has far too wide a prevalence, though it has no defenders. Some of the convict prisons of the U. S. do not even claim to conduct their discipline upon the strictly silent principle; in others, where the claim is made, the rule of silence has but a partial enforcement, while in comparatively few is the rigidity of the old discipline of absolute non-intercourse maintained in full force. The essential principle of the separate-cell system is that of a complete bodily separation of the prisoners in labor, recreation, and rest. The Eastern penitentiary at Philadelphia is the only State prison in the U. S. conducted upon the separate system. There are, however, two local prisons in Pennsylvania, at Chester and Media, where the system is still in operation. This system, known throughout the world as the Pennsylvania system, has been adopted with some modifications in several European countries, notably in Belgium, where it is in operation in all convict prisons, apparently with good results. In the U. S. it has not proved satisfactory. Isolation lies at the foundation of both these systems. The difference between them is one of application rather than of principle.

The System of Progressive Classification.—Capt. Alexander Maconochie was, on his own application in 1840, invested with the governorship of the British penal colony of Norfolk island, at that time containing a criminal population of 1,500, made up of the worst convicts ever sent out by the mother-country. He there became the originator and founder of the system of progressive classification as an agent in prison discipline and the reformation of prisoners. The discipline inaugurated by him was called by its author the "social system of prison treatment," because of the play therein given to the social instincts of humanity; but it is commonly known among penologists as the "mark" system, because of the use which it makes of marks in recording the progress of the prisoner in industry, education, order, and virtue. Capt. Maconochie sought to make prison life an image of free life. He treated the convict as a laborer, with marks for wages. His marks were made to play the part of money, for with them the prisoner was required to purchase his food, clothes, schooling, etc., while only the surplus of these earnings counted toward his liberation. Under this system the prisoner is not to be sentenced to a certain number of months or years, but to earn a certain number of marks over and above his keep. Maconochie fixed on ten marks as a fair day's wages, the men being paid by piece-work, and not by time, and for every ten marks saved the convict shortened his imprisonment by a day. At the stores he purchased his daily supplies, paying for them in marks. The rations were served out at three rates. The coarsest cost three marks per day, the next four, and the best five. The self-denying prisoner might thus save seven and the self-indulgent five marks each day for the purchase of his liberty. As extra marks were allowed for overwork, it was possible to hoard at the rate of eight or ten a day as the fruit of diligence and self-denial. Moreover, the marks furnished the means of disciplinary punishment, a proportionate fine in marks being the penalty for every act of disobedience or failure in duty. While, by this machinery of marks, Capt. Maconochie trained his convicts to habits of industry and frugality, he adopted different means to accomplish his other objects. He divided the convicts' sentences into three periods. During the first or penal stage the men worked under a sharp and stringent discipline. At the conclusion of this they were allowed to form themselves into companies of six each—the members of each company being left to choose their own companions—and then they entered into the second or social stage. In this stage the six prisoners forming a company had a common fund of marks, into which common stock the daily earnings of each member were paid, and from which the supplies and fines for the whole company were deducted. They were thus made responsible for each other's conduct, and naturally became watchful both over themselves and their companions. In the last or individualized stage the companies were broken up, and, though every man was still kept at work to earn his daily tale of marks, he was in other respects comparatively free. He had his own hut and garden, his own piggery and poultry-yard, the products of which he might sell to the officers of the colony or the ships that touched at the island. By thus giving the probationer property and rights of his own, Maconochie hoped to teach him respect for those of other people. He was four years on Norfolk island. His success was wonderful, though he was never allowed by the British Government to bring all the principles of his system into play, and so give it a full and fair trial.

A few years after Maconochie's retirement from Norfolk island, Capt. (later Sir) Walter Crofton, following in his footprints, devised and established a new system of convict prisons for Ireland. He adopted the mark system of Maconochie, with modifications which improved it in many important respects. The Crofton system consists of three stages: A penal stage of separate imprisonment, continuing eight months; a reformatory stage, longer or shorter according to the length of the sentence, with separation at night and associated labor by day, in which the principle of progressive classification is applied with a gradual lifting of restraint and enlargement of privilege, including an increased share in his earnings as the prisoner advances from class to class; and a testing stage, designed to verify the reformatory power of the preceding discipline, and also to serve as a period of natural training which shall gradually prepare the prisoner for full liberty. The Crofton system may be shortly defined as an adult reformatory, in which the will of the prisoner is brought into accord with the will of the prison-keeper, and held there for so long a time that virtue becomes a habit, and where the object is to teach and train the prisoner, during his detention, in such manner that on his discharge he may be able to resist temptation and inclined to lead an upright, worthy life. This must be done by placing the prisoner's fate, as far as possible, in his own hands, and by enabling him, through industry and good conduct, to raise himself, step by step, to positions of increased freedom and privilege; while idleness and bad conduct, on the other hand, keep him in a condition of coercion and restraint.

CROFTON SYSTEM IN THE UNITED STATES.

In the U. S., reformatories for adult criminals upon the general principles of the Crofton system have been established in New York, Massachusetts, Pennsylvania, Ohio, Michigan, and Minnesota.

The Elmira Reformatory.—The first of these, the Elmira Reformatory, upon which the others are mainly patterned, was opened in 1876 at Elmira, N. Y., and is known as the New York State Reformatory. Prisoners received at Elmira are such as are convicted of their first offense for felony, and are held under what is known as the indefinite or indeterminate sentence; that is, they are not sentenced for any specific period of time, but may be held for the maximum period for which they might have been sentenced for the crime committed, and can not be discharged until they have served the minimum period provided by statute for such offense; but having served such minimum period they

may be allowed, under regulations established by the board of managers, to go upon parole outside of the buildings and inclosures, but to remain, while on parole, in the legal custody and under the control of the board, and subject at any time to be taken back to the institution.

Classification of Inmates.—The reformatory plan includes the dividing of prisoners into three grades, viz., the upper first, the lower first, and the second; and all enter the lower first, to rise or fall according to compliance with reformatory requirements. The measure of every man's career in the reformatory is the record appearing upon the pages bearing his name in the conduct, labor, and school ledgers. By maintaining a good record for six successive months prisoners in this grade may advance to the upper-first grade, from which alone they may secure release prior to the expiration of the maximum time for which they could have been imprisoned. In this they wear a uniform of sky-blue, their cells are more commodious, and they have more privileges in many ways. If their records continue perfect another six months they become candidates for conditional release, provided satisfactory employment can be secured for them. The downward step from the lower-first grade leads to the second or convict grade. Into this drop the lower-first grade men whose conduct, school, or labor records are imperfect for two or three months in succession. Those who are reduced to this class forfeit all credit marks, and may secure readmission to the next higher grade only by earning a perfect marking for three successive months. Those who fall to the second grade a second time may not emerge from it for six months, and the third degradation is not followed by advancement for a year. The uniform of the convict grade is a bright red. Its wearers are quartered in the smallest cells, are deprived of all room furniture not essential to health and cleanliness, have no sheets on their beds, receive no tea or coffee with their rations, lose the privilege of drawing literature of any kind from the library, and lose their right to receive trade instructions as such.

While men of the upper-first grade are allowed to write one letter each month, and those of the lower first one in every two months to known relatives, second-grade men are not permitted to have any communication whatever with the outside world.

In the cell blocks, on the drill-ground, and at general assemblages the members of the different grades are grouped and kept separate one from another; but it is impossible, of course, to maintain this separation in the shops and trade-schools. The engagements of each inmate are intended to absorb his thoughts completely during the most of his waking moments, and they are sufficiently varied, though systematized, to prevent any of the noxious effects upon the mind that are often the effect of monotonous habits. Their engagements are work in the shops, trade-schools, and other occupations, and the day is closed with military drill and dress parade. In the evening are class meetings in school studies and other educational opportunities.

The results of reformatory treatment under these conditions have been very satisfactory, and the records show that of the graduates of Elmira over 80 per cent. have reinstated themselves in society, and are earning an honest living.

Other Reformatories.—The reformatory at Concord, Mass., was opened in 1884. Like Elmira it has three grades, and a marking system by which the prisoner rises or falls, but unlike Elmira it receives misdemeanants as well as felons, and there is no limit as to age or number of offenses, and only a part of the prisoners are subject to the indeterminate sentence. The prison for women at Sherborn, Mass., established in 1877, is also conducted on a system similar to that of Elmira, although it has four grades instead of three. It is wholly under the management of women, and as a prison for women it has no superior.

Corporal Punishments.—In the U. S., in the best-regulated prisons, corporal punishments are no longer considered a necessity for the maintenance of discipline, and in many they are entirely abolished. In the Western penitentiary of Pennsylvania, at Allegheny, no form of physical torture has been tolerated since about 1870, and so also at the great prisons at Joliet, Ill., and the military prison at Leavenworth, Kan., and better discipline is reported than in previous years when the lash or its equivalents were in use.

In New Jersey, Minnesota, Kansas, and other States, corporal punishments are prohibited by law, and a majority of the most enlightened prison-wardens in the U. S. regard them as a relic of barbarism, and worse than useless in the maintenance of order in prison.

Prison Associations.—Among the agencies in the U. S. which have been largely instrumental in educating the public mind to the requirements of better methods in dealing with the criminal classes are the various prison associations, State and national, and State boards of charity and correction. The most important of these is the National Prison Congress, which was organized in 1870 and brings together annually, for the discussion of prison questions, prison officials and others interested in prison management. The annual reports of these various associations constitute a library upon prison subjects, and as knowledge accumulates penology is more and more becoming an exact science.

Among the principles already established sufficiently to be considered axioms by penologists in the U. S. are—

1. County jails should be solely places for the detention of prisoners awaiting trial, and in them no prisoner should be permitted to associate with any other prisoner. 2. Prisoners convicted of misdemeanors should be sent to district workhouses and employed at productive labor. 3. Prisoners convicted of felony should be sent to penitentiaries, of which there should be at least two in each State—one a reformatory for young men, and the other for life-prisoners and incorrigibles. 4. All sentences, except for life, should be indefinite, subject to parole and police supervision within a minimum and maximum limit. 5. All able-bodied prisoners should be kept at productive labor, but those in reformatories should receive such educational and industrial training as will enable them to earn an honest living after discharge. 6. All prisoners upon discharge should be systematically aided to obtain employment. 7. Prisoners convicted more than twice for felony should be adjudged incorrigible and sentenced for life, or at least for long periods, with the privilege of parole for good conduct at the maximum limit of a first conviction. 8. Prison officers should be as thoroughly trained for their duties as are army and navy officers, and their tenure of office should be as secure and their compensation as liberal. 9. Prisoners convicted of violations of Federal laws should be confined in prisons owned and controlled by the general Government. 10. In all prisons moral and religious culture should be the leading reformatory influences, and a prison school, with competent instructors, should be an indispensable requirement.

Prisoners of War: See War.

Pris'tidæ [Mod. Lat., named from *Pris'tis*, the typical genus, from Gr. πρίστις, assumed to mean sawfish (deriv. of πριειν, saw), properly πρῆστις, a kind of whale, liter., blower, spouter, deriv. of πρήθειν, blow, spout]: a family of selachians of the order *Raiæ*, represented by the sawfishes. The body combines peculiarities of the sharks and rays, being elongated like the former, but with the pectoral fins developed and the branchial apertures inferior, as in the latter; the shagreen is very fine; the snout produced into a very long, flat, dagger-like appendage, which is armed on each edge with a row of strong, compressed, straight teeth. The nostrils are inferior: mouth small and transverse; teeth on the jaws minute; branchial apertures inward from the base of the pectoral fins; spiracles large, behind the eyes; dorsal fins two, unarmed, the first more or less behind the ventrals; pectorals with the front margins free, and not extending on the head. The teeth which are on the margin of the saw are of peculiar development, and must not be confounded with the true teeth of the jaws; the skeleton of the saw-like appendage has from three to five hollow sub-cylindrical tubes which taper toward the end, and are incrusted with a grain-like osseous deposit. The sawfishes are found in all tropical seas, and one species (*Pristis antiquorum*) occurs on both coasts of the U. S., especially in the more southern waters. An East Indian species lives in part in fresh water.

Pritchett, Henry Smith: See the Appendix.

Privateering: the act or practice of cruising in a privateer for the purpose of preying on merchant vessels of a hostile power. As there may be legalized land forces of an irregular character to supplement a regular army, on the condition of their conforming to the rules and usages of war, so upon the high seas the war navy of a belligerent may be assisted in certain of its duties by private armed vessels.

These vessels, with their crews, might be hired by the governments, or impressed into the sovereign's service, whether owned by natives or by foreigners—the latter called the *jus angariæ* or *droit d'angarie*; or they might be vessels owned and manned by private persons, but kept up at the public

expense; or public vessels with a crew and outfit provided for by private persons; or, finally, private vessels officered and sent to sea at the charges and risk of private persons under a government commission. Of these four ways of sending vessels out to sea, the last-named only has been in vogue in the most modern times. In commercial states this has been a favorite way of employing sailors and merchant ships when trade was crippled by war; and to a nation with a small navy but with a large seafaring class it offered the prospect of something like equality on the sea with a nation possessing a good-sized fleet.

Although sometimes bounties have been offered to privateers for the capture of the men-of-war of an enemy, this can hardly be considered a usual part of their duty or be reasonably expected of them. They are neither built, armed, nor manned with such service in view, but rather to prey upon the commerce of an enemy, being entitled to a share in their captures.

In commissioning privateers it is usual for a government to put their owners and captains under bonds. A letter of marque is given, which alone entitles a vessel to any share in a capture made from the enemy, after adjudication by a prize court, and the absence of which exposes a vessel calling itself a privateer, with its crew, to harsh treatment, as having almost a piratical character. Any great irregularity or lawlessness will involve forfeiture of vessels and other penalties, including by English usage damages from the owners; but, in truth, lawlessness and harsh treatment of the enemy could never be prevented. The motive of the expedition being plunder, the captain and officers having no professional honor, the crews being often a motley collection of adventurers, privateering was long felt to be a great evil, and earnest voices were raised against it, especially by enlightened men in the U. S. Thus Franklin inserted a provision forbidding reciprocally the issue of letters of marque in the treaty between the U. S. and Prussia negotiated by him in 1785. At length, in 1856, the parties to the Declaration of Paris brought about a new era in international law by the four rules relating to warfare on the sea, one of which was that "privateering is and remains abolished." Other nations were invited to give their assent to these rules on the condition of accepting all or none, and nearly all Christian states accepted them. Several of them were such as the U. S. had always contended for, but adhesion was refused on the ground that the republic would have no adequate force, if it abandoned privateering, to cope with nations possessing a large navy, as its own policy was to have a small one. The offer, however, was made—but without effect—to adopt the rules, provided that the signers of the Declaration of Paris would go further and exempt all innocent traffic of enemies on the sea from capture. This was called the Marcy amendment. In 1861 Mr. Seward, being Secretary of State, made offer to two of the principal European powers, on the part of the U. S., to come under the operation of the four rules; but as it was understood that the stipulation would be for the entire republic, including the Confederate States, and as thus these powers would be parties in imposing a rule of warfare on the Confederate States, as, in short, it was a scheme to prevent them from using privateers by the aid of international law, the offer was declined. See DECLARATION OF PARIS.

The abandonment of the use of privateers by so large a number of states, and the provision for the safety of enemies' goods on neutral vessels in the same document, put a new face on maritime warfare. At the outbreak of a war, if the risk of capture is great enough, neutral vessels henceforth will take the place of belligerent ones for commercial purposes, and the motive of capture is greatly diminished for public cruisers, the only ones now remaining. Thus it can be no very great concession that belligerents may safely use their own merchant ships, unless neutrals regard it of importance for them to get the business of times of contest into their hands. The parties to the four rules may still legitimately employ privateers against non-signers.

Subjects of the U. S. are, by statute, forbidden to accept letters of marque from powers at peace with it, and this, apart from the Declaration of Paris, is a common rule. Privateers were not employed by either North or South in the civil war in the U. S., the Confederate ships commonly called privateers being really commissioned men-of-war, though in some cases illegally fitted out.

Private Road: See the Appendix.

Privet [other Eng. names for the same are *primprint*, *primet*, Scotch *privie*. The introduction of the *v* is unexplained; *primet* is probably connected with *prime*, to trim]: the *Ligustrum vulgare*, an oleaceous shrub of Europe, now naturalized to some extent in the U. S.; chiefly used as a hedge-plant, both in the Old and New Worlds. It makes a close, handsome hedge, though it is not thorny. Its wood, though small, is saved for turners' use in Europe, and its berries yield a pink coloring-matter used by map-colorers. There are several rather ornamental allied species, one of which, *L. japonicum*, is known popularly as the California privet. Revised by L. H. BAILEY.

Privilege [from Lat. *privile'gium*, an ordinance in favor of an individual; *pri'vus*, private + *lex*, *le'gis*, law]: a benefit or immunity which is not enjoyed by all. Some forms of privilege are considered in the articles on LIBEL AND SLANDER and on MONOPOLIES (*qq. v.*). The present discussion will be confined to the privileges of legislators, and to those of citizens under the U. S. Constitution.

Privileges of Legislators.—Members of the British House of Commons are not liable to be sued for any words uttered in the House, however injurious they may be to others; nor can they be detained by the civil process of any court during a session of Parliament, nor during a convenient time before and after the close of a session. The U. S. Constitution provides that the Senators and Representatives "shall in all cases, except treason, felony, and breach of the peace, be privileged from arrest during their attendance at the sessions of their respective houses, and in going to and returning from the same; and for any speech or debate in either house they shall not be questioned in any other place." (Art. I., § 6.) Similar privileges are secured to State legislators by the State constitutions.

Privileges and Immunities of Citizens.—Article IV., § 2, of the U. S. Constitution declares: "The citizens of each State shall be entitled to all privileges and immunities of citizens in the several States." This guaranty is confined, it will be noticed, to those privileges which belong to citizenship. It does not extend to the privilege of taking fish in the public waters of another State. Public fisheries are the property of the State, and its inhabitants have a right in them by virtue of citizenship and domicile, and not by virtue of citizenship only. Nor does it secure to the citizen of one State that community interest in property owned by his wife in another State which is accorded by the laws of the latter to its resident citizens. (*Conner* vs. *Elliott*, 18 Howard 591.) Nor does it apply to artificial persons—corporations—which possess only such attributes as are bestowed by the State creating them. Many political rights, such as the right of suffrage and the right to hold office, are not within this constitutional guaranty, for these do not pertain to citizenship necessarily. In every State large numbers of citizens do not possess them. The provision in question applies to "those privileges and immunities which are fundamental, which belong to the citizens of all free governments, and which have at all times been enjoyed by citizens of the several States which compose this Union, from the time of their becoming free, independent, and sovereign; . . . protection by the Government, with the right to acquire and possess property of every kind, and to pursue and obtain happiness and safety, subject, nevertheless, to such restraints as the Government may prescribe for the general good of the whole." (*Corfield* vs. *Coryell*, 4 Washington Circuit Court 371.) Hence a statute which makes it unlawful for any person to appoint a non-resident trustee in a deed or other instrument is unconstitutional. *Shirk* vs. *La Fayette*, 52 *Federal Reporter* 857.

The Fourteenth Amendment to the Constitution prohibits the States from making or enforcing "any law which shall abridge the privileges or immunities of citizens of the United States." This provision recognizes a citizenship of the U. S. which is distinct from that of a State, and it guards only the privileges and immunities that pertain to the former; "those which arise out of the nature and essential character of the national Government, the provisions of the Constitution or its laws and treaties made in pursuance thereof." (*Butchers' Association* vs. *Crescent City Company*, 16 Wallace 36.) In the decision just mentioned the following were named as such privileges: "To come to the seat of government to assert any claim upon that Government, to transact any business with it, to seek its protection, to share its offices, to engage in administering its functions. Free access to its seaports; . . . to the sub-treasuries, land-offices,

and courts of justice in the several States. To demand the care and protection of the Federal Government over life, liberty, and property when on the high seas or within the jurisdiction of a foreign government. To peaceably assemble and petition for redress of grievances. The writ of *habeas corpus*. To use the navigable waters of the United States however they may penetrate the territory of the several States. To become a citizen of any one of the several States by a *bona fide* residence therein." Freedom from State discrimination against citizens of other States in respect of commercial transactions is an immunity of U. S. citizenship, unless such discrimination is a valid exercise of the police power.

The amendment under consideration applies only to State action, and not to that of individuals. Congress, therefore, is not authorized to declare it a crime for individuals to conspire to deprive any person of his privileges and immunities as a citizen of the U. S. *Civil Rights Cases*, 109 U. S. 3.

FRANCIS M. BURDICK.

Privy Council: "This is a most noble, honorable, and reverend assembly of the king . . . in the king's court or palace; with this council the king himself doth sit at his pleasure. These councilors, like good sentinels and watchmen, consult of and for the public good, and the honor, defense, safety, and profit of the realm. . . . They are called *concilium regis privatum*, *concilium secretum*, *et continuum concilium regis*. . . . To these counsellors all due honor and reverence is to be given, for they are incorporated to the king himself, and bear part of his cares; they are his true treasurers, and the profitable instruments of the state." (4 Coke's *Institutes* 53.) Such was the privy council for centuries—a council within the great council; a small body selected by the king to be in constant attendance upon him, and to aid him in the performance of legislative and judicial as well as administrative duties.

Its name dates from the reign of Henry VI., while it attained its greatest importance under the Tudors and the first two Stuarts. During this period its judicial functions were so grossly abused in its court of the star chamber that they were "clearly and absolutely dissolved, taken away, and determined" by the Long Parliament in 1640. With the Restoration the privy council revived, but not its court of the star chamber. However, "the king in council was still the resort of the suitor who could not obtain justice in one of the dependencies, and the act which took away the original jurisdiction of the king in council at home did not touch petitions from the adjacent islands or plantations." Anson's *Law of the Constitution*, pt. ii., p. 442.

Its judicial functions remained somewhat uncertain until 1833, when they were defined by statute (3 and 4 William IV., c. 41). They are exercised by the judicial committee of the privy council, consisting of the lord-president, those members of the council holding or having held high judicial office, the lord justices of appeal, two other persons being privy councilors whom the crown may appoint, and one or two paid members who have held the office of judge in the East Indies. A quorum consists of four members, and only those members attend who have been summoned. This judicial committee does not give formal judgment in a case, but humbly advises the Queen to give effect to the conclusions it has reached. Its report, when approved by the Queen at a meeting of the privy council, is adopted by an "order in council" as the judgment of the Queen in council. It is a rule of this committee, having its origin in the secret and consultative character of the ancient council, that after a case has been decided "no publication is afterward to be made by any man how the particular voices or opinions went." (*Order in Council*, 1878.) The jurisdiction of this committee embraces all appeals made to the crown in council, the most important of which are appeals from the colonial courts, and such other matters as the crown may choose to refer to it.

Its legislative functions are exercised by means of orders in council, which are made under authority bestowed by statute or which issues from the royal prerogative. In the former case it is acting simply as a delegate of Parliament, and in subordination to the national legislature. Even in the latter case, according to some authorities, the crown in council is not legislating, is not enacting law, but is enforcing it. Dicey declares that "the only instances where, in modern times, proclamations or orders in council are of any effect are cases either where at common law a proclamation is the regular mode, not of legislation, but of announcing the executive will of the king, as when Parliament is summoned by proclamation, or else where orders in council have authority given to them by act of Parliament." (*The Law of the Constitution*, p. 50.) The better view seems to be that the crown still retains a fragment of its ancient power to legislate without the assistance of Parliament; that, especially in matters connected with the colonies, where Parliament has neither legislated nor vested the exclusive power of legislation in some other body nor forbidden the crown to legislate, it may enact new laws by means of orders in council. Burgess, *Political Science*, vol. ii., p. 199; Cox, *The Institutions of English Government*, 27–30.

Its administrative functions are exercised at present by committees or boards. The most powerful of these, as it is the one that has absorbed all of the most important privileges of the ancient privy council, is the CABINET (*q. v.*). Other committees are those for trade and plantations, for education, for local government, for corporations, for the Channel islands. When a petition is addressed to the crown touching matters within the administrative jurisdiction of the council, it is referred to the appropriate committee for advice. Many matters are brought before the council as a body. Modern legislation has created new boards and transferred to them much of the business which belonged formerly to the council.

Appointment, Oath, and Dismissal.—A person becomes a privy councilor by royal nomination, upon taking the oaths of office and allegiance at a council meeting. "The members composing the privy council may be said to fall into three groups. Members of the cabinet must necessarily be made members, as the confidential advisers of the crown. Beyond these there are great offices which, though unconnected with politics, are usually associated with a place on the council board. Beyond these, again, is a group of persons eminent in political life or in the service of the crown, upon whom the rank of privy councilor is conferred as a complimentary distinction." (Anson's *Law of the Constitution*, pt. ii., p. 135.) At present the number of privy councilors is about 200. The tenure of office is for life, subject to dismissal at the pleasure of the crown. The oath binds the councilor to be a true and faithful servant of the crown; to resist to his uttermost any affront to the monarch and to report the same; to truly declare his opinion upon all matters before the council; to keep secret all matters treated of in the council; to bear faith and allegiance unto the crown, and in all things to do as a faithful and true servant ought to do to the crown. See Nicolas, *Proceedings and Ordinances of the Privy Council*; Dicey, *The Privy Council*; Palgrave's *Original Authority of the King's Council*; and Finlason's *Judicial Committee of the Privy Council*.

FRANCIS M. BURDICK.

Privy Seal: the minor seal of the British Government, affixed to papers of minor importance, and also to important documents preparatory to the affixing of the great seal. The privy seal is in the care of a great officer of state, usually one of the cabinet, called the lord privy seal.

Prize [from O. Fr. *prise*, a taking or seizing, something taken or seized, deriv. of *prendre* (perf. partic. *pris*), take]: something taken on the sea, as belonging to an enemy in war or to a neutral—i. e. to a person resident in a neutral state who is identified with such enemy. A vessel of a nation taken by its own cruisers, if engaged in illegal trade, may also be called a prize. A prize can become the property of the captor only after trial and condemnation by a competent court. This will be the prize-court of the state to which the captor belongs. In Great Britain questions of prize are decided by her Majesty's high court of justice, which is one division of the Supreme Court of Judicature, in which the old admiralty and other courts were merged by act of 1873. A corresponding court in France is the council of prizes, subject to appeal. In the U. S. admiralty cases are tried by the U. S. district courts, with appeal to the Supreme Court.

Revised by T. S. WOOLSEY.

Prjeval'sky, or **Prejevalsky**, NICOLAI MICHAELOVITCH: explorer; b. on the family estate of Otradny, government of Smolensk, Russia, Mar. 31, 1839; descendant of a Cossack of the Zaporog, whose heroism gave him the surname of Prjevalsky (from the Polish *Prje*, very, and *valit*, to make war), and who was ennobled by Stephen Bathory, King of Poland. He was educated in the civil gymnasium of Smolensk, where he was noted for an extraordinary memory. In 1855 he entered the military profession, and five years later the Military Academy, where he showed

stronger predilections for history and natural science than for military subjects. In 1863 he rejoined his regiment as adjutant, but remained with it only a year. He then obtained the post of lecturer on history and geography in the cadet school at Warsaw. In 1867 he received an assignment as geographical explorer, and was sent to the Ussuri country in Eastern Siberia, where he remained two years. His results were published in Russian in 1870. From the maritime province he traveled southward to the Yang-tse river, thence northward through the desert of Gobi to Irkutsk, reaching the latter place in 1873. In 1876–77 he explored Lob-Nor and the Altyn-Tag Mountains. He crossed into Tibet in 1879, but was turned back before Lhassa was reached, and returned to Russia through great dangers and hardships. In 1883–85 he again explored the desert of Gobi, the sources of the Hwang-ho and the Lob-Nor district, and again unsuccessfully attempted to reach Lhassa. Later he was placed in command of a large force and instructed to reach Lhassa at all hazards, but he died on Nov. 1, 1888, of typhus fever, before the expedition had been fully organized.

Though of Polish descent, he was an intensely patriotic Russian. His geographical work was recognized by many honors received from geographical societies and others throughout the world. His explorations after the first were described in numerous publications, which have been translated from Russian into the other European languages. A sketch of his life was published in St. Petersburg in 1890, by N. T. Dubrovin. MARK W. HARRINGTON.

Pro'a, or **Pra'hu** [from Malay *prāū*, *prāhū*]: a canoe-like sailing vessel of the Malays, Ladrone islanders, etc. The lee side is straight and flat from stem to stern, the other rounded. Both ends are alike. The vessel carries a lug-sail of matting. A framework projects to windward, and counterbalances the effect of the wind upon the sail, which would otherwise upset the craft. Proas are commonly some 30 feet long and very rapid sailers. They were once much used by pirates. The name is often applied to Malay vessels of other kinds, some propelled by oars and paddles, and some by sails also.

Proach, Lucky: See FATHER LASHER.

Probability, Theory of, or (more usually) **Calculus of Probabilities** [*probability* is from Lat. *probabi'litas*, deriv. of *proba'bilis*, probable, liter., provable, deriv. of *proba're*, try, approve, prove]: the application of mathematical reasoning to the art of judging in cases where only probable evidence can be obtained. The mode in which the judgment may be thus assisted can be best seen by beginning with some simple examples before laying down any general principles. Suppose a die to have two of its six sides painted black, the remaining four being left white, and a person to be required to judge whether, upon the die being thrown, a white or a black side will be uppermost. Common sense will teach him to guess the white side, not because he can certainly say it will be thrown, but because it will be more likely to be thrown. In common language it would be said that the chances were two to one in favor of white. In mathematical language a slightly different expression is used, the probability of an event being a proper fraction, of which the denominator is the entire possible number of chances or cases, while the numerator is the number of those cases which favor the proposed event. In the case just supposed, for instance, there are six sides to the die, of which one and one only must be thrown. Four of these sides being white, the probability of white being thrown is $\frac{4}{6} = \frac{2}{3}$, and that of black is $\frac{2}{6} = \frac{1}{3}$. If one of the four white sides were painted yellow, the probabilities would be white $\frac{1}{2}$, black $\frac{1}{3}$, yellow $\frac{1}{6}$. If the event is impossible, there are no cases which favor it, and in the notation just indicated its probability is 0. If all the cases favor it, and its occurrence is therefore certain, the probability is 1. As no degree of probability can exceed certainty, all degrees of probability are somewhere between the limits 0 and 1.

The mathematical solution of problems in probabilities consists, first, in dividing the possible processes or results into elementary and equally probable cases; and, secondly, in finding how many of these cases favor the proposed event. In the case just supposed of a single die this is very simple, and no one could mistake the mode of arriving at a solution; but when the result depends on the concurrence of a number of circumstances, the reasoning becomes much more complex. Suppose, for instance, that two dice are thrown. Then any one of the six sides of one die may be combined with any side of the other, making, in all, thirty-six combinations. To find the probability of any result from the throw of such a pair, we must find how many of these combinations will give rise to the combination in question, and divide the number by 36. In making this calculation there is great room for mistakes; indeed, the subject of probabilities is by far the most slippery one with which the mathematician or logician has to deal. Suppose, for instance, that a sharper should offer to a countryman to give him three cents every time two *ones* were thrown with two dice, provided the other would give him two cents every time a *one* and a *two* were thrown. At first sight the countryman might consider the two results equally probable, and therefore feel sure, in the long run, of gaining; but he would be sure to lose, because two different numbers are twice as likely to be thrown as a pair of the same number. To have two *ones* each die must fall with *one* uppermost; but to have a *one* and a *two*, one may be a *one* and the other a *two*, or the first may be *two* and the second *one*; so that for this result there are two cases out of thirty-six, while in the first there is but one. It can not be doubted that an understanding of this calculus would afford a very material aid to the judgment in weighing and estimating the probabilities of events in the affairs of life; for, although these events, or the causes which give rise to them, can not generally be made the subject of mathematical calculation, yet the examination and enumeration of the various combinations of circumstances which may give rise to an event affords our only means of judging of its probability. The longer a man's experience of worldly affairs and the sounder his judgment, the more nearly he will conform to the rules and methods of the mathematical calculus in estimating probabilities. An eminent writer happily described the calculus of probabilities as common sense expressed in numbers.

One of the most generally useful rules of this calculus is that although an event may be extremely improbable if it has but one opportunity to happen, yet if we increase the numbers of opportunities indefinitely it will be sure to happen in the long run. By the same principle, if the concurrence of a large number of circumstances is necessary to the production of an event, each of these circumstances may be, in itself, very probable, and yet their concurrence, and consequently the event itself, very improbable. The mathematical rule for determining probability in such a case is that the probability of the concurrence of all the events is equal to the continued product of the probabilities of all the separate events. As one example, suppose that a law requiring the concurrence of the two houses of Congress and the President were as likely as not to be rejected by any one of them, and that each one of the three authorities formed his own opinion independently of the other two. Then the probability of each authority approving the law being $\frac{1}{2}$, the probability of its passing all three would be $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \frac{1}{8}$. We can get at the same result in this way: Out of 8 laws introduced into the House only 4 would pass and go to the Senate. Out of these 4 the Senate would pass 2, and of these 2 the President would approve 1. On this principle an event which has to pass the ordeal of a great number of small dangers is sure to fail at last, though each separate danger may itself be small. Suppose, for instance, that a bridge has 100 holes in it, and that a person passing over this bridge has 9 chances out of 10 of going safely past each individual hole. Notwithstanding so many chances in his favor for any particular hole, the chance that he would escape them all is only 1 in 37,650. That is, if we take the fraction $\frac{9}{10}$, which expresses the probability of passing any one hole safely, and multiply it by itself 100 times, the result will be about equal to $\frac{1}{37650}$. One of the principal marks of the practical wisdom of age and experience is the ability to recognize this principle, and there are plenty of proverbs which are really founded on it.

One of the most curious and important results of this calculus is seen in what is termed the law of averages, or the tendency of chance events which occur in great numbers to follow regular laws. The life of an individual is proverbially one of the most uncertain things in human affairs; but when we take large bodies, like the population of a state or a great city, the deaths follow a law so exact that mathematical tables of their probable number can be formed, and on these tables life-insurance companies can arrange their rates of premium with the moral certainty that the death-rate will not vary seriously from that calculated. Not only the total number of deaths, but the proportion of deaths from the most fortuitous causes follow

nearly their regular law. No doubt if we could learn how many men are killed by falling from houses, we should find it wonderfully constant from year to year. In cases like this the constancy of the result is the consequence of some widespread underlying cause, hidden by other accidental causes acting in different ways in individual cases. Thus a table of mortality is the combined expression of a certain law of the human constitution and certain conditions of the climate. The number of deaths by falling from scaffolding expresses the degree of general carefulness or carelessness which characterizes men engaged in building. The general rule is that in order that a law of averages may be closely followed it is necessary that the seemingly accidental events enumerated should be the result of two sets of causes, of which one is invariable throughout the whole period of time, while the other is entirely accidental in each individual case. When the variable or chance causes are not purely accidental, but affect large masses or vary from year to year, there is no longer any such exact law. For instance, if a large fraction of the population died from occasional epidemics, there could no longer be an exact law of mortality. The great classic treatise on this subject is Laplace, *Théorie Analytique des Probabilités*, which involves much profound mathematics. Bertrand's *Calcul des Probabilités* (Paris, 1889) is most interesting, philosophical, and amusing, using only elementary mathematics; De Morgan's *Theory of Probabilities* is the best-known book in English.

S. Newcomb.

Probate Courts: See the Appendix.

Proboscid'ea [Mod. Lat., from Lat. *probos'cis*, *probos'cidis* = Gr. προβοσκίς, προβοσκίδος, proboscis; πρό, in front, before + βόσκειν, feed, graze]: an order of mammals distinguished by the extension of the nose into a proboscis and the columnar form of the legs and feet, and typified by the elephants of the present epoch. The placenta is deciduate and zonary; the incisors variable in number—$\frac{2}{0}$, or in extinct forms $\frac{2}{2}$ or $\frac{0}{2}$—but always with persistent pulps, and developed as long tusks curved outward; the feet have the palmar and plantar surfaces invested in extended pad-like integuments, which also underlie the toes; the carpal bones are in two regular (not interlocking) rows, and are broad and short; the toes are in all the known forms five to each foot, and incased in shallow hoofs. The order is represented by one living family (*Elephantidæ*), to which belong the extinct mastodons; and to it by almost all authors an extinct family (*Dinotheriidæ*) has been also referred; these are distinguished from each other by great differences in the structure of the skull, as well as in the development of the teeth, the peculiar dentition of the elephants not being shared by the dinotheriids. See Elephant, Dinotherium, Mammoth, and Mastodon. Revised by F. A. Lucas.

Proboscis Monkey: See Kahau.

Pro'bus: Roman emperor from 276 to 282 A. D. He was put to death in the latter year by his own soldiers, after a very efficient administration of six years, chiefly occupied with the defense of the northern frontier. G. L. H.

Probus, Marcus Valerius: the most distinguished of Roman grammarians bearing the name of Probus. Coming from Berytus (now Beyrout), he taught in Rome in the latter half of the first century A. D., and edited, after the manner of the Alexandrine grammarians, the text of Horace, Vergil, Lucretius, Terence, Persius, and probably other writers. The *Commentary* to the *Eclogues and Georgics* of Vergil, still extant, under his name is of later date, as are several grammatical treatises bearing the name of Probus. See especially Teuffel, *Gesch. der Röm. Lit.* (§ 300), where the abundant literature on the subject is cited. M. Warren.

Procedure [from O. Fr. *procedure*, deriv. of *proceder*, proceed < Lat. *proce'dere*; *pro*, forward + *ce'dere*, go]: in the usage of modern legal writers, all the formal steps and proceedings in the conduct of a judicial controversy as established by the legal rules which control their use.

Development of Procedure in General.—Certain uniform principles seem to have determined the nature and moulded the history of procedure in every national jurisprudence that has made a complete progress from rude beginnings to a condition of comparative philosophical and equitable perfection. The earliest stages are always characterized by an intense formalism; the remedies which the law affords are restricted almost wholly to such as can be pursued by the use of arbitrary technical forms, each appropriate to a particular wrong or remedy, which must be followed with scrupulous exactness; and the defenses which can be interposed are likewise restricted by forms equally arbitrary and technical. The growth of the jurisprudence for a considerable period consists in the modification of these forms and their extension to new facts and relations; in time the dominion of forms is relaxed, the technical and arbitrary features gradually disappear, and at last the methods of administering justice become simple, and are based upon equitable notions. The state of legal procedure and the judicial remedies of a nation closely reflect the condition of its civilization; and the number and scope of remedies, and the methods of enforcing them, must keep pace with the culture of the nation and provide for its wants. The necessities, however, arise first, and the law afterward responds to them. This course of development marks an entire progress of the Roman Law (*q. v.*), and has been exhibited no less clearly in the development of the jurisprudence of England and the U. S.

Development of Procedure in English Law.—The most striking feature of the procedure originally prevailing in England is the separation into two distinct and widely differing systems, the common law and the equitable—the former exclusively used by the courts of law for the enforcement of legal rights in connection with the jury trial; the latter employed by the courts of equity for the enforcement of equitable rights alone without the jury.

Of the two, the common-law methods were much the elder. From the earliest periods rights were enforced in the law courts by means of different actions, the most important of which, denominated "real actions," were solely used for the recovery of lands. Prior to Edward I. there existed but three actions for the recovery of money—debt, covenant, and trespass. By virtue of a statute passed in the reign of that king (13 Edw. I., c. 24) other forms were afterward invented. The highly technical real actions were subsequently abandoned, with a few occasional exceptions, and the following actions became established as the ordinary means of enforcing legal rights: "ejectment," to recover possession and to try the title of lands; "detinue" and "replevin," to recover possession of chattels; "covenant," to recover damages for the breach of a sealed agreement; "debt," to recover a fixed and certain sum of money owed by the defendant, not as damages; "assumpsit," to recover damages for the breach of a contract not under seal, whether written or verbal, express or implied; "trespass," to recover damages for a wrongful act of violence to person or property; "case," to recover damages for a wrong to person or property unaccompanied with violence, or when the injury was consequential; "trover," to recover damages for the wrongful detention and conversion of chattels. The rules which governed these actions were technical and formal, and the courts were more often employed in deciding whether the proper kind of action had been brought, or whether the correct formulas of words had been used, than in adjudicating upon the actual merits of causes and determining the real rights of the parties. Inseparably connected with this diversity of actions was the common-law system of pleading; the two reacted upon and supported each other, and the technicalities of the one brought out and strengthened the formalism of the other.

The procedure in equity was based upon more simple and natural notions, and, however much it may have become encumbered by dilatory and unnecessary practices, these were not inherent and essential. No forms of actions existed, but a single method sufficed for all kinds of claims, defenses, and reliefs. The complainant stated his case with great minuteness of detail in a "bill," the defendant set forth his version in an "answer"; and upon these pleadings and the proofs the chancellor rendered his decree. In this judgment the rights, claims, and liabilities of all the parties were adjusted, and relief could be granted alike to defendants or to complainants. It was therefore a cardinal principle of the equity procedure that all persons interested in the controversy and who could be affected by the decree should be made parties to a suit.

All these principles, methods, and rules of the common-law and the equity procedure were incorporated into the jurisprudence of the U. S., and although they have been modified in many of the commonwealths, in others they are retained substantially as they existed at the time when Blackstone wrote his *Commentaries*.

The Codes.—A revolution has finally been effected in the U. S. and in England in every respect identical with that which took place in the Roman law when the prætor's ex-

traordinary jurisdiction was extended to all kinds and classes of litigations. In 1848 the Legislature of New York adopted a code of civil procedure—chiefly planned and created by David Dudley Field—which entirely abandoned all former existing methods, and inaugurated a new system for the enforcement of rights and the recovery of remedies. Its central principle is the abolition of all distinction between actions at law and suits in equity, and of all forms of action, and the establishment of a single judicial instrument called the "civil action," by which all rights are maintained, duties enforced, and reliefs obtained. Legal and equitable claims, defenses, and remedies may be combined, and the single judgment of the court may determine and establish the final sum of all the rights and interests belonging to the litigant parties. With the common-law forms of action the common-law forms of pleading are also abandoned, and in their stead is substituted one simple and natural mode which only requires the parties to state in ordinary language the actual facts which constitute their causes of action or defenses. The system has been accepted—sometimes with unimportant modifications, but often without any change from the original type—in most of the States and Territories, and may be styled the "reformed American procedure." Passing beyond the limits of the U. S., it prevails in several of the British colonies, and has been adopted in all its essential principles in England itself. The first step in England was made by the Common Law Procedure Act of 1854, but it was not fully adopted until, by the Judicature Acts of 1873 and 1875, all law and equity courts were consolidated into one tribunal, and all distinctions abolished between legal and equitable forms of actions and procedure. The history of procedure does not present another so remarkable instance of legislation. See Bigelow's *History of Procedure in England*; Stephen's *History of the Criminal Law of England*, and the general treatises on pleading and practice. Revised by F. STURGES ALLEN.

Procellar'idæ [Mod. Lat., named from *Procella'ria*, the typical genus, from Lat. *procel'la*, storm]: a family of birds of the order *Tubinares*, including the petrels and albatrosses. These have a gull-like body; the neck rather short; the bill moderate, and composed of several pieces, and in some species, if not in all, the bill is shed and renewed as well as the plumage; the nostrils at the end of tubular processes, which are more or less immersed in grooves; the wings are generally elongated and pointed, rarely (as in *Pelecanoides*) short; front toes connected by a web, posterior rudimentary or wanting; the skull is schizognathous, and in most respects agrees with that of the gulls and loons, but exhibits some distinctive characters, and has been regarded by Streets as indicating a peculiar superfamily (*Nectriomorphæ*). The family is generally divided into three subfamilies: (1) *Procellarinæ*, including most of the small species; (2) *Diomedeinæ*, comprising the albatrosses; and (3) *Pelecanoidinæ*, represented by the single aberrant genus *Pelecanoides*. See ALBATROSS, FULMAR, MOTHER CAREY'S CHICKEN, and PETREL. Revised by F. A. LUCAS.

Process [viâ O. Fr. from Lat. *proces'sus*, a going forward, advance, progress, process, deriv. of *proce'dere*, go forward; *pro*, forward + *ce'dere*, go]: in law, a generic term primarily used to designate all the means by which a defendant is compelled to appear and answer to an action brought against him (*original process*), the means of enforcing the judgment recovered therein against him, and also the means by which his property is secured or taken in satisfaction of such judgment (*final process*); and also various other judicial writs or orders issued pending the suit or action upon collateral or interlocutory matter, as to summon witnesses, juries, etc. (*mesne process*). In the criminal procedure it denotes the warrants or other writings authorizing and directing the arrest of persons charged with offenses. In a more general sense it embraces all judicial writs commanding public officers or private individuals to do a specified act; and, finally, it is used, although not technically, as synonymous with "proceeding." Actions at law were formerly begun in England by a process called the "original writ," which was issued in the king's name, contained a statement of the complaint, and was addressed to the sheriff, commanding him to summon the defendant. This writ was practically abolished in the reign of William IV., when it was enacted that all personal actions should be commenced by the writ of CAPIAS (*q. v.*), directing the sheriff to arrest the defendant; or if he was not to be arrested by the writ of SUMMONS (*q. v.*), directing the defendant to appear. The corresponding process in chancery suits was the "writ of subpœna," while that in the ecclesiastical and admiralty courts was termed a "citation"; both were, like the summons, personal orders to the defendant. At present all actions are commenced in England by a process in the nature of a summons. In the U. S., wherever the reformed procedure has been adopted, all actions in the superior courts are begun by a summons or notice to the defendant directing him to appear and answer within a specified number of days; in several of the States it is issued directly by the plaintiff or his attorney, in others by the clerk of the court in which the suit is brought. In those commonwealths which retain the common-law methods different forms of preliminary process are used, but, under whatever names, they are generally analogous to the writ of summons. A peculiar local practice prevails, however, in New England, of beginning legal actions by attaching the defendant's property. (See ATTACHMENT.) Final process is of two kinds —that against the property and that against the person. Final process is now commonly called EXECUTION (*q. v.*). In addition to these preliminary and final steps, there may be, under certain circumstances and in a special class of actions, intermediate (*mesne*) proceedings in the nature of process against the defendant—namely, an order or warrant of arrest, by virtue of which he is taken and held to bail or detained, and a warrant or order of attachment, by virtue of which his property is seized and held to wait the final judgment. Revised by F. STURGES ALLEN.

Procession of the Holy Spirit [*procession* is from Lat. *proces'sio*, deriv. of *proce'dere*, *proces'sum*, go forth; *pro*, forward, forth + *ce'dere*, go]: a term based on John xv. 26, where Christ says of the Spirit whom he will send from the Father that "he *proceedeth* from the Father" (*παρὰ τοῦ πατρὸς ἐκπορεύεται*, hence *ἐκπόρευσις*, *processio*). It designates in the orthodox theology the characteristic individuality (*ἰδιότης*, *proprietas*, *character hypostaticus*) of the third Person of the Holy Trinity, as the eternal generation (*γεννησία*, *generatio*) is the characteristic property of the Son, and the unbegotten paternity (*ἀγεννησία*, *paternitas*) the exclusive peculiarity of the Father. There is an old difference between the Greek and Latin Churches about the *single* procession (from the Father *alone*) and the *double* procession (from the Father *and the Son*). The Nicene Creed as enlarged at Constantinople (381) asserts only the procession from the Father (*Sp. S. qui ex Patre procedit*), in verbal adherence to the passage in John, and the Greek Church understands this in an exclusive sense (from the Father *alone*). The Latin Church, after Augustine, taught the double procession, and afterward embodied it, without asking the consent of the Greeks, in the Nicene Creed by the insertion of *filioque* ("and from the Son"). This famous clause first appeared in 589, at a synod of Toledo in Spain (in strong opposition to Arianism), and in spite of the protest of Pope Leo III. (809) it was gradually adopted in the Latin Church, from which it passed into the Protestant churches. This difference has caused a great deal of bitter controversy since the days of Photius, Patriarch of Constantinople (d. 891). The councils of Lyons (1274) and of Florence (1439) endeavored to settle it, but in vain. The Greek divines plead in favor of the single procession the letter of the Scripture, the original text of the Nicene Creed, and the dignity or monarchy (*μοναρχία*) of the Father as the sole fountain, cause, and root of the Deity; they also make a sharp distinction between the eternal metaphysical *procession* of the Spirit from the Father alone, and the historical *mission* of the Spirit from the Father and from the Son (John xiv. 26; xvi. 7). The former belongs to the Trinity of essence, the latter to the Trinity of revelation, and begins with the day of Pentecost. The Latin divines infer the double procession (taking this term in a wider sense) from the double mission and from the essential unity (or *homoousia*) of the Son with the Father, so that if the Spirit proceeds from the essence of the Father he must proceed also from the essence of the Son, both being the same. A compromise was suggested by the formula that the Spirit proceeds from the Father *through the Son* (*διὰ τοῦ υἱοῦ*). When Pius IX. invited the Eastern patriarchs to the Vatican Council in 1870, they renewed the old protest against the heretical *Filioque*. The Döllinger Union Conference between Old Catholics, Orientals, and Anglo-Catholics discussed this controversy at Bonn in Aug., 1875, and came to an agreement which surrenders the *Filioque* as an unauthorized interpolation to the Creed, and indorses the single procession of

the Spirit from the Father alone, but through the Son, as taught by John of Damascus, the last of the Greek Fathers. See Holy Ghost. Philip Schaff.

Procida, prō'chĕĕ-dăă (anc. *Prochyta*): island; in the province of Naples, Italy, lying between Ischia and Cape Miseno. It is not more than 8½ miles in circumference, and is composed of volcanic tufa; the town of Procida, on the east side, stands on a high and rugged rock which is almost surrounded by water. The principal edifice, besides the churches, is the royal palace of the Bourbons, who frequently came here for health or amusement. Procida was originally a Greek settlement, and in spite of the long Roman domination, of the devastations of the Saracens, of Spanish and British occupations, the inhabitants still claim to be of Greek descent. They are occupied in agriculture, in tunny-fishing, and in the search for coral. Pop. 13,131.

Proclamation of Emancipation: See Emancipation, Proclamation of.

Pro'clus: philosopher; b. at Byzantium, Feb. 8, 412 A. D.; educated at Xanthus in Lycia, from which his family descended; studied at Alexandria and Athens, and became a celebrated teacher in the latter city, where he died Apr. 17, 485. He was the last member of the Neoplatonic school who acquired any celebrity. He labored hard to make converts from Christianity. There is no complete edition of his works which are still extant. That by Cousin (6 vols., Paris, 1820–27) contains the treatises on *Providence and Fate*, the *Ten Doubts about Providence*, the *Nature of Evil*, and the commentaries on the *Alcibiades* and *Parmenides*. There are translations in English by Thomas Taylor of the *Commentaries on the Timæus*, the *Theology of Plato*, the *Commentary on Euclid*, and of *Five Hymns* (London, 1816).

Proc'ne: See Philomele.

Proconsul [= Lat.; *pro*, for + *consul*]: a magistrate in the ancient Roman government who exercised consular authority over a province or an army, but not over Rome. In many cases he was a consul, who after the expiration of his term of service was sent to control a province, but sometimes the proconsul was not even of consular rank.

Proco'pius: author; b. at Cæsarea, Palestine, in the beginning of the sixth century A. D.: studied at Constantinople; accompanied Belisarius as his secretary on his campaigns in Asia, Africa, and Italy, and held after his return to Constantinople the highest dignities in the civil service of the Byzantine government. His extant works include *Historiæ*, a representation of the history of his own time, clear, trustworthy, and interesting, translated into English by Henry Holcroft (London, 1653); *Ktismata*, a work on the public buildings erected during the reign of Justinian; and *Anecdota*, translated into English under the title of *The Secret History of the Court of the Emperor Justinian* (1674). The Procopian authorship of the *Anecdota* has been questioned, but recent investigation seems to be decidedly in favor of the genuineness of the work. See Krumbacher, *Geschichte der byzantinischen Litteratur*, p. 43; Teuffel, *Studien und Charakteristiken*, p. 267. A complete edition of his works was published by W. Dindorf (3 vols., Bonn, 1833–38). Revised by B. L. Gildersleeve.

Procopius the Great: soldier; b. about 1380; was ordained a priest, but on the outbreak of the Hussite war he joined the army and distinguished himself so greatly that after Ziska's death in 1424 he was chosen commander-in-chief by the Taborites. On the approach of the German armies of crusaders the different Hussite parties, among which were the Orphans under Procopius the Less, united under the leadership of Procopius the Great, and a war ensued (1527–32), remarkable at once for the valor and cruelty which the Hussites evinced. They made successful campaigns in Saxony, Silesia, Moravia, Hungary, Austria, and Bavaria. In 1433 the Hussites consented to send eight delegates to the Council of Basel. Procopius was one of them, and he took part with great energy in the debate, but after the lapse of fifty days the Bohemian delegates grew tired and returned to Prague. Papal commissioners followed them, and at last a compromise was brought about between the Roman Catholics and the Calixtines. The Taborites, however, refused to have anything to do with the pope, and thus arose a controversy between them and the Calixtines which soon grew into open warfare. At the battle of Bömischbrod (May 30, 1434) a sudden panic seized the Taborite army; it was utterly defeated, and both Procopius the Great and Procopius the Less fell.

Procrus'tes [in Gr. Προκρούστης, the stretcher]: a surname commonly given to the famous robber Polypemon or Damastes, who used to place all persons that fell into his hands on an iron bed, and cut off or stretch out their limbs until they fitted the bed. He was slain by Theseus near the Cephissus in Attica.

Procter, Bryan Waller: poet; familiarly known under his pseudonym of *Barry Cornwall*; b. in London Nov. 21, 1787; educated at Harrow; studied law in Wiltshire; removed to London, where he was admitted to the bar in 1831, but did not attain prominence as a counsel. The lucrative position of commissioner of lunacy, however, which he held for many years, supplied the means as well as sufficient leisure for the culture of his literary and poetic tastes. In 1819 he published a volume entitled *Dramatic Scenes and Other Poems*, which was the beginning of his literary career. In 1821 his tragedy of *Mirandola* was produced at the Covent Garden theater with much success. It is as a writer of refined, melodious, and inspiring songs that he is best remembered and esteemed. D. Oct. 5, 1874. His *Poetical Works* have had wide circulation in Great Britain and the U. S.—His daughter, Adelaide Anne Procter, b. in London Oct. 30, 1825, wrote two volumes of verse, *Legends and Lyrics* (1858 and 1860). D. Feb. 2, 1864. Her works were reissued in 1865 with an introduction by Charles Dickens.
Revised by H. A. Beers.

Proctor [M. Eng. *proketour*, viâ O. Fr. from Lat. *procura'tor*, manager, agent, deriv. of *procura're*, take care of, manage; *pro*, for + *cura're*, to care, deriv. of *cura*, care]: in law, an officer of the admiralty and ecclesiastical courts in England, empowered to bring and conduct proceedings therein on behalf of suitors, corresponding to the attorney and the solicitor of the ordinary tribunals. From an early day a body of men were attached to these ecclesiastical and admiralty courts who had the exclusive authority to appear therein, and to bring or defend all causes in the same manner that actions at law and suits in equity are brought and managed by attorneys and solicitors. Admission to the body was obtained, after a long clerkship, by means of a commission issued in the name of the Archbishop of Canterbury. The class of professional men who actually tried or argued the causes, or performed other duties, before the court itself —whose functions, in other words, were similar to those of the barristers or counsel—were termed "advocates." The title of proctor is still used, but the distinction between proctors and the other members of the legal profession has been abolished. The jurisdiction of the ecclesiastical courts in matrimonial and testamentary causes having been taken away (see Courts), compensation to the proctors, whose practice was in these courts, was made by admitting them to practice not only in the probate and divorce courts, but in the courts of equity and common law also. (See 20 and 21 Vict., c. 77, §§ 43, 105, 106, and c. 85, § 69; 21 and 22 Vict., c. 95, § 9, and c. 108, § 13; also 23 and 24 Vict., c. 27.) By the Solicitors' Act of 1877 (40 and 41 Vict., c. 25, § 17) solicitors are allowed to practice as proctors, and the Legal Practitioners' Act of 1876 (39 and 40 Vict., c. 66) allows solicitors to appear in the provincial courts of Canterbury and York.

There are no proctors, as a separate order or class, in the legal profession of the U. S., although the designation is often assumed by attorneys in admiralty cases, or when practicing before surrogates or courts of probate.

"Proctors of the clergy" in the English ecclesiastical law are the delegates or representatives of cathedral and other collegiate churches, and also of the common clergy in every diocese, appointed to sit in the convocation of the Church, that is, the assembly of the clergy held during the session of parliament, but which has long since ceased to exercise any legislative powers. Revised by F. Sturges Allen.

Proctor, Redfield: U. S. Senator; b. at Proctorsville, Vt., in 1831; graduated at Dartmouth College in 1851; studied at the Albany Law School; when the civil war broke out was practicing law. He enlisted in 1861 in the Third Vermont Regiment; became major of the Fifth, and afterward colonel of the Fifteenth Vermont, but returned home, after the battle of Gettysburg, in broken health; served in Vermont Senate and as Lieutenant-Governor; was Governor 1878–80; chairman of the Vermont delegation in the Republican National Convention of 1888, and became Secretary of War in 1889; resigned in 1891 and was appointed U. S. Senator to fill the vacancy caused by the resignation of Senator Edmunds, and in 1893 and 1899 was elected.

Proctor, Richard Anthony: writer on astronomy; b. in London, England, Mar. 23, 1837; entered King's College, London, in 1855, and St. John's College, Cambridge, in 1857, and graduated in 1860. His first literary effort was an article on *Double Stars* in *The Cornhill Magazine* for Dec., 1863. In 1865 he published his first book, *Saturn and its System*, which was soon followed by his *Gnomonic Star Atlas*, and in 1866 by his *Handbook of the Stars*. In 1867 he published *Constellation Seasons*; in 1868, *Half Hours with the Telescope*: in 1869, *Half Hours with the Stars*; in 1870, his most celebrated work, *Other Worlds than Ours, The Plurality of Worlds Studied under the Light of Recent Scientific Researches*; in 1871, *The Sun, Elementary Lessons in Astronomy*, and the first series of *Light Science for Leisure Hours*; in 1872, *The School Atlas of Astronomy, Essays on Astronomy, Orbs around Us*, and *Elementary Lessons on Physical Geography*; in 1873, *Light and Science, The Moon, The Border-land of Science, The Expanse of Heaven, The Universe and the Coming Transits*; in 1874, *Transits of Venus* (3d ed. 1878); in 1878, *A Treatise on the Cycloid and all Forms of Cycloid Curves, and on the Use of Cycloid Curves in dealing with the Motions of Planets, Comets, etc., and of Matter projected from the Sun*; in 1887, *Easy Lessons in Differential Calculus*; in 1888–90, *Old and New Astronomy*. In 1881 he founded the science periodical *Knowledge*. He several times visited the U. S., and lectured in the larger cities. He also lectured in Australasia. D. in New York, Sept. 12, 1888. Revised by S. Newcomb.

Procura'tor: the designation of a Roman administrative officer, charged with the management of the revenues and business affairs of a province. Although not of military rank troops were assigned to him for the administration of his office, and he was recognized as second in authority to the governor. He might therefore, in the absence of his superior, or during temporary vacancy of the governorship, assume entire charge of a province, or he might be put at the head of a whole district in a province too large to be governed by one person. G. L. Hendrickson.

Procyon'idæ [Mod. Lat., deriv. of *Procyon*, the typical genus; Lat. *Procyon* = Gr. προκύων, a constellation rising before the Dog Star, πρό, before + κύων, dog. The word has been, however, falsely used here, as if signifying "instead of or like a dog"]: a family of carnivorous mammals represented by the raccoons and the coatis. The teeth are in number 40 (M. $\frac{2}{2}$, P. M. $\frac{4}{4}$, C. $\frac{1}{1}$, I. $\frac{3}{3} \times 2$); the last molar of the upper jaw is more or less transverse and compressed forward; of the two molars in the lower jaw, the first is broadest; the last premolar of the upper jaw and the first molar of the lower are tubercular. The snout is more or less slender; the feet elongated, and with separated digits capable of grasping in a hand-like manner. The family includes two sub-families: (1) *Procyoninæ*, with the genus *Procyon*, or the raccoons, and (2) *Nasuinæ*, with the genus *Nasua*, or the coatis. They are peculiar to America, and naturally to the warmer regions, although a species of raccoon ascends far to the northward in the U. S. See Coati and Raccoon.

Profit à Prendre: See Hereditaments.

Profits [Fr., from Lat. *proficio, profectus*, to progress]: an excess of earnings above expenses. In order to ascertain the real profit of an enterprise, we must take care to count *depreciation* of capital as an expense. Thus if the gross earnings of a business are $10,000 a year, and the current expenses $6,000, the apparent profit is $4,000, but if the invested capital is worth $1,000 less at the end of the year than it was at the beginning, the real profit is only $3,000. It is a disputed question whether taxes should be deducted from earnings before estimating profits. There is another and narrower sense of the word under which interest is deducted before estimating profits. Thus, in the case supposed, if the capital invested is $20,000 and the current rate of interest 5 per cent., there is an interest account, actual or nominal, of $1,000 a year, and the net profit on this basis of reckoning is only $2,000 instead of $3,000. Profits in this sense represent the earnings of management as distinct from those of capital, and will vary according to the business ability of the man in control. It is hard to make an accurate distinction between profits and rent. In general, the former term is applied to income from personal property and the latter to income from real estate. See Political Economy and Hereditaments (*Incorporeal*).
A. T. Hadley.

Profit-sharing: the name generally given to a modification of the wages system under which a share in the realized profits of the year's business is given to the employee, in addition to his wages already received. This bonus may be definitely determined at the beginning of the year, as when a firm promises to give 10 per cent. of its net profits to its men, or the percentage may be left to be determined at the end of the twelve months. The essential features of any such scheme are that the firm shall make known its intention at the beginning of the period, and that the sum allotted to each employee, usually on the basis of his wages, shall not be trifling. The principle of the admission of the workmen to this species of partnership (strictly limited, according to the wishes of the employer, who, in fact, has the whole matter in his own hands) is the application to modern conditions of the product-sharing common in agriculture and the fisheries. Its advocates claim for it that it tends to advance "the prosperity of an establishment by increasing the quantity of the product, by improving its quality, by promoting care of implements and economy of materials, and by diminishing labor difficulties and the cost of superintendence." In a very large majority of cases where the system has been thoroughly applied and time given for its educating effects, one or more of these results have followed, with no diminution of the employer's average profits.

In comparison with plans of co-operative production proper, profit-sharing, often styled "industrial partnership" in England, has had a much larger percentage of success in practice, as well as the general indorsement of the economists from Mill and Fawcett to Marshall and Walker. It is obviously most applicable to occupations such as handicrafts, where the extra interest naturally awakened in the workmen by the prospect of a bonus can produce an immediate and visible effect, and less adapted to manufactures where labor bears a lower proportion to the cost of material and plant. Nevertheless, some of the most prosperous trials of profit-sharing have been made in cotton and woolen mills in France and the U. S. "The father of profit-sharing" was the well-known Edme Jean Leclaire, the Parisian house-painter and decorator, whom J. S. Mill first brought to the notice of English readers. He introduced the system in 1842, and the celebrated Maison Leclaire has since been the standard example of "participation"; in the years 1870–86 the number of its employees varied from 710 to 1,129, and the ratio of bonus to wages from 12 to 24 per cent. The Laroche-Joubert paper-works at Angoulême, the noted Bon Marché, and the Maison Chaix, a very large printing-house at Paris, are other prominent instances of long and successful application of the principle of profit-sharing in France. That country counts over 100 establishments successfully conducted on this system. In England the abandonment of the Briggs Colliery Industrial Partnership in 1875 caused a cessation of effort in this direction for several years, but there has since been a notable revival of interest and faith in the plan, and there are (1894) over 100 instances of British profit-sharing firms. In the U. S. fully 100 business houses in a great variety of occupations practice the system.

Profit-sharing is not put forth by its wiser advocates as a panacea for industrial troubles, but as a modification of the wages system, applicable in many quarters with good results to both parties to the labor contract. The details of its application to any special occupation require care, but it is based on human nature and the wages system as they are; and the larger part of the failures in practice have been due to insufficient preparation and haste for results.

There are two societies devoted to the extension of profit-sharing. The French society, the head of which is Charles Robert, is composed entirely of men of business who practice the system; the American association has for its president the U. S. commissioner of labor. Both societies issue quarterly periodicals devoted to the cause.

The standard work on the subject in English is *Profit Sharing between Employer and Employee*, by N. P. Gilman (Boston, 1889; 3d ed. 1891; translated and adapted into German by L. Katscher). Later information may be found in two chapters of another work by the same writer, *Socialism and the American Spirit* (Boston, 1892). See also the *Report* to the Board of Trade by D. F. Schloss (London, 1894) and his *Methods of Industrial Remuneration* (London, 1892).
Nicholas P. Gilman.

Prognathism [from Gr. πρό, before + γνάθος, jaw]: the condition of having projecting jaws or a large craniofacial angle, as in Negroes. See Face.

Progression [from Lat. *progres'sio*, a going forward, progress, progression, deriv. of *pro'gredi*, go forward; *pro*, forward + *gra'di*, step, go]: in mathematics, a series in which each term is derived from the preceding by a uniform law.

An *arithmetical progression* is a series in which each term is formed from the preceding one by the addition of a constant quantity called the *common difference*. If the common difference is *positive*, each term is greater than the preceding one, and the progression is said to be *increasing*; if the common difference is *negative*, each term is less than the preceding one, and the progression is said to be *decreasing*. From these definitions we see that every increasing progression when taken in a reverse order becomes a decreasing progression, and that every decreasing progression when taken in a reverse order becomes an increasing progression. An arithmetical progression is said to be *given* when we know one term and the common difference: thus if one term is 9 and the common difference 5, we have, by the continued addition of 5, the series 9, 14, 19, 24, etc.; in like manner, by the continued subtraction of 5, we have the series 9, 4, − 1, − 6, etc. These two series written in proper order form a single progression, as follows:

$$\ldots, -6, -1, 4, 9, 14, 19, 24, \ldots$$

If the series has a beginning and end it is called limited; otherwise it is infinite or *unlimited*. Any term of a limited arithmetical progression, whether increasing or decreasing, is equal to the first term plus the product of the common difference by the number of terms that precede the term in question. The sum of all the terms of such a progression is equal to half the sum of its extremes multiplied by the number of terms.

A *geometrical progression* is a series in which each term is equal to the preceding term multiplied by a constant quantity called the *ratio of the progression*. If the ratio is *positive* and greater than 1, each term is greater than the preceding one, and the progression is said to be *increasing*; if the ratio is *positive* and less than 1, each term is less than the preceding one, and the progression is said to be *decreasing*; if the ratio is negative, the terms of the progression are alternately positive and negative. In all cases if two consecutive terms are given, we can find the ratio by dividing the second by the first. The following series, extending to an infinite number of terms in both directions, is an example of a geometrical progression:

$$\ldots, \frac{1}{4}, \frac{1}{2}, 1, 2, 4, 8, 16, \ldots$$

In this progression the ratio is 2, and this being given, together with any term of the series, the progression may be extended to any desired limit. If we consider a finite number of terms as constituting a limited geometrical progression, the nth term of the series, n being any positive whole number, is equal to the first term multiplied by the $(n-1)$th power of the ratio; the sum of all the terms is equal to $\frac{lr-a}{r-1}$, in which l is the last term, a the first term, and r the ratio.

An *harmonical progression* is a series such that of any three consecutive terms the first is to the third as the difference between the first and second is to the difference between the second and third. The reciprocals of the terms of an arithmetical progression form an harmonical progression; thus from the arithmetical progression, 2, 4, 6, 8, etc., we form the harmonical progression—

$$\ldots, \frac{1}{2}, \frac{1}{4}, \frac{1}{6}, \frac{1}{8}, \ldots$$

Taking the first three terms, we see that

$$\frac{1}{2} : \frac{1}{6} :: \frac{1}{2} - \frac{1}{4} : \frac{1}{4} - \frac{1}{6}, \text{ or } \frac{1}{2} : \frac{1}{6} :: \frac{1}{4} : \frac{1}{12}.$$

Revised by S. Newcomb.

Prohibition: the suppression, by law, of the manufacture, importation, and sale, for beverage purposes, of all alcoholic liquors.

Principles.—The advocates of prohibition base their demands on the following facts: (1) Scientific. Science has demonstrated that alcohol is a deadly poison, not a food, and neither necessary nor beneficial, but positively injurious, to healthy persons. Its sale for beverage purposes should therefore be entirely prohibited, and for other purposes should be regulated by the strict laws governing the sale of other poisons, such as strychnine, arsenic, opium, etc. (2) Social. Alcoholic liquors affect not only the drinker, but transmit to his descendants the seeds of epilepsy, insanity, and the worst diseases that afflict mankind. The use of alcoholic liquors breaks down moral restraints, excites the basest passions, and instigates to crimes through which the innocent are sufferers. The effect is not only to destroy social order, disrupt families, and ruin the home life, but to deteriorate the race and mortgage future generations. (3) Economic. The raw material consumed, the labor performed, and the money spent in the manufacture and purchase of alcoholic liquor as a beverage constitute a waste of wealth. Furthermore, the public expense incurred in caring for the pauper, insane, diseased, and criminal products of the alcoholic habit comprises a very large part of the government expenditure, and is an unnecessary and unjust public burden. (4) Political. The deterioration and degradation of the citizen is a national injury, and the organized liquor-trade has become an active and damaging factor in government, defying legal restraint, thwarting justice, dominating politics, and corrupting elections and officials.

Legality.—Legally, the prohibitive principle is the basis of all restrictive legislation: but liquor license falls short of the logical procedure just to the extent that partial permission falls short of absolute prohibition. The constitutionality of liquor license is denied by many able jurists, but the constitutionality of prohibition has been established by the highest courts of the U. S. and Great Britain. "There is no inherent right in a citizen to sell intoxicating liquors by retail; it is not a privilege of a citizen of a State, nor of a citizen of the United States." (137 U. S. 86.) "No Legislature can bargain away the public health or the public morals; the people themselves can not do it, much less their servants." (101 U. S. 816, reaffirmed in decision in Kansas cases.) "We can not shut out of view . . . the fact, established by statistics accessible to every one, that the idleness, disorder, pauperism, and crime existing in this country, in some degree at least, are traceable to the evil. . . . That legislation by a State prohibiting the manufacture within her limits of intoxicating liquors, to be sold or bartered for general use as a beverage, does not necessarily infringe any right, privilege, or immunity secured by the Constitution of the United States, is made clear by the decisions of this court rendered before and after the adoption of the Fourteenth Amendment." (123 U. S. 623.) The court has declared in fact that the constitutionality of prohibition is no longer an open question.

The Prohibition Movement.—The agitation for prohibition began with the republic. The first Colonial Congress in 1774 passed the following: "*Resolved*, That it be recommended to the several legislatures of the united colonies immediately to pass laws the more effectually to put a stop to the pernicious practice of distilling, by which the most extensive evils are likely to be derived if not quickly prevented." From 1829 the movement was pushed, and some local prohibition laws were enacted, but between 1850 and 1860 a number of State laws were secured, beginning with the "Maine law," enacted in 1851.

The civil war (1861–65) interfered with the movement, and gave the liquor-trade an opportunity to organize a powerful financial and political opposition which secured the repeal of prohibition in many States. With the woman's crusade, 1873–74, and the organization of its successor the Women's Christian Temperance Union, 1874–75, the agitation took on a wider and more systematic sweep, and not satisfied with evanescent and perfunctorily enforced statutory prohibition, constitutional amendments were demanded, and since the year 1881 the States of Kansas, Maine, Rhode Island, North Dakota, and South Dakota have adopted constitutional prohibition, though Rhode Island within two years rescinded her action. Many cities, towns, and counties in all parts of the U. S. are under prohibition by virtue of local laws.

The prohibition movement is worldwide, is spreading rapidly into Australasia, and gaining adherents in Europe and the East. It has a strong press and platform propaganda, and many organizations are committed to prohibition, among them the Women's Christian Temperance Union, the British Women's Temperance Association, the Good Templars, Sons of Temperance, United Kingdom Alliance, Prohibition party, etc. The evangelical churches generally in English-speaking countries have declared themselves in sympathy with the prohibition cause, and most of the leaders of the movement are members of religious bodies.

Frances E. Willard.

PROJECTILES.

Prohibition Party: a political party organized in the U. S., pledged to the election of officers committed to certain political reforms, among which prohibition of the alcoholic drink traffic is an essential element.

Soon after the adoption of prohibition laws in many States it became apparent to some that such laws were in danger of non-enforcement by the officers of the law. As early as 1857 the Independent Order of Good Templars, an organization committed to prohibition, declared it to be one of its cardinal purposes to secure the election of good, honorable men to administer the laws. During the civil war in the U. S. the liquor-trade organized for the expressed purpose of preventing the enforcement and securing the repeal of existing prohibition laws, and preventing further prohibitory legislation. In 1867 the seventh beer-brewers' congress declared that they would "sustain no candidate, of whatever party, in any election, who is in any way disposed toward the total abstinence cause." This was more than two years before the Prohibition party was organized.

During the session of the Right Worthy Grand Lodge of the Independent Order of Good Templars at Oswego, N. Y., May 27, 1869, a meeting of those favoring independent political party action was held, and a committee named to issue a call for a national convention for the purpose of organizing a National Prohibition party. Pursuant to this call nearly 500 delegates from twenty States met in Farwell Hall, Chicago, Sept. 1, 1869, adopted a platform, and assumed the name of the National Prohibition party.

The first national nominating convention of the party was held in Columbus, O., Feb. 22, 1872. The platform adopted strongly arraigned the liquor-traffic and the complicity of the Republican and Democratic parties therewith, and declared for entire prohibition. There were also emphatic declarations on the questions of public service, finance, interstate commerce, tariff, labor, education, immigration, and favoring equal suffrage for women. Hon. James Black was nominated for President, and Rev. John Russell for Vice-President. Electoral tickets were nominated in only six States, and received 5,607 votes. The second national nominating convention was held in Cleveland, O., May 17, 1876. Hon. Green Clay Smith, of Kentucky, was nominated for President, and Hon. Gideon T. Stewart, of Ohio, for Vice-President, and at the ensuing election they received 9,737 votes in eighteen States. At the third national convention, held in Cleveland, June 17, 1880, Hon. Neal Dow, of Maine, and Rev. H. A. Thompson, of Ohio, were nominated for President and Vice-President, respectively, and received 10,366 votes in eighteen States.

Since 1882, when a convention was held in Farwell Hall, Chicago, and a reorganization effected, the National Prohibition party has been actively engaged in the work of organizing. The national committee, of which Hon. Gideon T. Stewart was chairman and Rev. A. J. Jutkins secretary, issued an open call for a national convention, which met in Pittsburg, July 23, 1884. There were present 465 delegates from thirty-one States and Territories. A platform of political principles, advocating prohibition, equal suffrage, and reforms in finance, tariff, civil service, etc., was adopted, and Hon. John P. St. John, of Kansas, to whom, as Governor of that State, was largely due the adoption of State constitutional prohibition, was nominated for President, and Hon. William Daniel, of Maryland, for Vice-President. Hon. John B. Finch, of Nebraska, head of the Order of Good Templars, was made chairman of the national committee, and a vigorous organizing campaign was conducted. At the presidential election in 1888 the National Prohibition party ticket received 150,626 votes in thirty-four States. Immediately after the election the national committee issued an address which was widely circulated.

The party work was strengthened by a national lecture bureau, organized by W. Jennings Demorest and Horace Waters, of New York. The convention of 1888 was held in Indianapolis, and Hon. Clinton B. Fisk, of New Jersey, and Rev. John A. Brooks, of Missouri, were nominated for President and Vice-President, respectively. They received 249,945 votes. In 1892 the national convention was held in Cincinnati, June 30, and Gen. John Bidwell, of California, and Rev. James B. Cranfill, of Texas, were nominated. The vote cast for them at the ensuing election was 270,813. The National Prohibition party is (1894) organized in every State, nominates tickets at all elections, has elected members of the Legislature in a number of States, has several good newspaper organs, and is indorsed by many temperance organizations, notably by the Women's Christian Temperance Union. Its chairman is Prof. Samuel Dickie, of Michigan, and its leading journal *The Voice*, published weekly in New York.

FRANCES E. WILLARD.

Projectiles [from Lat. *proji'cere* (*proi'cere*), *projec'tum*, hurl forth or forward; *pro*, forth, forward + *ja'cere*, throw, hurl]: bodies projected forward by a force. Generally speaking, they are missiles to be used in warfare, and to be fired from a gun by means of an explosive substance. They are divided into two classes—spherical and oblong. The former are used in smooth-bore guns, and are obsolete; oblong projectiles are used in rifled guns. In each class are found three varieties—solid shot, shell, and case-shot. Other varieties, now also obsolete, were formerly used in smooth-bore guns. These were: *Chain-shot*, two projectiles connected by a short chain; *bar-shot*, two projectiles connected by a bar; *carcass*, a shell filled with an inflammable composition used for incendiary purposes; *light ball*, a combustible shell used to illuminate an enemy's works. A *hand-grenade* is a shell intended to be thrown by hand at an assaulting party.

FIG. 1.—Stand of grape.

Spherical projectiles were the first projectiles used, and were made of stone, lead, wrought and cast iron. *Solid spherical shot* was used against masonry and armored vessels. A *shell* is a hollow projectile containing a bursting charge which at some point of its flight is ignited by means of a fuze. Its effect is therefore not as local as is that of a solid shot. A shell is used against earthworks, unarmored vessels, and against such armor as it can penetrate. *Case-shot* is used against animate objects on account of the greater number of fragments resulting from the separation of its cluster. Case-shot comprise grape-shot, canister, and shrapnel. *Grape-shot* (Fig. 1) consists usually of nine spherical shot arranged in three tiers of three balls each, all being held together by two rings and a top and bottom plate connected by a central bolt. *Canister* (Fig. 2) consists of a number of small balls inclosed in a tin or malleable iron case. The shock of discharge of the piece causes grape-shot and canister to break up at the muzzle of the piece; they are used for firing at short ranges. *Shrapnel* consists of an envelope containing a number of small balls and a bursting charge, which, by means of a fuze, is exploded at any desired distance from the muzzle of the gun. During the U. S. civil war a form of shrapnel known as *spherical case-shot* was used. It consisted of a shell (Fig. 3) filled with lead balls, between the interstices of which was poured a matrix of melted rosin or sulphur; when the matrix had hardened a cylindrical hole was bored through the center to hold the bursting charge. To the side of the shot diametrically opposite the fuze-hole was strapped a wooden sabot. This sabot is used with all spherical fuzed shot to keep the fuze away from the powder charge.

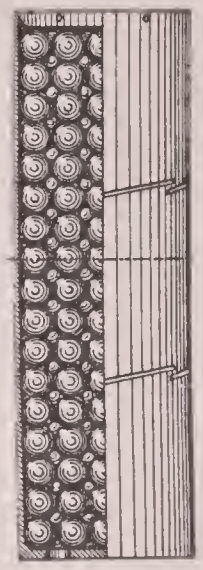

FIG. 2.—Sawyer canister.

Oblong projectiles possess many advantages over spherical projectiles, among which may be mentioned greater ranges for equal muzzle velocities, greater penetrations for equal striking velocities, capacity for a given caliber, and greater accuracy. In order to cause an oblong projectile to travel with its longest axis in the direction of its motion it is necessary to impart to the projectile a motion of rotation about its longest axis sufficient to overcome the tendency of the projectile to revolve about its shortest axis, or, technically speaking, to "tumble." Many attempts have been made to fire oblong projectiles from smooth-bore guns by means of wings or spiral channels intended to give rotation to the projectiles, but none of the attempts have proved successful. The use of oblong projectiles is therefore confined to rifled guns. In order to cause an oblong projectile to take the rifling it must be fitted with a rotating device, which differs for muzzle-loading and breech-loading guns.

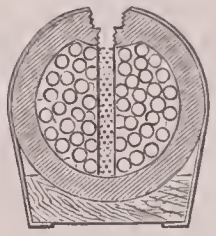

FIG. 3.—Spherical case-shot.

Muzzle-loading projectiles may be caused to rotate in two ways—by the use of studs, and by the use of some device which the pressure of the powder gas expands into the rifling. In the studded system the studs are pressed into under-cut holes on the projectile. These studs fit in the rifle grooves in the gun, and cause the projectile to rotate as it moves down the bore (Fig. 4). The Butler projectile is one of the best examples of the expansive system. The rotating device (Fig. 5) consists of a brass or copper ring screwed or cast on the projectile. The ring is divided by a deep, annular groove into an outer and inner flange or lip. On firing, the powder gas enters this groove, presses the inner lip against the projectile, thereby assisting to prevent the stripping of the ring, and forces the outer lip into the rifling. Other projectiles of this class are the Eureka, Parrott, and others. Muzzle-loading oblong projectiles are fast becoming obsolete, as all guns now made are breech-loaders.

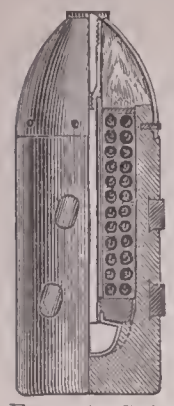

Fig. 4.—British shrapnel, muzzle-loading.

Breech-loading projectiles, since they are loaded through the breech of the piece, are fitted with a device which, being larger than the bore of the gun, is compressed into the rifling when the projectile is fired. This device at first consisted of a lead jacket cast on the body of the projectile (Fig. 6). Two copper bands were next substituted for this jacket, one band being near the head and the other near the base of the projectile. With the increasing twist of the rifling two bands were objectionable, and one band near the base was found to be all that was necessary. When one band is used the head of the projectile, where it joins the body, is slightly enlarged so as to fit the bore accurately and thus steady the projectile. The bands are made of copper or brass rings pressed into undercut grooves. The compressive system of rotation is superior to the others, as it increases the accuracy of the projectile and decreases the erosion of the bore by the rush of gases past the projectile.

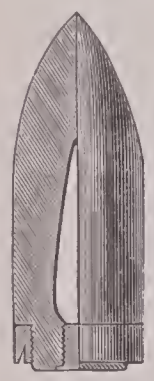

Fig. 5.—U. S. cored shot, muzzle-loading.

Oblong projectiles consist of a cylindrical body and an ogival head, the radius of the ogive being from 1½ to 2 calibers. Some armor-piercing shells have heads which start with a curve whose radius is greater than 2 calibers, and terminate with almost a hemispherical point. The solid shot used in the 12-inch U. S. breech-loading rifle (Fig. 7) is 3½ feet long and weighs 1,000 lb.; it is fired with a muzzle velocity of 2,000 feet per second. The materials used for the manufacture of oblong projectiles are steel and cast iron. Chromium is often added to the steel to increase its hardness. Steel projectiles may either be cast or forged; the latter method gives the best but also the most expensive projectiles. A new process of rolling projectiles has been extensively adopted in Europe. Among the best projectiles may be named the Holtzer, St.-Chaumont, St.-Étienne, and Firminy. The processes by which they are manufactured are kept secret. A recent test of metal from a Firminy projectile showed an elastic limit of 196,000 lb., a tensile strength of 233,000 lb., and an elongation of 7½ per cent. The manufacture of the St.-Étienne steel shell is in general as follows: A casting of steel, closed in front and presenting on the interior and exterior the general form of the projectile, is prepared by a hammer or hydraulic press. The cylindrical part is strengthened in rear by increased thickness. It is then rolled on a steel mandrel and drawn through grooves of an ordinary rolling-mill until the desired dimensions are reached. One of these shells, exhibited at the Paris Exposition of 1889, was 13·5 inches in caliber, and had been fired through a 15·7-inch iron plate without either appreciable upsetting or rupture.

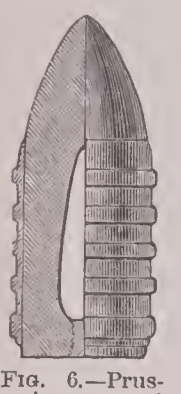

Fig. 6.—Prussian cored shot, breech-loading.

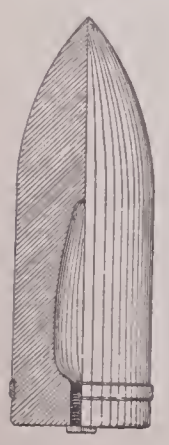

Fig. 7.—Cored shot. For U. S. 12-inch breech-loading rifle.

The tempering of a projectile is a very important step in its manufacture. At the St.-Chaumont works, in France, to temper a projectile it is first heated to a cherry red and then cooled in oil. When cold it is again heated to a cherry red and the head only is then plunged in water and allowed to remain eight or ten minutes, and then the whole projectile is plunged in oil and left until cold. In this way a very hard head and tough body are secured. In casting both solid shot and shell the point is generally cast down to secure a denser head. For armor-piercing projectiles the heads are cast in iron moulds to increase their hardness by quick cooling. Oblong solid shot have a limited use, since shells can be made which will pierce almost the same thickness of armor, and with more destructive effect.

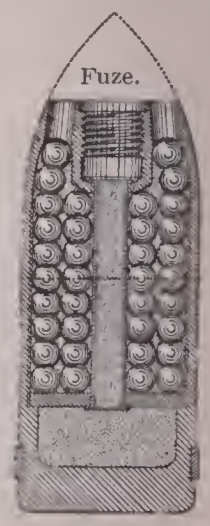

Fig. 8.—Shrapnel. For U. S. 3·2-inch breech-loading rifle.

Oblong shells are of two kinds—battering or armor-piercing shells and common shells. The first kind are made of forged steel, and the second kind are made of cast steel and cast iron. Shells are also made by Electric Welding (*q. v.*). The head and base are stamped out in dies; the body is made by rolling or drawing a tube. The three parts are then placed in a welding-machine, and a current of electricity of enormous quantity and low intensity is passed through them while they are pressed firmly together. The operation is completed in about three and a half minutes. Some of the modern shrapnel for the U. S. 3·2-inch field breech-loading rifle are manufactured in this way (Fig. 8). The base and body are welded together, then the steel diaphragm and tube are dropped in place and the head is welded on. Holes are drilled in the head connecting with the interior cavity, and through these holes the shrapnel is filled with bullets; a matrix of plaster-of-Paris is then poured in, and the holes are closed by screwing in small plugs. The bursting charge is placed in the cavity in rear through the central tube. A time-fuze is screwed in the point, and at the proper distance it ignites the charge and the cluster is swept out to the front by the diaphragm.

Oblong projectiles vary in length from 3 to 5 calibers, and are fired with a muzzle velocity which ranges from 1,800 to 2,500 feet per second; a velocity of 3,300 feet has been attained. Against earthworks very long shells are used. Some of these are 6 to 8 calibers in length.

The bursting charges used in projectiles are generally composed of gunpowder, though the high explosives are sometimes desirable, particularly in armor-piercing shells. The charges are generally ignited by means of time or impact fuzes. In the case of armor-piercing shell the heat developed in piercing the armor is usually sufficient to explode the charge. The projectiles used in the small-arms are generally made of lead, and being of a slightly larger caliber than that of the gun, the lead is forced into the rifling, thus causing the projectile to rotate. In the small-caliber rifles, which are about 0·3 inch in diameter of bore, a much more rapid twist is required for the rifling, and lead would be too soft to take the grooves, consequently the projectile is made with a lead body and covered with a jacket of a harder material, such as copper, German silver, or steel (Fig. 9). For detailed descriptions and history, see Holley, *Ordnance and Armor*; Meigs and Ingersoll, *Ordnance and Gunnery*; Morgan, *Handbook of Artillery Material*; Reports of the Chief of Ordnance; Mackinlay, *Text-book of Gunnery*; *Journal of the United States Artillery*, etc. See Gunnery, Artillery, Ballistics, etc.

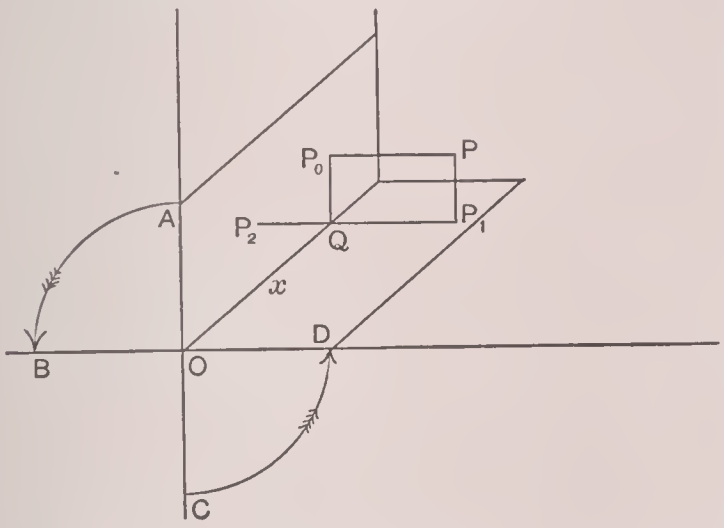
Projection [from Lat. *projec'tio*, a throwing forward, stretching out; *pro*, forward + *ja'cere*, *jac'tum*, throw, hurl]: the representation of a magnitude on a plane or other surface made in accordance with some geometrical law. In geometry, projection is restricted to the delineation of an object upon a plane surface by rays issuing from a point and intersecting the contour of the object; and this is in most cases the meaning of the word. If the point be supposed infinitely distant the rays form a system of parallels. If

their direction is perpendicular to the plane we have *orthographic* projection; if the direction is not perpendicular we have *oblique* projection; and if the point is at a finite and proper distance for ordinary vision we have *perspective* projection, or linear perspective. (See PERSPECTIVE.) Other systems of projection are used for delineating the earth's surface. In geometry the object projected is a geometrical figure; the fixed point is called the vertex, the joining lines form a cone, and the section in which the cone is cut by any plane (the plane of projection) is called the projection. This method supplies very important conclusions, according to which from a particular theorem, the general one under which it is contained, may be inferred. It is due to Poncelet, whose *Traité des Propriétés Projectives des Figures* may be regarded as marking a new era in geometry. By this method theorems concerning infinitely distant points may be extended to finite points on a right line; while theorems concerning imaginary points and lines may be extended to real points and lines. In the last we have the principle of continuity, according to which the properties of a figure are asserted to be equally true, whether any of its points or lines are real or imaginary. (See IMAGINARY QUANTITIES.) In what follows, however, orthographic projection and spherical projections alone are considered.

Orthographic Projection.—This projection is the feature of Monge's descriptive geometry, a method which was devised for the purpose of giving a representation of solids and other figures in three dimensions by means of a drawing in one plane. In this method a figure is represented by its orthographic projections on two planes, one horizontal and the other vertical. The first projection is called the plan and the second the elevation. The line of intersection of the planes is called the axis. If the drawing-paper is the surface of the plan, the plane of the elevation will be the plane perpendicular to it drawn through the axis. In order to bring the plane of elevation into the plane of the paper, we may turn it round the axis until it coincides with the horizontal plane, in which case A moves to B and C to D. This process is called rabatting.

Let P_0 P_1 be the feet of the perpendiculars from a point P on the vertical and horizontal planes, respectively; then if we turn the vertical plane toward the left round the axis until it coincides with the horizontal, P_0 will come into the position P_2, a point evidently lying on the perpendicular to the axis drawn through P_1 at a distance $P_2Q = P_0Q = PP$, from the axis. In the figure it is seen through the vertical



plane. Thus any two points, P_1, P_2, on the plane of the paper lying on a perpendicular to the axis will be the projections of some point in space, after the vertical plane has been turned round the axis so as to become horizontal. Hence we have a method of representing points in space. We take in the plane of the paper a line x as axis; then any pair of points on a perpendicular to the axis represent a point in space.

The horizontal and vertical planes divide all space into four parts, called quadrants. The first is the upper part on the right in which P lies, the second the upper part on the left, and the third and the fourth the other parts taken in rotation from right to left. Thus if P_1 is said to be below and P_2 above the axis, a point lies in the first quadrant, if the elevation is above and the plan below the axis; in the second, if elevation and plan are both above; in the third, if the elevation is below and the plan above; and in the fourth, if elevation and plan are both below the axis.

As we can represent any point thus, we have a representation of any figure in space by considering it as an assemblage of points. A plane, however, can not be represented in this way, as the projections of its separate points would entirely cover the planes of reference, and all planes would become alike. But any plane cuts the two planes in two lines meeting on the axis. These lines are called the traces of the plane. Thus a plane is determined by its traces, which are two lines intersecting on the axis; and, conversely, any two lines intersecting on the axis determine a plane. If the plane is parallel to the axis its traces are two lines parallel to the axis. One of the traces is altogether at infinity if the plane is parallel to the plane on which the trace lies. If the plane passes through the axis both traces coincide with the axis and the method of representation fails, as all planes fulfilling this condition become alike. We therefore introduce a third plane at a point O of the axis perpendicular to both the other planes. Then this plane with its trace is rabatted about the perpendicular to the axis at O, so as to become horizontal, and then the traces of the plane to be represented are the axis x and a line passing through O.

In order to represent a line we consider it either as the connector of two points which have each their appropriate representation or as the intersection of two planes with their corresponding traces. In the first case the line may be represented by its projections on the two planes. These lines are entirely arbitrary, so that any two lines represent a line in space, for when we bring the plane of elevation into its original position the perpendicular planes through the two lines must intersect in some line in space. In the second case a line is represented by its traces, namely, the two points in which it meets the vertical and horizontal planes, as these two points are not connected by any relation, and two points determine a line in space. If the traces coincide at a point on the axis this representation fails, and we must introduce a third plane or have recourse to the representation by projections.

For the further numerous problems of descriptive geometry and their solution, we must refer the reader to formal treatises upon the subject.

Spherical Projections.—In the construction of maps we have to consider the means of representing the surface of a sphere upon a plane. There is no method by which the length of lines is strictly preserved, but there is a variety of methods which have their special appropriateness, that is, produce the least amount of distortion, in particular cases. If orthographic projection is used the plane is supposed to pass through the center and the eye to be at an infinite distance perpendicular to the plane. If the plane is the equator the parallels and meridians become concentric circles and rays passing through the center, respectively. If a meridian is the plane of projection the meridians become ellipses having a common transverse axis, and the parallels a system of parallel lines perpendicular to that axis. In other cases meridians and parallels both become ellipses. In this method places near the plane of projection are crowded together, while those farthest away are fairly represented. In perspective projection the eye is supposed to be at the vertex, and the plane of projection is taken perpendicular to the line joining it to the center, and by suitably choosing the distances of the eye and plane from the center we can arrive at different systems of projection which are serviceable in representing certain portions of the earth. In general both meridians and parallels are projected into ellipses. If the point is on the sphere and the plane passes through the center the projection is called *stereographic*; and circles whose planes pass through the eye are projected into straight lines, while all other circles are projected into circles. In this method places near the plane of projection are fairly represented, and those farthest away are crowded together, but all angles remain absolutely unaltered. In *gnomonic* projection the eye is at the center and the plane of projection touches the sphere. This method gives a map of a limited portion of the sphere with little distortion. A series of star maps was constructed on this principle by R. A. Proctor; he first circumscribed the sphere by a regular dodecahedron, and then projected the entire sphere upon the several faces of the dodecahedron.

There are several other methods of representation, of which a few may be enumerated. In *conical* projection the eye is at the center of the sphere, and the projection is made on the surface of a cone touching the sphere along the parallel which most nearly divides the area to be represented,

or sometimes of a cone passing through two parallels midway between the central parallel of the area and the extreme parallels. After projection the cone is cut along a generator and opened out into a plane. The parallels here are represented by concentric circles, and the meridians by lines passing through the common center of the circles. This method is useful if the tract of country to be represented is of no great extent in latitude, but of any extent along a parallel.

In *cylindric* projection the eye is at the center of the sphere, and the projection is made on a cylinder touching the sphere along the equator. After projection the cylinder is opened out on a tangent plane. Here meridians and parallels become rectangular systems of parallel lines. This method is applicable to the case in which a map of the equatorial regions is to be made.

In *polyconic* projection each parallel of latitude is developed symmetrically from an assumed meridian by means of a cone touching the surface along the parallel. Here the parallels become arcs of circles, and the meridians may be constructed by laying off on each parallel the degrees of longitude according to their true lengths. This is the method of projection used by the U. S. Coast Survey in projecting small maps and charts. For Mercator's projection, see the article under that heading. R. A. Roberts.

Prolap'sus U'teri [Lat., falling of the womb]: the descent of the uterus below its normal position in the pelvis; in extreme cases a protrusion of part or the whole of the organ from the body. The chief causes are the enlargement of the uterus by inflammation, uterine and abdominal tumors, relaxation of the tissues which are the anatomical supports of the organ, rupture of the perineum by instrumental delivery, and sudden violence in falling or jumping.

Prome'theus (in Gr. Προμηθεύς): one of the most interesting creations of Greek mythology; a son of Iapetus and Clymene, Themis, or Asia, the brother of Atlas, Menœtius, and Epimetheus, and father of Deucalion. The myths relating to him are very variously told by Hesiod, Æschylus, and later poets and philosophers, but there are nevertheless certain fundamental traits in which all the different versions agree. They all represent Prometheus as a benefactor of the human race. According to some, he was the creator of man; according to others, he only brought to him fire and the arts depending on the use of fire. Next, they all agree that those benefits which he conferred on the human race for some reason excited the wrath of Zeus, who chained him to a rock and sent a vulture or an eagle to feed daily on his liver. From these sufferings, under which the Titan did not succumb, Hercules at last delivered him by shooting the vulture and unlocking the chains, after which Prometheus returned to Olympus. Of Æschylus's trilogy only the middle piece, *Prometheus Bound*, is extant. For Prometheus in art, see the article *Prometheus* in Baumeister's *Denkmäler*. J. R. S. Sterrett.

Promise (in law): See Contract.

Promise, Breach of: See Marriage.

Promissory Note [*promissory* is from Lat. *promis'sor*, promiser, deriv. of *promit'tere*, *promis'sum*, send forth, promise]: an unconditional promise in writing made by one person to another signed by the maker, engaging to pay, on demand or at a fixed or determinable future time, a sum certain in money, to, or to the order of, a specified person or to bearer. (British Bills of Exchange Act, 1882, § 83.) Sealed notes were unknown to the early law merchant, and as a rule the courts have held that attaching a seal to a promissory note destroys its negotiable character. This doctrine has been changed by statute in many of the U. S., and the British Bills of Exchange Act authorizes a corporation to use its seal as a signature to commercial paper. Government and corporate bonds, though under seal, have long been treated by the courts in the U. S. as negotiable, on the ground that modern commercial usage had given to them a negotiable character. *Morris Canal Co.* vs. *Fisher*, 1 Stockton (N. J.) 667.

The negotiability of promissory notes was denied by Lord Holt, but was secured by act of Parliament (3 and 4 Anne, c. 9, A. D. 1704). In the U. S. this statute or its equivalent has become a part of the law of every jurisdiction. The better view seems to be that it was declaratory only of existing law. (*Goodwin* vs. *Roberts*, Law Reports, 10 Exchequer 337; appendix to 1 Cranch 367; see *Holloway* vs. *Porter*, 46 Ind. 62, *contra*.) It should be noted that words of negotiability are not necessary to a valid promissory note. A non-negotiable note is entitled to days of grace; it imports a consideration, and the holder suing upon it need not allege or prove a consideration. (*Cornwright* vs. *Gray*, 127 N. Y. 92.) Bank-notes, certificates of deposit, and instruments which are so ambiguous that they may be construed as either notes or bills of exchange, may be sued on as promissory notes. A bank-note (that is a promissory note issued by a banker, payable to bearer on demand) differs from an ordinary note in some respects; for example, it may be reissued after payment. The maker of a note is not allowed to deny to a holder in due course the existence of the payee or the payee's capacity to indorse at the time the maker issues it. Nearly all the rules which determine the rights and liabilities of the parties to notes, and the manner in which the rights are to be exercised and the liabilities to be fixed, have been described in the article on Bill of Exchange (*q. v.*). Francis M. Burdick.

Promorphology: See Morphology, Animal.

Pronghorn: See Antilocapra.

Pronouns [*pro-* + *noun*, representing Lat. *prono'men*, a translation of Gr. ἀντωνυμία; ἀντί, instead of + ὄνομα, name, noun]: a class of words which serve the purpose of indicating objects without naming them. They do this in terms of the context or situation and of relations to the speaker. Thus when *he said* is used to replace *John said*, the pronoun *he* indicates either in relation to something said before, or in relation to what is in the speaker's presence. Nouns are name-words. Pronouns are essentially gesture-words. They act as proxies for nouns. They are not, however, mere stop-gaps or dummies, but, being universal or public proxies—i. e. capable of substitution for any noun—they are selected according to the relations borne by the object named either to context or speaker. They therefore give to language the possibility of expressing vastly more than the use of nouns alone would permit.

The so-called adjective-pronouns or pronominal adjectives, like *this*, *that*, *other*, *all*, etc., are pronominal in the sense that they express general relations to context, situation, environment, but not in the sense that they are necessarily substitutes or proxies for nouns. They may dispense with the use of the noun, but generally the apposition of the noun is found desirable; thus *get that* may require, in order to clearness, the addition of the name of the object, *get that hat*. A large class of so-called adverbs, like *here*, *there*, *then*, *thus*, are pronominal in precisely the same sense as *this*, *that*, *such*; they may be called pronominal adverbs. In the sentence *he speaks so*, the action-name *speaks* is modified by the pronominal adjunct *so*, just as, in the sentence *he uses such language*, the name language is modified by the pronominal adjunct *such*. The conjunctive adverbs *where*, *when*, *while*, *as*, etc., are pronominal in precisely the same sense as the relative pronouns *who*, *which*, etc.

Benj. Ide Wheeler.

Pronunciation [from Lat. *pronuntia'tio*, proclamation, publication, deriv. of *pronuntia're*; *pro*, forth + *nuntia're*, announce]: the act of giving the proper sounds and accent to the individual words of a language. Besides this specific meaning, pronunciation is used in general for either the right or the wrong form of the spoken word. The more distinctive term is orthoëpy (Gr. ὀρθοέπεια), which from derivation means right or correct pronunciation.

The history of English pronunciation in its general sense has been written by Alexander J. Ellis, *Early English Pronunciation* (1869–89), and by Henry Sweet, *History of English Sounds* (1888). Both of these writers trace pronunciation from the earliest times, showing the changes sounds have undergone, and the standard pronunciation in different periods. Orthoëpy, as the attempt to establish and govern pronunciation, is of comparatively recent date, but its history is interesting as showing upon what such attempts have rested and what has been their effect upon speech.

The earliest English dictionaries made no attempt to mark pronunciation, but gave their whole attention to definition and etymology. Later, as in the time of Bailey, whose *Universal Etymological Dictionary* was published in 1721, the accent of words began to be marked. Even Johnson's great dictionary, which ran through seven editions from 1755 to 1783, marked accent only, and Boswell tells us that Johnson justified this as sufficient for all purposes of speech. The first dictionary to make special mention of orthoëpy in its title is that of Benjamin Martin, published in 1749. The dictionary of William Kenrick (1773) was the first to separate words into

syllables, and to indicate the pronunciation of vowels by numbers referring to a table of English sounds. Since Kenrick's time pronunciation has had an established place in English dictionaries, as shown by those of Perry, 1775, Sheridan, 1780, Walker, 1791, as well as by those published in Great Britain and the U. S. during the nineteenth century.

In considering the pronunciation of dictionaries and orthoëpists the fundamental question is "How does the orthoëpist arrive at his standard of correctness?" Kenrick, who first marked sounds in an English dictionary, claimed to register the speech of "polished speakers in the metropolis" —that is, London. He complained especially that rules of pronunciation had hitherto been "laid down by Irishmen and Scotchmen who did not themselves know how to pronounce." Perry took a similar standard, that of "men of letters, eminent authors, and polite speakers in London." Sheridan set up the standard of Queen Anne's court, a pronunciation which he claimed to derive from his schoolmaster, a contemporary of Swift. He thus undertook to follow the pronunciation of a previous generation, which he could not have heard in its purity, and it is therefore not strange that his dictionary received much severe criticism in his own time. Walker took still a different standard, a sort of "compound ratio" of the pronunciation of the "learned, the polite, and the bulk of speakers," whatever that may mean. He also took into account in doubtful cases what he called the "analogies of language," the meaning of which is by no means clear. Of lexicographers in the U. S., Webster in 1806 gave it as his opinion that "a living language admits of no fixed state," but he clearly regarded American English rather than the "London dialect" as correct. Worcester, on the other hand, in his dictionary of 1827 followed London English as the standard for American speech.

It will thus be seen that orthoëpists themselves have variously settled the question of standard English speech. It is not strange, therefore, that as to the pronunciation of many words they should differ among themselves and sometimes from the majority of good English speakers. Moreover, orthoëpists in determining pronunciation have failed to take into account certain necessary factors. The first of these is the history of English sounds and the laws of sound-development. These laws show that certain sounds have developed differently under various phonetic influences, as of accent or different phonetic environment. For example, the reason we speak *exile* with a *ks* sound and *exist* with a *gz* sound is one of accent. So the reason we pronounce *man*, *path*, *far* with two or three different vowels is due to the different consonants following the original short *a*. Moreover, sound laws, rather than the spelling of English words, point out the true analogies of speech, and by them in doubtful cases the proper sound may be more easily determined.

Another element to be regarded by the orthoëpist is the comparatively new science of phonetics, or the doctrine of speech-sounds. This treats of the true nature of sounds, their exact relationships, and the correct classification of them. The importance of phonetics is clear when we understand that the common classifications of dictionaries are often radically wrong. For example, the long *ā* sound, as it is called, should be classed with the *e* of *men*, and not with the *a* of *hat*, *ask*, *fær*, *care*. So the *a* of *all* is not an *a* sound, but an *o* sound, and should be classed with the *o* of *not*, *strong*, and the long *ō* of *no*, *note*. The sounds of *i* are the short as in *hit*, the long as in *see*, and not at all the diphthong in *might*. It is not necessary that the minute distinctions of phoneticians should be regarded, but it is certainly important that no misleading classifications should be used. Nor can such a classification be upheld because it has been followed by orthoëpists for more than a century. Moreover, the orthoëpists have sometimes overstepped their province in trying to force a particular pronunciation, because it seemed to be in accordance with "analogy." This was particularly true of Walker, many of whose blunders might have been prevented by a knowledge of phonetics.

From the very nature of language, a single standard of pronunciation can not be followed by all the English-speaking peoples of the world. The natural divisions and the wide separation make it impossible that the usage of Great Britain, of North America, and of Australia should be exactly the same, although it is highly important that there should be as much harmony as possible. For citizens of the U. S. an American standard of spoken English is inevitable. This should be as slightly different from the spoken English of Great Britain as is warranted by the pronunciation of the better classes, while it should be equally free from servile imitation of British speech. An American standard, however, is by no means easily determined. It is at best a compromise of varying usages in different parts of the republic, since the speech of no single city or section can be regarded as standard in every particular. No city in the U. S. exercises such influence on speech as London does in England, and it is therefore absurd to set up the speech of one city as necessarily better than that of another. Still, certain general principles may be laid down for guidance in determining standard pronunciation.

The first of these principles is that present usage must always be taken instead of past or antiquated usage. Lexicographers tend to preserve the old, but it must be clear that the orthoëpists of a former generation or century are no authority in those cases in which the best present usage generally differs. Thus if the present established accent of such words as *ally*, *canine* is on the first syllable, the authority of a dozen dictionaries does not make correct the accent on the last syllable; for it is the province of the dictionary to register the best present usage, not to set up the standard of a past age, or of some supposed analogy. But past usage may assist in determining the analogies of speech, and so deciding in doubtful cases. For example, past usage shows that *wound* has had the vowel-sound of *fool* rather than of *pound*, probably because of the influence of the preceding *w*. Walker gave *wound* an alternative pronunciation rhyming with *pound*, and this has been generally followed, although Walker himself admits it was not the pronunciation of his time. The older pronunciation of *wound* is therefore better, not because it is older, but because it has been and is the best usage.

The second principle is that reputable usage indicates the standard. Reputable usage avoids the extremes of affected precision on the one hand, and ignorance or slovenliness on the other. It is neither the usage of fastidious society nor of the half-educated. It is rather that of the well-educated, who are carried away neither by the extremes of fashion in speech nor by hypercritical standards sometimes set up by orthoëpists themselves. For example, reputable usage makes no distinction between the vowel-sounds in such words as *her* and *urn*, yet the majority of orthoëpists insist on marking these sounds differently. Reputable usage implies, therefore, that careful observation of the best speakers should be compared with standards set up in books.

Lastly, national usage is to be taken as the standard rather than local or dialectal use; that is, the present reputable usage of the well educated in a whole nation is to be regarded as distinct from the usage even of the well educated of a single section. Even when this can not be determined with precision in all cases, local or dialectal use may be distinctly avoided. Thus dictionaries printed in the U. S. still recognize the pronunciation of *r* before a consonant, since it is only in the extremes of speech in the Eastern and Southern States that *r* in this position is wholly lost (as in *caad* for *card*, *faather* for *farther*). So *a* in *ask*, *path*, *far* is marked as a sound between *a* of *man* and *a* of *far*, because such a sound is a compromise between the extreme broad *a* used in some parts of the East and the extreme flat *a* of the West and South. Oliver Farrar Emerson.

Pronunciation of Botanical Names: It is a law of the science of botany that the names of species, genera, tribes, families, orders, classes, branches, etc., shall be in Latin, or where derived from words taken from other languages they shall be Latinized. The occurrence of these names in English books has led to much confusion of pronunciation, since they can not properly be treated as English words. In the absence of any formulated system of rules there has been little uniformity in practice. In a general way the pronunciation of these Latin or Latinized names, as practiced by English-speaking botanists, approximates that of the so-called "English pronunciation" of Latin in vogue twenty or more years ago, but long since discarded.

There is a growing feeling among botanists that the pronunciation of botanical names should conform to the usage of Latin scholars, and at least one attempt has been made to accomplish this end. The editors of Nicholson's *Dictionary of Gardening* (1884–88), after consultation with eminent English-speaking botanists, adopted for their work the so-called Roman system of pronunciation. Accordingly, the long sound of *a* is as heard in psālmist; short *a* as in ăpart; long *e* as in vēined; short *e* as in slĕnder; long *i* as in machīnist; short *i* as in thĭn; long *o* as in vōter; short *o* as in rŏtten; long *u* as in rūler; short *u* as in powerfŭl; *c*,

g, and *ch* always hard, as in muscular, *g*ood, and *Ch*ristian; *s* always hard, as in this; *t* always with its proper sound, as in Latin. We have then Ac'-er (*ăk'-er*, not *ā'-ser*), Cer'-as-us (*ker'-* not *ser'-*, much less *sē-rā'-sus*), Chel-o'-ne (*kel'-*, not *chel'-*, nor *shel'*), Gen-ti-a'-na (*g* hard, not *jen-shĭ-ā'-na*), etc. The only exeeption to this rule is that in the ease of words derived from the names of persons, in whieh the Latin ending only comes under the rule, the preeeding part being pronounced like the original name. This is unfortunate, since it gives us Jones'-i-a (instead of *Jo-nēs'-i-a*), Stokes'-i-a (instead of *Sto-kē'-si-a*), etc., pronunciations whieh could not be followed by any non-English botanists.

Charles E. Bessey.

Pronunciation of Foreign Names: The purpose of this artiele is to afford some help for the pronuneiation of the many foreign geographieal and personal names met in reading. The eommoner geographical names whieh have been thoroughly Anglieized in pronuneiation are not included, and those names whieh eome from the most remote and least-known languages, and in general those not originally written in Roman letters, are respelt by English writers or by continental Europeans who use the Roman alphabet. The main diffieulties in their pronuneiation come from the different orthographieal usages of the best-known languages of Europe, and the resulting doubt whether a Russian or Oriental name, for example, is spelt for English readers aecording to English, Freneh, or German usage. For geographieal names not originally written in Roman letters much of this uneertainty would be removed if the system of spelling devised by the Royal Geographieal Soeiety in London in 1885, and substantially adopted by the U. S. Government, were in exelusive use in English-speaking countries. (See *Proceedings of the Royal Geographical Society*, vii., 535–536; xiv., 116–119, 770–777; and for a eomparison with similar Freneh and German systems, *Phonetische Studien*, vi., 322–334.) Aeeording to this system vowels are pronouneed as in Italian, and eonsonants generally as in English. The vowels are accordingly as in *father*, *fête*, *machine*, *note*, *rude*, and *ai* is about like *i* in *ice*, *au* like *ou* in *out*, etc., *aw*, however, being added with the sound it has in *law*. The sound of *k* is always written *k* (never *c*), and *s* is preferred for the sound of *s* in *mason*, *ch* is always as in *church*, *g* always as in *go*, *get*, *j* is always used for the sound of *g* in *gem*, *j* in *joke*, *hw* is written for the sound of *wh* in *what*, *ng* is as in *finger* or as in *singer*, *ph* is as in *loophole*, never like *f*, *kw* is written for the sound of *qu* in *quite*, *sh* is as in *shire*, *th* as in *thin*, or, less often, as in *this*, *y* is always a eonsonant as in *yard*, *zh* is like *s* in *pleasure* or *z* in *azure*, while *kh* and *gh* are used for Oriental guttural sounds. Unfortunately, older spellings, like *Foochow* (instead of *Fuchau*) are frequent, and often ause embarrassment. In general, these older spellings are to be pronouneed aecording to the analogies of ordinary English spelling. The system just deseribed aims only at an approximate indieation of the native pronunciation. For the numerous other foreign geographical and personal names, that is, those belonging originally to European languages (including those spoken in Ameriea and elsewhere) always or often written with Roman letters, the list of letters and letter-groups below, with indieation of the pronuneiation, has been prepared. It also covers to a considerable extent modern Greek names and Slavic names originally written with the Russian alphabet. It is not intended to give an exaet or eomplete description of native pronuneiations, but to furnish a guide to the eommonest orthographie usages of the most important European languages. Some sounds not existing in English are entirely ignored, or are described as resembling eertain English sounds. Since there are, espeeially in proper names, many individual eases and exceptions, reeourse must often be had to pronouncing gazetteers or other lists of names with indieation of pronunciation. The following general prineiples, though not entirely free from exeeptions, will be useful:

1. The number of syllables is generally determined by that of the vowels (or diphthongs) written, exeept that doubled vowels are generally equivalent to the simple vowels pronounced long. See, however, *e*, *ie*, and other vowel combinations below.

2. Unaeeented syllables are pronouneed more distinctly than in English.

3. In German, Duteh, Danish, Swedish, Norwegian, Icelandic, Hungarian, and Bohemian the aeeent is usually on the first syllable. In Freneh, in whieh language it is very weak, it is always on the last syllable, unless this contains the so-called "mute *e*" (see *e* below) as its only vowel, in which case it is on the preeeding syllable. In Italian it is most often on the penult; so also in Spanish and Portuguese if the word ends in a vowel preeeded immediately by one or more eonsonants; in Spanish it is most often on the last syllable if the name ends in a consonant. The plaee of the aecent is sometimes marked in Spanish with the acute aceent, in Italian with the grave. In Polish the aecent is commonly on the penult. For Latin names the well-known rule is that the accent is on the penult if that syllable is long, otherwise on the antepenult, and elassic Greek names are usually given in Latinized forms and pronounced aeeording to Latin rules.

4. A written aeute accent indicates a long vowel in Hungarian and Bohemian.

5. In elassic Greek, Latiñ, and Hebrew names vowels and consonants are usually pronounced aeeording to English analogies, *ch*, however, having the value of *k*. In other names the vowels have commonly the Italian values as indicated above.

6. In German, Dutch, and the Slavic languages (as Russian, Polish, and Bohemian) the sounds of English *b*, *d*, *g* (whether in *go* or in *gem*), *v*, *z* (whether in *zone* or in *azure*), ean not oeeur at the end of a word; if the letters for these sounds are written in that position in one of these languages they are sounded respectively like *p*, *t*, *k* (or *ch* in *church* instead of *g* in *gem*), *f*, *s* (instead of *z* in *zone*), *sh* in *she* (instead of *z* in *azure*). See, however, *g* below.

7. Doubled eonsonants are pronounced long or doubled (e. g. *tt* as in *that time*) in Italian, Swedish, and Hungarian.

Alphabetical List of Noteworthy Letters and Combinations.

a is generally as in *father*. In Hungarian a is nearly equivalent to *o* in *hot*, and á as *a* in *father*.—â in Roumanian is like Roumanian *î* (see below).—ä in German and Swedish is like *e* in *net* or *there*; in German ae is sometimes written for *ä* (see *ae*).—ă in Roumanian approaches *u* in *hut* or *hurt*.—ã in Portuguese is nasal *a* (see *ãe*, *ão*, below).—ą in Polish is like *o* in *nor*, pronouneed through the nose.—å in Swedish and aa in Danish and Norwegian are like *aw* in *law*.—ae or æ in German, Danish, and Norwegian is like *e* in *net* or *there*; in Latin names ae is like English *e*; in Welsh it resembles *i* in *ride*.—ãe in Portuguese resembles *i* in *ride*, pronouneed through the nose.—ai is generally like *i* in *ride*, but in French it is like Freneh *é* or *è* (see below, but also *ail*, *aill*, *aim*, *ain*), and in modern Greek spelling ai (αι) approaches *e* in *red*.—ail in Freneh, when final, and aill in Freneh: see *il*, *ill*, below.—aim, ain in Freneh, if final or followed by any eonsonant except another *m* or *n*, are similar to *a* in *fag*, pronounced through the nose.—aj is in Danish like *i* in *ride*; in Hungarian like *oi* in *boil*, but Hungarian áj approaches *i* in *ride*.—am, an, under the conditions given above for *aim*, *ain*, represent in Freneh and Portuguese nasal vowels resembling *a* in *part*, pronounced through the nose.—ão in Portuguese is similar to *ou* in *loud*, pronounced through the nose.—au is usually like *ou* in *loud*, but in French it is like *o* in *note*. In modern Greek *au* (αυ) is equivalent to *av* before vowels and voiced eonsonants (as *b*, *d*, *g*), and to *af* before voieeless consonants (as *p*, *t*, *k*).—äu in German is like *oi* in *boil*.—auw in Duteh is like *ow* in *now*.—av in Danish before a consonant is generally like *ou* in *loud* (see *v*).—aw is generally like *a* in *father* followed by *v*, but in Welsh it is like *ou* in *loud* (see *w*).—ay is generally like *ai* above; in Freneh it is like French *ai*, but if a pronouneed vowel immediately follows, it has this sound (or sometimes that of *a* in *father*) followed by *y* as in *ye*.

b is in general as in English; but if final in German and some other languages (see 6 above) it is like *p*. Between two vowels *b* in Spanish approaches the English *v*, and the same pronuneiation is the usual one of *b* (β) in all positions in modern Greek. The sound may be described as a *v* formed with the lips alone, instead of with the lower lips and upper teeth.—bh is sometimes used in Sanskrit or East Indian names to express *b* followed by an aspiration. It need not be distinguished from *b*.

c is equivalent to *k* in most European languages except when it stands before *e* or *i*. In Welsh and Gaelic it is always like *k*. In Polish, Bohemian, and Hungarian, *c* always means *ts* (see also *ch*, *cs*, *cz*). Before *e* and *i* (or *y*) in Freneh, Portuguese, and Catalan it is like *s*; as also in English and in Latin names, in which last it has the same sound also before *ae* and *oe*. In German *c* (little used) before *e*, *i*, *ä* (*ae*) is like *ts*. In Italian and Roumanian *c* before *e* or *i* is like *ch* in

chin (but before *î* in Roumanian it is like *k*; see also *sc*), and in Spanish before the same letters like *th* in *thin*. In names from Sanskrit *c* is sometimes used, and has the sound of *ch* in *chin*, but *ch* is also used in sueh words. See also *ch*.—ç is like *s* in *mason*; in names from Sanskrit many pronounce it like *sh* in *she*.—č in Bohemian is like *ch* in *chin*.—ć in Polish is between *ts* and *ch* in *chin*.—ec, ech, ees. In Italian and Hungarian *c* before another *c* only indicates a lengthening of the consonantal sound.—eh is pronounced *k* in Latin, classic Greek, Hebrew, Italian, Catalan, and Roumanian names. In Freneh and Portuguese it is like *sh* in *she*, in Spanish like *ch* in *chin*. In German it has two sounds, one somewhat resembling the hawking sound heard in clearing the throat, a strong aspiration in the back of the mouth, heard after *a*, *o*, *u* (this sound is also written *ch* in Welsh and Gaelie), the other pronounced farther forward in the mouth (a voiceless German *j*), after *e*, *ä*, *i*, *ö*, *ü*. The same two sounds occur in modern Greek for *ch* (representing χ), the former before *a*, *o* (not *oi*), *ou*, the latter before the sounds *e* and *i* (however written). In some Slavic words (as Polish and Bohemian) *ch* is used as in German, but the Russian letter corresponding in sound is often indieated in Roman letters by *kh*, and *ch* in names from Russian oftener means *ch* in *chin*. In Sanskrit and East Indian names *ch* is like *ch* in *chin*, and *chh* need not be distinguished from this. (See also *sch* below.)—es in Hungarian is like *ch* in *chin*.—cu in Spanish, when a vowel follows and the *u* is not aecented, is like *kw*, or *qu* in *quite*.—cz in Polish is like *ch* in *chin* (so also in the word *Czech*). In Hungarian cz is like *ts*.

d is generally as in *did*. If final in German and some other languages (see 6 above) it is like *t*. If final, it is usually silent in French, and like *th* in *thin* in Spanish. In modern Greek *d* (δ) is usually like *th* in *that*, and it may have this sound in Spanish when between vowels.—dd in Welsh is like *th* in *that*.—dh is sometimes used in Sanskrit or East Indian names to express *d* followed by an aspiration. It need not be distinguished from *d*.—ds is in Hungarian like *j* in *joke*, and dseh is oeeasionally found in imitation of German spellings for the same sound.—dt is like *t*.—dż (Polish) and dž (in some Slavic names) are like *j* in *joke*.

e is usually nearly like *a* in *fate* or *e* in *pet* or *there*; but when final in French it is regularly silent (mute *e*), unless written with an accent (*é*). It is usually also silent in Freneh (or very short, like *e* in *battery*) if in the middle of a word and not followed by a eonsonant in the same syllable, unless it has an accent (*é*, *è*, *ê*). In German e in final syllables is similar to *e* in *battery*. In modern Greek e, if representing ε, is like *e* in *pet*; if it represent η, like *i* in *machine*. In Slavic words *e* is often pronouneed like *ye* in *yet*. (See also *ae*, *ei*, *ej*, *em*, *en*, *er*, *es*, *et*, *eu*, *ey*, *ez*, *ie*, *oe*, *ue*.)—é, è in French are pronounced, the former nearly like *a* in *fate*, the latter nearly like *e* in *pet*.—ê in French is similar to *e* in *red* or *there*. In Roumanian ê is like Roumanian î (see *î*).—ę in Polish is nearly like *e* in *red*, pronounced through the nose.—eau in French is like *o* in *note*.—eeu, eeuw in Dutch are long *e* (*a* in *fate*) followed by *u* (in *rule*) in the same syllable, not like Dutch *eu*.—ei is in French like French *è* (see above); in German, Dutch, and Welsh similar to *i* in *ice*; in modern Greek *ei* (ει) is like *i* in *machine*; in other cases it is generally *e* followed by *i* in the same syllable, that is, nearly like *ey* in *they*.—eil, eill in French: see *il*, *ill*.—ein in French is like French *ain* in the same position (see above).—ej in Danish approaches *i* in *ride*; in Hungarian it is similar to *ey* in *they* (that is, *e* followed by *i* in the same syllable).—em, en in French represent a nasal vowel under the conditions described above for French *aim*, *ain*, *am*, *an*, and the sound is the same as that described for French *am*, *an*, but final *em* (not common) is sometimes like *em* in *hem*. In Portuguese, under the same conditions, *en* (and *em* before *p* or *b*) is like *a* in *fate*, pronounced through the nose, and *em* is generally like Portuguese *ãe* (see above), or (in Brazil) like *ey* in *they*, pronounced through the nose. (See also *ien* below.)—er when final in French is generally like French *é* (see above).—es when final in French is generally silent unless the *e* is accented (*é*, *è*), in which case *s* is generally silent.—et when final in French is generally like French *è* (see above).—eu in French and Dutch is nearly like *u* in *hurt*; more exactly, it is like *a* in *fate* or *e* in *pet*, with the lips rounded as for *o* in *note* or *nor*. (See also *eeu*.) In German eu is like *oi* in *boil*. In modern Greek eu (ευ) is pronounced *ev* or *ef*, according to the rule given above for *au* in that language. In other languages both e and u have their usual sounds, one following the other in the same syllable.—ey is, in general, like *ei*, but in Freneh it is followed by a distinet *y* (as in *ye*) when a pronouneed vowel comes after the *y*; that is, it is then French *è* followed by *y*.—ez final in French is like French *é* (see above).

f in Welsh is pronounced *v*, and ff in Welsh is like *f*.—fv in Swedish is pronouneed *v*.

g is generally as in *go*, *get*. When *e*, *i*, or *y* follows, it is in Freneh and Portuguese like *z* in *azure*; in Italian, Roumanian, Latin, and classic Greek names like *g* in *gem*; in Spanish like a strong *h*. In Norwegian and Swedish g before *i* is similar to in *ye*, and is silent before *j*. Final g in German and Dutch is pronounced like German *ch* (see above), or in German by some like *k* (see 6 above). In modern Greek and in Dutch g is in all positions regularly a spirant, with the voieed sounds of *ch* as deseribed above for those languages.—gh in Italian and Roumanian is like *g* in *get*. In Irish it is nearly like *ch* in Welsh and German. In Sanskrit and modern East Indian names it is sometimes used to express *g* (as in *go*, *get*) followed by an aspiration which need not be imitated. In some Oriental names it represents a peeuliar guttural sound.—gli in Italian is similar to *lli* in *million*; if no vowel follows, the sound is the same followed by *i* as in *machine*.—gn in French and Italian is nearly equivalent to *ni* in *union*.—gu in French, when followed by *e*, *i*, or *y*, is generally like *g* in *get*, but like *gu* with French *u* if a eonsonant or *ë* follows the *u*. In Spanish gu before *e* or *i* is like *g* in *get* unless the *u* is marked with the diæresis (*ü*), in whieh case, as before other vowels, gu is like *gu* in *languid*, and this last is the regular value of gu in Italian before a vowel.—gy in Hungarian is somewhat like *dy* (with *y* as in *ye*).

h is silent entirely in French, Italian, Spanish, and Portuguese; see, however, *ch*, *gh*, *lh*, *nh*, *sch*. In German it is heard when initial, but is generally silent when preceded by a vowel and followed by simple *e* (not *ei*, before which it is heard), and when final it is generally silent in German and other languages. In Roumanian, however, h regularly has the first sound deseribed above for German *ch*. In Seandinavian names h is silent in initial *hj* (= *y* in *ye*) and *hv*.

i is as in *machine*, or sometimes as in *pit*, and î is like *i* in *machine*, except in Roumanian, where it is like Polish *y*, or somewhat like *i* in *pit* (see *y*).—ie in German and Dutch is like *i* in *machine*; in other languages it is oftener like *ye* in *yet* (for French, see *e* above).—ieuw in Duteh is like *i* in *machine* followed by *u* as in *rule* in the same syllable.—ien in Freneh, when final or before a consonant (except another *n*), is like *y* (in *ye*, *you*) or a short *i* followed by the Freneh nasal vowel written *in* (see *in*).—ij in Duteh is similar to *i* in *ice*.—il in Freneh when final and ill in French mean usually, after a consonant or silent *u* (see *gu*, *qu*), the sound of *i* in *machine* followed by a strongly consonantal *y* as in *ye*; after a pronounced vowel they indicate the latter sound (*y*) alone, the preceding vowels having their usual French sounds (written *e* = French *è*).—In French im, in, under the conditions described above for *aim*, *ain*, have the sound there described, nearly like *a* in *fag*, pronounced through the nose. In Portuguese, under the same conditions, im, in are about like *i* in *machine*, pronounced through the nose.

j is generally like *y* in *ye*, *you*. In French, Portuguese, and Roumanian it is like *z* in *azure*, and for the Russian letter with this sound j has sometimes been used (see *zh*). In Spanish it is a strongly aspirated *h*. When in Scandinavian or Hungarian names it stands before a consonant and after a vowel it combines with that vowel to form a diphthong as *i* would do (see *aj*, *ej*, *oj*). In Italian j sometimes is a vowel, with the long sound of *i* in *machine*. In names from Sanskrit or modern East Indian tongues j is as in *joke*, as is also *jh* (properly the same followed by an aspiration).

k is generally as in English; but in Swedish before *e*, *i*, *ö*, *y* it resembles *ch* in *chin*, and in Norwegian before *i* and *y* it has the second sound of *ch* in German (voiceless *y*).—kh is sometimes used for a Russian letter sounded like German *ch* (see above); also for an Oriental guttural sound. In Sanskrit and modern East Indian names it is nearly as in *inkhorn*.—kj in Swedish and Norwegian respectively has the sound of Swedish or that of Norwegian *k* before *i* described above.

l is generally as in English.—ł in Polish is an *l* with guttural quality, resembling somewhat the *l* of some Englishmen in *hill*.—lh, ll are used, the former in Portuguese, the latter in Spanish, for a sound similar to *lli* in *million*, and *ll* in Welsh is voiceless *l*.—ly in Hungarian represents for

some speakers the sound of *lh* just described, but it is now oftener pronounced as *y* in *ye*.

m, n in French and Portuguese, when final or before a consonant (except another *m* or *n*), serve only to mark that the preceding vowel is nasalized. (See *aim*, *ain*, *am*, *an*, *em*, *en*, *ien*, *im*, *in*, *om*, *on*, *um*, *un*).—mp (μπ) in modern Greek is like *b*, but it may also mean *mb* if not initial.—ñ in Spanish is similar to *ni* in *union*, and ń in Polish and ň in Bohemian have the same value.—ng in German, Dutch, and Scandinavian is generally like *ng* in *singer*.—nh in Portuguese is about like *ni* in *union*.—nt (ντ) in modern Greek is like *d*, but it may also mean *nd* if not initial.—ny in Hungarian and Catalan represents the same sound as the preceding (*nh*).

o is like *o* in *note* or *nor*.—ô in French is like *o* in *note*.—ö in German, Danish, Swedish, Norwegian, and Hungarian is like French *eu* or nearly like *u* in *hurt*, and ø in Danish has the same sound.—õ in Portuguese is like *o* in *note*, pronounced through the nose (see *õe* below).—oe or œ is sometimes written in German or Scandinavian names; it is pronounced like *ö* above. In Dutch oe is like *u* in *rule*, *oo* in *fool*. In Latin names oe is pronounced like English *e*, in Welsh it is similar to *oi* in *boil*.—õe in Portuguese is similar to *oi* in *boil* pronounced through the nose.—oei in Dutch is Dutch *oe* (= *u* in *rule*), followed in the same syllable by *i* as in *machine*.—œu in French is like French *eu*.—oi is as in *boil*, except that in French it is nearly like English *w* followed by *a* as in *father*, and in modern Greek οι (οι) is like *i* in *machine*.—oin in French, if final or followed by a consonant other than *n*, is similar to English *w* followed by the French nasal vowel written *in* or *ain* (see these above).—oj, öj in Danish are like *oi* in *boil*.—oo is like *o* in *note*.—ou in French and modern Greek (ου) is like *u* in *rule* or *oo* in *fool*; it is often used for this sound in other names. In Portuguese ou is nearly like *o* in *note*, and in Dutch like *ou* in *out*.—ouw in Dutch is like *ou* in *out*, *ow* in *now*.—oy is generally like *oi*; in French, if a pronounced vowel follows, it is like French *oi* followed by *y* as in *ye*.

ph is generally like *f*, except in Sanskrit and some East Indian names, where it is like *ph* in *loophole*.

q is like *k*.—qu in French is generally like *k*, so too before *e* and *i* in Spanish and Portuguese. In other words it may be pronounced as in *quite*, though in German it is more like *kv*.—qv in Swedish is like *kv*.

r may be pronounced as in *red*; it should not be omitted (see, however, *er* above).—ř in Bohemian is like *r* followed by *z* as in *azure*.—rh, if both letters are in the same syllable, is as in *Rhine*.—rz in Polish is generally like *z* in *azure*.

s is generally as in *mason*, but in French, German, Italian (generally), and Portuguese a single *s* between vowels is like *z* in *zone*, and initial *s* in German before a vowel may be pronounced as *z*. In German initial *s* in *sp*, *st* may be pronounced like *sh* in *she*. In Hungarian *s* (see also *ss* below) is like *sh* in *she*. In French final s is generally silent; in Portuguese final s or s before a voiceless consonant, except another *s* (*p*, *t*, *f*, etc.), is like *sh* in *she*, and s before a voiced consonant (*b*, *d*, *v*, etc.) is like *z* in *azure*. (See also *sc*, *sch*, *sk*, *skj*, *stj*, *sz* below.)—š is written in some Slavic languages, as Bohemian, for the sound of *sh* in *she*, and ş in Roumanian has the same sound; also ş is sometimes used in names from Sanskrit with the same value.—ś in Polish is a palatalized *s*, between *s* in *see* and *sh* in *she*.—sc before *e* or *i* is like *sh* in *she* in Italian; in Roumanian it is like the same sound followed by *t*.—sch in German is like *sh* in *she*, and this German spelling is sometimes found in names not properly German. In Dutch it is like *s* followed by Dutch *ch* (see *ch*); in Italian and Roumanian like *sk*.—sh is like *s* followed by *h*; but in Russian names it is as in *she*.—sj in Dutch, Danish, Norwegian, and Swedish is nearly like *sh* in *she*.—sk is generally as in *skin*, but in Swedish before *e*, *i*, or *y* it is like *sh* in *she*, as also in Norwegian before *i* or *y*, and skj in Swedish and Norwegian has the same sound.—ss is generally like *s* (sometimes lengthened; see 7 above); in Hungarian it is like *sh* in *she* lengthened.—stj in Swedish is like *sh* in *she*.—sz in Polish is like *sh* in *she* (see also *cz*); in Hungarian sz is like *s* in *mason*, and *ssz* is a long *s*.

t is generally as in *state*. If final in French it is usually silent.—ţ in Roumanian means *ts*.—th is generally like *t*; but in modern Greek (θ), Icelandic (representing þ), and Welsh it is as in *thin*.—tsch in German is like *ch* in *church*; it is sometimes found in names not properly German with the same sound.—tsh in Slavic names is like *ch* in *church*.—ty in Hungarian is similar to *ty* with consonantal *y*.—tz is like *ts*.

u is generally as in *rule* or as *oo* in *fool*; but in French (see, however, *um*, *un*) it has a sound not existing in English, produced by pronouncing *i* as in *machine* with the lips rounded as for *u* in *rule*. In Dutch it has the same sound when it ends a syllable (see also *uu*); if a consonant follows in the same syllable Dutch u is nearly like *u* in *cut* or *hurt*. In Welsh u is generally like *i* in *machine*. Written u is sometimes silent (see *gu*, *qu*).—ü in German and Hungarian is like French *u*.—ue is sometimes written instead of *ü*; except in German both vowels are usually heard; see, however, *gu*, *qu*.—ui in French is French *u* followed by *i* in *machine* in the same syllable, but the *u* is sometimes silent (see *gu*, *qu*). In Dutch ui is somewhat like *oi* in *boil*.—um, un often represent in French and Portuguese nasal vowels (see *m*, *n* above), though French final *um* is sometimes pronounced *om* (somewhat like *om* in *Tom* or *um* in *hum*). The French nasal sound is French *eu* nasalized, much like *u* in *hut*, pronounced through the nose; the Portuguese one is *u* in *rule* or *oo* in *fool*, pronounced through the nose.—uu in Dutch is like long French *u*.—uy is in French like French *ui*, but, if a pronounced vowel stands after *y*, the *ui* is followed by *y* as in *ye*. Dutch uy is like Dutch *ui*.

v is generally as in English; but in German initial v is like *f*, and in Danish v is written instead of *u* as the last vowel of some diphthongs. See also *w* and see 6 above.

w is in general like *v*. In a few German names in *-ow* the final w is silent (see also *auw*, *eeuw*, *ieuw*). In Welsh w is generally a vowel, like *u* in *rule*. The Russian letter sounded like *v* is sometimes written *w* in Roman letters, and sometimes *v*, or when final *ff* (see 6 above).

x is generally like *ks* as in English; but in Portuguese and Catalan *x* is like *sh* in *she*, and in some Spanish names *x* is occasionally found for the sound of a strong *h*, where the usual modern spelling has *j* or *g*.

y is generally like *i* in *machine*. Before a vowel it is like *y* in *ye* in Spanish and French (see also *ay*, *ey*, *oy*, *uy*). In Danish, Swedish, and Norwegian it is like French *u*. In older Dutch spelling it was like *i* in *ice*, as in Flemish; Dutch now writes *ij* instead. In Polish, and when it represents a certain Russian letter, it is a kind of retracted *i*, somewhat resembling *i* in *pit*. In Welsh it is sometimes like *i* in *sir*, and sometimes resembles *i* in *pit*.—(See also *gy*, *ly*, *ny*.)—ym, yn in French are like French *im*, *in*.

z is often as in English; but in German it is always like *ts*; in Italian it is like *ts* or sometimes, especially when initial, like *dz*, and in Spanish it is like *th* in *thin*. Final z in Portuguese is like *sh* in *she*.—ż (in Polish), ž (common in Bohemian), zh (sometimes representing a certain Russian letter), and zs (in Hungarian) are all like *z* in *azure*.—ź in Polish is a palatalized *z*, between *z* in *zone* and *z* in *azure*.—zz in Italian is generally like *ts*.

Some letters with diacritic marks, as dots or other signs, not included above, are mentioned in the list of PECULIAR PHONETIC SYMBOLS at the beginning of this volume; see also the KEY TO THE PRONUNCIATION. For fuller information as to the sounds and the orthography of the languages concerned, see the articles on FRENCH, GREEK, LATIN, and other languages, and various grammars; also PHONETICS, and the works there referred to, especially *Phonetische Studien* and the bibliographical list in Sievers's *Grundzüge der Phonetik*.

E. S. SHELDON.

Pronunciation of Greek: the prevailing methods of pronouncing the ancient classical Greek. Though characterized by minor diversities, these may be grouped in general under three heads: (1) The English method, which gives to the symbols the value common to them in English, and accents according to Latin rules, disregarding the written accents. This method has been almost entirely discontinued in the U. S., but is still widely used in Great Britain and Canada. Among the different nations of continental Europe analogous methods are in vogue—i. e. the letters are sounded according to the general analogies of the native tongue, though the written accent is observed. This does not, however, necessitate, in general, so wide a departure from the original pronunciation as the English method. (2) The modern Greek method. This assigns to the letters the values they have in modern Greek; see under GREEK LANGUAGE (*Modern Greek*). Though this method has many advocates, it is unlikely of adoption, because it sadly confuses the original vowel-sounds, and departs widely from the clearly ascertained facts of the ancient pronunciation. The application of the modern English pronunciation to the reading of Chaucer would be a fair parallel. (3) The ancient

Greek method. The present tendency is strongly toward the adoption of what can, with reasonable certainty, be determined to have been the Attic pronunciation of the fourth century B. C. Its chief characteristics are approximately indicated in the following table:

Vowels.	Consonants.
α as *a* in Eng. *father*.	γ as *g* in Eng. *go*.
ε as *é* (close) in Fr. *blé*.	γ before κ, γ, χ, ξ, as *n* in Eng. *ink*.
η as *e* (open) in Eng. *there*.	ζ either as *zd* or *dz*.
ι as *i* in Eng. *machine*.	θ, ϑ as *th* in Eng. *hothouse*.
ο as *o* (close) in Fr. *mot*.	ξ as *x* (*ks*) in Eng. *box*.
ω as *o* (open) in Fr. *encore*, and nearly as *o* in Eng. *orb*.	σ, ς as *s* (sharp) in Eng. *siss*.
υ as *u* in Fr. *ruse*, or Germ. *ü* in *für*.	τ always as *t* in *tip* or *cat*.
	φ as *ph* in Eng. *uphill*.
	χ as *kh* in Eng. *blockhead*.
	ψ as *ps* in Eng. *autopsy*.

Diphthongs.
αι as *ai* in Eng. *aisle*.
αυ as *ou* in Eng. *out*.
ει as *ei* in Eng. *vein*.
ευ as ε followed by *u* of Eng. *rude*.
οι as *oi* in Eng. *boil*.
ου as *ou* in Eng. *you*.
υι as *u* of Eng. *rude* followed by ι.

Other consonants have the ordinary sounds of their equivalents in English. Rho (ρ) should always be given its own distinct sound, and not be dropped at the end of words after a vowel, as is common in English. The vowels ε and ο were close and short, and have no equivalents in English; η and ω were, however, open and long. The long vowels corresponding to the shorts ε and ο were, at least until the middle of the fourth century, when ου became *ū*, the pseudo-diphthongs ει and ου. In direct contrast with the Greek it is to be noted that in Latin *ĕ* and *ŏ* are open and *ē* and *ō* are close. See F. Blass's *Pronunciation of Ancient Greek* (trans. from the 3d German ed., 1890); K. Zacher, *Die Aussprache des Griechischen* (1888). Benj. Ide Wheeler.

Pronunciation of Latin: The pronunciation of the Romans themselves at the height of their civilization (i. e. in the Augustan age and the time of the early empire) was substantially as follows:

A. *Vowels.*—*ā* as in father, *ă* as in the first syllable of *ahá*; *ē* as in *they*, *ĕ* as in *met*; *ī* as in *machine*, *ĭ* as in *pin*; *ū* as in *rude*, *ŭ* as in *put*; *y* like French *u*, German *ü*.

B. *Diphthongs.*—*æ* like *ai* in *aisle*; *œ* like *oi* in *oil*; *au* like *ow* in *how*; *eu* with its two elements pronounced in rapid succession.

C. *Consonants.*—*b*, *d*, *f*, *h*, *k*, *l*, *m*, *n*, *p*, *qu* were pronounced as in English; *bs* and *bt* had the sound of *ps* and *pt*; *c* always as *k*; *t* always a plain *t*, never with the sound of *sh* as in English *oration*; *g* always as in *get*, except that when *ngu* precedes a vowel *gu* has the sound of *gw*, as *anguis*, *languidus*; *j* like *y*; *r* slightly trilled; *s* always voiceless as in *sin*, but in *suadeo*, *suavis*, *suesco*, and in compounds and derivatives of these words *su* has the sound of *sw*; *v* like *w*; *x* always like *ks*, never like English *gz* or *z*; *z* like English *zd* or *dz*. The aspirates *ph*, *ch*, *th* were pronounced like English *ph*, *ch*, *th* in such compound words as *loop-hole*, *block-house*, *hot-house*. Geminated consonants (e. g. *ll*, *mm*, *tt*) were pronounced with each member of the combination distinctly articulated.

For Latin scientific names the following pronunciation (often called English) is usually followed; but a strong tendency is now manifesting itself among scientists to adopt the Roman pronunciation:

A. *Vowels.*—These have their long English sounds (*a* in *make*, *e* in *me*, *i* in *kite*, *o* in *go*, *u* in *rude*, *y* in *lyre*) when final; before another vowel; in penultimate (next to the last) and unaccented syllables, not final, before a single consonant or before a mute followed by *l* or *r*. Vowels have their short English sounds (*a* as in *bat*, *e* as in *met*, *i* as in *pin*, *o* as in *not*, *u* as in *run*, *y* as in *myth*) in final syllables ending in a consonant; in all syllables before *x* or any two consonants, except a mute followed by *l* or *r*; in all accented syllables, not penultimate, before one or more consonants.

B. *Diphthongs.*—*æ* and *œ* like *e* in the same situation; *au* as in *author*; *eu* as in *neuter*.

C. *Consonants.*—These are pronounced in general as in English, but *c*, *s*, *t*, when preceded by an accented syllable and followed by *i* and another vowel, have the sound of *sh*; *x*, under the same circumstances, is pronounced as *ksh*; *ch* is always hard, as in English *echo*.

See Seelman, *Die Aussprache des Latein* (1885); Lord, *The Roman Pronunciation of Latin* (1894).

Charles E. Bennett.

Propagan'da [abbrev. from Lat. *Congrega'tio de Propagan'da Fi'de*, the Lat. name, liter., association for spreading the faith]: a congregation of cardinals at Rome, first fully established in 1622 by Gregory XV., for furthering the spread of the Roman Catholic religion among the heathen; also, the great college (Collegium Urbanum) for training missionaries sustained by this body.

Proper'tius, Sextus: elegiac poet of Rome; b. in Umbria, near the frontier of Etruria, probably at Assisi; lost while still a youth most of his property by confiscation, and lived in Rome on a small competence; devoted himself to poetry; attracted the attention of Mæcenas, and resided on the Esquiline in familiar intercourse, as it seems, with Mæcenas, Vergil, and Ovid. The exact dates of his birth and death are unknown, but he was probably born about 49 and died about 15 B. C. His *Elegies* (in five books), which appear to have been much appreciated in antiquity, have come down only in a very corrupt text, and are in a way less enjoyable than the similar productions of Tibullus and Ovid on account of their style, which is cumbersome and obscure. These defects are offset by his strength of imagination, and vivid power of description, the genuine fervor of his passion, and his delicate sense of beauty. There are editions by W. Hertzberg (Halle, 1843–45, 3 vols.), Keil (Leipzig, 1850), Haupt (revised by Vahlen, Leipzig, 1885), A. Palmer (Dublin, 1880); a translation into English verse by Charles Robert Moore (Oxford, 1870); and an excellent edition of selections, with introduction and notes, by Postgate (London, 1881). See also W. Y. Sellar, *Horace and the Elegiac Poets* (Oxford, 1892). Revised by M. Warren.

Property [from O. Fr. *proprete* < Lat. *propri'etas*, property, liter., ownness, deriv. of *pro'prius*, own, proper]: in the broadest sense, all private rights of economic value. In this sense the term covers (*a*) real rights—i. e. rights over corporeal objects; (*b*) obligations—i. e. rights of demanding from particular persons that they do or refrain from doing particular things; (*c*) rights of a monopolistic nature (patents, copyrights, etc.), which confer an exclusive power of making and selling certain things. As here treated the word property is confined to rights over corporeal things.

Roman and European Law.

Roman Law.—Many provisions of the Roman law are applicable only to immovables, and many other provisions only to movables; but in general the same body of rules governs both classes of property, both as regards relations *inter vivos* and as regards inheritance.

Rights over things are either general or partial. The general right is ownership (*dominium*, *proprietas*). This includes all rights over the thing not expressly withheld by the law or granted by the owner to other persons. Ownership is acquired either from a former owner, so that the title of the new owner depends upon that of his predecessor (*auctor*), or by the operation of some rule of law which vests in the new owner an independent title. In the former case the acquisition is "derivative"; in the latter case it is "original." The most important modes of derivative acquisition recognized at Roman law were (*a*) conveyance, which implies an agreement between the conveyor and the conveyee and the delivery of possession (*traditio*), and (*b*) inheritance or legacy. (See Succession.) The modes of original acquisition were occupation, accession, specification, and prescription. (*a*) Occupation signifies, literally, taking possession. If the thing occupied has no owner (*res nullius*), the assumption of possession with the intention of assuming ownership creates ownership. Among *res nullius*, capable of occupation, the Romans classed wild animals; shells, stones, etc., on the seashore; and things derelict. Dereliction is the opposite of occupation; it consists in the abandonment of possession with the intention of abandoning ownership. Things lost are not derelict, and the finder does not acquire ownership; but treasure-trove (*thesaurus*) is regarded as *res nullius* when the articles found have been so long hidden that the owner can not be discovered. In such case half the treasure goes to the finder, the other half to the owner of the soil. (*b*) Accession signifies that what was previously an independent thing has become a part of some other thing, and has thereby passed into the ownership of him who owns the principal thing. An example of accession is the planting of a tree. No separate ownership is possible in the tree; it goes with the land. The same rule properly applies to a building erected on another man's land, and to the materials employed in its construction; but here the original ownership of the materials is not deemed to be extinguished, but simply suspended. Other cases of accession

are *alluvio*, or the gradual deposit of soil by the action of running water; and *avulsio*, or the sudden deposit of soil torn from another's land by a freshet or a landslide. Accession is also possible in the case of movables; so when a leg is fitted into a chair, a blade inserted in a knife, etc. (*c*) Specification takes place when a thing is converted by labor into a new and different thing (*nova species*). Cases of specification range from the conversion of wine into vinegar to the manufacture of watch-springs out of a bar of metal, and from these purely mechanical transformations to such as are effected by the artistic skill of a sculptor or painter. In all these cases the maker of the new thing becomes owner, although the material was not previously his, provided he has acted in good faith; provided also (by a positive rule of Justinian's) the new thing can no longer be reduced to its previous condition.

Partial rights (*jura in re*) were divided by the Roman jurists into rights of use and rights of pledge or mortgage. Rights of use were (*a*) servitudes; (*b*) hereditary leaseholds. The ordinary lease was a purely contractual relation, and created no *jus in re*; but where unimproved land was leased for long terms a very liberal measure of "tenant right" was accorded to the lessee. Such leaseholds were termed *emphyteusis* when the land was used for agricultural purposes, *superficies* when it was used for the erection of buildings.

Mediæval Developments.—Teutonic custom drew a much sharper distinction between realty and movables than was drawn at Roman law. The feudal system, which associated political powers with the ownership of land and public or quasi-public duties with its possession, accentuated the distinction; so that mediæval law developed quite different rules for realty and personalty, both as regarded relations *inter vivos* and as regarded inheritance.

Rights in immovables could be acquired as a rule only by inheritance or by some public form of "investiture" or conveyance. Transfer of realty was generally restricted: partly in the interest of the ruling classes by the system of feudal tenures, and partly in the interest of the family by the system of family community. As regarded movable property, delivery of possession regularly passed title. Except in the case of lost and stolen things, and except as between bailor and bailee, Teutonic custom treated possession as equivalent to title. Transfer of movables was regularly unrestricted.

In neither field of property rights was the distinction between ownership and the lesser rights so sharply formulated as in the Roman law. As regarded realty the confusion was increased in the course of the Middle Ages by the systems of feudal and of peasant tenures. The feudal system gave to one person, the lord, general residuary rights in the land, and in particular a more or less effective reversionary right; to another person, the vassal, it gave rights of possession and use which everywhere tended to become hereditary and alienable. When Roman legal theories began to dominate mediæval thought the jurists found some difficulty in deciding whether the lord or the vassal really owned the land; and they solved the problem by attributing to the former a higher or superior ownership (*dominium eminens* or *directum*), and to the latter "practical ownership" (*dominium utile*). Similar difficulties were encountered in dealing with peasant tenures, especially in Germany. In many parts of Germany the private or property rights of the manorial lord (as distinguished from his jurisdictional rights) were limited to the receipt of customary rents and services, the peasants having perpetual and hereditary leases (*Erbpacht*). Here again, with the reception of the Roman law, the jurists worked out the un-Roman distinction of superior and inferior ownership (*Obereigenthum* and *Untereigenthum*). With the decay of the feudal system and the disappearance of the reversionary rights of the feudal lord, the inferior rights of the vassal developed into the full right of ownership, while the eminent domain of the lord gradually lost the character of a property right and became simply governmental power. Peasant rights also have usually been converted by modern legislation into full proprietorship. In all modern European states the confused system of the Middle Ages is rapidly disappearing, and ownership in the Roman sense is sharply distinguished on the one hand from political power and on the other from lesser and partial rights in the land.

The feudal system has nevertheless left permanent traces in the modern law of property, both as regards inheritance of realty (see Succession) and as regards other modes of acquisition. The effort of the feudal princes to reserve control over forests, hunting, and fishing, paved the way for the modern governmental control of all these matters. Early in the Middle Ages animals *feræ naturæ*, if regarded as objects of sport, ceased to be open to occupation except by him who had the right to take them. The efforts of the feudal princes to increase their revenues led also to an assertion of exclusive governmental right over other things which the Romans regarded as *res nullius* (e. g. things washed up by the sea, abandoned land, enemy's goods; in some territories *thesaurus*, or treasure-trove). The same efforts gave rise to the theory that mining privileges belonged to the feudal lord, and could be exercised only by his license, which was regularly issued to the first finder. The owner of the soil could demand only compensation for damage done to the surface, and in some territories a share in the venture. The right to minerals was thus separated from the right to the surface. Nearly all these "royalties" (*regalia*) have passed into modern European law as rights of the state or "fiscus."

Modern Legislation.—Some of the older codes confuse rights over things with property rights in the broader sense, and speak of an "ownership" of obligations, etc.: but in the more recent codes rights over things are sharply distinguished from rights *in personam*. Immovables and movables are subjected to very different rules, but the distinction is obscured by a formal unity of treatment.

Ownership (*domaine, propriété, Eigenthum*) is the general right in the Roman sense. As regards original acquisition, the list of *res nullius* has been limited and the field of occupation narrowed by the development of fiscal rights. The Code Napoléon declares that all property without an owner belongs to the state, but it makes an exception in the case of treasure-trove (*trésor*) and applies the Roman rule. Some of the existing German codes give a share of treasure-trove to the state or the commune, but the draft code for the whole empire proposes to re-establish the Roman rule. As regards accession, the Roman rules are generally accepted. The law of specification is substantially Roman; but the Saxon code and the German draft code discard the distinction between the honest and the dishonest maker, and all the modern codes reject the distinction between a new thing that can be reduced to its original form and one that can not be so reduced. In determining the ownership of the new thing many codes lay stress on the relative value of the material and the labor.

As regards conveyance, the French law breaks with the Roman law by declaring that title passes with the conclusion of the contract and without delivery of possession; but while this rule governs the relations between the conveyor and the conveyee it does not operate against third persons.

The most sweeping changes that have been introduced in the modern law of property are due, in the case of movable property, to the protection given to the honest possessor (see Possession), and in the case of immovable property to the registration laws. See Recording etc. Munroe Smith.

English and American Law.

The English law of property, from which that of the U. S. is derived, followed an independent line of development. Whereas, to the Roman law, land and goods were only differing forms of property, accidentally discriminated by the physical differences between them, but both of them subject to ownership in the same sense of that term and for the most part governed by the same rules of law, in the English system this physical difference became fundamental, and resulted in two distinct bodies of law—the law of "real property" and the law of "personal property." This result was due to the peculiar and exceptional character impressed upon land as the subject of property by the feudal system. As explained in the articles on Estate and Landlord and Tenant, that system was wholly based on the conception of land, not as subject to ownership, as chattels are owned, but as subject to a qualified interest or estate, limited in duration, and exacting of the holder, or "tenant," the performance of feudal services as the condition of his tenure. Nor was the "lord," of whom the land was held, in any better situation; he in his turn held the land as tenant of some superior lord, and so the feudal hierarchy ascended until it reached the king as lord paramount. So while goods and chattels continued to be subject to that absolute control which we call ownership, lands were merely "held" by a variety of tenures or estates, the ultimate ownership being vested in the crown or state.

It would be a mistake, however, to assume that the distinction between real and personal property coincides with

that between land and goods, or between the "movables" and "immovables" of the Roman law. Here, as so often in the history of the common law, the inflexible methods of procedure by which rights were enforced gave rise to an artificial distinction, based, indeed, on the fundamental difference between movables and immovables, but not following the natural line of cleavage between them. The terms "real" and "personal," now employed to describe different classes of rights over things, originally described only different forms of action. The *real* action was a proceeding for the recovery of the *res*, the very thing of which the party complaining had been deprived; the *personal* action, on the other hand, was an action against a certain person for the infringement of a right, but it sought to recover, not the property itself, but damages for its detention or destruction. By reason of the permanent, indestructible character of lands, the real action was especially appropriate for recovering possession of them. Hence lands were called *real* property. But goods and chattels, being easily susceptible of destruction, or loss, or concealment, and being, moreover, infinitely less important to feudal society than freehold interests in land, could not be pursued and recovered by a real action. The only remedy provided by law for the unlawful destruction or detention of a chattel was the personal action for damages. Hence goods, or chattels, came to be known as *personal* property.

Not all interests in land, however, could be recovered by a real action. All estates of freehold—fees simple, fees tail, life-estates—were considered worthy of recovery by this solemn form of procedure; but leases for years, which were not properly estates at all, which existed by virtue of contract merely, and which were deemed unworthy of freemen, were not recoverable by real action. In other words, the tenant for years, if he was unjustly dispossessed, whether by his lord or by a stranger, had originally no remedy but a personal action for damages. Accordingly, terms of years came to be regarded as personal property, notwithstanding the fact that the right to recover possession of his leasehold by ejectment was conferred upon the tenant for years at a very early period. By virtue of this right to maintain ejectment for its recovery, the term of years became a true estate or interest in lands, but it has never lost the anomalous character which its humble origin impressed upon it. A leasehold of 1,000 years is still, in the U. S. as well as in England, regarded as personal property, whereas an estate for life is a freehold, and has all of the incidents of real property. In Massachusetts and a few other States, however, leaseholds of great length are assimilated to real property.

Personal property, then, includes not only goods or chattels, but also such interests in lands as the early common law did not deem worthy of protection by a real action. The legal conceptions to which the feudal system gave rise were responsible for another anomalous extension of the notion of personal property. All property rights are in their nature rights of control over material objects—called rights *in rem*—and are opposed to those legal rights which do not directly concern things, but persons, which are known as rights *in personam*. A large body of rights of this latter class—i. e. rights of action, such as claims, demands, etc., called *choses in action*—were brought into the classification of personal property. To these must be added those other intangible rights recognized by modern law, such as trademarks, patent rights, copyright, etc.

Real property, on the other hand, comprehends much besides those estates or interests in land, called freehold interests, which were anciently deemed worthy of protection by real action. The term includes also all those rights of use or enjoyment in the lands of others which, under the description of easements, profits and rents, fill so large a space in the modern as well as in the ancient law of property, together with all those movables which, by becoming attached to the soil, have acquired the character of FIXTURES (*q. v.*). On the other hand, certain things which are usually regarded as real property, may, because of special circumstances or as between particular persons, fall into the category of personal property. This is true of such growing crops as have acquired the character of "emblements," of trees standing or cut, of stones which have been quarried but not removed, etc. In all such cases, however, the special circumstances must be shown in order to rebut the presumption arising from the apparent connection of the articles in question with the land.

The complicated system of feudal tenures above referred to has long since been swept away. The freehold tenant no longer holds his land as the fee of a lord, excepting in a few manors which still survive in England. But the tenure of lands, in the U. S. as well as in England, continues to exhibit the feudal form. In some of the States it is expressly provided by statute that all lands shall be held by "allodial"—that is, absolute—titles; but, notwithstanding that declaration, there is no such thing as absolute ownership of lands. The state is lord paramount, and the landowners hold their fees in subordination to its paramount title.

The popular notion of *ownership* is, for most purposes, a sufficiently accurate definition of the extent of the right of property; it indicates in general either a present or an ultimate right of possession, coupled with the control of the thing and the power of transferring this ownership in whole or in part to another. Of course, the actual physical possession may be in another than the owner, and even the right of possession may be temporarily vested in another person—as in a tenant of lands or a bailee of goods—but there can be no property without actual or constructive possession, or the right to resume or control the possession at some time in the future. Indeed, so important is the fact of possession even without right, and the right of possession without ownership, that they have in law many of the attributes of actual property rights. Attention is called in the article on LIMITATION OF ACTIONS to the extraordinary consequences of a disseisin, whereby a disseisor, by dispossessing the rightful owner of lands and installing himself in his place, acquires the lawful seisin, the "property" of the former owner, and becomes a new root of descent. But it is also true that the disseisor has by his act acquired a right of possession and a title against the whole world besides the rightful owner: and if he is, in his turn, disseised, he can recover the lands by process of law. So, in the law of personal property, one, not the owner, who has the temporary right of possession of chattels (as a pledgee, for example), is said to have "a qualified property" in the goods, giving him certain rights of control and disposition, which could not be lawfully exercised by one who had no proprietary interest. The term "seisin" was originally identical in meaning with "possession," and was applied indifferently to real property and to chattels, but it was ultimately appropriated exclusively to describe the possession of freehold interests in land, the term possession being reserved for chattels and chattel interests. Accordingly, if X, a tenant in fee simple, leases his lands to Y for a term of years and the latter enters and occupies them, there is a double possession; Y is *possessed* of the premises as tenant for years, and X is at the same time *seised* of them by virtue of his freehold.

The two classes of property under consideration differ greatly in the extent and kind of use and enjoyment which are the attributes of ownership of them respectively; but this difference is wholly due to the nature of the subject-matter in each case. As has been said before, the right of property in chattels is in its highest estate absolute and untrammeled. A man may do what he will with his own. But while the right of property in land is unlimited in extent—extending to an indefinite distance below and above the surface—it is nevertheless strictly limited and circumscribed by the physical and social conditions which prevail.

Land, as the seat of man's habitation, is so bound together with and related to all other adjoining land, that to admit an absolute right of property in one man would be to devote his neighbor's property rights to destruction. Hence we have the principle that a man may make only such use of his land as is compatible with the due and reasonable enjoyment by his neighbor of *his* land. In order to enforce this obligation of mutual forbearance the law recognizes three so-called "natural rights" of property: I have a right to require of my neighbor that he shall not by excavations on his own land withdraw the natural support of my land; that he shall not vitiate the air which visits my premises with noxious or disagreeable substances, odors, or noises; that he shall not unreasonably interfere with the watercourse which passes over my land. These are fluctuating rights, however, and vary in degree according to the conditions of life and industry which prevail in the locality, the test of infringement of the property right in each case being the reasonableness or unreasonableness of the act complained of in view of all the circumstances.

In addition to these original and natural limitations on dominion, the absolute right of property is further extensively limited by that numerous class of rights over the land of others known as easements, profits, etc. While these rights are in themselves, as has been explained above,

a species of real property, they are from the point of view of the person over whose land the rights exist, serious limitations on his enjoyment of his own lands.

The principal remaining differences between the two classes of property under consideration display themselves in the mode of conveyance requisite to transfer them, respectively, and in the disposition which the law makes of them upon the death of the former owner intestate. Personal property is still transferred by delivery, so far, at least, as it is susceptible of manual delivery; where this is not possible the transfer is effected by delivery of some evidence of the property or by some writing. The transfer of real property, which passed at common law only by "livery of seisin" (a symbolical delivery of possession), or, in the case of incorporeal hereditaments (see HEREDITAMENTS) by grant, or instrument under seal, is now effected by deed, sealed and delivered. (See DEED.) For the alienation of goods by SALE and GIFT, see those titles.

By the laws of descent and distribution, upon the death of a property-owner intestate his real estate passes at once to his heir, and his personal property into the jurisdiction of a probate or surrogate's court, where its distribution to creditors and next of kin is supervised and effected. This process of distribution is known as the "administration" of the estate, and is carried out through the medium of an administrator appointed by the court. If the decedent leaves a will his lands go directly to the devisee, but the personal property to the executor for distribution according to the terms of the will. See DESCENT and WILL.

The principal modes of acquiring property are considered elsewhere, and need only be referred to here. Under the head of "original acquisition" are included the taking of title to chattels by occupancy or finding, by capture (of wild animals), by confusion and accession, and the acquisition of title to new lands by accretion. The acquisition of title by disseisin and lapse of time is discussed in the articles on LIMITATION OF ACTIONS and PRESCRIPTION. Conveyances, by deed or otherwise, include gifts. Gifts *causa mortis* are a kind of informal will which has been much favored by the courts. (See WILL.) At the present time both real and personal property may be freely alienated by will, though the right to devise real property did not exist at common law. It was created by the Statute of Wills (32 Hen. VIII., ch. i., A. D. 1540). The subjects of descent and distribution are now wholly regulated by statute.

The law of property as above outlined prevails over the whole of North America, except in the State of Louisiana, the Province of Quebec, and the republic of Mexico, where modifications of the Roman or civil law are in force. The states of Central and South America are also governed by codes which are mainly derived from the civil law.

See also articles on FEUDAL SYSTEM, CHATTEL, and REMAINDER. Consult Leake, *Digest of Law of Land*; Washburne, *Real Property*; Schouler, *Personal Property*; Pollock and Wright on *Possession*; and Raleigh's *Outline of the Law of Property*. GEORGE W. KIRCHWEY.

Prophet [from Gr. προφήτης, interpreter, one who declares and explains clearly (πρό). The word is, however, also used to translate the Hebrew *nābi* with its sense of one who has insight into God's mind and reveals it]: he who speaks for another, *proclaimer*, preacher; or one who predicts future events. In the records of all nations from the most remote antiquity there are accounts of men who claimed, and were believed to have, special and immediate intercourse with the Deity. The most remarkable and familiar instances of these phenomena appear in the nations of the East, more particularly among the Hebrews. In the Old Testament they are called נביא, speaker, interpreter—i. e. revealer—of the divine will to man (in no case does it mean predicter of future events), Ex. iv. 16; vii. 1. Comp. חזה, ראֶה, seer. In the earlier ages they appear chiefly as seers (ראה, 1 Sam. ix. 9), leading a contemplative life apart from the world. Apparently about the time of Samuel, with whom the prophetic age begins, they were organized into communities, known as בני אלהים (comp. *Darwîs* of the present day), established in various places under the charge of old and experienced prophets, devoting their time to the study of the sacred writings and ecstatical religious exercises. After the exile all trace of these organizations is lost; the prophets appear separately and at intervals, and from Malachi to John the Baptist there arose no prophet in Israel. The prophets led in the main an ascetic life, supported by the contributions of the charitable (2 Kings iv. 42), by the gifts of those who sought counsel from them (1 Sam. ix. 7; 1 Kings xiv. 3; 2 Kings v. 15, 16 ff.; *ib.* viii. 8), or by fruits herbs, etc., gathered by themselves (2 Kings iv. 39; Matt. iii. 4). Their costume was a mantle of skin (Zech. xiii. 4; 1 Kings xix. 13) girded around the loins (2 Kings i. 8; Matt. iii. 4).

The call to the prophetic office was an inward one from God, but those so called were not at all times in a state of inspiration, nor was this under control of their will. The divine revelations were not received in a state of ecstasy, but in visions or in an elevated though entirely rational condition. The form in which the prophecies were communicated to the people depended entirely on the age and the individuality of the prophet, whether by verbal communication, symbolic actions, which were mostly unreal, or by writings (Isa. xl. ff., and some of the later prophets). The prophets had mainly in view the reformation and elevation of the people, but announced future calamity or deliverance of their own or neighboring peoples as an aid to present guidance. Revised by S. M. JACKSON.

Propion'ic Acid [*propionic* is from Gr. πρῶτος, first + πίων, fat; so called because it is the first member of the series of fatty acids that has oily or fatty properties]: the third member of the series of fatty acids. Its composition is $C_3H_6O_2$. It occurs in the fruit of *Gingko biloba*, in sweat, and in wood-vinegar. Gottlieb, its discoverer, obtained it by oxidizing metacetone, and therefore called it metacetonic acid. It can be made in the laboratory by a number of methods, the most satisfactory being the oxidation of propyl alcohol, to which it bears the same relation that acetic acid bears to ordinary or ethyl alcohol, and formic acid to methyl alcohol. It is a liquid that mixes with water in all proportions. It boils at 140·9° C. IRA REMSEN.

Prop'olis [= Lat. = Gr. πρόπολις; πρό, before + πόλις, city, so called because it is used to close small approaches to the hive]: a resin which the honey-bee collects upon its posterior tibiæ and carries to the hive, where it is used in filling crevices, finishing combs, and the like. In the U. S. it is mainly collected from the buds of the birch, the horse-chestnut, and the balsam-poplar.

Proportion: in mathematics, an equality of ratios, a ratio being the relation, expressed by division, which one quantity bears to another. Four quantities are said to be in proportion when the ratio of the first to the second is equal to the ratio of the third to the fourth. A proportion may be written in either of two ways; thus if the ratio of a to b is equal to the ratio of c to d, the equality may be indicated by either of the following expressions:

$$\frac{b}{a}=\frac{d}{c}, \text{ or } a:b::c:d.$$

Either of them may be read *a is to b as c is to d*. The first and third terms are *antecedents*; the second and fourth terms are *consequents*; the first and fourth are *extremes*; the second and third are *means*. The first ratio is called the *first couplet*, and the second ratio is called the *second couplet*. Two varying quantities are said to be directly proportional when their ratio is constant; inversely, or reciprocally, proportional when their product is constant. But this distinction of proportion does not seem to serve any useful purpose. A continued proportion is an expression of continued equality between three or more ratios; thus

$$\frac{b}{a}=\frac{d}{c}=\frac{f}{e}, \text{ etc., or } a:b::c:d::e:f\ldots, \text{ etc.,}$$

is a continued proportion. The terms of a geometrical progression form a continued proportion.

The following are some of the ways in which proportions may be transformed: (1) The antecedents may be made consequents, and the consequents antecedents; the proportion is then said to be transformed *by inversion*. (2) Antecedent may be compared with anteeedent, and consequent with consequent; the proportion is then said to be transformed *by alternation*. (3) The sum of the antecedent and consequent of each couplet may be compared with either the antecedent or consequent of the corresponding couplet; the proportion is then said to be transformed *by composition*. (4) The difference of the antecedent and consequent of each couplet may be compared with either the antecedent or consequent of the corresponding couplet; the proportion is then said to be transformed *by division*.

The most important principles of proportions are the following: (1) If four quantities are in proportion, the product of the means is equal to the product of the extremes; *con-*

versely, if the product of two quantities is equal to the product of two other quantities, the first two may be made the means and the other two the extremes of a proportion. (2) If a couplet in each of two proportions is the same, the remaining couplets will form a proportion. (3) If four quantities are in proportion, they will also be in proportion by inversion, by alternation, by composition, or by division. (4) Equimultiples of two quantities are proportional to the quantities themselves. (5) In a continued proportion the sum of all the antecedents is to the sum of all the consequents as any antecedent is to the corresponding consequent. (6) If the corresponding terms of two or more proportions are multiplied together, the products will be in proportion; consequently, like powers or like roots of all the terms of a proportion are in proportion. Proportional Representation: See REPRESENTATION.

Proposition: See LOGIC.

Propylite [Gr. *πρόπυλον*, or *τὰ προπύλαια*, gateway]: a name given in 1867 by von Richthofen to certain altered forms of andesites and allied volcanic rocks (formerly called greenstone trachytes), which are greatly developed in the silver districts of Hungary and the Comstock lode (Nevada). The name was selected under the impression that these rocks constituted a distinctive type which ushered in a renewed period of volcanic activity at the beginning of the Tertiary period, after long-continued inactivity in Mesozoic times. These rocks have since been shown by Wadsworth, Becker, and others to be only normal and widely distributed igneous varieties, whose ferromagnesian constituents have been extensively altered to fibrous hornblende, epidote, chlorite, and similar secondary minerals. The name propylite can not, therefore, be regarded as having any petrographic significance except to denote a certain phase of alteration, which may be closely connected with the deposit of silver ores in the regions above named. See Monograph III. and Bulletin No. 17 of the U. S. Geological Survey.

GEORGE H. WILLIAMS.

Prosecutor: in law, one who institutes and carries on a criminal proceeding against another in the name of the government.

In most countries the duty of making a preliminary investigation into the circumstances of an offense, collecting the evidence for trial, and managing the trial of the case is imposed upon public officers. This is the case throughout the continent of Europe. In Scotland there are officers (procurators-fiscal) charged with the duty of instituting criminal proceedings, obtaining evidence, securing the accused, etc.; and in Ireland (where in general the same laws, with slight variations only, prevail as in England) criminal prosecutions are conducted principally by solicitors and counsel who represent the crown.

In England, and in some English colonies, the prosecution of persons for public offenses is left entirely to private persons, or to public officers who act in their private capacity and have hardly any legal powers not possessed by private individuals. Every private person has exactly the same right to institute any criminal action as the attorney-general or any one else, and a private person may prosecute for high treason, a seditious conspiracy, or a libel upon a third person in which he has no sort of interest. Formerly there was no public official whose duty it was to inquire into cases of supposed criminal offenses; but as a matter of fact the duty was undertaken by the police, who in cases of any importance were usually authorized by the superior officers to instruct a solicitor, who in some cases instructed counsel to appear and prosecute. Now, by act of Parliament (47 and 48 Vict., c. 54), the chief officer of every police district is bound to give information to the director of public prosecutions of indictable offenses alleged to have been committed in his district.

When a private person has instituted a prosecution he is usually bound over to prosecute, and when a bill has been sent to the grand jury the matter must take its course (unless the proper court sanctions the withdrawal, or unless the attorney-general enters a NOLLE PROSEQUI, *q. v.*), and the injured party must pay all the costs of the prosecution, unless the court allows him costs, which it may now do in all cases of felony and in all common cases of misdemeanor. This system of prosecution by private individuals, which is the result of historical causes and not of design, while apparently liable to great abuses, in practice is found to work well and to afford a very effectual guarantee of the due observance of the laws.

In the U. S. the system of prosecution by public officers is followed, and private prosecutions, except for petty offenses and in the lowest courts, are almost unknown. DISTRICT ATTORNEYS (*q. v.*) or prosecuting attorneys are appointed by the Federal and State governments to take exclusive charge of prosecutions, oversee the finding of indictments, and conduct the trial for the state. The injured person can do no more than lodge a complaint before the committing magistrate or the grand jury, and thus secure the arrest of the accused for examination and indictment. The public officer may employ private counsel in some instances or surrender the case to them, but they act as his delegates. This is the course of proceedings that generally prevails throughout the U. S. See Stephen's *History of the Criminal Law of England* and Bishop's *Law of Criminal Procedure*.

F. STURGES ALLEN.

Pros'elytes [via O. Fr. and Lat. from Gr. *προσήλυτος*, convert, proselyte, liter., one who has come to (a party); deriv. of *προσελθεῖν*, come to; *πρός*, to, toward + *ἐλθεῖν*, come]: among the post-exilic Jews, Gentiles who conformed to Judaism. The rabbins speak of "proselytes of the gate," who simply observed the seven precepts of Noah; and "proselytes of the covenant," or of "righteousness," who were circumcised, baptized, and allowed all the privileges of the Jews; but Lardner recognized only the latter.

Prosencephalon: See BRAIN.

Proserpina: See PERSEPHONE.

Prosim'iæ [Mod. Lat.; Lat. *pro*, before + *si'mia*, ape, monkey]: a division, usually considered as a sub-order, of the order *Primates*, containing the lemurs, aye-aye, and tarsius. These animals agree with the apes and monkeys in many particulars, but have a considerable portion of the cerebellum not covered by the cerebrum, the lachrymal opening in the cheek outside the orbit, and the orbit open behind. The ears are more or less pointed and turned outward, and without a lobule. The female has a two-horned uterus, and the clitoris perforated by the urethra.

F. A. LUCAS.

Prosobranchia'ta: an order of gasteropod molluscs in which the gills are in front of the heart. It includes the majority of the sea-snails, as well as some of those occurring in fresh water or on the land. See GASTEROPODA.

Prosody [from Lat. *proso'dia* = Gr. *προσῳδία*, what accompanies the song, marks of accent, punctuation, breathings, quantity, etc.; *πρός*, in addition + *ᾠδή*, *ἀοιδή*, song, deriv. of *ἀείδειν*, sing]: a term properly meaning "accent," but including ACCENT, QUANTITY (*qq. v.*), and versification. Here the general principles of versification are treated, the special verses being given under METRES (*q. v.*). This branch of prosody relates to the reduction of speech to rhythmical form. See RHYTHM.

Speech is composed of syllables that are either short, or long, or doubtful. In versification the long is made equal to two short syllables, and the doubtful or "common" may be used either as short or as long. In the treatment of syllables to produce rhythm some special processes arise. In the classic languages hiatus ("yawning" or "gasping" resulting from the concurrence of two vowels) between two words is not allowed except in special cases. It is prevented by elision, or crasis, or shortening (partial elision) of a long vowel or diphthong, or by synizesis (slurring) of two long vowels. Also within a word a short vowel may be slurred with a following vowel. Rarely in Latin *i* receives the sound of y, as *arjete* = – ⏑ ⏑, for *ariete* = ⏑ ⏑ ⏑ ⏑, and *u* rarely receives that of *w*, as *tenvia* (– ⏑ ⏑) for *tenuia* (⏑ ⏑ ⏑ ⏑). Sometimes syllables are lengthened or shortened seemingly for metrical reasons, that is, to make an indispensable word suit the verse; but generally the quantity thus created was in use, though perhaps rare or obsolescent.

Elements of Verse.—As in speech there are syllables, words, clauses, etc., and in music notes, bars, or measures, etc., so in metre there are syllables, feet or measures, cola (clauses or sentences), periods. To the *χρόνος πρῶτος* of rhythm corresponds the mora or short syllable of verse, as the unit of measure. From its name *σημεῖον*, or *σῆμα*, syllables are called monoseme, diseme, triseme, etc., when the number of moræ they contain is one, two, three, etc. Sometimes a syllable was prolonged (by *παρέκτασις*, now usually, but inappropriately, called syncope) to the length of three or more short syllables. Again, a long in certain feet may, as an irrational, serve as a short. Moreover, two short syllables may be used as one irrational, thus having the metrical

value of one short, and a long and a short may have the time of a long. Rests or pauses also occur in catalexis, i. e. at the end of cola or periods. Hence we have the following elements of metre, with their rhythmical analogues (the *χρόνος πρῶτος* being conventionally represented by the one-eighth note or quaver):

Note.	Syllable.	Length.
𝅘𝅥𝅯	⏑	1 mora, monoseme.
𝅘𝅥	–	2 moræ, diseme.
𝅘𝅥.	⏖	3 moræ, triseme.
𝄽	⏓	4 moræ, tetraseme.

Even a pentaseme is mentioned by some. The greater pauses are indicated by the caret (∧) with quantity marks over it, but the monoseme pause by the simple caret. The irrational is indicated by >, two short syllables equivalent to one by ⏑, and a short and a long, equivalent to one long, by –⏑.

By resolution in some metres two short syllables may replace one long, and by contraction one long may replace two short ones.

Feet.—In rhythm the units of time must be marked. In English the accent serves as a mark, while in Latin and Greek the mark is the stress or loudness of long syllables as compared with short. Hence every fundamental foot must contain at least one long and one short syllable. The strong part of a foot was called thesis (*θέσις*, down-beat), and the weak part arsis (*ἄρσις*, up-beat); but some, following Roman grammarians, now interchange these terms.

Feet may be classified (1) according to the ratios between thesis and arsis (*γένος ἴσον*, *γένος διπλάσιον*, *γένος ἡμιόλιον*, etc., for the respective ratios 1, 2, 1½, etc.); or (2) according to the number of syllables they contain; or (3) according to their length as measured by moræ. Adopting the last method there are:

1. *Triseme Feet.*—(*a*) Descending: the trochee ⏑ and its substitutes, the tribrach ⏑⏑⏑, the irrational choree >, ⏑>, the triseme syllable or syncopated trochee ⏖, the catalectic trochee –∧, the cyclic and trochaic dactyls –⏑⏑, –⏑. (*b*) Ascending: the iambus ⏑ and its substitutes, the tribrach ⏑⏑⏑, the irrational iambus > , the irrational choree >⏑⏑, and the cyclic anapæst (perhaps ⏑–, or sometimes ⏑⏑>).

2. *Tetraseme Feet.*—(*a*) Descending: the dactyl ⏑⏑ and its substitutes, the spondee –, the tetraseme trochee ⏖⏑ (?), the tetraseme syllable or syncopated dactyl ⏓, the catalectic dactyl –⏑∧. – . (*b*) Ascending: the anapæst ⏑⏑ and its substitutes, the spondee – and the dactyl –⏑⏑. The proceleus-maticus ⏑⏑⏑⏑, ⏑⏑⏑⏑, is rare, and generally due to corruption.

3. *Pentaseme Feet.*—(*a*) The cretic ⏑ and its equivalents, the first and fourth pæons, ⏑⏑⏑⏑, ⏑⏑⏑. (*b*) The bacchius and anti-bacchius, ⏑, ⏑⏑.

4. *Hexaseme Feet.*—(*a*) Ionicus a minori ⏑⏑, ionicus a majori ⏑⏑⏑⏑, with resolutions ⏑⏑⏑⏑–, etc.; by contraction the molossus –––, and by anaclăsis (*ἀνάκλασις*, breaking up) ⏑⏑ for ––⏑⏑. Otherwise the ditrochæus and the diiambus, –⏑–⏑, ⏑–⏑–, are dipodies. (*b*) The choriambus = trochee or choree + iambus, ⏑⏑. The antispast ⏑⏑⏑ has only apparent existence.

5. *Heptaseme Foot.*—The epitrite (*ἐπίτριτος*, 3 : 4), ⏑⏑–, probably two feet with change of tempo making –⏑ = ––, but usually read either ⏖⏑–– or –⏑–>.

6. *Octaseme Foot.*—The dochmius ⏑⏑⏑, which through irrational syllables and resolutions assumes many forms.

Two short syllables, ⏑⏑, though not a foot, receive the name pyrrhic. Sometimes, in logaœdic verse, a polyschematic (many-formed) foot—the so-called basis—consists of two syllables, either long or short, ⏑ ⏑, or three short syllables.

Measure.—In iambic and trochaic verse, where one ictus or stress is stronger than the other, and in anapæstic verse used in the march, a dipody or pair of feet is the measure, so that a dimeter, for instance, has four feet; in other metres the single foot is the measure.

Colon (*κῶλον*, member), called also clause or sentence.—When a verse contains more than eighteen moræ it is divided into members, each marked by an ictus stronger than that of the ordinary foot. Verses of less than eighteen moræ consist of a single colon, which, however, may be divided into commata (*κόμμα*, section) by cæsura or diæresis.

Period (*περίοδος*, circuit).—Either a single colon or several cola may form a fully rounded rhythmical unit, or period. Such a period is usually a verse, but may exceed the limits of a legitimate verse.

Verse (Lat. *versus*, a turning).—A verse is a period of rhythmical speech, sufficiently short to be perceived as a whole by the rhythmical sense. The ancients limited it to thirty or thirty-two moræ. *Versus* and *στίχος* (line) were both used of lines in prose as well as poetry. When a continuous rhythmical series or period exceeds thirty-two moræ it is usually divided into cola written as separate verses. A true verse is distinguished by its end, which (1) must not divide a word; (2) may end with a vowel when the next begins with a vowel; (3) does not usually allow elision; (4) admits the *syllaba anceps*, that is, a short where the rhythm calls for a long, and *vice versa*; in other words, a verse allows at its end a slight pause not included in the rhythm. Exceptions to the requirements stated are rare, such as the division of a compound proper name (*Ἀριστο | γείτων*) between a hexameter and a pentameter, and elision at the end of an iambic trimeter (*εἶδος Σοφόκλειον*) in Greek, and a dactylic hexameter in Latin.

Cæsura, Diæresis.—When a word ends in a foot the cutting of the foot is called cæsura (*τομή*). It is masculine when it follows the ictus, feminine when it divides the weak part of a foot, ⏑⏑, ⏑ ⏑. When a word ends with a foot there is diæresis (*διαίρεσις*, pulling asunder) or "incision" between the foot and the next one, –⏑⏑–⏑⏑. Every verse of more than one colon has either a "main cæsura" or "verse-cæsura," or else a diæresis between the cola. Both the main cæsura and the diæresis are called simply "the cæsura."

In the following examples (:) denotes masculine cæsura, (;) feminine cæsura, (‖) main cæsura or diæresis, (,) diæresis.

Membranam poscas, scriptorum quæque retexens.
⏑– | ⏑ : – | ⏑ ‖ – | ⏑–, | ⏑⏑ ; ⏑ | ⏑–

Εἰς ὅσον κλύδωνα δεινῆς συμφορᾶς ἐλήλυθεν.
–:⏑ | –:⏑ | –⏑, | – > ‖ –⏑ | –:⏑ | –⏑– ∧

Catalexis (*κατάληξις*, an ending).—A verse whose last foot is incomplete is catalectic; if the last foot is complete the verse is acatalectic. See the verses just cited.

Compound Verses.—Verses may consist of cola in different rhythms. For examples, see METRES.

Combinations of Verses.—Most recited poems of the ancients were stichic, that is, composed by the line. For hypermeters or systems, exceeding the length of a normal verse, see METRES. In elegiac and melic poetry larger units than the single verse were employed, as follows:

1. *Distich.*—The oldest couplet is probably the hexameter and pentameter of elegy. Later distichs are found in Epodes.

2. *Stanza.*—The Lesbian poets introduced four-lined logaœdic stanzas in songs. These were imitated and modified by Roman poets. The most famous are the Alcaic and Sapphic. Stanzas were, and sometimes still are, included under the name strophe. They usually, though not always, contain two or three different forms of cola.

3. *Strophe.*—In choric poetry a group of lyric cola, usually more complex in form than the stanza, was followed by an exactly similar group, the former being a strophe, the latter an antistrophe. (See STROPHE.) Finally, a strophe as an epode was added, so that the great unit became the triad, AA′B, which may be used once, or any number of times, as in Pindar. Sometimes in the drama a still more complex form is presented, the second strophe and antistrophe being unlike the first, the third unlike the second, and so on, thus: AA′, BB′, CC′, etc.; and to such a series may be added an epode.

M. W. HUMPHREYS.

Prosopyg'ii [Mod. Lat., from Gr. *πρόσω*, in front + *πυγή*, buttocks]: a class of worms, embracing the POLYZOA, BRACHIOPODA, and SIPUNCULACEA (*qq. v.*), in which the body may be either long or short, the mouth is surrounded by a circle of tentacles, the alimentary canal doubled upon itself so that the vent is far in front, the body without evident segmentation, and provided with at most but two pairs of excretory organs (nephridia). With the exception of a few freshwater polyzoans all are marine.

J. S. K.

Prosper of Aquitaine: saint; commemorated June 25; b. in the southwest part of Gaul about 400; d. about 463. Little is known of his personal history, but he was certainly only a layman. He visited Rome during the pontificate of Celestine (in 431), and spent perhaps the latter part of his life there in the service of Leo the Great. The earlier part of his life appears to have been spent in Marseilles, where he came in contact with Semi-Pelagianism, and wrote those tracts against it on which his fame now principally rests.

His *Carmen de Ingratis* against the Semi-Pelagians, written about 430 in defense of Augustine, shows him to have been a poet of considerable technical merit. A book of epigrams, over 100 in number, contains theological dicta of Augustine done into elegiacs. He was author also of a *Chronicon Consulare*, in continuation of Jerome, reaching down to 455. The standard edition of his works is by the Benedictines Le Brun de Marette and Mangeaut (Paris, 1711; Rome, 1758); Migne, *Patrol.*, vol. li.

Revised by M. WARREN.

Prossnitz: town; in the province of Moravia, Austria; on the Rumsa; 13 miles by rail S. W. of Olmütz (see map of Austria-Hungary, ref. 4–F). It manufactures brandy, linen, and woolen fabrics, and has a large trade in grain, flax, cattle, and geese. Pop. (1890) 21,192.

Prostate Gland [*pros'tate* is from Gr. *προστάτης*, liter., standing before; *πρό*, before + *ἱστάναι*, stand]: a glandular mass which surrounds the neck of the bladder and urethra in the male.

Pro'tagon [possibly first introduced as an abbreviation of *protagonist*, one who plays the leading part; Gr. *πρῶτος*, first + *ἀγών*, contest, drama]: a fatty compound which, according to Liebreich, its discoverer, forms the chief constituent of nervous tissue. It is prepared from brain-substance, first washed with water and ether, by the action of warm alcohol, in which it is soluble. At the temperature of melting ice the protagon is precipitated from the alcoholic solution, and may be obtained crystallized by further purification and resolution. The composition assigned is $C_{160}H_{308}N_5PO_{35}$. See NEURINE.

IRA REMSEN.

Protag'oras: philosopher; b. about 480 B. C. at Abdera; was instructed by Democritus; lived afterward at Athens, where he was the first who taught philosophy and rhetoric for money, and assumed the title of *sophist*, teacher of wisdom, but was banished on account of his frivolous statements concerning the existence of the gods, and died in exile 411 B. C. His impeachment was, indeed, founded on his book on the gods which began thus: "Concerning the gods, I am unable to say whether they exist or not" (*Diog. Laert.*, ix., 51). None of his works is extant.

Protection: a term in political economy correlative with free trade, referring especially to the relation of legislation to the movement of industry. Free-traders are those who hold that legislation should offer no inducement to capital to take any direction which it would not assume in the absence of such legislation. (See FREE TRADE.) Protectionists hold that situations arise in which the general interest may be best served by offering such inducements. They regard the legislative authority as possessing the right and responsibility of co-ordinating in a general way the industrial growth of the country, and as exercising this rightly to bring up the home production of necessary articles to the home demand.

The issue between the two parties is, therefore, a part of the larger controversy as to the sphere and duties of government. At one time the free-trade policy was advocated on grounds which practically reduced civil government to the functions of the policeman. The reaction against this *laissez-faire* theory in politics has taken the point from many arguments once alleged for the free-trade policy, and it is now defended on grounds chiefly of its economic expediency.

The same division of opinion has appeared in the politics of France, Belgium, Germany, Sweden, Russia, Italy, and Spain. In France the protectionist policy introduced by Henry IV., extended and systematized by Colbert, was exaggerated to caricature by Napoleon in his Continental System, although even that proved of great benefit to the continental industries, especially those of France, Saxony, and Switzerland. The congress of Vienna, by an inevitable reaction, tended toward the free-trade policy, but a few years' experience of it forced a return to protection. The Bourbons restored the policy of Colbert; Germany, under the lead of Prussia, organized the Zollverein, whose moderately protective tariff caused the British to work, through their hold on Hanover, for its dissolution.

The antagonism between the two policies first came into view in the closing quarter of the seventeenth century. In earlier times the protective policy had been accepted by governments generally. Even the Roman empire levied protective duties on imports at its frontier towns. In the Middle Ages, however, the practice was generally the other way, because the dominant interest was agriculture, and the value of manufactures to a country's prosperity was not understood. The contemplation of the wealth of the Low Countries, and its contrast to the poverty of his own kingdom, led Edward III. to take vigorous steps to naturalize the woolen industry in England. He forbade the export of English wool to Flanders, and thus forced the Flemings to bring their industry to his dominions; and he enacted that every Englishman should be the owner of at least one suit of English-made woolen. The striking success of these measures, which laid the foundation of England's manufacturing system, led to the prohibition of a list of imports which was enlarged in successive reigns. It was in Queen Elizabeth's time that these prohibitions were converted into duties on imports, and thus became a source of national revenue. Henry IV. of France, Gustavus Adolphus, and Cromwell made notable and successful use of the same methods, which grew in favor with the rise of national feeling in their time.

The discovery of America exercised a profound influence on the economic condition of Europe through the rapid inflow of gold and silver from the Spanish possessions. Since the reign of Augustus there had been no substantial addition to the supply of these metals in European circulation, and industry of every kind felt the constriction produced by a growing scarcity of the instrument of association and of exchange. Within the four centuries after Columbus the European supply was increased thirty-fold (Humboldt), and the effect was even greater than that of European colonization upon America. Harbors were constructed, rivers bridged, great exploits of engineering were executed, the cities filled with splendid structures, the country better tilled, and manufactures took an impetus of growth never seen before. These results led to economic study into their cause, and the best means of extending them. Hence the rise of the mercantile school of economists, of which Colbert, John Locke, the Abbé Galiani, Sir James Steuart, and the banker-statesman Necker are the best representatives. (For the principles of this school, see the article POLITICAL ECONOMY.) They saw palpable evidence that the possession of an abundance of money was one of the surest means of national prosperity, and they planned, by means wise and otherwise, to secure its inflow and prevent its outflow. Some advocated the free-trade policy as the best and surest means to this. Most, however, held that the protection of manufactures by making a country independent of others for necessary articles, and furnishing it with those it could sell its neighbors, was the surest way of bringing in money and keeping it at home. This policy was often called Colbertism, after the great French statesman.

In France in the first half of the eighteenth century the school of economists known as Physiocrats, whose leading representative was Quesnay, asserted that agriculture is the only source of wealth, and therefore opposed the protectionist policy. Adam Smith, in his *Inquiry into the Nature and Causes of the Wealth of Nations* (1776), gives evidence of having studied in this school and of having gone beyond it. He enunciated for the first time the free-trade doctrine in its modern shape as a principle of "natural liberty." He holds that when every man is left "free to do what he will with his own," he will do that which will be most beneficial to society. An assertion so broad as this could not, of course, be derived from observation. Dr. Smith bases it on what he regards as an axiom of natural religion, viz., that the highest social well-being must result from the freest exercise of that principle of self-interest which our Maker has implanted in each of us.

The teachings of the *Wealth of Nations* were gradually absorbed by the educated classes of Europe and America, although they did not pass unchallenged. Hence the rise of free-trade parties on both sides of the ocean, especially in England, where the industrial situation favored an experiment of this kind. The destruction of the small farmer class, the comparative neglect of agriculture, and the immense development of manufactures, prepared the way for a combined and successful attack on the corn-laws as tending to keep up the cost of factory labor without enabling the country to feed its own people. Since their repeal in 1846 England has been the leading champion of the free-trade policy, but only after having pursued the other successfully for more than five centuries.

For the first thirty years after the adoption of the U. S. Constitution there was substantial agreement among public men in the support of protection. The colonies from

the outset had tried to establish all the industries known to the mother country. Their own circumstances, but especially the repressive enactments of the British Parliament, had prevented their manufacturing extensively. Yet they observed that in the case of articles which could not be imported cheaply, such as stoves and hollow-ware, farming was greatly benefited by the neighborhood of these home industries. This was re-enforced by the experiences of the war for independence, when the country, and especially the army, suffered dreadfully through the cessation of the supplies of goods from Europe. The industries which sprang up to meet this need were crushed after the peace, because the national Government had no power to protect them. It was this more than any other circumstance which forced the adoption in 1789 of a more perfect form of government "to provide for the common defense and promote the general welfare." President Washington and Alexander Hamilton, as Secretary of the Treasury, pressed the policy upon Congress, which legislated expressly for this purpose, keeping in view the need of manufactures as an element in national defense. It was not until the failure of the well-meant but fatally defective tariff of 1816 that the antagonism over this question became an element in U. S. politics. The Southern States had owed to the protective policy the establishment and development of their cotton-growing. They supported that policy so long as they cherished the hope of becoming a manufacturing region, or found in the Northern cotton-mills the only open market for their staple, which Great Britain taxed in the interest of her East and West Indian cotton-growers. When their hope of manufacturing proved futile, and Great Britain in 1832 repealed the import duty on U. S. cotton, the South changed front. Then came the great alliance of the U. S. cotton-grower with the British cotton-spinner, which supported the free-trade policy in both countries. The first free-trade tariff, that of 1835, had such effects as to provoke a protectionist reaction, which resulted in the tariff of 1842. Four years later the repeal of the British corn-laws re-enforced the cotton-planter interest by the support of the Western wheat-grower. The result was the mongrel tariff of 1847, carried by the casting vote of Vice-President Dallas, and further reduced in 1857.

The withdrawal of Congressmen from the Southern States in 1861 left Congress in the control of representatives and Senators from States interested in manufactures. The Morrill tariff of that year, signed by President Buchanan, marked a return to the earlier policy of the republic, and was framed as much in compliance with the demands of national defense as of economic theory. It was feared that the war for the Union would involve the U. S. in war with Europe, where the South had many friends. To leave the republic dependent on Europe, therefore, for staple commodities of any kind would be to invite attack, and the increased duties would bring a larger revenue so long as commerce was uninterrupted. The policy thus adopted has now (1894) continued for over thirty years, with the result of placing the U. S. among the foremost of industrial nations, a chief producer, and by far the greatest consumer of great staples like cotton and woolen goods, iron and steel, with a *per capita* average of national wealth surpassed only by Great Britain.

In the middle of the nineteenth century, Great Britain—in the words of *The Saturday Review*—became the propagandist of "a new religion, made up of free trade and the pleasanter parts of Christianity." The commercial treaty negotiated with Napoleon III. by Richard Cobden came quickly after the reduction of the U. S. tariff to almost a free-trade footing, and Cavour's free-trade experiment in Italy. Germany in 1864 made reductions in her Zollverein tariff which carried her in the same direction. Only the reaction in the U. S. darkened the prospect of universal free trade; but the example of the U. S. and still more experience at home have carried all these countries back to their former policy, which has come into favor also with the autonomous colonies of the British empire. The French Republic hastened to denounce the Cobden Treaty, which Napoleon never had dared to submit to the judgment of his Corps Législatif. Bismarck in 1879 carried Germany back to the earlier policy of the Zollverein, alleging the astonishing success of the U. S. under protection as his justification. Canada the same year became protectionist by a popular reaction, following the example of Victoria, and to be followed in its turn by other colonies. As *The Times* has said, a wave of protectionist sentiment seemed "sweeping round the world," and in Great Britain itself a small party demands a return to protection in the interest of agriculture.

As in so many other cases, the practice of protection to home industry antedates the theory, and the theory itself has taken different forms according to the environment of the thinkers who have elaborated it. These forms, which may be distinguished as four, are not antagonistic, but mutually corroborative.

I. The mercantile school generally defended the protectionist policy in view of the industrial use and the international circulation of money. Seeing that the increased supply of this instrument of industrial association had resulted in a rapid and great development of productive industry, furnishing employment to idle people, bringing neglected resources into use, raising the standard of comfort, and making the collection of an adequate revenue an easy thing, they insisted that a "favorable balance of trade" was an object of national policy. No country could safely import to a larger extent than it exported, and if its imports fell below its exports, so that it drew upon its neighbors' reserve of coin in payment of the difference, so much the better. To this end the development of manufactures and the checking of imports by duties (or even prohibitions) were desirable means. The former enabled the country to sell more; the latter insured its buying less.

It was also found that it was hard, if not impossible, for a country to maintain a favorable balance, unless it were possessed of a body of shipping to carry on its own commerce. The surplus of exports would be swallowed up in paying freight to foreigners. Hence the navigation laws enacted under Oliver Cromwell, re-enacted by the first Stuart parliament, copied by the U. S. in Washington's first administration, and maintained by Great Britain until 1850. These laws confined the ships of foreign countries to bringing in the produce of those countries and their colonies and dependencies, and levied tonnage taxes on these ships in British harbors. Thus the British destroyed the monopoly of the carrying trade previously enjoyed by the Dutch; and thus the foundations were laid first of the British, and then of the U. S. mercantile marine.

This theory of protection rested entirely upon observed facts as to the use and functions of money, made during a period particularly favorable for such observation. It was in a different period that Hume and Turgot put forward a theory of money calculated to undermine it. In their view, money is merely a standard of value and an instrument of exchange, and exerts no definite and permanent influence upon production. An addition to a nation's supply of money could be of no lasting benefit to its industries; and the diminution of that supply could not harm them. The only real effect of an increase must be to raise prices; of a decrease, to lower them. The drain of money from a country would thus make it "a good place to buy in, and a bad place to sell in," as prices would fall. An influx of money would make it "a bad place to buy in, but a good place to sell in," as prices would rise. In the former case foreigners would bring coin and take away goods; in the latter, bring goods and take away coin. In each case the balance would be restored, "all things would find their level." In fact, the wiser point of view was to regard money as "a commodity like any other," and to treat its export or import as a matter of indifference to the nation. If it went abroad, it must be to secure in exchange commodities for which the country had greater demand, and adapted to meet human needs more directly.

This theory, which obtained the support of Adam Smith's school and holds its own even in the school which has displaced his, did not rest on observed facts. No case has ever occurred which conforms even remotely to its diagnosis of the results of an export or import of money. Nowhere do we find this lowering of prices as a result of the diminution of a country's supply of coin, or this beneficent reaction which restores the supply. The case of Portugal under the operations of the Methuen Treaty (1703), and of Japan under the treaties of 1868, signally refute the notion that "things find their level" in this easy way. Tooke and Newmarch, in their elaborate and irrefutable *History of Prices*, have proved that in Great Britain itself the fluctuation of prices has not corresponded to the fluctuation of the currency in this mechanical fashion. The common sense of the business world also has rejected the notion that "gold is a commodity like any other." Every great emporium of trade watches the export of it as a calamity, and uses all the means available to check it and to set the current moving in the opposite direction.

Prof. Stanley Jevons complains that the money articles of the London newspapers are "steeped in the mercantile theory."

The theory that money is merely an instrument of exchange and a commodity like any other failed as a diagnosis of the industrial movement because it was defective fundamentally. Money has a far more important function as the instrument of industrial association. It was this fact of which the mercantile school were conscious. In his *Growth of English Industry and Commerce* (London, 1894) Dr. W. Cunningham gives a much juster view of their aims and achievements than has been current. Under their guidance, one of his English reviewers says, "English statesmen strove to build up shipping, industry, and agriculture. They succeeded in their aims, and made England mistress of the sea and the workshop of the world."

II. The nationalist school of protectionists arose in the new awakening of national feeling in the revolt against the imperialism of Napoleon. Its first and most extreme representative was the philosopher J. G. Fichte, who proposed to confine foreign commerce strictly to the exchange of the products of different climates. Friedrich List, the founder of the German Zollverein, is its best representative, but it was substantially the point of view occupied by the earlier American statesmen. In this view nations are industrial no less than political units, and national boundary lines are economic boundaries also. Industrial power and independence are essential to political power and independence. National industry is one of the forms of national wealth, and is as much entitled to protection as is any other. This principle is implied in all the relations of peoples to their governments. They demand of their rulers not only an efficient police, which shall keep men's hands out of their neighbors' tills or pockets; they also hold them responsible, though less directly, for the general welfare of the country.

The duty thus imposed upon government is discharged only by promoting a full and balanced development of the industries needed for the largest industrial life each people is capable of, and securing the employment of all the resources offered by national character and natural environment. Experience, however, shows that the countries already in possession of profitable foreign markets for their products have the means and the will to resist the establishment in other countries of industries which would deprive them of these markets. This they do by selling for a time at cost, or even below it, often making great sacrifices to crush out incipient competition, and then recouping their losses by higher charges when they have the market to themselves. John Stuart Mill points out that under these circumstances it can not be expected that individuals should, "at their own risk, or rather to their certain loss, introduce a new manufacture and bear the burden of carrying it on until the producers have been educated up to the level of those with whom the processes have become traditional." By enacting a protective duty on the import, the nation assures the undertaker of a new industry against unfair competition, and enables him to overcome the grave initial disadvantages of such enterprises. By this means the people are lifted out of that uniformity of occupation which always keeps them poor and frequently exposes them to famine. Living in this uniformity they have few of the interchanges of commerce with each other. The great lines of commercial intercourse run all to the seaboard or the frontier to meet the foreign trader and his agents. So before the civil war the great railway lines of the U. S. ran to the Atlantic seaboard. They were the warp without the woof of a great national system. In Germany, the removal of all custom-house lines to the frontier and the establishment of free trade within and protection without the Zollverein is recognized to have been one of the great promoters of German unification. Hence the eagerness of Austria to obtain admission, and the successful efforts of Prussia to exclude her.

The second public interest is national defense. A country which can not supply from its own industrial resources the outfit of an army, and can not thus meet the needs of its people during the suspension of foreign commerce commonly attendant on war, is in a position to invite attack from those which are better situated. The war for independence found the British colonies in North America at a great disadvantage in this respect. They had a poor supply of arms and gunpowder, without the materials needed for tents, clothing, and shoes. The blood which marked the tracks of the men on the wintry roads, the terrible suffering from nakedness and frost in the Valley Forge encampment, were the fruit of the nation's industrial dependence and gave point to Washington's exhortations to Congress to put the country in a position to defend itself by cherishing its own manufactures. Yet the war of 1812–15 found the republic nearly as ill-fitted for a great war, there being neither tents nor gunpowder nor blankets in any adequate quantity. The sufferings of the soldiers and even their defeat in the first years of the struggle were due to this in large measure. (See Horace Bushnell's article in *Hours at Home*, July, 1870). In the civil war the Southern States were at a great disadvantage in this respect, as their dependence on slave labor had resulted in their securing hardly any manufacturing industry as the outcome of the protective tariffs of the U. S. Jefferson Davis congratulated the Confederate Congress on the growth of a few manufactures, and if the Confederacy had achieved its independence, it probably would not have been able to abide by the free-trade provisions of its constitution.

It is notable that whatever tends to awaken a strong sense of nationality tends also to the protectionist feeling about national industry. All the periods of strong national feelings have been periods in which the policy of promoting home industry by collective action has been popular. On the other hand, periods of decay in this feeling have been the free-trader's best opportunity. Richard Cobden was quite right, from his standpoint, in regarding nations as necessary evils, and wishing all boundary-lines effaced from the map of Europe.

III. What may be called the biological school of economists was founded by Henry C. Carey, of Philadelphia. He points out that at the starting-point of economic development man is isolated and feeble, his first need being association with his fellows for the conquest of nature. Until he attains this he is occupied with a struggle for bare existence. With the growth of numbers and of association this struggle becomes easier, and sets some free to provide for less primary but not less real wants. Hence the rise first of the artisan or manufacturing class, and afterward of classes which serve the intellectual needs. At each step onward production grows faster than numbers, nature rewards more largely the toils of her conqueror, and the share of each individual in the joint product increases. At the same time the industrial order passes from its primitive simplicity to one of constantly increasing complexity through the growth of association. In the earlier stages in the development, when population is still scanty and the different classes of producers are separated by distance, a check to the freedom and the profit of their exchanges is offered by the power of the trader, who is able to levy a heavy tax on production. With the increase of population in density the artisan and the farmer naturally come into closer neighborhood, so that they can exchange their products directly, if necessary, and thus dispense with his services. Wherever this result is not attained, and commerce in the necessaries of existence continues to be transacted at long distances, the trader still reaps a high profit at the expense of the producers. Especially the farmers and other producers of raw materials suffer from the necessity of having to pay the cost of carrying their bulky products to distant markets; and farming suffers in quality through the forced monotony of its cropping, and the loss of opportunities to make returns to the soil, which the neighborhood of manufactures offers. The farmer so situated is constantly injuring a valuable instrument instead of improving it. This, however, must be the result of some obstacle to the operation of natural law, interposed by the selfishness of peoples or of individuals, or by the currency of false theories. To remove obstacles of the former class is the work of the statesman; of the latter class that of the economist. The power of highly developed nations to check the industrial growth of those less advanced than themselves he was obliged by the evidence of facts to recognize. That power he would check by legislation to lay duties on imports, not in order to contravene natural law or find a substitute for it, but to remove an obstacle to its operation. He thus held strongly to the conception of natural economic law, which the current reaction against the abuses of that conception has thrown out of vogue for a time.

IV. Among protectionists there has been a tendency to treat the development of domestic industry in this way as a branch of the great social problem, which presses upon us from all quarters. The policy is defended as securing juster and more adequate remuneration to the laboring classes of the U. S. George Gunton and Erastus B. Bigelow might be regarded as representatives of this view. It can not be as-

serted, of course, that a protective tariff works directly to raise wages. It contains no specifications to that effect. Where it secures the producer a fairer price for his product it does not provide that part of the difference between this and the lower price he would have got under free trade shall go to raise the wages of his workmen; but its indirect operation does raise wages, and has done so in America, France, and Germany. One reason of this is that the demand for labor more nearly approaches the supply in countries of diversified industry than in those where there is but one kind of employment. Another reason is seen in the fact that agriculture calls for little else than unintelligent and ill-paid labor, while manufactures demand intelligence and skill, and must pay for them.

It has been rightly indicated by Francis A. Walker that the public opinion of a country plays a great part in determining the rate of wages. In aristocratic countries this works to the disadvantage of the working classes, as requiring that they shall "know their place," and be content with such a standard of living as social tradition permits them. In democratic countries, like the U. S., the same social force works to elevate the standard of comfort for the working classes, requiring that all citizens shall be housed, clothed, and fed in a manner becoming their place as a part of the sovereign people. This, however, would be impossible in the absence of all restrictions on international commerce, as the products of depressed labor, if freely admitted to the markets, would make it impossible to pay home labor at a properly American rate. The difference between the rates of the U. S. and those of Great Britain is shown by a report of the Massachusetts Bureau of Labor Statistics for 1884, which also proves that the tariff does not "take from labor with one hand"—in prices—"what it gives with the other"—in wages. In the industries pursued both in Great Britain and Massachusetts the average of wages was 62 per cent. higher in the latter, while the cost of living was but 17 per cent. higher, and of this 11 per cent. was due to the higher outlay for housing, leaving 6 per cent. for the higher cost of food, clothing, etc. The standard of living, the report shows, was 50 per cent. higher in Massachusetts. If the U. S. workman chose to live as the British workman does, he could save three-eighths of his income, while the British workman can save but 2 per cent. That this difference is not due to the abundance of land open to settlement, or other local advantages peculiar to North America, is seen from the wretched condition of laborers in the U. S. in the earlier decades of the history of the nation, as Prof. Macmaster describes this in the first and second volumes of his *History of the People of the United States*, and Matthew Carey in his *Letters on the Charities of Philadelphia* (1829). It is rather due to the more favorable conditions for the operation of public opinion which the protective policy has created, especially during the last thirty years. The census of 1880 showed that the average wages of the skilled workman in the U. S. had risen in twenty years from $460 to $720 a year, while the price of all the staple articles he buys had fallen at a rate varying from 26 to 46 per cent. In fact, the wages of 1880 had about twice the purchasing power that the wages of 1860 had, and the census of 1890 showed that this advance had been sustained, both in the rise of wages and the cheapening of commodities.

It is not necessary, however, to the vindication of the protective policy to show that in no case is the price of an article higher to the workman than it would be under free trade. To "buy in the cheapest market and sell in the dearest" is good policy only when you are sure of having a good market to sell in. It is not a question, especially for the workingman, merely of the price at which he is to buy what he needs, but of the relation of that price to his wages. The immense immigration of European workmen to share what free-traders call the "burdens of protection" is a practical comment on the workings of the system.

The protective policy finds an exact parallel in the laws to prevent the importation of coolie and contract labor into the U. S. There would, however, be no justice in excluding such laborers if the products of their labor were admitted freely. It would be grossly unfair to compel the American employer to hire his labor in a close market and sell his product in an open one. The abandonment of the protective principle would carry with it, as in Great Britain, the removal of all restrictions on the importation of labor.

Objections brought by the Free-trade School against Protection.—1. The first is that "protection is an artificial system, like the forcing of plants in a hothouse. It creates a mushroom growth of industries, which are unable to stand the free open air of competition, and which, by their constantly increasing demand for higher duties, show that they become weaker instead of stronger with the lapse of years. Free trade stands for the principle that a thing shall keep its place by the vitality it possesses, and not by governmental support or bolstering of any sort."

Protection is artificial in the sense in which clearing away the forests, inclosing and reclaiming farms, building houses, constructing roads, canals, and railroads, and educating the young are artificial, but in no other. To seek the establishment of industries for which the abilities of the people, the resources of the country, and the climatic conditions are all favorable, is to move on the lines of natural law.

That industries thus established by the aid of protective legislation will not attain the vigor which secures their permanence is an assumption contradicted by nearly every page of the world's industrial history. The silk-manufacture of France, the woolen, iron, and cotton industries of Great Britain, the linen industry of Ulster, the cotton-growing of the U. S., are striking instances of well-established industries which owe their very existence to protection. It would be difficult, indeed, to point out a single great manufacture which is now competing for the markets of the world that did not make its beginning in the same way.

That protected industries demand ever higher rates of duty is not the truth. It is true that in some cases such industries have made a start under a protection, which experience proves to be inadequate, and which has to be increased. It is true also that the facilities for cheap transportation in other cases have so altered the conditions of trade as to make the earlier duties ineffective; but in every case there is reason to expect a gradual reduction of protective duties, and finally their abolition with the consent of the manufacturers themselves. The former is illustrated by the successive reductions of the duty of the U. S. imposed on Bessemer steel and other articles; the latter by Great Britain's adoption of free trade after a long course of protection.

2. It is objected that "protection is an anti-social policy, seeking the good of classes at the expense of the people at large. It aims at making certain commodities dearer for the benefit of their producers, who constitute only a class in a community, while the interest of the consumer is always in cheapness, and the consumers are the whole community." The object of protection is not dearness, but to bring up the home production of some important staple to the measure of the national demand. In no case is the increase in price a permanent one, unless the conditions are such as to forbid the development of that line of production up to the national demand, as in the case of the duties on sugar imported into the U. S. In such cases the application of a protective duty is a questionable measure. Moreover, the interest of "the consumer" is not separable from that of "the producer." An illustration of this is the condition of the consumer in "hard times." Abstractly considered, he is well off, but the actual human beings who consume find those times not at all to their liking. It is not necessary that every form of production should be protected in order that all may share in its benefits. It is the freedom of the laboring men to choose between the protected and unprotected industries that puts up the wages paid them.

3. To much the same effect, protection is challenged as "a scheme of taxation" which enables the producer to levy a tax on the whole community for his private benefit. So much of a protective duty as falls upon the imported article goes into the public treasury; but a tax of the same rate is levied also upon the home-made equivalent by its maker, and goes into his pocket. The duty is added to the price, and the tariff is a tax.

A tariff duty generally secures its end by offering a special inducement to capitalists to turn their capital into that line of production. It offers them a chance of profits above the average, and a certain security in possession of their market. In the earlier stages of the manufacture these hopes are fulfilled; but profits above the average rapidly attract other capital, and domestic competition for the market pulls down prices to the level which permits of an average profit. At no stage can the home producer "add the duty to the price" simply. To do so would be to forego the advantage the duty offers, and keep the market open to his foreign competitor. Besides this, the foreigner commonly prefers to forego a part of his former profits rather than lose his hold.

on the imperiled market. The profits of the home manufacturer therefore are limited both by the amount of this sacrifice of profits by the foreigner and the margin needed to give his own product an advantage in price. Even this, after a time, is cut down by the rise of domestic competition, as McCulloch and other free-traders admit: for in no line of production that is not guaranteed by a patent or some similar monopoly can profits remain above the average for any length of time. It is noteworthy that very few of the great fortunes in the U. S. have been made in manufacturing. On the other hand, as Mill points out, the transfer of an industry to an entirely new set of conditions is generally attended by great improvements of method, which tend to reduce the cost of that product to the country and ultimately the whole world. This was seen in the establishment of the cotton-manufacture in Great Britain and of cotton-growing in the U. S. In the same way protection in the U. S. has led to the improvements which have cheapened cutlery, silks, earthenware, Bessemer steel, cottons, nails, and many other staples to all consumers.

4. It is objected that "protection is a wasteful use of a country's capital, since it diverts it from the more profitable into less profitable lines of production." No country can produce more than it has the capital to undertake; but no country has attained the amount of production that it has the capital for. The establishment of new industries by protection is effected not so much by a diversion of active capital into new channels as by awakening dormant capital to flow in them. It is not safe to assume it is always worth while for some individual to do whatever it is the common interest to have done. This assumption of the absolute identity of private and public interest is untrue in many matters. The destruction of the forests of the U. S. is illustration sufficient. So a country may have need of new industries which no person would find profitable to initiate.

5. It is objected that "protection is hostile to commerce. It seeks to destroy that division of labor among the nations by which each produces what it can to the best advantage, and exchanges this with what the others produce in similar circumstances. It aims at making every nation self-contained and self-sufficing, by fostering on its soil even those kinds of production for which it has less fitness, and refuses to allow it to benefit by the natural advantages of the rest. It is typified by the great Chinese wall, built to restrict intercourse to the utmost with all the neighboring states. If it were consistent, Bryant once objected, instead of digging harbors it would fill them up, would grow tea, coffee, and spices under glass, and make imports to cease altogether."

Commerce, as protectionists understand the word, is the interchange of services and productions between persons of different industrial function, whether these are of the same or of different countries. The protectionist policy certainly aims chiefly at the development of domestic commerce. To this end it seeks to secure the greatest possible diversification of industrial function at home. Protectionists hold, with Adam Smith, that this home commerce, "the trade between town and country," is by far the most profitable to the country. They see in its extent and prosperity the truest test of national well-being. They deplore the wretchedness of those countries in which uniformity of occupation prevents this commerce, as in Ireland, India, and Japan since the treaties of 1868. Their people are thus unfitted to render industrial services to each other. Foreign trade flourishes at the expense of commerce at home.

Protection not only favors the freest development of trade at home, but cherishes the freest trade with foreign countries in those products which can not be produced at home. It forbids such duties on tea, coffee, spices, and the like, as make up the schedules of the tariff of free-trade countries like Great Britain and Norway. It thus favors the commerce which moves along the meridians, exchanging the products of different climates. On the same principle it fosters the commerce which grows out of different industrial capacity. By its preference for specific duties—a preference also shown by Great Britain, but not by the free-traders of the U. S.—it favors the exchange of the more valuable and highly elaborate products, which represent the best-trained productive capacities of sister nations. At the same time the policy fits the country to supply its less developed neighbors with manufactures they are not capable of making for themselves, as well as farm products not produced in their climates. In this way the tariff law of 1892 secured the U. S. twenty-four reciprocity treaties which gave special advantages to its commerce in return for the free admission of sugar and other tropical or semi-tropical products, an advantage which was abandoned by levying a revenue duty on sugar in the much less protective tariff of 1894. The fields the protectionist policy thus leaves open to foreign commerce are so extensive that the progress of the U. S. has been as rapid in this department as that of any of its rivals since 1864.

Bryant's illustration suggests the question whether, on his principles, government should create or maintain harbors. If it has nothing to do with industrial development, as free-traders contend, why should it concern itself about commerce any more than manufactures? He once admitted his inability to justify the construction of the Erie Canal by the State of New York, instead of leaving such work to private enterprise; why not leave the harbors of New York and Liverpool to the private enterprise of the ship-owners and commercial firms, and trust to the identity of private and social interest in this matter, as in the growth of manufactures?

6. "The protectionist policy has driven the U. S. flag from the ocean by making it costly to build ships in U. S. dockyards and by refusing leave to the people of the U. S. to buy them from the ship-builders of other countries." Statements of this kind are still current, but the only fragment of truth in them is that the higher wages paid under protection makes it costlier to build ships in the U. S. The decline of ship-building in the U. S. began under the tariffs of 1847 and 1857. It was begun by the withdrawal of subsidies to steamship lines in 1855, at a time when all rival countries were paying them. It was accelerated by the civil war, which cost the loss of many vessels, caused the transfer of others to foreign registration, and checked the building of merchant ships. To remove all complaints on that score, protectionists enacted the admission of ship-building materials free of duty, but without any marked result. They did not place shipping inside the protective system, as was done in Washington's time with the best result. They left the merchant marine absolutely to the chances of free trade, charging foreign vessels with neither tonnage dues nor lighthouse dues, nor discriminating duties on their cargoes, while they left them free to bring in the produce of all the world. Citizens of the U. S. are free to buy and own ships of foreign build to any extent they please, as they are refused nothing but U. S. registration, and are exempted from the specially severe requirements of the laws of the U. S. as to the care to be taken of its seamen. If ship-building and ship-owning have declined in the U. S., this has been chargeable not to protection, but to free trade.

7. Protection is charged with being "a selfish policy, in that it leaves out of account the well-being of all countries but one, and teaches its people indifference to the depressions of trade and loss of markets which it may inflict upon other peoples."

Protection is distinctly a less selfish policy than is free trade, which teaches each individual to regard simply his own self-interest as a consumer and to practice entire indifference to welfare of the producing classes. Protection is a declaration of national interest in the welfare of the laboring classes, while free trade tells them they must shift for themselves. As *The Spectator*, a strongly free-trade paper, said in 1884, "Protection appeals to men on the side of their duties, free trade on that of their interests." As to the injury done to other countries by a shift of markets, that is not chargeable to the protective policy. A market which can exist only so long as other countries fail to produce that article for themselves must result from a bad economic management in the country affected, and the total of the injuries thus inflicted is trifling compared with those inflicted by free trade on Ireland, India, China, Japan, and in the U. S. in 1783, 1817, 1837, and 1857. (On this point, see Kirkup's *Study of Socialism*.) The ultimate object of the protective policy is the maximum of national life throughout the world, through each nation attaining the largest measure possible to it. Besides, the best the U. S. can do for the working classes of other countries is to establish and maintain the highest possible level of comfort for itself. Thus it will furnish them the best fulcrum for raising their own condition and beating down the social prejudices against them.

Of works on the protectionist's case, the most important are the Abbé Antonio Genovesi's *Lezioni di Commercio* (Naples, 1757); the Abbé Ferd. Galiani's *Dialogues sur le Commerce des Blés* (Paris, 1770); Jacques Neeker's *Sur la Législation et le Commerce des Grains* (Paris, 1775) and *Éloge*

de Colbert (Paris, 1773); Alexander Hamilton's Treasury Report for 1791; Matthew Carey's *The New Olive Branch* (Philadelphia, 1820); John Rae's *New Principles of Political Economy* (New York, 1834); Willard Phillips's *Propositions concerning Free Trade and Protection* (Boston, 1850); Henry C. Carey's *The Past, the Present, and the Future* (Philadelphia, 1848), *The Harmony of Interests* (Philadelphia, 1851), and *System of Social Science* (Philadelphia, 3 vols., 1858–59); Friedrich List's *National System of Political Economy*, with introduction by Stephen Colwell (Philadelphia, 1856); E. Peshine Smith's *Principles of Political Economy* (New York, 1853); Francis Bowen's *Political Economy applied to the Condition and Institutions of the American People* (Boston, 1884); Judge Byles's *Sophisms of Free Trade* (London, 1849; 10th ed. Philadelphia, 1872); Andrew W. Young's *National Economy: a History of the American Protective System and its Effect on the Severat Branches of American Industry* (New York, 1866); Dr. Friedrich Stoepel's *Freihandel und Schutzzoll* (Frankfurt, 1867); Sir Edward Sullivan's *Protection to Native Industry* (London and Philadelphia, 1870); David H. Mason's *How Western Farmers are benefited by Protection* (Philadelphia, 1875); Henry M. Hoyt's *Protection versus Free Trade* (New York, 1886); R. W. Thompson's *History of Protective Tariff Laws* (New York, 1888); Henry V. Poor's *Twenty-two Years of Protection* (New York, 1888); R. E. ROBERT ELLIS THOMPSON.

Proteids: See ALBUMINOIDS.

Proteine [from Gr. *πρῶτος*, first]: a term applied by Mulder to a product of the metamorphosis of ALBUMINOIDS (*q. v.*), which is produced by the action of caustic potash, and which he believed to constitute the basal molecule of all the proteids, whence the name. Its formula, according to him, is $C_{36}H_{26}N_4O_{10}$. Although this theory is obsolete, the name *proteids*, being very convenient, remains still in use.

Proterozoic Era [Gr. *πρότερος*, earlier + *ζῷον*, animal]: the earliest of the great divisions of geologic time based on life. The co-ordinate succeeding divisions are Paleozoic, Mesozoic, and Cenozoic, and the Proterozoic era was theoretically preceded by an Azoic or lifeless era. No faunas and floras of this era have been discovered, and only a few traces of organic forms. The life of the Paleozoic periods is shown by fossils to have been varied and highly organized, and, in accordance with the doctrine of evolution, it is inferred that long periods were necessary for its development. It has been suggested that a full record of Proterozoic life has not survived because the animals of that period were pelagic, rather than littoral, and were not furnished with shells and other hard parts. Consult Bulletin 86 of the U. S. Geological Survey.

G. K. GILBERT.

Protest: See BILL OF EXCHANGE and NOTARY PUBLIC.

Protestantism [from Lat. *protes'tans*, pres. partic. of *protesta'ri*, declare in public, bear witness; *pro*, before, forth + *testa'ri*, to witness, deriv. of *tes'tis*, a witness]: the religious tenets of Protestants; the liberal influences and tendencies of the Protestant movement. This began with the second Diet of Spires (Speyer), when the Lutheran members of the diet, on Apr. 25, 1529, *protested* against the action of the Roman Catholic members in condemning the innovations Luther had introduced, and in forbidding, on pain of the imperial ban, any further reformation until the meeting of the general council promised for 1530 by Charles V. and the pope. (See REFORMATION.) This protest was a renewal and expansion of Luther's at Worms, Apr. 17 and 18, 1521. At the suggestion of the Landgrave of Hesse a protest was also made against the diet's repudiation of the Zwinglian doctrine of the Eucharist. (See Gieseler, *Ecclesiastical History*. The term Protestantism as used to-day, however, has the broader meaning of opposition to the Roman and Greek Catholic Churches. Protestants oppose the Roman Church chiefly because it (1) raises tradition to the level of Scripture as source of doctrine; (2) denies justification by faith alone; (3) makes the pope the spiritual ruler of the entire Christian Church. The first two counts hold against the Greek Church, but, because the Greeks reject the pope, have done less to prevent the circulation of the Scriptures, and do not insist on sacerdotal celibacy, there is more friendly feeling for them on the part of Protestants, and the Church of England and the Protestant Episcopal Church of the U. S. contain many influential members who labor for some sort of union between their communions and the Greek Catholics.

SAMUEL MACAULEY JACKSON.

Pro'teus [Mod. Lat., from Gr. *Πρωτεύς*, a sea-god fabled to assume many forms]: a genus of tailed batrachians (see URODELA). *Proteus anguinus*, the only known species, is found in the caves of Southern Europe. It is whitish, about 6 inches long, has rudimentary eyes, and large external gills. Its only relatives are the water-dogs (*Necturus*) of the U. S.

Proteus (in Gr. *Πρωτεύς*): in classic mythology, a subject, or according to some versions a son, of Poseidon, whose flocks of seals he tended on the island of PHAROS (*q. v.*), off Egypt. He was gifted with the power of foretelling the future, but, as he disliked prophesying, he used to escape from those who succeeded in catching him when he came up from the depths of the sea to sleep among the rocks, by assuming the most horrible or disgusting shapes. The conflict of MENELAUS (*q. v.*) with Proteus is narrated in Homer's *Odyssey* (4, 351, *seq.*).

Revised by J. R. S. STERRETT.

Prothallium: See FERNWORTS.

Prothero, ROWLAND EDMUND: See the Appendix.

Protista [Mod. Lat., from Gr. *πρῶτος*, first]: a term introduced by Haeckel to include the simplest forms of life, both animal and plant, since it is impossible to draw the line between these two kingdoms of nature. The division is not generally recognized.

Protococ'cus [Mod. Lat.; Gr. *πρῶτος*, first + *κόκκος*, berry]: a poorly defined genus of minute unicellular algæ, of the family *Palmellaceæ* and order *Protococcoideæ*. The cells are globose, solitary, or aggregated into loose masses; the walls are thin, and the protoplasm is stained with chlorophyll (green); and this, when old, may be replaced with red coloring-matter. Under favorable conditions the cells may divide, each into two, and these may again divide, and so on. By a subdivision of the cells zoöspores, also, are produced, which, in related genera at least, unite to give rise to new cells. About twenty species are admitted to the genus as limited, among which the best known is *P. viridis*, very common on the bark of trees and the surface of damp walls. Formerly many more species, now referred to *Pleurococcus*, *Stichococcus*, *Hæmatococcus*, etc., were included in the genus.

The name *Protococcus* is often applied in a general way to any unicellular green plant, and in this sense protococci constitute the so-called gonidia of lichens. Finally, it is probable that *Protococcus* in the narrower sense is composed of younger states of higher algæ.

CHARLES E. BESSEY.

Protogene: See GRANITE.

Protog'enes: painter; b. at Caunus, Caria, in the middle of the fourth century B. C.; lived mostly at Rhodes, and was one of the most celebrated painters of his time. When Demetrius Poliorcetes besieged Rhodes he refrained from attacking one of the weakest points because here was kept the masterpiece of Protogenes, *Ialysus*. This picture was still at Rhodes in the time of Cicero, and later it was brought to Rome. Another celebrated work of his was *The Satyr*. Nearly all that we know of him is contained in Pliny's *Natural History*. He is thought to have died about 300 B. C.

Pro'tophytes [from Mod. Lat. *Protoph'yta*; Gr. *πρῶτος*, first + *φυτόν*, plant]: the *Protophyta*, the lowest branch or division of the vegetable kingdom. The plants collected here consist of single cells, or loose chains of cells, with little, if any, differentiation of the cells. They reproduce by the division of cells and by the asexual production of spores or cysts. No sexual reproduction is known. Most of the species are of some shade of green, as blue-green, smoky green, brownish green, reddish green, etc., but never chlorophyll-green. The coloring-matter is regarded as a modification of chlorophyll, and is distinguished as phycocyanin. The parasitic and saprophytic species (*Bacteria*) are colorless.

Protophytes may be all grouped under one class—*Schizophyceæ* (or *Cyanophyceæ*), and under this two orders may be distinguished—viz., *Cystiphoræ* (or *Chroococcaceæ*) and *Nematogeneæ* (or *Nostochineæ*). See PLANTS, FOSSIL.

CHARLES E. BESSEY.

Protoplasm [Gr. *πρῶτος*, first + *πλάσμα*, anything formed or moulded, deriv. of *πλάσσειν*, form, mould]: a substance,

or, better, a group of substances, of varying chemical composition known only in connection with, and as products of, life. It is semi-fluid, will not dissolve in water, refracts light more strongly than water, and varies in appearance as minute particles—microsomata—are more or less abundant in the ground substance (hyaloplasm), which under lower powers of the microscope appears homogeneous. Much attention has been given to the minute structure, and it is now known that protoplasm is far more complex than the "drop of jelly" to which it is frequently compared. With the use of stronger and better microscopes it has been shown to consist of a small amount of firmer substance combined with more fluid matter, and that these differ in chemical as well as physical properties, but it is not yet certain as to how these parts are arranged. Passing over the hypothetical micellar theory of Nägeli, the view of Heitzmann, Fromman, and Leydig first demands attention. According to this the firmer portions are in the shape of fine fibrillæ which interlace, forming a network, in the interstices of which the fluid portions are contained. In other words, the whole might be compared to a sponge; but, as Bütschli has pointed out, the different supporters of the fibrillar or sponge theory have not all been looking at the same things. Flemming, on the other hand, thinks that protoplasm consists of extremely fine threads imbedded in a ground substance, but is not certain whether each thread is distinct throughout or whether it interlaces here and there with others. Bütschli advocates the view that the firmer portions have a foamy nature, and that they bear the same relation to the fluid parts that the comb does to the honey, a condition which would also explain the observations of others, their threads and networks being optical sections of the foam fibers. He has imitated these conditions by a foam of thickened sweet oil and carbonate of potash or salt or sugar, in which the oil lamellæ represent the firmer framework of the protoplasm, and the intersection of the lamellæ the microsomata. Especially interesting is the fact that, like its prototype, this imitation protoplasm is capable of spontaneous motion. Satisfactory as it is in some respects, this foam theory is open to certain objections. It does not allow room for the spindles of the dividing cell; and, further, the nucleus of the cell presents several conditions which are greatly unlike a foam. Last in order is the granula theory of Altmanns. According to this the elementary parts of protoplasm are minute particles—granula—imbedded in a ground substance, either isolated or arranged in rows or threads. Protoplasm therefore is a colony of these granula, bound together by indifferent substance. Altmanns's views, which go much further than we can indicate here, have attracted few supporters. He has ascribed the most important position to those parts which others regard as secondary and in some cases adventitious substances.

Concerning the chemical nature of protoplasm even less is known than of its physical structure. Here it is most clearly shown that protoplasm is at least a collection of different substances in varying proportions, so that the word must be understood as implying not a compound of fixed and definite composition, but rather as a group of compounds which exhibit certain physical properties. The analysis of these offers extreme difficulties, for all ordinary processes transform the living into non-living matter, a change which may be accompanied by chemical alterations of more or less complexity, "so that the bodies we identify as components of protoplasm may be simply alteration products, or fragments of the larger and more complex molecules resident in living matter." Of these supposed components most numerous are the phosphorus-containing nucleo-albumens; next come the globulins, lecethin and cholesterin; and certain phosphates and chlorides are always present. Some of these are substances of extreme complexity, with hundreds of atoms in the molecule. These substances are unstable, are easily broken down, and that development of energy which is one of the characteristics of protoplasm is due to the chemical action involved.

In the remaining matters to be mentioned we are on firmer ground. Protoplasm exhibits certain phenomena. As was said above it always occurs in connection with life, and all the phenomena of life are those of protoplasm. Protoplasm has the power of spontaneous motion, as shown not only in the motion (cyclosis) of the plant-cell, but in the less evident but no less real motions of all cell-contents. It is irritable and responds to stimuli of various kinds. It has powers of assimilation; it can take non-living matter and build it into a substance like itself. It grows by the operation and is capable of reproducing its kind. These various phenomena—motion, construction (anabolism), etc.—call for an expenditure of energy, and this is developed by the oxidation or breaking down of the higher compounds into lower and more stable substances. As we know it, homogeneous protoplasm does not occur in nature. It is always aggregated into individual particles or cells, and in each of these different portions—all protoplasm—may be recognized both by physical and chemical tests.

LITERATURE.—Besides the older works of Beale, Huxley, etc., see especially Altmanns, *Die Elementarorganismen und ihre Beziehung zu den Zellen* (Leipzig, 1890); Bütschli, *Investigations on Microscopic Foams and on Protoplasm* (London, 1894); Flemming, *Zellsubstanz, Kern und Zelltheilung* (Leipzig, 1882); Nägeli, *Theorie der Abstammungslehre* (Leipzig, 1884); Chittenden (Chemistry), *American Naturalist* (Feb., 1894); Wendt (Chemistry), *Jenaische Zeitschrift* (1893); Heidenhain, *Kölliker Festschrift* (1892).

J. S. KINGSLEY.

Protop'terus: one of the three living genera of the dipnoan fishes. See DIPNOI.

Prototheʹria [from Gr. *πρῶτος*, first + *θήρ*, beast, i. e. lowest or most generalized mammals]: a term used by Gill as equivalent to *Ornithodelphia* or egg-laying mammals (see MONOTREMATA), these being considered as one of two grand divisions of mammals, the other being the *Eutheria*, or viviparous mammals. By other authorities the term is employed as an equivalent of *Promammalia* to designate the supposed ancestors of the monotremes. F. A. L.

Protozoʹa [Mod. Lat., from Gr. *πρῶτος*, first + *ζῷον*, animal]: one of the grand divisions or branches of the animal kingdom which receives its name from the fact that its members are simplest in structure and therefore come first in logical order. Each protozoön consists of a single cell, or, in those cases where several-celled protozoa are found, each cell performs all the functions of life without assistance from its fellows. In other words, there is no differentiation of the cells into tissues or organs. In all (except the doubtful *Monera*) each individual consists of a mass of protoplasm, with an internal nucleus. In some no cell-wall is present; others may secrete an external or internal horny, calcareous or siliceous skeleton, frequently of wondrous beauty and complexity. In the protoplasm there are usually spaces or vacuoles, and some of these (contractile vacuoles), which rhythmically expand and contract, are supposed to be excretory in function. The protoplasm in the *Rhizopoda* is capable of protrusion in temporary lobes or pseudopodia; in the *Infusoria*, on the other hand, there may be either long, hair-like slowly vibrating outgrowths (flagella), or shorter, more numerous, quickly moving cilia. These processes serve for locomotion and for obtaining food. Food may either be taken in at any part of the body surface, or there may be specialized regions for its admission. There is no alimentary canal, but the nourishment contained in the food is extracted and metabolized by the protoplasm of each cell. There is no true sexual reproduction, but instead a propagation of the species by division of the individuals, in which all of the material of the parent persists in the second generation. There is thus, as Weismann has pointed out, no natural death in the protozoa. Accompanying the processes of reproduction is an occasional temporary union (conjugation) of individuals, in which an exchange of nuclear protoplasm takes place. The protozoa are all minute, and but few can be seen by the naked eye. They live abundantly in both fresh and salt water, and a few live in moist earth or as parasites on or in other living organisms. Notwithstanding their minute size, they play an important part in the world. Some are scavengers, some cause diseases (hay-fever is said to be caused by an infusore), while the dead skeletons of others form extensive beds of rock.

The *Protozoa* are divided into the following classes: 1. MONERA; 2. RHIZOPODA; 3. INFUSORIA; 4. SPOROZOA, which should be referred to for further accounts of these organisms. See also PALEONTOLOGY. J. S. KINGSLEY.

Protracheata: See ONYCHOPHORA.

Proudhon, proo'dōn', PIERRE JOSEPH: socialist; b. at Besançon, France, July 15, 1809; became a printer; employed all his spare time in study, and in 1838 received from the academy of Besançon a stipend of 1,500 francs yearly for three years as a reward for an essay on general grammar. He went to Paris, and in 1840 wrote *Qu'est-ce que la propriété?* In this he assumes that simply by being born into the world every man has a right to a share of what the world

contains of necessaries, comforts, and enjoyments. From this assumption he develops his famous definition of property: "La propriété, c'est le vol." The academy withdrew the stipend, and even threatened him with a prosecution, from which, however, it was restrained by Blanqui, who declared the essay to be perfectly innocent. From 1843 to 1847 Proudhon lived in Lyons, but his two large works from this time were published in Paris, *De la Création de l'Ordre dans l'Humanité* (1843), in which he gives a new theory of political organization; and *Système des Contradictions économiques, ou Philosophie de misère* (1846). When the revolution of February broke out in Paris, he immediately repaired to that city, and (Apr. 1) began the issue of a daily paper, *Le Représentant du Peuple*, in which he set forth the most radical opinions, and which in a short time made him immensely popular. He was elected a deputy to the Constituent Assembly, but he soon discovered that he could do nothing there with his ideas, as nobody would hear him when he spoke, and he consequently returned to the press, editing in succession three daily papers. He was fined for his outrageous sarcasms and personalities against his adversaries, but his readers paid the fines. He started a people's bank in which he tried to reduce his theories to practice, but the project failed and the bank was closed by the authorities. In Mar., 1849, he was sentenced to three years' imprisonment for illegal publications, and he fled to Geneva. Shortly after, however, he returned and delivered himself up to the police. During his imprisonment he wrote *Confessions d'un Révolutionnaire*, *Gratuité du Crédit*, and *La Révolution sociale démontrée par le Coup d'état*. After his liberation he went to Belgium, where he published from time to time works embodying his peculiar theories. D. in Paris, Jan. 19, 1865. Proudhon was the founder of that school of political philosophy which is known as scientific or individualistic anarchism. In *Qu'est-ce que la propriété?* he holds that while property in its existing form is the cause of all social evils, it is so closely connected with the state that the only way to prevent the evils is to destroy the state itself. To communism he was as hostile as to the state, the only proper basis of society being, in his opinion, a voluntary contract between its members. He wished to abolish money as a medium of exchange, substituting for it a sort of bank-paper based on products, in application of his theory that "services should exchange for services and products for products."

F. M. Colby.

Prout, Father: See Mahony, Francis.

Provençal (prō′vǎǹ′saal′) **Language** [*Provençal* = Fr., deriv. of *Provence* < Lat. *Provin'cia*, liter., the Province, the part of France anciently constituting a separate Roman province]: the group of dialects spoken in Southern France in the Middle Ages, which are of great literary importance, and both in the mediæval and the modern forms of high philological interest also, on account of the intermediate position they occupy among the Romance languages and for other reasons. The name Provençal is commonly and conveniently applied to these various dialects, not only covering Provence, but also other territory, as Languedoc, Auvergne, Limousin, Gascony, etc., a rough division from the French dialects being made by a line running from the mouth of the Garonne so as to leave on the S. the greater part of the departments Gironde, Dordogne, Haute-Vienne, Creuse, and also parts of Allier and Loire. E. of Lyons is a considerable territory, with Geneva about in the middle, roughly covering the departments Isère, Ain, Jura, Doubs, Savoie, Haute-Savoie, and also Western Switzerland; in this the so-called Franco-Provençal or Middle-Rhonish dialects are spoken, which agree in some respects with the French dialects, in others with Provençal. The Gascon dialects in the southwest may also be considered as a group by themselves, though they are generally included under Provençal. Another name for the language is preserved in the geographical designation Languedoc (originally "language of yes," from the Provençal word for "yes," just as the French of Northern France has been occasionally called *langue d'oïl* from the Old French word for "yes"). The number of speakers of Provençal has been estimated at about 10,000,000, but this includes, in part, the Franco-Provençal dialects, whose territory has a population of about 2,500,000. For the subject of dialect divisions and for an historical view of Old Provençal phonology and inflexions, see Suchier's article in Gröber's *Grundriss der romanischen Philologie*, i., 561 ff. (or the French translation, *Le Français et le Provençal*, by Monet, 1891), and the maps at the end of the same volume.

In several respects Provençal diverged less from late spoken Latin than was the case with French, or even with Italian or Spanish. Its most obvious distinction from French is that it retains Latin accented *a*, and (in its old form) the *a* of Latin final syllables, while French changed the former under certain conditions into *é* and the latter into *e*. In modern Provençal the older final unaccented *a* has generally become *o*. The Latin diphthong *au* remained unchanged in Provençal. The simple sounds of Provençal in the twelfth century were probably very nearly the same as those of the French of the same period, but the nasal vowels of French do not appear. The sound of *th* in *that* seems to have changed pretty early into *z*, and the palatalized *l* has in the modern dialects generally lost the *l* sound, becoming an *i* or rather *y*, as in modern standard French. The Latin pluperfect indicative was, as in very old French, retained for a time as a simple past tense, but it commonly took in old Provençal the sense of a conditional, as it has done in Spanish.

It is remarkable that we have in Provençal grammatical works on the language itself belonging to the thirteenth century. See Stengel, *Die beiden ältesten provenzalischen Grammatiken* (1878). In modern times Provençal has generally been looked upon as a group of vulgar *patois* until the nineteenth century, when a certain literary standing has again been acquired.

Besides the books mentioned already, the following, among others, are of use (see also Romance Languages):

For the older language: Raynouard, *Choix des poésies originales des troubadours* (6 vols., 1816–21) and *Lexique roman* (6 vols., 1838–44; still useful, but Raynouard's grammatical and comparative work is antiquated); E. Levy, *Provenzalisches Supplementwörterbuch* (1892, *seq.*); Mahn, *Die Werke der Troubadours* (1846–82) and *Gedichte der Troubadours* (1856–73); Bartsch, *Chrestomathie provençale* (4th ed. 1880); P. Meyer, *Recueil d'anciens textes bas-latins, provençaux et français* (1877); H. Suchier, *Denkmäler provenzalischer Literatur und Sprache* (i., 1883); V. Crescini, *Manualetto provenzale* (1892–94).

Mostly for the modern dialects: F. Mistral, *Loutresor dóu felibrige ou Dictionnaire provençal-français* (2 vols., 1879–86); Chabaneau, *Grammaire limousine* in *Revue des langues romanes*, ii.–viii.; Mushacke, *Geschichtliche Entwicklung der Mundart von Montpellier* in *Französische Studien*, iv.; Koschwitz, *Grammaire historique de la langue des félibres* (1894); also articles in the *Revue des patois gallo-romans* (1887–93), the *Revue de philologie français et provençale*, and other periodicals.

E. S. Sheldon.

Provençal Literature: the literature written in the language or dialects of the south of France; one of the most interesting, though least extensive, of the group of Romance literatures. Though born at the same time as French literature, and but little earlier than the Italian and Spanish literatures, Provençal literature is peculiar in that it has not had an uninterrupted history down to the present day. The conquest of Southern by Northern France in the thirteenth century, and the destruction of the former's political autonomy thereby, led to the entire decay of independent Provençal culture and to the decline of the Provençal tongue to the level of a mere dialect. In the nineteenth century there have been efforts toward a revival both of the languages and the literature, efforts that have engaged men of great ability and given rise to excellent literary works; but it can not be said that a new Provençal literary language, fully unified and regulated, like French, for example, has been attained. While it lasted, however, Provençal literature was accepted universally in Europe as the most refined of all. It served as a model for the first Italian, the first Spanish, and the first Portuguese lyric poets; it gave rise to one of the chief poetic schools of Northern France; and hardly any literature in Europe fails to show numerous traces of ideas and poetical forms that had their origin in this.

First Period (950–1100).—None of the first scanty monuments of Provençal verse and prose contain clear indications of the ideas that were later to become dominant in Provençal poetry, and as a consequence they are of interest chiefly to the philologist. The earliest monument of all is a fragment of a poem by some moralizing clerk, based on the story of the Roman philosopher Boethius, and showing an uncritical use of his *De consolatione philosophiæ*. This was written toward the end of the tenth or early in the eleventh century. Likewise the work of clerks are several

fragments of lives of saints and religious lyrics, whose precise dates can not be fixed, but which undoubtedly belong to this time. The earliest monument of Provençal prose is a fragment of a translation of the Gospel of John (ch. xiii.–xvii.) in the Vaudois dialect. Much more interesting to the student of literature is a fragment of 105 octosyllabic verses on the legendary Alexander the Great, written by a certain Albéric of Besançon (or Briançon) early in the eleventh century. This is based on the fabulous life of Alexander, written in the second century A. D., and known as the Pseudo-Callisthenes. It is the first monument of the extensive literature of mediæval Europe devoted to Alexander, and, if we may judge by the indications of the *Alexanderslied* of the German Pfaffe Lamprecht (twelfth century), which was partly based on it, must have been one of the most interesting.

Second Period (1100–1226).—The first name in this period introduces us to that form of poetry that is most characteristic of Provence. It is that of William VII., Count of Poitou (IX., as Duke of Aquitaine), who ruled from 1087 till 1127, and was one of the most famous persons of his time. He was the first of the troubadours (Prov. *trobaire*, acc. *trobador*), as the mediæval lyric poets of Provence called themselves. In him we have the earliest exponent of the new society, with its new ideals of conduct and of art, which had at last come to replace the Roman society that the barbarians had destroyed. This new society had doubtless for some time been forming itself at the feudal courts of Southern France, and had been elaborating its peculiar theories of life. It was an aristocratic society, and the very words by which it expressed its social conceptions are those of a rich and elegant upper class. Such are *cortesia*, or what is suitable at courts; *valor*, or the high spirit of the perfect gentleman; *mesura*, or due self-restraint in demeanor and action; *largueza*, or unbounded liberality; *jovens*, or the gayety and grace of the young in spirit; *joi*, or the glad energy of the heart intent on deeds of excellence and renown. One other conception, the most important of all, was that of *amor*, or chivalrous love, which for Provençal society was not merely the subjective passion universal in the race, but rather a form of conduct, an ideal of excellence, which was at once the source and the criterion of all other excellences. Essentially, the poetry of the troubadours deals with very little of interest besides this chivalrous love; and this was the chief contribution made by them to the poetry and the society of other countries. Indeed the whole modern conception of love has been profoundly modified by it, and that, too, despite the fact that it contains elements at first sight highly repugnant to modern feeling on the subject. Based upon an idealization of woman that was a reaction against the unhappy consequences both of the low idea of her common among the clergy and of the degradation of her caused by the necessities of feudal marriage, the love of the troubadours was avowedly antagonistic to the conventions both of society and of the Church. It was declared by them that love was impossible between husbands and wives, or between persons who might expect to enter into this relation with each other. In general, the lover must serve a lady already married to another; and it was obligatory in a lady thus served to return the love, without regard to her marital obligations. As runs one of the rules of the amorous jurist André le Chapelain, whose *De arte amandi* (*circa* 1200) embodies the theorizings of the time, *Causa conjugii non est ab amore excusatio.* Clearly love of this kind, if it remained honorable, must be a social function rather than a personal passion. Clearly, also, the danger was great that this would not always be the case; nor, in point of fact, was it. Still, it is clear that for a considerable period such relations between men and women were held to be not merely permissible, but in the highest degree ennobling to both. The essentially troubadour love of Dante for Beatrice, wife of Simone de' Bardi, and the high consequences that proceeded from it, are proof enough of this.

During the whole twelfth century the elaboration and discussion of this theory of chivalrous love went on in Southern France, and with it went on the development of the poetical art of the troubadours. The extreme variety and intricacy of the forms of this art were natural results of the essentially external and formal character of the subject-matter; yet these lyric varieties, which are too numerous even to name in a brief article, served as models for the first modern poets of the rest of Europe, and have powerfully affected the history of all modern poetical literature.

The vogue of the new poetry in and out of Provence was very great, and even kings were proud to be counted among the troubadours. The great nobles, like Richard Cœur de Lion, the Count of Poitou, and later King of England; Raymond V. and Raymond VI. of Toulouse; Alfonso II., Count of Provence; William VIII., Lord of Montpellier; Robert, Dauphin of Auvergne; Henry I., Count of Rodez; Barral, Viscount of Marseilles; Ermengarde, Countess of Narbonne; and many others, welcomed the singers to their courts and heaped them with favors. Beyond the borders of Provence they fared no less well, as at the courts of Aragon, Leon, and Castile, in Spain, and at those of the Emperor Frederick II., Marquis Boniface II. of Montferrat, and the Marquises Azzo VI. and Azzo VIII. d'Este in Italy.

The list of troubadours of the twelfth and thirteenth centuries contains no less than 412 names, of whom the great majority belong to the period we are now treating. Of many of these, however, we have but scanty remains and little biographical information. After William IX., mentioned above, there was in the first half of the twelfth century a small group of poets who were felt by the later troubadours to have belonged to an older school, but whose art is not for us markedly different from that of their successors. Chief of these were Cercamon, Marcabrun, and Jaufré Rudel, Prince of Blaya, whose romantic passion for the Countess of Tripoli was long famous. Whatever the change of style was, it seems to have taken place about the middle of the century; and the name given as that of the first really excellent troubadour is Peire d'Alvernh. Another innovator, according to tradition, was Guiraut de Bornelh, who first used the lyric form called *cansos*, or canzone. Practically contemporary, however, or little later, were all the most famous troubadours: Bernart de Ventadour, the best singer of love; Guillem de Cabestaing, whose passion ended in a tragic death; Arnaut de Maruelh, more simple in style than most, and more delicate in sentiment; Pons de Capduelh, eagerly sincere in his service of love; Peire Vidal, a fantastic spirit, but truly a poet; Peire Rotgier, in whom theory overbalances art; the flippant Rambaut III., Count of Orange, and Beatrice, Countess of Die, whose avowed passion for him has obtained for her the name of the Provençal Sappho; Folquet de Marseilles, somewhat later, whose amorous youth was followed by the stern zeal of the fanatic bishop; Rambaut de Vaqueiras, who carried his art into Italy; Peirol, the passionate crusader. Still more noted than any of these were Bertran de Born, who sang more of arms than of love, and Arnaut Daniel, whom Dante thought the best of all the troubadours (*Purg.*, xxvi., 118, *seq.*). In the latter, however, art was carried to the point of extreme artificiality, for the poet even prided himself on the unintelligibility of his difficult style (*rims cars* or *oscurs*).

In the thirteenth century a change began to come over the spirit of Provençal song. The political situation in Provence became ever more threatening. The Church had become uneasy about the heretical sects so numerous there —Albigenses, Cathari, Vaudois—while the Northern French were looking with greedy eyes upon the fair lands of the south. In 1207 the tempest burst, and for nearly forty years the Albigensian crusades continued, devastating the land, destroying the courtly life, dispersing the poets, and finally merging Provence itself in France. The culmination of the tragedy may be said to have been reached in 1226, when the last revolt in Toulouse, the center of Provençal resistance, was crushed. For the next quarter of a century the conquerors were busy with the last details of their task. The Inquisition, established for this purpose, hunted down and destroyed the few surviving heretics; and so far did the violence of the Church go that in 1245 Pope Innocent IV. issued a bull declaring the Provençal language heretical and forbidding students to use it. With the same ruthlessness the French crushed all those, whether nobles or commoners, who desired political independence.

The necessary result of these disasters was a falling off in the art of the troubadours. Though we have many names from the first quarter of the thirteenth century, they are not of the first rank. Love was sung with less of high conviction, and political passions usurped a larger place. We may name from this time Gaucelm Faidit, a man of many loves; Savario de Mauleon; Uc de Saint Circ, from whose pen several brief biographies of earlier troubadours have descended to us; Aimeric de Pegulhan; Cadenet; Perdigon. The two most characteristic poets, however, are Peire Cardinal and Guillem Figueira, the former of whom,

in grave and noble fashion, denounced the vices of his day, especially those of the clergy; while the latter, a scorner of all gentle practices, lived like a roysterer, making mock of the pretensions of noble and churchman alike.

One or two other kinds of literature, though not esteemed like the lyrics of the courtly poets, afford monuments of interest. The first of these is the historical or popular epic, like the *Chansons de Geste* of Northern France. Though it is certain that these were never produced in Provence in the profusion formerly imagined (e. g. by Fauriel), they certainly existed, especially in the region nearest France. Several specimens are extant, in whole or part, and one of these, the poem of *Girart de Rossillon*, is one of the finest epics of the Middle Ages. Here, too, should be mentioned several historical poems, of which the most important is that on the *Crusade against the Albigenses* (early thirteenth century). Probably as early as the twelfth century, also, romantic narrative poems began to be written, but our examples are chiefly from the next period. Of great interest are several didactic poems, particularly those known as *ensenhamens*, in which the ideals of conduct of the time were discussed. These, too, flourished more in the thirteenth century.

Third Period (1226–1323).—The successful termination of the crusade against the Albigenses produced almost a cessation of lyric poetry in Provence proper. A few names of unimportant troubadours of the latter part of the thirteenth century are known to us, but we have only scanty remains of their work. Chief of these poets is Guiraut Riquier, who was, however, little more than *laudator temporis acti*. The real life of the troubadour poetry was at this time to be found in Italy and the Spanish Peninsula. In the former the vogue of this poetry was so great that native Italians began to write it, and the Mantuan Sordello, the Venetian Bartolomeo Zorgi, and the Genoese Bonifacio Calvo deserve honorable mention in the list of troubadours. As is well known, this Provençal poetry served as a model for the first Italian verse. In the Spanish Peninsula, as has been mentioned above, there were several courts frequented by the troubadours during the thirteenth century; and also, especially in Catalonia, not a few poets who employed the Provençal tongue.

In Provence itself there was in this period a considerable development of literature other than lyric poetry. Romances and novels after the French style became popular, and in the *Roman de Jaufre* we have a work of some interest. The poetical novel of manners *Flamenca* gives us important information about the customs of the time. Didactic literature increased greatly in extent, and gives us several *ensenhamens* and treatises of a moral kind. We have a number of scientific or pseudo-scientific works also, and the extensive encyclopædia of Matfre Ermengaud, entitled *Breviari d'amors*, illustrates the speculations on the constitution of the universe then current. Historical poetry is cultivated to some extent. The religious literature is much larger in amount than in the preceding period, and includes legends, in both verse and prose, connected with the life of Christ and of various saints, prayers, sermons, etc. Of special interest are several versions of parts of the Bible, chiefly of heretical origin. Toward the end of this period we get the first example of the Provençal drama, the mystery entitled *L'Esposalizi de nostra dona sancta Maria verges e de Josep*.

Fourth Period (1323–1500).—By the end of the thirteenth century the aristocratic poetry of Provence had entirely come to an end; but here, as elsewhere in Europe, an attempt was made in the *bourgeoisie*, now become rich and prosperous, if not to revive it, at least to imitate it. In short, mastersong succeeded minnesong. In the year 1323 a group of *bourgeois* of Toulouse associated themselves together under the name of the Sobregaya companhia dels VII. trobadors de Tholoza, and in order to promote poetic composition appointed for May 1, 1324, a poetical contest—the first of the long series of Floral Games of Toulouse. The prize offered was a golden violet for the best canzone; and we learn that a certain Arnaut Vidal de Castelnaudari was the first to obtain it. In 1355 the contest was still further developed, and other flowers of gold or silver were offered for excellence in other forms of verse. At the same time the chancellor of the consistory (for so it was then called), Guillem Molinier, was instructed to draw up a treatise on the poetic art. He did this in his famous *Leys d'Amors*, which, though fantastic in the extreme, has great interest for the student. The most remarkable thing about this bourgeois poetry is the fact that though the forms and even phrases of the troubadours were scrupulously preserved, the old meaning had been entirely lost. It was not permitted these new troubadours to address their lyrics to real ladies; they had to write canzoni, ballades, albas, pastourelles, etc., to the Virgin Mary, and to a certain abstraction, *Clemenza* by name, who became almost a goddess. We know the names of about 100 winners in these contests, reaching down to 1498.

Beyond these lyrics this period affords little of interest, except a certain number of mysteries and miracle-plays. Some considerable body of religious literature there is, but of so slight consequence that little of it has yet been published.

Fifth Period (1500–1825).—This is really not a literary period at all, but an interregnum. Not that all versifying had ceased in Southern France, but the language had so degenerated as no longer to deserve the name of literary language, and what was written in it was merely the rude utterance of local dialects. Interest in the troubadours was indeed not entirely lost, especially after the appearance of the romantic, lying book of Jean de Nostradame, *Vies des plus celebres et anciens poetes provensaux* (1575). Others, more truly scholars, like the Italians Castelvetro and Crescimbeni, and the French La Curne de Sainte-Palaye, did much in the way of investigating the history of Provençal song. Still no permanent and fruitful restoration of the decayed tongue took place, and it rapidly sank to lower and lower depths.

Sixth Period (1825 to the present).—After the nineteenth century had well begun, two influences combined to make possible a renaissance of Provençal poetry. The first of these was interest aroused by the studies and publications of the French historian Raynouard, the German philologist Diez, and their numerous followers both in France and Germany. The other was the appearance in Provence of several dialect poets of unusual powers. Chief of these was the barber-poet of Agen, Jasmin (1798–1864), the appearance of whose *Charivari* in 1825 may well be taken as the starting-point of the movement. Contemporaries of Jasmin were Diouloufet, Cabanes, Azaïs, Morel, and, above all, Roumanille. In 1854 an important step was taken by the last named with six other poets—Mathieu, Tavan, Aubanel, Mistral, Brunet, Giera. This was nothing short of the re-establishment of the dead consistory of Toulouse, under the name, however, of the Society of Félibrige, and not limited to Toulouse, but extended to all Provence and even Catalonia. Curiously enough, the title thus assumed was one whose exact meaning was unknown to the associates, and remains even to-day without certain explanation. The poet Mistral had heard at Maillane a poem in honor of the Virgin Mary, which contained the phrase *li sèt félibre de la lèi*. The poets were seven; they proposed to be a law to the other poets of their region; the word *félibre* they were willing to accept on faith as meaning doctors or expositors. The society thus established has extended itself over the whole region in which Provençal and Catalan were once spoken, and is organized in the greatest detail. It has undoubtedly, by the poetical contests it has held, stimulated the production of much verse; but it may be doubted whether it has evoked many great poets. After all, Jasmin, Roumanille, Aubanel, and Mistral remain the chief figures of the new Provençal poetry, and the appearance of all of these antedates the society. On the other hand, the latter has undoubtedly done much for the study of Provençal literature and the Provençal tongue, not so much by its annual pronunciamento, in the form of a poetical almanac, *Armana prouvençau* (1855, *seq.*), as by fostering learned societies, like the Société pour l'étude des langues romanes, whose organ is the *Revue des langues romanes* (Montpellier, 1870, *seq.*).

Bibliography.—Millot, *Histoire littéraire des troubadours* (3 vols., Paris, 1773); F. Diez, *Die Poesie der Troubadours* (1826; 2d enlarged ed. by K. Bartsch, 1883) and *Leben und Werke der Troubadours* (1829; 2d enlarged ed. by K. Bartsch, 1882); Fauriel, *Histoire litt. des troubadours* (3 vols., Paris, 1844; too speculative); Karl Bartsch, *Grundriss zur Geschichte der Provenzalischen Literatur* (1872); P. Meyer, *Provençal Literature* (in *Encyclopædia Britannica*, 9th ed.), *Derniers troubadours de la Provence* (1871), and *De l'influence des troubadours sur la poésie des peuples romanes* (in *Romania*, 1877); Fr. Hueffer, *The Troubadours* (London, 1878, untrustworthy); A. Restori, *Letteratura Provenzale* (Milan, 1891); A. Stimming, *Provenzalische Lit-*

eratur (in Gröber's *Grundriss der romanischen Philologie*, vol. ii., pt. 2, Strassburg, 1893); E. Portal, *La Letteratura Provenzale moderna* (Palermo, 1893); M. Milá y Fontanals, *De los trovadores en España* (2d ed. Barcelona, 1889); A. Thomas, *Francesco da Barberino et la littérature provençale en Italie au moyen âge* (1884).

The chief collections of the works of the troubadours are: Rochegude, *Parnasse occitanien* (Toulouse, 1819); F. Raynouard, *Choix des poésies originales des troubadours* (6 vols., 1816–21) and *Lexique roman* (6 vols., 1838–44); Mahn, *Werke der Troubadours* (4 vols., 1853–86) and *Gedichte der Troubadours* (4 vols., 1856–73); P. Meyer, *Recueil d'anciens textes bas-latins, provençaux et français* (1877). The best introductory books are K. Bartsch, *Chrestomathie provençale* (4th ed., Elberfeld, 1880), and V. Crescini, *Crestomazia provenzale* (Padua, 1892). A. R. Marsh.

Provence': an old province of France; bounded E. by the Alps and S. by the Mediterranean, and now divided into the departments of Var, Bouches-du-Rhône, Basses-Alpes, and Vaucluse. It derived its name from the Latin *Provincia*, by which the Romans pre-eminently designated it. After the fall of the Roman empire Provence was overrun by the Goths and the Saracens, and during the Middle Ages it was ruled by independent counts. In the twelfth century this land, celebrated for its climate, its sky, and its fruit, produced the famous Provençal songs. In 1481 it was annexed to the French crown by Louis XI.

Proverbs [from Lat. *prover'bium*; *pro*, for + *ver'bum*, word]: popular wisdom, often expressed by "the wit of one," always concentrated in a handy sentence, and actually in use by the people. The last of these limitations is important. For example, many of the sayings of Mrs. Poyser, in George Eliot's *Adam Bede*, would be good proverbs, if they were proverbs. Metaphor and alliteration, though not essential, are common in the proverb, and show origins akin to those of the oldest poetry; for, contrary to the current ideas about didactic verse, proverbs are now regarded by critics as belonging, together with choral song (the later ballad) and popular tale (*Märchen*), to the oldest phase of primitive poetry. The proverb is a general statement which fits a number of particular cases; it is the wisdom or wit of the masses, and therefore flourishes best among unlettered folk—like the ballad and the popular tale. Like the latter, moreover, it is often imported, and is particularly at home in the Orient. These are general proverbs. Others attach to place or person, but spread far beyond original limits—as, "to go round [by] Robin Hood's barn." Proverbs often give a lively notion of the popular attitude in regard to certain classes or institutions; although historical estimates based on such evidence are, to say the least, uncertain: for example, the saws and quips about the mediæval clergy—in particular, monk and nun—or the ever-youthful jibes at medicine and law. Here, again, we have an interesting parallel with popular songs, and as we must distinguish the latter from individual lyric, so should all possible care be taken to sunder a real saying of the people from the incisive phrases of speaker or writer. Moreover, the distinction between the humorous and the didactic must always be kept in view.

Collections of proverbs were attempted even among the Greeks, but modern interest in the subject was awakened and led by Erasmus. His *Adagia* were published in 1500, and found speedy imitation in several countries. The Germans were among his most successful followers, and they have outdone all competitors for later times, with the single exception of Spain. On the other hand, for whatever reason, witty as the Celtic folk is known to be, but scant harvest of proverbs has been gleaned from Irish fields. English proverbs, however, are fairly plentiful, and proverbial poetry has always been popular with Germanic races. A peculiar form of this poetry is preserved in the so-called gnomic verses of the Anglo-Saxon. (See Grein-Wülker, *Bibliothek der Angelsächsischen Poesie*, i., 338 ff.). Other collections of the same character are found in the Old English period, but later proverbs increase in wit, terseness, and subtlety. Chaucer, like Shakspeare, had a liking for proverbs, and collectors have gathered good spoil from many old plays, sermons, pamphlets, tales, and the like.

Of the numerous collections the following may be mentioned for the general subject: Rheinsberg-Düringsfeld, *Sprichwörter der germanischen und romanischen Sprachen* (1872 ff.), and Bohn, *Polyglot of Foreign Proverbs*; for English, Bohn, *A Handbook of Proverbs*, and W. C. Hazlitt, *English Proverbs and Proverbial Phrases* (London, 1869). The Germans have an excellent work in Wunder's *Deutsches Sprichwörter-Lexicon* (5 vols., 1863–80).

Francis B. Gummere.

Proverbs, Book of: a title which comes through the Vulgate from its Greek equivalent, Παροιμίαι, in the Septuagint, and which must be taken in its widest acceptation in order to make it embrace all the varieties of expression comprised in the collection. The original Hebrew term (*mashal*) means properly a "comparison;" but as every utterance of a truth involves a comparison, we find included in the book apophthegms, maxims, enigmas ("dark sayings," in the English version of Prov., i. 6), and sometimes longer connected discourses of the same didactic nature.

It is said in 1 Kings v. 12 that Solomon spoke 3,000 proverbs, and it is probable that many of these are found in this book, as the superscription prefixed to each of their three main divisions assigns it to Solomon. The first division (chs. i.–ix.) is devoted to a description of wisdom and an exhortation to its pursuit. The second (chs. x.–xxiv.) contains individual proverbs, and in its latter part brief proverbial discourses. The third (chs. xxv.–xxix.) was a compilation by "the men of Hezekiah." In chs. xxx. and xxxi. we have three appendices. The first is by an author known to us only by the name Agur, given to him in ch. xxx. 1; the second (ch. xxxi. 1–9) contains precepts for a King Lemuel, given by his mother. *Lemuel* ("one belonging to God") is clearly only a symbolical name, and a general resemblance in style has led some to infer that this, as well as the final section (ch. xxxi. 10–31), was also written by Agur.

The Proverbs exhibit the results of reflection upon the moral and spiritual value of its precepts in the concerns of life. It is noteworthy that they do not once mention the priest nor exalt the externals of worship, nor allude to any conflict between the worship of Jehovah and that of idols. There are good commentaries in English by C. Bridges (London, n. e. 1859), W. Arnot (Edinburgh and New York, 1869), F. Delitzsch (1875), and in *The Expositor's Bible* by R. F. Horton (1891). Revised by S. M. Jackson.

Providence [viâ O. Fr. from Lat. *providen'tia*, foresight, provision, deriv. of *provide're*, foresee, provide; *pro*, for, before + *vide're*, see]: in theology, the doctrine which teaches that God upholds, preserves, and governs the entire universe which he has created. The scriptural doctrine affirms at the same time the omnipotent power of God and the liberty and responsibility of man. It is removed equally, on the one hand, from Stoicism and the rigid doctrine of Fate, and on the other from the Epicurean affirmation that it is an unworthy condescension of the Deity to concern himself about the affairs of men. (Pliny, *Hist. Nat.*, iii., 4, *seq.*) It includes the two essential ideas of preservation and of government. Modern philosophy, which is increasingly monistic, emphasizes the *immanence* of God, and tends to resolve all matter, in its ultimate essence, into a manifestation of the present agency of God. Hence preservation differs from creation only as the beginning of an agency differs from the continuance of the same agency. The scriptural affirmation is, that God upholds all things by the word of his power—that his agency is everywhere seen in the continued existence of his creatures and in the operations of nature. "By him all things consist," Col. i. 17; "In him we live and move and have our being," Acts xvii. 28. The *extent* of providence is unlimited. It includes all the creatures of God, intelligent and non-intelligent, since nothing is so high as to be above his control, nor anything so minute as to be beneath his notice. The *end* of providence is the realizing of the divine plan in the universe. The end is infinitely wise, holy, and beneficent. The *means* are such as are best adapted for the certain accomplishment of this end. Instead of chance, or necessity, or inexorable fate, to which gods and men are equally subject, the doctrine of the Scriptures substitutes the intelligent control of the omnipotent and omnipresent Jehovah, in accordance with designs as gracious as they are vast and inscrutable. The *method* of providence—*how* it is that God governs the world consistently with the liberty of rational beings—is not a subject of revelation. The employment of motives to govern human action in many cases is plain. The difficulty of the problem lies in the reconciliation of divine foreknowledge and government with human freedom.

That there are powers, unseen and supernatural, operating to sustain and control both nature and man seems to be the instinctive faith of the race, aside from the special

teaching of revelation. This imparts a deep significance to many fables of ancient mythology. The belief in a providence of some kind seems well-nigh universal. It is affirmed or implied in the writings of ancient classical poets and philosophers, although disfigured with crude and unworthy conceptions of the divine nature or character. Cicero in his dialogues, *De Nat. Deorum*, states at considerable length the speculations of the most distinguished philosophers among the Stoics and Epicureans on the existence, attributes, and providence of a Divine Being. In lib. ii., while allowing the principle of pantheism—that God is the Universe and the Universe is God—he affirms the existence of minor deities, and then argues in favor of the divine government and providence—(1) from the existence of the gods, which implies their actual control of the world; (2) from the laws of nature—nature, properly interpreted, being another name for God; and (3) from the order, harmony, beauty, and wisdom manifested in the works of creation. Although not very complete or satisfactory, the argument shows the tendency of philosophic thought unaided by revelation. See also *Tusc.*, Disp. i., 49, *et al.*

The doctrine of providence was affirmed with great unanimity by the most distinguished early Christian Fathers, and maintained with equal subtleness of discrimination and strength of argument. The objections, too, early brought against the doctrine, were nearly the same as those revived and reaffirmed in our day. By some it was held to be unnecessary, or an implication of imperfect work on the part of the Creator, rudely supplemented afterward. Others "maintained that God concerned himself only about the genus, but not about the species," distinguishing between a general and a special providence—*gubernatio generalis* and *gubernatio specialis*. Still others held it to be derogatory to the Supreme Deity to suppose that he would condescend to notice the small concerns of men. Origen represents Celsus as affirming that God interferes as little with the affairs of men as with those of monkeys and flies. The opposite and Christian view of this article of faith was eloquently maintained in the East and the West by Chrysostom and Theodoret, by Augustine and Salvian. Augustine especially objects to the comparison of God to a master-builder, whose work remains though he himself withdraws. "The world would at once cease to exist," he says, "if God were to deprive it of his presence." Nearly two centuries earlier, about A. D. 230, Minucius Felix, in his apologetic dialogue entitled *Octavius*, in a passage of singular beauty, says: "We are not only under God's eyes, but we even live in his bosom."

The doctrine of providence is not inconsistent with the idea of a government of law. The Scriptures affirm that God is the creator of the universe. He is the author of what we call the laws of nature, and can surely change or suspend or overrule them. But he does not govern the world arbitrarily, but according to a fixed plan and for a great end. The laws of nature are the ordinances of God, but a man even may use some powers of nature to control or limit other powers. So, in a far higher sense, and with a method infinitely more perfect, may the Creator control that which he has made. Nor can we deny that he may act directly upon the rational mind, as one finite mind may seek to modify another; or upon both nature and spirit by methods to us now, and perhaps always, incomprehensible.

Some theories of evolution have been used against the doctrine of providence. The laws of the development of living forms being reduced to few, and their rigid and invariable application being assumed as the process of all the modifications resulting in the existing life of the planet, it has been argued that there is no place for providence. But evidently there is no *new* problem added by a new view of the *nature* of the laws under which providence must proceed to that given by the idea of natural law in general; and this problem is simply that of the personality of God.

Some of the proofs of the doctrine are the following: (1) It is inferred from the idea of a personal God, infinite in intelligence, wisdom, goodness, and power; (2) from the evidence of intelligence and design in nature; (3) from the evidences in history of moral order and law. History would otherwise be a tangled skein without beginning or end, without significance, and incapable of harmony or intelligent interpretation. The story of races and nations, the epochs which seem to mark the movements of society and the progress of civilization, would lose their importance, and our hope for the world would vanish, if we destroy the reality and the end of providential control. (4) From the experience of individuals, which may be misinterpreted, but can not be overlooked altogether. (5) The proofs from the Holy Scriptures: (*a*) in the passages which indicate or declare the government of God over nature, over irrational animals, over men and nations; (*b*) in the lives of eminent men—e. g. Abraham, Moses, Elijah, Saul, David, Daniel, Paul; (*c*) in the Jewish history, conspicuously everywhere; (*d*) in passages which affirm the truth of prophecy; (*e*) and in those which affirm the efficacy of prayer.

The literature of this subject is voluminous. Some of the most important works which treat of the history of opinion are (*a*) in philosophy: Ritter's *History of Philosophy* (12 vols.); *History of Ancient Philosophy* (4 vols.), translated from the first volumes of the general history by A. J. W. Morrison; Ueberweg's *History of Philosophy*, translated by Prof. G. S. Morris (2 vols.). (*b*) In theology: Neander's *General Histories of the Christian Religion and Church*, translated by Prof. Torrey (5 vols.); Hagenbach's *History of Doctrines*, translated by Prof. H. B. Smith (2 vols.); Van Oosterzee, *Christian Dogmatics* (2 vols.), in Theological and Philosophical Library, edited by Prof. Smith and Prof. Schaff; Knapp's *Christian Theology*, translated by President Leonard Woods; and Rev. Dr. Charles Hodge's *Systematic Theology* (3 vols.). Revised by FRANK H. FOSTER.

Providence: city (founded in 1636); capital of Rhode Island and also the capital of Providence County; at the head of navigation on Narragansett Bay; seven railways, all controlled by the New York, New Haven and Hartford Railroad Corporation, enter the city; 30 miles N. by W. of Newport, 44 miles S. W. of Boston (for location, see map of Rhode Island, ref. 8–N). Two small rivers meeting divide it into two parts, the east and west sides. At the junction of these rivers was formerly the Cove, now filled in. With the promenade which surrounded it the space, amounting to 1,585,134 sq. feet, is devoted to the use of the railways. Of public parks the most important is the Roger Williams (102 acres). It contains a fine statue of Roger Williams (see WILLIAMS, ROGER), the founder of the city and State. The surface of the city is very uneven. Many of the best business blocks rest on "made land," while parts of the residence portions rise 200 feet above tide-water. These inequalities add much to the picturesqueness. The streets are remarkably well cared for. Those in the business portions are paved, the others macadamized. All are clean. The electric and cable railways are owned by one company. The city is noted for its large private houses. Its most important public buildings are the old State-house (1762), Providence County court-house (1877), the city-hall, built in 1879 at a cost of over $1,000,000; the Rhode Island State Normal School, and the new State Capitol. This last was finished in 1900 at a cost of $3,500,000. Among the business blocks should be noted the Arcade (1828), a three-storied structure, connecting the two principal business streets; the Butler Exchange (1872), the buildings of the Rhode Island Hospital Trust Company (1891), the Industrial Trust Company (1894), the Union Trust Company (1901), and the Banigan Building. All these buildings front on Westminster Street, the chief business thoroughfare. There are 129 churches and other places of worship. Of these the Baptists have 21; Episcopalians, 14; Congregationalists, 10; Methodists, 18; Roman Catholics, 16; Unitarians, 4; Universalists, 3; and Presbyterians, 4. The most noted is the First Baptist meeting-house, built in 1775 "for the public worship of Almighty God, and also to hold commencements in." It is of wood, and has a very beautiful spire. The largest edifice is the Roman Catholic cathedral (1885). The principal educational institution is BROWN UNIVERSITY (*q. v.*). The Rhode Island School of Design furnishes the art instruction needed in a great manufacturing community. The chief private school is the Friends Yearly Meeting Boarding-school, opened in 1818. Here is also the State Normal School. The public schools in 1893 had 18,772 pupils, 451 teachers, and 66 buildings. The most important hospitals are the Rhode Island (1868), and the Butler Hospital for the Insane (1847). The last is situated on the east bank of the Seekonk river in a park of 140 acres, and accommodates 200 patients. The Dexter Asylum for the Poor was founded in 1827; its grounds comprise 39 acres. The city is especially rich in public and private libraries. Besides that of Brown University (110,000 volumes) should be noted the Public Library, 100,000 volumes, the Athenæum Library, 70,000 volumes. The library of the late John Nicholas Brown is unequaled in its Americana. The city debt Apr. 1, 1900, was $14,008,484.14; assessors'

valuation of real and personal estate, $188,501,780; rate of taxation, $16 per $1,000. Providence is especially noted for its manufactories of cotton and woolen goods, jewelry (167 establishments), silverware, tools, locomotives, boilers, steam and electrical engines, screws, files, sewing-machines, etc. The census of 1890 showed that 1,883 manufacturing establishments (representing 154 industries) reported. These had a combined capital of $54,274,227, employed 37,955 persons, paid $18,789,500 for wages and $36,674,308 for materials, and had products valued at $71,810,173. The city is a great wholesale and distributing-point. Immense quantities of coal are transhipped from its wharves. The commerce is mostly coastwise. Lines of steamships run to Baltimore, Philadelphia, and New York. It has 33 banking institutions with an aggregate capital of $30,000,000. The deposits in the savings-banks exceed $40,000,000. As a seaport for 200 years the town grew slightly, though its commerce was extensive. With manufactures came marvelous development. Since 1860 the population has increased three-fold. Pop. (1890) 132,146; (1900) 175,597.

WILFRED H. MUNRO.

Provincetown: town; Barnstable co., Mass.; on the northern extremity of Cape Cod and the N. Y., N. H. and Hart. Railroad; 55 miles by water and 120 by rail S. E. of Boston (for location, see map of Massachusetts, ref. 5–K). It is noted as the first landing-place of the Pilgrim Fathers in America; as the birthplace of the first child born in New England of English parents; and as a popular summer resort. It has a deep and commodious harbor on the inner side of the cape, almost entirely landlocked, and free from obstructions. The principal industries are whaling and cod and mackerel fishing. The town has a national bank with capital of $200,000, a savings-bank, a public library, several hotels and summer boarding-houses, and a weekly newspaper. Pop. (1880) 4,346; (1890) 4,642; (1900) 4,247.

Proviso: a clause or provision introducing a condition, as into a contract, a statute, or a will; a conditional stipulation. See CONDITION.

Provo: city; capital of Utah co., Utah; on the Provo river, and the Union Pac. and the Rio Grande West. railways; 3 miles E. of Utah Lake, 48 miles S. S. E. of Salt Lake City, near the western base of the Wasatch Mountains (for location, see map of Utah, ref. 4–M). It is in an agricultural region; contains the Utah Insane Asylum, Brigham Young Academy (Latter-Day Saints, opened in 1876), Proctor Academy (Congregational, opened in 1887), a national bank with capital of $50,000, a savings-bank, 2 private banks, a semi-monthly, 2 daily, and 2 semi-weekly periodicals; and has manufactories of flour, leather, woolen goods, and lumber. Pop. (1880) 3,432; (1890) 5,159; (1900) 6,185.

Provoost, prō'vōst, SAMUEL, D. D.: bishop; b. in New York, Mar. 11, 1742, of Huguenot ancestry; graduated at King's College, New York, 1758, and the University of Cambridge, England; entered the Church of England ministry 1766, and in same year became assistant minister of Trinity church, New York; espoused the popular side at the breaking out of the war, and retired to his country home during the struggle; became in 1783 rector of Trinity church, chosen by the patriot churchmen of New York, and in 1787 was consecrated Bishop of New York at Lambeth, England; was chaplain of Congress in 1785, and in 1789 chaplain of the U. S. Senate; read prayers at St. Paul's chapel on occasion of the presence of Washington and the Congress directly after the inauguration exercises in 1789; resigned the care of Trinity church in 1800, and in 1801 received a coadjutor. During the closing years of his life he retired from all public offices. D. in New York, Sept. 6, 1815.

Revised by W. S. PERRY.

Provo River: a river of Utah which rises on the west slope of the Uinta Mountains, flows westward in a deep, wild cañon through the Wasatch Mountains, and empties into Utah Lake, which is tributary to Great Salt Lake. It is about 100 miles long, and of sufficient volume without storage to irrigate 100 sq. miles of land. The upper portion of the stream was formerly a branch of Weber river, but was turned from its original course by *débris* deposited by the stream itself in Kawas valley. It was one of the principal tributaries of Lake Bonneville, and built the large delta on which the town of Provo now stands. Consult *Report on Arid Lands*, by J. W. Powell (Washington, 1879), and *Lake Bonneville* by G. K. Gilbert (Monograph No. 1 U. S. Geol. Surv.).

ISRAEL C. RUSSELL.

Provost-marshal: in the army and navy, an officer who attends to the execution of martial law, the fulfillment of sentences by courts martial, and the like. He preserves order in towns and districts under military control, and has certain summary powers under the articles of war.

Prowse, DANIEL WOODLEY: See the Appendix.

Prudden, THEOPHILE MITCHELL, Ph. B., M. D.: b. at Middlebury, Conn., July 7, 1849; educated at Yale College, Heidelberg, Berlin, and Vienna, graduating M. D. from the Yale Medical School in 1875; devoted himself to pathology, and was lecturer on normal histology at Yale Medical School; in 1881 became director of the pathological laboratory of College of Physicians and Surgeons, New York; in 1892 was elected Professor of Pathology in the latter college. Among his works are *Manual of Normal Histology* (1881); with Delafield, a *Handbook of Pathological Anatomy and Histology* (1885); *Story of the Bacteria* (1889); *Dust and Its Dangers* (1891); and *Water and Ice* (1891).

Pruden'tius, AURELIUS CLEMENS: poet; b. in 348 A. D. in Northern Spain; studied law; practiced as an advocate; held several high positions, and received in 394 a military appointment at Rome under the Emperor Theodosius, but retired afterward from public life and devoted himself exclusively to theological studies and religious poetry. The date of his death is unknown. He is last heard from in 405. Of his *Liber Cathemerinon* and *Liber Peristephanon*, two collections of hymns, several pieces became very popular, were translated into other languages, and are still in use. Among his other books, all written in Latin verse, are *Hamartigenia*, on the origin of sin; *Psychomachia*, on the contest between good and bad in the human soul; *Contra Symmachum Libri Duo*, to persuade the Roman emperor not to restore the altar and statue of Victory cast down by Gratian. There are complete editions of his works by Arevalus (Rome, 1788; rep. Migne, lix., lx.), by Obbarius (Tübingen, 1845), and by Dressel (Leipzig, 1860). A new revision of the text is promised by Huemer for the *Vienna Corp. Script. Eccl. Lat.* An English translation of the *Cathemerinon and other Poems of Prudentius* appeared in 1845 (London). See also F. St. John Thackeray, *Translations from Prudentius* (London, 1890; Latin text and verse translations; notes, introduction on life and times, etc.). See J. Schmitz, *Die Gedichte des Prudentius und ihre Entstehungszeit* (Aachen, 1889), and A. Puech, *Prudence: Étude sur la poésie lat. chrétienne au IVe siècle* (Paris, 1888).

Prudhommes, Conseils de: See FRANCE (*Justice*).

Prume, FRANÇOIS HERIN JEHIN: See the Appendix.

Prune [viâ Fr. from Lat. *pru'num*. See PLUM]: the dried fruit of certain kinds of plums. The finest sorts are called *prunelles*. The best-known prunes come from France, but Germany furnishes large amounts of a coarse kind. Turkey and Spain also export prunes. They are used as a mild laxative for children, and are extensively employed in cookery. They are sometimes dried by artificial heat and sometimes in the sun, or perhaps more commonly are half dried by stoves, the process being finished in the sun. California is an important prune-producing country. Its product is usually lighter colored than that of France, because the fruit is dried without heating or cooking. The chief variety used there for the commercial article is Prune d'Agen. The plums are shaken from the tree and dipped in lye to facilitate the drying process.

Revised by L. H. BAILEY.

Pruning [*prune* < M. Eng. *proinen*, from O. Fr. *provain* > Mod. Fr. *provin* < Lat. *propa'go*, *propa'ginis*, slip, cutting. Cf. Eng. *propagate*]: the act of cutting off parts of a tree or shrub, either for the purpose of producing a certain shape or of increasing the production of fruit or timber, or improving the size and quality of the fruit and the ease of picking the crop and caring for the plant; also to facilitate the fighting of insects and fungi. Forest trees are pruned to increase the quantity of timber in the trunk by diminishing the side branches, beginning at the lower part of the tree. In fruit trees the branches are thinned out in order to admit the air and light more freely to the leaves, blossoms, and fruits, and to concentrate and increase the nourishment for the branches which remain. In pruning for the purpose of producing fruit it is necessary to know on what branches and buds the fruit grows. The grape generally bears on shoots of the current year (see GRAPE), the peach on those of the preceding year, and the apple and pear on wood of two or three years' growth. It is generally considered that early spring or late winter is

the best season for pruning. For explicit directions, see the various fruit manuals. The only special volume devoted to the pruning of fruits in the U. S. is Bailey's *American Grape Training*. Revised by L. H. Bailey.

Pruri'go [Mod. Lat., from Lat. *pruri'go*, an itching, deriv. of *pruri're*, itch]: a condition of the skin, characterized by intense itching and by the presence of small points filled with a watery liquid.

Prussia (in Germ. *Preussen*): the principal state of the German empire, comprising almost two-thirds of its entire area.

Boundaries, Area, and Physical Features.—It extends from lat. 49° 6′ 45″, its extreme southern point in the Rhine province, to 55° 53′ 40″ N., and from lon. 5° 50′ to 22° 50′ E. It is bounded by the North Sea, Oldenburg, Denmark, Mecklenburg, and the Baltic on the N., by Russia on the E., the Austrian empire, the kingdom of Saxony, Thuringia, Bavaria, Hesse, and Alsace-Lorraine on the S., and by Luxemburg, Belgium, and the Netherlands on the W. It includes also the detached territory of Hohenzollern. Among the islands belonging to it are Rügen, Fehmarn, and Alsen in the Baltic and the North Frisian islands and Heligoland in the North Sea. Its area is 134,463 sq. miles. The principal part of the kingdom in the north and east belongs to the great northern plain of Europe. In the main it slopes gently to the N., and only in places along the coast is broken by sand-dunes, the highest in Europe. At Rügen chalk cliffs rise abruptly from the sea. The northeast coast of Schleswig-Holstein is high and cut in by numerous fjords. Along the North Sea, however, it has frequently been necessary to build dikes to protect the low-lying land from overflow. In the south and southwest the surface is for the most part hilly or mountainous. The principal mountains are the Sudetic range, including the Riesengebirge (5,255 ft.), on the S. toward the borders of Austria, further westward the Thuringian and Hartz Mountains, and still further to the W. the Teutoburgerwald, the Weser Mountains, the Taunus, and the Westerwald. Hohenzollern lies in the Swabian Alps. The principal rivers are the Rhine, Ems, Weser, Elbe, Oder, Vistula (Weichsel), Niemen, and their affluents. The coast has a number of bays, among them the Kiel, Rügen, and Pomeranian Bays and the great Gulf of Dantzic so called, and some large inlets, the most important of which are the Stettin, Frisches, and Kurisches Haff. There are small lakes in the north and northeast—in Holstein, Pomerania, West and East Prussia—but they also occur in other parts of the kingdom.

Climate, Soil, and Products.—The climate of Prussia is temperate and on the whole salubrious. The harvest season is short in the northeast, and the higher regions of the west are characterized by raw winds; the more protected parts of the country, however, adjoining the Sudetic range, Saxony, the S. of Hanover, and the middle Rhine, are mild and equable. The mean annual temperature of East Prussia is 6·33° C.; about the confluence of the Moselle with the Rhine it reaches 10·1° C. About the lower waters of the Vistula and the Oder only careful draining carried on through centuries has rendered the land available. The highest parts of this region consist for the most part of sand and clay. The northwestern provinces have in parts dry and barren soil alternative with marsh and turf moor. The most fertile portions of the kingdom are in the province of Saxony, the foot-hills of the Sudetic Mountains, and the Thuringian, Weser, Westerwald, and Taunus uplands. The total productive area occupied by crops and forests is 20,853,532 hectares. The principal agricultural products, arranged in the order of the area occupied in their production, are rye, hay, oats, potatoes, wheat, barley, beetroot, rape-seed, flax, hops, and tobacco. Fruit is grown in the warmer parts of the country. Wine is produced on the Rhine and the Moselle, the Saale and Unstrut, and in Silesia. Stock-raising is extensively carried on. Of minerals there is a large production. The most important are coal, iron, zinc, lead, copper, cobalt, nickel, and rock-salt. Amber is found on the Baltic coast.

Population and Government.—The population of Prussia in 1895 was 31,855,123, divided among the fourteen provinces as follows: East Prussia, 2,006,689; West Prussia, 1,494,360; Pomerania, 1,574,147; Posen, 1,828,658; Brandenburg, 2,821,695; Berlin, 1,677,304; Saxony, 2,698,549; Silesia, 4,415,309; Hanover, 2,422,020; Schleswig-Holstein, 1,286,416; Westphalia, 2,701,420; Hesse-Nassau, 1,756,802; Rhine province, 5,106,002; Hohenzollern, 65,752. With respect to nationality 26,438,070 are Germans, 2,872,197 are Poles, 164,162 are Czechs, 139,399 are Danes, 121,345 are Lithuanians, 89,786 are Dutch and Frisians, 67,967 are Wends, and 64,441 are of other nationalities. With respect to creed 19,232,449 are Evangelical, 10,252,807 Roman Catholics, 372,058 Israelites, and 95,349 belong to other denominations. The Roman Catholics are settled principally in the Rhine province, Silesia, Westphalia, and Posen. In 1900 the population was 34,463,377. The government is a hereditary constitutional monarchy administered by the king and the Landtag. The latter consists of two chambers—the Herren-haus, or House of Lords, and the Abgeordneten-haus, or House of Delegates, with 433 members elected for three years. The king is the German emperor. As the principal state in the empire, Prussia has 17 representatives in the Bundesrath and 236 members in the Reichstag. See German Empire.

Army, Finance, and Education.—The Prussian army forms the principal part of the army of the empire. Including the contingents of the minor states, but exclusive of the armies of Saxony, Bavaria, and Würtemberg, its peace footing consists of 376,841 men in the different branches of the service, with 19,382 officers, surgeons, etc. The state of its finances, according to the budget of 1893–94, was as follows: Total receipts, 1,893,313,260 marks, the principal items of which were direct taxation, 135,166,000; indirect taxes, 71,164,000; mines and salines, 138,361,229; railways, 938,732,081; domains and forests, 88,773,734; total national debt, 6,243,773,430 marks, with a sinking fund of 17,079,453 marks. The public educational system has reached a particularly high standard of development. Education is general, and in the elementary schools compulsory. There were (1891–92) 34,742 public elementary schools, 606 public middle schools, 315 gymnasiums, pro-gymnasiums, and Real pro-gymnasiums, 122 schools for the training of teachers, 10 universities (with 14,635 matriculated students), and various institutions for special and technical training.

Manufactures, etc.—Prussia is one of the greatest manufacturing countries of Europe. Its iron industry is among the foremost in the world; it also yields about half of the world's product of zinc. The principal manufactures are metallic wares, machinery, cotton goods, silk, velvet, linen, cloth, paper, and leather. Its exports include manufactured goods of great variety, grain, timber, wool, live stock, etc. In 1893 Prussia had 18,367 miles of railways, about 90 per cent. of which is the property of the state. Of internal waterways all the rivers named are navigable, and there are in addition several canals.

History.—A Prussian people (Pruzi, Prutheni), akin to the Letts and Lithuanians, first appeared in history near the end of the tenth century in the region to the E. of the Vistula. In that same century Adalbert, Bishop of Prague, endeavored to convert them to Christianity, but was killed by them in 997. In the eleventh and twelfth centuries they were involved in conflicts with the Poles, who failed to effect a conquest; but in 1283 the Teutonic Order conquered the country. In 1309 Marienburg became the headquarters of the order. For more than 200 years the Teutonic Order ruled the country, but ultimately it broke down through the enmity of Poland and Lithuania and its own internal deterioration. By the peace of Thorn (1466) the whole country W. of the Vistula was ceded to Poland, and her sovereignty was acknowledged over the remainder. In 1511 Albrecht, Margrave of Brandenburg, of the family of Hohenzollern, was elected grand master and in 1525 he dissolved the order and transformed the greater part of East Prussia and a small part of West Prussia into a temporal hereditary dukedom. The connection between the dukedom and Brandenburg thus begun was not, however, finally accomplished until after the death of Duke Albrecht Friedrich (1618), and the consequent extinction of the lateral line, when the dukedom fell to the electoral house of Brandenburg. It continued, however, a fief of the Polish crown until 1656, in the time of Friedrich Wilhelm, the Great Elector, whose long and successful reign (1640–88) marks the real beginning of the Prussian state.

For the subsequent history of Prussia, see German Empire (*History*), and for further details see the biographies of her kings—Frederick William I., II., III., and IV., Frederick II., William I., and the articles on the Seven Years' War, the Franco-German War, and Napoleon I.

Bibliography.—General works: Stenzel, *Geschichte des preussischen Staates* (5 vols., Gotha, 1831–54); Eberty, *Geschichte des preussischen Staates* (7 vols., Breslau, 1873); Pierson, *Preussische Geschichte* (4th ed. 2 vols., Berlin,

1881); Joh. Gust. Droysen, *Geschichte der preussischen Politik* (5 vols. in 14, Leipzig, 1868–86). Works on special periods: Ranke, *Memoirs of the House of Brandenburg, and History of Prussia during the Seventeenth and Eighteenth Centuries* (translated from the German by Sir Alexander and Lady Duff Gordon, 3 vols., London, 1849), and *Denkwürdigkeiten des Staatskanzlers, Fürsten von Hardenberg* (5 vols., Leipzig, 1877); Thomas Carlyle, *History of Friedrich the Second, called Frederick the Great* (6 vols., New York, 1858–66); Hillebrand, *La Prusse Contemporaine et ses Institutions* (Paris, 1867); Seeley, *Life and Times of Stein; or Germany and Prussia in the Napoleonic Age* (3 vols., London and Boston, 1879). WILLIAM H. CARPENTER.

Prussian Blue, or **Berlin Blue**: ferric ferrocyanide, Fe_4Cfy_3, or Fe_7Cy_{18}. It is produced by precipitating ferric chloride or sulphate with potassium ferrocyanide; or by precipitating the ferrous sulphate (copperas) with the same reagent, and oxidizing the product by some convenient method. It is intensely blue, and is used as a pigment. Its solution in oxalic acid is used as a blue ink and for bluing linen, etc. It is used in dyeing and calico-printing, being formed in the cloth. See CALICO-PRINTING.

Prussian Carp: See GIBEL.

Prussian Language, Old: See OLD PRUSSIAN LANGUAGE and LETTIC RACE, THE.

Prussic Acid: See HYDROCYANIC ACID.

Pruth: a tributary of the Danube. It rises on the northeast side of the Carpathian Mountains in Galicia, runs through Bukowina, forms the boundary between Roumania and Russia, and enters the Danube at Reni, 13 miles below Galatz, after a course of about 520 miles. It becomes navigable from near Jassy.

Prutz, ROBERT EDUARD: poet; b. at Stettin, Prussia, May 30, 1816; studied philology, philosophy, and history at Berlin, Breslau, and Halle, and afterward edited with Arnold Ruge the *Halleschen Jahrbücher*, a periodical which advocated liberal ideas in science, religion, and politics. Owing to his radical views he was for a long time excluded from the academic career until in 1849 he became Professor of Literature at the University of Halle. He soon resigned this position, and devoted himself entirely to literary and scientific pursuits. As a poet Prutz belongs to the patriotic bards who, previous to 1848, fought for greater political liberty in Germany. Besides the *Gedichte* (1849), *Aus der Heimat* (1858), *Herbstrosen* (1865), he published several dramas filled with the same patriotic spirit (*Moritz von Sachsen, Erich der Bauernkönig*), and a number of novels that disclose a great talent for satire. His researches in the history of German literature, which are embodied in the monographs *Der Göttinger Dichterbund* (1841), *Geschichte des deutschen Journalismus* (1845). *Vorlesungen über die Geschichte des deutschen Theaters* (1847), have insured Prutz a permanent position in the history of literature. He also exerted great influence on the literary production of his time as a critic in the *Deutsche Museum*, a literary periodical which he edited 1851–66. D. at Stettin, June 21, 1872. JULIUS GOEBEL.

Prynne, WILLIAM: Puritan writer and agitator; b. at Swanswick, Somersetshire, England, in 1600; studied at Oriel College, Oxford, and graduated 1620; studied law at Lincoln's Inn; was converted to Puritanism by Dr. John Preston, lecturer at that inn; in 1633 issued his celebrated *Histrio-Mastix, the Player's Scourge*, which was construed into a libel upon the queen; was brought before the Star Chamber, fined £5,000, expelled from the University of Oxford and from Lincoln's Inn, set on the pillory at Westminster and Cheapside, had both ears cut off, and was sentenced to imprisonment for life. Having issued from his prison a tract entitled *News from Ipswich*, he was again fined and pilloried, had the letters S. L. ("Seditious Libeler") burned upon his cheek, was imprisoned in close confinement in Caernarvon Castle, and afterward in the castle of Mont Orgueil in the island of Jersey. In 1640 Prynne was released by warrant from the House of Commons. Elected a member of Parliament for Newport, he conducted the proceedings against Laud; became recorder of Bath 1647; took an active part in favor of the Presbyterians in their struggle with the Independents; advocated a reconciliation between Parliament and the king; was arrested for denying the supremacy of Parliament in a pamphlet entitled *A Brief Memento* (1648); was with others ejected from Parliament by the army Dec. 6, 1648; attacked Cromwell and the army in his writings; was again imprisoned in 1650 and 1651; advocated the restoration of Charles II.; was elected to the new Parliament 1660; was made keeper of the records in the Tower; was reprimanded by the House of Commons 1661 for new offenses in his writings; published a vast number of political, legal, and antiquarian treatises. D. in London, Oct. 24, 1669.

Pryor, ROGER ATKINSON, LL. D: lawyer; b. near Petersburg, Va., July 19, 1828; graduated at University of Virginia 1848; studied law; became connected with the press at Petersburg 1851; was an editor of the Washington *Union* 1852 and of the Richmond *Enquirer* 1853; went as special commissioner to Greece 1855; edited a newspaper entitled *The South* 1856–67; sat in Congress 1857–59; was again elected in 1860, but did not take his seat on account of the secession of Virginia; was chosen to the provisional congress of the Confederate States at Montgomery, and to the first regular Confederate congress; entered the Confederate army as colonel of the Third Virginia Regiment; was made brigadier-general after the battle of Williamsburg; was taken prisoner Nov., 1864, and imprisoned in Fort Lafayette, but was released after four months' detention. In 1865 began the practice of law in the city of New York, devoting himself to his practice until in 1890 he was appointed judge of the court of common pleas, to which office he was elected in 1891 for a term of fourteen years. By virtue of the revised constitution of 1894 he becomes a justice of the Supreme Court on and after Jan. 1, 1896, for the remainder of his term of fourteen years, the court of common pleas being then abolished. Revised by F. STURGES ALLEN.

Przemysl, pzhem'is'l: town; in the province of Galicia, Austria; on the river San, an affluent of the Vistula; 61 miles by rail W. of Lemberg (see map of Austria-Hungary, ref. 3–J). It is the see of a Roman Catholic and a United Greek bishop, has many educational and benevolent institutions, and manufactures of spirits, machinery, etc. Since 1874 it has been strongly fortified. Pop. of the commune (1890) 35,619.

Psalmana'zar, GEORGE: the assumed name of a literary impostor, whose real name and early history have remained unknown. He is supposed to have been born in the south of France in 1679; received a good education under Jesuit instructors; led for some time a vagrant life, roaming through France, Germany, and the Netherlands; ultimately attracted the attention of Mr. Innes, chaplain of a Scotch regiment at Sluys, Holland, who succeeded (as he supposed) in converting Psalmanazar to Christianity, took him to London, and presented him to Bishop Compton and others as a native of Formosa. It is uncertain whether Innes was a dupe or an accomplice in this affair, but he received promotion for his missionary zeal, and Psalmanazar was encouraged to draw up a *History and Description of the Island of Formosa off the Coast of China* (1704), illustrated with many engravings and with copious specimens of the pretended Formosan language, into which he translated the Catechism of the Church of England. Psalmanazar was sent to Oxford, but soon repented of and confessed his imposture, applied himself to study, became skilled in Oriental history and literature, and spent nearly half a century in London, chiefly occupied in writing for the booksellers. He completed Palmer's *History of Printing*, wrote several volumes of the *Universal History*, and led an exemplary life. D. in London, May 3, 1763. His autobiographical *Memoirs* appeared in 1764.

Psalmody [via O. Fr. and Lat., from Gr. ψαλμῳδία, liter., singing of psalms; ψαλμός, psalm + ᾠδή, song, singing]: as usually defined, the act, art, or practice of singing psalms; but properly, in a wider sense, not only the vocal rendering of the songs used in public worship, but also the study of their origin and history, as well as of the tunes to which they are sung. Psalmody may be considered as ancient and modern. In the former the songs were all rhythmical, and necessarily performed in the chanting or recitative style.

That God was worshiped publicly in song before David's time is clear, not only from the inherent probability of such praise, but also from the readiness and facility with which the responsive hymn of male and female voices was sung after the passage of the Red Sea. No direction, however, was given for such worship in the Law. It was David, the Psalmodist as well as the Psalmist of the Old Testament, who instituted the formal, stated, liturgical services of praise. He had a trained choir of 4,000 Levites, who, however, came out in full force only on great occasions. Over

these were three leaders—Heman, Asaph, and Ethan or Jeduthun—who directed them by beating time upon cymbals. The treble (*Alamoth*, 1 Chron. xv. 20) was led by the harps ("psalteries" in the English version), and the bass (*Sheminith*, 1 Chron. xv. 21), not in harmony, but simply an octave lower, by lyres or citharas ("harps" in our version). Many, though not nearly all, of the Psalms of David and his followers were composed partly for use in this service, and the superscriptions of a considerable number have reference to this design. In some of these allusion is made to the musical instruments by which they were to be accompanied; in others to the pitch (treble or bass) in which they were to be sung; and in a few to some familiar tune to which they were to be adapted. Some of the Psalms give evidence of adaptation to responsive singing, which was usually done by the two divisions of the choir, though sometimes, as in Ps. xxiv., the service was probably divided between the Levites and the people. The latter did not commonly join in the singing, except, apparently, in refrains and familiar formulas of praise, where they were enjoined to come out in full chorus. Some alterations in matters of detail were made in the service of praise in the second temple, the system being extended also, so as, for example, to have one psalm appropriated to each day of the week.

As to the musical system of the ancient Jews, nothing definite is known. The primary design of the accents in the Hebrew Psalter is that of musical notation, but these are no longer understood except in their secondary use of interpunction. It is possible that the synagogue-worship of later times and the old Christian chants retain traces of the simple recitative melodies of the ancient temple.

In the New Testament little is said of praise in public worship. The temple-service was of course maintained, with gradual modifications, until the dispersion. Hearty and unrestrained singing, being a necessary part of Christian worship, is often enjoined in the Epistles. The services were no doubt a selection from the temple-psalms, with the old tunes, which held a place far into the history of the early Church. To these were gradually added Christian hymns, which were at first modeled after the psalms, and were doubtless set to the same simple music. The Syrian Church had a larger hymnology and more elaborate music than its sister churches.

The development of psalmody in modern times in accordance with the needs of the Church has been due chiefly to two causes—the gradually increasing and ultimately predominant use of metrical songs as supplementing the old rhythmical forms, with a corresponding change in the tunes, which improved with the progress of musical science, and the growth of an hymnology in which the manifold experiences of Christians have found full expression. Still, many of the psalms have always been retained in essential substance, and have remained the best source of inspiration and culture for good hymn-writers. Music became a regularly constituted portion of church-service in the fourth century. Its early development in the Western Church was largely due to Ambrose, Bishop of Milan, and its progress during the Middle Ages to the improvements effected by Pope Gregory I. From them the names of the two old standard styles of chanting have been derived. Until the Reformation sacred music was under the control of the clergy. Metrical psalmody with harmony probably arose long before that era in Germany, but had not made much general progress. The efforts of Luther and many of his helpers, by the adaptation of secular airs and the composition of new tunes, resulted in a widespread enthusiastic interest in sacred music among the Protestants in that country. Ever since, also, it has been from Germany that the greatest influence and the healthiest tone have been given to the musical department of psalmody. In those lands where the influence of Geneva has had chief control, as most conspicuously in Scotland, this part of worship has been largely influenced by a tendency to plainness and severe simplicity in both words and music; yet congregational singing is hearty and general.

J. F. McCURDY.

Psalms [M. Eng. *psalm, salm* < O. Eng. *sealm, salm*, early loan-word from Lat. *psalmus* (cf. Fr. *psaume*) = Gr. ψαλμός, song to the harp, deriv. of ψάλλειν, twitch, play a stringed instrument]: the title given in the Septuagint version to the book in the canon which the Hebrews called the Praise Songs, and in English the Psalter. They are sometimes called the Psalms of David, as if all or the majority of the 150 had been composed by him. In the Hebrew Bible we find the whole collection divided into five books (i.–xli.; xlii.–lxxii.; lxxiii.–lxxxix.; xc.–cvi.; cvii.–cl.)—a division which assumed its final shape before the completion of the Old Testament canon, but was only accomplished after several hands at various periods had helped toward the permanent arrangement. This partition is doubtless a designed correspondence with the five books of the Law. In the places assigned to the several psalms also there is evidence of careful arrangement according to principles more or less obvious, such as a tendency to place in the same group compositions of the same individual, or of the same period, or upon the same general subject, or written in the same style, or for a similar liturgical purpose.

As to the *authorship* of the several poems the superscriptions traditionally attached to many of them are the only guide. Seventy-three of the psalms are thus assigned to David, and in nearly every case the correctness of the title is attested by strong evidence in their matter and style. The same criteria enable us to assign with great confidence a certain number of the anonymous psalms to the same author, making his whole contribution to be about eighty. Twelve are ascribed to the singer Asaph, which designation also included certain of his descendants who inherited his poetical and musical gifts. Thirteen or fourteen proceeded from the "sons of Korah." Two were written by Solomon (lxxii., cxxvii., in whose superscriptions we should read "of" and not "for," as in the Revised Version). One, Ps. xc., is accredited to Moses. It is difficult or impossible to assign the remaining psalms with certainty to their true authors. The dominant school of Hebrew critics questions the correctness of these traditional ascriptions, and assigns almost all the psalms to a period long after David—indeed, some scholars set the whole collection in the Maccabean era.

As to the *matter* of the Psalms, it must suffice here to say that they were the outflow of the spiritual life of the most highly endowed natures of a long period of Israel's history. Thus they contain a record of their adoration, confessions, petitions, and aspirations as these were conditioned, on the one hand, by their conceptions and knowledge of God and of his dealings with men, and on the other by their own inner history and outward circumstances. We find in the Psalms a vital appreciation of the ideas of God and Providence that had been unfolded in the teachings of the Law, and the most practical illustrations of the duty and privilege of worship and obedience. And so fresh, various, just, and profound are their views of the spirituality, holiness, and goodness of God, and their representations of the yearnings, conflicts, and triumphs of the earnest soul, that the Psalter has not only prompted and made valuable all the hymnology of the Church, but has always been the chosen consoler and counselor of the Christian heart. See PSALMODY.

LITERATURE.—Of modern commentators in English on the Psalms may be recommended J. A. Alexander (3 vols., New York, 1850); J. M. Neale and R. F. Littledale (4 vols., London, 4th ed. 1884, rich in patristics); J. J. S. Perowne (2 vols., 6th ed. 1886, the best, on the whole); C. H. Spurgeon (7 vols., 1870–84, strong in Puritan and pithy comment); A. Maclaren (in *Expositor's Bible*, 3 vols., 1894).

Revised by S. M. JACKSON.

Psalms of Zoroaster: designation of the *Gāthās* or metrical selections in the AVESTA (*q. v.*), containing the teachings, exhortations, and revelations of Zoroaster, the prophet of ancient Iran. The Gāthās are five in number, and they comprise seventeen short psalms, averaging about a dozen stanzas each. The fivefold grouping is based upon the meters in which they are composed. The pith of Zoroastrianism is contained in these psalmodic selections; the prophet exhorts men to eschew evil and choose the good, the kingdom of light rather than the kingdom of darkness, and their reward shall be eternal. He enunciates the doctrine of dualism in a sort of Iranian Sermon on the Mount. The Gāthās are the oldest part of the Avesta, and the language in which they are written is more archaic than that used elsewhere in the ancient sacred books of the Parsis. See ZOROASTER.

A. V. WILLIAMS JACKSON.

Psammetichus I. (Egypt. *Psemthek*): the first king of the twenty-sixth Egyptian dynasty (666–612 B. C.). By marriage he gained alliance with the Ethiopians of NAPATA (*q. v.*), and by the aid of Ionian and Carian mercenaries he overthrew the Assyrian governors of the Delta region who

had been installed by Assurbanipal of Assyria. His ambition was to make Egypt strong at home, hence he encouraged Greek immigration (see NAUCRATIS and TAHPANHES), giving the colonists exclusive trade privileges. He built largely at various places, such as Heliopolis, Mendes, Memphis, Abydos, and Thebes, and during his reign a very remarkable renaissance in art occurred. He was succeeded by NECHO (*q. v.*), who continued the same policy. Psammetichus II. and Psammetichus III. were rulers of small importance. The latter was defeated at Pelusium by Cambyses, who set up the twenty-seventh or Persian dynasty in 527 B. C.

CHARLES R. GILLETT.

Psa'ra, or **Ip'sara**: a small island in the Grecian Archipelago, W. of Scio, belonging to Turkey. It is rocky and barren, but was densely peopled and very prosperous before the Greek revolution, but having been taken by the Turks in 1824 its commerce was destroyed, its agriculture fell into decay, and its population decreased very much. At present its inhabitants live mostly by fishing.

Pseudepig'rapha [Mod. Lat. = Gr. ψευδεπίγραφα, neut. plur. of ψευδεπίγραφος, falsely inscribed or ascribed; ψευδής, false + ἐπιγράφειν, inscribe; ἐπί, on + γράφειν, write]: those writings which bear the names of Old or New Testament characters as authors or principal subjects, but which never formed part of the canon, either Hebrew or Christian. They were produced between 300 B. C. and 300 A. D. Those which antedate Christ are to be distinguished from the APOCRYPHA (*q. v.*) of the Old Testament, which have a place in the Septuagint translation and in the canon of the Greek and Latin Churches, and were formerly printed along with the canonical Scriptures in English Bibles. These books are: I. and II. Esdras, Tobit, Judith, The Rest of Esther, Wisdom, Ecclesiasticus, Baruch with the Epistle of Jeremiah, The Song of the Three Children, The Story of Susanna, The Idol Bel and the Dragon, The Prayer of Manasses, I. and II. Maccabees. As no distinction is made between the New Testament Apocrypha and Pseudepigrapha, since all alike are and have always been uncanonical, both will be treated in this article under the term "Apocrypha." These pseudepigrapha are worthless as history of the time they pretend to date from, yet have a certain value as specimens of the thought of the times in which they were produced. They were surely not written by the authors they claim, yet are not on that account to be classed as forgeries, in the modern sense of the term, since it was allowable then to issue writings under the name of some well-known man of a past age. Thus in the Hebrew canon the name Solomon is attached to writings or parts of writings with which he had nothing to do. So, in the nearly unanimous judgment of Hebrew scholars, is it with the names Moses, David, Isaiah, Zechariah, and others. The object of such attribution was to gain the wider currency for the real author's views. The device was of a very naïve kind.

I. PSEUDEPIGRAPHA OF THE OLD TESTAMENT.—The best collection is still that of J. A. Fabricius, *Codex pseudepigraphus Veteris Testamenti* (2d ed. Hamburg, 1722). O. F. Fritzsche, as appendix to his *Libri apocryphi Veteris Testamenti Græce* (Leipzig, 1871), gives these Pseudepigrapha: The Psalms of Solomon, the Fourth and Fifth Book of Esdras, the Apocalypse of Baruch, and the Assumption of Moses. Migne devotes the greater part of the first volume of his *Dictionnaire des Apocryphes* (Paris, 1856, 2 vols., small folio) to the Old Testament Pseudepigrapha, and gives annotated French translations of the Book of Adam, the Book of the Conflict of Adam, the Book of Enoch, Third and Fourth Esdras, the Ascension of Isaiah, the Book of Joseph, Third and Fourth Maccabees, Prayer of Manasses, the Testament of the Twelve Patriarchs, the Psalms of Solomon, Odes of Solomon, Letters of Solomon. E. C. Bissell, in his commentary on the Apocrypha in the Lange Series, gives a revised English translation of all the Apocrypha mentioned above, and an account of Fourth and Fifth Maccabees, the Book of Enoch, the Sibylline Oracles, the Apocalypse of Baruch, the Psalms of Solomon, the Assumption of Moses, the Ascension of Isaiah, the Book of Jubilees, and the Testaments of the Twelve Patriarchs. The Five Books of the Maccabees in English translation were edited by Henry Cotton, Oxford, 1832 (but still in print). A translation of the Ethiopic Apocrypha, which will include some Pseudepigrapha, into French has been begun (Paris, 1893, *seq.*). The variations in the numeration of Esdras, or Ezra, comes from the fact that the Roman Church, following the Vulgate, calls Ezra and Nehemiah respectively I. and II. Esdras. It also classes as canonical some books which Protestants call apocryphal. The Pseudepigrapha, as a whole, have been recently studied by W. J. Deane, *Pseudepigrapha* (Edinburgh, 1891), who discusses the Psalter of Solomon, the Book of Enoch, the Assumption of Moses, the Apocalypse of Baruch, the Testaments of the Twelve Patriarchs, the Book of Jubilees, the Ascension of Isaiah, and the Sibylline Oracles, and by J. E. H. Thomson, *Books which Influenced our Lord and his Apostles, being a Critical Review of Apocalyptic Literature* (Edinburgh, 1891), which is a study of the Book of Enoch, the addition to Daniel, the Apocalypse of Baruch, the Psalter of Solomon, the Book of Jubilees, and the Assumption of Moses. Of many pseudepigraphical works we know only the names. (See list in Migne, *l. c.*) The better and fuller known may be divided into—

A. *Lyrical Writings.*—(1) *The Psalms of Solomon*, eighteen psalms of a Messianic character, dating about 75–63 B. C., designed to cheer the drooping hopes of the Jews. The place of composition is Palestine, and the language was Hebrew. They throw much light upon the Pharisee opinion in the time of Christ. Best edition, with English translation, by H. E. Ryle and M. R. James, *Psalms of the Pharisees, commonly called the Psalms of Solomon* (Cambridge, 1891).

B. *Prophetical Writings.*—(1) Numerous apocalypses in the general style of the genuine prophets, and, like their writings, giving a picture of the future greatness of Israel. Of these may be mentioned (2) *The Book of Enoch*, particularly noteworthy because quoted by Jude (vv. 14, 15) and frequently in the Christian Fathers. (3) *The Assumption of Moses.* Latin translation in Fritzsche, *l. c.* (4) *Fourth* (or *Second*) *Esdras* is found among the Apocrypha of the English Bible, but has no proper place there. It dates from the time of Domitian (close of the first century), and consists of seven visions in the style of Daniel. English translation in the Apocrypha, revised by Bissell, *l. c.* (pp. 641–664). Cf. R. L. Bensly, *The Missing Fragment of the Latin Translation of the Fourth Book of Ezra, Discovered and Edited with an Introduction and Notes* (Cambridge, 1875). Its general purport was to foretell that the Romans would be overthrown. It was written in Greek, but by a Jew. (5) *The Apocalypse of Baruch.* Cf. J. J. Kneucker, *Das Buch Baruch* (Leipzig, 1879). It was written in Greek and in Palestine by a Jew soon after the destruction of Jerusalem by Titus. In it Baruch so completely supplants Jeremiah that God makes to him the revelation of the future and the consolatory speeches. It closes with a letter to the nine and a half tribes in the Babylonian captivity. It was apparently used by PAPIAS (*q. v.*), but not much known in the early Church. (6) *The Rest of the Words of Baruch.* Cf. edition by J. Rendel Harris (Cambridge, 1890); not the same as the preceding, though similar. It closes with an account of Jeremiah's martyrdom, caused by his persistence in praising Jesus as the Son of God. This fact marks it as a Christian apocalypse, at least in its present form. It is dated by Harris in 136 A. D. (7) *The Ascension of Isaiah*, an account of what Isaiah saw as he was being borne to the seventh heaven, dating from the first Christian century, and essentially a Jewish apocalypse with Christian additions and interpolations. From it comes the patristic references to the alleged fact that Isaiah was martyred by being sawn asunder. There is a Latin translation by A. Dillmann (Leipzig, 1877), and an English translation by G. H. Schodde in the *Lutheran Quarterly* for Oct., 1878.

C. *Testaments or Wills.*—(8) *The Testaments of the Twelve Patriarchs*, English translation by R. Sinker, in *The Ante-Nicene Fathers* (New York, vol. viii., 1–38). It is the supposed utterances of the twelve sons of Jacob, and is a tissue of moral precepts, prophecies, especially of the Messiah, and various facts about themselves. It was written in Greek in the second century by a Jewish Christian. (9) *The Testament of Abraham.* Greek text, for the first time edited with introduction and notes, by M. R. James, with an appendix, containing extracts from the Arabic version of the Testaments of Abraham, Isaac, and Jacob, by W. E. Barnes (Cambridge, 1892). It was known to the early Church, and apparently popular. It has come down in two forms, but may be dated from the second Christian century. It purports to give the sights seen by Abraham in the future world. Perhaps the most remarkable single trait is Abraham's flat refusal to die when God requests him to do so, and the pains God took to overcome his aversion. (10) *The Testaments of Abraham, Isaac, and Jacob* (see just above). That of Abraham is similar to the one just noticed. The Testament of

Isaac is an account of the death of Isaac and the ethical discourse which preceded it, and of the experiences in the future world which followed it. Of the same nature is the Testament of Jacob.

D. *Historic and Haggadic Literature*, or tendency writings on the basis of genuine canonical Scriptures. (11) *The Book of Jubilees*, or *Little Genesis*, essentially the history of the chosen people down to Sinai, as contained in Genesis and the first part of Exodus, with legendary and haggadic additions, written originally in Aramaic by a Jew in Palestine in the first Christian century. It pretends to be revelations made to Moses on Mt. Sinai. In complete form it only exists in Ethiopic, in which language it was edited by A. Dillmann in Ewald's *Jahrbücher der biblischen Wissenschaft* (1849–51). There is an English translation by R. H. Charles, in the *Jewish Quarterly Review* (1893, *seq.*), and another by G. H. Schodde (Oberlin, 1888). Cf. H. Rönsch, *Das Buch der Jubiläen* (Leipzig, 1874). (12) *The Book of Adam and Eve*, also called *The Conflict of Adam and Eve with Satan*, probably written in Arabia by an Egyptian Christian, perhaps as late as the fifth century. It goes over the history as given in Genesis, down to the call of Abraham, with much haggadic matter of an interesting character. There is an English translation by S. C. Malan from the Ethiopic text as edited by E. Trumpp (London, 1882). (13) *Life of Adam and Eve*, in Latin, edited by W. Meyer (*Vita Adæ et Evæ*, Munich, 1879). It gives in rather an interesting manner an account of the adventures of the pair after their expulsion from paradise, the difficulties they had to get food, their journeys, etc. (14) *The Testament of Adam*, edited and translated into German by C. Bezold, *Die Schatzhöhle* (Leipzig, 1883–88, 2 parts). (15) To the same general class belong *The Sibylline Oracles*, a collection of pseudepigraphical poems of various dates, written in hexameters in Greek, studied imitations of Homer in meter and diction. The oldest part is the third book, which was apparently produced in Alexandria by some Jew of the second pre-Christian century who worked up current fragments of the old Greek and Latin Sibylline books for the purpose of the Jewish propaganda. But the present work, in twelve books, contains pagan and Christian elements, and is from the second or third Christian century. It was much quoted by the early Fathers as inspired, particularly its allusions to the advent of Christ, which they took to be prophetic. In contents it combines history and prophesy, rebukes heathen idolatry, and exhorts to repentance before it is too late. It was lost to sight during the Middle Ages, but regained and first printed at Basel in 1545. The best editions are by C. Alexandre (2d ed. Paris, 1869) and Aloisius Rzach (Vienna, 1891). There is an English translation by M. S. Terry (New York, 1890).

II. Apocrypha of the New Testament.—Unlike the Old Testament Apocrypha, the New Testament Apocrypha have never had a place in the canon. They are also of decidedly minor importance. The most of them are found collected in English trans. in vol. viii. of *The Ante-Nicene Fathers*, ed. Coxe (New York, pp. 349–598), and are divisible into A. Gospels; B. Acts of the Apostles; C. Apocalypses; D. Epistles; E. Apostolic Liturgies; F. Didactic; G. Apostolical Canons and Constitutions; H. Apostolic Church Directory. The best editions of the original texts are those of J. A. Fabricius (2d ed. Hamburg, 1719), and by C. Tischendorf, *Acta apostolorum apocrypha* (Leipzig, 1851); *Evangelia apocrypha* (1854); *Apocalypses apocryphæ* (1866).

A. *Gospels.*—(1) "The Protevangelium of James the Lord's brother," or "the birth of Mary the holy mother of God, and very glorious mother of Jesus Christ." It gives an account of the conception, birth, and infancy of Mary and the same facts concerning her son. (2) "The Gospel of Pseudo-Matthew." It has substantially the same matter as the preceding by way of introduction, but contains an account of the flight into Egypt, and of the youth of Jesus full of miracles. (3) "The Gospel of the Nativity of Mary." It includes the betrothal of Mary and the conception. (4) "The history of Joseph the carpenter." It is supposed to be told by Jesus Christ, and mostly relates to the death of Joseph. (5) "The Gospel of Thomas": confined to the childhood and youth of Jesus, and a tissue of miracles. (6) "The Arabic gospel of the infancy of the Saviour." (7) "The Gospel of Nicodemus": Part i., the acts of Pilate—the events of the Passion; part ii., the descent of Christ into hades. (8) "The letter of Pontius Pilate" which he wrote to the Roman emperor concerning our Lord Jesus Christ. (9) "The report of Pilate the procurator concerning our Lord Jesus Christ," sent to Augustus Cæsar in Rome. Two Greek forms are extant. (10) "The giving up of Pontius Pilate"—i. e. an account of his alleged arrest and transportation to Rome by the Cæsar as a punishment for the "darkness and the earthquake which had come over the whole world" after the death of Jesus. Pilate shifts the blame of the deed upon the Jews, is, however, beheaded, but not before a heavenly voice assured him that all the generations and families of the nations would count him blessed, because under him had been fulfilled the things prophesied of Christ. (11) "The death of Pilate, who condemned Jesus." In contradiction of the preceding, this Apocrypha attributes Pilate's death to suicide, and tells how malignant spirits forced the transportation of the body from Rome to Lausanne. It is a late production. (12) "The narrative of Joseph of Arimathæa, that begged the Lord's body; in which also he brings in the cases of the two robbers." One of the most popular Apocrypha, limited in time to the death day of Jesus. (13) "The avenging of the Saviour." This is a combination of two distinct legends—the embassy of Nathan from Judæa to the Emperor Tiberius to carry the treaty of the Jews to Rome and the story of Veronica. (14) "The Gospel of Peter." A fragment of it, in Greek, was discovered by Ulysse Bouriant in a tomb at Akhmim, Upper Egypt, in 1886, but not published till 1892. It relates only to the passion and resurrection history. It is one of the best of the apocryphal gospels, and was believed in the early Church to be authentic. The original text has been edited by several scholars—e. g. Adolf Harnack (Leipzig, 1893), J. Armitage Robinson and M. R. James (London, 2d ed. 1892), H. von Schubert (Eng. trans. Edinburgh, 1893). English translations are given by the last two.

B. *Acts of the Apostles.*—There exist Acts of Peter and Paul, Paul and Thekla, Barnabas, Philip, Philip in Hellas, Andrew, Andrew and Matthias, Matthew, Thomas, Thaddeus, John, Consummation of Thomas, Martyrdom of Bartholomew.

C. *Apocalypses.*—There exist Apocalypses of Paul, John, and Peter. The last was found in the same MS. which contained the Gospel of Peter, mentioned above. It is the merest fragment, but revolting in its gross conception of the future world. There is also an apocalypse entitled "The Book of John concerning the Falling Asleep of Mary" and another on the "Passing of Mary."

D. *Epistles.*—(1) One by Jesus in reply to Abgarus, King of Edessa, who wanted Jesus to come and cure him. It is given by Eusebius, *Church History*, i., 13 (Am. trans. ed. McGiffert, pp. 100, 101). Jesus promises after his ascension to send one of his disciples to heal the king. In the "Acts of Thaddeus" the correspondence is alluded to, and there is added that Jesus sent Abgarus his portrait miraculously stamped upon a towel. Cf. R. A. Lipsius, *Die edessenische Abgarsage kritisch untersucht* (Brunswick, 1880). (2) Three by the Virgin Mary—viz., to Ignatius, urging him to constancy; to the Messinians of Sicily conveying a blessing; and to the Florentines an exhortation to faith, prayer, and patience. These epistles are of the briefest, being only 11, 17, and 5 lines long respectively in the annotated edition of Fabricius, *Codex Apocryphus N. T.*, 2d ed., pp. 834–852. (3) A letter of Paul to the Laodiceans (Fabricius, *l. c.*, 873–879), another to the Corinthians (*id.*, 918, *seq.*), and the famous correspondence with Seneca—six letters of Paul and eight of Seneca. Cf. Teubner, ed. of Seneca, by F. Haase (Leipzig, 1872–74, vol. iii.), and Fabricius, *id.*, 880–904. The best discussion of the matter is by J. B. Lightfoot, *Com. on Philippians.* The genuineness of the correspondence was widely accepted from very early times, but it is now considered a clumsy forgery. (See for text and discussion also, E. Westerburg, *Der Ursprung der Sage, dass Seneca Christ gewesen sei*, Berlin, 1881.) (4) A letter of Peter to James (Fabricius, *id.*, 907–913), in which among other things secrecy is enjoined upon him as respects his preaching. (5) A letter of John in reply to a dropsical man who had asked him to heal him, or rather a single sentence, ordering in the name of the Trinity a cure. This was wrought on receipt of the letter, and the man out of gratitude sought John and was baptized. Cf. Fabricius, *id.*, 926–928. There are other similar forgeries known by title. By far the most elaborate publication upon the whole subject of these apocryphal remains of the apostles was produced by Richard Adelbert Lipsius, *Die apocryphen Apostelgeschichten und Apostellegenden* (Brunswick, vol. i., 1883; vol. ii., 1st part, 1887; vol. ii., 2d part, 1884 (*sic*); supplement, 1890).

E. *Apostolic Liturgies.*—These are alleged to be the work of Mark, James, and the blessed apostles collectively. They are translated into English in *The Ante-Nicene Fathers* (New

York, vol. vii., 529–572). Another liturgy is attributed to the apostles in the Apostolical Constitutions, *id.*, pp. 470, *seq.*

F. *Didache*, or *The Teaching of the Twelve Apostles.*—Found by Bryennios in 1873, but not published till 1883. It is one of the earliest Apocrypha and the most respectable. It doubtless embodies much genuine apostolic teaching, and throws welcome light upon the primitive Church usages. It is one of the most precious relics of the post-apostolic age. The best edition in English, with translation and notes, is by Philip Schaff, *The Oldest Church Manual* (New York, 1885; 3d ed. 1889).

G. *Apostolic Canons and Constitutions.*—See Apostolic Canons and Constitutions. Eng. trans. in *The Ante-Nicene Fathers* (New York, vol. vii., pp. 387–508).

H. *Apostolic Church Directory*, independent of, yet similar to, the seventh and eighth books of the Apostolic Constitutions. Greek text and German trans. by J. W. Bickell, *Geschichte des Kirchenrechts* (Giessen, 1843, pp. 107–132).

Samuel Macauley Jackson.

Pseudo-Clementines: See Clementines.

Pseudo-erysipelas: See Phlegmasia.

Pseudo-Isidorian Canons: See Decretals, False.

Pseudoneurop'tera [Mod. Lat., from Gr. *ψευδής*, false + Mod. Lat. *Neuroptera*, an order of insects]: a group of insects, recognized by some entomologists, which contains the dragon-flies, day-flies, and stone-flies. See Odonata and Plecoptera; also Entomology.

Pseudopodia [plural of *pseudopodium*, Mod. Lat., from Gr. *ψευδής*, false + *πούς, ποδός*, foot]: the temporary variously shaped processes given off from the body-substance of various protozoans, as amœbas and foraminifers, and serving for locomotion, ingestion, etc. See Cilia.

Pseudoscorpii [Mod. Lat., from Gr. *ψευδής*, false + *σκορπίος*, scorpion]: a group of arachnids or spider-like animals which resemble the scorpions in the general shape of the body, the segmentation of the abdomen, and the large pincer-like first pair of legs, but which differ from them in the absence of pectines, tail (see Scorpiones), and terminal poison-stings, as well as in the possession of a tracheal respiratory system. All of the species are small and are to be sought in dry places—under bark and among moss and some among old books and papers. They appear to feed upon mites and small insects, and are occasionally found adhering to flies, bees, etc., and in this way they are carried from place to place. The order first appears in the Carboniferous. Some sixteen species are described from the U. S. See Hagen, *Proceedings of the Boston Society of Natural History*, xiii., 1870.

J. S. Kingsley.

Pseudotsu'ga: a genus of coniferous trees established by Carrière in 1867, closely related to the firs (*Abies*) and the hemlocks (*Tsuga*), but differing from the former by having pendulous cones whose scales are persistent, and from the latter by having smooth branchlets after the fall of the leaves. Only one species is known, *P. taxifolia*, the Douglas spruce, mostly known in books and catalogues as *P. douglasii*. It is a gigantic tree of the Oregon, California, and Rocky Mountain region, 200 to 300 feet high, and 8 to 15 feet in diameter. See Conifers. Charles E. Bessey.

Psittaci [Lat. *psittacus* = Gr. *ψιττακός*, parrot]: an order of birds containing the parrots (see Parrot), characterized by a hooked and cered beak movably articulated with the brain-case, a strong lower jaw, and by having the outer toe turned backward. The tongue is thick, fleshy, and sometimes brushy; the number of primaries and tail-feathers is ten. The furculum is weak, imperfect, or absent. The order is divided into from one to nine families; but a good division is into three families, *Psittacidæ*, the true parrots, *Stringopidæ*, owl-parrots, and *Cacatuidæ*, cockatoos. F. A. Lucas.

Pskov, or **Pskoff**: government of European Russia; bounded N. by the governments of St. Petersburg and Novgorod. Area, 17,069 sq. miles. The surface is mostly flat, abounding in small lakes and rivers; marshes are numerous, forests extensive. Agriculture is almost the only branch of industry, with the exception of cattle-rearing; hemp and flax are staple products. Pop. (1897) 1,136,580.

Pskov, or **Pleskov**: capital of the government of Pskov, Russia; 160 miles S. S. W. of St. Petersburg (see map of Russia, ref. 6–C); 9 miles N. W. is Lake Pskov, 50 miles long by 13 broad. Pskov is the see of an archbishop, and has a cathedral, numerous churches, and considerable manufactures, and a trade in fish and flax. Pop. (1897) 29,555.

Psocidæ [Mod. Lat., from Gr. *ψώχειν*, rub to pieces]: a family of insects, the sole representatives of the order *Corrodentia*. They are small forms with incomplete metamorphosis, with biting jaws, sometimes without wings, but when these are present, having the fore wings the larger. All of the species feed on dry vegetable matter, and several species (winged) occur on many of the forest trees of the U. S. through the summer. Among the wingless forms are the so-called book-lice, minute light-colored forms occurring in neglected books, etc., where they may do considerable damage.

J. S. Kingsley.

Psophi'idæ [Mod. Lat., named from *Psophia*, the typical genus, from Gr. *ψόφος*, an inarticulate noise]: a family of birds represented by the trumpeters of South America. The form is heron-like; the neck comparatively short; the bill short, compressed, and curved toward the tip, which is prolonged over the lower mandible; the nostrils inserted in a membranous groove, large and oblique; the wings short, concave, and rounded; the tail very short, the tarsi long and slender, covered with transverse scales; the toes moderate, the three in front united at the base, the hind one small and somewhat elevated; the claws curved and acute. Only a single genus is known (*Psophia*), containing five species, found in various parts of Brazil and the northern portions of South America. Revised by F. A. Lucas.

Psori'asis [Mod. Lat., from Gr. *ψωρίασις*, itch, deriv. of *ψώρα*, itch, scurvy, mange]: a skin disease in which there are at first elevated red patches upon which large scales of epidermis appear, the skin between the patches often cracking and bleeding. There are many varieties distinguished by writers, but, except in the case of the syphilitic diseases called psoriasis, the causes are very obscure. There seems to be some connection between psoriasis and the rheumatic habit or chronic rheumatism. Fortunately, syphilitic psoriasis can often be distinguished from true psoriasis. For the former the appropriate remedies for the specific disease are to be employed. For the latter the best treatment appears to be the use of vapor-baths, followed by strong alkaline applications, and then by tarry ones, with the internal administration of arsenic. These means will very much mitigate, but will scarcely cure, the disease, which tends to linger, relapse, and become chronic.

Revised by W. Pepper.

Pso'rosperms [from Gr. *ψωρός*, scab (in allusion to the sores they make on fishes) + *σπέρμα*, seed]: parasitic protozoa, allied to the Gregarinida (*q. v.*), which occur on and in fishes, where they make sores or cysts, and at times are so numerous as to cause extensive mortality.

Psyche, sī'kĕ [= Lat. = Gr. Ψυχή, liter., soul]: in a Greek legend preserved by Apuleius, a lovely mortal, the daughter of a king. Venus was jealous of her beauty, and ordered Cupid, her son, to inspire Psyche with a desire for the basest of men, but the god of love, on beholding her, himself loved her. Thenceforth he visited her every night, requesting her never to see him or inquire who he was. But from curiosity, and the dread lest he should prove to be a monster, as her sisters told her he was, she came to him with a lighted lamp while he slept. Overcome with joy at his loveliness, she carelessly allowed a drop of hot oil from her lamp to fall upon his arm. Cupid therefore left her with reproaches. After many calamities she became the menial slave of the jealous Venus, who treated her with great cruelty; but her lover invisibly assisted her, and finally, having secured her immortality, made her his wife. The myth is plainly allegorical, and is a figure of the progress of the soul, by the aid of divine love, through the calamities of this life to a happier life hereafter. In art she is represented as a tender virgin with the wings of a butterfly, or as a butterfly itself, for the word *ψυχή* means butterfly as well as soul. Revised by J. R. S. Sterrett.

Psychological Apparatus and **Psychological Measurement**: See Recording Apparatus, Psychological, in the Appendix.

Psychology [Gr. *ψυχή*, soul, mind + *λόγος*, discourse, reason]: the science of the mind.

Historical.—Modern psychology has had its principal development in Great Britain, Germany, and France. Germany has undoubtedly had greatest influence in this movement considered in all its branches. The two main currents of development previous to the rise of the new so-called "scientific" psychology, designated as respectively "speculative" and "empirical," had their initial impulse, as well as their fruitful pursuit, respectively in Germany and

Great Britain. German psychology down to the rise of the Herbartian movement was a chapter of deductions from speculative principles. English psychology was a detailed analysis of the experiences of the individual consciousness. Kant, Fichte, and Hegel may sufficiently represent the succession in Germany; James Mill, John Stuart Mill, Hume, Reid, and Bain, that in Great Britain.

The work of Herbart and his school tended to bring a more empirical treatment into German thought, and its significance was twofold. It excited opposition to the speculative method; and it prepared the Germans for the results of English analysis. It is, further, a legitimate supposition that the spirit of experimental inquiry which has swept over Germany in the nineteenth century was made more easily assimilable by workers in this department, also, by the patient and extraordinary attempt of Herbart to construct a "mechanic" and "static" of mind in his *Psychologie als Wissenschaft* (1824).

To German thinkers also belongs the credit which is due to originators of all new movements which show their vitality by growth and reproduction, in that the experimental treatment of the mind was first advocated and initiated in Germany. This is treated of more fully below.

The contribution of France to psychology has been decidedly of less importance, yet the work of these writers has also illustrated a fruitful and productive movement. It has been from the side of medicine that French work has influenced current widespread conceptions of consciousness. Mental pathology and the lessons of it for the theory of the mind have come possibly most of all from France, or at any rate—not to disparage the admirable recent work of English and German investigators—the tendency, so to speak, of the French treatment of consciousness has been to approach mental operations from the abnormal side.

In the U. S. the influences which have tended to control psychological opinion have been mainly theological on one side and educational on the other. The absence of great native systems of speculative thought has prevented at once the rationalistic invasions into theology which characterized the German development, and the attempts at psychological interpretation which furnished a supposed basis of fact to the idealistic systems. In Germany various "philosophies of nature" sought to find even in objective science support for theoretical world-dialectic, and psychology fared even worse, since it is, *par excellence*, the theater for the exploitation of universal hypotheses; but in the U. S. men did not speculate much, and those who did were theologians. So, naturally, the psychologists were theologians also. Jonathan Edwards had a doctrine of the agent, because free will was a question of theology.

The educational influence was auxiliary merely to the theological. The absence of large universities with chairs for research; the nature of the educational foundations which did exist under denomination control; the aim of education as conceived in the centers where the necessity for supplying growing towns with pastors was urgent; the wholesome fact for civilization that the Puritans had traditions in favor of the school and the religious school—all these things made it only necessary that books sound in their theological bearings, or affording homiletic lessons in living, should be written in a topic of such central importance. Even the term "psychology" is only now becoming domesticated; "mental" and "moral" philosophy were the titles of courses of instruction on the "soul."

The type of philosophy which these conditions encouraged was, it may easily be imagined, realistic; and it is probably for the reasons which have been indicated that the Scottish natural realism was the North American type of thought, and is now, except in the great university centers where systematic philosophy has become an end in itself, apart from its duty to theology and education. As far as psychology was concerned, this realistic tendency was a great good. It led to a magnification of mental reality, to a reverence for the "utterances of consciousness," to a realistic interpretation of the "immediate knowledge of self," to a firm settling of the great "intuitions," cause, time, space, God, etc.; and in as far as this led to the direct examination of consciousness and to the testing of philosophical claims by consciousness, it prepared the way for a better and broader method. This tendency is marked even in the more influential works in theology. Channing and Emerson, no less than Henry B. Smith and Charles Hodge, lay the corner-stone of argument again and again in the proof "from consciousness."

This tendency to a psychological view of philosophy and its basis in the religious motive is seen also in Scotland, the home of realism; and it is there a part of the British method of thought which has already been spoken of. The works on psychology written in the U. S. up to 1880 were, as would be expected, from the hands of theologians and educators, usually both in the same person; for it is a further proof of the association of psychology and theology that the mental and moral philosophy in the colleges was almost without exception put in the hands of the president of the college, and he was by unanimous requirement a preacher. Edwards's *Freedom of the Will* (1754); Tappan's *Review of Edwards* (1839) and *Doctrine of the Will Determined by an Appeal to Consciousness* (1840); Hickok's *Rational Psychology* (1848) and *Empirical Psychology* (1854); Porter's *Human Intellect* (1868) and *Moral Science* (1885); McCosh's *Psychology* (1887) and *First and Fundamental Truths* (1889)—these and similar books, all works of the highest value, show the psychology of the U. S. up to about 1880.

Coming to the present state of psychological thought, the writer's task is made easier by reason of the divorce which has been forced between psychology as a science on the one hand and metaphysics on the other. As was said above, Herbart, while failing in his attempt to apply mathematics to mental "permutations and combinations," yet prepared the way for a new treatment of mental phenomena. After his attempt it began to be seen that the facts of conscious life were first in order of importance, and were capable of treatment in a detailed way quite independently of the questions of Being, the Absolute, and the like. The works of Volkmann, *Lehrbuch der Psychologie* (4th ed. 1894), and Lipps, *Die Grundthatsachen des Seelenlebens* (1883), illustrate this.

This was only to begin to do what had been doing in England since Locke; but the Germans went further: they asked the question—which had been groped upon before by Descartes, by Leibnitz, and by Reid—how can psychology be a science when one of the evident conditions of the flow of mental states, of their integrity and their trustworthiness, the brain, is left quite out of account? What is the law of connection of mind and brain? Is it possible to modify the brain and so to modify the mind? If so, then that great instrument of scientific work, experiment, may perform a part for the psychologist, also, and his resources be magnificently enlarged. This is the question of experimental psychology. It was answered in Germany in the affirmative. Lotze, in the author's view, deserves the credit of it; and Wundt is the founder of the science in the sense that he first realized the expectations of Lotze's genius by actually planning and executing experiments on a large scale, which made the affirmative answer an irreversible fact of history. Lotze's *Medicinische Psychologie* appeared in 1852, Wundt's *Grundzüge der physiologischen Psychologie* in 1863. Between the two came Fechner, whose theoretical construction of the new work and its methods shows all the exactness of treatment of similar discussions of natural-science principles by electricians and chemists, and published the formulas in which he attempted to give universal statement to the discoveries of E. H. Weber on the intensity of sensation-states. Fechner's *Elemente der Psychophysik* appeared in 1860. Apart from the actual development of this new method—a point to be spoken of later on—it has profoundly modified the general conception of psychology, even where its validity as a method has been denied. There has been nothing less than a revolution in the conception of psychology since the publication of the works just named. One of the motives of this revolution came thus from Germany. The other—for it has two great phases—is due to English thinkers, the evolutionists, of whom Herbert Spencer (*Principles of Psychology*, 1855) is the chief. These two influences are seen in two great points of contrast, easily made out between the psychology of to-day and that of yesterday in the U. S. The two main characteristics of the latter, for purposes of the present contrast, are, first, its character as so-called "faculty-psychology," and, second, its character as holding to what may be called a "ready-made" view of consciousness—technically an "intuition" view of consciousness. In opposition to these characters, current psychology is "functional," holding to mental functions rather than to mental faculties; and finds this function to be genetic rather than intuitive—the functions "grow" instead of being "ready-made."

The old conception of "faculties" made the different phases of mental process in large measure distinct from one another. Its earliest and most defensible statement was by Aristotle. Memory was a "faculty," a "power" of the

mind; thought was another, imagination a third. The new functional conception asks how the mind as a whole acts, and how this one form of activity adapts itself to the different elements of material which it finds available. The old terms "memory," "thought," etc., are retained; but with the distinct understanding that they do not stand for divisions in the mind, or different processes, one of which may be held in reserve when another is acting, etc. On the contrary, the process in consciousness is one, and it is a psycho-physical process as well. The particular way in which this one function shows itself is a matter of adaptation to the changing conditions under which the activity is brought about. This transition is due in part also to the insight of Herbart and to the demand for unity insisted upon by the evolutionists. The other point of contrast is equally plain. The "genetic" point of view, in current discussion, is opposed to the older "intuitive" point of view. The mind is looked upon as having grown to be what it is both as respects the growth of the man from the child and as respects the place of man in the scale of conscious existences. The understanding of mental facts is sought in the comprehension of their origin as well as their nature; and the question of the validity or worth of "intuitive" beliefs in consciousness is subordinated to the question as to how the mind came to have such beliefs. Both of these points of contrast have been further defined by the progress of general philosophy in the U. S. The demand for unity in mental interpretation has not come from naturalistic evolution alone (John Fiske, *Outlines of Cosmic Philosophy*, 1874; Thompson, *System of Psychology*, 1884); an equally pressing demand has come from idealistic metaphysics, which seeks for continuity in the natural series as zealously as does the advocate of evolution. The influence of Hegel, as interpreted in the works of Green of Oxford, and later in those of Edward Caird, has been potent in effecting this transformation. It is easy to see also that the same union of forces is quite feasible as respects the genetic development of consciousness, although the new idealists have not done justice to this growing tendency in modern psychology.

The line of cleavage, in the current discussions of general psychology, is drawn on the question of the interpretation of mental "function," both sides claiming the same full liberty of genetic research and the same resources of analysis and experiment. The "associationists," on one hand, carrying on the tradition of the British empiricists, construe mental function after analogy with the ordinary interplay of forces in the objective world; the "apperceptionists," on the other hand, hold that mental function is a form of irreducible cosmic process. Apart from original monographs on special topics, no work on psychology to-day commands much attention, either from psychologists or from students of philosophy, which does not show itself alive to this main issue. In the U. S. the works of Lotze and Wundt have had great influence in the direction of this general statement of the problems of psychology, and it is especially the philosophy of Lotze which is replaeing by a reasoned and critical realism the earlier theological dogmatic view so long prevalent in the U. S. by inheritance from Scotland.

On the literature of present-day psychology the following passage is translated from a German work, itself fully representative of the state of knowledge, *Grundriss der Psychologie*, by Prof. O. Külpe, of the University of Leipzig (pp. 27, ff.): "About the middle of the nineteenth century experimental and psycho-physical psychology began its course in Germany. While Herbart recognized a threefold influence of the body upon the mind . . . it was Lotze who made a thorough beginning in the employment of the data of physiology. Lotze, indeed, began his work with certain metaphysical expositions after the manner of the older German writers, and is very far from the recognition of a universal psycho-physical parallelism; but he does not hesitate to speak of the nervous conditions of mental processes, and he had the good fortune to suggest hypotheses of value where exact knowledge was wanting. The real foundation of experimental psychology was laid, however, by G. T. Fechner, who sought to carry out in a thorough-going way the conception of a functional relation between mental and physical processes. Although the mathematical form which he gave to this relation does not hold, yet he gave to the exact science of psychology an extraordinary impulse by reason of the new conceptions which he introduced, the methods of proeedure which he both formulated and applied, the working over which he gave the material he had in hand, and the observations and researches which he himself carried out. . . . The union of the experimental and psychophysical was finally accomplished by Wilhelm Wundt . . . in his classical *Grundzüge der Physiologischen Psychologie* (1874; 4th ed. 1893). By this unity of conception and his comprehensive treatment of all mental phenomena . . . he has made the current phrase 'modern psychology' applicable. . . . Wundt gave a further important impulse to the cultivation of experimental psychology by founding the laboratory in Leipzig in 1879, and establishing the *Philosophische Studien*, a journal devoted mainly to the publication of researches in his institute.

"Additional works may be mentioned of very recent date which must be reckoned in their character as belonging to the modern psychology thus founded by Wundt, although they differ more or less essentially in system and in theory from him and from one another: Höffding, *Psychologie in Umrissen* (2d ed. 1893; German trans. from the Danish; English trans., 1891); Ladd, *Elements of Physiological Psychology* (1887); Sergi, *La Psychologie Physiologique* (trans. from the Italian); W. James, *The Principles of Psychology* (1890); Ziehen, *Leitfaden der physiologischen Psychologie* (1891; Eng. trans., 2d ed. 1894); Baldwin, *Handbook of Psychology* (2d ed., 1891; 1st ed. 1889–90); J. Sully, *The Human Mind* (1892)."

It will be seen that of the seven works thus cited by Külpe three are by U. S. writers, and to them must be added *Psychology: Descriptive and Explanatory* (1894), by George T. Ladd, and the journal, *The Psychological Review*, edited by J. McK. Cattell and J. Mark Baldwin (vol. i., 1894). Another important French work of recent date is *La Psychologie des Idées-Forces*, by A. Fouillée (1893). Other important contributions to experimental psychology—apart from the long series of monographs and research articles published in Germany and the U. S.—are Helmholtz, *Physiologische Optik* (1867; French trans., 2d ed. 1890, ff.) and *Tonempfindungen* (1863; English trans.); Stumpf, *Tonpsychologie* (1883, 1890); and Münsterberg, *Beiträge zur Experimentellen Psychologie* (parts i.–iv., 1889–93).

The contribution from the side of mental pathology has become important on account of the *rapprochement* which has obtained in recent years between the alienist and the psychologist. The works of Pierre Janet, *Automatisme psychologique* (1889) and *L'État mental des Hystériques* (1892–93); and of Bernheim, *Suggestive Therapeutics* (English trans., 1889) and *Études de la Suggestion* (1892), are most important. To them should be added the works of Ribot, *Diseases of the Will* (English trans.; 5th French ed. 1889); *Diseases of Memory* (English trans.; 5th French ed. 1888); *Diseases of Personality* (2d ed. 1888; English trans. 1891), together with the many original contributions on the subject of hypnotism and aberrations of personality published in the *Revue Philosophique*, edited by T. Ribot (vols. i.–xxxvi., 1876, ff.), and summed up in part in *Les Altérations de la Personnalité* (1893), of A. Binet.

Further, the treatment of psychology, in accordance with the British tradition, from the point of view of description and analysis, has been carried forward by Ward in the article *Psychology* in the *Encyclopædia Britannica*, 9th ed. This type of research has also had its organ of publication in *Mind: a Journal of Psychology and Philosophy*, edited by G. Croom Robertson (vols. i.–xvi., 1876, ff.) and by G. F. Stout (new series, vols. i.–iii., 1892, ff.).

Finally, the genetic treatment of consciousness has been advanced by the works of Spencer, *Principles of Psychology* (1855; 3d ed. 1880); Romanes, *The Origin of Human Faculty* (1884–88); Morgan, *Animal Life and Intelligence* (1891); and Galton, *Inquiries into Human Faculty* (1883) and *Natural Inheritance* (1889).

Experimental Psychology.—The present age is the age of science because it is the age of devotion to science and of the results in science. But it is a very different thing to say that this is the age of scientific method. Former ages have seen devotion to science and results in science, but no former age has, as an age, realized a scientific method. In general philosophy what has been called scientific method is better known, as has been said above, in a twofold way—as empirical and critical. Retrospectively, what we have to rejoice at in philosophy is due about equally to two traditions, represented by Hume and Kant. The burden of current idealism, as far as it is worthy of consideration in our time, is to purify and conserve the work of Kant; and the burden of empiricism, under the same restriction, is to refute Kant with the only weapons which he himself considered of worthy temper. The battle is drawn at these close

quarters, and round them both is thrown a common ring of scientific procedure.

In psychology the modern transformation comes most strongly out. Here we find an actual department of knowledge handed over to a new class of men for treatment, so remarkable is the demand for scientific method. It is no longer sufficient that a psychologist should be familiar with general philosophy and its history or capable of acute logical criticism of systems; it is necessary, if he would deal successfully with the new problems and gain the ear of the advanced philosophical public, that he should reason from a basis of fact and by an inductive procedure. In short, he must not bring his philosophy as speculation into psychology, but must carry his psychology as fact in its connection with physiology, ethnology, etc., into general philosophy. To illustrate this change and its effects on general theories, recent discussions of the idea of space may be cited in comparison with its earlier and more speculative treatment. The reasoning of James, Wundt, Bain, and Spencer differs so essentially from the argumentation of Kant and earlier men that it is almost impossible to find common ground between them. No one among those who accept Kant's results depends, in our day, very largely upon his reasons; the question is shifted to another field. The physiologist has as much to say about it as the psychologist, and the speculative philosopher must recognize them both. This tendency in philosophy may be expressed by a chemical figure as a "precipitating" tendency. We are endeavoring, and successfully, too, to throw all questions which are capable of such treatment to the bottom as a precipitate—a psychological precipitate—and are then handing them over to the psychologist for positive treatment. As long as the data remained in a solution of ninety parts water (which, being interpreted, means speculation) it was difficult to handle them scientifically. While admitting the utility and necessity of ontology in its place, psychology claims that its place must be better defined than formerly, and that whenever a sediment, a residuum, a deposit, apart from a speculative solvent, can be secured, this is so much gain to positive science and to truth.

One of the ideas which lie at the bottom of the so-called new psychology, therefore, is the idea of *measurement*. Measurement (determination in quantity and time) is the resource of all developed science, and as long as such a resource was denied to the psychologist he was called a scientist only in his function of description and classification; not in the more important functions of explanation and construction. And the justification of the application of measurement to psychological facts has come, not from theoretical considerations—for they were all opposed, and still are in many of the books of the new idealism—but from practical attempts to do what philosophy declared to be impossible; that is, experiment has been the desired and only reagent. It is true that theoretical justifications are now forthcoming of the application of experiment to consciousness, but they are suggested by the actual results, and were not in sufficient currency to hinder the influence of Kant's ultimatum, for example, that a science of psychology was impossible.

By experiment is meant experiment on the nervous system, with the accompanying modifications it occasions in consciousness. Efforts have been made in earlier times to experiment upon states of consciousness directly. Descartes deserves credit for such efforts, and for the intimation he gives us in his theory of emotions of an approach to mind through the body; but the elevation of such an approach to the place of a recognized psychological method was not possible to Descartes, Kant, or any one else who lived and theorized before the remarkable advance made in the nineteenth century in the physiology of the nervous system. Even as it is, many questions which will in the end admit of investigation from the side of the organism are in abeyance till new light is cast upon obscure processes of the brain and nerves.

A little further reflection will show us that the employment of experiment in this sphere proceeds upon two assumptions which are now generally admitted and are justified as empirical principles, at least, by the results. They are both assumptions which the physical scientist is accustomed to make in dealing with his material, and their statement is sufficient to exhibit their elementary importance, however novel they may sound to those who are accustomed to think and speak of mind as something given to us in entire independence of its organic basis. The first of these assumptions is this: That our mental life is always and everywhere accompanied by a process of nervous change. This is seen to be necessary to any method which involves the passage of mind to body or the reverse by the interpretation of effects. Which is cause and which effect, the mental or the physical change, or whether they both are effects of an unknown cause, is immaterial; to consider such a question would be to introduce what has been called the speculative solvent. It is sufficient to know that they are always together, and that the change in one may be indicated in symbols which also represent the change in the other. The second assumption is based upon the first, viz., that this connection between mind and body is uniform. By this is meant what in general induction is called the uniformity of nature. Any relation sufficiently stable to admit of repeated experiment in the manipulation of its terms is in so far uniform. Experiment would be useless if the relation it tends to establish were not stable, since the result of such experiment would give no antecedent likelihood as to the result of others under similar circumstances. Experimental psychology, therefore, rests upon the assumption that a relation of correspondence—be it coexistence or causation—once clearly made out between a mental and a nervous modification, it must hold good under any and every repetition of the same experiment under the same conditions. These two assumptions made, we have at once the possibility of a physical approach to the facts of consciousness. The result is a relative measurement of such facts in terms of the external stimulation of the nerves, in regular and normal conditions of the activity of attention.

The need of experiment in psychology is exceedingly great. When we remember that, in the search for causes in the natural world, the difficulties are vastly enhanced by the fact that single causes are never found at work alone, and that it is the function of experiment so to eliminate elements in a causal complex that isolated agencies may be observed at work; and when we further reflect that no single function of mind is ever found operating alone, but that all accompany and modify each—the inadequacy of simple observation in this field becomes apparent. A sense-stimulation, for example, may arouse an intellectual train, an emotional outburst, a course of action; are all these the effects of a single cause? A course of action, conversely, may result from an emotion, a thought, a memory, an association, a sensation, an inspiration; can the simple description of the resulting action indicate which is its cause? Antecedents and consequents are thrown into the mental life in inextricable confusion. External or bodily causes—an odor, a spoken word, a pain, an internal organic movement—may start a train. This train may be hindered or advanced by a thousand considerations or emotions; other bodily or mental causes may modify it. And all together make up the cause or complex antecedent state; while vague analogies of thought and feeling, such as temperament, heredity, education, make variations between individuals, and the present condition of the brain and nerve centers make variations in the same individual. How can we single out the cause, in this network, by observation? It is as vain as to discover the cause of a conflagration from examining the blaze; was it a match, lightning, friction, chemical composition? Only one step can determine: The reconstruction, under artificial circumstances, of the conditions, and the endeavor to exhibit a single isolated cause. This is experiment.

Further, it is apparent that such a means of experimentation may become available either under artificial or under natural conditions, according as the nervous stimulation is due to an external excitation, or arises from some unusual condition of the organism itself. All cases of brain or nervous disease, on the one hand, offer opportunities for boundless observation, the unusual manifestations being changes due to the organic disturbances of disease. Here nature has arranged and actually performed the experiment for us, the only difficulty being the physiological one that the cerebral disturbances are as obscure as the mental states which they are used to explain. All such cases of mental changes due to internal organic changes are classed together under the name of *physiological psychology*. On the other hand, experiments may be arranged for the normal stimulation of the sense organs—skin, muscles, special senses—under artificial conditions. This is, strictly speaking, *experimental psychology*. See PSYCHO-PHYSICS, PSYCHOMETRY, MEMORY, VISION, and SENSATION. See also RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Physiological Psychology.—This branch of psychology includes all the matter covered by such topics as HYPNOTISM, ILLUSION, LOCALIZATION (*Cerebral*), and PHYSIOLOGY (of brain and nerves). It aims to discover all the facts of the connection between mind and body, and to propound theories of the central nervous processes of thought, feeling, etc. The methods of this science are largely those of experimental physiology, the results of experiments upon living animals being the most direct aid to it. Its contributions to the welfare of man through the practical work of the brain surgeon, the oculist, the aurist, and the alienist, are of the highest importance.

Race or Folk Psychology.—The science of the mental traits of races and peoples and of the mental development of man; the study of mind in its social characteristics, and in its products in society, the state, religions, customs, and institutions. It accepts all the results of ANTHROPOLOGY (*q. v.*), and views them as the manifestations of the mind. It examines ancient philosophies, cults, and civilizations; literatures, history, laws, mythologies, traditions, the sources from which the human mind has drawn its culture in all ages. It values the reports of travelers in respect to savages, heathen, and degenerate races; the conditions of social life everywhere. For in all these manifestations of the life of the human mind we have direct information respecting its nature and capacities.

Animal or Comparative Psychology.—As might be expected, the study of animals is of extreme importance for the science; for animals show striking evidences of the phenomena of consciousness both in its lower and in many of its higher forms. It is perhaps destined, judging from the contributions it has already made to some departments of research, to throw as much light upon human psychology as comparative anatomy has upon human physiology. As is the case with many physical functions, so certain intellectual states are seen in animals in a less developed and complex state, or in a more sharpened and predominant state, than in man; and thus the necessity for a genetic study of these states is met to a greater or less degree. Instinct, for example, attains its most perfect form in animals, memory is often remarkably developed, and certain of their senses show a degree of acuteness which we would never expect the corresponding human senses to possess. And the study of animals for psychological purposes is not limited to observation of their habits, productive as such observation is; but the physiological method is capable of much more extended use than in experiment upon man. Condemned animals may be directly used for purposes of neurological research under conditions which rule out all pain to the creatures. The variety of problems which may thus be reached is limited only by our ability to state them and our ingenuity in planning the experiments. See INSTINCT, IMPULSE, and LOCALIZATION (*Cerebral*).

Infant Psychology.—The importance of the early study of mind is to be equally insisted upon. By it mental facts are reached, as far as they ever can be, at their origin and in their simplest form. It is more important to know what mind is than what it becomes. The child serves to correct the reports of adult life by opening up object lessons in the growth of mind. At the outset the child mind is lower than the highest animal mind, since, while its human possibilities have not emerged, its instinctive equipment is not as varied as that of animals; but in its rapid development it exhibits the unfoldings of organic mental growth in correspondence with the growth of the bodily system, an advantage found in none of the other fields of observation. See GENETIC PSYCHOLOGY.

Abnormal or Medical Psychology.—As in the former sources of information we deal with mind in health, here we come to consider it in disease—that is, we look to all abnormal or diseased conditions of the mental life for light upon its nature and upon its legitimate operations. It includes all cases of variation from the normal and healthy activity of conscious mind—sleep-walking, dreams, insanity in its multiplied forms, loss of memory, loss of speech, hypnotism, idiocy, hallucination, disturbances of consciousness generally. All these variations afford—as such variations in any science afford—instructive views into the working of mind in its most intimate character. And the reason for this is plain. Such cases offer immediate occasion for the application of the logical *method of difference*, which consists in removing part of a cause or effect and observing the consequent variations in the corresponding effect or cause. This procedure enables us to attach an effect to its true cause. One most general result of the study of mental disease, for example, is this: that we have learned to seek its cause in diseased conditions of the body, rather than in obscure mental movements or supernatural influences. It has been well said that a man deprived of one of his senses from birth is a subject especially prepared by nature for the application of the method of difference. The science of mental disease and its cure is called *psychiatry*. See INSANITY.

Social or Collective Psychology.—This department of psychological study endeavors to investigate the mental and moral life of man in its social and collective conditions. The evident need of such subjects as sociology and criminology is the knowledge of the laws of human feelings and action when man is found in crowds, orderly or disorderly, and in organizations, legitimate or criminal. This need is felt in construeting the history of society, both by sociologists and by psychologists.

Individual or Introspective Psychology.—The older psychologists proceeded by introspection or direct observation of the events of the individual consciousness. The various branches of the experimental science now described deal rather with mind in its objective and collective aspects. It must be remembered, however, that all the results of objective psychology must have their final interpretation in terms of the consciousness of each normal man. The method of the old psychology, *internal observation*, must finally be appealed to, therefore, after all is said, for the actual confirmation of all psychological truth.

This final psychological resort, introspection or internal observation, takes on three distinct phases. In the first place, the simple fact of *consciousness*, that inner aspect which makes mental facts what they are, in its primitive form, is at once awareness of the states of self. However vague and indefinite this primitive awareness is at first, it is still a beginning. There is no experience in conscious life which leaves absolutely no trace of itself. Once it is an experience, a modification of subjectivity; then it may become the object of the developed act of inner observation. The first fleeting sensations of the child, when there is no subject or object, no store of memory images, no idea of self, exhibit in isolation the kind of primitive consciousness that lies at the basis of all knowledge of self. In adult life these experiences are assimilated to the developed forms of intellect and their separate meaning is lost. But in this category are included the vast number of first experiences as they pass steadily on in time, something every moment; and all the information we glean from them before we recall, examine, and reflect upon them. Second, the state of mind called *primary-memory*—the lingering in consciousness of an event just after the event itself is gone. The immediate past hangs around us as a line of trailing cloud on the horizon of consciousness. So speedy and involuntary is this presence of the shortly-past that it is sometimes considered the first stage of our inner observation; yet this can not be held in the sense of denying the immediate awareness of the primitive consciousness. For example, a loud noise, or a spoken word, may be unintelligible until its quick recall enables us to recognize it. We have had, in these cases, the "immediate awareness" of the first event, but the examination of the after-image which it leaves adds much to the scientific value of the experience. Third, we reach *reflection*, or conscious observation. By reflection is meant the inspection of the events of the inner world as distinct objects of our knowledge. It is the highest form of internal observation. Thus, by reflection, inner happenings are built up into hypotheses concerning the nature and processes of the mental life. See PERCEPTION, MEMORY, IMAGINATION, THOUGHT, CONSCIOUSNESS, WILL, ASSOCIATION OF IDEAS, SENTIMENT, MOTIVE, MIND, and PHILOSOPHY.

Applied or Educational Psychology.—It is evident that education has two claims to make upon this study. The first of these two duties of psychology to education is this: It should take its place as a factor in liberal collegiate culture in both of the functions which a great branch of learning serves in the university curriculum—i. e. undergraduate discipline and instruction, and post-graduate research discipline. The second great educative function of psychology is this: It should mould and inform educational theory by affording a view of mind and body in their united growth and mutual dependence. Education is a process of the development under most favorable conditions of full personality, and psychology is the science which aims to determine the nature of such personality in its varied stages of growth, and the conditions under which its full development may

be most healthfully and sturdily nourished. One of the first duties of psychology, therefore, is to criticise systems of education, and to point out "the better way" in education.

Pedagogy as a science treats of the application of psychological principles to the development of normal and cultured personality. The ground-work of such a science must be afforded, therefore, by psychology; and inasmuch as the teacher has to do with body as well as mind, and with mind principally through the body, it is experimental or psychophysical psychology to which this duty to theoretical education mainly comes home. It is needless to say that there is no such science of pedagogy in existence. Most of the books on this topic are unworthy of serious attention. Further, the German *a priori* systems of pedagogics find their main value in keeping awake the expectation and the *amour penser* of teachers, not in affording them much empirical assistance in their task. Psychology is aware of this duty, however far she may be from performing it. Children are studied with some soberness and exactness of method. Statistical investigations of the growth of school children, of the causes and remedies of fatigue in school periods, of the natural methods of writing, reading, and memorizing, are carried out. The results of several such inquiries were plotted for exhibit in the department of anthropology at the Columbian Exposition in Chicago. Questions of school hygiene are intelligently discussed. The relative values of different study-disciplines are weighed in view of the needs of pupils of varying temperaments and preferences. Among those who have addressed themselves to this task in the U. S., with information and influence, two names may be mentioned—that of Dr. W. T. Harris, U. S. Commissioner of Education, and President G. Stanley Hall, of Clark University, editor of *The Pedagogical Seminary* (vols. i.–iii., 1891–94). Another journal for the application of sound psychology in education is *The Educational Review*, edited by Prof. Nicholas M. Butler, of Columbia College, New York (vols. i.–vii., 1891–94).

Relation of Psychology to Philosophy.—The traditional connection with philosophy is not severed by these directions of psychology. The change in psychological methods was due in part, as has been said above, to changes in philosophical conception, and it is only part of the same fact that scientific psychology reacts upon philosophy in the way of healthful stimulus. Both the critical idealistic and the critical realistic methods of philosophy are richer and more profound by reason of the lessons of the new psychology. It was only just that the modern science which owed one of its earliest impulses in the U. S. to a book from an advanced thinker of the former school, the *Psychology* of Prof. John Dewey, should repay the debt by its reconstruction of the Kantian doctrine of apperception in terms acceptable to the later thinkers of that school. And it is no small gain to both schools that their issue should be joined on ground which stretches beyond their old battlefields by all the reach of territory covered by the modern doctrines of naturalistic evolution and the association psychology. Philosophy escapes the charge of Lewes that her discussions are logomachy when the disputants on both sides are able to look back upon those even of the late period of Lewes and admit the essential truth of both of their hotly contested formulas. As far as this is the case, the writer ventures to say that it is due to the progress of psychology in giving content to the terms of the logomachy and in enabling the best men to reach more synthetic and more profound intuitions.

The relation of psychology to theology, also, is close, and must remain so. And the obligation must become of greater mutual advantage as psychology grows to adult stature and attains her social self-consciousness in the organization of knowledge. The benefits which theology might have gained from psychology have been denied in great measure through the unfortunate attempt to impose the theological method upon the treatment of the whole range of mental fact. The treatment of "anthropology," included in the textbooks of systematic theology, bears about the same relation to that of psychologies like Höffding's and James's as the physiology of the traditional philosophy bore to the work of the neurologists and morphologists.

Bibliography.—Besides the works already mentioned and those given under Insanity, the student may consult the following: *General Works*: E. Wallace, *Psychology of Aristotle*; W. Wallace, *Hegel's Philosophy of Mind*; and Volkmann, *Lehrbuch der Psychologie* (4th ed. 1894).

Histories of psychology are Siebeck's, Carus's, Harmus's, and Dessoir's, each entitled *Geschichte der Psychologie*; see also the historical sections of Volkmann's *Lehrbuch*, and the histories of philosophy by Windelband, Erdmann, and Ueberweg.

Comparative, Genetic, and Educational Psychology.—Schneider, *Der Menschliche Wille* and *Der Thierische Wille*; Darwin, *Expression of the Emotions*; Baldwin, *Mental Development in the Child and the Race* (London and New York, 1895); Preyer, *The Mind of the Child*; Tracy, *The Psychology of Childhood*; Compayré, *Évolution Intellectuelle de l'Enfant*; Guyau, *Education and Heredity*; Tarde, *Les Lois de l'Imitation*; Sighele, *La Foule criminelle*; Ward, *The Psychic Factors in Civilization.*

Abnormal Psychology.—Lewis, *Textbook of Mental Diseases*; Starr, *Familiar Forms of Nervous Disease*; Ziehen, *Psychiatrie.*

J. Mark Baldwin.

Psychom'etry, or **Mental Chronom'etry** [*psychometry* is from Gr. ψυχή, soul, mind + μέτρον, measure]: the science of the measurement of reaction-times, or of the duration of mental acts. It is only since 1860 that anything like exact and scientific efforts have been made to measure the time or duration of mental states. The necessity of some such measurement first arose in astronomy, where the most exact determinations of transit and other periods must be made. A source of error in such observations was early seen to be the time taken up by the transmission of the excitation of the retina to the brain, and the time taken by the impulse given to the hand to record the event, to travel from the brain to the hand. This element of "personal equation" in astronomical work is elevated to a distinct problem in psychometry, and its conditions are extended to include all mental states which have the physical basis accessible for the employment of experiment.

Before the rise of experiment desultory treatment had been given to the comparative rapidity or slowness of our "ideas," such questions as whether all "ideas" were successive or some simultaneous, speculations on the cause of the rapidity of dreams, etc.; but being only general descriptions of fact, and depending on individual experience and testimony, such observations were almost useless in general mental theory. With the positive work now done in psychometry, it is quite astonishing how many side-lights are thrown on other questions and to what unexpected uses time determinations may be put.

Proceeding on the assumptions made in Psycho-physics (*q. v.*), we observe that any period of time which is occupied jointly by a physiological and a mental process, and which may be recorded by movements traced by a time-registering apparatus, will involve as one of its factors the time of the mental process considered for itself. If, then, we have means of measuring the time taken by the physiological process alone, we may by subtraction find the mental time. Now these conditions are realized in every instance in which we perform a movement in response or reaction to a sensation from without. For example, suppose one hears a word and then writes it; the sensation of sound is the central link in a chain of nervous processes beginning in the ear and ending in the hand. From the ear the stimulus is transmitted to the brain, and from the brain the command to move is carried to the hand; between these two processes the third or mental fact, sensation and volition, has taken place. Such a chain of events involving any sensation and movement, and a conscious event connecting them, is called a "simple reaction," and the time that it takes the "simple reaction-time." The determination of this time is the first problem of psychometry.

The simple reaction-time is determined for any sense with its reaction in movement (for example, a sound and consequent movement of the right hand) by connecting the hand's movement with a very delicate clock (chronoscope or chronograph) in such a way that there is an instantaneous stoppage of the clock upon the movement of the hand. This is arranged by directing the person experimented upon to press an electric button when he hears a signal, say a bell-stroke. Let the bell-stroke emanate from the clock as it reaches a certain indication upon its dial, and the experiment is ready for trial. The experimenter stands ready to press the button—the bell sounds—he presses—the clock stops. The dial-face indicates the time which elapsed between the actual sound of the bell and the movement of the hand. Calling the time taken up by the nervous process from the ear to the brain "sensory-time" (*S*), that taken by the nervous process from the brain to the hand "motor-time" (*M*), and the time of the mental event between them

"perception-time" (P), the simple reaction-time (R) can be expressed in this equation:

$$(1) \qquad R = S + P + M,$$

in which S and M are purely physiological.

This determination has been made by a great number of observers upon three of the senses—sight, hearing, and touch—with remarkable uniformity of result. It varies with different classes of sensations and individuals from $\frac{1}{8}$ to $\frac{1}{5}$ sec.

Experiments of Helmholtz and Dubois-Reymond have determined the velocity of both sensor and motor nerve-transmissions, so that we may substitute known values for S and M in the formula given above, as follows:

$S + P + M = \cdot 15$ sec. (about).
$S + M = \cdot 06$ sec. (about).
$P = \cdot 09$ sec. (about).

The word "about" indicates variations for the different senses. For all the senses the general law will hold that the purely physiological time ($S + M$) is less than half of the entire reaction-time.

Having the simple reaction-experiment arranged, we may vary the conditions in a variety of ways, and thus arrive at the most favorable mental attitudes for quick reactions. In the simple experiment the excitation was expected, but the exact moment of its occurrence was not known. If this exact moment is given to the "subject" by a preliminary signal, the reaction-time is diminished. Again, if neither the kind of excitation nor the time of its occurrence is known, the time is greatly increased. From these two variations we gather that the state of the attention has a great influence upon the reaction. As we would expect from our ordinary experience, when the attention is taken unawares a longer time is required to respond actively to external influences.

Another exceedingly important influence is practice. This is due to the artificial conditions of all experiment, and the increased facility we acquire by personal adjustment. We react a thousand times daily under less artificial circumstances, and since the reaction-time is diminished by practice, it is probable that our customary, habitual responses to stimuli of sense are more quickly performed than the most favorable experiments would indicate.

Having now reached what may be called the "mental" time (P), the question arises: How is this to be divided between the perception or apprehension of the sensation and the volition to respond by movement? Two methods of experiment have been devised for breaking up this period into its elements. The first consists in experimenting on cases of very close physical association—as between hearing and speech, right hand and foot, etc.—where the reaction is almost automatic and the will-element is practically ruled out. The subject agrees beforehand to repeat any familiar word spoken to him as soon as he hears it. Experiments of this kind led Donders and Jaager to the following principle: The relative times of perception and volition depend upon the degree of physiological association between the receiving and reacting organs; when this association is close, the mental time is largely taken up with perception; when loose, it is nearly all occupied with volition.

The other method, that of Wundt and Baxt, consists in repeating the excitation one or more times before the voluntary impulse for the reaction is given. Thus the perception-element is repeated, and the difference between this time and the simple reaction-time is the time due to the additional act of perception. For example, let two equal and moderate excitations, say bell-strokes, follow each other quickly, the reaction being made only after the second; we then have the equation (here p represents the perception of the first stroke, which carries no volition with it):

$$(2) \qquad R' = S + p + P + M.$$

On repeating the experiment with only one stroke, we have as before:

$$(1) \qquad R = S + P + M.$$

Subtracting (1) from (2), we have:

$$R' - R = p.$$

Here R' and R are readings from the clock. This gives a numerical determination for p. The volition-time will then be $P - p$.

From this latter experiment a curious result follows if the successive excitations are of very different intensities. If the more intense really follows, it is, nevertheless, heard first, and the less intense, really first, follows after; or they may appear to be simultaneous, though really successive. This is the case, in general, whenever the attention is strongly drawn to the second stimulus and follows from the principle already spoken of, that the attention, when concentrated, diminishes the reaction-time. This will be the case in general whenever the diminution in the reaction-time of the second exceeds the real interval between the two. The same phenomenon is experienced often when one is awakened by a loud noise. He hears the noise after he awakes, though it was the noise that awaked him. It simply means that because of the dormancy or preoccupation in dreamland, the reaction-time of the sound is lengthened into his waking consciousness, while the shock to the nervous apparatus was sufficient to rouse him from sleep. This shows also the dependence of the order of associated states of memory upon the movements of attention in the first experience rather than upon the order of external events. The fact is also important in astronomical observation; a new excitation to the eye, such as the appearance of an expected star on the meridian, is anticipated by the attention and given a reaction earlier than its true position would confirm.

The distinction between perception and reproduction—that is, between a direct intuition and a memory-picture—is very artificial, inasmuch as reproduced images enter in all our perceptions and influence their time. We have dealt heretofore with simple perception as if this influence did not exist, but a moment's reflection shows that it should be taken into account in all time-measurements. In the experiments just spoken of, in which attention plays a part—that is, in which the subject knew before he experienced the excitation, its nature and quality—the reaction-time was diminished, for the reason that it was possible to call up a memory-picture of previous experiences and hold it before the attention in such a way that the voluntary impulse could be set in play almost immediately upon the discharge of the sensory centers. For example, if the subject expects the stroke of the bell, he recalls the sensation of a previously heard stroke and the organs are in readiness to respond. So what the writer has called pereeption-time really results from a diminution due to reproduction. The true time for perception must be obtained by experimenting with excitations entirely unexpected, and the differences between the reaction-time in this case and that of an expected excitation of the same nature due to the influence of reproduction simply is sometimes half the true perception-time.

The problem then arises to determine the reproduction or simple "association-time"—that is, the time which elapses between the full pereeption of a first image and that of a second which the first suggests. To do this, we must first determine the time of a complete association-reaction—that is, the time which elapses from, say, the hearing of a word, as "storm," and the utterance of a closely associated word, as "wind." The association must be spontaneous with the subject, and the original word a monosyllable and very familiar. The uniformity of result is surprising, considering the variety and indefiniteness of our customary associations. Our equation is (A representing the new element due to association):

$$(3) \qquad R' = S + P + A + M.$$

Reacting again for the word alone without the associated image, we have

$$(1) \qquad R = S + P + M.$$

By subtraction, $A = R' - R$; hence value for A.

The average of experiments gives this value about $\frac{3}{4}$ to $\frac{4}{5}$ sec. These results hold only for close associations established by long habit, especially those dating back to childhood or early life. A third process upon which experiment has been employed is that of discernment—that is, the act of distinguishing between given images and indicating the distinction by choice. The excitation, say a red light, is agreed upon, and is exhibited to the subject indiscriminately with another, say a blue; the subject to react only when he sees the red. In this process, it is seen, two intellectual acts occur: 1, Comparison of the visible light with the reproduced image in consciousness; 2, a judgment as to their identity or non-identity, and these imply, 3, the act, first of all, of simple perception, and 4, last of all, the act of volition, as in preceding cases. Letting D represent the whole distinction-time, we have:

$$(4) \qquad R' = S + P + D + M.$$

Reacting simply:

$$(1) \qquad R = S + P + M.$$

By subtraction, $D = R' - R$.

Thus arrived at, the time of "distinction" is found to be for two indiscriminate stimuli, $\frac{1}{20}$ to $\frac{1}{10}$ sec. longer than the simple reaction-time. The reason for saying two stimuli is that the time is lengthened, as we would expect, when the possible choices are increased. For example, if we use three lights, red, blue, and green, the time occupied in a true discrimination is longer, and it increases geometrically. Wundt experimented with the letters of the German alphabet, and Cattell with both Roman and German printed characters. Cattell finds that it takes about $\frac{1}{2}$ sec. to see and name a single letter, and that it takes longer to distinguish the German characters than the Roman.

The time of the judgment has entered also into all our measurements heretofore, and it is impossible to isolate it as a distinct intellectual act for the purpose of experiment. As an act in time, it can be viewed only in particular cases and under prescribed conditions, and even then the time is to be considered relatively to that of other processes of necessity involved. Trautscholt has studied the time of the "judgment of subordination," from genus to species. A word is spoken, and the subject reacts as he conceives a word in logical subordination to the given concept, for example, animal—dog. An element of association which it is impossible to eliminate enters largely here. By the same process as before, we find the value of J (judgment) from the equation of the entire reaction to be about 1 sec.—slightly longer than that of the simple association. It varies also with the nature of the logical terms. That is, (1) the time is longest when the subject is abstract, and the predicate a more general notion (virtue—honesty); (2) shortest when the subject is concrete, and the predicate particular (hound—Bruno).

Besides these and other positive results, additional important contributions to psychological science have been made. It may be well, in closing, to indicate some of the more general bearings of these time-measurements.

All this work has tended to the emphasizing and defining of the voluntary side of the mind, as given in acts of the attention. The results here alone more than pay for the entire work the researches involve. That the will is the question of capital importance both in psychology and general philosophy, and that philosophers are hopeful and expectant of results in the theory of our active life as never before under the lead of speculation, are largely due to the new psychology. The experimental work described above has cleared up the problem of the attention in many of its conditions: its relation to the time-sense and the origin of the idea of time, its inseparable connection with muscular activity, its bearing upon intensities everywhere in mental experience, its influence in our perception of the external world and of space—indeed, one can not arise from the study of experimental psychology as it spreads its data out before us without the conviction that it is upon the theory of mental effort in attention with feelings of resistance that the psychology of the future will be erected.

Again, such experiments show both the isolated character of mental states in their dependence on physiological states, and at the same time the clear necessity of a circumscribing, grouping, and arranging consciousness of which they are states; a unity, an individual active self, which the manipulation of single states does not impair. From the work now spoken of, we have the emphatic emphasis of a principle of activity by which alone single, successive, or simultaneous states have any meaning or significance in our mental life. For description of psychometric apparatus, see RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

J. MARK BALDWIN.

Psycho-physic Law: See PSYCHO-PHYSICS.

Psycho-physics [Gr. ψυχή, the soul + φύσις, nature, physics]: literally, the science of the mind considered in its relation to physical nature. The word has been used in this broad sense, i. e. to indicate the general topic of the relation of mind and body. This is, however, better covered by the phrase physiological psychology. (See PSYCHOLOGY.) Psycho-physics is accordingly now restricted to a particular kind of research, and so becomes a department of psychology considered as an experimental science.

In this restricted sense, psycho-physics deals with the measurement of the intensity, as it is properly called—the quantity or "mass," as the psychologist uses the words—of sensation. The conception of intensity needs no further explanation; it is simply the difference between the light of one candle and of two or more, the sound of a bell near and far. It is a property of all sensation. The problem which presents itself is to reach a formula for such intensities in terms of the amount of stimulus required at the end organ to produce a given increase or decrease in conscious intensity. To illustrate, suppose a candle illuminates a page to a certain extent, how many candles would illuminate it enough to enable one to see twice as distinctly, or as distinctly at twice the distance? Is there any general law of the ratio of intensity of external stimulus to intensity of internal sensations which will hold good for all the senses? Or is there a different law for each of the different senses? Or, again, is the entire case simply a matter of subjective estimation, varying with the mental and bodily conditions of the individual?

These questions were at one time hotly discussed, but have now been practically answered by the establishment of a single law of relation between stimulus and sensation, which holds good for most of the senses found to be most easily accessible, has been partially proved for other classes of sensations, and is under judgment in default of sufficient experimentation for a remaining group of sense-experiences. Before entering more particularly into details it is well to define and explain several terms of current use among physiological psychologists.

By excitation (or stimulus) is meant the external force which excites a sense-organ, whether it be of sufficient intensity to produce a sensation or not. The feeblest sensation which we are able to experience or feel from any sense is called the perceptible minimum; the theoretical point at which such a sensation, when further enfeebled, disappears from consciousness, the threshold of sensation; and the amount of excitation which is just sufficient for the perceptible minimum of sensation, the threshold excitation for that sense. For example, air-vibrations are the excitation for sensations of sound; the feeblest sound which it is possible to hear under determined conditions is the perceptible minimum, and the number of units agreed upon—bells, notes, etc.—which are needed to produce this perceptible minimum makes the threshold excitation for this sense. Further, the amount of excitation needed to raise or lower the intensity of a sensation by the smallest amount which can be distinguished, and the corresponding difference in the sensation, are called the smallest perceptible difference in excitation and sensation respectively. Thus if 1 unit be the threshold of excitation for sound and an addition of 1/3 unit is necessary to produce any perceptible increase in the sensation, then 1/3 is the smallest perceptible difference of excitation for sound.

With these definitions in mind, we may turn to the problem of finding a law of measurement for intensities of sensation. The preliminary question as to a standard of measurement is already answered in the resort to experiment, viz., the standard must be a scale of excitation-values, determined by physical measurement, as pounds, velocities, etc. Given a threshold-value of each excitation, we may double, treble . . . it, endeavoring to find some law of increase in the corresponding sensations whereby a corresponding internal scale may be erected. The first step is seen, therefore, to be the discovery of the perceptible minimum of each sense, which may serve as zero point on the sensation-scale, its exciting stimulus being the unit point on the excitation-scale. This brings the investigator to an actual research on all the sense-organs in turn—experiments to determine the minimum of sight, hearing, touch, etc. The methods by which this is done are simple. Any device by which excitation may be lowered or heightened gradually below or above the threshold may serve the purpose. For touch and the muscular sense small balls of cork may be used—differing so slightly in size that when placed, say on the back of the hand in succession, the difference between the last one which is felt and the next which is too light to be felt is as small as possible. By running the series in the reverse order, from weights too small to be felt to others barely felt, and by an equation and average of errors, the point is determined where the excitation produces the smallest perceptible sensation.

Simple as this procedure seems, the conditions are so complicated in some of the senses as to occasion great embarrassment. The eye, for example, is found to have a

"natural light" of its own, arising from mechanical movement, friction or chemical action, from which it is never entirely free, and the smallest perceptible sensation of light must always include this natural factor. The conditions of the body before the experiment also cause great variations, as is seen in experiments on temperature and smell sensations. The threshold-value for temperature is much higher or lower, for example, according as the earlier state has been one of higher or lower temperature. The following table exhibits the results of Fechner's experiments on the perceptible minimum:

PERCEPTIBLE MINIMA.

Touch	Pressure of ·002–·05 gramme.
Muscular sense	Contraction of ·004 mm., right internal muscle of the eye.
Temperature	1–8° centigrade (normal heat of skin 18·4°).
Sound	Ball of cork 1·001 gramme falling ·001 meter on glass, ear distant 91 mm.
Light	Cast on black velvet by candle distant 8 ft. 7 in.

It is not necessary to examine each of these determinations, for the actual numerical values are not of great importance, even where Fechner has not been confirmed by other experimenters. The fact that there is a minimum under normal conditions, and its determination with sufficient accuracy to give ground for further inferences, is all that the theory requires.

So far two points have been gained—i. e. the zero on the sensation-scale and the unit-value, a positive known quantity from the table above, on the excitation-scale. Next in order is the graduation of both scales in an ascending way by relatively equal values.

It is a common fact of experience that excitations and sensations do not apparently sustain the ordinary relation of cause and effect to each other. Two candles do not illuminate a page twice as much as one; two violins, pitched in the same key, do not double the sound of one; and as intensities increase it is a matter of ordinary observation that very little variations are brought about by well-marked changes in the stimulus. This result of general observation recurs to us as we advance in the consideration of the values on our scales, for we would expect, from this rough judgment of daily life, that larger increments would have to be made the higher we ascend on the excitation side to produce regular equal increments on the sensation side.

This is confirmed by a further research undertaken on all the senses in turn, an experimental determination of the amount of increased excitation necessary to produce the smallest perceptible difference in sensations of the same kind. Let us suppose a given excitation for pressure, then increase it slightly until it is judged greater than before, determine the ratio of the increment to the former excitation, repeat the experiment with a much larger excitation, making the same fractional determination, and compare the results. It is found that the fractional increase in excitation necessary to produce a perceptible difference is constant for each sense. This means that the absolute increase is not constant, but becomes greater as the intensity of the initial excitation becomes greater. For example, if the initial excitations in two experiments be 6 and 9 grammes, a relative fractional increase of 1/3 would be in one case an absolute increase of 2, and in the other of 3 grammes.

There are three general methods of determining the smallest perceptible difference for any sense, due in their formal statement and description to Fechner. They are known as the methods (1) of smallest perceptible differences, (2) of true and false cases, and (3) of mean errors. There is a fourth, of especial importance in researches on sight—that of mean gradations (Plateau); but it is not necessary to speak of it further.

1. The method of smallest perceptible differences is most direct. It consists in adding to a given excitation until the difference is barely perceived. The difference between the initial and the resulting excitation is the first determination of the quantity required. A plainly perceived difference is then added to the same initial excitation, and reduced till no longer perceived. This gives a second determination. The averaging of these two results is the correct value, which may be called DE (difference or differential of excitation). Its ratio to the first excitation is expressed by the fraction $\frac{E}{DE}$. The relative degree of sensibility for any sense, it will be observed, is inversely proportional to the amount of excitation required to give the smallest perceptible difference in sensation, i. e.

$$S\,(\text{sensibility}) = \frac{DE}{E}.$$

2. The method of true and false cases consists in comparing two excitations (say weights), the subject of the experiment judging them to be equal or not. The number of true and false judgments is recorded, and the ratio between them indicates the approach of the difference of excitation to its minimum value. The relative sensibility again varies, as the actual difference between the excitations varies, and also directly as the number of true judgments (in relation to total cases), i. e.

$$S = E\,\frac{S\,(=\text{total cases})}{N\,(=\text{true cases})}.$$

3. The method of mean errors consists in comparing two stimuli (weights, etc.) and judging them equal, then in taking their real difference, positive and negative, in a great number of cases, adding these differences without regard to signs, and dividing by the entire number of cases. The mean error is thus arrived at. The sensibility is inversely proportional to the mean error, i. e.

$$S = \frac{1}{D}\,(=\text{mean error}).$$

Proceeding by one or all of these methods, the smallest perceptible difference of excitation for each of the senses is established. The following table gives these values, subject to revision for certain classes of sensation, especially sight, when the conditions of experiment can be made more free from error:

SMALLEST PERCEPTIBLE DIFFERENCES.

Touch	1/3
Muscular sense	1/17
Temperature	1/3
Sound	1/3
Light	1/100

The values given, it may be well to repeat, represent the amount of a given excitation which must be added to that excitation to be felt in consciousness. For example, if the eye is already stimulated by a light which represents 1,000 candles, at least 10 candles (a fractional increase of 1/100) must be added to produce any perceptible increase in the intensity of the light. Any number less than ten would seem to have no effect on consciousness whatever, and so with the relative values given for the other senses.

To revert to the original problem, it will be remembered that the two determinations already arrived at for all the senses are only steps in a process of measuring the intensity of sensations in terms of external stimuli. So far there have been determined the smallest perceptible sensation (giving the starting-points on the scale) and the smallest perceptible differences of excitation in the upward graduation of the scale. The results of this second research may be stated in general language thus: In order that sensation may increase by successive equal additions, their excitations must increase by a constant fraction of the excitation itself, i. e. by additions which are not equal, but which increase in ascending the scale of intensities. For example, the successive additions to a sound, to be barely perceived, would require the following series of additions to the stimulus:

$$1/3,\ \frac{1+1/3}{3},\ \frac{1+1/3+\frac{1+1/3}{3}}{3},\ \text{etc., or } 1/3,\ 4/9,\ 16/27,\ \text{etc.,}$$

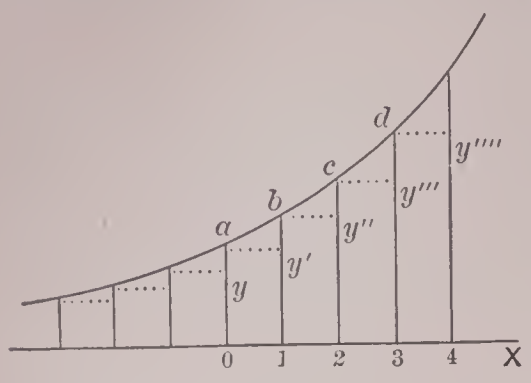
and the actual excitations would be the series

1, 4/3, 16/9, 64/27, etc.

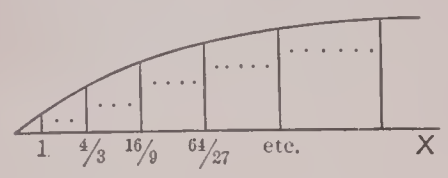
This general principle is called the law of Weber, and may be stated in a variety of ways, of which perhaps the easiest to carry is this: That in order that sensations may increase in intensity in an arithmetical series, their excitations must increase in a geometrical series. The law may be exhibited in a linear way to the eye in diagram 1 below.

Let X represent a series of sensations 0, 1, 2, etc., increasing by a constant quantity from the zero-point 0; let the upright lines represent at each point the excitation necessary for the sensation of that intensity. By drawing the dotted lines parallel to X, it is seen that the successive additions made to the vertical are not equal, but grow constantly greater, i. e. for hearing, $y' = y + y/3$, $y'' = y'$

$+ y'/3$, etc. Having erected these vertical lines by the law of increase given in the table, the curve *a b c d*, etc., may be plotted through their extremities, being the "curve of excitation."



The same relation may be shown in an inverse way, in diagram 2 below, in which the scale of increasing excitation is given on the line X, the vertical line representing the sensations increasing by a constant quantity. The curve connecting the extremities is the "curve of sensation."



A further mathematical expression has been given to this law by Fechner. As may be seen below, it is open to some criticism; yet it is ably defended, and whatever may be its fate as a mathematical deduction, the law of Weber as given above will not be involved.

Assuming, says Fechner, that the smallest perceptible differences in sensation are equal for any value of the excitation (an assumption which has no proof), and that very small increments of sensation and excitation are proportional to each other, we may throw Weber's formula into the following equation (*DS* being increment of sensation, *DE* increment of excitation, and *K* a proportional constant),

$$DS = K\frac{DE}{E},$$

in which all the quantities have been determined in the tables already given. Considering this as a differential equation, we may integrate it and reach the form

$$S = K \log E,$$

or the sensation varies as the logarithm of the excitation—the celebrated "logarithmic law" of Fechner.

Considered under its more general form, as indicated in the principle of Weber, this law has an unequal application to different sensations. For sight, touch, and hearing it is fully established; for taste and smell it is still in doubt, by reason of the mechanical difficulties which these senses offer to experimental research. It applies under restrictions to estimation of linear distance by the eye, to perception of the passage of small periods of time, and to discrimination of local positions in the skin. In all cases its application is restricted within upper and lower limits of intensity of sensation. When too intense the organism fails under the stimulus, reaching the limit of its vibratory responsiveness, and when too faint, either the stimulus does not excite a conscious reaction, or the attention fails to discriminate the sensation.

It may not be out of place to indicate the principal criticisms which have been urged against Weber's law, both in its general result and in the method of research which it involves.

Both of the assumptions made by Fechner—that the perceptible differences of sensation of the same sense are equal for all intensities of stimulus, and that the increments of sensation and excitation are proportional—are called in question. The results of late physiological work tend strongly in favor of the first assumption, and it is probably safely established. The second with the application of the differential calculus is so plainly subject to criticism that even its strongest advocates only attempt to justify it by the results. Really it is only infinitely small quantities that can be considered differentials or proportional to each other; while by the law of growth, arrived at by Weber, they are shown not to be proportional. This argument, adverse to Fechner's formula, is ably presented by Delbœuf. Another objection is brought also to the doctrine of "threshold." It is claimed that there is not a constant threshold for any of the senses, but that the minimum of sensation varies with the condition of the organism, the concentration of attention, etc. If this criticism should be shown, however, to be valid, it would still be possible to establish a table of variations or a coefficient of "personal equation" for individuals, and still preserve the principle of Weber. The objection formerly drawn from the fatigue of the organ under prolonged experiment is now met by the principle called by Fechner the "parallel law"; if the experiments are performed at very close time-intervals, the degree of exhaustion may be considered as approximately the same for any two successive excitations. Any modification, therefore, which either excitation undergoes from the element of fatigue is corrected in the ratio between that and the other excitation. For example, the smallest perceptible difference *DA* above an excitation *A*, reached by adding a new excitation *B*, is expressed by the fraction $\frac{B}{A}$; but any modification which affects both *B* and *A* to an equal degree does not alter their ratio.

The philosophical significance of Weber's law is the ground of main interest. That it is an established law of the relation of the mind and body as respects sensation, that it confirms the general assumption that there is a universal and uniform connection between the mental and the physiological—these points must be admitted, whatever may be a more particular interpretation of the law itself. As to its meaning for our theory of the mind, and whether it has any such meaning, there is more room for difference of opinion, and three distinct interpretations are commonly held among psychologists. Each of these is advanced in answer to the question which Weber's law obviously suggests, i. e. why is it that the relation of cause and effect does not hold between sensation and excitation? why is sensation proportional to the logarithm of excitation and not to excitation itself?

The first of these interpretations, that of Fechner, is that Weber's law represents the ultimate principle of connection between mind and body; that they are so constituted as to act upon each other in a logarithmic relation. It is of necessary and universal application wherever mind and body are brought into organic connection. In short, on this view the law is strictly psycho-physical. This interpretation has been very generally discredited, principally because it forbids all further research or explanation. Nothing is ultimate which may be explained, and if physical or mental reasons can be given—as the other two theories hold they can—for the disproportion between sensation and stimulus, then the assumption that it is ultimate is gratuitous. Fechner supports his view by two considerations: first, that the physiological theory, as stated below, is inadequate, and, second, that the law holds in cases of nervous exhaustion. The latter point is met by the consideration that in cases of extreme exhaustion the entire series of stimuli is intensified by a given amount throughout, and when the exhaustion is not extreme it corrects itself by the "parallel law" spoken of above.

Again, it is held, especially by Wundt, that the law is strictly psychological—that is, that the disproportion between sensation and excitation is due to the perception or discrimination of the sensation. On this theory it is not the real sensation which is experimented upon, but perceived sensation, and in the process of taking the sensation up into our apperceptive life it is modified as to its intensity. For example, the single fact of attention to a sensation changes its intensity; what effect might not the act of directing the mind to it, as is required in the above experiments, have upon it? In answer to this interpretation it may be said that it can never be critically established, since there are no means of getting at the true worth of sensation except as it is interpreted in our attentive consciousness. By intensity we mean intensity to us, in our intellectual life, and to speak of the intensity of sensations in a relative way, apart from the appereception and comparison of them, is to become unintelligible. Wundt, however, has an ulterior end in view—the support of his doctrine of apperception—and he himself admits that he would not exclude the physiological interpretation.

The third interpretation, which is probably the true one, makes the disproportion spoken of purely physiological. According to the advocates of this theory the law of cause and effect does hold in this case, as in others, but a part of the internal cause is lost in the transmission by the nerves, so that the true excitation at the brain-center is less than at the peripheral organ, and is in direct proportion to the intensity of the sensation which it causes. Briefly stated the following facts tend to support this view: (1) The phenomenon of nervous arrest would lead us to expect a diminution of the stimulus between the organ and the brain; (2) nerve-action is dissipated in heat; (3) force is lost in the exciting

of the internal organ, hence, by analogy, we would expect the same in the stimulation of the centers; (4) the general parallel between electricity and nerve-action would indicate resistance to be overcome in the one case as in the other; (5) on general grounds a loss of force may be expected in an extended or complicated mechanism. A decided preference for the last view seems justified by the facts, although Wundt has been recently re-enforced by reliable results. Criticism so far seems to show that Weber's law represents the method of nervous "summation" of stimulations at the centers, but under this term a great many particular influences have to be included. See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

LITERATURE.—Fechner, *Elemente der Psychophysik* and *Revision der Hauptpunkte der Psychophysik*: Wundt, *Physiologische Psychologie* (1893); Müller, *Zur Grundlegung der Psychophysik*; Külpe, *Grundriss der Psychologie* (1894); Ladd, *Elements of Physiological Psychology* (1887); Jastrow, *Critique of the Psychophysical Methods* in *The American Journal of Psychology*; Ribot, *German Psychology of To-day* (1886). J. MARK BALDWIN.

Psychosis: a mental state considered as subject for investigation, generally in connection with the accompanying nervous condition or NEUROSIS (*q. v.*), which accompanies it.

Psychotheism: See ETHNOLOGY.

Psychrometer: See HYGROMETER.

Ptah (The Opener): "the father of the gods"; perhaps the oldest of the Egyptian deities; worshiped in Memphis from the first dynasty on. He is represented in the form of a mummy, with head and hands free. In his hands was the scepter which stood as the symbol of power, and beneath his feet was the symbol of truth. Among several composite forms in which he appears was that of Ptah-Sokar-Osiris, the god of the resurrection and of the nether world. In this form he was regarded as the first King of Egypt and as creator of the world. CHARLES R. GILLETT.

Ptarmigan [(by analogy of Gr. words in *pter-*) from Gael. *tarmachan*: Ir. *tarmochar*]: any grouse of the genus *Lagopus*, the members of which are distinguished by the legs being densely feathered to the claws, the nasal grooves closed over with feathers, and the development of sixteen or eighteen tail-feathers. Ptarmigans are characteristic of the high northern regions of the globe, and, with the exception of one species, assume a white coat during winter; in summer they are of a more or less reddish or brownish gray. They are thus an instance of a double protective mimicry, harmonizing with the snow in winter and the rocky barrens in summer. In winter they seek the shelter of thickets of willows, birches, etc., but in summer they frequent plains. When pursued in winter they frequently dive into the loose snow, in which they work their way with great ease. The female begins to lay her eggs about May or June, and deposits about eight or ten eggs in the nest. A number of species have been recognized, of which *Lagopus albus* inhabits both hemispheres, *L. rupestris* and *L. leucurus* North America, and *L. mutus*, *L. hemileucurus*, and *L. scoticus* the Old World. *L. scoticus* is extremely closely related to *L. albus*, and has been even regarded as the permanently dark insular form of that species. Revised by F. A. LUCAS.

Ptenoglossa [Mod. Lat., from Gr. πτηνός, feathered + γλῶσσα, tongue]: a name employed in some schemes of classification of the molluscs to include the purple shells (*Ianthinidæ*), the sun-shells and mason-shells (*Solaridæ*), and the wentletraps (*Scalaridæ*).

Pteran'odon [Mod. Lat.; Gr. πτερόν, wing + ἀν-, un-, without + ὀδούς, ὀδόντος, tooth]: a genus of pterodactyls, or extinct flying reptiles, from the Cretaceous of Kansas, distinguished from all previously known genera of the order by the entire absence of teeth, and hence regarded as the type of a sub-order, *Pteranodontia*. The typical *Pteranodon longiceps* has the skull about 30 inches long and the lower jaw nearly 2 feet. The rami of the lower jaw are closely united for more than half their length, as in the skimmers (*Rhynchops*). *P. comptus* is a small species, while *P. ingens* was very large, and the skull must have measured nearly 4 feet. O. C. MARSH.

Pteridophytes: See FERNWORTS.

Pterocarpus: See KINO.

Pterocletes [from *Pte'rocles*, the leading genus]: a sub-order of birds, sometimes considered as an order, containing the sand-grouse forming the single family PTEROCLIDÆ (*q. v.*).

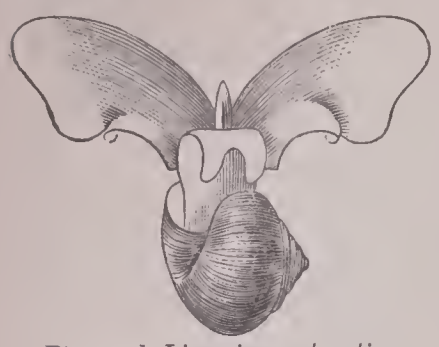
Pteroc'lidæ [Mod. Lat., named from *Pterocles*, the typical genus, from Gr. πτερόν, wing + κλείς, κλειδός, key, bolt, tongue of a buckle]: a small family of birds peculiar to the Old World, containing the so-called sand-grouse; birds about the size of pigeons and intermediate in structure between them and the grouse, although the balance of characters is rather in favor of the pigeons. The form is as much that of the pigeon as the grouse; the bill is short, compressed, and the culmen curved to the tip; the wings and tail are elongated and pointed; the tarsi moderately robust and covered with feathers; the toes rather stout, the three in front more or less united, the hinder rudimentary or wanting. Two genera are recognized by authorities—(1) *Pterocles*, with about fifteen species, and (2) *Syrrhaptes*, with two. In color these birds are dull yellowish above, with darker markings, harmonizing well with the surface of the country they inhabit. They are found in Southern Europe, as well as in Africa and Asia, in dry sandy places or deserts, rocky plains, and wooded grounds. They feed chiefly upon hard seeds, bulbs, and insects. The females lay from two to four eggs on the bare ground. *Pterocles arenarius* and *P. alchata* are found in Southern Europe. *Syrrhaptes paradoxus*, although strictly an Asiatic species, sometimes makes incursions into Europe as far westward as the British islands. One of these visitations was made in 1859, another in 1863, in which year it made its appearance at 148 European localities, as recorded by Prof. Alfred Newton—"from Galicia to Donegal, and from Gascony to the Faröe islands." Another irruption occurred in 1888. The reason for these curious and irregular migrations is unknown, but the primary cause may be failure of food-supply in some portion of their habitats. Revised by F. A. LUCAS.

Pterodactyl [Gr. πτερόν, wing + δάκτυλος, finger]: any one of a group of extinct flying animals, confined to the Mesozoic or Reptilian age, and usually regarded as an order of reptiles. The anterior limbs were adapted for flight by the elongation of the fore arm and fifth or outer digit, corresponding to the little finger of the human hand. By this means an expanse of membrane was supported as in the bats, which these animals in some respects resembled. The head was large, the jaws long, and in most forms armed with teeth. In many points the skull approached that of birds. Nearly all the bones were pneumatic, with very thin walls, as in most birds. The skin seems to have been destitute of scales or feathers, as no traces of either have been discovered. The earliest pterodactyl yet known is *Dimorphodon macronyx* from the Lower Lias of England. Many species occur in the Oolitic lithographic slates in Bavaria. A few fragments only are known from the Wealden, while the English Greensand has furnished many large species. Others from the Upper Cretaceous were the latest forms of this group known from the Old World, and were perhaps contemporaneous with the gigantic species from the Upper Cretaceous shales of Kansas. These were all destitute of teeth. The largest of them (*Pteranodon ingens*, Marsh) probably measured between the tips of the fully expanded wings nearly 25 feet. Several smaller species occur in the same formation, but all were large in comparison with the common European forms. O. C. MARSH.

Pterodactyl.

Pteroglossus: See Rhamphastidæ and Aracari.

Pterop'oda [Mod. Lat.; Gr. *πτερόν*, wing + *πούς*, *ποδός*, foot]: a group of molluscs formerly regarded as a class but now known to be merely a subdivision of the tectibranch division of the opisthobranchiates. (See Gasteropoda.) They are fitted for a free-swimming life upon the high seas by the development of the lateral lobes (parapodia) of the foot into fins or wing-like swimming organs. Two divisions are recognized, the *Thecosomata*, with a shell (either external or internal), which feed on protozoa or algæ, and the shell-less *Gymnosomata*, which are rapacious, feeding largely upon the members of the other group. The pteropods frequently occur (especially in the Arctic seas) in immense schools, and some species form the food of the right whales, the "brit" of the whalers. None of the pteropods are large, and the numbers required to make the fields of brit, sometimes miles in extent, can hardly be imagined. J. S. K.



Pteropod, *Limacina antarctica* (enlarged).

Pterylog'raphy [from Mod. Lat. *pteryla*, feather tract (from Gr. *πτερόν*, feather + *ὕλη*, forest), + *γραφία*, from *γράφειν*, write]: that branch of ornithology which treats of the arrangement of the feathers of birds. The science originated with Nitzsch, who first showed that not only are few birds evenly clad with feathers, but that the feathers are disposed in definite tracts, or pterylæ, between which are bare spaces, apteria, and that the arrangement of these tracts and apteria differs in and is characteristic of various groups of birds. F. A. Lucas.

Ptolemaic System: the name generally applied to the ancient system of astronomy, because the only systematic description of it extant is found in the *Almagest* of Ptolemy. (See Ptolemy, the author.) There is no reason to believe that any important part of it was the work of Ptolemy himself; its development was probably the work of many generations of observers and thinkers before his time. The writings of these men are nearly all lost, and thus it happens that the name of Ptolemy is associated with the system. The fundamental doctrines of the system are these: (1) The earth is a globe. The proofs given by Ptolemy that we do not live upon an extended plain, but on the surface of a globe, are those familiar to every schoolboy. They were better known and appreciated in ancient times than is commonly supposed. (2) The celestial sphere, with all the heavenly bodies, performs a revolution around the earth every day, on an axis called the axis of the world. We now know that this apparent motion is caused by the revolution of the earth on its own axis, but the ancients referred the motion to the heavens. (3) The earth is in the center of the celestial sphere. The apparent proofs of this given by Ptolemy must have seemed to him very strong, but they are a simple result of the revolution of the earth on its own axis. (4) The celestial sphere is so much larger than the earth that the latter is a mere point in comparison. (5) The earth has no motion of translation, but remains at rest in the center of the sphere. (6) The seven planets are arranged in the following order from the earth: the Moon, Mercury, Venus, the Sun, Mars, Jupiter, Saturn. (7) The moon and sun revolve around the earth in eccentric circles—that is to say, in circles whose center does not coincide accurately with the center of the earth. Mercury, Venus, Mars, Jupiter, and Saturn do not move uniformly around the sphere, but move around the circumference of an epicycle, whose center does move uniformly. The epicycle was intended to account for the alternate, direct, and retrograde motions of these planets, which we now know to be due to the revolution of the earth around the sun.

Notwithstanding the falsity of this system it had two merits—that of being founded on careful and exact observations and reasonings, and that of accounting for the salient phenomena of the celestial motions. S. Newcomb.

Ptolemais: See Acre.

Ptolemy [from Lat. *Ptolemæ'us* = Gr. *Πτολεμαῖος*]: the name of thirteen kings of Egypt, forming the thirty-third dynasty, who ruled for nearly three centuries, from the death of Alexander of Macedon till the Roman occupation (323–30 B. C.). The period, in its earlier portion, till the death of Ptolemy III. (221 B. C.), was one of considerable splendor, rivaling that of previous dynasties. The policy of employing Greek mercenaries was continued, and they grew to be the ruling class. The dominant spirit was Greek, not Egyptian. The royal residence was at Alexandria, whose population was mainly foreign, and that city became the center of Greek culture and science. For political reasons toleration was shown to the religious ideas and preferences of the Egyptians, who were regarded simply as servile subjects, and their land as the principal possession of the Ptolemies. Temples were repaired or built anew, as at Karnak, Edfu, and Philæ, and the most important of the native deities found entrance into the Greek pantheon. Twice during the period the native spirit broke forth into insurrection. The first revolt was at the death of Ptolemy IV. (204 B. C.). It emanated from Thebes and spread through the Delta region. With the aid of Rome it was crushed in the Delta in 198 B. C., and the reign of Ptolemy V. established firmly, but Thebes did not succumb till 186 B. C. The other insurrection occurred at Thebes in 88 B. C. during the reign of Ptolemy VIII. In 85 B. C. it was subdued, and Thebes was given over to final destruction. Roman power had been increasing in Egypt during a large part of the period after Ptolemy III., and it was actually dominant long before the final occupation after the defeat of Antony and Cleopatra by Augustus (30 B. C.).

The founder of the dynasty was Ptolemy I. (Soter), the reputed son of Lagus; hence the name *Lagides*, given to the dynasty. He had been one of Alexander's most trusted generals, and at the partition of the empire received the governorship of Egypt (323 B. C.). He remained as a nominal tributary to the Macedonian power till 306 B. C., when he became the actual king, assuming the titles of the Pharaohs and reigning till 284 B. C. By reason of the victory of the allies over Antigonus at Ipsus in 301 B. C., Palestine, Phœnicia, Syria, and Cyprus were added to his kingdom. Ptolemy I. strengthened his land and naval forces, and established the administration and commerce of Egypt. He also laid the foundation of the greatness of Alexandria by inaugurating its library and school. His name *Soter* was given by the Rhodians, whom he aided against Demetrius (305–304 B. C.).—Ptolemy II. (Philadelphus) (284–246 B. C.) enjoyed a peaceful reign and continued the work of his father, extending trade, building roads, canals, and cities for this end. He erected the lighthouse on the island of Pharos. He also stimulated scholarship by adding to the schools and library of Alexandria. It was during his reign that Manetho compiled his history of Egypt, and that the Greek version of the Old Testament, known as the Septuagint, is supposed to have been made, in part at least.—Ptolemy III. (Euergetes) (246–221 B. C.) extended the limits of his kingdom to the N. E., it is said, even to the Indus, and he also made conquests in Arabia, while at home he showed himself an intelligent patron of learning. He received the name *Euergetes* because he restored to Egypt the gods which Cambyses had carried away.—With Ptolemy IV. (Philopator) (222–204 B. C.) the period of decadence began. His possessions in Asia were wrested from him in part by Antiochus III., and his course in sending grain to Rome at the time of the second Punic war was the occasion of the growth of the Roman power in Egypt. He founded the temple at Edfu.—His successor was Ptolemy V. (Epiphanes) (204–181 B. C.), who began his reign in his fifth year. In 201 B. C. he became the ward of the Roman senate, in 195 B. C. the Rosetta Stone, with its trilingual inscription, was erected in his honor, and in 192 B. C. he married Cleopatra I., the daughter of Antiochus.—The later succession was as follows: Ptolemy VI. (Philometor) (181–146) reigned from 181 till 170 alone, and conjointly with Ptolemy VII. (Euergetes II.), surnamed *Physcon*, from 170 till 165. During the period 165–146 he was under Roman tutelage.—Ptolemy VII. succeeded him and ruled from 146 till 117 B. C., with the exception of an interval about 130 B. C., when he was in temporary exile in Cyprus.—Ptolemy VIII. (Soter II.), surnamed *Lathyrus*, reigned from 117 till 106 B. C., when he was banished. He was recalled in 87 B. C. and ruled till 81 B. C.—Ptolemy IX. (Alexander I.) was coregent with Cleopatra III. from 106 till 89 B. C., when he was banished. He died in 87 B. C. in a naval battle.—Ptolemy X. (Alexander II.) was placed in power by the Roman senate in 81 B. C., but was soon afterward slain by an outraged people. With him the legitimate line became extinct, and the succession fell upon Ptolemy XI. (Neus Dionysus),

surnamed *Auletes*, an illegitimate son of Ptolemy VIII. He ascended the throne in 81 and died in 52 B. C. His successors were PTOLEMY XII. (DIONYSUS II.) (51–48 B. C.) and PTOLEMY XIII. (47–44 B. C.), who were successively coregents with Cleopatra VII., the daughter of Ptolemy XI. She continued to be queen till 30 B. C., when with her the line and dynasty both became extinct, and Egypt became a Roman province. CHARLES R. GILLETT.

Ptolemy (*Claudius Ptolemæus*): author; b. at Pelusium in Egypt; flourished at Alexandria in the middle of the second century after Christ. Of his personal life nothing more is known. Of his works, the *Syntaxis Mathematica* and the *Geographia* are extant. The former is a representation of the science of astronomy at the time of the author, based partly on his own researches, partly on those of Hipparchus and others. As it is the only authority for the views of astronomy entertained by the ancients, and as it formed the foundation of all astronomical science down to the time of Copernicus, the book is of the greatest interest. Having disappeared during the Dark Ages, it again became known to the Europeans through the Arabs. About 827 it was translated into Arabic, and of this Arabic translation—the *Almagest*—a Latin translation was published in 1230 under the auspices of the Emperor Frederick II. The best edition of the Greek text, accompanied by a French translation and notes, is by Halma (4 vols., Paris, 1813–28). (For the fundamental ideas of this system see the article PTOLEMAIC SYSTEM.) Of the *Geographia* a Latin translation with maps was frequently reprinted at Rome in the latter part of the fifteenth century, and it was almost the only source of geographical knowledge until the voyages of discovery by the Portuguese made its information antiquated. Editions by Wilberg and Grashof (Essen, 1838–44), and Müller (Paris, 1883).

Ptomaïnes, tō′mā-inz [Gr. *πτῶμα*, a corpse]: certain substances found in the process of putrefaction. Some of these are extremely poisonous, while others are harmless or nearly so. Nencki, in 1882, first isolated a definite substance from the products of putrefaction, starting with gelatin. Later, probably the same substance was obtained from putrid fish. Other basic products were subsequently obtained from putrid meat and fibrin. Brieger has prepared a number of the ptomaïnes, and, by his careful studies, contributed largely to our knowledge of this important class of compounds. (See Brieger, *Die Ptomaïne*, Berlin, 1885 and 1886; *Sitz. K. preuss. Akad. d. Wissenschaften zu Berlin*, 1889.) Among the ptomaïnes described by Brieger the following may be mentioned: Cadaverine, putrescine, peptotoxine, muscarine, and mydaleine. It has been shown that the ptomaïnes are the products of the vitality of micro-organisms, and this discovery is plainly of the highest importance to the science of medicine. It was formerly held that many diseases are due directly to the presence of micro-organisms in the body, but now it appears that, in some cases at least, these organisms act indirectly by secreting poisons, which are the immediate cause of the disturbance of the normal functions. If the poisons secreted by the various organisms that cause disease were thoroughly understood, the foundation would be laid for the use of remedies acting chemically as antidotes.

IRA REMSEN.

Ptosis [Mod. Lat., from Gr. *πτῶσις*, a falling, deriv. of *πίπτειν*, perf. *πέπτωκα*, fall]: a dropping of one or rarely both upper eyelids; an inability to open the eye. It may come from a degenerate or undeveloped condition of the muscle-tissue, or from palsy of the third nerve which controls the muscle of the upper lid. It has been successfully treated by tacking the orbicular muscle to the occipito-frontal. It often passes away without surgical treatment, and there are cases which are not benefited by any treatment whatever.

Revised by W. PEPPER.

Puberty [from Lat. *puber′tas*, deriv. of *puber*, mature, adult]: the period of life at which the exercise of the reproductive function becomes possible. In males of the human race it usually takes place between the ages of thirteen and sixteen, and in females somewhat earlier; and it appears that in very warm and very cold climates puberty is reached somewhat earlier than elsewhere. There are also cases of precocious development in this respect. The period of puberty is attended in males by a more complete development of the larynx, a deepening of the voice, the first appearance of the beard, etc. In the female the contour becomes rounded and more graceful, the catamenia appear, and the mammary glands are developed. There is no doubt that to those who are inclined toward constitutional disease this is a period of some danger, especially to the female. At this time, too, the mind and tastes are often rapidly developed.

Publicans [from Lat. *publica′nus*, pertaining to the public revenues, hence (masc. adj.) one who farms the public revenues, deriv. of *pub′licus*, public, deriv. of *po′pulus*, people]: in ancient Rome, tax-gatherers, farmers of the revenue, who, on the payment of a stipulated sum, obtained the privilege of levying taxes within certain districts of the Roman dominions. The extortion to which their avarice or the high price paid for the privilege often gave rise made these tax-gatherers a detested class, especially in the conquered provinces, as in Judæa, where the contempt felt for them by the Jews appears from many passages in the New Testament. The right to farm the revenues was sold at public auction for a period of five years. As the purchase became too expensive for a single person, societies of the nature of stock companies were formed, whose members contributed to the payment and received a proportional share of the revenues. After the middle of the second century B. C. the publicans belonged to the order of Equites.

Publil′ius Sy′rus: a Syrian slave, probably from Antioch, who attracted great attention in Rome in Cæsar's time as a writer of mimes. St. Jerome mentions a collection of moral sentences extracted from the writings of Publilius Syrus which was used in his time as a school-book in Rome. There exists a compilation of this description, *Publilii Syri mimi Sententiæ* (about 700 verses in all), edited by Wölfflin (Leipzig, 1869), A. Spengel (Berlin, 1874), W. Meyer (Leipzig, 1880), and O. Friedrich (Berlin, 1880). See W. Meyer, *Die Sammlungen der Spruchverse des Publilius* (Leipzig, 1877). Of the mimes themselves we have only two titles.

Revised by M. WARREN.

Puccoon, or **Indian Dye**: a general name applied in the U. S. to several dissimilar plants which yield a yellow or reddish juice, often utilized for dyestuffs. The best-known representatives are species of *Lithospermum* (*L. hirtum*, *L. canescens*, etc.), of the borage family. In many places the blood-root (*Sanguinaria canadensis*) of the POPPY FAMILY (*q. v.*) bears this name. *Hydrastis canadensis* (of the family *Ranunculaceæ*) is the yellow puccoon.

Pückler-Muskau, pük′ler-moos′kow, HERMANN LUDWIG HEINRICH, Prince of: author and landscape-gardener; b. on the family estate of Muskau, in Silesia, Oct. 30, 1785; studied law at Leipzig; served in the army during the wars against Napoleon; traveled much, and became widely known both for his enthusiasm for landscape-gardening and through his spirited traveling sketches. D. at Branitz, Feb. 4, 1871. Under his direction gardens were laid out at Muskau and at his usual residence, Branitz, in the Prussian province of Brandenburg; he also wrote *Andeutungen über Landschaftsgärtnerei* (1834). Of his traveling sketches several have been translated into English—*The Travels of a German Prince in England*, by Mrs. Sarah Austin (3 vols., 1832); *Tutti Frutti*, by Edmund Spencer (5 vols., 1834); *Mehemet Ali and Egypt* (3 vols., 1848).

Puddling: See IRON (*Manufacture*) and FURNACE.

Pudici′tia: the Roman personification of female purity, the virtue *par excellence* of womanhood, as bravery was that of manhood. From early times there was a temple to this goddess in the Forum Boarium, to which, however, only women of patrician families were admitted, though somewhat later a shrine to *Pudicitia plebeia* was established for women of plebeian origin. The cult seems to have fallen into neglect by the middle of the second century B. C.

G. L. H.

Pueb′la: an interior state of Mexico; between Tlascala, Hidalgo, Vera Cruz, Oajaca, Guerrero, Morelos, and Mexico. Area, 12,739 sq. miles. It is entirely included in the region of the plateau, most of the surface consisting of plains or rolling lands, with an average elevation of about 6,500 feet, but these are varied by groups of hills or mountains and, toward the S., by deep valleys. It is partly surrounded by the highest mountains in Mexico. The climate is temperate and healthful; the soil is generally fertile, and agriculture is the principal occupation, the most important crops be-

ing maize, agave (supplying pulque for the markets of Mexico city), and, in the valleys, sugar-cane and cotton; cattle and sheep raising are important industries in some districts. Deposits of silver, copper, and other metals, and coal are known, but are worked only on a small scale. The beautiful "Mexican onyx," a variety of alabaster, comes principally from this state, and many varieties of marble are quarried. The manufactures, especially of cotton and woolen goods and of pottery, are considerable. The state has many interesting antiquities. Pop. (census 1895) 979,723, of whom a large proportion are civilized Indians.

HERBERT H. SMITH.

Puebla (in full, *Puebla de Zaragoza*; formerly *Puebla de los Angeles*): capital of the state of Puebla: on the plateau, near the confines of Tlascala and the Malinche Mountain; 7,200 feet above the sea (see map of Mexico, ref. 7–H). It is clean and healthful, but, aside from the fine cathedral and churches, there are few pretentious buildings. Two parks and a large number of public squares add to the beauty of the place. It is noted for its manufactures of cotton and woolen cloths, etc., and for the onyx and marble quarries of the vicinity. It is connected by rail with Mexico, Vera Cruz, and Oaxaca, and has a thriving trade. The Indian element is largely represented in the population. Puebla was founded as a mission village by the celebrated Toribio in 1532. The U. S. troops under Scott had their headquarters here June–Aug., 1847. Later it was a noted center of the clerical party, and was twice besieged and taken by Comonfort 1856–57. The French, on their first advance, were repulsed from Puebla May 5, 1862, in a battle which is annually celebrated under the name Cinco de Mayo; they captured it in May, 1863. Pop. (1895) 91,917.

HERBERT H. SMITH.

Pueblo: city; county-seat of Pueblo co., Col.; on both sides of the Arkansas river, at the confluence of the Fontaine qui Bouille, and on the Atch., Top. and S. Fé, the Chi., Rock Is. and Pac., the Denver and Rio Grande, the M. Pac., and the Colorado Southern railways; 120 miles S. of Denver: elevation 4,660 feet above sea-level (for location, see map of Colorado, ref. 5–E). It is in an agricultural, mineral, and stock-raising region; has the largest iron and steel works between the Missouri river and the Pacific coast; and is noted for its extensive smelting works. It is easy of access from Leadville and other mining centers and from the great coal-deposits of Trinidad, Cañon City, and nearer fields. There are 3 smelters (the largest in the world), 5 great blast furnaces, numerous machine-shops, rolling, blooming, planing, and nail mills, iron and brass foundries, fire-brick works, lead-pipe works, brewery, large slaughtering-plant, oil-refinery, canning factory, artificial-ice factory, pipe-works, and many minor manufactories. Artesian wells in the city supply a wonderful mineral water. Within a radius of a few miles are thirty oil-wells. The Union Stock-yards occupy an extensive tract of land. The city has gas-works, Holly water-works, electric lights, electric street-railways, 39 churches, 16 public-school buildings, public-school property valued at over $800,000, a collegiate institute of the Methodist Episcopal Church South, 2 Roman Catholic schools, 8 hotels, public library, board of trade building, the Colorado Mineral Palace, a permanent structure for the exhibition of the mineral resources of the State, grounds and buildings of the State Agricultural Society, and the State Asylum for the Insane, together with 7 other hospitals and asylums. In 1900 there were 4 national banks with combined capital of $600,000, and 2 savings-banks with capital of $100,000, and 2 monthly, 3 daily, and 11 weekly periodicals. The assessed valuations of 1894 aggregated $9,877,134. Pop. (1880) 3,217; (1890) 24,558; (1900) 28,157. C. H. SMALL.

Pueblo (pweb'lō) **Indians**, or **Pueblos**: certain families of North American Indians. The term *pueblo*, meaning a town or village, as distinguished from a mere encampment or temporary settlement, was applied by the early Spanish explorers to the great terraced communal house-structures of the sedentary agricultural Indians of Mexico, New Mexico, and Arizona. Later it was adopted as the name of the inhabitants themselves rather than of their villages; hence the use here of the term to designate principally the sedentary town-building Indians of the arid region—or Aridians—of whatsoever stock or period.

Stocks or Families.—The Pueblos proper, who still maintain more or less perfectly their original modes of life, are all included in four linguistic families or stocks, representing twenty-eight tribal groups occupying as many villages in New Mexico, Arizona, Texas, and Chihuahua, in Mexico, detailed in the articles on the KERESAN, TAÑOAN, SHOSHONEAN (*Tusayan*), and ZUÑIAN INDIANS. As the special characteristics of each of these families are treated under the titles given, only those traits more or less common to all of them and to other extinct representatives of the Aridian phase of culture, such as the Mansos, who were probably Tañoan, will be described. See TAÑOAN INDIANS.

Physical Appearance.—Setting aside the changes which have been wrought on the Pueblos by various admixtures with other peoples during the last three centuries, they were, although representing distinct linguistic families, curiously similar to one another. All were originally a comparatively diminutive people, the men averaging not much more than 5 feet in height; the women were even shorter. As a rule, the men were dark or tawny, the women comparatively fair or olive. The men were spare, and rather sharp-featured, but mild of expression and intellectual in appearance. It is significant that while the Pueblos were strictly Indian in type, though more diminutive and refined, there was far greater individual variation among them than among the less advanced Indians. This variation was more pronounced among the Zuñian Indians and least so among the Tañoans, who led a less restricted life.

Dress.—Their wearing material was mostly woven of bark, yucca fiber, cotton or cottonwood down, fur, and feathers. The men wore cat-skin or rabbit-skin robes or pelisses of feather work, or else elaborately striped and embroidered mantles of cotton, gayly embroidered coats of the poncho variety, kilt-skirts tasseled and embroidered, held in place by long, broad cotton girdles, buckskin tights reaching above the knee, or else leggings of long strips of the same material wound round and round the leg, and fastened at the knee with beautifully woven garters or interbraided strands of colored cotton yarn; or, again, long crocheted stockings reaching high up the thighs. The feet were protected by sandals of plaited yucca, or more rarely by buskins or moccasins of buckskin with rawhide soles. The hair was banged to the eyebrows; two long side-locks depended from the temples, and the back hair was tied in a bunch with a plaited ribbon into which a bunch of brilliant feathers (preferably of the macaw) was stuck; a fillet of fiber, or plaited husks, dyed of the color symbolizing the quarter to which the wearer belonged, was bound about the crown. The costumes of priest-chiefs were far more elaborate, being symbolically varied. The warriors wore cone-shaped helmets of thick hide, or headgear made from the headskin of the puma, bear, horned antelope, or bison. They also wore cuirasses of skin, or of padded cotton and yucca, and carried round shields of basketry, of heavily and closely netted cotton, or of thick rawhide, symbolically painted. They carried short lances, javelins, and throwing-slats, long-bows, war-clubs, very broad flint or obsidian knives sheathed in pouches suspended from the belt in front, wood-hafted stone axes stuck through the left fold of the girdle, or else wooden swords edged with close-set blades of obsidian or other flinty material, and slings of skillfully braided yucca.

The costume of the women differed little. They wore a long *camisa* or sleeveless gown of cotton which reached below the knee. An embroidered mantle of cotton, a light head-shawl, leggings and sandals, or moccasins like those of the men, but uncolored, or, for house wear, thickly knitted stockings, completed the dress. The hair of the women was banged slightly in front, parted lengthwise over the middle of the head, and done up in two square knots back of the ears for matrons; in two round coils, "like pitcher handles" (as the early explorers describe them), over the ears for the unmarried women. They wore numerous ornaments, certain of them as amulets of maternity, and others, like those of the men—bracelets, finger-rings, and ear pendants.

Habitations.—Among the Eastern tribes the parallelogrammic form of house-clustering seems to have prevailed, while among the interior and Western tribes the polygonal or rounded village was more usual; but in all, the outer walls were usually built highest, the terraced stories of the town descending from them and looking inward on open courts and alleys. There were no doorways in the lower stories, but access was gained by means of very long-poled ladders, arranged like well-sweeps, so that they could be easily swung up at night for protection. The houses, particularly of the lower stories, were entered through scuttles in the roofs by means of step-logs or ladders. The windows below were mere portholes, while above they were larger and

sometimes well glazed with plates of selenite or mica. In the upper stories were both doors and windows. The cellular houses of these villages were divided, but slightly, into wards or septs corresponding to the number of tribal divisions, and again subdivided into sets of quarters, according to the number of clans in each division. These quarters were permanently occupied only by the women (to whom they belonged) and the children. The men of the tribe, both married and single, had as permanent quarters the large semi-subterranean kivas, of which there was one for every division of the tribe. Here all councils of the clan-clusters were held and ceremonials of the secret cult-societies belonging to them performed. Here also, especially in winter, the men assembled to labor at their looms, at weapon-making, and at minor arts. Here also they sought amusement, and here the "elders" taught the adult youth the lore and regulative usages of the particular division to which they belonged. Lawsuits or disputes between the clans were settled here, while the affairs of the tribal divisions were administered from the principal kiva of the town, usually that of the leading division. In this kiva also, all tribal affairs were conducted, and strangers from other tribes were entertained. Each household in the clan-quarters occupied three or more rooms, according to numbers—for the rooms were very small—and was presided over by the eldest matron. There were always a kitchen, a storeroom, and an eating and living room, in the latter of which the husbands came to meals with their families or visited their wives.

Occupations and Methods of Life.—The women cared for the families, prepared all food, made the pottery and basketry, and fashioned the stone-mills and other household utensils. The men were the principal weavers and spinners. They tilled the fields, raising their crops mainly by means of irrigation. The women had little truck-gardens close to the towns, where leeks, chile, or red peppers, and a few fragrant herbs were raised by hand-watering. The main meat-supply was gained by hunting, which was usually communal, and whole divisions joined in great round-ups of game, for which purpose enormous corrals were constructed. However, turkeys and other small animals were domesticated by some of the Pueblos. Land-tilling, the construction of irrigating-dams, ditches, and embankments, and all other operations conducted at a distance from the towns, were, like the hunts, communal undertakings, since the villagers, with their rich stores of food, were ever liable to predatory attacks from the neighboring nomadic tribes. This state of affairs reacted powerfully on their sociologic organization, forms of town-building, and methods of life. It also affected their intercourse with the outside world. Journeys of all descriptions were communal. This again had the effect of making the Pueblos of the interior essentially home-dwelling and extraordinarily conservative and exclusive.

Culture Characteristics.—All the Pueblo tribes were composed of clans, and descent was in the female line. These clans were families of kindred named after some animal, plant, mineral, or element. Some of the smaller tribes grouped these clans in two divisions—those of the North and South or of Summer and Winter; others had four clan-groups (those of North, West, South, and East, or of the Four Seasons), while the highly developed Pueblos had rarely fewer than six, usually (as with the Zuñians) seven groups—namely, those of the North, West, South, East, Upper, Lower, and Middle regions. The clans were grouped or related, according to the supposed analogies of their totems or namesakes (the animals, etc., from which they were named), to the various phenomena of the different regions. Thus the Puma, being fierce and loud-roaring, belonged in the north, whence came the fiercest winds and raging storms of winter; and as the Live-oak never withered in these storms, it too pertained to the north and winter; hence the clans of the Puma and the Live-oak, and others like them, belonged obviously to Winter and the North, and therefore belonged together. The Sun and the Eagle, dwellers in the skies, the Turquoise, a bit of the sky itself, were no less surely of the upper world than were the Rattlesnake and the Frog of the lower world.

Over each group of clans was a priest-chief, or "elder," the worshiper-in-chief, keeper of the medicines or powers and mysteries of the great animal-spirits and gods of the region or world-precinct which his division represented.

This priest-chief was also the oracle in all religious and secular matters in his "household." There were generally seven of these divisional priests or leaders of clan-groups, and rarely fewer than four. Among them were the "Peaceful Leader" and "Wrathful Leader," now popularly known as Governor or Alcalde, and Captain of War. These have their assistants, or *tenientes*, whose offices, like those of their superiors, are of Spanish adoption, and who are annually elected with the sanction of the supreme council of priest-chiefs or *caciques*.

The people were controlled not so much by the Peace and War Chiefs (to whom they were nevertheless obedient generally) as by the oracular and magical fathers behind them. These deserved the reverence and respect in which they were held as the "fathers and mothers" of the tribe, for they were the *penitentes* of their people, and had to labor at the sacred rites from season to season, to watch, fast, and repeat rituals, etc., days at a time on stated occasions. Therefore, under the auspices of the divisional societies, nearly all the great "customs" (such as the games, races, communal hunts, tillings, harvestings, and journeyings for wood) were annually performed for their benefit.

There were in every considerable tribe of Pueblo Indians from four to thirteen secret or tabu societies or priestly fraternities of the so-called "medicine-men" of popular tradition. These societies were systematically adjusted to the tribal sociologic organization. They pertained separately, according to their special functions, to the various regional clan-groups or divisions. Their members, with the divisional priest-caciques, were the keepers and teachers of the mythic lore and rituals, religious regulations, magic mysteries, and medicines or "potencies" of the divisions to which they belonged. Thus the name of *cult-societies*, as given them by Powell, is most appropriate. The societies of the North were wind and cold makers, and took precedence in winter; those of the South—fire-makers or masters of fire—had control in summer. Above all, the members of these cult-societies were doctors, or priest-doctors, each according to the region, season, element, and associated function of his particular society. Their practice of medicine and the application of remedies was, in theory, irrational, though strictly regulated and often both simple and surprisingly successful. The belief in the universality of disease and its spiritual or ghostly origin vastly enlarged the field of supposed usefulness and the power of these fraternal priest-doctors. Not only did they treat disease, but their more regular labors were directed toward its (spiritual) prevention.

Religion.—The religion of the Pueblos was a Nature-religion. Their gods (equally of both sexes) were animal gods, phenomenal gods, ancestral gods, and celestial gods. Supreme among the immortals was the God of the Sun-shield, the Creator of the All-makers, Water or Generation, personified in the Ocean-mother, the Sky-man, and the Earth-woman, whence all mortal things were born. Under the Sun-god were the God of Fate and his twin younger brother, the God of War; the God of Time or the Seasons, and his younger brother, the God of Dawn, etc. Apart from all was the Master of Life—son of the Sun-god and of Life, or the Great Waters. He was the Messiah of the Pueblos, who was supreme over the animal and phenomenal gods and the mediator between these mortal-like beings and the celestial or attribute gods, and was a personification of the reflection or image of the sun in the water, as the Goddess of Love, or of the Ocean, was the reflection of the Moon (Goddess of Menstruation or Maternity).

All of these gods were supposed to be related to one another as are men, creatures, and things in this world; their organization was like the sociologic organization of men. The heavenly or spiritual world was over, yet interpenetrated the visible world. As this world had a center or middle in the center of the Pueblo country, so the spiritual world had a center or middle over the Lagune of Shipapu (the hot springs of Colorado in the north of the Pueblo country), which was the place of umbilical connection between the parent spiritual world and the offspring mortal world. Thither, therefore, the rituals and offerings to the Master of Life, or Nether-sun God, were always addressed by the priests of the cult-societies.

Just as the Pueblo theory of medical practice was spiritual, so their theory of spiritual worship was largely medical. The ills of life and times were diseases to be remedied by charms and formulas and by rules of spiritual hygiene (observances and right behavior), or to be prevented by work, the business or industry of worship. In all this it was necessary to aid and be aided by the gods, and to this end, in token of sincerity, the priests abstained from meat and all other carnal things four days each month, and from eight to ten days at the summer and winter solstices, or for

longer or shorter periods whenever evil times demanded. At such times they labored day and night, making symbolic, plumed prayer-wands, as testimonials of constancy to be set up in shrines abroad as "prayers from season to season." These labors were accompanied by the repetition of traditional rituals and incantations of great length, and dramaturgic performances (the so-called *cachinas* or dances) before altars set up to symbolize one or another of the sacramental regions. Offerings of sacred prayer-meal were also made on various occasions; shell, coral, or turkois beads or other treasures were sacrificed as spirit-medicines or as payments or gifts of good will.

The people at large joined for a day in each month and four days semi-annually in these exercises of worship. In autumn the dead were remembered by all with offerings of the substance of food and other articles consumed or set free by fire, and at New Year or the "mid-time" (in November) the solemn festivals and dramaturgic celebrations of creation and of the "middle of the world" were held. The dancers of the *cachinas* were masked as animals or as demons (see Zuñian Indians), joining the priests in these representations of the re-creation of the world and the seasons.

Customs as to Marriage, Burial, etc.—The men of a clan could not marry the women of the same clan, and marriage was, therefore, almost as much an affair of the clans as of individuals, alliances taking place as much as possible outside of the clan-group as well as the clan (in order that diverse seasons and elements might be "wedded"). Until after betrothal, lovers wooed very indirectly; that is, a young man, in courting, would strive to attract the attention of his choice by general, not pointed, displays and actions. After betrothal the young man was accepted by the maternal relatives as a perpetual rather than temporary guest of their clan and of his wife. Thus divorce, of course, was chiefly in the hands of the women.

A midwife (usually a cult-priestess), the maternal grandmother or matron, and, if a priestess, the paternal grandmother, or in her place grandfather (called on the occasion "grandmother"), presided at birth. Immediately afterward birth-offerings were made by the paternal female relatives, and the child was laid, with many ceremonial observances, on a sand-heap, and an ear of "male corn" for a boy, or of "female corn" for a girl, was placed by the infant's right side. After nine days the child was presented to the Sun by the paternal elders, and formally adopted from them, and clan-named by the clanspeople of the mother, to whom thenceforward it belonged.

After death these observances were reversed. A jar of water was broken by the dead, who was thus renounced by the clanspeople of the mother to the clanspeople of the father. Presents of food and personal property were given, and the body was then washed and wrapped in blankets with sacred offerings and plumes. If the dead had been a clan or cult priest, he was buried under the ladders outside or inside of the house, the presents or offerings of the kin being burned; if not priestly, then the body of the dead (in order that the soul be facilitated in its escape from the flesh and from sorcerers) was burned with the offerings, thus being given back to the sun and earth.

Pristine History.—Originally, the Pueblos included representatives of several more stocks. In the south the Mansos, already mentioned, the Sumas, Janos, and Piman tribes belonged to them; in the west two or more Yuman tribes; others, the stocks of which are unknown, have been exterminated or absorbed principally by the Apache, Navajo, and Comanche within the last four centuries. But, howsoever diverse the stocks of the original Pueblo Indians may have been, they everywhere followed practically the same line of development, and proceeded so far toward becoming a distinctive people that the term Aridian has been adopted as best characterizing them. Evidence is complete that these Pueblo peoples were derived from numerous (probably small) tribes bordering the great arid region in an irregular semicircle from Central Utah and Colorado on the N. and Central Texas on the E. These tribes were driven southward into the deserts by stronger tribes from time to time, and were forced to live in limited areas near scant water-supplies, in widely sundered bands. As these bands increased, cultivation by means of a crude system of irrigation was necessitated. Thus the bands became fixed, and built more substantially earth-covered wooden huts: then, from scarcity of timber, larger and better houses of stone and mud were constructed, separate, yet in straggling groups around their watering-places and scattered fields. Then came their time of trial, which only the hardiest survived; tilling the soil and remaining fixed in habitation, they acquired food-stores and possessions which drew their enemies once more upon them, and forced them to flee to the cañon walls, where they became cliff and cave dwellers. The necessity of building on limited sheltered shelves of the rocks and of living in such crowded villages as the Cliff-dwellings (*q. v.*) developed at once the characteristic terraced and cellular type of architecture, and the divisions of quarters (for example, of the men from those of the women), etc., so peculiar to their pueblos of later times. Here they abode until they became too numerous for their footholds in the cliffs, and sought safety in numbers, climbing to the heights of their valley or cañon fields, and there building their many villages in one. Yet for a long time they still used their cliff-towns as farming villages, and often fled to them and built others like them when pressed by enemies. This was substantially the history of the development of the Pueblo Indian village life as found in the sixteenth century by the Spaniards.

The Zuñians were probably the first Pueblo peoples who, still living in the sixteenth century, had become fixed in the habit of *plain-dwelling* in segregated and definitely interrelated but not wholly autonomous communal villages. Nearly all of the Pueblos of other stocks were rapidly following their example at the time of the Conquest, as the Keresans had long done, and the Tusayan villagers had, although building the latest-made pueblos, most perfectly done.

Ruins.—Throughout the whole vast arid Southwest, from Central Nevada, Utah, Colorado, and Texas southward to and far beyond the boundary of Mexico, occur everywhere, except in the highest mountains, ruins which mark the presence and wanderings of the Pueblo peoples, and record vividly the stages of their slow development as communal villagers. Many hundreds of these ruins are buried under sand and drift, while others remain to be revealed only by accident. Of the conspicuous ruins, there are doubtless more than 3,000 in New Mexico, Arizona, and a small part of Utah and Colorado alone, and of smaller remains fourfold that number.

These ruins may be roughly classified, for convenience of reference, as lava-pueblos, small or single house pueblos, cliff-pueblos, communal pueblos, group-pueblos, and aggregate or city pueblos (towns), such as the Casas Grandes of Southern Arizona and Northern Mexico. An example of group-pueblos is furnished by the Seven Cities of Cibola, now in ruins, which were the original towns occupied by the Zuñis, the name being given by their Spanish discoverers in 1539–40. Some of these types are practically universal, and there are sections in which all are present; but the group-pueblos and city-pueblos occur only in comparatively limited areas. This variation in type and relative distribution represents the successive phases in development of a single or of similar peoples.

Population.—At the time of the Spanish conquest the Pueblo Indians numbered, all told, more than 30,000. That their numbers were not less is evidenced by the ruins of Pueblos which were recorded as occupied in the sixteenth century. The number of Pueblo towns in the U. S. now inhabited is only twenty-seven, an additional village (Senecú del Sur) being in Chihuahua. The total population of the modern towns is about 10,000. The Pueblo Indians, as a whole, are not materially diminishing in numbers.

Authorities.—See the works cited under Zuñian Indians; also Holmes and Jackson in Bulletin of the U. S. Geol. and Geog. Survey of the Territories, vol. ii. (1876); Wheeler Survey Report, vol. vii., *Archæology* (1879); Morgan, *Houses and House-life of the American Aborigines* (*Cont. N. A. Ethnology*, vol. iv.); and the annual reports of the Bureau of Ethnology. joints may occur as complications. The disease runs a rapid course, usually terminating fatally within a week, the patient dying from exhaustion.

Puerperal fever is a septic disease that is always due either to infection from some micro-organism already existing in the woman's genital tract (auto-infection) that finds an ingress into the system through the tissues that are lacerated and bruised during labor, or (as is generally the case) to infection by the midwife or attendant, or to contact with infected bedding, clothing, or instruments (hetero-infection). In 1843 Dr. Oliver Wendell Holmes promulgated this latter theory in America, and in 1847 Semmelweis proclaimed the doctrine in Europe. It was not until bacteriologists had conclusively demonstrated to what septic infection was due that the foregoing idea was generally adopted. Now there is no obstetrician of any scientific attainments who would question the fact. There should be no deaths from puerperal fever in properly attended obstetrical cases, in which absolute cleanliness of the midwife's hands and of all things coming in contact with the patient are secured.

On the first symptoms the genital tract should be irrigated, at intervals of three to four hours, with from 3 to 4 quarts of a 1-per-cent. solution of table-salt in boiled water, to which may be added 2½ per cent. of creolin or carbolic acid, that is allowed to cool to a temperature of from 100°–105° F. If this dose does not reduce the fever in a short time, the physician may be certain that a portion of the after-birth is left within the uterus and is decomposing, and he should place the patient on an operating-table, and by means of a speculum expose the uterus and scrape its interior with a long wire scoop (curetting), following this by irrigation with a hot-salt and creolin solution. This, with a hot-water coil or hot-turpentine stupe to the abdomen, and iron, quinine, and brandy internally, comprises the necessary treatment. S. T. Armstrong.

Puerperal Insanity: perversion of the mind in women immediately after childbirth, although it may also occur before delivery, or weeks or months after labor, when excessive nursing has undermined the strength. It may therefore be considered as a derangement of the mind due to the influences of the childbirth upon the nervous system and emotional nature of the mother. Puerperal insanity may be characterized by mental agitation or excitability, or, reversely, the patient may sink into a state of mental apathy, moodiness, reticence, or despondency. There will be restlessness, inability to sleep, headache, impaired appetite, coated tongue—in some cases an increase of temperature. The bowels are usually constipated and the urine diminished in quantity. The secretion of milk is often lessened or suspended, and a sudden maniacal condition may follow immediately upon a cessation of the flow of milk. Although the delirium in some cases is violent, no evidence of inflammation or other organic disease of the brain or its membranes has been detected, on post-mortem examination, as the lesions to which the symptoms might be due. In the delirious form and in the melancholic form there is equally an aversion to the father or the child. Suicide and murder of the child are occasional occurrences. Puerperal insanity may be expected to occur in women of nervous temperament or those predisposed to insanity; in such also as are greatly reduced by previous ill health, by hæmorrhage during or following delivery, or whose blood has been impoverished. The maniacal form is apt to occur immediately after childbirth and in the young and more vigorous, whereas the melancholic type more often begins late during lactation, or in the old and debilitated, immediately after labor. The prognosis is favorable; the mind in most cases is, in time, restored to a normal condition. The patient may wholly escape it at subsequent childbirths if the system be fortified in advance by iron to correct anæmia, and care be taken to prevent unusual loss of blood during parturition. Where insanity or emotional excitability are family traits mania may recur with successive labors despite all precautionary efforts. The infant, in most cases, should be removed. Firm but gentle control of the patient is essential, and often removal from husband, family, and familiar friends is essential. Rest and sleep must be insured by cerebral sedatives and soporifics, and even the hypodermic injection of morphine may be required in obstinate insomnia and delirium. The strength must be sustained and the blood enriched by cod-liver oil, quinine, and iron.

Revised by W. Pepper.

Puerto Caballos: See Puerto Cortez.

Puerto Cabello, pwār′tō kăă-bāl′yō: principal port of the state of Carabobo, Venezuela; on a small peninsula, which, with a chain of small islands and reefs, forms a very secure and commodious harbor admitting the largest vessels (see map of South America, ref. 1–C). A railway runs inland to the copper region of La Luz. The trade of Carabobo, Lara, Zamora, and Los Andes centers here, and the port is the most important in Venezuela after La Guayra; the principal exports are coffee, cacao, dye-woods, hides, and copper ores. The port was strongly fortified in the eighteenth century, and repulsed the attack of a British fleet. During the war for independence it changed hands several times, and was the last stronghold taken from the Spaniards in 1823. Pop. (1891) 10,145. H. H. S.

Puerto Cortez′, or **Puerto Caballos**: a town and port of Honduras; on a bay of the Caribbean coast; 125 miles N. N. W. of Tegucigalpa (see map of Central America, ref. 3–G). The bay forms an excellent harbor, where the principal railway of Honduras terminates. The town, although small, is the principal northern port of Honduras. Hernando Cortés founded here (1525) the town of Natividad, subsequently abandoned for Omoa. H. H. S.

Puerto de Santa Maria, pwār′tō-dā-saan′tăă-măă-rec′ăă, or simply **El Puerto**: town; in the province of Cadiz, Spain; at the mouth of the Guadalete in the Bay of Cadiz; 22 miles by rail N. E. of Cadiz (see map of Spain, ref. 20–D). It is a handsome and well-built town, surrounded with fine promenades, and in communication with the great commercial centers, as it is the principal place for the exportation of sherry wine. Leather, soap, hats, brandy, and liqueurs are manufactured, and in May of each year an important bull-fight takes place here. Pop. (1887) 20,590.

Puerto Lamar: See Cobija.

Puer′to Prin′cipe: a town near the center of the island of Cuba; 45 miles by rail W. S. W. from its port of Nuevitas, on the northern coast (see map of West Indies, ref. 4–D). It is the third city of the island in size, is the center of a rich agricultural and grazing district, and exports sugar, hides, cattle, etc. It was originally founded in 1514 on the site of an Indian village near the coast, but was subsequently moved inland. Pop. with the district (1899) 53,140; of the city proper, 25,102. H. H. S.

Puerto Rico, pwār′tō rec′kō, or **Porto Rico**, pōr′tō ree′kō: the smallest island of the Great Antilles; separated from Santo Domingo on the W. by the Mona Passage, and having the Virgin islands on the E.; area, 3,530 sq. miles, and its dependencies, the small islands of Mona, Culebra, etc., aggregate 184 miles more. A low range of mountains, the Sierra Cayey, traverses it from E. to W., and numerous branches separate fertile and well-watered valleys; near the coasts there are equally fertile plains of considerable extent. The highest peak, Mt. Yunque, near the northeast end, is 3,688 feet above the sea. There are no volcanoes, and few severe earthquakes have been felt. The climate compares favorably with that of any other of the West Indies; foreigners easily become acclimated; the heat, even in the summer months, is seldom severe, and almost the only drawbacks are the hurricanes which sometimes blow between July and October. Nearly the whole surface is under cultivation, forest being restricted to a few mountain sides. The principal products are sugar, coffee, and tobacco for exportation, and maize, mainly for home consumption; the grazing industry is considerable, and hides are exported. There are no minerals of importance. Puerto Rico is one of the most thickly populated regions of the New World. In 1887 it had 807,708 inhabitants, or about 216 to the square mile; in 1899 the total population was estimated to be 957,000; the proportion of Negroes and mulattoes is less than in most of the other islands. With its dependencies it formed a province of Spain from 1870. The official chief was a governor chosen by the crown. Spanish is the common language, and nearly all the inhabitants are Roman Catholics; education is somewhat backward. The island was discovered by Columbus in 1493, and was conquered by the Spaniards under Ponce de Leon 1509–18. As a result of the war with Spain the U. S. demanded the cession of the island and assumed sovereignty over it and its dependencies Oct. 18, 1898. The war and the terrible hurricane of August, 1899, almost completely wrecked the commercial prosperity of the island. However, since the final settlement of the tariff relations, and through the able administration of Gov. Charles H. Allen, appointed Civil

Governor under the Act of Congress approved Apr. 12, 1900, commerce has increased rapidly. In the fiscal year ending June 30, 1900, the exports to the U. S. were valued at $3,078,648; the imports at $4,640,449.

Pueyrredon, pwā-ĕe-rā-dōn', Juan Martin: general and politician; b. at Buenos Ayres about 1780. He was chosen supreme director of the united provinces of La Plata July 9, 1816. His efficient support of San Martin resulted in the independence of Chili. He resigned in June, 1819. D. near Buenos Ayres about 1845.

Pufendorf, Samuel, Baron von: jurist and historian; b. near Chemnitz, Saxony, Jan. 8, 1632; son of a Lutheran clergyman; studied theology at Leipzig, public law at Jena, and in 1658, after a short residence and imprisonment in Denmark, published anonymously at Geneva *Elementa Jurisprudentiæ Universalis*; in 1661 became Professor of the Law of Nature and of Nations at Heidelberg; in 1667 published *De Statu Imperii Germanici*, denouncing the house of Austria and exposing the inherent weakness of the holy empire; in 1670 accepted the professorship of law at Lund, and in 1672 published *De Jure Naturæ et Gentium* (Of the Law of Nature and of Nations). Although in this work there is much that is commonplace, it marks an epoch in legal literature, being the first to give a systematic treatment to the subject-matter contained in it. He followed largely, but not servilely, the doctrines of Grotius, and supplemented them with his own ideas and with theories derived from the works of Hobbes, with whom he differed on many points. In 1677 he went to Stockholm as royal historiographer and remained there till 1688, when he entered the service of Frederick William, Elector of Brandenburg. He wrote a number of historical works on Swedish and Prussian affairs which in general are reliable, but are very tedious reading. D. in Berlin, Oct. 26, 1694.

F. Sturges Allen.

Puff-adder: a deadly serpent (*Clotho arietans*) of South Africa, deriving its popular name from its habit of puffing up the neck when irritated. It is very large and thick, and is ordinarily slow, but can move very quickly when angered. There is no known remedy for its bite.

Puff-balls: saprophytic plants of the family *Lycoperdaceæ* and order *Gasteromyceteæ*, in which the dust-like spores escape in a cloud when the ripe spore-fruit is suddenly compressed. They grow on the ground or on decaying stumps, logs, etc., and are abundant in all temperate and warm climates.

The proper plant of a puff-ball consists of a mass of white branching threads (often called the mycelium) which creep through the soil or decaying matter, gathering food and moisture for its nourishment. After a time there appear upon the plant at various points small rounded bodies, the young spore-fruits, consisting of compacted threads. These bodies grow rapidly, and eventually emerge from the ground. When young there is little differentiation in the tissues of the spore-fruits, but as they grow the outer layers become modified as a boundary tissue (*peridium*), more or less separable into an outer and an inner stratum, while the interior differentiates into (1) a sterile and (2) a spore-bearing portion (*gleba*), the former constituting the base or supporting part of the spore-fruit, while the latter fills the upper, usually enlarged part.

The spore-bearing tissue is penetrated by numerous narrow, tortuous passages lined with perpendicularly placed cells (the *basidia*), each of which produces several spores. The young basidia are smooth, but protrusions appear upon them later, grow out, become elongated, and finally form spores by enlargement at the distal end. Thus it follows that the tortuous passages above mentioned contain myriads of spores. When ripe these are set free by the deliquescence of most of the spore-bearing tissue and the evaporation of the surplus moisture. Certain thick-walled threads do not deliquesce, and are known collectively as the "capillitium." The peridium now breaks irregularly, or in some species more or less regularly, allowing the spores to escape and be carried away by the wind.

The more common puff-balls of North America may be arranged under several genera as follows:

1. *Geaster*, the earth-stars, in which the outer peridium splits stellately, becoming reflexed away from the thin persistent inner one. Of the sixty-eight known species, many have a wide distribution, while others appear to be restricted to particular regions. Thus *G. saccatus* (Fig. 1) occurs in North and South America, the East Indies, and Australia. *G. fimbriatus* is found throughout Europe, North and South America, the West Indies, South Africa, and

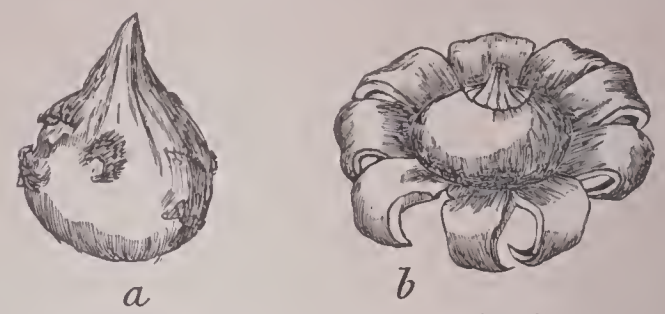

Fig. 1.—*Geaster saccatus*. *a*, before, and *b*, after the rupture of the outer peridium. Slightly reduced.

Australia. *G. hygrometricus* (Fig. 2) appears to be found in all parts of the world. The segments of its outer peridium

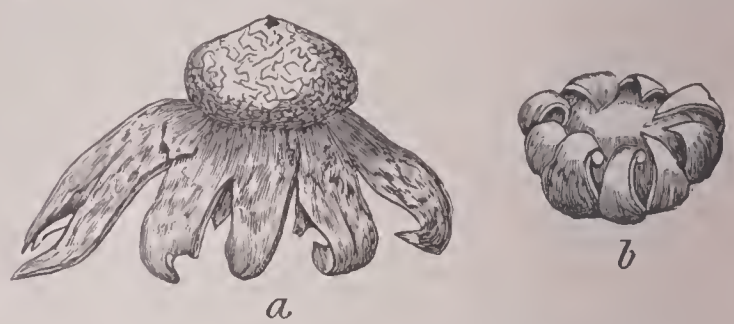

Fig. 2.—*Geaster hygrometricus*. *a*, when moist; *b*, when dry. Slightly reduced.

are strongly hygrometric, opening when moist, and becoming inflexed when dry. On account of some structural peculiarities, it is regarded by Morgan as the type of a separate genus, *Astræus*.

2. *Tylostoma*, the stalked puff-balls, in which at the maturity of the spore-fruit its sterile base rapidly elongates into a stalk. About twenty-five species of these curious plants are known. They occur in all parts of the world, especially in dry and sandy regions. One of the most widely distributed species is *T. mammosum* (Fig. 3, *a*), which occurs in Siberia, Europe, North America, and Australia. *T. fimbriatum*, another common species, occurs in Europe and Australia also. *T. campestre* (Fig. 3, *b*) and *T. meyenianum* (Fig. 3, *c*) are known only from the Rocky

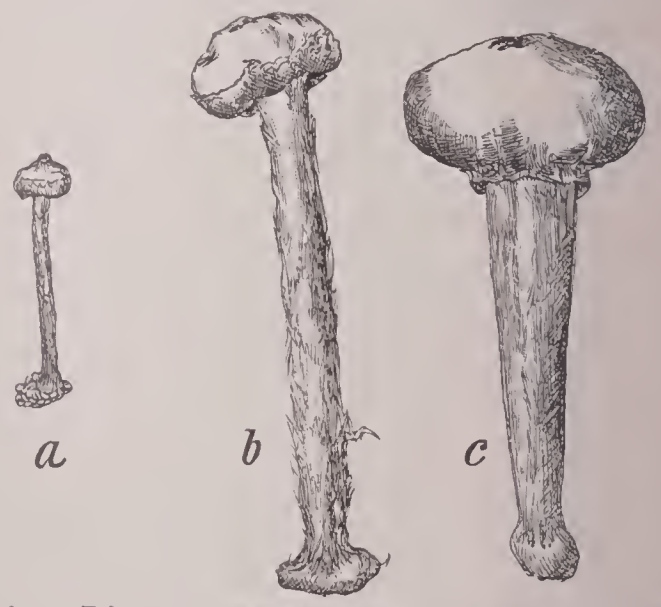

Fig. 3.—*a*, *Tylostoma mammosum*; *b*, *T. campestre*; *c*, *T. meyenianum*. All two-thirds natural size.

Mountains and adjacent regions, the latter ranging southward to Peru.

3. *Calvatia*, the big puff-balls, in which the spores escape by the irregular rupture of the peridium of the large spore-fruit, the gleba soon breaking up entirely. When young and perfectly fresh they are edible and nutritious.

One of the most common of the big puff-balls is *C. maxima*, which is globular or nearly so, white, and from 6 inches to a foot in diameter. Occasionally it attains an enormous size; one found in Ohio was 20 inches in diameter and weighed 17¾ lb. It is found in grassy fields in Europe, Asia, and North America. Another common species is *C. craniiformis* (Fig. 4), which is much like the preceding, but smaller, and with a more distinct sterile base.

4. *Lycoperdon*, the common puff-balls, in which the spores escape from the small spore-fruit by a regular mouth at the top.

More than 100 species are known in all parts of the world. Morgan describes thirty-one species found in North America, some of which are very pretty — e. g. *L. echinatum* (Fig. 5)—when young. *L. piriforme* is found in clusters on old logs and stumps, and is of a rich brown.

Fig. 4.—*Calvatia craniiformis*, reduced.

5. *Bovista*, the little puff-balls, in which the sterile base of the small spore-fruit is very small or wanting and the inner peridium thin and papery.

Among species indigenous to the U. S. are *B. nigrescens* and *B. plumbea*, common in pastures and meadows across the continent. *B. minor* (Fig. 6), from Ohio and Nebraska, is a good representative of the genus. Morgan has separated several species of *Bovista* and placed them in the new genus *Catastoma* because of the remarkable fact that the mouth by which the spores escape is below, as shown in Fig. 7. The outer peridium splits transversely, the lower part

Fig. 5.—*Lycoperdon echinatum*, slightly reduced.

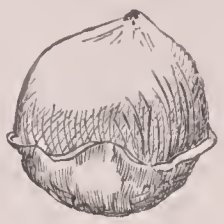

Fig. 6.—*Bovista minor*, about natural size.

adhering to the earth, while the remainder, with the attached inner peridium and its contents, blows away, thus scattering the spores.

6. *Mycenastrum*, the hard puff-balls, are similar to *Bovista*, but are of larger size and have a thick and hard inner peridium. *M. spinulosum* is 2 to 4 inches in diameter, and grows on sandy soil upon the prairies and Great Plains.

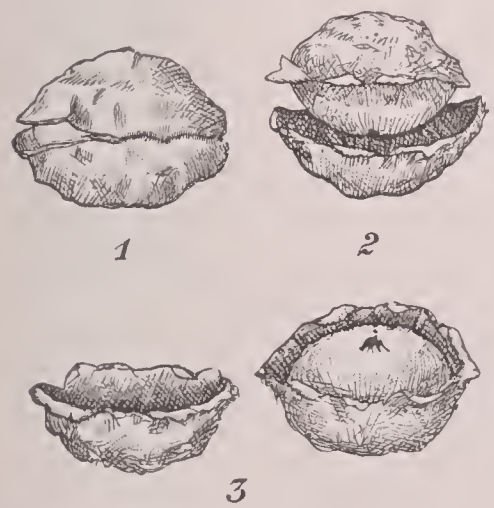

Fig. 7.—*Catastoma circumscissum*, slightly reduced.

The puff-balls are closely allied to three other families of fungi, and with them constitute the order *Gasteromycetæ*, known in a general way as the Puff-ball order. The four families may be briefly characterized as follows:

Hymenogastraceæ, the subterranean higher family.—Spore-fruit subterranean; gleba fleshy, persistent; peridium single, not separating. In many ways these fungi remind one of the subterranean sac-fungi (*Tuberoideæ*).

Lycoperdaceæ, the puff-balls.—Spore-fruit emerging from the ground; gleba spongy, deliquescing, and then powdery; peridium mostly double, separating regularly or irregularly.

Nidulariaceæ, the bird's-nest fungi.—Spore-fruit external, cup-shaped: gleba spongy, deliquescing, and leaving egg-like "peridiola." These small fungi are common on decaying wood.

Phalloideæ, the stink-horn fungi.—Spore-fruit at the surface of the ground; gleba fleshy, deliquescing into a fetid jelly, then emerging from the peridium by the elongation of the sterile base.

Literature.—P. A. Sacardo, *Sylloge Fungorum*, vol. vii. (1888); A. P. Morgan, *North American Fungi*, in *Journal of the Cincinnati Society of Natural History* (1889 to 1893); A. de Bary, *Comparative Morphology of the Fungi, Mycetozoa and Bacteria* (1887). Charles E. Bessey.

Puff-bird: any member of the *Bucconidæ*, a family of small birds having large heads and stout bills, peculiar to the tropical or warmer regions of America. They are mostly of dull plumage and equally dull disposition, sitting motionless for a long time with their feathers erected, looking as if they were puffed up, whence the popular name. F. A. L.

Puffer (in auctioning): See By-bidding.

Puffin: any bird of the auk family (*Alcidæ*, see Auk), belonging to the genera *Fratercula* and *Lunda*, which are characterized by high, compressed, highly colored bills. The best-known species is the common puffin, coulterneb, or sea-parrot (*Fratercula arctica*), found abundantly on both sides of the Atlantic. This bird is about a foot long, black above, white below, with a gray face and black collar about the neck. The bill is red with yellow and bluish markings, and is in great part shed and renewed annually, together with a little excrescence on either upper eyelid. In all, nine pieces are shed, leaving the bill of the adult in winter looking like that of a young bird. The Arctic puffin breeds

The puffin.

in burrows and lays a single white egg with a few faint gray markings at the large end. The nestlings are clad in thick down. A closely related species (*Fratercula corniculata*), known as the horned puffin, from the rather long outgrowth on the upper eyelids, occurs in the North Pacific, as does also the tufted puffin (*Lunda cirrhata*), a rather larger bird with a long tuft of yellowish feathers curving backward from above either eye. Puffins swim and dive well and fly rapidly though heavily. They feed on fish and go long distances to catch food for their young. The flesh of the various species is much used for food, and tastes much better than might be supposed from their fishy diet. F. A. Lucas.

Pug: a small, short-haired, short-muzzled breed of dogs, represented by at least three varieties, probably derived from the bulldog. The head should be massive, forehead wrinkled, eyes large and prominent, body short and wide, tail tightly curled. Color fawn with black muzzle and a dark spot on forehead, and dark line down the back. The pug is a stupid but good-natured dog. F. A. L.

Pugatcheff', Yemelyan: adventurer; b. in 1720 at Simoweisk, a village on the Don, in the territory of the Cossacks; grew up as a member of a band of robbers; served in the Seven Years' war, first in the Russian, then in the Prussian, and at last in the Austrian army, and was imprisoned for

some time after his return to Russia for attempts at sedition. In 1770 he went to Poland, and there joined the Raskolniks (*q. v.*). He resembled the murdered Emperor Peter III., and in 1773, after a rumor had been spread that Peter was not dead, Pugatcheff presented himself as the monarch, and was joined by a few other adventurers. The Raskolniks acknowledged him, and the peasantry rose in his favor; he occupied several forts on the Ural and Don; some Tartar and Finnish tribes joined him, and he was on his march to Moscow with a considerable army when he was sold by his comrades for 100,000 rubles to Suwarow. He was executed at Moscow Jan. 10, 1775.

Puget, pü'zhā', Pierre: painter, sculptor, and architect; b. at Château-Follet, near Marseilles, France, Oct. 31, 1622. At the age of fourteen he became the pupil of a wood-carver and builder of galleys named Romano. In 1639 he found his way to Florence, where he worked as a carver in wood, and then went to Rome, where he studied painting. In 1653 he returned to Marseilles, where he built a rich galley for the Queen of France, and then devoted himself to painting. In 1656 he finished the doorway and balcony of the hôtel de ville of Toulon, and later designed the new hôtel de ville at Marseilles. He was employed by Fouquet, the superintendent of the Treasury, and went to Genoa on Fouquet's business, where he remained after his patron's fall and designed palaces and produced important works in sculpture and painting. Colbert invited him to return to France and gave him employment at Toulon in the artistic decoration of Government ships, then an important branch of fine and decorative art. About 1670 he resigned this post, settled in Marseilles, and occupied himself in architectural and other art works there, and in Toulon and other cities. D. at Marseilles 1694. In the Louvre Museum one hall is named after Puget and contains his sculptures *Hercules Reposing*, *Perseus and Andromeda*, *Milo of Crotona*, and *Alexander and Diogenes*. In Marseilles is the important bas-relief, the *Plague at Milan*. W. J. Stillman.

Puget, pyu'jet, **Sound**: an arm of the Pacific Ocean; extending S. from the Straits of Juan de Fuca, in the State of Washington, and between the Coast Range of mountains on the E. and the Olympic Mountains on the W. It is perhaps the most beautiful sheet of water in the world; is about 100 miles long, has a coast-line of 1,600 miles, and an area of 2,000 sq. miles; has very many bays, coves, islands, channels, and inlets; is very deep even abreast of the shores, and forms of itself a magnificent harbor, though lacking in good anchorages on account of its depth. The tide varies from 9 feet at the N. to 15 in the narrow inlets at the extreme S. It formerly extended much farther S. (to the Willamette valley), and its regression has left a large area of low-lying, fertile land between it and the Columbia river. It has also a large area of tidal lands which can be reclaimed at small expense. Along its shores lie Seattle, Tacoma, and Olympia, with many other rapidly growing places. The shores were originally covered with forests of pines, firs, and cedars—the finest in the U. S. These have since been extensively felled, and lumber has formed the principal interest, but the timber resources are still very large. The neighboring country has fine agricultural resources and large supplies of coal and other minerals exist in the mountains. Settlement and development have proceeded with great rapidity. The entrance to the sound is dominated by the British naval establishment of Esquimault. The Olympic peninsula is but little explored. M. W. Harrington.

Pugin, pü'zhăń', Augustus: architectural draughtsman; b. in Normandy in 1762; is known by works illustrating mediæval architecture—*Architectural Antiquities of Normandy*, *Specimens of Gothic Architecture in England*, *Architectural Illustrations of the Buildings of London*, *Gothic Ornaments from Buildings in England and France*. These appeared during the years 1821–40, and were among the important aids to the new study of mediæval archæology. D. in England, Dec. 19, 1832.

Revised by Russell Sturgis.

Pu'gin, Augustus Northmore Welby: architect and architectural designer and draughtsman; b. in London, England, Mar. 1, 1812; son of Augustus Pugin, whose love for mediæval art he inherited. Having been converted to Roman Catholicism, he devoted himself with zeal to the revival of ecclesiastical architecture in England. His influence was great in fostering a taste for Gothic forms in architecture and ornament. He was a skillful etcher, and produced several works which he illustrated in this way. His principal works are *Contrasts, or a Parallel between the Architecture of the Fifteenth and Nineteenth Centuries*, *Examples of Gothic Architecture*, *Principles of Pointed or Christian Architecture*, *An Apology for the Revival of Gothic Architecture*, and *Glossary of Ecclesiastical Ornament*. D. at Ramsgate, Sept. 14, 1852.

Pugin, Edward Welby: architect; son of Augustus N. W. Pugin; b. in England, Mar. 11, 1834: at the age of seventeen undertook the completion of his father's designs and contracts; a devoted Roman Catholic, designed the cathedral at Queenstown; built more than 100 churches, besides orphanages, colleges, priories, etc.; restored the archiepiscopal palace at Mayfield; finished a superb Gothic structure begun by his father at Scarisbrook Hall. D. June 5, 1875.

Pugwash: a seaport in Cumberland co., Nova Scotia, on Northumberland Strait, 50 miles W. of Pictou (see map of Quebec, ref. 2–B). It has quarries of gypsum, limestone, and sandstone. Deals are largely shipped to Great Britain.

Pujet, Pierre: See Puget.

Pujunan Indians [*Pujunan* is from *Pusuna*, the name of a small band formerly near the mouth of American river, Sacramento co., Cal.]: a linguistic stock of Indians comprising the Maidu and Nishinam divisions, with their numerous sub-tribes, who occupied the eastern bank of the Sacramento in California, beginning some 80 or 100 miles from its mouth and extending northward to within a short distance of Pit river. Upon the E. they reached nearly to the border of the State.

Maidu (signifying man, Indian) is a collective name given to a large number of tribes or villages formerly occupying the territory between Deer creek, Lassen butte, and Honey Lake on the N., Cosumnes river on the S., the Sacramento, and in places points W. of the Sacramento, on the W., and the summit line of the Sierra Nevada on the E. The Maidu correspond to the usual type of the California Indian, being naturally peaceable, inoffensive, and indolent. They are described as extremely nomadic within a very limited area. The Maidu dialect is homogeneous.

The customs of the Nishinam, who live S. of the Maidu, differ considerably from those of the Maidu tribes, as also does their language. The tribal organization of the Maidu appears to be of an extremely loose character even for Indians. The tribal-village organization of the Nishinam answered to the tribal system of more advanced Indians, as is shown by the strictness obtaining with regard to the ownership of land. Their boundaries were defined with great precision by physical features, such as springs, hills, and valleys. They did not ordinarily destroy a member of another tribe for trespassing on their territory, but if he caught fish or game or gathered acorns on it they demanded reparation in kind.

Few representatives of the tribes survive, and these are scattered. See Stephen Powers, *Tribes of California* (*Cont. N. A. Ethnology*, iii., pp. 282–345, Washington, 1877); H. H. Bancroft, *History of California* (vols. i.–vii., San Francisco, 1884–90). See also Indians of North America.

F. W. Hodge.

Pukhtu: See Afghan Language and Literature.

Pulaski: town; capital of Giles co., Tenn.: on the Louisv. and Nashv. Railroad; 33 miles S. of Columbia, 81 miles S. by W. of Nashville (for location, see map of Tennessee, ref. 7–F). It is in an agricultural and stock-raising region, has flour and planing mills, and contains 2 national banks with combined capital of $120,000, a State bank with capital of $38,600, Martin Female College, and 2 weekly newspapers. Pop. (1880) 2,089; (1890) 2,274; (1900) 2,838.

Pulaski, Casimir, Count (called in Polish Kazimierz Pulawski): soldier; b. in Lithuania, Mar. 4, 1748; son of Count Joseph Pulaski, who in 1768 formed the Confederation of Bar for the preservation of the liberties of Poland; was educated for the law; saw some military service under Charles, Duke of Courland, and in 1769 joined his father and two brothers in the national struggle against the despotism of King Stanislaus Augustus. His father and brothers having perished in the war, Casimir was for some time commander of the insurgents, and made a bold attempt to seize the king in Warsaw. Being outlawed on the failure of this attempt, he escaped to Turkey 1772; participated in a war against Russia; proceeded to France in 1775, where he made the acquaintance of Franklin, and offered his services to the cause of American independence. Arriving at Philadelphia in the summer of 1777, he joined

the army as a volunteer; distinguished himself at the battle of Brandywine, and four days later (Sept. 15) was appointed by Congress brigadier-general, and given command of the cavalry. He took part in the battle of Germantown, and in Mar., 1778, having resigned his command, he formed at Valley Forge an independent corps of lighthorse and infantry called Pulaski's Legion, officered chiefly by foreigners. By a surprise at Little Egg Harbor, N. J., a large part of his infantry were bayoneted, but the legion was again recruited to 350 men. In Feb., 1779, he set out for the South; reached Charleston May 8; made a vigorous but unsuccessful attack upon the British advance guard May 11; accompanied Count d'Estaing to the siege of Savannah, where he was given the command of the French and American cavalry; was mortally wounded in the assault of Oct. 9; was carried on board the U. S. brig Wasp in Savannah, where he died Oct. 11, 1779. He was buried at sea. A monument to his memory was erected by the citizens of Savannah, and the corner-stone laid by La Fayette in 1825. See his *Life* in Sparks's *American Biography*, 2d series, vol. iv.

Pulci, pōōl'chĕe, Luigi: poet; b. in Florence, Italy, Aug. 15, 1432; d. Oct., 1484, probably at Padua. His was a poetic family, his two brothers, Luca and Bernardo, and the latter's wife, Antonia, having all made some name in letters. His relations with the Medici family were close, Cosimo and Piero showing him much favor, while his *Lettere a Lorenzo il Magnifico* (edited by S. Bongi, Lucca, 1886) imply considerable intimacy between the two men. His fame rests upon his *Il Morgante* (1st ed., 23 cantos, 1482), or, as it came to be called after the second and larger edition had appeared, *Il Morgante Maggiore* (28 cantos, Florence, 1483. See Italian Literature.) There is a translation of the poem by Byron. Besides this, Pulci left several lesser works, the most important, a so-called *Confessione*, satiric in character. See J. Hübscher, *Orlando, Die Vorlage zu Pulci's Morgante* (Marburg, 1886). Lucy A. Paton.

Pulkowa: village near St. Petersburg, Russia. Ten miles N. is the famous Nicholas Central Observatory (lat. 59° 46′ 18″ N., lon. 30° 19′ 40″ E.), founded by the Czar Nicholas (1838–39). The staff consists of a director and four astronomers besides assistants, etc. The *Pulkowa Observations* are published by the Academy of St. Petersburg. One of the largest telescopes in the world, a 30-inch refractor, was erected here in 1882.

Pullman, James Minton, D. D.: clergyman; b. Aug. 21, 1836, at Portland, Chautauqua co., N. Y.; graduated at St. Lawrence Divinity School in 1860; pastor of First Universalist parish of Troy, N. Y., same year; ordained in 1862; pastor of the Church of Our Saviour, New York city, from 1867 until early in 1885, when he became pastor of First Universalist Society of Lynn, Mass. He organized the Young Men's Universalist Association of the City of New York in 1869; was secretary of the General Convention of Universalists 1868–77; was chairman of the publication board of the New York State convention of Universalists, having in charge *The Christian Leader* 1869–73; received the degree of Doctor of Divinity from the St. Lawrence University in 1878; founded the Children's Country Week charity in 1882.

Pulmonaria: See Lungwort.

Pulmona'ta, or **Pulmonif'era** [*Pulmonifera* is from Lat. *pulmo*, lung + *ferre*, to bear]: an order of Gasteropod Mollusca in which gills are absent, the animal breathing air by means of a "lung" formed by the ramifications of the blood-vessels upon the surface of the mantle-cavity. It embraces the common snails and slugs, and all its members live either on the earth or in fresh water. Two sub-orders are recognized—the *Stylommatophora*, in which the eyes are placed upon the tips of the tentacles, and these last are capable of being retracted by an inversion like the pushing in of the finger of a glove; and the *Basommatophora*, in which the eyes are at the base of the non-retractile tentacles. Most prominent of the first group is the family *Helicidæ*, embracing the common snails, of which about 5,000 species have been described. Recent authors have divided the principal genus *Helix* into a large number of so-called genera, most of them being based upon totally inadequate characters. The snails are largely vegetarians, and where abundant may cause extensive ravages in gardens, vineyards, etc. The family *Limacidæ* embraces the slugs, in which the visceral hump has undergone degeneration, and the shell has been reduced to a small internal plate. Most of the fresh-water snails of the U. S. belong to the *Limnæidæ* of the sub-order *Basommatophora*. The *Onchidiidæ* embraces some amphibious forms living on the shores of tropical seas. In one species Semper has described numerous eyes scattered over the back, these eyes being formed like those of the Vertebrates. J. S. Kingsley.

Pulo-Kalamantin: See Borneo.

Pulque, pool'kā [the Aztec name]: the fermented juice of various species of *Agave*, but principally the maguey (*A. americana*), which grows wild and is also extensively cultivated on the table-lands of Mexico. (See Agave.) Mexicans consume such quantities that special pulque trains are run on the railways to supply the city markets. Some physicians recommend it for chlorosis and other diseases; others condemn it as unwholesome. Pulque was first made and used by the Aztecs. H. H. S.

Pulsatilla: See Anemone.

Pulse [M. Eng. *puls*, from Lat. *puls*, *pul'tis*, pottage of meal pulse, etc.]: a general name for such seeds of leguminous plants as are used for human food. All kinds of pulse abound in vegetable caseine, and all are highly nutritious; but as a rule they are not easy of digestion, and are best suited for hard-working men. Beans, peas, and lentils are the most important kinds of pulse.

Pulse [(with *-l-* restored from Lat.) < M. Eng. *pous*, via O. Fr. from Lat. *pul'sus*, pulse, liter., beating, deriv. of *pel'lere*, *pulsum*, strike, beat]: the result of the blood-wave sent through the arteries of the body by the ventricles of the heart. Each contraction of these ventricles sends into the arteries 2 to 4 oz. of blood, which entering vessels, already full but contracted, expands, elongates, and uplifts them, and produces a sudden lifting and impulse on the finger applied to them. This impulse is equal in all the arteries of equal size throughout the body, but the physician usually examines it on the thumb-side of the wrist (in the radial artery), because there the vessel is near the surface, resting on bone, and its varying movements can be best appreciated. The frequency of the pulse in a healthy adult, at rest, is 72 to 75 beats in a minute—in women a little more frequent than in men; more frequent while standing than while sitting, least frequent in the recumbent position. But a slow pulse is sometimes found in healthy, strong persons; 40 or 45 is not a very uncommon rate; Heberden and Fordyce have found it as low as 30 and 26, the latter in one instance no more than 20. At birth the normal frequency is 140; in youth, 90; and in old age, 70. Muscular exertion increases the number of heart-beats in a given time in proportion to its amount and duration. Certain mental states, as surprise, anger, or a sudden sense of danger, will produce great increase in its frequency. See Sphygmograph.

The pulse in disease sometimes becomes very frequent, and sometimes very slow. In inflammation of the membranes of the brain in children it has been often found, toward the termination, beating at the rate of 180 per minute for a day or more; it has sometimes reached 200. The condition known as tachycardia (see Heart Disease) not rarely occasions pulsations of 250 or 300 per minute. The latter number can not be easily counted at the wrist; 160 is often with difficulty made out; but the heart-beats can be appreciated by the ear at almost any rate of possible frequency, except in the mere flutter of some conditions of heart disease. In some states of disease of the brain, liver, and of the heart the pulsations are no more than 40, or even 30, in the minute. In the most marked cases of slowing the rate may be but 10 per minute.

The pulse may be small or full, rapid or slow, hard or soft, quick or prolonged; or it may be irregular in various ways, giving a varying number of beats in the different fractions of a minute, the beats tumultuous, frequent, and slow alternately, or sometimes double (*dicrotic*). It is often intermittent; that is, a single beat is lost. This occurs both with and without disease of the heart; it is often caused by the use of tobacco. In some states of imperfect innervation of the heart its pulsations cease entirely, to be resumed after the lapse of a considerable fraction of a minute. An instrument has been invented by which many conditions of the pulse can be inscribed on paper attached to a revolving cylinder. It is called a "sphygmograph." The study of the pulse by the finger or by the sphygmograph reveals to the physician, much more than the mere rapidity of the circulation, the existence of fever, and the like. Above all, he appreciates the condition of the arterial wall itself and the general state of the patient, as well as the probable condition of the heart.

Venous Pulse.—The arterial pulsation reaches the very

small arteries, but is lost in the capillaries, so that the blood returns to the heart in a continuous, steady stream; but when the tricuspid valve is insufficient, a wave of venous blood may be sent back into the venous trunks producing a visible pulsation, mostly in the veins of the neck. Such pulsations will correspond, as those in the arteries do, with the contractions of the ventricles (systole). Hypertrophy of the right auricle of the heart may also produce venous pulsations. So may aneurism of the aorta when it obstructs the current of blood descending through the vena cava, the enlarged artery communicating its pulsation to the blood in the vein. In some instances of difficult breathing the veins of the neck are seen to become distended in a sort of wave, apparently from below, but really from above, because the outlet is obstructed at the heart. This filling occurs in expiration, and the veins are emptied in inspiration. Though this action has been called pulse or pulsation, it is very different from the movement to which the term is commonly applied.

The Pulse in Animals.—Nysten (*Dictionnaire*, etc.) states that the arterial pulsations in the horse are from 32 to 38 in the minute; in the ass, from 45 to 48; in oxen and cows, 35 to 42; in sheep, 70 to 77; in the dog, 90 to 100. These countings were made when the animals were at rest.

Revised by W. Pepper.

Pulsometer: See Pump.

Pulteney, pŭlt'ni, William, Earl of Bath: statesman; b. in England in 1682; educated at Westminster School and at Christ Church, Oxford; entered Parliament as a Whig 1705; took part in the prosecution of Dr. Sacheverell; defended Walpole in the prosecution made in 1712; became, on the accession of George I., privy councilor and secretary of war 1714–17; refused a peerage but accepted an unimportant post under Walpole in 1723; went over to the opposition 1725, becoming the bitterest political enemy of his former friend, against whom he wrote several pamphlets; fought a duel with Lord Hervey, in which both combatants were wounded, 1731; became extremely popular as the leader of the general crusade against Walpole; associated with Pope and the wits of the day, who paid him extravagant compliments for his literary ability; was the real framer of the cabinet of 1742 on the downfall of Walpole, though the Earl of Wilmington was the ostensible head; was created at this time Earl of Bath; lost much political influence by his transference to the Upper House of Parliament, and was premier for two days in Feb., 1746, on the resignation of the Pelham ministry, but was unable to form a cabinet. D. in London, July 8, 1764. He was the author of many political pamphlets, and chief assistant of Bolingbroke in writing the journal *The Craftsman*.

Pu'lu, or **Vegetable Silk**: a richly beautiful fiber produced by tree-ferns of the genus *Cibotium*, growing in the Malay and other Pacific islands. The attempt to manufacture it has not proved successful. It is a very useful styptic, and is considerably used as such by Dutch surgeons.

Puma [= Peruv.]: the common name for *Felis concolor*, a large member of the cat family (*Felidæ*) inhabiting America; also known as panther, mountain lion, lion, tiger, and—in books at least—as cougar and catamount. It is of a general reddish gray, or tawny, above, whitish beneath, end of tail dusky, outside of ears and a spot on either side of the muzzle black. The young, two to five in number, are spotted. Next to the jaguar the puma is the largest cat of the New World, attaining a length of 8 feet and a weight of 200 lb., although individuals of this size are very rare. Few terrestrial mammals have a more extended north and south range. It is found from Patagonia to 60° N. lat., from Maine to California and throughout South America up to a height of 9,000 feet on the Andes. Naturally with such a range there are great variations in size, color, coat, and ferocity. The puma is ordinarily a cowardly animal, but when wounded or brought to bay it is dangerous. It is usually silent and the tales of its "blood-curdling scream" are mostly apocryphal. The creature feeds largely on deer, but smaller animals are eaten, even the Canada porcupine. In South America the aguti, capybara, and rhea are extensively preyed upon, and, when accessible, calves, sheep, and pigs. For a full account of the puma, with numerous references to literature on the subject, see *The Puma, or American Lion*, by F. W. True, Report U. S. Nat. Museum (1889), pp. 591.

F. A. Lucas.

Pumacag'ua, or **Pumacahua**, Mateo Garcia: Indian general; b. near Cuzco, Peru, 1758. He was the chief of a powerful mountain tribe under the Spanish viceroys, and received the military rank of brigadier for taking part in the suppression of the revolt of Tupac Amaru, 1781. In 1814 he headed at Cuzco the first serious rebellion against Spanish rule in Peru. For a time he was very successful; nearly all the southern districts supported him; he occupied Arequipa and had an army of 40,000, but his men were poorly disciplined and badly armed. He was eventually defeated by the Spanish general Ramirez at Umachiri, Mar. 10, 1815; Pumacagua escaped, but was captured soon after and hanged at Sicuani.

Herbert H. Smith.

Pumelo, or **Pomelo**: See Shaddock.

Pumice [Lat. *pumex*]: See Obsidian.

Pumice Foot: See Farriery.

Pump [a word appearing in various Europ. languages: Fr. *pompe*, Dutch, *pomp*, Germ. *pumpe*, but of uncertain source and history]: an hydraulic or pneumatic machine for elevating water or other liquids, or for forcing fluids through a pipe or passage. The height to which water is raised by a pump is called the "lift." Pumps sometimes act not by raising water, but by forcing it into a vessel against a pressure, as in the case of the feed-pumps of steam-boilers. Such pressure may, however, be always represented by a head of water. Pumps for operating on air (see Pneumatics) are known as air-pumps, air-compressors, blowers, etc. Pumps for raising viscous matters, as tar, paper-stock, the slip of potteries, etc., are very strongly built, have large valves and valve-chambers, and move slowly. The necessities of industry and science and the rivalry of inventors and manufacturers have given rise to innumerable varieties of this machine. The accompanying figures are examples of the types in most common use.

Fig. 1 shows the simplest form of pump. It is used for lifts of but a few feet, for draining shallow pits and bailing flat-bottomed boats. As it can be made by a carpenter in a few hours, it is frequently applied where there is but temporary need of a pump. It consists of a square wooden barrel, a foot-valve, *a*, and a piston, *b*. The foot-valve is a leather flap on a wooden seat; the flap has a leaden back to give it due stiffness and weight. The piston *b* is a leather cup attached to a wooden rod. On its downward stroke the water folds it together, and allows it to pass freely. In its upward movement the water distends or bags it out, causing it to press against the interior of the barrel, and making it tight. The water above the piston is simply lifted, while the water follows the piston and flows through the valve *a* in virtue of the atmospheric pressure.

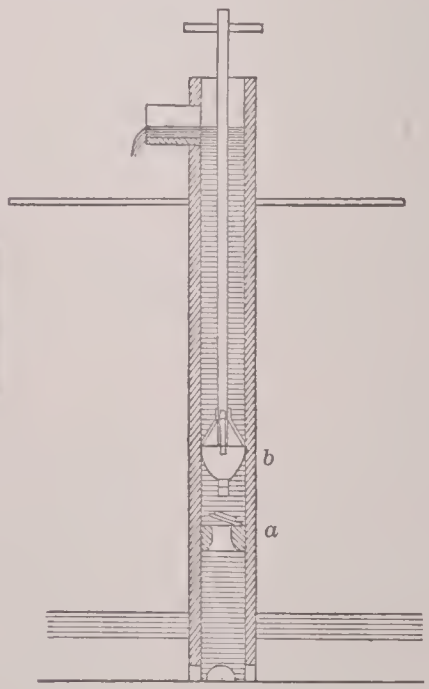

Fig. 1.

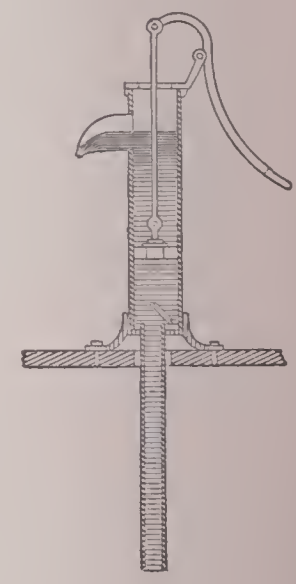

Fig. 2.

Fig. 2 shows an ordinary well or cistern pump. It is not different in principle from Fig. 1, but is arranged for more convenient working and adapted to a higher lift.

Fig. 3 represents a section of a force-pump much used for domestic purposes—as for filling a tank in the upper part of the house. Fig. 6 represents a general view of the same. The valves, the most important organs of the pump, are fully shown here and in Figs. 4 and 5. Fig. 4

represents the valve *m* or *k*, the outer ring of which serves as the joint-packing. The inner circle is the valve or flap. The neck between the two is the hinge. A backing of lead gives weight and stiffness to the flap. The piston-rod passes through a stuffing-box P in the cover *q*, and is moved by a handle, as shown in Fig. 6. The action of

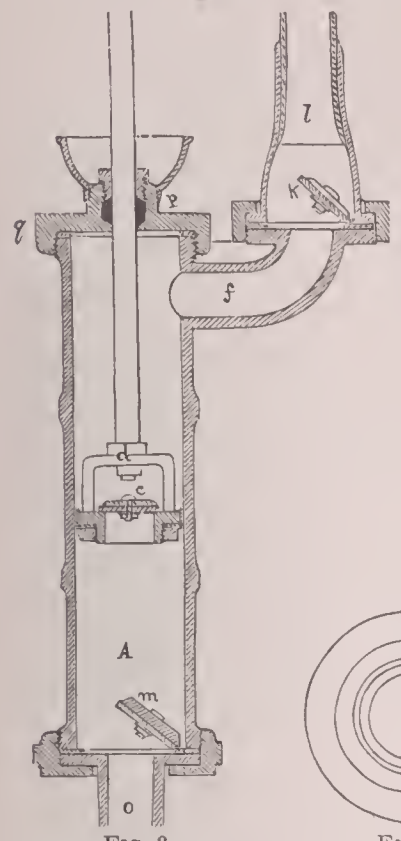

Fig. 3.

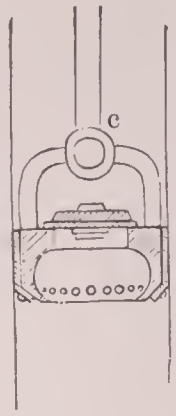

Fig. 5.

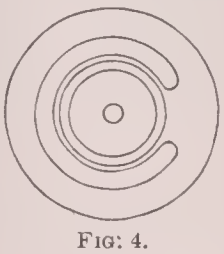

Fig. 4.

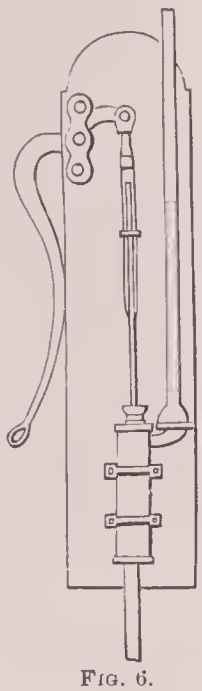

Fig. 6.

the pump is readily understood. During the downward movement of the piston the valves *m* and *k* close, preventing the backward movement of the water. The pressure of the water raises the valve *c* in the piston, and allows the water to pass through the piston as it descends. During the upward movement of the piston the valve *c* is closed. The water above the piston is forced through the branch *f*, raising the valve *k* and passing into the ascending pipe *l*. The atmospheric pressure forces the water through the supply-pipe *o* into the pump-barrel A, raising the valve *m*. This pump differs from the ordinary domestic pump only in delivering the water above the pump. If the cover *q* and the branch *f* were removed, it would be the ordinary suction-pump discharging at *f*. The valve *k* is inserted to relieve the stuffing-box and prevent leakage. It is manifest that the pump would work perfectly well if this valve were removed. The piston of the ordinary suction-pump is more commonly made as shown in Fig. 5. It has a joint at *c*, as the piston-rod does not move in a straight line. The leather packing is also differently applied from that shown at *d*, Fig. 3.

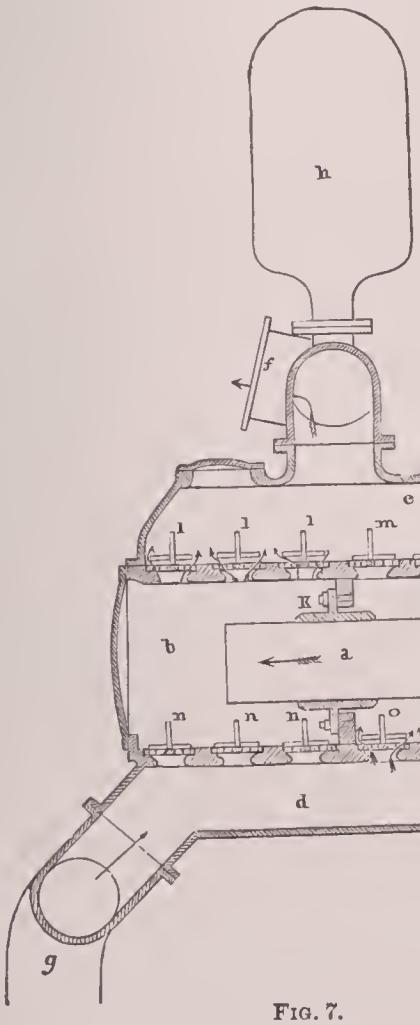

Fig. 7.

It will be noticed that the pumps shown in Figs. 1 and 3 are *single-acting*. They furnish a stream only during the ascent of the piston. Fig. 7 represents a double-acting pump driven by a powerful steam-engine. The plunger *a* moves horizontally through water-tight packing. It is supposed, in the drawing, to be moving as indicated by the arrow. In so doing it diminishes the water-space in the chamber *b*, forcing the water through the valves *l l l* into the chamber *e* communicating with the force-main *f*. At the same time it tends to create a vacuum in the chamber *c*, which tendency causes the water to rise from the pump-well through the pipe *g* and chamber *d*, lifting the valves *o o o* and entering the chamber *c*. During the return stroke the water enters the chamber *b* through the valves *n n n*, and passes from *c* to *e* through the valves *m m m*, the valves *l l l*, *o o o* remaining closed. This is called a *double-acting* pump, because it discharges an unintermittent stream. *h* is an air-chamber communicating with the force-main. This is an appendage usually applied to powerful pumps, especially those which force the water through a considerable length of pipe. Its object is to diminish the shocks due to the sudden starting of a long column of water. Figs. 8 and 9 show the valves of this pump:

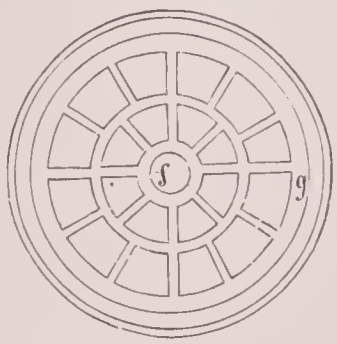

Fig. 8.

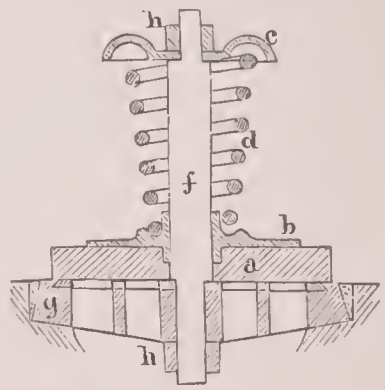

Fig. 9.

g is the valve-seat, of iron with a brass face. It is leaded into a recess in the plate; *a* is the valve, of rubber; *f*, a spindle on which the valve slides in rising and falling; *b*, a plate forming a socket for the valve and a bearing for the spring; *d*, a spiral spring of brass wire; *c*, cap; *h h*, nuts. Each pump has twenty-four valves, there being two rows, only one of which appears in the drawing. This pump is designed to be operated by a "direct-acting" steam-engine, the piston of the engine and plunger of the pump being attached to opposite ends of the same rod. This arrangement of valves is used in the Worthington steam-pump.

Atmospheric pressure plays an important part in the action of pumps. The normal pressure of the atmosphere is 14·7 lb. per square inch, which is equivalent to that of a column of water 34 feet high. The pipe *o*, Fig. 2, being supposed to descend into the water of a well, if the fixed valve is 34 feet or more above the surface of the water, the water can not be raised. Practically the limit of suction is materially less than this. Thirty-four feet implies a perfect vacuum over the column of water, which can not be secured with ordinary pump-valves. Moreover, when the air is entirely removed from the suction-pipe the latter is filled with vapor of water which can not be exhausted, being produced as fast as the pump can withdraw it. The pressure of this vapor is very slight in cold water and increases with the temperature.

The limit of suction at		32°	F. is	33·80	feet.
"	"	60°	"	33·42	"
"	"	90°	"	32·39	"
"	"	120°	"	30·10	"
"	"	150°	"	25·41	"
"	"	180°	"	16·58	"
"	"	212°	"	0·	"

That is to say, water at 212° can not be raised at all by suction, the suction-pipe being constantly filled with vapor of the same tension as the atmosphere.

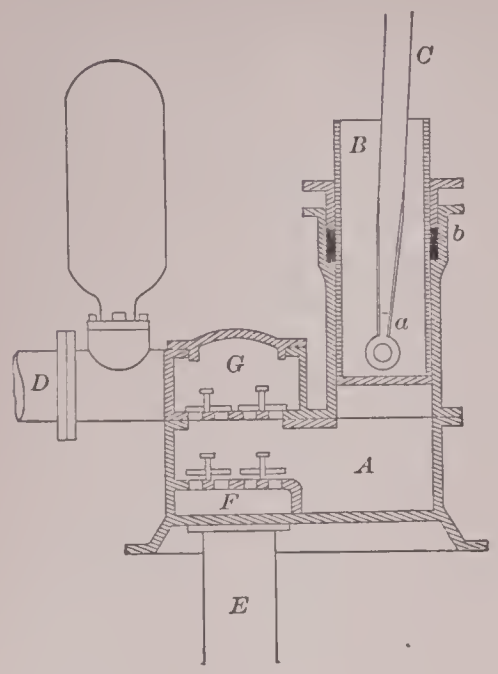

Fig. 10.

Fig. 10 shows a form of pump much used in mills. It is driven by a crank movement. The plunger B is a hollow barrel or bucket open at the top. The connecting-rod or pitman C is jointed near the bottom of the barrel. This barrel moves in an exterior cylinder with a stuffing-box *b*, and requires no other guide in its motion. The opening of the cylinder admits the necessary lateral movement or "play" in the pitman consequent upon the rotation of the crank.

This pump, it will be perceived, is single-acting. The raising of the barrel B causes the lower valves to open, and draws water through the supply-pipe E. The down stroke raises the upper valves, and forces water through the discharge-pipe D. Such pumps are more commonly arranged in groups of three, all driven from the same shaft, the cranks making an angle of 120° with each other. In this case the chambers F and G are common to all the barrels, but each barrel must have a separate chamber A with its set of valves. Arranged in this manner it is a continuous-acting pump, giving a constant stream through the pipes E and D.

This pump, with a single barrel, is well suited to be worked by a windmill, especially when it can be so placed that the suction is one-half the lift, so that the crank exerts the same pressure on the up stroke as on the down stroke. Where the suction is but a small part of the lift the inequality is too great, causing shocks which are injurious. In that case it is better to use two barrels, uniting them by a beam so that one rises as the other falls.

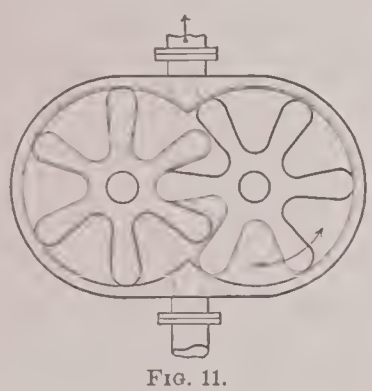

Fig. 11.

Fig. 11 is the typical form of the modern rotary pump. It consists of two gear-wheels with very large and long teeth, very closely fitting each other and the case in which they revolve. They revolve as indicated by the arrow. The water is carried around in the spaces between the teeth. The close meshing of the teeth prevents its return between the gears, and it is forced through the discharge-pipe, entering the case through the supply-pipe under the action of atmospheric pressure. No valves are necessary with this pump, though a valve in the suction-pipe is convenient to prevent the pump from running down.

An engine specially designed for driving a pump, the engine and pump being inseparable, is called a pumping-engine or steam-pump. In the simplest form of pumping-engine the piston or plunger of the pump and the piston of the engine are on opposite ends of the same rod. This is the form contemplated in Fig. 7, in which the rod of the plunger *a* passes through a stuffing-box in the water-cylinder and enters the steam-cylinder through another stuffing-box. This is a cheap and serviceable form of pumping-engine, but it does not use steam in the most economical manner, being ill adapted for expansive working. With two cylinders, one drawing direct from the boiler and exhausting into the other at a lower pressure, it can make some use of the expansive action of the steam. An engine driving a pump through the intervention of a heavy fly-wheel can make full use of the expansive power of steam, and works most economically. Fly-wheel engines are used for pumping where economy of working is more important than economy of first cost. The Cornish pumping-engine, used mainly for draining deep mines, differs from both the above types. The steam acts only to raise the piston with its attachment of heavy rods reaching down into the mine. These descend by their own weight.

Besides the Archimedes's Screw and the Hydraulic Ram (*qq. v.*) there are many devices in use for raising water which can not be classed as pumps, or are more properly described under other headings, as:

The *Noria.*—A water-wheel carrying a series of vessels at its periphery, which fill at its lowest position and discharge at its highest.

The *Chain Pump.*—A series of disks linked together, which being drawn rapidly through a close-fitting pipe draw the water with them.

The *pulsometer*, in which the pressure of steam acts directly on the surface of water in a closed chamber, forcing the water through a pipe to a higher level; then the steam condenses and refills the chamber by suction.

The *jet pump and injector*, in which a jet of water or steam discharged through the center of a pipe draws the surrounding water with it. If an open vertical pipe be two-thirds or three-fourths immersed in water, and air be injected at its lower end, the water will rise and flow from the top in a continuous stream, as long as the supply of air is kept up.

The *centrifugal pump*, in which the centrifugal force developed in a revolving mass of water raises it to a higher level.

This machine is much used in hydraulic constructions requiring the temporary removal of large volumes of water. The water is caused to revolve with great velocity in a circular chamber. The tendency which water, in common with all heavy bodies, has to move in a straight line causes a pressure upon the circumference of the chamber sufficient to make the water rise to a greater or less height, depending on the velocity. The simplest, most efficient, and most reliable form of the centrifugal pump is the one indicated by Fig. 15. It is placed at the lowest point of the pit to be drained, and being once put in position, can not be readily changed. The water receives a rotary movement from arms attached to a vertical shaft within the case. It enters the pump at the center and rises through a pipe at the circumference. The shaft is driven by a steam-engine by means of a belt and pulley at the top. This form of pump requires no valves and is not readily deranged. The height to which the water will rise is theoretically the height from which a body must fall in a vacuum to attain the same velocity as that with which the periphery revolves.

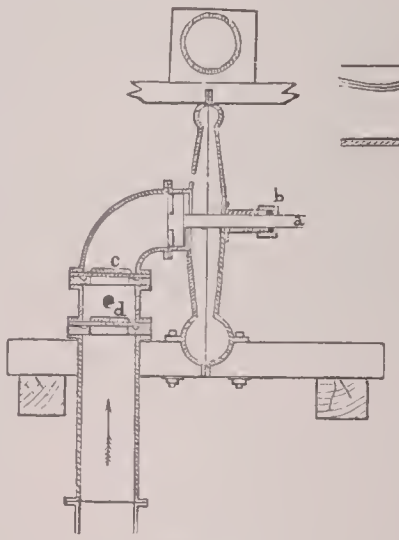

Fig. 12.

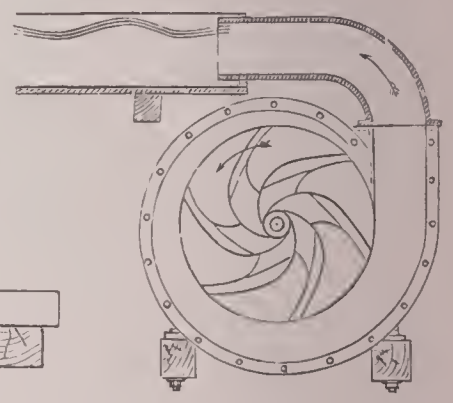

Fig. 13.

It is not always convenient, however, to place the pump at the lowest point of the pit. Some excavations require pumping before reaching the lowest point. Some also require frequent changes of the position of the pump. For such cases a pump has been devised which can be placed at the top of the lift, raising the water by suction. Figs. 12, 13, and 14 show such a pump in detail. The cylindrical shell is made in two halves. Fig. 13 shows one half with the arms. Fig. 12 is a vertical section showing the valves. *a* is the driving-shaft passing through a stuffing-box, *b*, and carrying the arms, which are not shown in the section. The shaft carries a pulley through which it receives motion from a portable steam-engine; *c d* are the valves. They are made

of thick rubber, cut out as shown at Fig. 4, serving as joint packing as well as valves. Fig. 14 is an auxiliary hand-pump attached outside the suction-pipe between the valves, for the purpose of filling the latter and the pump before

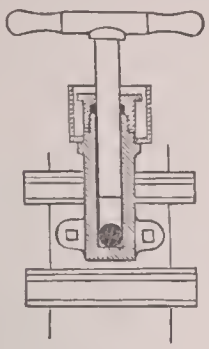

Fig. 14.

starting. It is a single-acting plunger-pump. When the plunger rises, the valve *d* (Fig. 12) is lifted, admitting air or water into the space between the valves. When the plunger falls, *c* rises, etc. This small pump is called the primer. While the pump is in operation the water flows continuously through the valves. These are not essential to the action of the pump while running, but only necessary in filling it and preventing it from emptying when it stops. The length of the suction-pipe is increased as the excavation progresses. This pump is of course subject to the same restriction as all suction-pumps. Its lift can not exceed the height due to the pressure of the atmosphere. In fact it can not work efficiently with more than three-fourths of that lift. The most powerful existing pumping plant is the system of centrifugal pumps built by J. & H. Gwynne, of Hammersmith, England, for draining the Ferrara marshes in Italy. It is said to be capable of raising to a height of 12 feet 2,000 tons of water per minute, being equivalent to a river 100 feet wide and 4 feet deep flowing with a velocity of about 13 miles per hour. The Appold centrifugal pumps have found many applications of this kind, and are much used for emptying dry-docks and for raising the level of water in the great commercial docks of European harbors. For air-pumps, see Pneumatics.

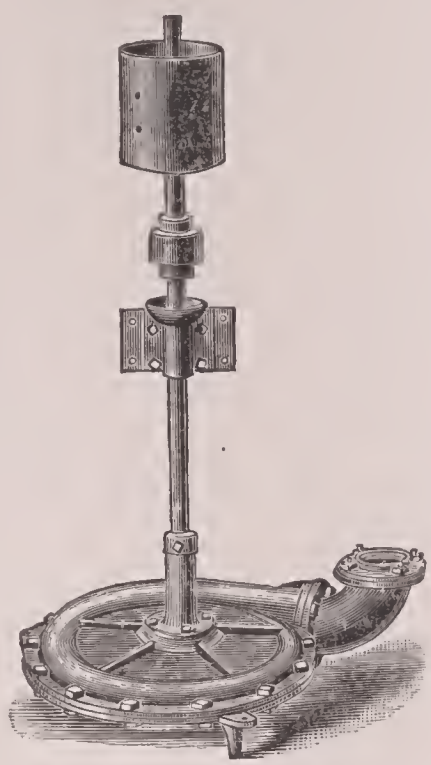

Fig. 15.—Centrifugal pump.

J. P. Frizell.

Pumpel'ly, Raphael, M. N. A. S.: geologist; b. at Owego, Tioga co., N. Y., Sept. 8, 1837; educated at Paris, Hanover, and Freiberg, Saxony, 1854–60; was engaged in mining operations in Arizona 1860–61; was employed by the Government of Japan to explore the island of Yezo 1861–63; by the Government of China to report upon the coal-supply of that empire 1863–64; returned to the U. S. overland through Mongolia, Siberia, and Russia; became Professor of Mining Engineering at Harvard 1866; made a survey of the copper region of the upper peninsula of Michigan 1870–71; was State geologist of Missouri 1871–73; geologist in charge of the Archæan division of the U. S. Geological Survey 1879–92; and vice-president of the international congress of geologists, Washington, 1891. He is the author of numerous articles in scientific journals; of *Geological Researches in China, Mongolia, and Japan* (Washington, 1867); *Across America and Asia* (New York, 1870); of volumes of the *Geological Survey* of Michigan (1873) and of Missouri (1873), each accompanied by an atlas; and vol. xv. of the census reports on *The Mining Industries of the United States* (Washington, 1886).

Pumpkin [dimin. of earlier *pompion*, pumpkin, from O. Fr. *pompon*, for earlier *pepon* < Lat. *pe'po* = Gr. *πέπων*, a kind of melon]: any plant of the genus *Cucurbita*, of the family *Cucurbitaceæ*. There are three species of this genus in common cultivation: *Cucurbita pepo*, with lobed leaves and rough, almost prickly stems and leaf-stalks, a strongly angled fruit-stem, and widely flaring flower with erect and pointed lobes; *C. moschata*, with leaves usually less lobed, grayish pubescent stems and leaf-stalks, fruit-stalks ridged, enlarged next the fruit, and flower much like that of the last, but the lobes broader and the calyx often leafy; *C. maxima*, with rounded large leaves, stems and leaf-stalks not rough and only minutely, if at all, pubescent, the fruit-stalk cylindrical and spongy, and the flower-tubes nearly cylindrical or gibbous, the lobes obtuse and drooping. These species are probably native to the New World. The first one (*C. pepo*) is the pumpkin of North America—the one which is grown in corn-fields and which produces the great reddish fruits commonly used for making pies and also as food for stock. This species is immensely variable. In some forms it is scarcely running. The summer or warty crookneck squashes and the bush scallop and patty-pan squashes are of this species, and here belong, also, the common inedible, ornamental gourds, as this term is understood in the U. S. The second species (*C. moschata*) is the parent of the large, striped winter or Canada crookneck squashes, and the Cushaw pumpkins or squashes. To the third species (*C. maxima*) belong the turban and the true winter squashes, like the Hubbard, Marblehead, Essex, Boston Marrow, etc. The larger type of fruits of this species are known as pumpkins in Europe, while they are called squashes in the U. S. In Great Britain the word gourd is used generically for all three species. It is a common notion that the different species will cross-fertilize when planted near together in the field; but it is now known that the varieties belonging to different species do not cross, with very rare exceptions. There are no crosses or hybrids of *C. pepo* and *C. maxima*, nor of *C. maxima* and *C. moschata*, but *C. pepo* and *C. moschata* can probably be induced to cross, although it is doubtful if spontaneous mixing often occurs.

L. H. Bailey.

Pun [perhaps from the local English *pun*, pound, and the Anglo-Saxon *punian*, bruise]: a kind of play upon words, in which a word is capable of being understood in two or more quite different senses, the combination of which, or the mental change from one to the other, presents an odd idea, generally a ludicrous one. Punning is usually considered the lowest species of wit, being in general purely mechanical in character, and not, like the higher forms of wit, justifying itself by presenting an idea in some new and unexpected form. Not unfrequently the point of a pun lies in the juxtaposition of two or more words similar or identical in sound, but different in spelling and signification, like the Latin *amantes sunt amentes*. The wit in a pun is not unfrequently polyglot—that is, a phrase of one language is used which in sound or spelling closely resembles a phrase in another language, but which has a wholly different meaning. The figure of speech called *paronomasia* by writers on rhetoric, and defined by them as "the use of words in the same connection which are similar in sound, but dissimilar in sense," is simply punning. This was a favorite form of expression among the Hebrews, and the books of the Old Testament, in the original, abound in examples of it, although it is of course usually lost in translating, and thus the precise point of many passages is necessarily missed in our version, unless the paronomasia is pointed out in a note.

Revised by A. R. Marsh.

Pu'na or **Despobla'do**: in Peru and Bolivia any very high, arid, and uninhabitable table-land; synonymous with *páramo*, used in Colombia. In a special sense, a high plain between two subchains of the Cordillera, extending from about lat. 13° S. southward into Bolivia. It consists of flat or rolling, generally stony or sandy lands, from 14,000 to 16,000 feet above sea-level, narrow northward but widening southward to 150 miles or more.

H. H. S.

Puna: a city of India; same as Poona (*q. v.*).

Punch, Punch and Judy, or **Punchinello** [Ital. *pulcinella* or *policinella*; Fr. *polichinelle*]: a kind of puppet-show frequently exhibited in the streets of European cities, especially of Italy. Its origin has been obscurely traced to the Atellan farces of ancient Rome, but in its present popular form the drama is ascribed to Silvio Fiorillo, an Italian playwright who flourished about 1600. The actors in the performance are wooden puppets, of whom the principal are Punchinello (in English Mr. Punch), his wife (called in English Mrs. Judy), and their dog Toby. The puppets are moved by the exhibitor, who puts his hands under the dress, making the second finger and thumb serve for the arms, while the forefinger works the head; he also supplies a comic dialogue, varying his voice to suit the different characters. As usually represented, Mr. Punch is a stout personage with protruding paunch, thin legs, hooked nose, and a chin which turns up so as almost to meet the point of the nose; Mrs. Judy is a thin, shrewish dame, grotesquely attired; and

the dog Toby, who is the embodiment of cunning, and usually wears a hat, plays an important part in the action. The play is a domestic tragi-comedy, in which Mr. Punch is greatly berated by his wife, and finally comes to grief. The French sometimes employ a cat instead of the dog Toby. Various explanations have been given of the origin of the name. The most probable supposition is that it is a diminutive of the Italian *pulcino*, a chicken, applied to a little child, and hence a puppet; but some suppose that it comes from the Latin *pollex*, *pollicis*, the thumb, a common appellation of dwarfs, as in "Tom Thumb"; while others conjecture that the name comes from Puccio d'Aniello, a famous buffoon of Acerra, near Naples, whose humorous eccentricities were in the seventeenth century transferred to the Neapolitan stage. In some of its aspects the show of Punchinello reminds one of the so-called "moralities" of the Middle Ages and of the clown of the later comic drama; and the grotesque faces of the performers have their prototypes in the masks worn by the actors in the ancient Greek and Latin comedies. Puppet-shows of an essentially similar character, but often much more elaborate, are common in China and Japan. A typical version of the modern play by Payne Collier, with colored illustrations by George Cruikshank, was published in 1828. Revised by R. A. Roberts.

Punctuation [from Mediæv. Lat. *punctua're*, punctuate, deriv. of Lat. *punc'tum*, something pricked, point, punctuation mark, deriv. of *pun'gere*, *punc'tum*, prick]: the act or art of dividing literary composition into sentences and parts of sentences to show grammatical or sometimes rhetorical relations, and thus assist the reader in apprehending the writer's meaning. It is also frequently asserted that punctuation is intended to assist the reader by indicating the pauses and inflections required by the sense. This is incorrect, however, although it is evident that punctuation marks, while indicating syntactical relations, may also guide the reader to some extent as to pauses and inflections.

Our present system of punctuation is of modern invention. Ancient manuscripts were not punctuated until after 364 B. C., when it became customary to place a mark of separation after each word. The beginnings of our present system are said to date from the time of Manutius (Manuzio), the first of a famous family of Italian printers, who died in 1515. In English writings a period was first used, though without great regularity, to indicate a break of any sort in the composition. In addition to this, a period on the line or above it, sometimes an inverted semicolon, was used in poetry to mark a metrical rather than a syntactical division. Caxton, the father of English printing, used only an oblique line to indicate the divisions of discourse.

The principal marks of punctuation in modern English are the comma, semicolon, colon, period, interrogation, and exclamation points, of which the last two are mainly rhetorical. Of these the *comma* is most frequently and most variously used. Its offices may be summed up in two general heads: First, the comma marks a syntactical division of the sentence having a certain completeness of its own; next, it may indicate an ellipsis. Under the first head come parenthetical and intermediate expressions, dependent and conditional clauses, relative clauses not restrictive, words or expressions forming a series, nouns in apposition or in the vocative case. Under the second head are included ellipses of verbs, nouns, and conjunctions. The principal uses of the *semicolon* are to mark the divisions of a compound sentence, to separate clauses and expressions with a common dependence, sentences connected in idea but without syntactical dependence, and final clauses of explanation or inference. The *colon* is used to mark the larger divisions in complex sentences, the beginning of long quotations, and a series of particulars introduced by *thus*, *as follows*, *namely*, and similar expressions. The *period* marks the end of a sentence, while it is also used after titles and abbreviations. The marks of interrogation and exclamation indicate respectively a direct question and an exclamation.

Among the more important minor marks of punctuation are the dash, parenthesis, bracket, apostrophe, and quotation marks. The dash is used for a sudden break in the sentence and for parenthetical expressions. For the latter the parenthesis is also used, and for explanatory words not syntactically a part of the sentence the brackets are employed. The apostrophe marks the possessive case and the omission of a letter or letters in words. Quotation marks inclose direct quotations. The apostrophe, as not denoting a syntactical division, is not strictly a mark of punctuation, and there are numerous others of like use sometimes considered under this head, as the hyphen, section and paragraph marks, and marks of reference.

Punctuation is to some extent a matter of taste and judgment, rather than of rigid rule. Certain writers seem to aim at using the largest possible number of points; others try to use the fewest points possible. As might be expected, the best punctuation lies between these two extremes. There is also some room for individual preference in pointing. Whether a parenthetical expression should be set off by commas, by the dash, or by marks of parenthesis, is often to be decided by individual taste. The same may be said of the use of the semicolon, some writers using the comma or the period, according as the separation requires the more or less distinctive mark. In any case punctuation is more largely a grammatical, rather than a rhetorical device. It should aid the reader in gaining the sense, but it should never be depended upon for clearness or precision.

Oliver Farrar Emerson.

Pu'nic Wars: the three great wars between the Carthaginians (*Punici*) and the Romans. The First Punic war lasted twenty-three years (264–241 B. C.). It was a contest for the possession of Sicily, which was finally won by the Romans. The Second war lasted sixteen years (218–202 B. C.). It was initiated by the capture of Saguntum by Hannibal (*q. v.*), who thereupon made his great invasion of Italy. The war was closed by the Roman victory at Zama. The Third war was undertaken by the Romans with the express intention of finally destroying Carthage, her long humiliated and now scarcely dangerous rival. The war lasted three years (149–146 B. C.). Carthage made a most heroic and persistent defense, but was at last utterly destroyed. Polybius, wherever his account is preserved, is our most trustworthy ancient source. The variations from his narrative presented by Livy and Appian are regarded with suspicion. See the histories of Rome by Arnold and Mommsen; C. Neumann, *Geschichte Roms im Zeitalter der punischen Kriege* (Breslau, 1883); T. A. Dodge, *Hannibal* (Boston, 1890).

Revised by G. L. Hendrickson.

Punishment: in criminal law, the suffering or deprivation of the enjoyment of rights which is visited by law upon those who violate the penal law.

The object and the methods of administering punishment for crime among the early or more crudely civilized peoples are based chiefly upon the idea of retribution, or the vindication of the law upon the offender, and the expiation of his crime by reparation to the injured person. Crimes among such peoples are looked upon more as offenses against the individual than against the state, the idea of which is not strongly developed; and the infliction of punishment for crime is frequently or usually intrusted to the person wronged, or to his kin, clan, or tribe. Hence under such a system the distinction between crimes and torts is not well defined; the punishments inflicted are usually characterized by cruelty; the severity of punishment is frequently graded according to the nearness of the time of the infliction of the punishment to that of the commission of the crime; indignities are frequently inflicted upon the body after death; and for the expiation of many or all crimes a pecuniary value is set, by the payment of which to the injured person, or to his family, the offender is made free from liability to further punishment. In many cases a way of escaping punishment is provided by the establishment of cities of refuge, sanctuaries, etc.

With the development of the idea of the state and of the duties of the citizen to the state, crime comes to be looked upon more as a wrong against the community, and the right to inflict punishment is taken from the individual and vested in the state alone; the injured party is left to obtain reparation for the wrong by resorting to his civil remedy; and the primary idea of punishment becomes the protection of society from criminal acts, coupled with the design of reforming the criminal, not merely as a means of preventing crimes, but as an end in itself. Traces of the early theory of punishment, however, survive in the modern code. Thus the husband, among Christian nations, is still permitted to kill an adulterer caught by him *flagrante delicto*, and vindictive features are seen in some of the severities which are still imposed in some modern methods of punishing.

Punishments inflicted for the protection of society may be divided into those which disable or remove wholly or partially the ability of the criminal; those which are intended

to deter him from committing it again; and those which are intended to act as a deterrent to others.

The punishments of the first class include such forms as capital punishment, deportation, mutilation, branding, perpetual imprisonment, etc.

Punishments of the second class include those which may deter the criminal from the repetition of his crime, either by the reformation of the criminal or by inflicting suffering or some other form of punishment dreaded by the criminal, such as public indignity or great cruelty.

Punishments of the third class consist almost wholly in the infliction of cruelty or public disgrace.

It is now generally believed that the deterrent effect of all cruel punishments and of those likely to bring the criminal into public disgrace are more than counterbalanced by the brutalizing and hardening effect upon the criminal and upon the public itself; and consequently public executions, public whipping-posts, branding, mutilation, etc., have either been entirely abolished or are rapidly disappearing from the different codes of criminal law.

The principal forms of criminal punishment now in use among civilized nations are as follows: Death, perpetual imprisonment with or without hard labor, imprisonment for determinate periods, enforced labor in mines, galleys, etc., banishment to penal settlements, pecuniary fines, and in certain cases the infliction of the lash.

The criminal is also often deprived of political or civil rights belonging to citizenship, such as the electoral franchise, capacity to testify in courts of justice, or to hold office, etc.

For various forms of punishment now discarded among civilized nations or used only among semi-civilized peoples, see PILLORY, TORTURE, etc.

The whole history of criminal punishment is a history of cruelties and horrors, but inflicted for the ends of justice. The reformation of the criminal law in England is due chiefly to John Howard and Sir Samuel Romilly. Howard introduced the changes which made capital punishment less frequent, and Romilly, seconded by Sir James MacIntosh, introduced laws which gradually did away with the barbarous character of the criminal laws and the use of the penalties.

The law of England, however, is still more severe than that of the U. S., but it is on the whole just and tolerant. The existing criminal law of both countries now consists principally of a great number of statutes meant to provide for the punishment of acts which formerly for some reason or other were not provided for by the law or are now supposed not to have been punished with sufficient severity by the former laws, such as stealing wills, malicious mischief, statutory burglary, etc. Of the different forms of punishments above mentioned, capital punishment is gradually being abolished among Christian nations. For a fuller treatment of the specific forms of punishment, see CAPITAL PUNISHMENT, IMPRISONMENT, PRISON, GALLEY, TRANSPORTATION, WHIPPING-POST, etc.

F. STURGES ALLEN.

Punjaub' [from Hind. *Panjāb*; *pānch*, five (< Sanskr. *pañca*) + *āb*, water (< Sanskr. *āpas*). So called from its five rivers]: a territory of Northwestern Hindustan, bounded N. and N. E. by Cashmere, S. E. and S. by the Sutlej, and W. by the Suliman Mountains, and since 1849 belonging to British India. Area, 110,667 sq. miles. The northern part of the country is mountainous, covered with spurs of the Himalayas, from 17,000 to 20,000 feet high, and inclosing deep valleys. The southern and western part is a great plain around the Indus and its five powerful affluents, hot, dry, and treeless, consisting of a hard clay or loam which in many places becomes sandy and arid. The heat of summer rises to 112°; the winter is cool, with frequent frosts. Rain is rare, but the large and numerous streams can easily be used for irrigation, and there is a large network of canals for this purpose. Wherever the soil is well cultivated its productiveness is very great. Sugar, rice, cotton, wheat, and indigo are raised in large crops and of superior quality. The manufacturing industry of the country is highly developed in the large cities of Amritsar, Lahore, Multan, etc. In 1845 occurred the first Sikh war, which ended with Great Britain appropriating the territory on the left bank of the Sutlej; in 1848 followed the second Sikh war, which ended with the conquest by the British of the whole country. Pop. (1901) 22,449,484, consisting of Afghans, Tibetans, and different Hindu races, such as Jats, Sikhs, etc.; about one-half are Mohammedans. Revised by C. C. ADAMS.

Pu'no: the southeasternmost department of Peru; between Bolivia on the E. and Moquegua, Arequipa, and Cuzco on the W.; area vaguely estimated at 20,000 sq. miles. It embraces the Peruvian portion of the Collado or high basin of Lake Titicaca, part of the lake, the Andes to the E. of the basin, and their eastern forest-covered slopes (Montaña), where the river Madre de Dios takes its rise. Nearly all the inhabitants are gathered in the Collado, and most of them are Aymara Indians. The Montaña is rich in cinchona, etc., and its gold washings were formerly very productive; but the region is nearly abandoned, owing to the difficulty of communication; the department is now one of the poorest in Peru and has hardly any exports. Pop. about 275,000.—PUNO, the capital and largest town, is in a valley near the western extremity of Lake Titicaca, 12,550 feet above the sea (see map of South America, ref. 5–C). It is a bishop's see and has a fine cathedral. It is connected by rail with Arequipa and Mollendo, and the trade from Bolivia to the Peruvian coast passes through it. During the colonial period rich silver mines were worked in the vicinity; they are now nearly abandoned. Pop. about 9,000.

HERBERT H. SMITH.

Punshon, WILLIAM MORLEY, LL. D.: clergyman and author; b. at Doncaster, England, May 29, 1824; became a local Wesleyan preacher in 1840; studied at the Wesleyan College, Richmond; became one of the most popular preachers in England; preached in London 1858–68; labored in Canada 1868–73; in 1873 returned to England, and was president of the British Conference 1874; wrote sermons and discourses, *Life Thoughts* (1863); *Sabbath Chimes*, in verse (1867); the *Prodigal Son* (1868). D. in London, Apr. 14, 1881. See his *Life* by Frederic W. Macdonald, (New York, 1888). Revised by A. OSBORN.

Punt, or **Pun-t**: a land on the Red Sea, from which the Egyptians made imports, at first indirectly and afterward directly, during a large portion of their history, extending from the early dynasties down to Ptolemaic times. During a part of the time regular tribute was rendered in kind to the Pharaohs. Its exact location has been disputed, some, as Brugsch, claiming that it was in Arabia, the "land of the East"; others, as Mariette, that it was on the African side of the sea on account of the nature of the objects of import; and again others, as Lieblein and Dümichen, arguing that it lay on both sides of the sea. The question is difficult of determination, but the weight of argument seems to favor the view that it lay on the west side of the Red Sea, or on the south side of the Gulf of Aden on the Somali coast, especially as Punt is often classed in the monuments with Ethiopia or Cush. It was ordinarily reached from Egypt by way of the caravan route from Koptos to Kosseir through the HAMMAMAT (*q. v.*) valley, and thence by ship. The mural representations at Deir el-Bahari, however, represent the vessels of HATASU (*q. v.*) as sailing from Punt and arriving at Thebes, thus giving the impression of a continuous navigable waterway. There are many references to commercial and other intercourse between Egypt and Punt, the most extensive and minute of which are those of Hatasu. These represent the inhabitants as a mixed race, the rulers being of a light color, approximating that of the Egyptians or Libyans (with whom they may originally have been closely allied), while their subjects vary from red to black. The name "Negro," applied by the Egyptians to all the inhabitants of Eastern Africa, is not distinctive enough for ethnological purposes. The predominating racial types, however, point to the Somali coast. The men look much like Egyptians, but the women are represented as abnormally and grotesquely fat. The products of the land are also mainly African; sycamore trees in tubs ready for shipment, various sorts of wood, such as ebony, also ivory, mother-of-pearl, incense, balsam, myrrh, gold, silver, and other metals, two species of ape, giraffes, greyhounds, and leopard skins. See W. Max Müller, *Asien und Europa*

(Leipzig, 1893, pp. 106–120); Mariette, *Deir el-Bahari* (Leipzig, 1877); Dümichen, *Flotte einer aeg. Königin* (Leipzig, 1868); Hoskins, *Travels in Ethiopia* (London, 1835); Lieblein, *Handel und Schiffahrt auf dem rothen Meere in alten Zeiten* (Christiania, 1886); Meyer, *Gesch. des alten Ægyptens* (Berlin, 1887); Krall, *Das Land Punt* (Vienna, 1890). CHARLES R. GILLETT.

Punta Arenas, Chili: See MAGALLANES.

Puntare'nas: the principal Pacific port of Costa Rica, on the eastern side of the Gulf of Nicoya (see map of Central America, ref. 8–I); a terminus of the Costa Rican railway system. The harbor is shallow. The climate is warm but generally healthful. Pop. about 4,500. It is the capital of a *comarca* of the same name, which embraces two-thirds of the Pacific coast of the republic. H. H. S.

Pupa [from Lat. *pu'pa*, girl, doll, puppet]: one of the three stages of those insects which undergo a metamorphosis. See ENTOMOLOGY.

Pupillometer: See RECORDING APPARATUS, PSYCHOLOGICAL, in the Appendix.

Puppets: See MARIONETTES.

Puracé, poo-raă-sā': the highest active volcano of the Andes of Colombia, E. S. E. of Popayan, Cauca; in the Central and near the junction of the Eastern and Western Cordilleras; altitude (Reiss and Stübel), 15,420 feet. Severe eruptions have several times occurred. It is impossible at any time to enter the crater, owing to the hot and suffocating vapors. H. H. S.

Purānas: eighteen old traditional stories, chiefly in Sanskrit verse, compiled by an ancient sage named *Vyāsa*, the supposed founder of the Vedanta philosophy. They contain the history of the gods interwoven with every variety of legendary tradition in other subjects. Six of them relate to Brāhma, six to Vishnu, and six to Siva. Each is supposed to treat of only five topics—the creation of the universe, its destruction, the genealogy of the gods and patriarchs, the reigns and periods of the Manus, and the history of the solar and the lunar kings. See SANSKRIT LITERATURE, DEVALOKA, and Monier-Williams's *Indian Wisdom*. R. L.

Purcell, HENRY: composer; the most eminent and most original of English musicians; b. at Westminster, England, in 1658; was appointed organist of Westminster Abbey in 1680; organist of the Chapel Royal in 1682. Had it not been for the overshadowing greatness of Handel (who made England his home so soon after this period) it is probable that Purcell's fame would have been still greater and more largely spread abroad. D. Nov. 21, 1695, and was buried in Westminster Abbey. In many respects he must have been looked upon with more or less doubtful eyes as an innovator, not to say "heretic." His sacred works have held their own, commanding the admiration of modern critical opinion. His dramatic and chamber music is also admittedly the work of real genius, despite the change of style, etc., which the centuries have brought about. See Grove's *Dictionary of Music and Musicians* (London, 1881). DUDLEY BUCK.

Purchas, SAMUEL: author; b. at Thaxted, Essex, in 1577; educated at St. John's College, Cambridge; took orders in the Church of England; was presented by James I. to the vicarage of Eastwood, Essex, Aug., 1604; subsequently obtained the rectory of St. Martin's, Ludgate, London, and became chaplain to Archbishop Abbot. D. in London in Sept., 1626. Compiler of *Purchas his Pilgrimage; or, Relations of the World*, etc. (folio, 1613), and *Purchas his Pilgrimmes* (4 vols., folio, 1625), a celebrated collection from the works of many hundreds of travelers, and author of *Microcosmos, or the History of Man* (1619), and *The King's Tower and Triumphant Arch of London* (1623).

Purchase: See TITLE.

Purdue University: an institution at Lafayette, Ind.; founded as the Indiana Institute of Technology by act of legislature accepting the national land grant for agricultural and mechanical colleges. The location was fixed at Lafayette in 1869, when the name was changed to Purdue University in honor of John Purdue, who made the institution a gift of $150,000. It was formally opened in Sept., 1874, with seven professors and sixty-four students.

Purdue University sustains schools in agriculture, in science, in civil, mechanical, and electrical engineering, and a school of pharmacy. The U. S. agricultural experiment station for Indiana located there in 1887. The university has a farm and campus of 189 acres, twenty good buildings, and property, including annuities, to the value of $1,700,000. The register of 1899–1900 shows a faculty numbering 71 and 908 students. A new mechanical laboratory and equipment, valued at $180,000, was destroyed by fire in Jan., 1894, but was immediately restored, with improvements. The income is derived from land-grant endowment, the Morrill fund, and annual appropriation by the State of Indiana. J. H. SMART.

Purgatives [from Lat. *purgati'vus*, deriv. of *purga're*, purify, purge; *pu'rus*, pure + *a'gere*, make, do]: in medicine, substances that produce more or less fluid discharges from the bowels. Very many drugs are purgative in sufficient dose, but those available in medicine as cathartics, and in common use, are castor oil, rhubarb, aloes, and calomel, forming a group of comparatively mild agents, causing only fluid feculent stools; certain salts, producing watery discharges, of which the most prominent are magnesium citrate and sulphate, sodium phosphate, acid potassium tartrate, and potassium and sodium tartrate; and, finally, a group of vegetable nature, likewise producing watery stools, but also being more or less irritant to the intestines. These are senna, jalap, podophyllum, scammony, colocynth, gamboge, croton oil, and elaterium. Setting aside senna, the others last mentioned are commonly spoken of as the *drastic* cathartics, from their highly irritant properties. Besides the foregoing, there are many substances which have a very mild effect upon the bowels, and are called *laxatives*. The more prominent of these are magnesia and magnesium carbonate and sulphur among inorganic substances, and cascara sagrada, manna, purging cassia, tamarinds, prunes, figs, and other fruits among vegetable. Purgatives operate partly by quickening the muscular contractions of the intestines, whereby the contents of the latter are hurried down to the rectum, and partly, especially with those causing watery stools, by determining an abundant pouring out of fluid into the intestinal canal. They are used for the primary object of emptying the bowels, and also to relieve congestion of distant organs and to induce the absorption of dropsical collections of fluid. Revised by H. A. HARE.

Purgatory [from Lat. *purga're*, purify. See PURGATIVES]: according to the Roman Catholic and Oriental Churches, a place in which the souls of those who died in the state of grace suffer for a time, either on account of venial sin or on account of the temporal punishment due to mortal sin already forgiven. Purgatory is not a place of probation, but of expiation. The Roman Catholic Church has committed herself to only two statements about purgatory: (1) that there *is* a purgatory, and (2) that the souls detained there are helped by the prayers of the faithful, and especially by the sacrifice of the Mass. See Council of Florence, *Decree of Union*, and Trent, *De Purgatorio, Sess. XXV.* Further the Roman Catholic Church does not go, but the theologians discuss many other points, as the character of the sufferings, the situation of purgatory, the number of its inmates, etc. JOHN J. KEANE.

Purging-flax: the *Linum catharticum*, an annual plant resembling the common flax on a small scale. It is a native of Europe. It has been considerably used in medicine as a gentle hydragogue cathartic.

Purim [Heb. *pūr*, plur. *pūrim*, a lot. So called from Haman's casting lots for the destruction of the Jews (Esth. iii. 7)]: a Jewish feast, lasting two days, which falls on the 14th and 15th of the month Adar (February and March), in commemoration of the deliverance described in the book of Esther. The festival was in former times, as still in many places, celebrated in a noisy and tumultuous manner, with loud expressions of hatred at the reading of Haman's name in the synagogue.

Purinton, DANIEL BOARDMAN, A. B., A. M., LL. D.; educator and author; b. in Preston co., Va., Feb. 15, 1850: educated at George's Creek Academy, Pennsylvania, and at the West Virginia State University, where he graduated in 1873. He has held the following positions: Instructor George's Creek Academy, professor and vice-president West Virginia State University; since Dec., 1889, has been president of Denison University, Granville, O. For seven years he was president of the West Virginia Baptist General Association. He has published *Christian Theism* (1889) and *The Contest of the Frogs*, a poem (1888). Besides these he has written hymns and music, both sacred and secular, and about forty of his pieces have been published. W. H. WHITSITT.

Puritans [irreg. from Lat. *pu'ritas*, purity, deriv. of *purus*, pure]: in general, persons who are scrupulous and strict in their religious life; in particular, a body of Christians which arose in England in the sixteenth century. The Reformation in England under Henry VIII. was unsatisfactory to many, because, in their view, it accomplished only a partial elimination of the corruptions and abuses of the Church of Rome. Through the ecclesiastical alternations of the reigns of Edward VI. and Queen Mary these recusants grew in numbers and influence. Many of them fled to Geneva, and there came under Calvin's influence. They returned on Mary's death with new notions upon theology and polity. They gave Queen Elizabeth no little trouble, and were in turn greatly harassed by the efforts made, through the high commission court, to force them to conformity. It was during her reign that they came to be called in derision *Puritans*, because they were ever calling for a simpler, purer form of worship and insisting on a stricter, purer life. They, however, supported her most heartily when, after the destruction of the Spanish Armada (1588), she threw herself decidedly upon the Protestant side. They stood forth as a distinct party, leading the opposition to the despotic claims for the royal prerogative asserted by the first two Stuarts, and their influence culminated in a triumph when royalty was overthrown and the Commonwealth was established. The genuine Puritans were mostly of the commoners of England, men of strong minds, good judgment, and sterling character. They adopted the Calvinistic creed, and rigidly conformed their lives to its principles. This gave an aspect of precision to their manners and stern severity to their lives, but it made them strong in their integrity and persistent in the struggle for liberty and right. Much as they have been ridiculed and maligned, England owes to the Puritans some of the best features of her free constitution; and never before had her power in Europe been felt as it was under the Commonwealth, when, through Cromwell, they controlled the Government. The influence of the Dutch upon the Puritans, in toning them up and suggesting the reforms they advocated and, when able, instituted in Church and state, is now generally recognized. During the struggle with the Stuarts many Puritans emigrated to New England.

The term Puritans is applied loosely to embrace all who objected to the ceremonies of the Established Church, and advocated holy living, and resisted the royal prerogative. But, especially with reference to the early history of the U. S., a distinction of two classes should be recognized. The Puritans proper adhered to the Church, striving to mould it to their own views. The Independents, originally called Separatists and Brownists, despairing of accomplishing the needed reform in that way, insisted on an absolute separation from the Church for a new organization. The Pilgrims who established the first colony in New England at Plymouth were Independents. Those who subsequently established themselves on Massachusetts Bay were Puritans. Neal, *History of the Puritans*, ed. Choules (2 vols., New York, 1844); L. Bacon, *The Genesis of the New England Churches* (1874); G. E. Ellis, *The Puritan Age in Massachusetts* (Boston, 1888); D. Campbell, *The Puritan in Holland, England, and America* (New York, 2 vols., 1892). Also see ENGLAND, CHURCH OF, and INDEPENDENTS.

Revised by S. M. JACKSON.

Purlin: a beam or girder which connects two roof trusses, and upon which rafters are placed to support the covering of the roof. See ROOF.

Purneah: town; in the presidency of Bengal, British India, on both sides of the river Kosi, in lat. 25° 45′ N. and lon. 88° 23′ E. (see map of N. India, ref. 6–H). It occupies an area of 9 sq. miles, mostly single houses surrounded with gardens, orchards, and indigo plantations. Pop. about 20,000.

Purple of Cassius: a substance which is formed by adding a tin solution to a dilute solution of gold chloride. The tin solution must contain both stannous and stannic chloride. Analyses of this substance made by different chemists have not given the same results. From recent work it appears highly probable that the substance contains gold in the metallic state. The purple can be made by treating a solution of gold chloride with tin filings. When dry and powdered, the purple of Cassius has a metallic luster. It is used in manufacturing artificial gems, and for imparting a red, rose, or pink color to porcelain or enamel. I. R.

Purple, Tyrian: See TYRIAN PURPLE.

Purple Wood: a beautiful plum-colored wood from Guiana, of great strength and capable of a very smooth finish. It is the product of the leguminous trees *Copaifera bracteata* and *C. pubiflora*. It is adapted to a wide range of uses. L. H. B.

Purpura [Mod. Lat., from Lat. *pur'pura*, purple-fish]: a genus of marine gasteropods. This genus furnished a part of the Tyrian purple dye of antiquity, whence the name. There are numerous living and extinct species.

Purpura [from Lat. *purpura*, the purple-fish, purple dye or color, from Gr. *πορφύρα*, purple-fish, the dye obtained from the purple-fish]: a condition in which spots of deep purple color appear in the skin, produced by the escape of blood from the vessels. Purpura is not a disease, but merely a symptom, like cough, which may occur in many diseases. The immediate cause of the hæmorrhage in the skin is generally either a disorganized condition of the blood or a disease of the blood-vessel. Among the blood diseases producing purpura are leukæmia, progressive pernicious anæmia, scurvy, and the like. Among the causes which influence the blood-vessels are to be counted certain poisons, but in these the blood itself is also altered. A number of causes appear to affect both the blood and the vessel walls. Among these are the infectious fevers, like typhus and smallpox, poisoning by phosphorus, snake bite, etc. The treatment of purpura requires, first of all, a consideration of its cause. After this symptomatic treatment is useful. Iron, arsenic, quinine, or other tonics are useful, and styptics may be necessary to control hæmorrhage. WILLIAM PEPPER.

Purpurin: a substance whose formula is $C_{14}H_6O_5 = C_{14}H_5(OH)_3(O_2)''$. It exists in madder in the form of a glucoside, distinct from ruberythric acid, which is the alizarin glucoside. It is extracted from madder by the same processes as alizarin, and is usually separated from it by its greater solubility in a solution of alum. F. de Lalande converts alizarin into purpurin by treating it with sulphuric acid and arsenic acid or manganese dioxide; pours into water, and purifies the precipitate by alum, etc.

Purpurin appears as a red powder, in red feathery crystals (by sublimation), and in orange-red needles (from boiling alcohol). It is slightly soluble in boiling water, giving a rose-colored solution. It dissolves in alcohol, ether, benzene, glycerin, concentrated sulphuric acid, and acetic acid. Its solution in sulphuric acid may be heated to 400° F. without decomposition, the purpurin being thrown down unchanged on pouring the solution into water. It dissolves in a boiling alum solution to a pink fluorescent liquid, and does not separate on cooling, even from concentrated solutions. It dissolves in alkaline hydrates and carbonates, forming cherry-red or poppy-red solutions, from which acids reprecipitate it in orange-yellow flocks. The solutions in alkaline hydrates lose color on standing in the air, the purpurin being oxidized and destroyed. Boiling nitric acid converts purpurin into phthalic and oxalic acids. With bases it forms compounds; those with the alkalies are soluble in water. The basic, calcic, and aluminic lakes are soluble in boiling solutions of sodium carbonate.

Application to Dyeing and Calico-printing.—With alumina mordants purpurin produces bright reds; with iron, grayish violet. These tints resist cleaning with soap and nitro-hydrochloride of tin tolerably well, but are not so permanent as those produced by alizarin, nor do they resist light as well. There is a difference of opinion as to the part played by purpurin when madder, garancin, etc., are used in dyeing calico. Some think the purpurin of little importance; others consider it essential to certain pinks and reds. On account of its high price, this dyestuff is but little used.

Revised by IRA REMSEN.

Pur'ree, or **Indian Yellow** [*purree* is from Hind. *peori*, yellow]: a yellow coloring-matter brought from India and China in lumps weighing 3 or 4 oz., brown on the outside and deep orange-yellow within. It is made almost exclusively at Monghyr, in Bengal, from the urine of cows fed on mango leaves. When the urine is heated the coloring-matter separates. One cow produces on the average 2 oz. of purree a day. It is used for the preparation of Indian yellow, a fine, rich, durable yellow color, much used by artists, and often adulterated with chrome yellow. It consists mainly of the magnesium and calcium salts of euxanthic acid. Revised by IRA REMSEN.

Purslane Family: the *Portulacaceæ*, a family of succulent dicotyledonous herbs and shrubs, all harmless and

many of them with gay flowers. The purslanes (*Portulaca*), the calandrinias, and the claytonias, include a few ornamental species. Common purslane (*Portulaca oleracea*) is a well-known annual weed of fields and gardens in the U. S. (where it is colloquially called *pusley*). It was introduced thither from Southern Europe, where it is freely eaten as a pot-herb. C. E. B.

Pur'suivant of Arms: the lowest order of officers in heraldry. See HERALDRY and HERALDS' COLLEGE.

Purús, poo-roos': one of the most important tributaries of the Amazon, on its southern side; rises within the confines of Peru near lat. 11° S., thence passes through a small part of Bolivia, flowing N. E. through Brazil, and joining the Amazon (after receiving some of its water through several chanels, near lon. 61° 30′ W.). It is entirely a river of the forest-covered plains, and extremely crooked. Though the distance in a direct line between its source and mouth is only 900 miles, the channel is nearly 1,900 miles long. It was first explored in 1864–65 by the English traveler Chandless. He ascended it in a canoe until he found it reduced to a mere brook, and up to that point it was unobstructed by rapids. The Purús has many affluents. It is much frequented by rubber-gatherers, and steamers ascend regularly during the rubber season; but the few small settlements on the banks are near the mouth. See Chandless, *Ascent of the River Purús* (in *Journal* of the Royal Geographical Society, 1866). HERBERT H. SMITH.

Pūrva-mīmāṁsā: See HINDU PHILOSOPHY and MĪMĀṄSĀ.

Purves, GEORGE TYBOUT, D. D.: Presbyterian minister and professor; b. in Philadelphia, Pa., Sept. 27, 1852; graduated at the University of Pennsylvania 1872, and at Princeton Theological Seminary 1876; pastor at Wayne, Pa., 1877; at Baltimore, 1880; at Pittsburg, 1886; and Professor of New Testament Literature and Exegesis in Princeton Theological Seminary 1892. Called to Fifth Ave. Presbyterian Church in 1899. Besides articles in theological reviews, he has published *The Testimony of Justin Martyr to Early Christianity* (the Stone Lectures (Princeton), New York, 1889).

Pus: See SUPPURATION.

Pu'sey, EDWARD BOUVERIE, D. D., D. C. L.: theologian; b. at Pusey, Berkshire, England, in 1800; a nephew of the first Earl of Radnor; was educated at Eton and Christ Church, Oxford; graduated with high honors 1822; became a fellow of Oriel College 1823; studied in Germany, and in 1828 became Regius Professor of Hebrew at Oxford and one of the canons of Christ Church. His contributions to the *Tracts for the Times* (1835, *seq.*), of which series he wrote Nos. 18, 66, 67, and 69, gave to the Tractarian movement the name of "Puseyism." Newman's celebrated tract, No. 90, was in 1841 defended by Dr. Pusey in a published letter which excited much controversy. (See TRACTARIANISM.) He was suspended from preaching in the university for three years (1843–46) in consequence of the supposed utterance of heretical doctrine in a sermon on the real presence. Among the most important of his works are: *On the Benefits of Cathedral Institutions* (1833); *On the Royal Supremacy* (1850); *On the Real Presence* (1855, 1857); *History of the Councils of the Church* (1857); *Commentary on the Minor Prophets* (1860, *seq.*); *Daniel, the Prophet* (1864); *Eirenicon*, etc. D. at Oxford, Sept. 16, 1882.

Dr. Pusey's first publication (1828) was *An Historical Enquiry into the probable causes of the Rationalistic Character lately Predominant in the Theology of Germany*, in answer to Hugh James Rose's *Discourses on the State of Protestantism in Germany*. Both writers agreed that German theology was in a bad state, but differed as to its causes, Rose approaching the subject from the polemical, Pusey from the historical side. Each replied to the other, Pusey having the final word (1830), here first showing his hand as a religious controversialist. Later on, however, the book did not satisfy Pusey, and he withdrew it from circulation. He had taken in it a position more rationalistic than he was afterward willing to maintain. His next publication appeared in 1833, and was occasioned by Lord Henley's plan for the abolition of cathedral institutions. Pusey stood forth strongly in their defense, and looked at both their prospective and their past benefits in the promotion of sound religious knowledge. In this book the author's standpoint fully reveals itself. He had long been accustomed to hear the confessions of men and women who went to him for spiritual advice, and insisted that the Church of England allowed both confessions to its people and absolution through its priesthood. The disputes over the confessional led to his famous letter to W. Upton Richards, in 1850, entitled *The Church of England leaves her Children free to whom to open their Griefs*, which made a great impression at the time. He was also mainly instrumental in fostering the growth of conventual institutions in the Church, and in establishing voluntary penitentiaries for women. Canon Thomas Thelluson Carter's work at Clewer and Rev. Dr. John Mason Neale's work at East Grinstead were the outgrowth of his teachings. In 1865 came a new departure. Cardinal Manning, in a *Letter to an Anglican Friend*, challenged him to show that the Church of England was the Catholic Church, or any part of it, or in any divine or true sense of the word a Church at all. This was the occasion of Dr. Pusey's famous letter to John Keble entitled *The Truth and Office of the English Church*, in which he set forth the terms of an eirenicon between the Anglican and Roman Churches. This volume drew forth a friendly response from Rev. Dr. Newman, to which he replied in two successive pamphlets as large as the original work, the last of which appeared in 1870.

Personally, Dr. Pusey was an humble and holy man. His piety was of the ascetic or monastic type. His theology was essentially Catholic, consequently he was opposed to Romanism in many important questions—such as mariolatry, the infallibility of the pope, etc. It has truly been said of him that he was the moral, as Newman was the intellectual, and Keble the poetic, leader of the Anglo-Catholic movement. The acknowledged revival of the English Church dates from the Oxford movement, and is largely due to the loyal devotion to Anglicanism and the scholarly defense of its Catholicity which have made the name of Pusey famous. His *Life* was undertaken by Canon Henry Parry Liddon, who left it unfinished at his own death in 1890. It was then completed and published by Rev. John Octavius Johnston and Rev. Robert James Wilson (4 vols., London and New York, 1893–95). Revised by W. S. PERRY.

Pushkin, or **Ponchekin**, ALEXANDER SERGEIEVITCH: poet; b. in Moscow, Russia, May 26, 1799; studied at Tzarskoe Selo; entered in 1817 as clerk in the Government office of foreign affairs, but was discharged in 1820 for an *Ode to Liberty*, and banished to his estates; was recalled in 1825 by the Emperor Nicholas, who restored him to his office, charged him with writing the history of Peter the Great, and gave his widow a pension of 10,000 rubles when he was killed in a duel at St. Petersburg, Jan. 29, 1837. By his countrymen he is considered the greatest poet Russia ever produced, and those of his works which have been translated into German, French, or English have attracted great attention. He wrote romantic epics—*Ruslan and Liudmila* (1820), *Kawkázskij Plehnnik* (1822), etc.; one drama—*Boris Godunow*; several novels, under the pseudonym of *Belkin*, of which some were translated into English in 1875 by Mrs. J. Buchan Telfer in *Russian Romance*. His collected works in twelve volumes were published in St. Petersburg in 1839; a translation of his *Poems* in New York (1889).

Puteoli: See POZZUOLI.

Putnam: town; Windham co., Conn.; on the Quinnebaug river and the N. Y. and New England Railroad; 26 miles S. by W. of Worcester, Mass., 33 miles N. by E. of Norwich (for location, see map of Connecticut, ref. 7–L). It is noted for its manufactures, which include silk, cotton, and woolen goods, boots, shoes, and slippers, steam-heaters, cutlery, and carriages. There are several lumber-yards and wood-working plants, 2 national banks with combined capital of $225,000, 2 savings-banks with deposits of over $2,000,000, and 2 weekly newspapers. Pop. (1880) 5,827; (1890) 6,512; (1900) 7,348.

Putnam, FREDERICK WARD: anthropologist; b. at Salem, Mass., Apr. 16, 1839; was educated by his father until 1856, when he entered the Lawrence Scientific School under Prof. Agassiz, with whom he remained until 1864, when he returned to Salem; took an active part in the Essex Institute as superintendent of its museum. On the foundation of the Peabody Academy of Science in 1867 he was elected director of the museum, which position he held until Oct., 1875, when he succeeded Prof. Wyman as curator of the

Peabody Museum of Archæology and Ethnology at Cambridge. He was one of the founders of *The American Naturalist*; was elected permanent secretary of the American Association for the Advancement of Science; was appointed in Dec., 1875, civilian assistant on the U. S. surveys W. of the 100th meridian (in charge of Lieut. Wheeler), being intrusted with the special duty of reporting on the archæological and ethnological material that had been collected; and in 1876–78 had charge of the Agassiz collection of fishes at the Museum of Comparative Zoölogy; in 1886 was appointed Professor of American Archæology and Ethnology at Harvard; was chief of the department of ethnology, etc., at the World's Columbian Exposition 1893.

Putnam, George Haven: See the Appendix.

Putnam, George Palmer: publisher; b. at Brunswick, Me., Feb. 21, 1814; became a bookseller's clerk in Boston 1826, and in New York 1828; prepared in early youth *Chronology, or an Introduction and Index to Universal History, Biography, and Useful Knowledge* (New York, 1833), republished in 1850 and in later editions as *The World's Progress, a Dictionary of Dates*; visited Europe in the employ of John Wiley 1836–38, with whom he became a partner 1840; resided in London 1840–47; wrote *The Tourist in Europe* (1838) and *American Facts* (1845); and prepared a *Pocket Memorandum-book in France, Italy, and Germany* (1848). Returning to New York in 1847, he began business on his own account in 1848, and founded *Putnam's Magazine*, which ran from 1853 to 1856, was re-established in 1868, and merged with *Scribner's Monthly* in 1870. He held the position of collector of internal revenue in New York 1863–66; became one of the founders and honorary superintendent of the Metropolitan Museum of Art, and was chairman of the committee on art in connection with the universal exposition at Vienna. D. in New York, Dec. 10, 1872.

Revised by H. A. Beers.

Putnam, Israel: soldier; b. at Salem (that part now the town of Danvers), Mass., Jan. 7, 1718. With only a very rude education, his natural, vigorous mental endowments enabled him to exercise a wide influence upon the exciting events of his time, while his strong physical powers and daring disposition were displayed in the many romantic adventures related of him. In 1739 he married and removed to Pomfret, Conn., where he became a successful farmer and a large wool-grower. By various daring adventures he established a reputation for courage—a reputation he subsequently maintained in the French war, in which he commanded a company of Connecticut troops with distinction at Crown Point and Ticonderoga. In Aug., 1756, while in command of a party, he was captured by the enemy and bound to a tree, where during the continuance of the action he was frequently exposed to the fire of both friend and foe, but escaped unhurt. He was, however, borne away by the enemy in their retreat, and at night the fire had been lighted to burn him alive when he was saved by the intervention of a French officer, Molang. Taken to Ticonderoga, and subsequently to Montreal, he was, by the influence of Col. Schuyler, himself a prisoner at the latter place on Putnam's arrival, exchanged in 1759 and promoted to be lieutenant-colonel. He returned to his farm on the restoration of peace. The news of the battle of Lexington reached him while plowing, and leaving his plow he mounted his horse and rode rapidly to Cambridge. After a brief consultation he returned to Connecticut, when he was made brigadier-general by the Legislature, of which he was a member, and a week later was on his way back to Cambridge at the head of a regiment which he had raised. Spurning the offers of rank and money made to him by the British, he entered with zeal upon the struggle for independence, and soon conducted several successful expeditions. At the battle of Bunker Hill he displayed his usual energy and bravery throughout the day, as well as in the subsequent endeavor to rally the overpowered and retreating troops. Washington, upon his arrival to assume command (July 2), bestowed upon Putnam one of the four major-generals' commissions he bore from Congress, but the other three were not then delivered. Upon the evacuation of Boston, Putnam was ordered to take command at New York, and after the battle of Long Island and evacuation of New York was sent to Philadelphia to complete the fortification of that city; subsequently stationed at Crosswicks and Princeton, N. J., he was in May, 1777, assigned to command the army in the Highlands of New York. Owing to the dissatisfaction created by the surprise and loss of Forts Montgomery and Clinton in the summer of 1777, Putnam was removed from his command, although a subsequent court of inquiry acquitted him from blame for their capture, and he was restored to command. His success as a general, however, was not equal to his reputation for enterprise and daring. While on a visit to his home in Connecticut in 1779 he was stricken with paralysis, from which he only partially recovered. D. at Brooklyn, Conn., May 19, 1790.

Revised by C. K. Adams.

Putnam, Mary Traill Spence (*Lowell*): author; sister of James Russell Lowell; b. in Boston, Mass., Dec. 3, 1810; was early distinguished as a linguist; was married in 1832 to Samuel R. Putnam, a merchant of Boston (d. 1861); resided in Europe 1851–57; published a *History of the Constitution of Hungary and its Relations with Austria* (1850); *Records of an Obscure Man* (1861); *The Tragedy of Errors*, and *The Tragedy of Success* (1862), the latter two a dramatic poem in two parts, illustrative of slavery; a memoir of her son, William Lowell Putnam (killed at the battle of Ball's Bluff, 1861); *Fifteen Days* (1866); memoir of Charles Lowell (1885); contributed largely to *The North American Review* and *The Christian Examiner*, and translated from the Swedish Frederica Bremer's novel *The Neighbors*. D. in June, 1898.

Revised by H. A. Beers.

Putnam, Rufus: soldier; b. in Sutton, Mass., April 9, 1738; a millwright by trade, he abandoned his occupation to serve as a private in the French war of 1757–60; resuming his business on the return of peace, by study during spare time he attained proficiency in mathematics and surveying; in 1773 visited Florida, and was appointed deputy surveyor of that province. In the war of the Revolution, as lieutenant-colonel of a regiment, he superintended the defenses of Roxbury, Mass.; was appointed chief engineer with rank of colonel, and charged with the defense of New York by fortifications; constructed the fortifications at West Point in connection with his cousin, Israel Putnam; commanded a regiment in Wayne's brigade until the close of the war; in Jan., 1783, was appointed a brigadier-general; was frequently a member of the Massachusetts Legislature; was aide to Gov. Lincoln during Shays's rebellion 1787; formed a land company, which purchased large tracts of land in what is now Ohio and founded Marietta, the first permanent settlement in the Northwest; was judge of the Supreme Court of the Northwest Territory 1789; appointed brigadier-general 1792, he accompanied Gen. Wayne's army to Detroit against the Indians, and subsequently as U. S. commissioner negotiated an important treaty with numerous tribes; from 1793 to 1803 U. S. surveyor-general. D. at Marietta, O., May 1, 1824.

Putrefaction: See Fermentation.

Putty [from O. Fr. *potee*, calcined brass, tin, etc., putty, deriv. of *pot*, pot, the substance formerly called putty resembling putty-powder and being often made from the metal of old pots]: a cement used by glaziers for fastening window-glass in place, and by painters for filling holes in wood over nail-heads, etc. It is composed of whiting (calcium carbonate) and linseed oil, often colored with pigment.

Putty-powder: oxide of tin, or a mixture of this oxide with oxide of lead, used for polishing glass, etc. It is prepared by calcining tin or a mixture of tin and lead. For the optician's use it is prepared by precipitating a solution of tin in aqua regia with ammonia, washing, drying, and igniting the product.

Putumayo: See Içá.

Puvis de Chavannes, pü'vĕcs'de-shăă'văăn', Pierre: historical painter; b. in Lyons, France, Dec. 14, 1824; pupil of Henry Scheffer and of Couture; awarded medal of honor 1882; commander of the Legion of Honor 1889. He was one of the greatest artists of the French school, and his mural paintings in the Panthéon, the New Sorbonne, and the Hôtel de Ville in Paris, the museum at Amiens, and other public buildings in France, placed him at the head of modern decorative painters. His works are especially remarkable for their grand style, dignity of composition, and delicate schemes of coloration. D. in Paris, Oct. 25, 1898.

William A. Coffin.

Puy-de-Dôme, pwee' de-dōm': a central department of France; area, 3,070 sq. miles. The surface is high and on the W. covered with branches of the Cevennes and the Auvergne mountains, whose conical peaks and their extinct craters (*puys*), together with the large masses of lava and basalt, show the volcanic character of the country. The

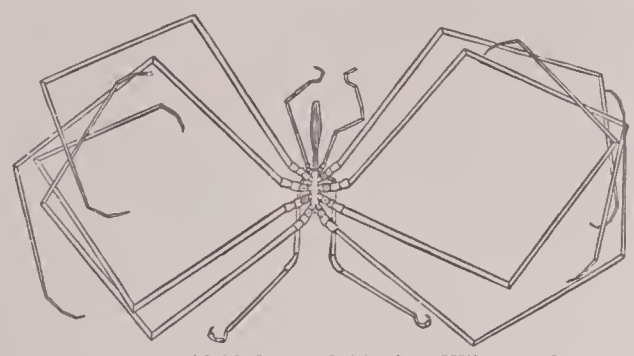
highest of these mountains is Puy-de-Sarcy (6,188 feet); on the E. are the Forez Mountains, reaching 5,380 feet. The chief rivers are the Allier and the Dordogne. The soil is generally fertile, but agriculture is not in an advanced state. Wheat and wine are produced: on the fine pastures of the mountain plateaus cattle and sheep are reared. Iron, lead, and silver are found in small quantities; marble, granite, and millstones are quarried. The manufacturing industry is not much developed. Pop. (1896) 555,078.

Puy, Le, or **Le Puy-en-Velay**, *le-pwee'ăañ-ve-lā'*: capital of the department of Haute-Loire, France; 70 miles S. W. of Lyons (see map of France, ref. 7–G). It is picturesquely built in terraces near the left bank of the Loire, on the slopes of Mt. Anis, on the summit of which is a basaltic mass called Mt. Corneille, crowned by a figure (53 feet high) of the Virgin, made of Russian cannon brought from Sebastopol. It has celebrated bell-foundries and manufactures of yarn, laces, linen, and woolen fabrics and cloth. Pop. (1896) 20,793.

Puzzolana: same as POZZUOLANA (*q. v.*).

Pyæ'mia: See BLOOD-POISONING.

Pycnogon'ida [Mod. Lat., from Gr. *πυκνός*, close + *γόνυ*, knee]: a group of marine arthropods of uncertain position. The common name sea-spiders alludes to their resemblances to the true *Arachnida*. They have a small jointed body terminated by a proboscis in front and a short abdomen behind, and upon this are borne, typically, six pairs of appendages, four of which are used by the animal in its slow motions over seaweeds and hydroids. In the male a seventh pair is present, and upon this the eggs are carried until they hatch. In other forms the number of legs may be reduced until only four pairs of appendages are present. The nervous system is on the regular arthropod plan; the four eyes (ocelli) on the first body-segment are peculiar in structure; circulatory organs are present, but those of respiration are lacking. The alimentary canal sends pouches into the legs. After hatching, the young of some species form galls upon hydroids, recalling the galls upon plants. By the older naturalists the *Pycnogonida* were regarded as *Crustacea*; more lately the tendency is to place them among the *Arachnida*. See Wilson, *New England Species*, Report U. S. Fish Commission for 1878; Morgan, *Development and Position*, Studies Biol. Lab. Johns Hopkins, v. (1891).



A deep-sea pycnogonid (*Colossendeis*) after Wilson. One-quarter natural size.

J. S. KINGSLEY.

Pygmalion (in Gr. *Πυγμαλίων*): a king of Cyprus, who fell in love with an ivory statue of a maiden which he himself had made. He prayed to Aphrodite to endue the statue with life; his prayer was granted, and the animated statue became his wife and bore to him Paphus. J. R. S. S.

Pygmy, or Dwarf, Tribes [*pygmy* is from Lat. *pygmæ'us* = Gr. *πυγμαῖος*, about a foot long, a *πυγμή* in length, deriv. of *πυγμή*, fist, the length of the forearm with the fist closed]: peoples much under average stature, found in small numbers in Southern India and Madagascar, constituting a large part of the inhabitants of the Andamans, and spread widely over the southern half of Africa. Their origin is unknown, but all seem to pertain to the Negro or Negrito families. They have been chiefly studied in Africa. Their existence has been known since the dawn of history, but when the world repudiated many statements of the earliest geographers it rejected also the pygmy tribes of whom Homer, Herodotus, Hekatæus, and other ancients wrote, and they were not rediscovered until the second half of the nineteenth century. The pygmy tribes of Africa have been distributed into four great groups: (1) The dwarfs of West Africa; (2) those of the central regions; (3) the East African dwarfs; and (4) the tribes that live S. of the Congo basin.

The first group (Obongo, Akoa, Babongo) live chiefly among the forests between the Gabun, Ogowe, and Congo rivers, where they are scattered among various Bantu tribes. The height of the adult male Obongo is 4·3 to 4·7 feet, while that of the women is less.

The second group (Akka, Wambutti, Batua) are the most important tribes of pygmies. They inhabit the vast forest-region S. of the upper part of the Mobangi-Makua tributary of the Congo, and are found also far S. along the Lomami, Chuapa, Bussera, and other southern tributaries of that river. They range in height from 4·3 to 4·8 feet, the Akkas being the smallest known people. The pygmies in groups one and two greatly resemble one another in appearance and mode of living. They are skillful, nomadic hunters, building rude temporary huts wherever game is plentiful, killing even the largest game with spears and poisoned arrows, or by means of pitfalls and traps, and supplying the Bantu tribes with flesh and skins in exchange for vegetable food, spears, knives, and other articles. They never engage in agriculture. They are usually lighter in color than the Bantus and many have slight beards. They often intermarry with other peoples and speak the languages of surrounding tribes. They have rarely been induced to speak their own languages in the presence of strangers.

The third group are the Dokos and other tribes living E. of the Nile and S. of Kaffa, and the river Omo. No explorer (1894) has visited them, but there is abundant evidence as to their existence. They are similar in size, appearance, and habits to the pygmies of the Upper Nile and Congo regions.

The Bushmen and their relatives, comprising the fourth group, are from 4 to 4·5 feet in height and subsist by the chase and on the roots and fruits of the Kalahari desert.

These groups, though separated by wide territories inhabited by many tribes of different origin, have so many similarities that their relationship is regarded as proven. Very little is yet known of their languages, but some words collected in the various groups are identical. The assumption that these tribes are remnants of the original population of Africa is plausible on several grounds. The Andaman islanders are from 4·6 to 4·9 feet high, are more pleasing to look upon than the African dwarfs, and differ from them in other respects. Very little is known of the Kimo of Madagascar except that they exist. See *The Pygmy Tribes of Africa*, by Dr. Henry Schlichter, *Scottish Geographical Magazine* (June and July, 1892); *Ueber Zwergvölker in Afrika und Süd-Asien*, by H. Panckow, *Zeitschrift der Gesellschaft für Erdkunde zu Berlin* (No. 2, 1892); *Les Pygmées*, by M. Quatrefages (1887); articles by Prof. Flower on the Akkas and the pygmy races of men in *Journal of the Anthropological Institute of Great Britain* (1889); and the works of Schweinfurth, Stanley, Junker, Lenz, Wissmann, Du Chaillu, Casati, and François. C. C. ADAMS.

Pygop'odes [Mod. Lat., from Gr. *πυγή*, rump + *πούς*, *ποδός*, foot; in allusion to the position of the feet]: a name given to an order of birds containing the loons (*Urinatoridæ*), the grebes (*Podicipidæ*, or *Colymbidæ*), and the auks (*Alcidæ*), all having the legs far back and only to a small extent free from the body. These birds are all expert divers. They are often placed together, but the order thus made rests chiefly on similarity of habits. F. A. LUCAS.

Pyle, HOWARD: See the Appendix.

Py'lus (in Gr. *Πύλος*): town of Messenia, on the promontory of Coryphasium; one of the last towns taken by the Spartans in the Second Messenian war. In 424 B. C. the Athenians built a fort on the site of the town, which became very famous in the Peloponnesian war. The present name, *Navarino*, is a corruption of *Avarino*, the Avars having settled here in the sixth century. J. R. S. S.

Pym, JOHN: b. at Brymore, Somersetshire, England, in 1584; spent some years at Pembroke College, Oxford, 1599–1602, but did not graduate; studied law at one of the inns of court; was elected to the Parliament of 1621, in which he became one of the leaders of the opposition to the royal encroachments on parliamentary rights, and suffered imprisonment for three months on the dissolution of the Parliament. In the first Parliament of Charles I. he was actively engaged in the impeachment of the Duke of Buckingham, 1626. He was the recognized leader of the "Short Parliament" of 1640 and of the "Long Parliament," which assembled in 1641; managed the impeachment of Strafford and the trial of Laud; presented the "grand remonstrance," which set forth all the evils endured from the beginning of

the reign of Charles I.; was the chief of the "five members" whose attempted seizure by the king (Jan., 1642) made reconciliation with Parliament impossible; was the real head of the provisional executive established at London after the king's flight; issued a manifesto in 1643 defending himself in moderate language from the king's accusation of treasonable dealings with the Scots; was appointed lieutenant of the ordnance in November. D. suddenly at Derby House, London, Dec. 8, 1643. He was buried with pomp in Westminster Abbey, and having impoverished himself in the cause of his country, £10,000 was voted by the House of Commons to pay his debts. By the royalists he was nicknamed "King Pym," and Clarendon testifies that at the opening of the Long Parliament he was "the most popular man in that or any other age." He was possessed of a peculiar eloquence, terse and vigorous, and was a perfect master of parliamentary law. See Foster's *Arrest of the Five Members* (1860), *The Debates on the Grand Remonstrance* (1860), and *Statesmen of the Commonwealth* (1864); Goldwin Smith's *Three English Statesmen* (1867); J. R. Green's *Short History of the English People* (1875); and Gardiner's *History of England from the Accession of James I. to the Outbreak of the Civil War* (1887). Revised by F. M. Colby.

Pynchon, Thomas Ruggles, D. D., LL. D.: educator; b. at New Haven, Conn., Jan. 19, 1823; was educated at the Boston Latin School and at Trinity College, Hartford, where he was graduated in 1841, M. A. 1844; was tutor 1843–47; ordained deacon at New Haven June 14, 1848, and priest at Boston July 25, 1849; rector of Stockbridge and Lenox, Mass., 1849–55; elected Scovill Professor of Chemistry in Trinity College, Oct. 2, 1854; received the degree of D. D. from St. Stephen's College, New York, in 1865, and LL. D. from Columbia College, New York, 1877; president of Trinity College Nov. 7, 1874–83; is still (1901) a professor in that institution; author of *Introduction to Chemical Physics* (New York, 1869; 2d ed. 1874), and of various sermons, scientific papers, and pamphlets. Revised by W. S. Perry.

Pynchon, William: colonist; one of the original patentees of the Massachusetts Bay Company; b. at Springfield, Essex, England, about 1590; emigrated to New England in 1630 with Winthrop and other patentees, and settled at Roxbury; in 1636 removed to Connecticut river and founded Agawam, renamed Springfield, after his birthplace; published a book opposing the Calvinistic view of the atonement, entitled *The Meritorious Price of Man's Redemption* (London, 1650). In consequence of the disfavor with which this book was received, and the persecution to which it subjected him, he returned to England in Sept., 1652. D. Oct. 29, 1662. He was also author of a treatise on the Sabbath and other works.—He left one son, John (1621–1703), to whom he bequeathed all his vast landed estate in the valley of the Connecticut river. The latter was an assistant under the first Massachusetts royal charter, and during 1686–1703 was several times councilor.

Pyramid [from Lat. *py'ramis*, *pyra'midis* = Gr. πυραμίς, πυραμίδος, pyramid]: a polyhedron having any polygon for a base, the remaining faces being triangles meeting at a common point called the *vertex*. The triangular faces taken together make up the *lateral surface* of the pyramid. A spherical pyramid is a portion of a sphere bounded by any spherical polygon, called the *base*, and by corresponding sectors of great circles. The vertex is at the center of the sphere.

Pyramidal Numbers: See Figurate Numbers.

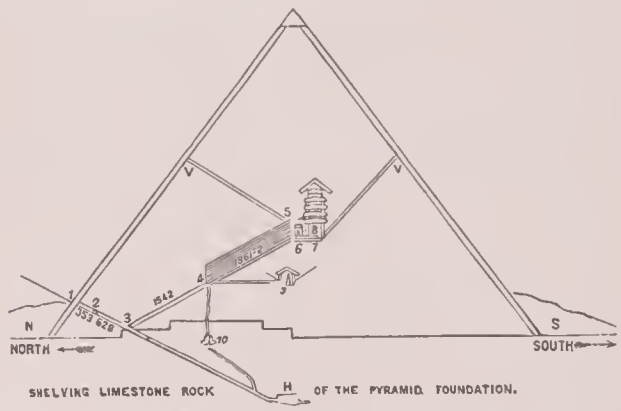
Pyramid Lake: a body of water in Western Nevada, near the Nevada-California boundary. It is 30 miles long and from 5 to 12 miles broad. It is without outlet, and varies both in depth and in extent with the seasons and with secular changes of climate. In Sept., 1882, its area was 828 sq. miles and its maximum depth 361 feet. It is fed principally by Truckee river, which rises in Lake Tahoe, and is remarkable for the purity of its waters. The inflow is counterbalanced by evaporation, and the waters have been concentrated until they contain about 3·5 parts per 1,000, of saline matter in solution. The waters are too alkaline to drink, but are inhabited by trout and other fishes in great numbers. The lake occupies one of the lower depressions in the bed of a former sea named Lake Lahontan, which flooded many of the valleys of Nevada in Pleistocene times. Immense deposits of calcium carbonate precipitated from the waters of the former lake occur in the form of castles and towers about the border of its modern representative.

Israel C. Russell.

Pyramid of Cestius: See Cestius, Pyramid of.

Pyramids: structures built in the form of a geometrical pyramid by several ancient nations. Of these the Egyptian are the most important. These are usually square at the base, and were erected as tombs of the Pharaohs down to the twelfth dynasty at least, their number being formerly much larger than now. Natural decay, fanatical zeal, and building activity in Cairo have reduced their number and mass. Like the Mastaba (*q. v.*), their purpose was that of a permanent tomb for the mummy of the royal builder. Their location, uniformly surrounded by tombs and cemeteries, their contents, whether funereal remains or magical and ritual texts, their close resemblance to the plans of the tombs of contemporary nobles—all point to the one reasonable explanation of their purpose. Theories which find in them occult mysteries of a mathematical or astronomical sort are entirely fanciful. Their orientation (which was connected with the native religious beliefs of the builders), upon which so much stress has been laid, while showing considerable knowledge of astronomy, is not always exact.

The number of those in the region near Memphis, now existing in greater or less degree of dilapidation, amounts to seventy-five, and they are arranged in several groups. The area which they cover is about 25 miles long, extending southward on the west side of the Nile from Abu Roâsh, opposite Cairo, to Dahshûr. They were oriented with more or less care, though some of them are considerably out of a correct alinement. Investigation shows that the ratio of height to base is approximately 7 to 22. They were built on the same general plan, though not without some variations of detail, and, like the mastaba, had certain essential features: the chamber for the reception of the mummy, or several chambers when more than the mummy of the king was to be deposited inside; the passageways more or less complicated, and the chamber of offerings, which was an integral part of the plan though actually located outside of the pyramid itself. The entrance was almost invariably on the north



Section of the Great Pyramid: 1, Entrance; 2, descending passage leading to (H) a rough, subterranean chamber; 3, passage leading upward through grand gallery (4) and anteroom (6) to king's chamber (8), containing (7) sarcophagus; 9, queen's chamber; 10, subterranean grotto with small passages leading to galleries above and below; V V, ventilating shafts; N S, *débris*. Dimensions are given in inches.

side, and opened into a descending passageway ending in a subterranean chamber. Another gallery midway of the first branched off upward and led to the sepulchral chamber near the center of the mass. In the Great Pyramid of Cheops at Gîzeh there were two sepulchral chambers, one below, presumably for the queen, and a second for the king on a higher level. A peculiarity of structure is seen in this case, in that hollow spaces, the top one triangular in cross-section and the others rectangular, were left above the king's chamber to reduce the weight of the superincumbent mass.

No theory of the method of construction is entirely satisfactory. Petrie's theory of the origin of the pyramidal form is that it was developed out of the mastaba by repeated additions, and has much in its favor. The older theory of Lepsius had long currency, and is still accepted by many. A rocky site was chosen and leveled to form a foundation, a portion of the rock being left in the center for a core. After the subterranean passages and chamber had been excavated the building was begun about the core and was completed so far as to make a finished whole, though perhaps of small size. It contained all the essential features, and only lacked its later gigantic size. During succeeding years more layers of stone were added, and the longer the reign of the building Pharaoh the larger his tomb. These added layers have been fitly compared to the rings which mark the growth of

a tree. When the structure was large enough to suit the ambition of the king, or after the builder's death, it was covered by triangular stones which rested on the successive steps, and was made to present a smooth outward surface. The stones for the building were brought from various quarries, principally from the opposite side of the Nile, and dragged to their places up an inclined causeway, which was raised as the work progressed. Remnants of these causeways are still visible in some places. The testimony of ancient and mediæval writers goes to show that in some cases the exterior was covered with hieroglyphic writing which was undoubtedly of a religious nature. The statement of Herodotus (ii., 125) that they recorded the amounts of provisions consumed by the workmen while the pyramid was building is very unlikely, and probably he was deceived by his guide. Destruction began with the limestone coverings, which were stripped off and burned in the kiln. Further destruction was due to the use of the inner blocks in building the city of Cairo. The earliest depredations go back to an early Pharaonic date; the Persians broke into the pyramids of Gîzeh, and probably into many others, in the fifth and fourth centuries B. C., and later the Romans did the same. In the first part of the ninth century A. D. the Arabs also entered the Great Pyramid of Gîzeh at least.

Taking the pyramids in their geographical order, beginning at the north, the first remains are those of *Abu Roâsh*. Only ruins survive, but these suffice to show that one of the buildings was 350 feet square at the base. An inclined passageway of 160 feet led to a subterranean chamber 43 feet long. The date of this pyramid is unknown. To the E. are the remains of a mile of causeway designed for the carriage

The pyramids of Gîzeh.

and elevation of material. Six miles S. are the three immense pyramids of Gîzeh, with several smaller companions. The largest is the oldest, having been constructed by Khufu or Cheops, the second king of the fourth dynasty. The name of the builder was found in red on one of the stones in the triangular chamber mentioned above. It is 755 feet square and 451 feet high, and was originally about 775 feet square at the base and 481 feet high. At the top is a flat space 30 feet square. It is estimated to contain 85,000,000 cubic feet of stone. It still contains the broken red granite sarcophagus of Cheops. The next largest pyramid was that of Khafra or Chefren, the successor of Cheops, though it does not contain his name. It measures 700 feet square at the base and is about 450 feet high. The sepulchral chamber is 46½ by 16⅓ by 22½ feet. It was opened and explored by Belzoni in 1816. The third pyramid of Gîzeh belonged to Menkara or Mycerinus, the fourth king of the same dynasty. The statement of Manetho that it belonged to Nitocris is undoubtedly incorrect, as the sarcophagus of Mycerinus was found inside by Col. Vyse in 1837. It is conjectured that it was left unfinished and completed by a later ruler. It was built on a sloping rock, is 350 feet square, and 210 to 215 feet high. Three smaller pyramids are near by, one of which contains the name of Mycerinus on the ceiling. About 3 miles southward are the pyramids of *Zâwyet el-'Aryân*, one of which has been almost entirely destroyed. The other must have been a large structure, as its remains are now nearly 300 feet square. At *Abusir*, about 3 miles farther S., are remains of fourteen pyramids built by Pharaohs of the fifth dynasty, only three of which were of any considerable size. One of these was built by Sahura, second king, and measures 117 feet high and 217 feet square. Another is 165 feet high, and 324 feet square at the base; builder unknown. Next are the pyramids of *Saqqarah*, of which that known as the Step Pyramid is the most noteworthy. It is supposed to have been built by Ata, the fourth king of the first dynasty, though its date can not be fixed. At all events, it is supposed to be older than the pyramids at Gîzeh. It rises by six steps which vary from 38 to 29½ feet in height, separated by ledges from 6 to 7 feet wide. The north and south sides are 352 feet long, and the east and west sides 396 feet; the height is 197 feet. It is not well oriented. A short distance to the S. W. is the pyramid of Unas, the last king of the fifth dynasty. It is 62 feet high and 220 feet square. When explored by Maspero in 1881 the sarcophagus and bones of Unas were found inside. In view of the uninscribed condition of the pyramids previously explored, it was a startling discovery to find the walls of two chambers and of two corridors covered with ritual prayers and religious texts. (See Egyptian Language and Literature.) Similar was the pyramid of Teta, the first king of the sixth dynasty, a little to the N. E. of the Step Pyramid. It is 59 feet high, 210 feet square, and has a platform at the top 50 feet square. It also contained texts in hieroglyphs which were painted green. Farther to the S. is the pyramid of Pepi I., the second king of the sixth dynasty, which was opened in 1880. It is 250 feet square and only 40 feet high. The sarcophagus of Pepi was found broken, surrounded by pieces of the mummy. This pyramid was also inscribed with similar texts. The name given to it was Men-nefer, pleasant dwelling, the original of the name of Memphis (*q. v.*). Near by is the Mastaba Far'ûn (mastaba of Pharaoh), which was supposed by Mariette to have belonged to Unas of the fifth dynasty. Ruins of several other pyramids are found in the group of Saqqarah. At *Dahshûr*, 3½ miles farther S., there are six pyramids, four of stone and two of brick. Two of the former are of immense size, rivaling those of Gîzeh, being respectively 700 and 620 feet square and 326 and 321 feet high. The latter is known as the Blunted Pyramid, on account of a break in the original angle of construction. The brick pyramids are respectively 350 and 343 feet square, and 90 and 156 feet high. Originally they were covered with a facing of stone. There are also some structures of less importance at *Lisht*, a few miles farther S. The False Pyramid of *Mêdûm* is so called because, unlike the rest, it rises in three sections, 69, 20½, and (originally 32) now about 25 feet high. It was never completed. Recent excavations show that it was constructed by Snofru (Gr. Soris, *q. v.*), the first king of the fourth dynasty, making it the oldest dated pyramid. Connected with it was the oldest Egyptian temple known to us, dating from the same reign. The pyramid at *Illahûn*, at the mouth of the Fayum, was the work of Usertasen II. (Sesostris of Manetho), the third king of the twelfth dynasty. Another at *Hawâra*, a little to the W., was erected by Amenemha III., the fifth king of the same dynasty. At *El-Kulah*, near Esneh above Thebes, is a pyramid which has the appearance of steps, owing to the decay of the coating material. It is undated and is of small importance, having a base of only 55 feet square and a height of 30 feet. The pyramids of *Ethiopia* (see Meroë) were simply late imitations of Egyptian structures. The literature of the subject is extensive, but somewhat scattered. Following are some of the important works: Maspero, *Egyptian Archæology*, translated by Edwards (London and New York, 1887); Perring, *Pyramids of Gizeh* (3 vols., London, 1839–42); Vyse, *Operations at the Pyramids of Gizeh* (2 vols., London, 1840–42); Petrie, *Pyramids and Temples of Gizeh* (London, 1887); *Season in Egypt* (London, 1888); *Hawara* (London, 1889); *Kahun* (London, 1890); *Illahun* (London, 1891). Guide-books, such as those of Baedeker, Murray, and Meyer, contain much detailed information. See Mexican Antiquities.

Charles R. Gillett.

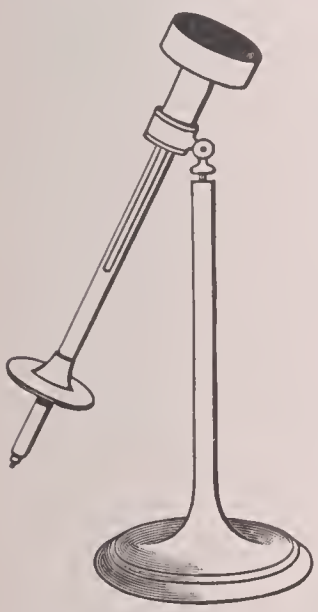
Pyrene, or **Phenylene-Naphthalene** [*pyrene* is from Gr. πῦρ, fire]: a solid hydro-carbon, whose formula is $C_{16}H_{10} = C_{10}H_6(C_6H_4)$. It occurs with chrysene in the last portions of the distillate obtained in distilling coal-tar to coke. The two bodies are separated by means of carbon disulphide, which dissolves the pyrene and leaves the chrysene. The carbon disulphide is distilled off, and the residue is repeatedly extracted with warm alcohol, and the cooled solution is mixed with an alcoholic solution of picric acid as long as a crystalline precipitate of pyrene picrate is produced. The precipitate is washed with alcohol, decomposed by am-

monia, washed with water, and recrystallized from alcohol till the melting-point is constant at 142° to 144° C. Pyrene crystallizes from hot alcohol in laminæ resembling those of anthracene. It is usually yellow from impurities, but may be decolorized by exposing the solution in benzene to sunlight. It is very soluble in benzene, ether, and carbon disulphide. It melts at 142° C., and distills at a temperature considerably above 360° C. Revised by IRA REMSEN.

Pyrenees [from Lat. *Pyrenæ'i* (sc. *mon'tes*, mountains), masc. plur. adj., Pyrenean, the Pyrenees, deriv. of *Pyre'ne* = Gr. Πυρήνη, the Pyrences]: a lofty mountain system, chiefly granite, overlaid by sedimentary strata, which forms the boundary between France and Spain, and stretches from the Mediterranean to the Bay of Biscay. Its entire length is 240 miles, its average breadth is about 75 miles. It is broadest and highest about midway, where the two almost parallel ranges of which the mountains consist are connected by a number of wild, towering peaks, of which the highest are Pic de Nethou, 11,168 feet; Mont Perdu, 10,997 feet; Vignemale, 10,820 feet; and Pic du Midi, 9,540 feet. In their eastern course, toward the Mediterranean, the Pyrenees fall rapidly to an average height of 2,000 feet, while the western part retains an average height of 5,000 feet, with many peaks rising 8,000 feet. Northward, toward France, the Pyrenees slope gradually, sending out forest-clad offshoots which inclose beautiful valleys; southward, toward Spain, they present steep, abrupt, and barren but bold and picturesque slopes. There are seven passes at an elevation of over 7,000 feet, making the Pyrenees notable for the great height of its passes in proportion to the height of the mountains. Revised by C. C. ADAMS.

Pyrenomyce'teæ [Mod. Lat.; Gr. πυρήν, stone of a fruit + μύκης, plur. μύκητες, mushroom]: an order of ascomycetous parasitic and saprophytic plants commonly known as the black fungi. Their ascospores are produced in sacs (*asci*), in usually hard-walled cavities (*perithecia*); conidia are produced singly or in clusters upon superficial threads. The common PLUM-KNOT (*q. v.*; *Plowrightia morbosa*) is a good example. See FUNGI. CHARLES E. BESSEY.

Pyrheliometer [Gr. πῦρ, fire + ἥλιος, sun + μέτρον, measure]: an instrument invented by Pouillet for measuring the heat received at the earth's surface from the sun. The requisites for such a determination are a surface of known size, the absorption coefficient of which is also known, together with a calorimetric device for measuring the energy thus transformed. Pouillet's instrument consisted of an inverted thermometer, the bulb of which was surrounded by a flat cylindrical closed vessel of silver foil. This contained a known quantity of water. Its upper surface was blackened by a coating of lampblack so as to raise its absorbing power to the highest point. The pyrheliometer was mounted (see illustration) so that its axis could be set parallel to the sun's rays. The lower disk (to the left in the illustration) was designed to facilitate this adjustment, since it was only necessary to bring it entirely within the shadow of the cylinder. E. L. NICHOLS.



Pyridine (C_5H_5N): an oily base found in bone oil, shale oil, peat-tar, coal-naphtha, and the products of the destructive distillation of cinchonine. It was discovered by Anderson, together with a number of other similar bases, in 1851, in bone-oil. It occurs in tobacco-smoke. It is produced artificially by the dehydration of amyl nitrate, by heating piperidine with nitrobenzene, and together with other similar substances by heating glycerin with ammonium sulphate and sulphuric acid. In medicine it has been used in the treatment of asthma by placing a few minims on a warm shovel or metal plate so that it is volatilized in the air of the room at some distance from the patient. The patient should not be exposed to the fumes for more than twenty minutes, three times a day. Revised by IRA REMSEN.

Pyri'tes [Lat. = Gr. πυρίτης, flint, a stone that strikes fire, deriv. of πῦρ, fire]: in its widest sense, a native mineral, massive or crystalline, composed of a metallic sulphide or arsenide, or both. Iron, copper, nickel, and cobalt pyrites are the ones generally mentioned. Iron pyrites is often found crystallized in cubes or in other forms. It is sometimes massive, and occasionally globular. From its bright-yellow color it is sometimes mistaken for gold. It is a more or less pure iron bisulphide. It is of great value for the manufacture of sulphuric acid and the sulphates and other commercial sulphur compounds. It also yields not unfrequently a considerable amount of silver, copper, or gold. Chemical reagents derived even remotely from it are apt to contain appreciable amounts of arsenic. Copper pyrites is an impure double sulphide of iron and copper. It is extensively employed, not only as a source of sulphuric acid, but of metallic copper.

Pyro-acetic Spirit: See ACETONE.

Pyrogal'lol, called also **Pyrogallic Acid** [*pyrogallic* is from Gr. πῦρ, fire + Eng. *gallic*]: a substance discovered by Scheele by subliming gallic acid of gallnuts, but considered by him to be identical with it. Leopold Gmelin and Braconnot proved it to be a peculiar substance. It forms a beautiful mass of snow-white crystals, extremely light and feathery. As it has been shown to belong to the class of bodies known as PHENOLS (*q. v.*), its name has been changed from pyrogallic acid to pyrogallol. Its formation from gallic acid by the action of heat is represented thus:

Gallic acid. Pyrogallol.

$$C_7H_6O_5 = C_6H_6O_3 + CO_2.$$

Pyrogallol is a useful reagent in the laboratory, by reason of the fact that in the presence of alkaline substances it unites readily with atmospheric oxygen at ordinary temperatures; it was therefore proposed by Liebig as an agent in analysis of gaseous mixtures containing oxygen, a method since in universal use. Revised by IRA REMSEN.

Pyr'ola [Mod. Lat., properly *Pir'ola*, dimin. of Lat. *pi'rus*, pear-tree; named from the aspect of its leaves]: a genus of *Pyroleæ*, a tribe of the *Ericaceæ* or HEATH FAMILY (*q. v.*), characterized by a calyx free from the ovary; the corolla polypetalous; anthers extrorse in the bud; seeds with a loose and translucent cellular coat much larger than the body. The species are nearly herbaceous and evergreen, with broad leaves. The tribe contains also *Moneses* and *Chimaphila*, the latter including the pipsissewa. CHARLES E. BESSEY.

Pyrolig'neous Acid [*pyroligneous* is from Gr. πῦρ, fire + Lat. *lig'num*, wood]: a name often applied to impure acetic acid produced by the distillation of wood. It contains empyreumatic tarry matter, which gives it a dark color and peculiar smell. These impurities, however, may be completely removed.

Pyrom'eter [from Gr. πῦρ, fire + μέτρον, measure]: an instrument for the measurement of high temperatures. The term is applied particularly to apparatus for the determination of the temperature of furnaces and flues. Pyrometry, which has to do with the range of temperatures lying above the red heat, involves great experimental difficulties, and, in spite of the large amount of labor expended upon it, remains in an unsatisfactory state. Pyrometers may be classified in general as *expansion pyrometers* and *electrical pyrometers*. The acoustical pyrometer, suggested by Preston (*Philos. Magazine*, July, 1891) and described in modified form by Sanford (*Physical Review*, p. 140), may furnish a third type, but it is an instrument about which no experimental data are as yet to be had. The only substances available for expansion pyrometers are (1) highly refractory solids and (2) gases inclosed in a refractory and gas-tight bulb or reservoir. The best-known instruments of the first class are the pyrometers designed by Josiah Wedgwood (1782) for the measurement of kiln-temperatures in his celebrated potteries, and by Daniell. The Wedgwood pyrometer, which depended upon the changes in a clay cylinder when subjected to the heat of the furnace, was unreliable, except, possibly, as an arbitrary indicator of the approximate degree of incandescence. Daniell used the relative expansions of a platinum and an earthen bar, and obtained more consistent results.

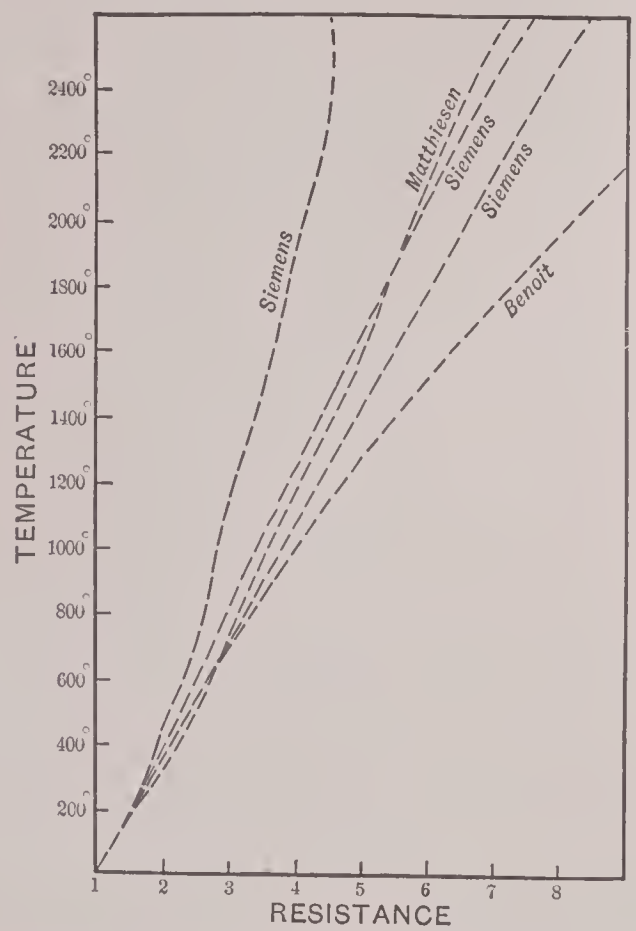
Various gas-thermometers have been used for high temperature measurements, and it is by means of this class of instruments that the most satisfactory absolute determinations have been made. Hydrogen, air, mercury, and iodine are among the gases and vapors thus employed; copper, iron, platinum, and porcelain among the materials for bulbs and reservoirs. Experience has shown that nearly all sub-

stances, with the possible exception of porcelain, become porous at extremely high temperatures, and this fact constitutes an almost insuperable difficulty in the execution of pyrometric measurements with the air-thermometer.

Some observers with pyrometric gas-thermometers have followed methods analogous to those in vogue for the measurement of ordinary temperatures. Others have employed various ingenious indirect methods for the determination of the contents of the bulb. Thus Regnault, working with a reservoir of hydrogen in the computation of furnace-temperatures, passed the gas over cupric oxide and determined the amount of water thus produced. The mercury in his mercury-vapor thermometer the same investigator estimated by weighing the mercury condensed within the cooled bulb. Deville, also, determined the amount of iodine vapor contained in a porcelain bulb at a high temperature by subsequent weighings.

The laborious character of operations with the air-thermometer has led later investigators to adopt the more manageable methods of pyrometry based upon thermo-electricity and the influence of temperature upon electrical resistance. The only metals available for either of these methods are platinum and the rare metals belonging to the same family. Iron is excluded on account of its oxidizability, even in many measurements in which its melting-point would be outside the range of experimentation.

The influence of temperature upon the resistance of platinum was exhaustively studied by C. W. Siemens with a view to the use of this property in pyrometry. The results were not altogether encouraging, it being evident that no general law could be laid down which would be applicable to all specimens, even when every ordinary care was taken with reference to the purity of the metal. The diagram,



constructed from the measurements of Siemens and others, is intended to show graphically the wide divergences which would arise from the attempt to use any single empirical formula for different specimens of platinum.

The diagram, the abscissas of which are resistances, while the ordinates are temperatures, is plotted from formulas obtained by Benoit and by Matthiesen, and from three separate results obtained by Siemens with different samples of platinum. It will be seen that the discrepancies amount to many hundreds of degrees. Later experience in the production of platinum has made it possible to eliminate some of the impurities to which the differences are due, but accuracy is still to be secured only by the direct calibration of each specimen.

Thermo-electric couples consisting of platinum and one of the alloys of platinum with one of the kindred metals, such as iridium or rhodium, afford a means of measuring high temperatures which is probably less open to objection than any other as yet devised. Couples containing commercial platinum will, it is true, show variations similar to those which characterize the curves of temperature and resistance, but modern methods of purifying platinum have made it possible, as Barns has demonstrated, to produce the metal and its alloys in such condition that the curve for electromotive force and temperatures remains virtually a straight line up to the melting-point of platinum.

The wide discrepancies between the results obtained by different observers and in the use of the different methods would leave the subject of pyrometry in confusion were it not that the melting temperatures of the metals afford fixed points of reference by which we can institute rigorous relative comparison of the above methods with other more indirect determinations—e. g. those based upon the constancy of the specific heat of copper or of platinum, or upon assumed laws of radiating power as a function of the temperature.

By means of such comparisons certain very different methods are found to give concordant results, while others, the claims of which, taken by themselves, would seem to be quite as strong, are not accordant. Thus there has gradually been established a set of values running up to the melting-points of silver, gold, and copper upon which great weight is laid. Above 1,100° C., however, pyrometry is still very far from being an exact science. See further, Barns, *Measurement of High Temperatures*; Guillaume, *Thermométrie de Précision*: Becquerel, *Comptes Rendus*. Deville and Troost, *Annales de Chimie*, vol. iii., 58; Regnault, *ibid.*, vol. iii., 63; Daniell, *Quarterly Journal of Science*, 11 (1821); Wedgwood, *Phil. Transactions*, 72, 74, and 76.

E. L. Nichols.

Pyr'ope [from Gr. πυρωπός, a kind of red bronze, liter., adj. fiery-eyed; πῦρ, fire + ὤψ, ὠπός, eye]: the precious garnet, a fine dark-red garnet, much used in jewelry, and incorrectly called hyacinth, ruby, and carbuncle. It comes from Ceylon, Germany, Scotland, etc. See Garnet.

Pyroph'ori [Mod. Lat.; Gr. πῦρ, fire + φέρειν, bear]: a term applied generally to some substances which kindle spontaneously and enter into combustion when exposed to the air, the term being confined, however, to solid substances, and not applied to spontaneously inflammable liquids. Carbon, phosphorus, and many easily oxidable metals may be made pyrophoric by preparation in a state of extreme division. "Homberg's pyrophorus" is formed by mixing intimately alum and sugar, drying and charring first in an open pan, then igniting in a closed vessel. Phosphorus, when left by evaporation of its solutions in very volatile liquids, like bisulphide of carbon, is pyrophoric. Iron may be obtained in pyrophoric form by many methods, even by simple reduction of the oxide with hydrogen gas at a minimum temperature. A lead pyrophorus is obtained by charring dry tartrate of lead in a close tube. If, after cooling, the tube be crushed, a beautiful shower of fire, metallic lead and carbon in combustion, makes its appearance. Some common lignites, very finely pulverized and thoroughly dried by heat, are pyrophoric when warm. Numerous other cases are described in chemical works.

Pyrophosphates: See Phosphoric Acid.

Pyrophosphoric Acid: See Phosphoric Acid.

Pyro'sis [Mod. Lat., from Gr. πύρωσις, burning, inflammation, deriv. of πυροῦν, to burn, deriv. of πῦρ, fire]: an affection of the stomach characterized by the regurgitation of a considerable quantity of liquid when the stomach is empty of food. The liquid expelled may be insipid to the taste or saltish, and it is sometimes acid. It is not vomited, but regurgitated, and the regurgitation is not accompanied by the sense of nausea which usually attends acts of vomiting. The popular name for the affection is water-brash. The regurgitation takes place especially in the morning, before food has been taken. A sensation of burning is generally felt in the region of the stomach, and frequently in the throat during and after the passage of the liquid. This burning sensation is implied in the name *pyrosis*. The regurgitation in pyrosis is to be distinguished from that of food or drink which has been taken into the stomach in other cases of dyspepsia. The liquid regurgitated in pyrosis is the morbid product of secretion from the glands of the stomach, the abnormality as a rule consisting in excessive acidity of the gastric juice. The affection occurs oftener in

women than in men, and is somewhat dependent on disturbance of the nervous system. Persons living on a poor, insufficient diet are more likely to suffer from it than those who live well or generously. It is not a grave affection, nor does it denote a tendency to any important disease in the stomach or elsewhere. It is generally relieved very speedily by the carbonate or subnitrate of bismuth in doses of from 20 to 30 grains, given twice or thrice daily. The treatment, in other respects, embraces the use of tonic remedies, nutritious alimentation, and hygienic influences to invigorate the system. Revised by W. PEPPER.

Pyrotechny [Gr. πῦρ, fire + τέχνη, art]: the art of making fireworks for the purpose of amusement or for signals. The methods in use have been developed almost independently of the direct aid of science, and largely "by rule of thumb." Fireworks are said to have originated in the East. It is certain that there were firework displays in China centuries before their introduction into Europe, and the Chinese and Japanese still excel in some branches of the art. The subject of pyrotechny covers both the mechanical and chemical branches. For the purposes of this article it is only necessary to treat briefly of the chemical features. All fireworks contain a substance or mixture of substances capable of burning, and therefore called the *fuel*, and a substance or substances rich in oxygen. Among the substances used as fuel the following may be mentioned: Sulphur, charcoal, shell-lac, resin, pitch. The chief supporters of combustion, or oxygen compounds, employed are saltpeter (potassium nitrate) and chlorate of potash (potassium chlorate). For the production of colored lights and stars different substances are introduced into the filling. The accompanying table gives the names of the substances and the proportions in which they should be mixed to produce red, green, blue, yellow, and white:

SUBSTANCES.	Red.	Green.	Blue.	Yellow.	White.
Potassium chlorate	2	..	5	4	..
Sulphur	2	1	2	..	4
Charcoal	1	..	..	..	..
Shell-lac	..	3	1	1	..
Calomel	..	..	2	..	..
Magnesium filings	2	2	2	1	2
Strontium nitrate	8	..	..	..	..
Barium chlorate	..	12	..	..	..
Copper oxychloride	..	..	2	..	..
Sodium oxalate	..	..	..	2	..
Potassium nitrate	..	..	..	..	12
Antimony sulphide	..	..	..	..	1

Iron-filings are frequently introduced into the mixtures to cause brilliant scintillations; long filings or those made with a coarse file are preferred. The famous Bengal lights are made with niter, 7 parts; sulphur, 2; antimony sulphide, 1. Rocket and Roman-candle stars are compressed portions of the powder. They usually contain the same constituents as ordinary gunpowder, the proportion of charcoal being somewhat reduced; steel-filings are sometimes added. Camphor, gum benzoin, and storax are frequently mixed with the powders to give an aromatic odor and mask the unpleasant odors arising from the firing of the mixtures without such addition. See Thorpe's *Dictionary of Applied Chemistry*, vol. iii. Revised by IRA REMSEN.

Pyroxene: See AUGITE.

Pyroxylic Spirit: See METHYL ALCOHOL.

Pyrox'ylin [Gr. πῦρ, fire + ξύλον, wood]: the technical name for guncotton. (See EXPLOSIVES.) When cellulose (cotton) is treated with concentrated nitric and sulphuric acids, it undergoes changes of the same kind as those effected in glycerin by the action of these acids. Different products are obtained, according to the strength of the acids, the temperature, and the time. The final product is the *hexanitrate*, $C_{12}H_{14}(NO_3)_6O_4$. Other products are the *pentanitrate*, $C_{12}H_{15}(NO_3)_5O_6$, the *tetra-*, *tri-*, and *di-nitrates*. The hexanitrate is the most explosive and is the true guncotton. It is made by treating dried cotton for twenty-four hours at 10° C. with a mixture of 1 volume nitric acid (sp. gr. 1·5) and 3 volumes sulphuric (sp. gr. 1·845). The lower nitrates are used for making COLLODION (*q. v.*) for photographic purposes. These are principally the tetra- and pentanitrates, which are made by using less concentrated nitric acid and a somewhat higher temperature than in the manufacture of guncotton. Among the directions given for its preparation is the following: Add 1 part cotton to a mixture of 20 parts saltpeter and 31 parts sulphuric acid (sp. gr. 1·830–1·835), the temperature of the mixture not above 50° C. The whole is allowed to stand twenty-four hours at 28–30° C., and then washed with water. The product dissolves in a mixture of 7 to 8 parts ordinary ether and 1 part alcohol. It is mainly the tetranitrate. "The pyroxilin made from tissue-paper for the celluloid manufacturers is made by taking 50 cubic cm. of nitric acid of 1·47 specific gravity, 100 cubic cm. nitric acid of 1·36 specific gravity, and 100 cubic cm. of sulphuric acid of 1·84 specific gravity. In this mixture 18 grammes of the finely shredded tissue-paper are immersed at a temperature of 55° C. for one hour. The paper gains about 40 per cent. in weight in the nitration" (*Sadtler*). IRA REMSEN.

Pyrrha: See DEUCALION.

Pyr'rhic Dance (in Gr. Πυρρίχη ὄρχησις): a Grecian war-dance in full armor. It originated in Dorian Crete, where its prototype was the dance instituted by the Curetes to drown the cries of the infant Zeus, though the Spartans referred it to Castor and Pollux, and the Athenians to Dionysus and Athene. It was a mimic fight, intended to illustrate the art of attack and defense. It became popular in imperial Rome. J. R. S. STERRETT.

Pyrrho of Elis: Greek philosopher 365–275 B. C.; founder of the skeptical school of philosophy and still used as a type of the doubting spirits. Nothing left in writing. See Ch. Waddington, *Pyrrhon et le pyrrhonisme* (Paris, 1877).

Pyrrhus [= Lat. = Gr. Πυρρός, liter., fire-colored, red-headed, deriv. of πῦρ, fire]: 1. Another name for Neoptolemus, the son of Achilles and Deidamia. 2. A king of Epirus, who claimed descent from Achilles through Neoptolemus. He was born in 318 B. C. of Æacides and Phthia. Æacides was banished when Pyrrhus was two years old, but trusty servants saved Pyrrhus and brought him to the court of Glaucias, King of the Taulantians. In 307 Glaucias succeeded in placing the boy on the throne, but in 302 he was banished, fled to Demetrius Poliorcetes, distinguished himself in the battle of Ipsus in 301, betook himself to Egypt, married the stepdaughter of Ptolemy, received money and troops from Ptolemy, and in 295 once again became King of all Epirus. He then embarked with varying fortune in wars against the neighboring princes, including Demetrius, King of Macedonia. In 287 he became King of Macedonia also in the stead of the fallen Demetrius, but soon lost it to Lysimachus. In 281 he espoused the cause of the Tarentines against Rome, and in 280 landed in Tarentum with 25,000 troops and 20 elephants, won in the battle on the Siris, advanced upon Rome, and won again at Asculum in 279. But when Rome and Carthage combined against him he abandoned Italy and applied himself to the conquest of Sicily, where at first he was received with joy and fought with success, but when he encountered the firm resistance of the Carthaginians at Lilybæum, the fickle Sicilians abandoned his cause for that of Carthage. In disgust he evacuated Sicily and returned to Italy in 276, after his fleet had been defeated by the Carthaginians, and in 275 he was utterly defeated by M. Curius Dentatus at Beneventum. Collecting the remnants of his army, he returned to Epirus in 274, leaving at Tarentum a garrison. He then attacked Antigonus of Macedonia and actually annexed a large part of that kingdom. In 272 he undertook the conquest of the Peloponnesus at the call of Cleonymus, King of Sparta; he attacked Sparta, was repulsed, retreated to Argos, where he was met by the forces of Antigonus of Macedonia; a fight ensued in the streets of Argos; Pyrrhus was knocked senseless by a brick hurled from a housetop by the mother of a man whom Pyrrhus was about to kill. He was then dispatched by one of the soldiers of Antigonus in 272 B. C.
J. R. S. STERRETT.

Pyrus: a genus of rosaceous trees and shrubs of some fifty species, among which are the APPLE, PEAR, and QUINCE (*qq. v.*).

Pythag'oras: a Greek philosopher, supposed to have been born at Samos about 582 B. C.; to have been the son of Mnesarchus; his earliest teacher to have been Pherecydes the Syrian, from whom he may have received Egyptian and Zoroastrian lore; his next teacher to have been Anaximander, who taught that the principle (ἀρχή) of things is the unlimited or indefinite (ἄπειρον); in early life to have traveled through Ionia, Phœnicia, and Egypt, where he was initiated into the mysteries by the priests. Some would have it that he was even carried away to Babylon, with other Egyptian prisoners, by Cambyses, who made his raid on Egypt in the year 525 B. C.; but the weight of authority

favors the view that he repaired to Crotona, in Lower Italy, 529 B. C., and there established a society with ethical, political, and philosophic tendencies. His school was allied with the aristocratic party, and consequently incurred the animosity of the democratic party. This occasioned (about 510 B. C.) the retirement of Pythagoras to Metapontum, where he died soon after. His school spread rapidly, and, after the manner of Oriental systems, was semi-ethical and religious, semi-political and social, tending to produce a fusion of state and hierarchy. It has bequeathed to us a multitude of philosophemes on mathematics, music, and astronomy, as well as on ethics. The doctrines of metempsychosis, of the cyclic return of events, of contraries (*ἐναντίαι*) —according to which he added to the principle of his master, Anaximander (which was "the unlimited"), its opposite, the limiting (*περαίνοντα*)—indicate Persian or Egyptian influence. This Oriental tendency may have had another origin than those named (his teachers or his travels), so far as the writings of his school are concerned (for no writing of the master has come down to us), in the Crotonian school of medicine, of whom Democedes, the celebrated physician, had resided at the Persian court under Darius. What belongs to the disciples and what to the master can not be told. Pythagoras is said to have anticipated the Copernican doctrine, making the sun the center of the cosmos; also to have discovered the numerical ratio existing between musical tones of the gamut (either by length of strings or by their degrees of tension). He is famous, according to Aristotle and subsequent writers, for his doctrine that "number is the principle of all things, and that the organization of the universe is an harmonic system of numerical ratios"; but this may be the doctrine of the Pythagoreans rather than of the founder of the school. There is, however, less doubt as to the fact that he sought to establish a new ethical basis for society in place of the unconscious use and wont that had prevailed up to his epoch. He laid the greatest stress on the discipline of the will into obedience, temperance, silence, self-examination, simplicity in personal attire, and self-restraint in all its forms. The original sources of information regarding him are Aristotle (*Met.*, i., 5; *Phys.*, iii., 4; *De Cœlo*, ii., 13 and 9; *Eth. Nic.*, v., 8), the writings of Aristotelian commentators, Herodotus (ii., 81; iv., 94–96, etc.), and the (mostly spurious) writings of his disciples, Philolaus, Ocellus Lucanus, Timæus Locrus, Archytes of Tarentum, Epicharmus, and the Neo-Platonists Iamblichus and Porphyry; Diodorus Siculus and Diogenes Lærtius are to be added to this list. W. T. Harris.

Pytheas (in Gr. *Πυθέας*): 1. An Athenian orator and antagonist of Demosthenes. 2. A native of Massilia (Marseilles), a geographer and navigator, who in the time of Alexander the Great made two voyages of discovery along the western and northwestern coasts of Europe from Gibraltar to Iceland. His accounts of his travels were received by the ancients with incredulity and disgust as being fables, but it is now known that they were in the main correct. His books, the chief of which was *τὰ περὶ ὠκεανοῦ*, are known only from the adverse criticism of later writers.

J. R. S. Sterrett.

Pyth'ia (in Gr. *Πυθία*): the priestess of the Pythian Apollo in Delphi. In early times this priestess was a virgin, but later on she was a married woman, more than fifty years of age, dressed as a virgin. There were two regular priestesses with an assistant, who acted as priestess in case of emergency. Clothed in long rich robes and with golden ornaments in her hair, the Pythia, after prayer, sacrifice, and the required purifications had been duly performed, took her seat upon the sacred tripod, which stood over the Castalian spring. The vapors that ascended from this spring, sacred to Apollo, were supposed to inspire her answer. The response of the god through the Pythia was usually couched in hexameters, though official versifiers stood ready to turn the answers into verse in case the Pythia made use of prose. In later times the response of the god was given regularly in prose. J. R. S. Sterrett.

Pythian Games [Gr. *τὰ Πύθια*, deriv. of *Πυθώ*, Pytho or Delphi]: festivals held late in August of the third year of each Olympiad at Delphi, in Phocis, in honor of Apollo, who established them in commemoration of his victory over the Python, a frightful dragon that lived on Mt. Parnassus. Originally the contests were purely musical, and consisted of songs accompanied by the lyre and by the flute, together with contests on the flute alone. After the sacred war (355–346 B. C.) the festivals were conducted under the direction of the Amphictyonic Council. A day devoted to athletic sports similar to those held at Olympia was added and by degrees various forms of horse races and chariot races were introduced. See Delphi, Olympian Games, and Mommsen, *Delphika*. B. B. Holmes.

Pyth'ias: See Damon and Pythias.

Python: See Boa.

Pyx [from Lat. *py'xis* = Gr. *πυξίς*, box, liter., a boxwood box, deriv. of *πύξος*, boxwood]: (1) a sacred vessel, having usually the form of a covered cup with a foot, used in the Roman Catholic Church to contain the sacred wafer when preserved after consecration; (2) the strong box used in the mint for the safe keeping of coins set apart from each successive coinage to be examined by a commission of experts for the purpose of testing their accuracy as to weight and fineness.

The examination of these reserved coins is called the "trial of the pyx," and in Great Britain this trial takes place "at least once in every year in which coins have been issued from the mint" before a sworn jury of at least six goldsmiths. Should the coins have been found accurate in weight and fineness within the limits allowed by law, commonly called *tolerance* or *remedy*, no further proceedings are taken; but in case the coinage in either or both these respects be found inexact, the officers of the mint are liable to censure or more serious penalties.

In the U. S. it is provided that a trial of the pyx shall be made at the mint in Philadelphia on the second Wednesday in February, annually. This takes place before the judge of the district court of the U. S. for the eastern district of Pennsylvania, the comptroller of the currency, the assayer of the New York assay-office, and other persons designated by the President. A majority of the commissioners constitute a competent board. Their examination is to be made in the presence of the director of the mint. The reserved coins from the coinage of other mints besides that at Philadelphia are transmitted quarterly to the Philadelphia mint; and in addition to these the director may at pleasure take any other pieces as tests. If the coins are within the limits of tolerance in fineness and weight, their report is simply filed; but if deviation in either or both respects is discovered, exceeding the limits of tolerance, the fact is to be certified to the President of the U. S., and "if, on a view of the circumstances of the case, he shall so decide, the officer or officers implicated in the error are thenceforward disqualified from holding their respective offices."

Q

: the seventeenth letter of the English alphabet.

Form.—The form is derived through the Latin alphabet from the Greek koppa Ϙ. This letter was used in the older Greek writing to indicate the velar or back-guttural sound of *k* occurring before the vowels *o* and *u*. From about 525 B. C. onward it was gradually displaced by kappa, and finally passed entirely out of use except as a numeral sign (= 90). The Semitic form of the letter was ϕ.

Name.—The Greek name koppa or qoppa (Ϙόππα) is an adaptation of the Semitic name *Qoph*, meaning head, back of head. This name was doubtless chosen analogously with the other letter-names, both because of the fancied resemblance of the letter to the human head and neck and because the sound of the letter was initial in the name. The English name *kyoo* (i. e. *kyū*), of which the variant *kyoof* occurs, is successor to O. French *cu*, Lat. *qu*.

Sound.—The letter occurs in English only in the combination *qu*, which generally has the sound *kw*, as in *quite*, *queen*, *equal*. This is a labialized guttural explosive, a single sound in which the *k*-position and the *w*-position are formed simultaneously and not successively; cf. *tw* in *twice*. The digraph *qu* stands for simple *k* in many late loan-words from the French, as *coquette*, *etiquette*, *piquant*, *grotesque*, *critique*, *bouquet*.

Source.—When it has the value *kw* the digraph *qu* commonly represents either (1) O. Eng. *cw* < Indo-Europ. *g* (velar-guttural); thus *queen* < O. Eng. *cwene*, cf. Sanskr. *gnā*, Gr. γυνή; *quick* < O. Eng. *cwic*, cf. Lat. *vivus*, Sanskr. *jivá-*; or (2) O. Fr. *qu* in loan-words which entered English before the French *qu* became *k*; thus *quart*, *quit*, *quarrel*, *quest*, *bequest*.

Symbolism.—Q = Quintus, question, farthing (*quadrans*); Q. d. = as if he should say (*quasi dicat*); Q. e. = which is (*quod est*); Q. E. D. = which was to be proved (*quod erat demonstrandum*); Q. v. = which see (*quod vide*).

BENJ. IDE WHEELER.

Qua-bird, or **Quawk**: the NIGHT-HERON (*q. v.*).

Quadrages'ima [= Lat., fortieth]: a name for LENT (*q. v.*), or for the first Sunday in Lent.

Quadrant [from Lat. *qua'drans*, *quadran'tis*, a fourth part, fourth of a whole, deriv. of *quat'tuor*, four]: in its common signification, a quarter of the circumference of a circle, or ninety degrees; in navigation and astronomy, an instrument for measuring angles, having a limb divided to ninety degrees. Astronomical quadrants of large dimensions were employed by the early observers for measuring meridian altitudes, being for this purpose firmly fixed in the plane of the meridian, but they were superseded by the mural circle, which, in its turn, has given way to the transit circle. In navigation the quadrant is superseded by the sextant. (See SEXTANT.) The invention of the quadrant is commonly ascribed to John Halley, a friend of Newton, on the ground that the instrument was first described by him in a paper read before the Royal Society in 1731, but the invention was independently made in 1730 by Thomas Godfrey, of Philadelphia, whose description was given to the same society in 1732; and the society decided the honor of the invention to belong equally to both. The real originator, however, of the ingenious idea on which the invention is founded was Sir Isaac Newton, who so early as 1727 communicated it to Halley, then astronomer-royal, in a paper which came to light only after the death of the latter in 1742.

Revised by S. NEWCOMB.

Quadratic Equation [*quadratic* is from Lat. *quadra'tus*, squared, deriv. of *quadra're*, make square, (in math.) square, deriv. of *quat'tuor*, four]: an equation of the second degree, containing but one unknown quantity. Every quadratic equation may be reduced to the form

$$x^2 + 2px = q, \qquad (1)$$

in which expression p and q represent known quantities; and when it has been so reduced the two roots of the equation are

$$-p + \sqrt{q + p^2}, \text{ and } -p - \sqrt{q + p^2}. \qquad (2)$$

If $q < p^2$, the roots are both real; if q is negative, and numerically equal to p^2, the two roots are equal; if q is negative, and numerically greater than p^2, both roots are imaginary. If p is equal to 0, the equation is said to be incomplete, and its roots are then numerically equal with contrary signs; in this case the roots are real when q is positive and imaginary when q is negative. The following properties are common to all quadratic equations, after being reduced to the form (1): (1) Every quadratic has two roots and only two. (2) If all the terms are transposed to one member, that member can be resolved into two factors of the first degree with respect to the unknown quantity, the first term of each factor being the unknown quantity and the second terms being the two roots, each taken with a contrary sign. (3) The algebraic sum of the two roots is equal to the coefficient of the second term with its sign changed. (4) The product of the two roots is equal to the second member with its sign changed. (5) If the second term is negative, and numerically greater than the square of half the coefficient of the second term, both of the roots are imaginary. See EQUATION and IMAGINARY QUANTITIES.

Quadrature [from Late Lat. *quadratu'ra*, deriv. of *quadra're*, make square, reduce an area to a square]: the operation of finding an expression for the area bounded by a line or lines, straight or curved, on a plane. See MENSURATION.

Quadrature of the Circle: the geometrical problem of finding a square whose area shall be rigorously equal to that of a given circle. It is one of four celebrated problems vainly attacked by the ancients, the other three being (1) the duplication of the cube, or the construction of a line the cube of which shall be double that of a given line; (2) the trisection of an angle; and (3) the insertion of two geometric means between two given lines. All of these problems are shown by modern mathematics to be unsolvable in the ancient sense; that is, it is shown that they can not be constructed by the ruler and compass, as problems in elementary geometry are required to be constructed by Euclid's postulates. The reasoning is very simple: No quantities can be constructed from given quantities except those which can be formed from them algebraically by the solution of quadratic equations; if the algebraic solution appears as the root of an equation of the third or higher degree, unsolvable by quadratics, then it can not be constructed geometrically.

The problem of the quadrature of the circle may be expressed in two different ways, according as an analytical or geometrical solution is required. The geometrical solution would, as we have already said, consist in constructing, by the ruler and compasses, a square which shall be equal to a given circle. The algebraic solution would consist in finding some numerical expression for the ratio between the diameter of a circle and the side of a square equal to it in area. Since the area is known to be equal to the rectangle contained by half the diameter and half the circumference, this problem amounts to the same thing as constructing a line which shall be equal in length to the circumference of a circle whose diameter is given. The question of its possibility could be settled only by showing that the numerical representation can not be made by solving a series of quadratic equations. That this is impossible has long been recognized, but never rigorously proved until the year 1882, when Lindemann, of Königsberg, showed that the ratio of the diameter to the circumference, commonly represented by the symbol π, could not be represented as the root of any algebraic equation whatever with rational coefficients.

The arithmetical solution may be expressed in two ways: (1) to construct an expression which shall represent the number π; (2) to express π to any extent by decimals. As to the first form, no expression which shall be at the same time rational and finite is possible, a result which follows at

once from Lindemann's theorem; but there are a number of infinite series which are equal to π, among which we may mention the following:

$$a = \frac{1}{2} - \frac{1}{3\cdot 2^3} + \frac{1}{5\cdot 2^5} - \frac{1}{7\cdot 2^7} + \text{etc.}$$

$$a' = \frac{1}{5} - \frac{1}{3\cdot 5^3} + \frac{1}{5\cdot 5^5} - \frac{1}{7\cdot 5^7} + \text{etc.}$$

$$a'' = \frac{1}{8} - \frac{1}{3\cdot 8^3} + \frac{1}{5\cdot 8^5} - \frac{1}{7\cdot 8^7} + \text{etc.}$$

$$\pi = 4(a + a' + a'')$$

$$b = \frac{1}{5} - \frac{1}{3\cdot 5^3} + \frac{1}{5\cdot 5^5} - \frac{1}{7\cdot 5^7} + \text{etc.}$$

$$b' = \frac{1}{239} - \frac{1}{3\cdot 239^3} + \frac{1}{5\cdot 239^5} - \text{etc.}$$

$$\pi = 16b - 4b'$$

If we attempt to represent the number π as a decimal fraction the decimals will go on without end. The practical question is simply that of computing any number of them. Various computers since the sixteenth century have made the computation to a great number of decimals, among whom the following are worthy of mention: In 1590 Ludolph von Keulen, of Leyden, computed it to thirty-five decimals. This work led to the term Ludolphean number, which the German mathematicians frequently use for π. In 1719 Lagny, a French mathematician, carried the computation to 121 decimals. During the nineteenth century Dr. Clausen, of Dorpat, calculated 250 decimals. In 1844 Dase, of Vienna, carried the computation to 200 figures. Dr. Rutherford, of London, and Shanks, of Durham, then entered into a competition in the matter, and the latter carried the computation to 607 decimals, as follows:

$\pi = 3{\cdot}14159$ 26535 89793 23846 26433

The effect of omitting the decimals which follow the six-hundredth is so slight that if the number as given were used to calculate the circumference of the entire visible universe the error would be inappreciable in the most powerful mieroseope. Revised by S. Newcomb.

Quadriga'rius, Quintus Claudius: a Roman historian of the first century B. C., who displayed a greater critical faculty than most of the early annalists. Beginning his history with the capture of Rome by the Gauls, because authentic documents for the early period were lacking, he continued it down to the time of Sulla in at least twenty-three books. For the fragments, see Peter, *Hist. Rom. Frag.*, pp. 136–151 (Leipzig, 1883). M. W.

Quadrilateral, The: the name commonly applied to the four Italian strongholds of Peschiera, Mantua, Verona, and Legnago, or to the trapezoidal-shaped territory the angles of which are indicated by these four towns. The Mincio forms its western and most important defensive line, and the Adige the eastern. From Peschiera to Verona is 15 miles, and from Mantua to Legnago 21 miles. This quadrilateral has formed the base of all military operations against Italy during almost a thousand years; its possession has been supposed to assure control of the peninsula. It has constantly been strengthened with utter disregard of expense. Austria's possession of it was a standing menace to the unification of Italy, but the alliance of the latter power with Prussia forced Austria to withdraw after the disastrous defeat at Sadowa (1866). In like manner Rustchuk, Silistria, Shumla, and Varna, form the quadrilateral of the Balkan peninsula, and were considered the main defense of Constantinople and of the Ottoman possessions in Europe until the Russo-Turkish war of 1877. It was then flanked, and the Ottoman empire conquered, although the Russians had been unable to reduce either of the four strongholds. The third or Asiatic quadrilateral was formed by Batum, Ardahan, Kars, and Baiezid at the northeast of the Ottoman possessions in Asia. All but Batum were captured by the Russians in 1877. The Treaty of Berlin ceded Batum, Ardahan, and Kars to Russia, leaving only Baiezid to the Ottomans. The four were a defensive, almost impregnable, line of fortresses rather than a real quadrilateral, though so called. E. A. Grosvenor.

Quadru'mana [Lat., four-handed; *quattuor*, four + *manus*, hand]: a name employed by Blumenbach (in 1791) as an ordinal designation for the monkeys, lemurs, and related types, man having been isolated as the representative of a peculiar order named *Bimana*. The views thus expressed were for a long time predominant, but a closer study of the structure of the forms indicated by those names has convinced almost all naturalists that they were erroneously separated, and the two types are now generally combined in one order named *Primates*, under which head man and the monkeys are combined in one sub-order (*Anthropoidea*), and contrasted with the lemurs, which constitute another sub-order (*Prosimiæ*). See Primates.

Revised by F. A. Lucas.

Quæstor [Lat. *quæstor*: Oscan, *kvaìsstur*: Umbrian, *krestur*, an ancient Italic official title, commonly associated with *quæ'rere*, search, investigate]: a magistrate of ancient Rome, appointed originally, the name would seem to imply, to assist the consuls in the detection of crime and the administration of justice, and later serving as their assistants in various capacities. Their number increased with the growth of Rome from four in 421 B. C. to twenty in the time of Sulla, and was raised to forty by Julius Cæsar, but reduced again to twenty by Augustus. The quæstorship, as being an office subordinate to a superior magistracy, was the lowest in the series of public offices (*cursus honorum*). At first it would seem that quæstors were chosen by the consuls, but from a comparatively early time (which can not be exactly determined) they were elected by the people. The duties of the quæstors may have been originally as extensive and manifold as those of the consul whom they served, but in the course of time certain special spheres of activity were assigned to them. At Rome they were charged with criminal jurisdiction (jurisdiction in civil suits falling to the prætor), with the management of the public finances and of the state archives. In the provinces the duties of the quæstor consisted in the management of financial affairs for his superior officer, at whose request or command he might also perform other tasks. Election to the quæstorship carried with it admission to the senate. G. L. Hendrickson.

Quagga: See Zebra.

Quahog, kwaw'hog, or **Quahaug** [of Am. Ind. origin]: the hard clam, *Venus mercenaria*, of the eastern coast of the U. S. See Clam.

Quail [from O. Fr. *quaille*, from Mediæv. Lat. *qua'quila*, from Dutch *kwakkel*, so called from its cry < *kwaken*, quack]: the popular name for various small gallinaceous birds, but strictly speaking belonging to the common quail (*Coturnix communis*) of Europe, Asia, and Northern Africa, a member of the sub-family *Perdicinæ*, and a near relative of the Partridge (*q. v.*). The European quail is 7 inches long, brownish or reddish gray above, marked with streaks of buff; below, general pale buff, fading into white on the belly. It is believed to be the quail mentioned in Exodus, but that bird may have been the sand-grouse (*Pterocles arenaria*). The great majority of European quails winter in Africa, and vast numbers are taken for market in Southern Europe during their migrations. Other members of the genus occur in Asia, Australia, and New Zealand. In the U. S. the name is commonly bestowed on the well-known bob-white (*Colinus virginianus*), the "partridge" of the Southern States, but is often extended to other species, such as the California quail (*Callipepla californica*). The New World birds belong in the sub-family *Odontophorinæ*.

F. A. Lucas.

Quain, Richard, F. R. C. S., F. R. S.: anatomist and surgeon: b. at Fermoy, Cork, Ireland, in 1800; studied at the Windmill Street and Aldersgate schools of medicine, London; in 1825 went to Paris to study; in 1828 became a demonstrator and in 1832 Professor of Anatomy in the Uni-

versity of London; in 1834 became assistant surgeon and in 1850 surgeon to the North London Hospital; retired in 1866. He held a number of official positions in the Royal College of Surgeons, being its president in 1868. In 1869 he delivered the Hunterian oration, his subject being *Some Defects in General Education*. He was surgeon extraordinary to the Queen. His elaborate treatise on the *Anatomy of the Arteries of the Human Body* ranks as a classical work. Among his other publications are *Diseases of the Rectum* (London, 1854) and *Clinical Lectures* (London, 1884). He edited, with others, the fifth edition of *Quain's Anatomy*, originally written by his brother, Jones Quain (1796–1865). D. in London, Sept. 15, 1887.—His cousin, Sir Richard Quain, LL. D., b. at Mallow, Ireland, Oct. 30, 1816, became in 1857 a fellow, and in 1889 was vice-president of the Royal College of Physicians. He was physician extraordinary to the Queen and edited the *Dictionary of Medicine* (1883; 2d ed. 1894). D. Mar. 30, 1898. S. T. Armstrong.

Quakers: See Friends, Society of.

Quaking-grass: any grass of the genus *Briza*. The spikelets are ovate, and have such delicate stalks that a light wind sets them quaking and rattling. *B. maxima* and *B. media*, from Europe, are cultivated in gardens, and the latter is partly naturalized in the U. S. In Europe it is considered a good pasture-grass for poor mountain lands. Its seeds lose their vitality in a short time after their ripening.

Quang-See: an old spelling of Kwangsi (*q. v.*).

Quang-Tong: an old spelling of Kwangtung (*q. v.*).

Quantin, kaǎn'tăn', Albert Marie Jérôme: printer; b. at Bréhémont, Indre-et-Loire, France, Jan. 19, 1850; studied law in Paris; became director of the Claye printing-establishment, at Tours, in 1873; moved to Paris; became printer to the Chamber of Deputies; published *Bibliothèque de l'Enseignement des Beaux-Arts* (to comprise 100 vols.) and special *Annuaires*, and wrote *Origines de l'Imprimerie et son Introduction en Angleterre* (1877).

Quantity (in meter): the time consumed in uttering syllables, or the duration of syllables. It is, of course, relative. The duration of a short syllable in slow utterance may be as great as that of a long syllable in rapid utterance.

Quantity and quality (nature, timbre) are often confounded. When the first *o* in "co-operate" is called "long" and the second one "short," these terms should be understood only of the quality. The confusion is increased, or rather the error is emphasized, by the use of quantity marks (–, ⏑) to indicate these sounds. The same remark applies also to *e* and *u*. Difference of quantity is, no doubt, often associated with difference of quality, but the latter does not constitute the former.

Among the ancient Greeks there was a dispute between the so-called rhythmists (*ῥυθμικοί*) and the metricians (*μετρικοί*) concerning quantity. The rhythmists held that syllables had a great variety of lengths. To illustrate this, some of them assumed the short vowel as a fixed unit, regarded a long vowel as equal to two short ones, and counted each consonant added to a vowel as equal to half a short vowel; hence they placed, for instance, $\epsilon = 1$, $\epsilon\nu = 1\frac{1}{2}$, $\epsilon\nu\tau = 2$, etc., $\eta = 2$, $\eta\nu = 2\frac{1}{2}$, $\eta\nu\tau = 3$, etc. The metricians, on the other hand, held that short syllables had a uniform length, and that long syllables were just twice as long. One writer, Aristoxenus, appears to have seen that syllables had no fixed length nor definite relation to each other, but were vaguely divisible into longer and shorter, with some doubtful cases. In constructing rhythm the long syllable was given twice the length of a short one, while the doubtful syllables were made either long or short, and were called "common." In particular cases any syllable, however long, could be shortened into an irrational (*ἄλογος*), so as to count as a short. Such syllables are not to be confounded with the "common" ones. Also in special cases a syllable could be made equal to three short ones, or four, or even more; but such prolongation, especially within a word, was confined, for the most part, to poetry intended to be sung.

While the ancient languages had great variety of quantity, that of each particular syllable was more fixed than with us. This may be seen by applying English analogy to ancient words. All pronounce "amicus," "amavi" with the second syllables long; but in "amicitia," "amavisti" many make those same syllables short, whereas they were just as long as in the former words. To the Roman ear āmăbāmŭs would have been as barbarous as "āmăbam."

In Greek and Latin, syllables are long "by nature" (*φύσει*, *natura*) when their vowel element is a long vowel or a diphthong; and long "by position" (*θέσει*, *positione*, i. e. by convention) when a short vowel is followed by a double consonant (*ζ*, *ξ*, *ψ*), or two or more consonants; but certain mutes followed by certain liquids do not necessarily lengthen a syllable. It will thus be seen that, while in syllabication we follow the musicians and connect as many consonants as possible with the vowel following, as *κλέ-πτω*, in prosody we connect as many as possible with the preceding vowel, as *κλέπτ-ω*. In fact, in speaking, it is the vowel before several consonants, rather the one after them, that is felt to drag. In singing, consonants are reduced to a minimum and carried forward.

It has often been denied that there is any consciousness of quantity in English. It is true that we do not feel any definite relation of long syllables to short ones in reading or speaking as we do in singing (and, indeed, this was the case with the ancients); but that there is sometimes difference of quantity can be perceived by comparing "furrow" with "furlough," "bonnie" with "spondee," "tory" with "turnkey," etc. In reading verse, however, we merely make the feet approximately equal without feeling or perceiving exactly how it is accomplished, just as in singing we can give the voice a definite pitch without any consciousness of the vibrations that determine the pitch.

Milton W. Humphreys.

Quanza: See Cuanza.

Quarantine [liter., a space of forty days, from O. Fr. *quarantaine*: Ital. *quaranti'na*, a forty of anything, deriv. of *quaran'ta*: O. Fr. and Fr. *quarante*, forty]: the time (formerly forty days) during which vessels and their passengers, cargo, etc., are detained and isolated on entering a port when they carry or are suspected of carrying contagion. The term is also used to denote such detention and isolation and, collectively, all the means employed therein.

History of Quarantine Regulation.—The necessity for quarantine, as now understood, arose out of the development of commerce, and it is generally believed that the earliest quarantine regulations were those promulgated about the beginning of the fifteenth century by Venice (then the greatest sea mart of the world) as a protection against the plagues of the East—the black plague and the Egyptian plague. As early as 1348 the household goods of those that died were destroyed, and health officers were appointed; the first lazaretto was established in 1403, and suspected incoming vessels, with their passengers and cargoes, were detained and isolated for forty days. Later, and especially in the eighteenth century, lazarettoes were established and maintained at most of the Mediterranean ports. These early lazarettoes, together with the sanitary cordons established about nearly all the principal cities, were directed only against the plague. Their measures taken for protection were often needlessly harsh, owing to the lack of scientific knowledge of the cause of the malady and of the means by which it spread. In the latter part of the eighteenth century efforts were made by John Howard and others to improve the lazarettoes and hospitals and to combat foolish superstitions and practices, and in the early part of the nineteenth century a call was made for an international congress to consider quarantine measures. By this time the plague had waned in power and had invaded Europe as an epidemic for almost the last time. Since the year 1821 quarantine regulations have, in the main, been directed against the yellow fever and cholera, although they are intended to act likewise as barriers to the ingress of all contagious or infectious maladies.

Quarantine Regulations in the U. S.—The present U. S. quarantine laws and regulations, the latter promulgated Apr. 26, 1894, are designed to obviate the detention of incoming vessels and passengers in so far as this is compatible with the practically absolute exclusion of infectious diseases, which is, of course, their paramount aim. As a means both to prevent delay and to exclude contagion, quarantines have been established by the U. S. Government at all foreign ports of departure, and every vessel leaving such a port for that country must have a bill of health from the proper U. S. officer, consular or medical, "setting forth the sanitary condition and history of the vessel, and that it has in all respects complied with the rules and regulations." There must be a personal inspection by the officer of "all vessels from ports at which cholera prevails, or at which yellow fever, smallpox, or typhus fever prevails in epidemic form,"

and "all vessels carrying steerage passengers." It is also required that all vessels shall be thoroughly clean before receiving cargo, crew, or passengers; that the bedding for steerage passengers must be renewed or disinfected before being used on the voyage; and that, if there were any case of infectious disease on the last voyage, all parts of the vessel that could possibly have been infected must be disinfected. The regulations as to the cargo vary according to its character.

The treatment of passengers is somewhat different according as they belong to the cabin or steerage class; but no one with cholera, smallpox, yellow, typhoid, or scarlet fever, measles, or diphtheria is allowed to ship, nor should any be received from an infected port. The weekly reports of the consular officers keep the Government well informed as to the exact sanitary condition of all ports of departure and the districts adjacent thereto or in direct communication with them.

Cabin passengers from ports or districts where cholera or other infectious diseases are prevalent are subject to inquiry as to their place of abode for the five days immediately preceding departure, and may be detained as long as the inspecting officer thinks best, and may also be required to have their baggage disinfected if there is any suspicion of exposure to infection. Steerage passengers and members of the crew from cholera-infected districts must be detained five days, those who have been exposed to typhus fever fourteen days, in suitable quarters, "the said periods to begin only after the bathing of the passengers, disinfection of all their baggage and apparel, removal of all food brought with them, and isolation from others not so treated." The same rules are applicable to those from districts where plague, smallpox, or yellow fever is prevailing and epidemic, and if any one of these five diseases should appear among those thus detained there must be a second isolation for the prescribed time, disinfection, etc., the new detention counting from the removal of the last case from the detention-barracks. Every passenger must have an inspection-card bearing the stamp of the proper officer, the name of the passenger, ship, and port of departure, and date of the latter, and all baggage must have labels with similar data (excepting passenger's name), and with statement and date of inspection or disinfection.

Under the terms of the statute the President has power, whenever existing conditions appear to justify it, "to prohibit, in whole or in part, the introduction of persons and property from such countries or places as he shall designate, and for such periods of time as he shall deem necessary."

The regulations require during the voyage a daily inspection, free ventilation, and thorough cleanliness of the vessel, isolation of the sick, etc., and at the port of entry the only delay required is that which will enable the proper officials to inspect the ship, crew, passengers, baggage-labels, ship's bill of health, physician's record, etc.

The Government provides for the maintenance of this inspection service at every port of entry under its jurisdiction throughout the year, and it applies to all vessels from foreign ports, all vessels with sickness on board or in which sickness has appeared since leaving the port of departure, and vessels from domestic ports where cholera or yellow fever prevails or where smallpox or yellow fever is epidemic. To these requirements the proper State or local authorities may add such others as may seem to them to be advisable or necessary.

The inspection being completed, and everything proving satisfactory to the inspecting officer, he fills out his certificate, which, together with the bill of health from the officer at the port of departure, must then be given to the collector of customs of the port, and without these two papers no vessel is permitted to disembark any of its passengers or cargo. Should there be any evidence or belief that there is possibly infectious matter on board, the inspector orders the vessel to proceed at once to the nearest national or other quarantine station, there to undergo treatment.

The following extracts from the regulations indicate the vessels that are to be remanded to quarantine at once by the inspecting officer of the port of entry: A. Those with quarantinable disease on board, the quarantinable diseases for the purposes of these regulations being cholera (cholerine), yellow fever, smallpox, typhus fever, and leprosy. B. Those having had such on board during the voyage or within thirty days next preceding arrival; or, if arriving in the quarantine season, having had yellow fever on board after Mar. 1 of the current year, unless satisfactorily disinfected thereafter. C. With some exceptions, those from ports infected with cholera, or where typhus fever prevails in epidemic form, coming directly or viâ another foreign port, or viâ United States ports, unless they have complied with the United States quarantine regulations for foreign ports: also vessels from non-infected ports, but bringing persons or cargo from places infected with cholera, yellow fever, or where typhus fever prevails in epidemic form. D. With some exceptions, those from ports where yellow fever prevails, unless disinfected in accordance with these regulations, and not less than five days have elapsed since such disinfection. Certain exceptions, with respect to vessels that would otherwise be quarantined on account of yellow fever, are made to rules C and D in consideration of (1) the time of arrival, as vessels arriving from Nov. 1 to May 1 may be admitted to entry: (2) the port of destination, as vessels with clean bills of health, etc., bound for ports in the U. S. N. of the southern boundary of Maryland, provided they have been five days from last infected or suspected port; (3) the nature of the cargo, as vessels engaged in the fruit-trade from ports declared safe, etc.

"No case of leprosy will be landed, and vessels arriving at quarantine with leprosy on board shall not be granted pratique until the leper with his or her baggage has been removed to the quarantine station"; and if the leper is an alien, measures are to be taken to have him returned to his native country.

In addition to the foregoing, all persons on vessels that have had smallpox on board during the voyage, and all but first and second cabin passengers on other vessels, must show evidence of recent vaccination or of a previous attack of smallpox, or be vaccinated, or be detained in quarantine for at least fourteen days.

There are a number of quarantine stations, more or less completely equipped, along the Atlantic and Gulf coasts of the U. S., and three on the Pacific coast, eleven being national and the rest maintained by the States in which they are located, or by the cities which they are designed to protect.

The treatment of a vessel, passengers, and cargo at quarantine is governed very materially by the disease which has caused its detention, cholera and yellow fever demanding the most prompt and energetic action. With either of these maladies the vessel is at once dispatched to the anchorage for infected vessels, and must remain there till she has been thoroughly purified and disinfected; the passengers in the meanwhile having been transferred to the lazaretto and barracks for suspects, or to other quarters where they may be isolated during the period of detention and observation, and such part of the cargo as may be necessary being removed, disinfected, and stored.

Within the barracks the passengers and others are separated into convenient groups, each of which is inspected twice daily by the physician, receives a separate water and food supply, and the individuals of which may not communicate with members of other groups except through the quarantine officer. Should a new case occur in any of the groups, the patient is immediately conveyed to the lazaretto, the other members of the group bathed, their clothing again disinfected, etc., and the whole group transferred to other quarters and sleeping apartments. There is the same isolation and segregation into groups in case of yellow fever, but infection by other diseases does not warrant so severe treatment. The duration of detention for cholera and yellow fever is five days after the last opportunity for infection and after the last disinfection of all articles taken by passengers into barracks; for smallpox the detention is extended to fourteen, and for typhus fever to twenty days.

The cargo and infected baggage are disinfected as far as practicable at the wharf or *in situ* in the vessel by means of steam, sulphurous acid gas, and strong corrosive sublimate solution. As to the vessel, nothing is thrown overboard if the infection is from cholera, though ballast may be discharged at sea, and ballast-tanks refilled with sea-water. A certificate from the quarantine officer, stating that the vessel has thoroughly complied with the regulations, and that he believes her to be free from infection, is necessary before the vessel may leave quarantine. She is then said to be granted free pratique.

To secure the U. S. against the entrance of infection by way of the Canadian and Mexican frontiers, the regulations provide that, "when practicable, alien immigrants arriving at Canadian and Mexican ports destined for the United States shall be inspected at the port of arrival by the United States consular or medical officer, and be subjected to the

same sanitary restrictions as are called for by the rules and regulations governing United States ports; and where such immigrants are not inspected at the port of arrival, they shall enter the United States only at certain designated points on the frontier, and then only after such inspection, detention, disinfection, vaccination, etc., as may be necessary or required by the officers there stationed."

Inland Quarantine has practically the same object as that of maritime quarantine, viz., the prevention of the transference of infectious disease from one locality to another, and the defining of certain portals through which all persons and things capable of conveying infection may be compelled to pass and undergo the necessary inspection, detention, etc. Such quarantine is in most cases invoked to limit the extension of epidemics, and depends for its efficacy upon two main features—the *sanitary cordon* and *camps of probation*.

The former "consists of a line of guards, military or civil, thrown around a district or locality, either to protect the same from the surrounding country when infected or to protect the surrounding country from the infected district or locality." The line may be a double one, in which case the innermost one encircles as much as possible of the area known to be infected, while the other includes all probable or possible cases. Of course, as soon as the zone between the two lines can be shown to be free from the particular infection, the necessity for the outer line vanishes, and it may be withdrawn; but as long as either exists, to be of any utility whatsoever, it must be so complete as to prevent all ingress or egress through it except at certain specified points—the camps of probation. The camps of probation must be distinguished from *camps of refuge*, which are "simply residence camps established to receive the population of an infected community when it has been determined to depopulate the infected district."

It may also be advisable at times to establish a *railway quarantine* at certain points, where all baggage and freight from a suspected district may be disinfected, and all passengers from the infected locality or without the requisite certificate from some authorized health officer may be remanded to the nearest camp of probation, and detained under observation the necessary length of time. See Hygiene.

Seneca Egbert.

Quarles, Francis: poet; b. near Romford, Essex, England, in 1592; was educated at Christ's College, Cambridge; studied law at Lincoln's Inn; afterward secretary to Archbishop Usher in Dublin; driven from Ireland, with the loss of his property, by the rebellion of 1641; espoused the royal cause in the great rebellion, joining King Charles I. at Oxford, and suffered sequestration of his property. D. in London, Sept. 8, 1644. Author of *Divine Emblems* (1635); *The Enchiridion of Meditations* (1641); and other moral works filled with quaint conceits, and of *The Loyal Convert* (1644), a defense of the royal cause, besides a number of poetical works: *Feast for Worms, or the History of Jonah* (1620); *Argalus and Parthenia* (1621); *The Shepherd's Oracles* (1644); etc.

Quartan: See Fever and Chill.

Quarter-crack: See Farriery.

Quarter Evil: See Black Quarter.

Quartering: See Heraldry.

Quartermaster-general: a military officer who has, in the U. S. army, the rank of brigadier-general—in the British army that of major-general or colonel. He is at the head of the quartermaster's department, which is charged with the duty of transporting troops and materials of war, of clothing, feeding, and sheltering troops, of constructing and repairing roads, military telegraphs, railways and bridges, docks and wharves, and generally with all disbursements attending military operations not expressly assigned by law or regulation to other staff departments. He has a number of assistants, and there is for each regiment of the line a regimental quartermaster, selected from among the lieutenants of the regiment, who is assisted in his duties by a quartermaster-sergeant.

Quartley, Arthur: marine painter; b. of English parents in Paris, France, May 24, 1839. He was self-taught; was taken to the U. S. when a child and passed the early years of his professional life in Baltimore, Md.; National Academician 1886; member of the Society of American Artists 1881; member of the American Water-color Society. D. in New York, May 19, 1886. A shore view, *Off the Isles of Shoals*, is in the Union League Club, New York; *Low Water, Long Island Shore*, in the collection of T. B. Clarke, New York.

William A. Coffin.

Quartz [from Germ. *quarz*]: a very abundant and important mineral, including a great variety of precious and semi-precious stones, all of them being essentially silica (oxide of silicon) more or less pure. These minerals may be divided into four groups—the crystalline varieties, the crystalline with foreign inclusions, the cryptocrystalline, and the amorphous, or non-crystalline. The first are more or less transparent, as also the second, the leading varieties being amethyst, rock-crystal, etc. The third group comprises the chalcedonies, agates, etc., which are translucent (see Chalcedony); and the fourth, the jaspers, which are opaque (see Jasper). The principal varieties of the crystalline group, or quartz proper, are the following, all of them having a hardness of 7, and usually crystallizing in hexagonal prisms with pyramidal terminations:

Amethyst is a transparent purple variety, owing its color to oxide of manganese. It was much used by the ancients in engraving and in jewelry. Superb deep-purple gems that change to red by artificial light are found near Mursinka, in the Ural Mountains, and single gems sell for several hundred dollars. Oriental amethyst is a purple variety of corundum or sapphire, and is a far more valuable gem than the ordinary amethyst. See Amethyst.

Cairngorm stone, citrine, false topaz, Saxon topaz, Scotch topaz, and *Spanish topaz* are names given to transparent quartz colored by oxide of iron or by carbonaceous matter, and having various shades of yellow to brown. The yellow and brown are produced by heating smoky quartz (see below), which is partially decolorized by high temperature. Much that is called topaz is this yellow quartz, which is quite different from true topaz (see Topaz), and less valuable as a gem. Oriental topaz is the yellow variety of sapphire.

Prase is a deep-green quartz, sometimes crystallized. It is somewhat rare, but is not much valued or used by the moderns.

Rock-crystal is the purest form of quartz, transparent and colorless, and exhibits the properties of the mineral in the most perfect degree. It is widely distributed, but is brought chiefly from Brazil, Madagascar, and North Carolina. It is wrought, especially by the Japanese and Chinese, into the polished "crystal balls" and other articles of elegant ornament. Superb coupes, ewers, caskets, etc., made in Italy, Austria, and Germany from the sixteenth to the eighteenth century, adorn the collections of the Louvre, the South Kensington Museum, the Dresden Green Vaults, the Imperial Museum at Vienna, etc. What are known as "Rhine stones," "Lake George diamonds," etc., are not quartz or rock-crystal, as generally believed, but only paste or lead-glass.

Rose-quartz is a pink or rose-tinted variety, rarely found crystallized, exceedingly beautiful if of pronounced color. Although occasionally employed for ornamental work, it is little used, owing to its liability to fade by long exposure to light. It is found in Maine, Moravia, and elsewhere.

Smoky quartz and *smoky topaz* are brown to almost black and probably are colored by carbonaceous matter. The lighter shades are occasionally cut for ornament, and are beautiful stones, but of little value. The finest crystals of smoky quartz from Mt. St. Gothard, in Switzerland, are now in the museum at Berne. It is also found at Pike's Peak, Col. The black quartz is called *morion*. By heating, smoky quartz is partially decolorized, yielding paler shades and yellows which then are called cairngorm stone, Spanish topaz, etc. (see above).

The varieties containing inclusions are as follows:

Aventurine, called also *gold-stone*, a brown ferruginous quartz containing spangles of mica or göthite, is found at Aventura, in Spain, and in Asiatic Russia. The artificial gold-stone, a brown glass filled with minute crystallized crystals of copper, is handsomer than the natural stone; it is made in Venice and is used for inlaid work, etc.

Cat's-eye quartz: See Cat's-eye.

Thetis's hair-stone, Venus's hair-stone, Sagenite, and *Flèches d'Amour* are names given to quartz penetrated by needle-like crystals of hornblende, rutile, göthite, and similar minerals. Quartz of this variety is occasionally cut and mounted.

There are many other semi-precious varieties of quartz, but they are rare, and of little importance save to collectors and students of mineralogy.

George F. Kunz.

Quasi-Contract: an obligation imposed by law for the enforcement of which the law gives the action resorted to for breach of contract. The distinction between a contract and a quasi-contract is as marked as is the difference between *assent* and *dissent*. While the assent—as that term is used in law—of the party to be charged is necessary to the existence of a contract, a quasi-contract may exist notwithstanding the dissent of the defendant. A contract is an obligation created by act of the parties. A quasi-contract is an obligation imposed by law. Although the source of the obligations is different, the remedy given to one seeking to enforce a quasi-contractual obligation is the action given for a breach of contract, the action of assumpsit, hence the use of the term quasi-contract in our law. The fact that the contractual remedy is used where an action is brought on a quasi-contract has given rise to the expression "contract in law," and this expression is too often abbreviated into the expression "implied contract." The use of the term "contract implied in law" is unscientific, since a contract depends upon the act of the parties, and can not exist without assent, and is therefore something which the law can not imply. The term means, however, nothing more than obligation imposed by law. The use of the term "implied contract" to represent quasi-contractual obligations is not only unscientific, but is misleading, and has caused great confusion. There is an "implied contract," but it is a genuine contract, not a quasi-contract, and differs from the ordinary simple contract, usually called an express contract, only as to the evidence by which its existence is proved. The express contract is so called because its existence is proved by the language used when the contract was entered into, while the implied contract is proved by circumstantial evidence. Implied and express contracts are genuine contracts, while a quasi-contract, as the term implies, is no contract at all. (*Steamship Co.* vs. *Joliffe*, 2 Wall. 450; *Louisiana* vs. *New Orleans*, 109 U. S. 285; *Dusenbury* vs. *Speir*, 77 N. Y. 144.) The terms "implied" and "express," when used properly with reference to contracts, are terms of evidence and not of contract. (*Marzetti* vs. *Williams*, 1 B. & Ad. 415; *Dusenbury* vs. *Speir*, 77 N. Y. 144.) If A should say to B "lend me $100 and I will repay it in one month," and B should lend the money, there would be an express contract, for the reason that A has used the language of promise, has promised in words. If A should say to B "C is pressing me for the payment of $100 which I owe him; if I send him to you please pay him that amount," and B should do so, there would be a contract on A's part to reimburse B, but it would be an implied contract, because words of promise can not be found, and the understanding of the parties is left to inference and must be gathered from the circumstances. The circumstances, however, leave no one in doubt as to the intention of A. Because of the use of the phrase "contract implied in law," it is usual to describe genuine contracts which are not created by the use of words of promise, as "contracts implied in fact."

It may be asked why not treat a quasi-contract as a tort if it differs so radically from a contract? The obligation giving rise to a right of action in tort is an obligation imposed upon persons in general, not upon any particular individual, to respect the inherent right which every man has to his person and property. This obligation is usually performed simply by refraining from interfering, by remaining inactive. In the case of a quasi-contract the obligation usually, if not always, exists in favor, not of the world at large, but of some particular person, and arises out of a relationship existing, or dealings had, between the plaintiff and the defendant. Furthermore, the obligation imposed by a quasi-contract requires the obligor to act. It can not be discharged simply by a failure or refusal to act.

The source of the quasi-contractual obligation is threefold:

1. Obligations of record.
2. Statutory, official, or customary obligations.
3. Obligations resting upon the doctrine that no one shall be allowed to enrich himself unjustly at the expense of another.

The typical obligation of record is a judgment, and it needs no argument to establish that an obligation which is created by law without regard to the will of the obligor, and in most cases notwithstanding his dissent and protest, has none of the elements of a contract, and is therefore quasi-contractual, and it is so regarded. (*Biddleson* vs. *Whytel*, 3 Burr 1545; *State of Louisiana* vs. *New Orleans*, 109 U. S. 285; *O'Brien* vs. *Young*, 95 N. Y. 428.) As a statutory obligation exists without regard to the assent or dissent of the defendant, such an obligation is, and must be, regarded as quasi-contractual. (*Steamship Co.* vs. *Joliffe*, 2 Wall. 450; *Louisiana* vs. *New Orleans*, 109 U. S. 285; *Inhabitants of Milford* vs. *Commonwealth*, 144 Mass. 64; *McCoun* vs. *R. R. Co.*, 50 N. Y. 176.) An example is the obligation imposed upon the owner of a vessel without a pilot to pay half pilotage fees in the event of his refusing to accept a pilot who tenders his services. Of the same character, it is submitted, are customary duties where the obligation is imposed regardless of the will of the party charged with the duty, as the duty of an innkeeper to receive guests, of a carrier to receive goods. An example of a quasi-contractual obligation founded on an official duty is the obligation of a sheriff to levy execution and pay the proceeds of the sale thereunder to the judgment creditor. (*Speake* vs. *Richards*, Hobart 206.) The great and important source of the quasi-contractual obligation, however, is the equitable principle that no one shall be allowed to enrich himself unjustly at the expense of another. But for this principle there would be a gross failure of justice in many cases, as, for example, where money has been paid under mistake as to the existence of an indebtedness, not to create but to extinguish an obligation; where a person has committed a tort and has enriched himself thereby, and yet the remedies in tort have, in the absence of statute, been lost because of the death of the tort-feasor. It is proposed to consider briefly some of the cases showing the importance of the doctrine of unjust enrichment and the necessity for its existence in our law.

That the remedy to recover money paid under mistake as to the existence or amount of an indebtedness must be quasi-contractual is evident, as neither party intended to create an obligation in favor of the person making the payment, and the latter, if not both parties, thought that the payment would extinguish an existing obligation. To recover money paid under mistake, it must appear not only that the money was paid because of mistake in a case where there was no enforceable claim, or none enforceable to the extent of the payment, but in addition thereto it must also appear that the circumstances are such that it would be against conscience to allow the defendant to retain the money so paid. Thus if one should pay a debt barred by the statute of limitations, in ignorance of the bar, because of a mistake as to the date when the debt became payable, there could be no recovery of the money so paid, notwithstanding the plaintiff's ability to prove that he would not have paid the debt but for the mistake. In paying the debt he only did what in conscience he should have done, notwithstanding the existence of a statute protecting him from liability, and the party to whom the money was paid is certainly not unjustly enriched in retaining what in conscience should have been paid to him. If the payment in any case is caused by ignorance or mistake of law, then, notwithstanding the retention of the money by the defendant is against conscience in that nothing was owing to him, there can not, according to the weight of authority, be a recovery of the money so paid. See IGNORANTIO JURIS.

If in the commission of a tort the tort-feasor enriches himself by taking from the injured party's property and adding to his own, he may be sued in tort, in which event the measure of the plaintiff's recovery would be the damage done the plaintiff, or he may be sued in quasi-contract, where the measure of recovery would be the extent of the unjust enrichment. When one having the right to sue either in tort or in quasi-contract uses the latter remedy he is said to "waive the tort." These words are misleading. "Waiver of tort," so called, is nothing but an election of remedies. What was a tort before does not cease to be a wrong by the bringing of the action in quasi-contract, for unless the plaintiff proves the commission of a tort he will not be able to recover. The plaintiff is said to waive the tort for the reason that it is a rule of law that a plaintiff loses his right to sue in tort by suing in quasi-contract. It is equally true that he loses the right to sue in quasi-contract by suing in tort. We do not hear, however, of the doctrine of waiver of quasi-contract, for the reason that the older remedy is the action of tort. Whether a plaintiff shall or shall not waive the tort and sue in quasi-contract is often a question of great practical importance. If, for example, A should take B's horse, of the value of $500, and sell him for $300, it would be to B's advantage to sue in tort, since in that form of action he will recover to the extent of the damage suffered by him, which would be $500, whereas if he sued in quasi-con-

tract, in a count for money had and received, he would recover only $300, as that was the sum received by A. In jurisdictions where in such circumstances the tort-feasor can be sued in quasi-contract in a count for goods sold and delivered, it would be immaterial whether B sued in tort or in a count for goods sold and delivered. If, however, the property is wrongfully taken and the value thereof increased by the labor of the tort-feasor, then in jurisdictions where the measure of recovery is the value of the property at the time of the wrongful taking it is advantageous to sue in quasi-contract, since the extent of the tort-feasor's enrichment exceeds the injury done the owner, and in quasi-contract the plaintiff will be entitled to recover to the extent of the defendant's enrichment. For the reason that unjust enrichment is the basis of recovery where the tort is waived, no action can be brought in quasi-contract where the tort does not enrich the tort feasor. (*Fanson* vs. *Linsley*, 20 Kan. 235; *National Trust Co.* vs. *Gleason*, 77 N. Y. 400.) Thus, if A should slander B or commit an assault upon him, B's only remedy would be in tort.

To recover the proceeds arising from the sale of property wrongfully taken, the plaintiff must have had a right to the property at the time of the sale. If A, for example, should wrongfully take B's horse and retain possession thereof until the lapse of time within which an action for the wrongful taking is required by statute to be brought, and should then sell him, he could retain the proceeds, since the effect of B's failure to bring an action for the wrongful taking within the statutory period of time was to vest the title to the horse in A, and A therefore sold his own horse. The loss of the right to sue in tort does not necessarily, however, mean the loss of the right to sue in quasi-contract. If, for example, the right of action in tort existed at the time when the proceeds of the sale were received, then, notwithstanding the right to sue in tort is subsequently lost by a failure to bring an action within the statutory period of time, an action may still be brought to recover the proceeds until the statutory period of time as to quasi-contractual rights has run. So the common-law rule that the tort died with the person did not prevent an action against the estate of the deceased tort-feasor, notwithstanding the loss of the remedy in tort, if it were a case where the tort-feasor could have been sued in quasi-contract had he been alive.

It frequently happens that a person who has not sufficiently performed a contract to entitle him to sue thereon has nevertheless materially enriched the other party to the contract by a partial performance thereof. In such cases, if there is to be a recovery by the person who has partly performed, it must be on principle of unjust enrichment, and the right will therefore be quasi-contractual, as the case assumes that the defendant is not liable for a breach of contract. A plaintiff may in these circumstances seek a recovery where he makes no attempt to justify or excuse his failure to perform, or he may rely upon the fact that he endeavored in good faith to perform the contract, or upon the fact that he can not be sued for a breach of contract, because of the fact that the contract was an oral contract, with no memorandum thereof in writing complying with the Statute of Frauds, or for the reason that the contract was illegal or impossible of performance. It is generally held that one who willfully refuses to perform a contract to the extent necessary to entitle him to recover thereon can not recover in quasi-contract, notwithstanding the enrichment of the defendant arising from the part performance. (*Collins* vs. *Stimson*, 11 Q. B. D. 142; *Stark* vs. *Parker*, 2 Pick. 267; *Lantry* vs. *Parks*, 8 Cow. 63; *Moritz* vs. *Larsen*, 70 Wis. 569; but see *contra Britton* vs. *Turner*, 6 N. H. 481.) To this rule there seems to be one exception—namely, where the plaintiff has supplied property under a contract and the defendant can return the property, but refuses to do so. In some jurisdictions, where the rule is recognized that in the case of a deliberate refusal to perform a contract there can be no recovery for benefits conferred by a partial performance thereof, a recovery is allowed in quasi-contract if it appears that the plaintiff endeavored in good faith to perform the contract.

The fact that the plaintiff by reason of the Statute of Frauds can not be sued for a breach of contract will not entitle him to recover in quasi-contract, as the Statute of Frauds was intended not to confer a right of action, but to give a defense to an action on a contract which, though oral, was not illegal, and the performance of which was therefore permissible in point of law. *Collier* vs. *Coates*, 17 Barb. 471; *Greton* vs. *Smith*, 33 N. Y. 245; *Clark* vs. *Terry*, 25 Conn. 395; *Abbott* vs. *Inskip*, 29 Oh. St. 59; see *contra King* vs. *Welcome*, 5 Gray 41.

If the contract which the plaintiff has partly performed is illegal, there can be no recovery on the contract because of the illegality thereof. If, therefore, the plaintiff recovers it must be in quasi-contract. If the plaintiff, having partly performed an illegal contract refuses to perform further, he is regarded as acting in disaffirmance thereof, and if the illegality is merely *malum prohibitum*, not *malum in se*, i. e. is not inherently wrong, but wrong simply because of a positive prohibition, there can be a recovery if the defendant has in fact or in legal contemplation been enriched by the performance. If the act is *malum in se*, there can be no recovery, notwithstanding the defendant's enrichment. *Taylor* vs. *Bowers*, 1 Q. B. D. 291; *White* vs. *Franklin Bank*, 22 Pick. 181; *Tracy* vs. *Talmage*, 14 N. Y. 162.

In the U. S., differing from the law of England (*Cutter* vs. *Powell*, 6 T. R. 320), if after part performance further performance becomes impossible, and it can be fairly said that the contingency which has happened was not within the contemplation of the parties, as, for example, where full performance is prevented by sickness or death, there can be a recovery to the extent of the benefit conferred. *Wolfe* vs. *Howes*, 20 N. Y. 197; *Green* vs. *Gilbert*, 21 Wis. 395.

One who has performed a contract either in whole or in part, and who has been prevented from fully performing by the other party to the contract, may find himself unable to recover for a breach of contract, and yet the circumstances may be such that not to allow a recovery for what was done thereunder would work great injustice. Suppose, for example, that A should agree to work for B for the period of two years, for a lump sum to be paid by B at the end of two years, and at the end of that time B should refuse to pay for the services, relying upon the Statute of Frauds, requiring a written memorandum of such contracts, or suppose that after A had served him for six months B should discharge him without cause, relying upon the statute aforesaid. Clearly it would be the grossest injustice to hold in such a case that A had no enforceable rights against B, and yet, if he must rely upon the contract, he clearly can not recover for the services rendered, since the statute gives B an absolute defense. Upon the principle of unjust enrichment, however, the law imposes an obligation upon him to compensate A for the services rendered. So, when, after a complete or partial performance by the plaintiff, performance on the other side has become impossible in circumstances affording a defense to an action for a breach of the contract, the law will in case of full performance and also in the case of partial performance, where the amount is ascertainable, compel restitution or compensation to be made. It may be that a defendant who has no scruples in allowing a plaintiff to perform an illegal contract is averse to performing his side of the contract. In such a case there can be no recovery on the contract because of its illegality, and if, in the eyes of the law, the parties are *in pari delicto*, there can be no recovery in quasi-contract, notwithstanding the enrichment of the defendant. This result is justified only on grounds of public policy. If, however, the parties are not *in pari delicto*, but the position of the defendant is regarded as the more reprehensible, then a recovery in quasi-contract can be had.

A recovery in quasi-contract against a defendant refusing to perform a contract is not only allowed in cases where there can be no recovery on the contract, and yet where the plaintiff should have relief of some kind, but is also allowed in quasi-contract, notwithstanding the plaintiff's right to sue for a breach of the contract, in cases where the defendant received a benefit from the plaintiff's performance. This right to sue in quasi-contract is often of great value to a plaintiff. For example, suppose that A should pay in advance to B the sum of $500 in exchange for a promise on B's part to deliver to A certain goods on a certain day, and that on the day when the goods were to be delivered the goods were worth only $450. Should B fail to perform the contract in circumstances rendering him liable for breach thereof, the measure of A's recovery would be the expense involved in his purchasing the goods at that time, which would be $450. In an action in quasi-contract, however, the law would compel B to make restitution to A of the $500 which he received from A. *Nash* vs. *Towne*, 5 Wall. 689.

Whether the plaintiff or the defendant be in default, and whether the defendant be or be not liable on the contract, there can be no liability in quasi-contract unless the defendant has in fact or in legal contemplation been enriched by

the plaintiff's performance; hence it is that a guarantor who has made an oral contract to answer for the debt, default, or miscarriage of another, and who, because the contract does not comply with the Statute of Frauds, can not be sued on the contract—can not be sued in quasi-contract. The principal debtor, not the guarantor, was enriched by the plaintiff's performance. It is for this reason that a plaintiff who has bestowed labor upon chattel belonging not to the defendant but to the plaintiff, under a contract not enforceable because of the Statute of Frauds, can not recover in quasi-contract. *Dowling* vs. *McKenny*, 124 Mass. 478.

It not infrequently happens that one who is unable to establish a contract is able to show that he has conferred a benefit at the request or with the consent of the party benefited. If it can be shown that the benefit was conferred with an expectation on the part of the defendant to pay therefor, and that the plaintiff expected to receive compensation therefor, the fact that for some technical reason a contract which the parties attempted to create did not come into existence does not necessarily mean that the plaintiff is without remedy. Suppose, for example, that services have been rendered under a mutual mistake as to the terms of an offer and acceptance without fault on either side, or that goods have been furnished to a principal through his agent who had authority to purchase but exceeded his authority in executing a contract under seal. In such cases the plaintiff will not be without remedy, but will be allowed to recover in quasi-contract for the benefit conferred. (*Turner* vs. *Webster*, 24 Kan. 38; *Van Deusen* vs. *Blum*, 18 Pick. 229.) That the plaintiff intended to make a gift to the defendant of the services or property is, however, always fatal to a recovery, even though the act was done at the request or with the consent of the defendant. (*Osborn* vs. *Guy's Hospital*, 3 Strange 728; *Doyle* vs. *Trinity Church*, 133 N. Y. 372.) The motive that prompted the gift resulting in disappointed expectations is immaterial. It is for this reason that persons who have rendered services gratuitously in the hope of receiving a legacy on the death of the beneficiary are unable to establish a claim against the estate. (*Houck's Executors* vs. *Houck*, 99 Pa. St. 552.) If the gift was made under a mistake known to the defendant, or if the gift was induced by the fraud of the defendant, it would seem that the plaintiff should be allowed to recover in quasi-contract. *Peter* vs. *Steel*, 13 Yeates 250; *Kinney* vs. *Cook*, 4 Ill. 232; *Hickam* vs. *Hickam*, 46 Mo. App. 496. See also *Franklin* vs. *Waters*, 8 Gill 322.

There can not, as a rule, be a recovery for benefits conferred without the request or consent of the party benefited, even though the plaintiff did not intend to make a gift of his services. A person so acting is usually regarded as an officious volunteer, and no rights will be given him, as, for example, when one under no necessity of doing so pays the debt of another. In such a case the payment gives him no rights against the debtor. If, however, without any fault on the part of the person paying the debt of another, such payment is necessary to protect the person or property of person paying from seizure for the debt, the money so paid can be recovered from the debtor. In some cases, also, even where the plaintiff acts without the necessity therefor on his part, as where necessaries are supplied to a wife whom the husband wrongfully refuses to support, a right of recovery exists.

While money voluntarily paid can not be recovered even if paid under protest, money paid to protect one's person or property from unlawful seizure, or to prevent serious injury to one's business, can be recovered from the person to whom it was paid. That the money was paid to avoid a threatened suit will not, however, entitle the plaintiff to recover the money as paid under compulsion. In legal contemplation the money if not owing can not be collected, and if the party upon whom the claim is made desires to contest it, he is required to do it as a defendant in an action brought by the claimant. For a full treatment of the subject, see Keener on *Quasi-Contracts*. WILLIAM A. KEENER.

Quass Beer: See BEER.

Quas'sia [Mod. Lat., named from *Quassi*, a Negro slave in Surinam who used it as a remedy for fever]: in medicine, the wood of certain trees of the family *Simarubaceæ*. All the species of this family are noted for the intense bitterness of their wood, and until about the end of the eighteenth century quassia-wood was obtained from a small tree or shrub native in Panama, Venezuela, Guiana, and Northern Brazil, the *Quassia amara*. The wood of *Picræna excelsa* being found to have the same properties, and the latter being a tree of much greater size, the quassia of commerce is now almost wholly obtained from this source. *P. excelsa* is a tree from 50 to 60 feet high, with small yellowish and greenish flowers; the fruit is a drupe, black and shining, and about as big as a pea. It is a native of Jamaica and the Caribbean islands, where it goes by the name of *bitter ash*. The wood is whitish, but turns yellow on exposure. It has no smell, but a most intense, though pure, bitter taste. The bitterness depends upon a neutral crystallizable principle called *quassine* which is somewhat poisonous. Commercial quassia-wood consists of pieces of the trunk and branches of the tree of various sizes. For use by the druggist it is supplied in the form of raspings or turnings. Quassia, like other pure vegetable bitters, tends in small quantity to excite appetite and promote digestion. In large dose it nauseates. It is sometimes used in medicine as a stomachic bitter, but other less harsh and disagreeable bitters are generally preferred. Cups turned out of the solid wood are sometimes employed to prepare a weak quassia infusion by simply allowing cold water to stand for a few minutes in them. The water speedily becomes impregnated with the bitter principle, and may then be drunk. Quassia in infusion is the best remedy against the seatworm or *Oxyuris vermicularis*. Revised by H. A. HARE.

Quaternary Era: a division of geologic time co-ordinate with Primary, Secondary, and Tertiary. The term Primary has almost ceased to be used, and though Secondary and Tertiary are still employed, there is a growing tendency to substitute as general classific terms Paleozoic, Mesozoic, and Cenozoic, the term Cenozoic being made to include the divisions once called Tertiary and Quaternary. The same tendency replaces Quaternary Era by PLEISTOCENE PERIOD (*q. v.*). G. K. G.

Quater'nions [from Lat. *quater'nio*, the number four, a body or group of four, quaternion, deriv. of *quater'ni*, four at a time, by fours, deriv. of *quat'tuor*, four]: a mathematical method invented by Sir William Rowan Hamilton about 1840. Its fundamental idea is that of a vector. This latter is defined as a line passing from one (initial) point in space to another (terminal) point. It has two elements, *length* and *direction*. Two vectors are considered equal only when these two elements are the same in each. A vector moved about in space will remain the same vector so long as it remains parallel to itself and unchanged in length; but if either length or direction are changed, it becomes a different vector. The sum of two vectors is the vector joining the initial point of the first to the terminal point of the second when the two are placed end to end without changing the direction of either, as already explained. Any number of vectors may be added on this principle. See IMAGINARY QUANTITIES.

A quaternion is first defined as an operator, of which the function is to change one vector into another by altering its direction and its length. The operation which changes the length of the vector is in this case called the *tensor* of the quaternion, and that which changes the direction is called the *versor*. One quantity, a number, determines the tensor, and three are required to determine the versor, making four in all. Hence the term *quaternion*.

The great principle, however, of Hamilton's method consists in assigning to the vector itself the function of a quaternion, which it fulfills by turning a line at right angles to itself through ninety degrees around the vector itself as an axis. Comparing with the analogous operation of multiplying by the imaginary unit, as explained in the article IMAGINARY QUANTITIES, it will be seen that a quaternion has a close analogy to an imaginary quantity extended to space. From the definition of vectors and their sums it follows that every vector can be made up of the sum of three vectors at right angles to each other. These three vectors correspond to the co-ordinates used in solid analytic geometry. The unit lengths in the three directions are designated as i, j, and k. Then if x, y, and z are numbers, any vector can be represented in the form

$$ix + jy + kz.$$

A quaternion is formed by adding a pure number called a scalar to the vector as thus represented, and may therefore be written in the form

$$w + ix + jy + kz.$$

The reader must refer for a complete development of the method to special treatises on the subject, of which the

most complete and generally accessible to the student is that of Tait, *Elementary Treatise on Quaternions* (3d ed., Edinburgh, 1890). There are also American works on the subject, one of which is by Prof. Arthur S. Hardy, of Dartmouth College.

The question of the real scientific value or usefulness of the method of quaternions is one on which opinions differ widely. In the U. S. it is a popular subject of study in advanced mathematics, and in Great Britain it is regarded by Tait and others as the most simple and useful method of developing many problems in physics. Very little attention has, however, been paid to it in France, and scarcely any in Germany, where the general opinion is that it leads to no result which can not be reached as readily by other methods. But there can be no question of its value as a training in the logical methods of modern mathematics. S. NEWCOMB.

Quatre Bras, kăatr'braa' : See WATERLOO.

Quatrefages de Bréau, kăatr'făazh'de-brā'ō', JEAN LOUIS ARMAND, de, D. Sc., M. D. : anthropologist ; b. at Berthezème, department of Gard, France, Feb. 10, 1810 ; studied at Strassburg, Toulouse, and Paris ; was appointed Professor of Natural History at Toulouse in 1838, at the Lycée Napoléon in 1850, and in 1855 at the Historical Museum of Anatomy and Ethnology. In the early years of his career he devoted himself to natural science, especially the study of marine invertebrata, but on his election to the chair of Ethnology he devoted himself exclusively to anthropology, becoming its foremost exponent. Of his writings, several have been translated into English : *Souvenirs d'un Naturaliste* (1854 ; London, 1857) ; *Métamorphose de l'Homme et des Animaux* (1862 ; London, by H. Lawson, 1864) ; *Histoire de l'Homme* (1869 ; New York, by Miss E. Youmans, 1875) ; *Charles Darwin* (1870) ; *La Race prussienne* (1871) ; *L'Espèce Humaine* (1877) ; *Hommes fossiles et Hommes sauvages* (1884) ; *Les Pygmées* (1887). D. Jan. 13, 1892.

Revised by S. T. ARMSTRONG.

Quatremère, -mār', ÉTIENNE MARC : Orientalist ; b. in Paris, France, July 12, 1782 ; became Professor of Greek at Rouen in 1809, of Hebrew, Aramaic, and Syriac at the Collège de France in 1819, and of Persian in the École des Langues Orientales Vivantes in 1827. His principal works were *Recherches historiques et critiques sur la Langue et la Littérature de l'Égypte* (1808) ; *Mémoires géographiques et historiques sur l'Égypte* (1810) ; *Observations sur quelques points de la Géographie de l'Égypte* (1812) ; *Mémoire sur les Nabatéens* (1835). He also translated and edited Rashid ed-Din's *Histoire des Mongols de la Perse* (1836), and Makrizi's *Histoire des Soultans Mamlouks* (1837–40). He was also a contributor to the *Journal Asiatique* and to the *Journal des Savants*. D. in Paris, Sept. 18, 1857. C. R. G.

Quatremère de Quincy, -de-kăñ'see', ANTOINE CHRYSOSTOME : archæologist ; b. in Paris, France, Oct. 28, 1755 ; studied archæology and art ; took part very actively, but always as a stanch royalist, in the various movements of the Revolution ; was appointed superintendent of public monuments in 1815 ; Professor of Archæology in the Royal Library in 1818 ; censor in 1824. D. in Paris, Dec. 28, 1849. His most remarkable works are *Le Jupiter olympien* (1814) ; *De l'Imitation dans les Beaux-Arts* (1823) ; *Raphaël* (1824) ; *Canova* (1834) ; *Michel-Ange* (1835) ; and a *Dictionnaire historique d'Architecture* (2d edition, 2 vols., 1833). Quay, MATTHEW STANLEY : U. S. Senator ; b. at Dillsburgh, Pa., Sept. 30, 1833 ; graduated at Jefferson College 1850 ; admitted to the bar 1854 ; prothonotary of Beaver County 1856 ; re-elected 1859 ; colonel of the 134th Pennsylvania Volunteers ; military secretary to the Governor of Pennsylvania 1861–65 ; member of Legislature 1865–67 ; secretary of the commonwealth 1872–78 ; recorder of Philadelphia and chairman of the Republican State committee 1878–79 ; again secretary of the commonwealth 1879–82 ; delegate to the Republican national convention 1872–76, 1880–92 ; State treasurer 1885 : elected to U. S. Senate as Republican, and took his seat Mar. 4, 1887 ; chairman of the Republican national committee 1888. C. H. THURBER.

Quebec, kwĕe-bek' : a province of British America, formerly known as Lower Canada, lying N. and S. of the St. Lawrence, extending E. and W. from the Peninsula of Gaspé to the head of Lake St. Francis, an expansion of the great waterway N. W. of the county of Huntingdon, and N. and S. from 52° 30′ N. lat. to the forty-fifth parallel, or the boundary-line of the U. S. The length within these limits is about 700 miles, and the breadth about 300 miles. The land surface is 227,500 sq. miles in extent, the water area 1,400 sq. miles, making a total area of 228,900 sq. miles.

Physical Features.—The natural features surpass in boldness those of the adjacent provinces, chiefly along and near the backbone or chief mountain-range of the country, the Laurentides, as they extend eastward from the vicinity of the city of Quebec to the Labrador coast. This range of highlands, in many places over 1,000 feet high, marks the plain watered by the St. Lawrence and its tributaries, and extending to the Ottawa, loses itself in the milder altitudes of the great watershed of the sister province of Ontario. The scenery along this chain of heights is of the most attractive character. There are many districts that rival the rugged grandeur of the Grampians, such as the highlands of Val Cartier, Laval, Murray Bay, and the Saguenay region. In the Peninsula of Gaspé is the Notre Dame range, an extension of the Alleghanies from the New England States through New Brunswick. The tract between these great ridges and the shores of the St. Lawrence is for the most part undulating and fertile, equaling in fertility the great southern plain of the Eastern Townships.

The distinguishing feature is the waterway of the ST. LAWRENCE RIVER (*q. v.*) and its numerous tributaries, the most important being the Ottawa, the St. Maurice, and the Saguenay on the N., and the Richelieu, the St. Francis, and the Chaudière on the S. The St. Lawrence is navigable as far as Montreal, 520 miles from the sea. The first interruption to navigation is at the Lachine Rapids, 9 miles from that city. The Carillon Rapids, 12 miles in length, prevent passenger steamboats sailing from Ottawa to the Lachine Canal, unless advantage is taken of the canal at Grenville. Beyond the Chaudière Falls at Ottawa the river is navigable. The St. Maurice is interrupted by the Shawenegan Falls, 24 miles from Three Rivers : their height is 150 feet. The Montmorency river falls abruptly into the St. Lawrence over a ledge 250 feet high. Between the St. Lawrence and the Bay Chaleurs, as well as on the N. of that river near the gulf, are innumerable streams famous in the legends of the sportsman and angler : while all over the province, irrigated in every part by the main tributaries of the St. Lawrence and their streamlet tributaries, the province presents every variety of scenery. The most important lakes are St. John, a circular basin drained by the Saguenay and having an area of 360 sq. miles : Temiscaming, drained by the Ottawa, having an area of 126 sq. miles ; Champlain, partly belonging to Canada, partly to the U. S., and by a system of canals connecting the trade of the St. Lawrence with that of the Hudson ; St. Peter, an expansion of the St. Lawrence above Three Rivers ; Memphremagog, the greater part of which lies in the province ; Metapedia ; Massawippi, near Stanstead ; and Megantic, the source of the River Chaudière. The principal islands are Anticosti ; Bonaventure, a fishing station near Gaspé ; the Magdalen islands, a group in the gulf, N. of Prince Edward island ; and, in the river, Bic island, Hare island, Île aux Coudres, Grosse île, the quarantine station, Crane island, Island of Orleans, and the river-girt lands near the confluence of the Ottawa and the St. Lawrence at Montreal, and on the Ottawa at Calumet and Allumette.

Climate.—The climate is on the whole agreeable and bracing. The extremes of heat and cold are more intense than in districts of a corresponding latitude in Europe. There may be said to be but two seasons—winter and summer, the winter extending from about the middle of October to the middle of April. The thermometer in summer seldom registers beyond 90° F., and in winter it sometimes falls 20° below zero. The farmer has his sowings finished early in May, and begins his harvesting in August. September is perhaps the pleasantest month of the year, with its warm days and cool evenings. In November the snow begins to fall, and, in the districts N. of the St. Lawrence, covers the ground until March or April. In the Eastern Townships the snow does not fall so early nor does it lie so late. All over the province the climate is exceedingly healthful, the air being clear and dry both in summer and winter.

Geology, Mineral Resources, etc.—The Quaternary formation is represented by the usual superficial drifts. The Lower Carboniferous series is seen in the thin strips on the southeastern coast of the Gaspé peninsula that form the northern limit of the coal-measures of the maritime prov-

inces; the Devonian system is represented by the Gaspé sandstones and limestones, in which are to be found indications of petroleum; the Silurian and Cambro-Silurian formations occupy the valley of the St. Lawrence between Quebec and Montreal, and constitute the northwestern limit of the Eastern Townships' mineral district; the Cambrian system constitutes the mineral deposits of the Eastern Townships and their crystalline schists; the Huronian formation occurs in the neighborhood of Lake Temis, coming where galena occurs; and the Laurentian formation occupies the northern portion of the St. Lawrence river and gulf.

The mineral wealth is incalculable, but is in an undeveloped condition. There are valuable gold mines at Beauce, copper mines in Megantic and Brome Counties, nickel mines in Pontiac, and the best of iron ore to be found in St. Maurice. Slate-stone, mica, and asbestos also abound.

In the Laurentides, with their rich crop of beautiful crystalline specimens, are to be found indications of iron in the phosphate and magnetic condition, plumbago, mica, and splendid building granites and limestones. Slate-stone for roofing purposes has been quarried in large quantities from the clay schists of Kingsbury, while the copper mines near Lennoxville are very valuable. The Trenton limestones of the Silurian deposits have supplied building material for Quebec and Montreal, while the gray and white granites of Compton and Stanstead Counties have also been utilized for purposes of building and ornamentation.

Fauna.—The fur-bearing animals that exist, though in diminished numbers, are beavers, minks, bears, muskrats, foxes, caribou, squirrels, and rabbits. Of the game-birds there are still to be found duck, geese, partridge, and snipe. Eagles, hawks, and loons are often taken by the woodsman.

Industries.—Fifty per cent. of the population farm the lands on and near the rivers. The principal agricultural products are hay, oats, potatoes, barley, wheat, turnips, peas, buckwheat, maize, and tobacco, and the chief domestic animals, sheep, swine, horses, and cattle. The most fertile districts are to be found in the Eastern Townships, where creameries and cheese-factories yield great profit.

The forest wealth is very considerable, and can be extensively utilized, as there is hardly a stream which does not provide water-power. The ship-building interest has all but disappeared, but the export of lumber is still an active branch of trade. The practice of squaring the timber for exportation has very much declined. Most of the timber exported is pine and spruce. The forest-trees include also maple, birch, elm, beech, cedar, oak, ash, and cherry.

While in the fishery industry Quebec occupies only the fourth place among the provinces of the Dominion, there is perhaps no district in the world that is so famous for its inland fisheries. At the mouth of the St. Lawrence and on the Chaleurs Bay are to be found large quantities of cod, haddock, salmon, mackerel, and lobster; and in the lakes of the province the trout-fisheries all but equal the fame of the salmon-fisheries of its coast waters. The government of the province holds in its own hands the leasing of the inland waters, and a considerable revenue is realized from the letting of these waters to fish and game clubs. Over $2,000,000 is realized annually from the fisheries.

Railways and Canals.—The principal railway companies are the Grand Trunk, the Canadian Pacific, and the Intercolonial. The Grand Trunk and the Intercolonial have their eastern terminus at Levis, the Canadian Pacific in the city of Quebec. The minor lines are the Quebec Central from Quebec to Sherbrooke, the Lake St. John from Quebec to Chicoutimi, the line between Montreal and Sorel, the Central Vermont, from Montreal to the U. S., the Maine Central, the Boston and Maine, the Canada Atlantic, and the Pontiac and Pacific Junction Railway. The principal canals, forming a system the largest and most important in the world, are the Beauharnais (11¼ miles, with 6 locks), the Soulanges (14 miles, with 5 locks), the Lachine (8½ miles, with 5 locks), the Carillon and Grenville, and the Chambly. Highways between all places of importance and by-roads between the outlying portions of remote settlements are kept in repair by the provincial government.

Political Divisions and Government.—The province is divided into sixty-three counties, which send to the Legislative Assembly at Quebec seventy-three members. The head of the provincial government is the Lieutenant-Governor, appointed by the Governor-General of the Dominion. His councilors, generally six in number, form the executive, subject to the Legislative Council (of twenty-four members) and the seventy-three members of the Assembly. Thus there are represented the three estates of Great Britain—the Lieutenant-Governor (as the sovereign), the Legislative Council (as the House of Lords), and the Legislative Assembly (as the House of Commons). To the Dominion House of Commons Quebec sends sixty-five members, and is expected to have twenty-four Senators appointed by the Governor-General to the Dominion Senate.

In 1900 the provincial auditor reported the gross receipts from all sources to be $4,539,736, and the expenditure to be $4,626,472. On June 30, 1899, the total funded debt outstanding was $35,128,847; the net floating debt was $1,522,462.

The judiciary, except the local magistracy, is in the appointment of the Dominion Government, and consists of the court of queen's bench, the superior court, and the court of review. In addition to these there are the admiralty court, the court of quarter sessions, and the courts for petty causes.

Population.—In 1871 the population was 1,191,516; in 1881, 1,359,027; in 1891, 1,488,535. The English-speaking persons number about 300,000. In 1891 there were 1,291,709 Roman Catholics, 75,472 members of the Church of England, 52,659 Presbyterians, 39,416 Methodists, 6,854 Baptists, 4,296 Congregationalists, 3,364 Adventists, and 2,703 Jews.

The principal towns are Montreal (pop., 1891, 216,650), Quebec (63,090), Hull (11,265), Three Rivers (8,334), St. Hyacinthe (7,016), Sorel (6,669), Valleyfield (5,516), St. Johns (4,722), and Fraserville or Rivière du Loup (4,175).

Education.—The education of the people is in the hands of the Department of Public Instruction, at the head of which is a superintendent. The Council of Public Instruction consists of two committees, the Roman Catholic and the Protestant, each having control of the schools according to the religion of the majority of ratepayers in any municipality. The schools supported by the minority in any municipality are called dissentient schools. The common schools are for the most part under the supervision of the department, with its forty inspectors and other officers. The Protestant committee has the immediate supervision of what are called the Protestant superior schools, and has an inspector of its own to visit and examine the model schools, academies, high schools, and colleges under Protestant control. These schools have a course of study of their own which brings them in line with McGill University in Montreal, and Bishop's College University at Lennoxville. Affiliated to these institutions are Stanstead Wesleyan College, St. Francis College at Richmond, and Morrin College at Quebec. The Roman Catholic University is at Quebec, a development of the two seminaries founded by the first Roman Catholic bishop, and is known as Laval University.

The public revenue, derived from the subsidy of the central Government, the sale of crown lands, lease of inland fisheries, and direct taxation, amounts to nearly $5,000,000. The amount spent on education by the Government is less than $400,000, and the amount for charitable institutions over $300,000.

History.—The early history of Quebec is that of Canada. Jacques Cartier in 1534 sailed up the gulf, passing Anticosti, and exploring Chaleurs Bay and Gaspé Peninsula. He returned in 1535 and sailed up the St. Lawrence as far as Montreal (then Hochelaga). Champlain founded Quebec in 1608, and after exploring the upper waters of the St. Lawrence and its tributaries established forts and fur-stations in various parts. The early colonization of Quebec was more or less a religious enterprise, an adjunct to the Recollet and Jesuit missions. The government was French up to 1759, when the battle of the Plains of Abraham was fought by Gen. Wolfe and the government became English. In 1791 Quebec was known as Lower Canada, and as such was united to Upper Canada in 1841. In 1867, by the Act of Confederation, it became a province of the Dominion of Canada.

J. M. Harper.

Quebec: the capital of the province of Quebec and the oldest city in Canada; situated mostly on a plateau and its ridges, at the confluence of the St. Charles and the St. Lawrence (see map of Quebec, ref. 4–D). The plateau extends from Cap Rouge, the site of Roberval's encampment, for a distance of 8 or 9 miles toward the island of Orleans, just below Quebec and about 180 miles from Montreal and 300 miles from what is generally called the Gulf of St. Lawrence.

Area and General Plan.—Quebec is one of the most interesting cities in America, and has often been called a bit of the Old World set down on the shores of the New. The city, which covers an area of 16,000 acres, may be divided

into three sections for purposes of description—the Upper Town, crowned by the citadel and facing the harbor at the Dufferin Terrace and the Grand Battery; the St. John Suburbs, on the northern slope of the plateau beyond the walls, meeting the level tract of St. Roch and St. Sauveur; and Champlain Street, running along the shore of the St. Lawrence under the steep sides of the plateau on the S. Dufferin Terrace stretches along the rock for a quarter of a mile at a height of 180 feet. It forms part of the line of fortifications around the city proper, and in summer is the favorite promenade of the citizens. The plateau is intersected by two main thoroughfares, St. John Street, within and without, vanishing in the St. Foye Road, and St. Louis Street, with Grande Allée, having for its prolongation the St. Louis Road. These run parallel with Champlain Street, and meet at the one end at Cap Rouge and at the other by means of the short connecting links of Fabrique Street, Buade Street, and the Place d'Armes at or near the Château Frontenac, a hotel built near the site of the old Château St. Louis, once the residence of the French governors.

Public Buildings.—On approaching the city from the harbor the principal structures are the Parliament buildings on the height of land just outside St. Louis Gate, Laval University to the right, the citadel to the left, and the Basilica, the English cathedral, the court-house, and the Château Frontenac with Dufferin Terrace between. Of these, the Laval University is the largest Roman Catholic educational institution in Canada. It receives its name from Bishop Laval, who founded the adjacent seminary in 1663, and has a valuable collection of pictures and scientific apparatus and specimens. Within the magnificent group of buildings behind the Grand Battery are the two seminaries, and that historic Basilica where four French governors lie buried. The Parliament buildings form a majestic quadrangle. The citadel is the most prominent feature of the city proper. It covers an area of 40 acres on the summit of Cape Diamond, and is in charge of a small troop of Canadian regulars. Passing along St. Louis Street toward the St. Louis Gate, the principal buildings are the Ursuline Convent, founded in 1641, the St. Louis Hotel, the old Military Hospital, used for some time as the Palais de Justice, Chalmers (Presbyterian) church, the old Government House, and the Club House. Outside the St. Louis Gate are the Convent of the Franciscans, completed in 1900, containing a very beautifully decorated chapel; the Convent of the Good Shepherd with its prominent spire, the Female Orphan Asylum, St. Bridget's Asylum, the Ladies' Protestant Home, and the District Jail. In St. John Street are the two fine churches of St. Matthew and St. Jean Baptiste. Near this thoroughfare are Morrin College, which contains the library of the Literary and Historical Society, St. Andrew's church, the Methodist church, the Jesuits' church, the National School Building, the Hôtel Dieu, the Gray Nunnery, the Hotel Victoria, St. Patrick's church, Trinity church, the Y. M. C. A. Building, the Finlay Asylum, and the new Jeffrey Hale Hospital. On the St. Roch side of the city there are six churches, and on the Champlain Street side there are four. The most interesting of these is the Church of Notre Dame des Victoires, built in 1688. It is the second oldest church in America, and was built to commemorate the victory of the French over Sir Hovenden Walker's English fleet. After the victory over Sir Wm. Phips in 1690 the church received its present name. The chief buildings in the Lower Town are the Champlain Market-house and the custom-house.

Suburban Places of Interest.—Among the places of interest in and about the city are the Plains of Abraham, with its monument to Gen. Wolfe, commemorating the battle of 1759; Wolfe's Cove, where the British landed, afterward gaining the heights; Près-de-Ville, where Gen. Montgomery fell in 1775; Montmorency Falls, where Montcalm kept Wolfe at bay for months before the decisive battle was fought; Beauport and its asylum; the island of Orleans, called Île de Bacchus by Cartier; Levis, with its three commanding forts; the graving-dock, capable of accommodating the largest vessel afloat; the Louise Embankment and its basin of safety for ships; the River St. Charles and its picturesque scenes; Lorette, with its falls and ancient Indian church; the Chaudière Falls at the outlet of the Chaudière, a tributary of the St. Lawrence; Château Bigot, beyond the pretty village of Charlesbourg, once the residence of the Intendant Bigot; the mouth of the Lairet, where Jacques Cartier spent his first winter in Canada; and Cap Rouge.

Industries, Commerce, etc.—The chief industries are the manufacture of leather and the shipping of lumber and grain. The principal factories are for boots and shoes, tobacco, and peltries. In 1900 the value of exports was $4,879,503, and of imports $6,317,937; 627 sea-going vessels entered and cleared the port; total tonnage, 1,126,901. The docks and wharfage properties extend from the mouth of the St. Charles round the river frontage for nearly three miles. The first bank was established in 1818. Five banks have a combined capital of $6,600,000, and there are besides three savings and loan societies and three branch banks. The principal railway lines meeting in the place are the Intercolonial, the Quebec Central, and the Grand Trunk on the south side of the river, and the Canadian Pacific, the Lake St. John, the Great Northern of Canada, and the Montmorency and Charlevoix line on the north side. The city has an abundant supply of water from Lake St. Charles, 9 miles distant. It is also lighted with electricity, the power being obtained from Montmorency Falls, 7 miles distant, and from the Jacques Cartier river, 14 miles distant. There is also an excellent electric street-railway system.

Civic Government, Taxation, etc.—The city government has at its head the mayor, chosen by the council, which consists of thirty aldermen elected by the various city wards. The new civic buildings, a handsome block with two wings, are situated on the site of the old College of the Jesuits, in the center of the city, opposite the Basilica. Taxation is 17½ per cent. of the rental value of property, which for the whole city is estimated at $1,370,500, while the estimated value of the property itself is $27,741,000. The debt is $7,493,895, but this is offset by city property valued at $4,713,025. There are 5 daily newspapers—2 French and 3 English—and 7 weekly journals, only 2 of which are English.

History.—Quebec was founded by Champlain in 1608, but its site had been visited by Cartier in 1535. In 1663 it became the capital of the royal government established in New France. The French held possession of it till 1759. In that year the battle of the Plains of Abraham led to the Treaty of Paris in 1763, when the whole country became British, with Quebec as its first capital. Pop. (1881) 62,446; (1891) 63,090; present estimate, 76,000.

Revised by J. E. Middleton.

Quebracho, kĕe-braa'chō: an evergreen tree (*Aspidosperma quebracho*) of Brazil and the Argentine Republic, from the bark of which may be obtained six different alkaloids. The aspido-spermine of commerce practically represents all six of these substances. The bark is used in cases of disordered respiration, more particularly asthma.

Quedlinburg, kwed'lin-boorch: town of Prussia, province of Saxony, at the foot of the Harz Mountains, on the Bode (see map of German Empire, ref. 4–E). It was founded by Henry the Fowler in 920, and is surrounded with walls surmounted by towers, and has manufactures of damask, linen, and woolen, besides breweries, distilleries, and sugar-refineries. It is famous for its nurseries, and exports seeds to other parts of Europe and to America. Pop. (1890) 20,761.

Queen Anne's Bounty: See Bounty.

Queen Charlotte Islands: a small group in the North Pacific Ocean, about 80 miles from the coast of British Columbia. Only Graham and Moresby are of considerable size. The islands extend about 180 miles parallel with the coast of the mainland and their greatest breadth is 60 miles. Adapted by the genial climate and fertile soil to support a considerable population, the islands have but few colonists. The coast waters abound with fish. The Haida Indians living along the coasts now number only a few hundred. For best description see Dawson's *Report of Progress* (1878–79), Geological Survey of Canada.

Queen Charlotte Sound: See Vancouver Island.

Queens, Borough of: See the Appendix.

Queen's Counsel: See King's Counsel.

Queen's County: a county of Ireland in the province of Leinster. Area, 664 sq. miles. The surface is mostly flat, rising in the N. W. into the Slieve Bloom Mountains, whose summit, Ardern, is 1,734 feet high. It is drained by the Barrow and the Nore. The soil is fertile; agriculture and dairy husbandry are the principal occupations, and there is a little cotton and woolen weaving. The principal towns are Maryborough and Mt. Mellick. Pop. (1891) 64,883.

Queensland: the youngest of the Australian colonies of Great Britain, though it has surpassed all except New South Wales and Victoria in population and commercial importance. Occupying the northeast part of the continent between New South Wales and Torres Strait, it is surpassed in

size only by the colony of South Australia. Area, 668,497 sq. miles. The most important feature of its physical formation is the back-bone of hills known as the Great Dividing Range, which extends along the east coast from 50 to 200 miles inland. It forms, in large part, the water-parting between the eastern and western rivers, and though not so high as the southern Australian mountains, much of the moisture carried inland is condensed on its eastern slopes and carried back to the sea in numerous small rivers. The result is that the narrow, eastern part of the colony is better watered and more fit for agriculture than the great plains lying west of these ranges of hills. The plains are fresh and green in the spring, but most of the year they are parched for lack of water, though grazing in this region is one of the chief industries. The better settled districts are along the southern half of Eastern Queensland, where the annual rainfall is about 60 inches, while along the northeastern tropical coast the precipitation is about 120 inches a year, and on the western plains only 10 to 30 inches. Half of Queensland and four-fifths of its 2,500 miles of coast-line lie within the Torrid zone, but the climate of the large regions adapted for white colonists, although very hot, is, on account of its dryness, more salubrious than in most other countries in the same latitude. There is scarcely any fever, except in some new settlements.

Most of the flora peculiar to Australia is found in Queensland, with the addition of about 500 Indian and Malayan species. The fauna is for the most part identical with that of New South Wales. Of Australia's 700 species of birds, about 600 are found in Queensland. The agricultural possibilities are enormous, though much of the farming region suffers from alternation of droughts and floods. Maize is the principal product, though wheat and oats are also grown. Most of the grains and fruits of the U. S. thrive on the highlands, while all the best tropical fruits are grown to perfection in the low-lying coast districts. Sugar is becoming one of the great industries. The growing of sugar-cane centers chiefly in the neighborhood of 21° S. lat., though it is raised as far S. as Brisbane. Most of the work on the sugar-plantations has been done by natives of the South Sea islands, whom the Australians call Kanakas. Various abuses connected with their importation have led to legislation practically cutting off this source of labor supply and temporarily retarding the development of sugar-planting. The colony is unusually rich in valuable woods, both hard and soft, there being about 200 species that are useful. The semi-arid plains are adapted for raising cattle and sheep on a large scale, because some of their grasses have a remarkable power of enduring droughts. The Mitchell grass is most noted in this respect, and other very nutritive plants are the kangaroo and blue grasses. Of the 360 kinds of grasses found in Australia, about three-fourths thrive in Queensland. The settlements are steadily extending into the western downs since various lines of railway have made them easily accessible. All the rivers are shallow and not navigable for large vessels, but there are a number of good harbors and dredging operations are constantly improving them.

The colony has great mineral wealth, particularly in gold, silver, copper, tin, antimony, and mercury. The gold is found chiefly in quartz-veins, and only about one-fifteenth of the miners are working placer claims. Many mineral regions among the hills can not be developed until railways make them more easy of access. Some unexampled mines have been discovered, among them mountains of pure iron ore at Cloncurry, one of which is 200 feet high. Mt. Morgan, discovered in 1884, is the richest gold mine in Australia. Gold is found there under conditions not known elsewhere, being distributed throughout the mass of the mountain, which is 300 feet high, and was evidently produced in the tertiary period by a hot spring which deposited siliceous sinter, with some limonite and clayey substances, through all of which the gold was sprinkled. There is also a large production of gold in the Charters Towers district. The coal formations cover a vast territory, and Queensland promises to become the leading exporter of coal in the southern hemisphere.

The population in 1891 was 422,776, including 20,000 Chinese and about 21,000 aborigines. There are ten towns having over 5,000 population, and the growth of Brisbane, the capital, has been remarkably rapid. (See BRISBANE.) The population of the towns exceeds by very little that of the agricultural and grazing regions. There are about 140 men to every 100 women. The natives are rapidly dying out. Those living in the north are cannibals, and few of them seem able to live long under civilization. C. C. ADAMS.

Queens'town: town; in the county of Cork, Ireland; on the south side of Great island in Cork harbor; 12 miles S. E. of the city of Cork (see map of Ireland, ref. 14–F). Though poorly built on the whole, it presents a fine appearance from the sea. The principal feature is a large Roman Catholic cathedral. Queenstown is an important port of call in connection with the carriage of the mails between the U. S. and the United Kingdom. The place was known as *Cove* until 1849, when it received its present name in honor of the Queen's visit in that year. Pop. (1891) 9,123.

Quelpaert, kwel'pärt: island: about 60 miles S. of Korea, to which it belongs; is about 40 miles long and 17 miles broad (see map of China, ref. 5–L). A mountain range traverses its entire length, culminating in the center in the Auckland (Halla San) peak, 6,500 feet high. The natives follow both agriculture and fishing with much success. The chief towns are Chu'Song (pop. 20,000), Chong-Hai, and Tai-Chong (pop. 5,000 each). Pop. of island about 50,000. C. C. A.

Quemada: See MEXICAN ANTIQUITIES.

Quercia, kwär'chi-ää, JACOPO, della: sculptor; b. at Quercia, in the Sienese district, Italy, in the latter part of the fourteenth century. At the age of nineteen he produced an equestrian statue of Giovanni d'Azzo Ubaldini, composed of stucco and wood, materials which had never before been so employed. After having executed some marble statues of prophets for the cathedral façade, and some wood-carving of great merit, Jacopo went to Lucca, where, in the Church of San Martino, he made the monument to Ilaria del Carreto, the wife of Paolo Guinigi. In Bologna, under the patronage of Giovanni Bentivoglio, he executed the principal door of San Petronio. When he returned to Siena the Signoria commissioned him to make a fountain to adorn the piazza. This, his principal work, led to his being called Jacopo *del Fonte*; the Signoria bestowed knighthood on him and the office of chief of the works of the cathedral. Three years later he died at Pisa at the age of sixty-four. W. J. STILLMAN.

Quer'citron Bark [*quercitron* is irreg. < Lat. *quercus*, an oak + *citrus*, a tree of the lemon kind]: a valuable dyestuff obtained from the BLACK OAK (*q. v.*). The bark contains a glucoside, quercitrin ($C_{36}4_{38}O_{20} + 3H_2O$), which is decomposed by dilute acids, yielding a yellow dye, *quercetin*, and a variety of sugar known as isodulcite. Flavine is a concentrated product prepared by treating the bark with sulphuric acid. See DYESTUFFS. I. R.

Queres: See PUEBLO INDIANS.

Querétaro, kā-rā'-tăă-rō: an interior state of Mexico, between San Luis Potosí, Hidalgo, Mexico, Michoacan, and Guanajuato; area, 3,938 sq. miles. It lies entirely in the region of the high plateau, but the surface is mountainous, especially in the northern part. The valleys are very fertile, and the higher slopes are covered with pine and oak forests; the climate is temperate and healthful. Deposits of gold, silver, lead, etc., have been worked with profit, especially during the colonial period; but most of them are now abandoned. Agriculture and stock-raising are the most important industries; the chief crops are maize, beans, and maguey on the higher lands, and sugar-cane in the warm valleys. Manufactures, especially of cotton and woolen goods, are important. Pop. (1893) estimated, 211,475, the Indian element being largely represented. H. H. S.

Querétaro: city; capital of the state of the same name; on a fine plain, surrounded by wooded hills; 5,904 feet above the sea; 152 miles by the Mexican Central Railway N. W. of Mexico city (see map of Mexico, ref. 7–G). It presents a very pleasing appearance, owing to the numerous gardens and lines of trees with which it is ornamented, and its handsome and substantial buildings. The Church of Santa Clara is noted for its exquisite wood-carvings. A fine aqueduct, dating from the eighteenth century, supplies the city with water. Querétaro is one of the most important manufacturing centers of the republic, and contains the largest mills, principally devoted to the making of cottonades. The Hercules mill employs 2,000 workmen, and is remarkable for being fortified and for maintaining a small armed force, which has more than once defended it successfully during revolutionary outbreaks. The town was founded by Chichimec Indians in the fifteenth century, and was conquered by the Spaniards 1531–51. In 1867 Maximilian made his last stand here; the city was taken after a bloody siege, and the ex-emperor was shot on a hill near it. Pop. (1892) about 36,000. HERBERT H. SMITH.

Quern [O. Eng. *cweorn* : M. H. Germ. *kurn* : O. N. *kvern* : Goth. *qaírnus*, mill]: the old-fashioned hand-mill for grinding grain, in use in Asia at the present day, as well as in the Hebrides, in Ireland, and in various remote places. The quern is made of two stones, after the manner of millstones, or it is a rude mortar of wood or stone. Remains of querns belonging to prehistoric peoples have been dug up in many places in Europe.

Quesada, kā-saa′-dăă, Gonzalo Ximenez, de: conqueror of New Granada; b. at Granada, Spain, 1498. He was a lawyer of good family, and Pedro Fernandez de Lugo, who became governor of Santa Marta in 1535, made him his chief lieutenant. The settlement of Santa Marta had been recently founded, and its jurisdiction embraced the present northern coast of Colombia, with an undefined extension southward, including the unexplored river Magdalena. Quesada was given command of an expedition to the interior in Lugo's interests; he left Santa Marta Apr. 5, 1536, with 620 infantry, 85 cavalry, and many Indians. The route southward lay over mountains and then through vast swamps, where the Spaniards suffered terribly from famine, fevers, and hostile Indians. At Tamalameque, on the Magdalena, the survivors met vessels which Lugo had sent them; they then ascended the river to Tora, near the junction of the Sogamosa, where they arrived about Jan., 1537, and passed the rainy season. In exploring the mountains to the E. they heard of the rich kingdom of the Chibchas of Bogotá; and though the force was reduced to 166 men (including 62 horsemen), it was determined to attack this powerful nation. At Barbacoas Quesada (imitating Cortés) resigned his command, and had himself elected governor of the new conquests by the soldiers; in this way he threw off allegiance to Lugo. In the battles which ensued the Indians fled, terrified by the horses. The Spaniards occupied Bogotá, where they were besieged for a month, but gradually the neighboring tribes made peace with them. The *zipa*, or king of the Chibchas, who held out, was killed in battle; a usurping zipa who succeeded him swore allegiance to the King of Spain, but was subsequently tortured and killed. By raids and barter the Spaniards secured a large amount of gold and emeralds. The Spanish city of Santa Fé de Bogotá was founded Aug. 6, 1538. Soon after Benalcazar and Federmann (*q. v.*) joined Quesada, having fought their way respectively from Peru and Venezuela. The three chiefs went to Spain together to present their claims to Charles V. Meanwhile Lugo had died, but his son claimed the conquest. Quesada offended the emperor by unseemly ostentation, and was dismissed. For many years he led a dissolute life in various countries of Europe, until he had squandered the treasure brought from Bogotá. He then renounced all claim to the governorship, and, in consideration of his services, was made marshal of New Granada and given a large *encomienda* of Indians (1549). He took some part in subsequent conquests, and is said to have died, at a great age, of leprosy. An account of the conquest which he wrote has been lost, but it was used by Piedrahita.—His brother, Hernan Perez de Quesada, was left as governor of Bogotá in 1538, and long held the district against the agents of Lugo. In 1543 he made an expedition in search of El Dorado, was arrested and banished on his return, and perished in a shipwreck, 1545. His remains were buried in the Cathedral of Bogota. Herbert H. Smith.

Quesnay, kā′nā′, François: one of the most noted economists of the eighteenth century; b. at Mérey, department of Seine-et-Oise, France, June 4, 1694; studied medicine at Paris, and was appointed first physician to Louis XV. D. at Versailles, Dec. 16, 1774. He is now chiefly known as the founder of the physiocratic school of political economy, and is regarded as the inventor of the term political economy. He developed his views partly in articles in the *Encyclopédie*, partly in his *Tableau économique* (1758), and other writings, which were published in a collected edition in 1768 under the title of *La Physiocratie, ou Constitution naturelle du Gouvernement le plus avantageux au Peuple.* See Political Economy.

Quesnel, kā′nel′, Pasquier: theologian; b. at Paris, July 14, 1634; studied theology at the Sorbonne; entered in 1657 the Congregation of the Oratory; became director of the Paris house of the order in 1662, and prepared his famous *Réflexions morales sur le Nouveau Testament*, for the use of the young men under his charge. He edited the works of Leo I. the Great (Paris, 1675, rep. in Migne's *Pat. Lat.*), and took occasion to defend the Gallican liberties. Compelled to flee in consequence in 1685, he repaired to Brussels, where he joined Arnauld, and finished the *Réflexions*, which was translated into English (London, 1719–25, 4 vols., and the part on the Gospels, n. e., New York, 1867). The book was at first considered harmless by the Roman Catholic authorities, but soon it was discovered that it really contained all the most obnoxious doctrines of the Jansenists. A hot controversy arose, and the author was denounced to the Spanish police in Brussels, and his book was condemned by the pope in the bull *Unigenitus*, 1713. He fled to Amsterdam, where he afterward lived in retirement. D. in Amsterdam, Dec. 2, 1719. He was a very prolific writer, both on moral and historical subjects. His letters were edited by Le Courayer, Paris, 1721–23, 3 vols.

Revised by S. M. Jackson.

Quételet, ket-lā′, Lambert Adolphe Jacques: astronomer and statistician; b. at Ghent, Feb. 22, 1796; was appointed a professor of mathematics in 1814 in his native city and in Brussels in 1819; superintended the erection of the observatory of that city in 1826, and was its director to his death Feb. 17, 1874. His writings on physical science—*Positions de Physique* (1834), *Météorologie de la Belgique* (1864), *Sur la Physique du Globe* (1861), etc.—are valuable, but it is his statistical works—*Sur l'Homme, et le Développement de ses Facultés* (1835), *Sur la Théorie des Probabilités appliquées aux Sciences morales et politiques* (1846), *Du Système social et des Lois qui le régissent* (1848)—which have procured for him a wide reputation.

Quevedo, kā-vā′dō, José Heriberto García, de: poet; b. at Coro, Venezuela, in 1819; d. in Paris, June 6, 1871, in consequence of a bullet received in passing a barricade of the Commune. From the age of six he was educated in Puerto Rico, and later in France and Spain. He traveled extensively in Asia and America, but later became a Spanish citizen, and served first in the Royal Guards and then in the diplomatic corps. His poetical reputation was decidedly ephemeral. Among his *Odas á Italia* (1849), which show imitation of Filicaia and Manzoni, are bits of genuine poetic eloquence; but his long philosophical poems—*Delirium*, *La Segunda Vida*, *El Proscripto*—written in a great variety of meters, are turgid, vague, and confused to the last degree. He wrote also numerous dramatic pieces, and essayed the prose tale and the critical essay, but without permanent success. His *Obras poéticas y literarias* are collected in two volumes (Paris, 1863). A. R. Marsh.

Quezaltenango, kā-saăl-tā-naan′gō: a town of Guatemala, 96 miles W. N. W. of Guatemala city and 35 miles N. E. from its port of Champerico, on the Pacific, on the northern slope of the Cerro Quemado volcano, 7,700 feet above the sea (see map of Central America, ref. 4–D). It is the second city in the republic in size and importance, is the center of a rich agricultural district, and exports coffee and a little sugar. There are several good schools and lyceums and handsome churches. The climate is healthful, though somewhat cold and damp in winter. Quezaltenango was an Indian town before the conquest, and the Indian element still predominates. Pop. about 24,000. It is the capital of a department of the same name, which has an area of 957 sq. miles and a population of 104,800.

Quiché Indians: See Indians of Central America.

Quichua Indians: the Kechuan or Inca nation. See Indians of South America.

Quick, Robert Herbert: See the Appendix.

Quicksand: a sand which yields so readily that any heavy body placed upon it gradually sinks. Quicksands occur on beaches, in bars at the mouths of rivers, in the beds of streams, and are interbedded with formations on the land. Their unstable character renders them unfit for foundations and dangerous to men and animals which attempt to walk across them. Ordinary dry sand is compacted by pressure, and though moving somewhat when pressure is first applied, quickly becomes firm. A sand that is slightly moist has the same properties; but if water is present in such quantity as not merely to fill the interstitial spaces but to hold the grains apart, friction is largely overcome and the mass yields to pressure. This condition often obtains when a current of water moves horizontally through the sand, and always when the direction is upward. As the pressure of particles upon one another is influenced also by their size, a fine sand becomes quick more readily than a coarse one, and a strong movement of water is necessary to render a gravel insecure. The principle of the quicksand is utilized in the

engineering process known as "water-jet pile-driving." A hose or other pipe is attached to a pile so as to discharge water near its lower end. The pile is then placed in position, resting upon the sand to be penetrated, and a stream of water forced through the pipe. The water loosens the sand, and, rising through it, keeps it in a quick condition so that the pile is carried downward by its own weight. The pipe is then withdrawn, and if the sand is not disturbed by a natural water movement, it soon becomes compacted and holds the pile firmly. See FOUNDATION. G. K. GILBERT.

Quicksilver: See MERCURY.

Quietism: a peculiar movement within the Roman Catholic Church, which originated from the celebrated devotional work of the Spanish priest Molinos, *Guida Spirituale* (1675). Quietism makes perfection on earth consist in uninterrupted contemplation, during which the soul remains passive or quiet, under the influence of the Spirit of God, and does not bestir itself enough even to make acts of faith, hope, and charity, to desire heaven, to hate hell, or positively to resist temptation. In opposition to the worldly tendencies of the regular orders, the Jesuits and Dominicans, and to the external character of the Roman Catholic worship, quietism presents a somewhat mystical appearance. It is a sentiment, not a doctrine. It founded no sect, though it met with much sympathy outside of the Roman Catholic Church, especially among the Pietists. In spite of its peaceable character, it awakened, nevertheless, the enmity of other parties, and was even exposed to persecution. Some of its disciples —as, for instance, Madame Bouvier de la Mothe Guyon— described their devotional feelings and exercises in a peculiar manner, which could not fail to call forth severe censure, and even caused the police to interfere. Moreover, the emphasis which the Quietists laid on the inner state of the soul made the ceremonies and rules of the Roman Catholic worship seem somewhat superfluous, and provoked the rigid churchmen. Bossuet attacked Fénelon, their most conspicuous spokesman, who immediately submitted to the decision of the pope. The movement died out in the middle of the eighteenth century. See MOLINOS, MIGUEL.

Revised by J. J. KEANE.

Quilimane, kĕē-lĕē-maa′nā: port of the Portuguese province of Mozambique, East Africa; in a swampy, unhealthful district, at the mouth of the Quaqua river (see map of Africa, ref. 8–G). This river was used by commerce to attain the Zambesi river above the delta, before the discovery (1889) of the Chinde branch of the delta, where ocean vessels may meet river craft. The town was founded in the fifteenth century, but has never attained large importance owing to its insalubrity, difficulty of access, and Portugal's onerous restrictions on commerce. Its trade was formerly in ivory and slaves, thousands of whom were sent to Brazil. Ivory and the British interests in Nyassaland give it a trade of about $1,000,000 a year. Revised by C. C. ADAMS.

Quillota, kēēl-yō′tăă: a town of the province of Valparaiso, Chili; on the river Aconcagua; a station on the railway from Valparaiso to Santiago (see map of South America, ref. 8–C). It dates from before the conquest, and was formerly celebrated for gold-washings. Copper is mined in the vicinity. Pop. about 12,000. H. H. S.

Quills: the shafts of the large wing-feathers of birds. They were formerly the almost exclusive material from which pens were made, and there is still considerable commerce in them. Quills are obtained chiefly from geese, but also from swans, turkeys, and other birds. Crow-quills are valuable in some kinds of drawing. The so-called quills (spines) of the European porcupine have considerable commercial value. Quills are also used for making toothpicks, and for various other purposes. See FEATHERS.

Quillworts: See FERNWORTS (class *Lycopodinæ*, order *Isoetaceæ*).

Quiloa, kee′lō-ăă, or **Kilwa**: a port of German East Africa, about 170 miles S. of Zanzibar; founded by the Arabs in the tenth century; occupied by the Portuguese in the sixteenth century; surrendered in the seventeenth century to Arabs of Muscat, who settled in Zanzibar; acquired in 1888 by Germany from the Sultan of Zanzibar; chief town of the administrative district of Kilwa (see map of Africa, ref. 7–G). It has a fair harbor, and is the center of considerable trade, and was long famous as a shipping-point in the slave-trade. It is a regular port of call for German East African steamers. Pop. about 7,000. An island of the same name lies a little S. C. C. ADAMS.

Quinault, kēē′nō′, PHILIPPE: dramatist; b. in Paris, France, June 3, 1635. He studied law, but at eighteen appeared as a dramatic author. From 1653 to 1666 he produced sixteen comedies, tragi-comedies, and tragedies, which had considerable influence, though scathingly criticised by Boileau. His comedies—the best of which is *La Mère coquette* (1665)—are comedies of plot and situation; and his tragedies (for example, *La Mort de Cyrus*, 1656; *Amalasonte*, 1658; *Astrate*, 1663) are marked by excess of tender sentiment. His greatest originality was shown in the fourteen operas which he wrote for the composer Lulli, and they also had the greatest success. He was chosen to the Academy in 1670. D. Nov. 26, 1688. Editions of his works: *Théâtre* (5 vols., Paris, 1739); *Œuvres choisies* (2 vols., Paris, 1842); *Théâtre choisi*, ed. by V. Fournel (Paris, 1880). A. G. CANFIELD.

Quince [apparently a plur. form taken as singular < Mod. Eng. *quyne, coin*, from O. Fr. *coin* > Fr. *coing* < Lat. *Cydonium* (sc. *ma'lum*, apple), Cydonian apple, quince, from Gr. Κυδωνία, Cydonia, a city of Crete]: a small tree (*Pyrus cydonia* or *Cydonia vulgaris*) of the Rose family; native to Western Asia, and cultivated from the earliest times. The fruit (also called quince) is usually somewhat pear-shaped, yellow when ripe, and clothed with a floccose wool. The five cells are normally many-seeded, thus differing from other fruits of the genus *Pyrus*, as the apple and pear. It has no true peduncle or stem, but the flowers expand directly from the terminal bud of small shoots of the season. As these shoots must grow before the flowers appear, the blooming-season of the quince is two or three weeks later than that of most other fruit-trees. The large fruits, therefore, always terminate the branches, and they are directly subtended by the leaves. It is this habit of bearing flowers and fruit upon the ends of the twigs which makes a quince-orchard in bloom or in crop one of the most showy of all fruit-plantations. Quinces require a rather moist loamy soil. It is customary to plant them from 12 to 16 feet apart each way, and to allow the branches to start a foot or so above the ground. The leading variety in the U. S. is the Apple or Orange, and this generally reproduces itself very closely from seed. Other popular varieties are Rea, Champion, Meech, and Missouri Mammoth. The Angers quince is grown almost wholly as a stock upon which to graft or bud the pear to make it dwarf. (See PEAR.) The quince is chiefly propagated by means of hardwood cuttings, but it is sometimes grafted upon the apple-root, the latter serving only as a temporary nurse until the quince forms roots from its own tissue. The chief quince-growing region of the U. S. is Western New York.

The Chinese quince is *Pyrus cathayensis*. The fruit is much larger than that of the common quince, and wholly unlike it. The tree is not hardy in the northern parts of the U. S., and the species is not generally esteemed. The flowering or Japanese quince (*P. japonica*) is a popular low thorny tree or bush, planted for hedges and ornament. Its fruits are occasionally used for jellies. L. H. BAILEY.

Quincy: city (settled in 1822, incorporated as a city in 1839); capital of Adams co., Ill.; on the Mississippi river and the Burlington Route, the Omaha, Kansas City and Eastern, and the Wabash railways; 113 miles W. of Springfield, 263 S. W. of Chicago (for location, see map of Illinois, ref. 6–B). It is built on a limestone bluff, 120 feet above the river, and laid out regularly, with N. and S. streets 3 miles long and E. and W. streets 2¾ miles long. The city is lighted with electricity, is supplied with filtered water from the channel of the river by means of a reservoir 230 feet above tide-water, and is well drained. There are several lines of electric street-railway, a fine railway and wagon bridge across the river, and six public parks. The notable buildings include the court-house, cost $300,000; U. S. Government building, cost $250,000; and the group, on the cottage plan, comprising the State Soldiers' and Sailors' Home, surrounded by 210 acres of park, cost $400,000; city hall, cost over $100,000. There are 41 churches, 27 public and private school buildings, public-school property valued at $300,000, Chaddock School for boys (Methodist Episcopal, chartered 1876), St. Francis Solanus College (Roman Catholic, opened 1860), 3 libraries (free public and two college) containing over 40,000 volumes, a business college, erected in 1890 at a cost of $100,000, with an average attendance of 1,000 and the largest institution of its kind in the world, 2 national banks with combined capital of $500,000, a state bank with a capital of $300,000, a private bank with a capital of $100,000, and 4 monthly, 4 daily, and 14 weekly periodicals. Quincy is a manufacturing city, with excellent shipping facilities.

There are 7 stove-foundries, with an annual output of over 25,000 stoves, the largest governor works in the world, 10 machine-shops, 10 carriage and wagon factories, 2 agricultural-implement works, 3 incubator-factories, 4 shirt and overall factories, cigar and tobacco factories, flour and grist mills, breweries, brickyards, limekilns, saddle and harness factories, and artificial-ice plants. The assessed valuations in 1890 aggregated $11,651,418; and the net debt on Jan. 1, 1900, was $1,071,000. Pop. (1880) 27,268; (1890) 31,494; (1900) 36,252. EDITOR OF "MORNING WHIG."

Quincy: city (settled in 1625, set off from Braintree as a town in 1792, incorporated as a city in 1888); Norfolk co., Mass.; on the Quincy river and bay, and the N. Y., N. H. and Hart. Railroad; 8 miles S. of Boston (for location, see map of Massachusetts, ref. 5–I). The city is noted for its extensive granite-quarries and large shoe-manufactories; also as a terminus of the first railway built in the U. S. (for transporting blocks of granite from the quarries to the site of the Bunker Hill Monument). It contains 8 public-school buildings, public high-school building (completed in 1894, cost $60,000), 2 national banks, with combined capital of $300,000, a savings-bank with deposits of over $1,750,000, Merry Mount and Faxon parks (besides playgrounds of more than 6 acres each in five wards of the city, secured at a cost of $40,000), the Adams Academy (founded in 1823, opened for pupils in 1872), the Thomas Crane Public Library (founded in 1871) containing over 17,000 volumes, and a daily, a monthly, and 2 weekly periodicals. The assessed valuations in 1893 aggregated $16,338,070, and the total debt in Mar., 1894, was $1,103,730, including a water-debt of $714,000. Quincy was the birthplace of John Hancock, John Adams, and John Quincy Adams. Pop. (1880) 10,570; (1890) 16,723; (1900) 23,899. C. H. PORTER.

Quincy, EDMUND: author; son of President Josiah Quincy; b. in Boston, Mass., Feb. 1, 1808; graduated at Harvard 1827; was prominent as secretary of the American and the Massachusetts anti-slavery societies; contributed to magazines; was author of *Wensley, a Story without a Moral* (1854), and of a *Life of Josiah Quincy* (1867), and editor of the *Speeches of Josiah Quincy* (1875). D. at Dedham, Mass., May 17, 1877. *The Haunted Adjutant, and other Stories* was issued in 1885. Revised by H. A. BEERS.

Quincy, JOSIAH, Jr.: lawyer; b. in Boston, Mass., Feb. 23, 1744; son of Josiah Quincy (1709–84), a merchant; graduated at Harvard University in 1763, and became an eminent lawyer. He had already by his writings and speeches obtained prominence as an ardent advocate of the cause of liberty when called upon, in conjunction with John Adams, to defend the soldiers implicated in the Boston Massacre. Although successful in securing the acquittal of their clients, popular feeling ran so high that, notwithstanding their established reputation for patriotism, they incurred much odium by their connection with the defense. In 1774 he went to England, where he was active in promoting the interests of his country. D. on the return voyage, off Gloucester, Mass., Apr. 26, 1775. In 1774 he published his *Observations on the Act of Parliament, commonly called the Port Bill.* See *Memoir of the Life of Josiah Quincy, Jr., by his Son* (Boston, 1825; 3d ed. 1875).

Quincy, JOSIAH, LL. D.: statesman; son of Josiah Quincy, lawyer; b. in Boston, Mass., Feb. 4, 1772; graduated at Harvard University 1790; studied law with Judge Tudor, and was admitted to the bar in 1793; member of the State Senate in 1804, and member of Congress 1805–13, during which time he opposed the embargo law and the war with Great Britain; again State Senator 1813–21; member of State Legislature 1821–23, and Speaker of that body during his last term; appointed judge of the municipal court in 1822, but resigned the following year, having been elected mayor of Boston on the decease of the Hon. John Phillips, the first incumbent; continued in office until 1829, during which time many public improvements were carried out; was president of Harvard University from 1829 until Aug., 1845. Among his published works are *Centennial Address on the 200th Anniversary of Boston* (1830); *History of Harvard University* (2 vols., Boston, 1840); *History of the Boston Athenæum*, of which he was president 1820–30 (Boston, 1851), and *Municipal History of Boston* (Boston, 1852); *Memoir of John Quincy Adams* (Boston, 1858). *Speeches in Congress and Orations* have also been published, besides numerous *Memoirs*, including one of his father (1825). D. at Quincy, Mass., July 1, 1864. See the biography by his son, Edmund (Boston, 1867).

Quincy, QUATREMÈRE, de: See QUATREMÈRE DE QUINCY.

Quinet, kē'nā', EDGAR: author; b. at Bourg, Ain, France, Feb. 17, 1803. He studied at Paris, Geneva, Strassburg, and Heidelberg. He was profoundly influenced by German thought, and upon his return published a translation of Herder's *Ideen zur Philosophie der Geschichte der Menschheit* (3 vols., Paris, 1827). In 1828–30 he was a member of a scientific expedition to Morea; contributed from 1831 to 1839 to the *Revue des Deux Mondes* essays principally on foreign life and thought; was made Professor of Foreign Literature at Lyons in 1839, and of the Languages and Literatures of Southern Europe at the Collège de France in 1842. His political utterances, ardently liberal and anti-clerical, led to his removal in 1846. He then traveled in Spain, took part in the revolution of 1848, was a member of the Constituent and Legislative assemblies, was banished in 1852 after the *coup d'état*, lived in Holland and Switzerland, returned at the fall of the empire, and was deputy in the National Assembly in 1870. D. at Versailles, Mar. 27, 1875. He wrote vast philosophical epics dealing with the history of humanity (*Ahasvérus*, 1833; *Napoléon*, 1836; *Prométhée*, 1838), remarkable for loftiness of conception and striking ideas, but lacking measure and sobriety; and a large number of works of eloquent prose dealing with history, politics, religion, and literature, among them *Le Christianisme et la Révolution Française* (1846); *La Révolution* (1865); *France et Allemagne* (1867). They have been collected in *Œuvres complètes* (vols. i.–x., 1857–58; vol. xi., 1870; vols. xii.–xxviii., 1877–79); to them must be added *Le Livre de l'Exilé* (1875) and *Lettres d'Exil* (4 vols., 1884–88). A. G. CANFIELD.

Quinette de Rochemont, kē'net'de-rōsh'mōn', ÉMILE THÉODORE, Baron: civil engineer; b. at Soissons, France, Aug. 19, 1848; educated at the Polytechnic School and at the École de Ponts et Chaussées, where he graduated 1859; attached to the council general of bridges and roads 1862; 1863–79 resident engineer of the port of Havre; engineer-in-chief of the canal from the Escaut to the Meuse 1879; engineer-in-chief of the port of Havre 1883; inspector-general of bridges and roads at the ministry of public works 1892; and professor at the École de Ponts et Chaussées since the same year. He has published *Mémoire sur le Clyde, Glasgow, Port Glasgow, et Greenock* (1869); *Note sur les phares électriques de la Hève* (1870); *Régime des courants et des marées à l'embouchure de la Seine* (1874); *Notice sur le port du Havre* (4to, 1875); numerous memoirs and notices of the port of Havre 1877 to 1889; *Note sur l'Escaut maritime et le port d'Anvers* (1878); *Note sur le type d'écluse pour le Canal de l'Escaut à la Meuse* (1883); *Les ports maritimes de la Hollande* (1890); *Les ports Allemands de la Baltique* (1891); *Les ports Allemands de la mer du Nord* (1892); *Les ports de la Mersey et de la Clyde* (1892). W. R. HUTTON.

Quinine, ki-neen' or kwī'nīn [= Fr., from Span. *quina*, Peruvian bark, from Peruv. *kina*, bark]: the most important medicinal ingredient of cinchona or Peruvian bark. It was discovered in yellow or calisaya bark in 1820 by Pelletier and Caventou. It exists in all the official barks, but is most abundant in the calisaya. To obtain it, it is first extracted from the bark as a sulphate by means of a complex process. By treating this salt with the solution of an alkali, the quinine is precipitated, and is then washed, dried, dissolved in alcohol, and reobtained by slow evaporation. It may be amorphous, but with care it can be obtained in silky crystals. Quinine is an alkaloid with strong basic properties, and forms with acids crystallizable salts. Its formula is $C_{20}H_{24}N_2O_2$. It is without smell, but has an intensely bitter taste; is very insoluble in water, but dissolves freely in alcohol and moderately in ether. Solutions of the alkaloid or its salts, treated first with chlorine water and then ammonia, strike a brilliant green color. This test is very delicate, and distinguishes quinine from all other vegetable alkalies except quinidia. Quinine is used in medicine principally in the form of sulphate or hydrochloride, the latter salt having the advantage of being more soluble. Quinine salts are locally irritant, and internally in small dose are stomachic; in large, powerfully disturbing to the nervous system, while also tending to cause nausea and vomit. In medicinal doses the most prominent symptoms of cinchonism are headache and deafness, with buzzing or roaring in the ears, muscular debility, and some reduction of the force and frequency of the pulse. In poisonous dose the individual may become completely blind, deaf, and paralyzed, but death is rare. Quinine salts are powerfully anti-

septic, a small percentage preventing or arresting putrefactive and fermentative processes. They also, in small percentage, arrest protoplasmic movement, as in white blood-corpuscles, bacteria, etc., and even destroy permanently the vitality of the organisms. These salts are used in medicine, especially to cure malarial affections of all kinds, over which they have a well-known and unequaled power, by preventing activity in the peculiar micro-organisms (*Hæmatozoon malariæ*) of malarial disease. The five other alkaloids of cinchona bark—namely, quinidine and quinicine and cinchonine, cinchonidine and cinchonicine—are all more feeble than quinine in power and are rarely used, except cinchonidine. Quinicine and cinchonicine are both artificial alkaloids. Revised by H. A. Hare.

Quinisext Council [Lat. *quinque*, five, *sextus*, sixth]: the Oriental Church council which was convened in 692 A. D. to supplement the acts of the fifth and sixth œcumenical councils. It is called also the Second Trullan Council, because it was held in the domed room of the imperial palace at Constantinople, called the *Trullus*. The Greeks consider it the seventh œcumenical council, but the Latins do not recognize it. It was convened by Justinian II., and gave 102 stringent canons on clerical discipline, but allowed the marriages of priests to stand, provided they were first marriages and with virgins. See Trullan Councils.

Quino'a: a woody herb (*Chenopodium quinoa*), which, with other nearly related species, is cultivated in the highlands of Spanish America for its nutritious seeds. Its leaves are used as a potherb.

Quinsy [for *squinancy*, from O. Fr. *esquinancie*, *quinancie*: Span. *esquinancia* < Lat. *cynanche* = Gr. κυνάγχη, a kind of sore throat]: acute suppurative tonsilitis, or inflammation of the tonsil, terminating in abscess. One attack usually leaves subacute or chronic disease of the tonsil, which predisposes the person to repeated attacks in subsequent seasons. Quinsy is most often unilateral, less frequently attacking the two tonsils successively, and rarely coincident upon both sides. It attacks adults, less often children; the two extremes of life, infancy and old age, being quite exempt from it. It occurs in persons of full habit, especially when the diet has been excessive and luxurious. The rheumatic and gouty diatheses especially predispose. The immediate or exciting cause is some exposure of the body to wet or cold. The attack is manifested by soreness of the throat, increased by swallowing and talking, rigidity of the jaw, hypersecretion of saliva, coated tongue, labored breathing, and sense of obstruction, tension, and tumefaction in the throat. With the first development of pus intense throbbing pain exists. The disturbance of the general system is variable, but in general it is remarkable how much constitutional disturbance results from limited local disease in throat-troubles of this kind. In mild cases only impaired appetite and sense of lassitude exist; in graver attacks there may be a slight or marked chill at the onset, and a succession of light chills; the temperature elevated to 102° or 104° F.; the pulse full and bounding; delirium at night, and by day the face expressive of great fatigue, suffering, and alarm. Internal examination discloses the tonsil symmetrically enlarged, extending to the median line of the throat and obstructing it. Palpation by the finger may detect the softness and fluctuation of pus. In from five to eight days the suppurated tonsil bursts, all the symptoms vanish, and recovery is speedy. In its formative or first stage, quinsy may sometimes be aborted by scarification, by ice in the mouth, cold gargles or spray, and astringent gargles or applications, as of alum or tannin, and by administration of saline cathartics and arterial sedatives or quinine. When developed, the inhalation of steam, warm anodyne gargles, soothing poultices or fomentations, anodynes to secure rest, tonics and diet to sustain the strength, and early evacuation of pus with the knife, are the essentials of treatment. Sudden death may occur when the abscess opens spontaneously during sleep and the pus enters the air-passages, or from hæmorrhage when the internal carotid artery is involved by the suppuration. Revised by W. Pepper.

Quintain [Fr. *quintaine*: Ital. *quintana*, *chintana* < Lat. *quinta'na*, a street in the Roman camp between the fifth (*quintus*) and sixth maniples, where probably was set a post for use as a target]: an object, often in the form of a man, designed to be tilted at with a lance. It was sometimes placed at the end of a crosspiece so balanced upon a pivot that if the rider were not very quick a bag of sand at the other end of the crosspiece would strike him in the back.

Quintal [via Fr. and Span. from Arab. *qinṭār*, a weight of 100 lb., probably from Lat. *centena'rius*, consisting of a hundred, from *centum*, hundred]: a hundred weight, chiefly used in weighing fish.

Quintana, kĕĕn-taa'năă, Manuel José: author; b. in Madrid, Spain, Apr. 11, 1772. He studied at the University of Salamanca, and became a lawyer at Madrid. His first literary works, a tragedy and a volume of poetry, were intended to rouse the national spirit against the French, who were then invading the Peninsula; they were very popular. During part of the "war of liberation" Quintana was secretary of the Cortes and the regency; after the restoration his liberal principles led to his mild imprisonment in the castle of Pamplona. In 1833 he was made preceptor to the infant queen, Isabella, and in 1835 he became a senator. His principal work, and one of the modern Spanish prose classics, is *Vidas de Españoles célebres* (1807–34; many later editions). It includes biographies of the Cid, Gonzalo Fernandez de Córdoba, Balboa, Pizarro, Las Casas, etc., and is characterized by clearness and simplicity of style, with much original research. D. in Madrid, Mar. 11, 1857. H. H. Smith.

Quintard, Charles Todd, M. D., D. D., LL. D.: bishop; b. at Stamford, Conn., Dec. 22, 1824; graduated in medicine at the University of New York 1847; became a physician to the New York City Dispensary 1847; Professor of Physiology and Pathological Anatomy in the Memphis Medical College 1851; contributed to medical periodicals; took orders in the Protestant Episcopal Church 1855; was successively rector of churches at Memphis and Nashville; was a chaplain in the Confederate army, and was chosen Bishop of Tennessee 1865. He was the second founder of the University of the South at Sewanee, Tenn., after its destruction during the civil war. He obtained large endowments for this institution in England, and until 1893 was vice-chancellor and trustee. D. Feb. 15, 1898. Revised by W. S. Perry.

Quintil'ian (Lat. *Marcus Fabius Quintilianus*): author; b. at Calagurris, Spain, about 35 A. D.; educated at Rome, and gained there the highest reputation as a teacher of eloquence; received a regular salary from the treasury fund established by Vespasian, and was loaded with the highest civil honors and titles by Domitian. D. probably about 96. About 95 he published his *Institutio Oratoria*, a work in twelve books on the art of oratory, which, besides its great historical interest (bk. x.), may still be read for practical purposes. There are English translations by Guthrie (1756), Patsall (1774), and Watson (1856). The best critical editions are by Halm (2 vols., Leipzig, 1868) and Meister (2 vols., Prague, 1886–87). The lexicon to Quintilian by Bonnel (Leipzig, 1834), forming the sixth volume of Spalding's edition, is valuable. Separate editions of book i. are by Fierville (Paris, 1890), of book x. by Bonnel-Meister (Berlin, 1882), Krüger (Leipzig, 1888), and Petersen (Oxford, 1891). The two collections of *Declamationes*, 19 longer and 145 shorter, ascribed to Quintilian, are probably spurious. A complete edition is by Gronovius (Leyden, 1665) and Burmann (Leyden, 1720). Of the 145 shorter by C. Ritter (Leipzig, 1884). See Schanz, *Gesch. der Röm. Lit.* (Munich, 1892, 2d part, p. 442). Revised by M. Warren.

Quin'tus Cur'tius Ru'fus: the author of an historical work in ten books on Alexander the Great, *Historiæ Alexandri Magni Macedonis*, which was much read and much admired during the Middle Ages. Of the author nothing definite is known. He may have been a rhetor mentioned in an *Index* of Suetonius. Of the work, which was composed under the Emperor Claudius, the first two books have been lost, and some of the others considerably damaged. The narrative is very pleasing, but by no means accurate, and is full of fables. The best editions are by E. Hedicke (Berlin, 1867), Th. Vogel (Leipzig, 1881; and with notes, 1885), S. Dosson (with French notes, Paris, 1887). See also Dosson, *Étude sur Quinte Curce, sa vie et son œuvre* (Paris, 1887). Revised by M. Warren.

Quin'tus Smyrnæ'us, or **Calaber**: Greek epic poet, who composed *Posthomerica* (τὰ μεθ' Ὅμηρον), in fourteen books. The name *Smyrnæus* comes from his own statement (12, 310) that he had lived at Smyrna, *Calaber* from the fact that his poems were discovered in Calabria by Cardinal Bessarion in 1450 A. D. His versification points to an earlier period than that of Nonnus (*q. v.*). The poem covers too much ground and lacks unity. It produces the effect of a mosaic for which Homer, Hesiod, Sophocles, Euripides, Apollonius, Lycophron, and probably even Vergil and Ovid have been laid

under contribution. The style is simple, the descriptions do not lack epic detail, similes abound, and the work is further commended by purity of tone, but there is no true life in it, and no one comes back to Quintus except to investigate his sources. There is an edition by Köchly (Leipzig, 1850), another by the same in the Teubner Library, and a critical one by Zimmermann (Leipzig, 1891). B. L. GILDERSLEEVE.

Quir'inal [from Lat. *Collis Quirina'lis*, the Quirinal Hill; *col'lis*, hill + *Quirina'lis*, pertaining to *Quirinus*, a name of the deified Romulus, deriv. of *Cu'res*. See QUIRITES]: one of the seven hills of Rome, lying N. and a little E. of the Forum. Like the Palatine it was originally the seat of a separate community (as Mommsen has conclusively shown, *Roman History*, vol. i., p. 82) with religious and political institutions of its own. Aside from the ancient temple of *Quirinus*, restored by Julius Cæsar and Augustus, the most important buildings on the Quirinal, of which remains still survive, were the baths of Constantine and the baths of Diocletian. See Ch. Hülsen, *Zur Topographie des Quirinals*, *Rheinisches Museum*, vol. xlix. (1894), pp. 379–424. On the baths, see Middleton, *Remains of Ancient Rome*, vol. ii., pp. 177–186. G. L. HENDRICKSON.

Quiri'tes [= Lat., plur. of *Qui'ris*, probably meaning a citizen of CURES (*q. v.*)]: the citizens of ancient Rome, synonymous with *populus Romanus*, or even added to it, as *populus Romanus Quiritium*. The singular *quiris* is very rare, and the plural form is only used in certain set formulas —e. g. *Quirites* (as a form of address), *jus Quiritium* (full Roman citizenship), and the example given above. G. L. H.

Qui-tam Actions: See INFORMER.

Quit-claim: a word often employed in deeds in which the grantor or seller undertakes no responsibility in regard to the validity of his own assumed right to the property in question, but merely conveys to the grantee or buyer his own interest, whether valid or the reverse.

Quitman, JOHN ANTHONY, LL. D.: lawyer and soldier; b. at Rhinebeck, N. Y., Sept. 1, 1799; received a liberal education; became a lawyer, and was professor at the Mount Airy College, Pa., 1819; practiced law at Chillicothe, O., 1820–23; removed to Natchez, Miss., where he became a successful planter and rose to distinction in his profession and in the politics of the State; was chancellor of the superior court 1828–31 and 1832–34; member of the State Legislature 1828–32; president of the Senate in 1835 and Governor *pro tem.*; judge of the high court of errors and appeals 1839; distinguished in the Texan struggle for independence, he was, on the outbreak of the war with Mexico, appointed brigadier-general of volunteers; promoted to be major-general Apr., 1847; was distinguished at Monterey, Chapultepec, and assault and capture of the city of Mexico; Congress presented him with a sword for his services at Monterey, and Gen. Scott appointed him governor of the city of Mexico. Returning home at the close of the war, he was elected Governor of Mississippi in 1850, and from 1855 to 1858 was a member of Congress and chairman of the committee on military affairs. D. at Natchez, July 17, 1858. See his *Life and Correspondence* (2 vols., 1860), by F. H. Claiborne.

Quito, kee'tō: a city; capital of Ecuador; on the Andine plateau, 9,250 feet above the sea; a few miles S. of the equator, and 165 miles N. N. E. of Guayaquil (see map of South America, ref. 3–B). The plain or valley of Quito is an elevated basin nearly surrounded by some of the highest peaks of the Andes. The city itself is built on the lower spurs of the Pichincha volcano, and Cayambé, Antisana, Cotocachi, Cotopaxi, Sinchalagua, Corazon, and Iliniza are in plain sight, their snow-clad peaks forming a panorama of almost unequaled grandeur. The ground occupied by the city is very uneven and is traversed by deep ravines spanned by arches: the streets are narrow, indifferently paved, and so steep that carriages can not be used. Owing to the danger from earthquakes, most of the houses are built with only one story, but many of them are substantial, and the older ones recall the early colonial period. The public buildings are generally of stone; the cathedral, government and archbishop's palace, and city-hall are grouped about the Plaza Mayor, a handsome square and public garden. There are many churches and convents, a public (formerly the Jesuits') library, hospitals, observatory, and several educational institutions, including the ancient university, which is essentially a theological seminary. Many of the ecclesiastical buildings are adorned with paintings by native artists, and the city has a wide reputation as an art center. In population and commerce it is surpassed by Guayaquil; it has been impoverished by frequent revolutions. No railway connects it with the outer world, and there is only one good carriage-road out of the city—that to Guaranda. The bulk of the population consists of small tradesmen and artisans and Indian laborers and servants. The climate is spring-like, very equable, and salubrious. The natural drainage keeps the city healthful, though sanitary rules are neglected. Quito is probably the oldest existing city in America, having been the capital of the ancient Quitu chiefs. It was taken by the Inca Tupac Yupanqui about 1470, was thereafter a favorite residence of the Incas, and when their empire was divided in 1525, became the capital of the northern portion. The Spanish general Benalcazar took it and founded the modern city in 1534. During the colonial period it was the capital of the presidency of Quito (now Ecuador). The most destructive earthquakes were in 1797 and 1859. Pop. about 35,000. HERBERT H. SMITH.

Quittor: See FARRIERY.

Quoits, kwoits or koits [M. Eng. *coite*, from O. Fr. *coitier*, push, harass < Lat. *coactare*, force, freq. of *cogere*, compel]: a game of strength and skill, in which the player strives to pitch a flattened ring of steel (called a quoit) in such a way as to land it as near as may be to a peg or hob of iron stuck upright in the ground, or, if possible, to make it ring the hob. This game differs from the discus-play of the ancients, in which the player threw a disk of metal or stone as far as he could, the longest thrower winning the prize.

Quoratean Indians [*Quoratean* is an adaptation of Quoratem, or Kworatem, the native name of Salmon river, California, as well as of a small band formerly residing at its mouth]: a linguistic stock of Indians, whose geographic limits are somewhat indeterminate. The main area occupied by the tribes includes both banks of the lower Klamath, from a range of hills a little above Happy Camp to the junction of the Trinity, and Salmon river from its mouth to its sources. On the N., Quoratean tribes extended to the Athapascan territory near the Oregon line.

The tribal divisions are the Ehnek, Karok, and Pehtsik. The Ehnek are well formed and compact, and in stature are but slightly inferior to the whites. The women are better-looking, fairer, and of livelier disposition than any on the coast, and not a few have married among the settlers. The social organization is exceedingly democratic, the authority of their village chiefs being only nominal. In time of war they had a single chief, and instead of taking scalps, decapitated their captives. The Ehnek have many dances, among which is one performed in the fall, for the spirits of the earth and forest, and another immediately before the salmon-catch in spring. The term Karok means *up the river*, and is applied to the Indians who reside on the middle Klamath, in contradistinction to those living near the mouth. In 1889 the Indians of this stock numbered about 600. See INDIANS OF NORTH AMERICA, and Stephen Powers, *Tribes of California* (*Contributions to North American Ethnology*, iii., Washington, 1877). F. W. HODGE.

Quorum: See PARLIAMENTARY LAW (*Adoption of Motions*).

Quotidian: See FEVER and CHILL.

Quo Warranto, Writ of, or (as often abbreviated) **Quo Warranto** [Law Lat., by what authority; Lat. *quo*, by what + *warranto*, abl. of Mediæv. Lat. *warrantum*, warrant, authority]: a very ancient common-law writ, in the nature of a writ of right, for the crown against a person or corporation claiming or usurping any office, franchise, or liberty, to inquire by what authority the claim was supported, or to determine the right. The writ also lay in case of non-user or long neglect, and in case of misuse or abuse. The respondent was commanded to appear and show by what right he exercised the office, franchise, or liberty, not having a grant of it, or having forfeited it for non-user or abuse. The proceeding of *quo warranto* was long, and the judgment in it conclusive even against the crown. In England it was superseded at an early day by the proceeding called an information in the nature of a *quo warranto* (see INFORMATION), and it is little used in the U. S. F. STURGES ALLEN.

R

: the eighteenth letter of the English alphabet.

Form.—It is the Latin R or ℟ derived from the Greek R, ℟, a form of the letter Ρ (rho), particularly common in the alphabets of Eubœa, Bœotia, Phocis, Locris, Thessaly, and the Peloponnesus. The added dependent stroke was preserved in the Latin alphabet as a convenient means of distinguishing the letter from the form of *pi* (Ρ instead of Π) generally adopted there. The Phœnician form of the letter was ϟ.

Name.—The Semitic name *rēsh*, head (side view), was changed in Greek to *rhō* (ῥῶ). In Latin the letter received the phonetic name *er*, which appears in O. French as *erre*, Provenç. *erre*, *erro*. Adopted into M. Eng., this yielded in Mod. Eng. the present name *ar*; cf. *ferme* > *farm*, *persone* > *parson*, *persil* > *parsley*, *gerner* > *garner*, etc.

Sound.—In the standard English of Great Britain and in that of the southern and northeastern part of the U. S., *r* stands for a consonant only when it immediately precedes a vowel as in *ride*, *dry*, *try*. This consonant sound is a spirant, either voiced or voiceless, produced between the tip of the tongue and the forward palate or the ridge between palate and gums. Before the back-vowels the tongue-tip is turned back toward the palate, as in *raw*, *roar*, *rout*; otherwise it turns toward the ridge of the gums, as in *rid*, *red*. It is often voiceless after voiceless consonants; contrast *try* and *dry*. After vowels it denotes, in the language of the localities mentioned above, the sound of the obscure vowel ə, or is entirely silent. Thus it is pronounced as ə in *care*, *floor*, *dire*, *our*; it is silent or results in lengthening the preceding vowel in *far*, *sir*, *fern*.

Source.—In Teutonic words it generally represents either (1) Teutonic and Indo-European *r*; as *red* < O. Eng. *rēad*: Goth. *ráuþs*: Germ. *roth*, cf. Gr. ἐρυθρός: Lat. *ruber*: Sanskr. *rudhirá-*, or (2) Teutonic *z* < Indo-European *s*; as *ear* < O. Eng. *ēare*: Goth. *áusō*: Germ. *ohr*, cf. Lith. *ausis*; *sear* < O. Eng. *sēar*, cf. Lith. *saũsas*, dry, Gr. αὕειν, to dry up.

Symbolism.—R = rood, rod, king (*rex*), queen (*regina*), take (*recipe*); Rh. = rhodium. See Abbreviations.

Benj. Ide Wheeler.

Ra (Egypt. *Rā*): the Egyptian "sun-god," "father of gods and men," in whom in particular the solar worship of the Egyptians was centered. Heliopolis contained his principal sanctuary and was the center of his cult, which was very ancient. He was regarded as the offspring of the celestial ocean, and was believed to have appeared first at Heracleopolis (*q. v.*), where he gained a victory over the "children of the rebels" and assumed divine rule over the world. So long as he was young his kingdom was strong, but with advancing age his subjects became rebellious. With the aid of Hathor he revenged himself upon mankind and almost utterly destroyed them. Such are the main features of the myth of Rā. (See Brugsch, *Die neue Weltordnung nach Vernichtung des sündigen Menschengeschlechtes*, Berlin, 1881.) Rā is represented as hawk-headed, with the sun-disk and the uræus on his head, the sun-disk being his emblem. Rā himself was the sun at midday; the rising sun was Ra-Harmachis, "Horus on the horizon"; and the setting sun was Ra-Tum (Àtum, the closer), as an aged man. During the night he was regarded as in conflict with the serpent Àpepi, but from the contest he emerged each morning in victory. The *Adoration of Ra* was one of the chief and best-known poems of the Book of the Dead. The worship of Rā as Àten, the sun-disk (see Khunaten), was the nearest approach to monotheism which Egypt ever saw. Joined with Àmen, as Àmen-Rā, he became the principal national god after the expulsion of the Hyksos, and joined with Mont, as Mont-Rā or Menthu-Rā, he was the god of war. Rā was also conceived of as joined with various other gods of the Egyptian pantheon. Charles R. Gillett.

Raab: town of Hungary; at the influx of the Raab into the Little Danube, a branch of the Danube; 67 miles W. N. W. of Budapest (see map of Austria-Hungary, ref. 5–F). It was formerly fortified, and has a fine old cathedral. Its manufactures of tobacco and cutlery and its transit trade are extensive. Pop. (1890) 23,956.

Raabe, raa'be, Wilhelm (pseudonym *Jakob Corvinus*): novelist; b. at Eschershausen, Brunswick, Sept. 8, 1831; studied philosophy at Berlin and devoted himself entirely to literary pursuits. He is distinguished as a humorist among the German novelists of the nineteenth century. His principal works are *Die Chronik der Sperlingsgasse* (1857); *Leute aus dem Walde* (1863); *Der Hungerpastor* (1864); *Wunnigel* (1879); *Horacker* (1876); *Das Horn von Wanza* (1881); and *Der Lar* (1889). J. G.

Raba'nus Magnen'tius Mau'rus (spelled also *Hrabanus* and *Rhabanus*): archbishop; descended from an ancient Roman family, and pronounced by Kurtz "the most learned man of his age"; b. at Mentz about 776; studied in the monastery at Fulda, and afterward in Tours under Alcuin; teacher at Fulda from about 805 till 814 and again from 817, and made abbot there in 822; Archbishop of Mentz 847. D. at Winkel, Feb. 4, 856. The name of Maurus was given to him by his teacher, Alcuin, in remembrance of St. Maur, the disciple of St. Benedict. He opposed the doctrine of transubstantiation, first distinctly set forth by Paschasius Radbert in 831 (expanded in 844). His works fill six volumes (107–112) of Migne's *Patrologia*. See Bach's *Rabanus Maurus, der Schöpfer des deutschen Schulwesens* (1835); Kunstmann's *Rabanus Magnentius Maurus* (1841); and Spengler's *Leben des Rabanus Maurus* (1856).

Revised by M. Warren.

Rabat': strongly fortified town of Morocco, Northern Africa; at the mouth of the Wadi-el-Buregreg on the Atlantic; formerly a port of considerable importance, but less accessible now on account of a sand-bank in front of the river mouth (see map of Africa, ref. 1–B). Most European trade has therefore sought safer ports, though one or two steamers a month call to leave tea, sugar, cloths, candles, and small wares, and take away olive oil, beans, wool, skins, and bones. The fine and brilliantly colored carpets, woolen cloths, mats, leather goods, and potteries for which Rabat is famous are not extensively exported, but are widely distributed in Morocco. Pop. 25,000, one-sixth Jews, besides about 100 Europeans. Zelâ, across the river (pop. 10,000), has its own local government, its people following the same industries as those of Rabat. C. C. Adams.

Rab'ba: ancient capital of the native state of Nupé; on the middle Niger river, West Africa. It was destroyed by the Fulahs early in the nineteenth century when they were spreading the tenets of Mohammedanism. Though no longer the capital, it is a large town in a well-cultivated region, and has a considerable trade with Sokoto and other places in the Sudan. It was once one of the most important slave-markets in West Africa. Revised by C. C. Adams.

Rabbah: same as Amman (*q. v.*).

Rabbi [= Lat. = Gr. ῥαββί, from Heb. *rabī*, my master, deriv. of *rab*, master, lord, teacher; cf. Arab. *rabb*]: a title of honor anciently employed by the Jews to designate those learned in the law, in which sense it is frequently found in the Gospels. It was also used by disciples of other teachers, for it was applied to John the Baptist (John iii. 26) and to Jesus himself (e. g. Matt. xxvi. 25, 49; Mark x. 31; John i. 38). Luke employs the term *didaskale*—i. e. teacher—but this is only the Greek translation of rabbi. The term *rab* is applied by Oriental Jews in a manner similar to the use of the English "esquire."

Rabbinical Literature: a name wrongly given to the whole of the literature produced by the Jews, but one which may fitly describe that portion of it which is the result of the literary activity of the rabbi in his position as religious and judicial leader of the community. Its subject-matter is civil and ecclesiastical law, both the legislative and executive power in the Jewish community being in post-Talmudic times, the period treated of, in the hands of the rabbis.

The continuity of oral tradition had not been disturbed by the completion of the Mishnah and the Talmud (*q. v.*).

The latter became the basis for all further discussions in the schools, and was modified and developed as occasion required. The literature which resulted from these discussions took on the form of commentaries, glosses, compendia, and practical decisions. Of the two redactions of the Talmud, it was the Babylonian which soon acquired absolute authority, almost to the exclusion of the Palestinian. It was in the schools of Babylon (Sora and Pumpaditha) that the first attempts were made to bring order into the chaos of the Talmud. The most noted of the Gāōnīm ("Highnesses," 800–1037) as Talmudic scholars were Sherīra (980), who wrote an encyclical to the Jews of Kairowān in which he detailed the history of the formation of the Talmud; his son, Hai (969–1038), to whom a commentary on the Mishnah is ascribed; and Samuel ben Chofni (960–1034). Even before their death Jewish scholarship had sought a new home in Spain and North Africa. The Jews in Spain lived in greater freedom and busied themselves more with poetry and philosophy. Talmudic science had been transported there from the East by Moses ben Chanoch (960), and was kept alive by his son Chanoch and by Joseph ibn Abitur; but rabbinical science found its first real home across the Pyrenees—in Provence, in France, and then in Germany. The influence of Soloman ben Isaac (Rashi 1040–1105) of Troyes was supreme in France, and as a result of his commentaries there arose a school of Tosafists ("adders"), which, in contradistinction to the Spanish compilers and epitomizers, developed the careful criticism of the text and its application to the needs of actual life. Zunz has put together nearly 200 names of Tosafists, some of whom carried their methods into England.

In Spain the controversy evoked by Maimonides (*q. v.*) in favor of philosophy against the exclusive study of the Talmud produced two men who deserve notice: Moses ben Nachman (Ramban, Nachmanides, 1263) of Gerona, who wrote a commentary, and who may be called the Spanish Tosafist, and Solomon ben Adret (1300) in Barcelona, the author of novellæ to many Talmudic treatises. In Italy this period produced three scholars whose fame reached beyond their own country: Nathan ben Yechīēl (d. 1106) of Rome, the author of an excellent Talmudic dictionary; Isaiah ben Mali (1250) of Trani, who because of his rational and critical spirit is ranked even above the Tosafists of France and Germany; and Joseph Kolon (Maharik, d. 1480). In Germany the importance of the study of the Talmud was emphasized by the meeting of the rabbinical councils of Mayence in 1223 and 1245. Mēīr ben Baruch (d. 1293) of Rothenburg, called the German Tosafist, may justly be considered the head and front of the new school.

It was in the middle of the sixteenth century that the Jews began to wander into Poland, where the Talmud reached its culminating point as the supreme religious and legal authority. Being there largely excluded from all other employments, the Jews found their only consolation in the schoolhouse (Yeshībhāh), where they studied and restudied their ancient lore. This study developed into a mere exercise of ingenuity, into pure casuistry similar to the casuistry of the Christian and Mohammedan scholastics. This casuistry is called Pilpul (√pepper), and the new matter thus evolved Chiddūshīm (novellæ). A fair description of the method employed will be found in the *Autobiography* of Solomon Maimon (Boston, 1888, chap. vi.). Its origin is ascribed to Jacob Pollak (d. 1541) and to Solomon Shechna (1557) of Lublin. In Poland and Russia it still exists; but with a wider and more secular education it is gradually making way for a critical and intelligent study of the Talmud.

The numerous compendiæ which were written for the purpose of making the decisions scattered up and down the Talmud available for the practical office of the rabbi and the rabbinical decisions deserve a special mention. Very shortly after the completion of the Talmud a digest was attempted by Hai Gāōn (969–1038), who tried to put the whole material into memorial verses. Simon of Kahira arranged all the decisions upon the basis of 613 commandments supposed to be contained in the Pentateuch. Similar compilations were made by other writers. More important were the *Halāchōth* of Isaac ben Jacob (Alfasi), and more scientific the *Mishnēh Thorah* of Maimonides. This last codification by Maimon was, however, too scientific for actual use, and presupposed a too intimate acquaintance with the material. To remedy this other compendiæ were made by Moses ben Jacob of Coucy in his *Sēfer hammitzwōth*; Solomon ben Adret in his *Tōrath habbayith*, and others; and finally by Joseph Caro (1556) of Safed, in his *Shulchān Ārūch*.

The rabbinical decisions are in the form of questions and answers (*Sheēlōth Ūtheshūbhōth*). Such questions upon religious and juristic matters were sent to prominent Talmudic scholars all over Europe, Asia, and North Africa, but the authority of the teacher as such was not final. Apart from their intrinsic value, these decisions contain a large amount of material for the history of the social life of the Jews during the whole of the post-Talmudic period. They exist by the hundred thousands.

Among numerous works giving information on this subject, see Renan and Neubauer, *Rabbins Français* in *Histoire littéraire de la France*, vol. xxvii.; A. Geiger, *Nachgelassene Schriften* (Berlin, 1875, vol. ii.); M. Güdemann, *Geschichte des Erziehungswesen und der Cultur der abendländischen Juden* (Vienna, 1873–84, 3 vols.); Joel Müller, *Briefe und Responsen der vorgeonäischen Jüd. Lit.* (Berlin, 1886), *Die Responsen der Spanischen Lehrer des 10ten Jahrhunderts* (Berlin, 1889); and those given in bibliography of article Jewish Literature (*q. v.*). Richard Gottheil.

Rabbit [M. Eng. *rabet*; cf. dial. Fr. *rabotte*, Old Dutch *robbe*, and Gaelic *rabaid*, rabbit]: the English name for many species of the family Leporidæ (*q. v.*), but more especially applicable to *Lepus cuniculus*. This species is found generally distributed throughout Europe (except in its more northern portions), as well as the contiguous portions of Asia and Northern Africa, and is also naturalized in Australia, where it is a serious pest, and elsewhere. It lives in communities, burrows in the ground, and brings forth its young blind and naked. It is very prolific, beginning to breed at the age of about six months, and having several litters in the course of a year, and in each litter some four to eight young ones. In the U. S. the name rabbit is also generally given to all species, the best known of which is the common small rabbit of the Eastern and Middle States (*Lepus sylvaticus*); this species, as well as the other species of the family (*Lepus cuniculus* excepted), agrees with the hare in making forms, instead of burrowing, and in bringing forth its young provided with hair and able to see.

Revised by F. A. Lucas.

Rabelais, răă'be-lā', François: author; b. at Chinon, Indre-et-Loire, France, toward the end of the fifteenth century (1495?). Being the youngest son he was destined for the Church. He studied first at the abbey of Seuillé, then at the monastery of La Baumette, near Angers. About 1509 he entered the Franciscan monastery at Fontenay-le-Comte. There he passed his novitiate and was made priest in 1519. His intellectual curiosity was enormous, and he devoted himself to reading and study, attaining to an almost cyclopædic knowledge of the science of that time, becoming well read in Latin, Greek, law, mathematics, and astronomy. His passion for learning was directly opposed to the spirit of his order, and his devotion to books and relations with scholars made his brother monks distrust him. His cell was searched, his books seized, and he himself sought safety in flight. The intervention of influential friends, especially of Geoffroy d'Estinac, Bishop of Maillezais, and Guillaume Budé, saved him from further consequences. Clement VII. authorized him, in 1524, to leave the Franciscan order for the Dominican and enter the abbey of Maillezais; but he soon abandoned the monastic life, assuming with the consent of his superiors the garb of lay preacher, and began a kind of free, roving existence to which his great curiosity for knowing the world predisposed him, adding continually to his vast information. The story of this vagabondage is obscure. He took a course of medicine at Montpellier and was teaching there in 1530; from 1532 to 1534 he was at Lyons practicing medicine, editing the first of a series of almanacs, engaged in various works of scholarship, and beginning his great *Pantagruel*. In 1534 he went to Rome with Jean du Bellay, Bishop of Paris, who was there made cardinal, and returned with him to Paris in 1535. In 1539 he entered the abbey of Saint-Maur as canon, but with the privilege of freely practicing medicine. From 1540 to 1542 he was again in Italy with Guillaume du Bellay, as his physician, and wrote in Latin the history of his wars, now lost. In 1547 he was at Metz, in 1549 again in Rome with Cardinal du Bellay. In 1550 he was in Paris, and was made curate of Meudon, but surrendered this living, with that of Saint-Christophe-du-Jambet, previously given him, in 1552. D. probably in 1553. His main fame is due to his *Gargantua* and *Pantagruel*. The first *Gargantua* was but a new edition, with a few original additions by Rabelais, of an older popular romance. Its success provoked an original continuation,

Pantagruel. This too was very successful, and to bring the story of *Gargantua* to its level he rewrote it in 1535, and in this form it is now the first book of the complete work. In 1546 appeared with the royal privilege a third book of *Pantagruel*, generally considered the best; and in 1552 a fourth book appeared, also with the royal privilege, which did not prevent its being condemned by the Sorbonne. In 1562–64 a fifth book appeared, of which certainly not all, probably not much, is by Rabelais. The work recounts the marvelous lives and deeds of the giants Gargantua and Pantagruel; but it is the actual life of the time which it really pictures, with all its ferment of ideas, its struggle between mediævalism and the Renaissance, its mixture of fragments of the decomposing Middle Ages, and of elements of a new order. The spirit of these pictures is that of exuberant and jovial satire. They breathe a disrespect for the traditional authorities and conventional forms, and are especially keen against the ideas and practices of the Church. They are saturated with the sense of intense delight in life, the physical and sensuous existence of the human animal in all its manifold exhibitions, and it is rendered with such frankness and absence of reticence that throughout the work coarseness and obscenity are frequent and prodigious. Good recent editions are by Desmarets and Rathery (2 vols., Paris, 1857–58); Marty-Laveaux (4 vols., Paris, 1868–81); Jannet (2 vols., Paris, 1858–72). Cf. E. Gebhart, *Rabelais, la Renaissance et la Réforme* (Paris, 1877); P. Stapfer, *Rabelais* (Paris, 1889). The English translation by Sir Thomas Urquhart (1653), continued by Motteux (1693–94), and often reprinted, is a famous piece of translation. A. G. Canfield.

Rabener, raa′be-ner, Gottlieb Wilhelm: poet; b. at Wachau, near Leipzig, Germany, Sept. 17, 1714; studied law at Leipzig, and entered the civil service of Saxony; d. at Dresden, Mar. 22, 1771. He gained his reputation chiefly as a satirist, and, like his friend Gellert, he represents the perfection as well as the mediocrity of German literature previous to the classical era. Though his satires seem very tame they were widely read and admired by the middle class of his contemporaries. See P. Richter, *Rabener und Liskow* (1884). J. G.

Rabenhorst, Gottlob Ludwig: botanist; b. at Treuenbrietzen, Brandenburg, Prussia, Mar. 22, 1806; educated in Universities of Berlin and Jena, resided in Luckau and Dresden from 1831 to 1875, devoting himself after 1840 entirely to botanical studies. His most important publications are *Flora Lusatica* (1839–40); *Deutschlands Kryptogamen Flora* (1844–53); *Kryptogamen Flora von Sachsen* (1863–70); *Flora Europæa Algarum* (1864–68). He was editor of *Hedwigia* (1852–71); published exsiccati as follows: *Algen Sachsens* (1,000 species, 1848–61); *Hepaticæ Europææ* (with Gottsche, 660 species, 1856–78); *Bryotheca Europæa* (1,450 species, 1858–75); *Lichenes Europæi Exsiccati* (900 species, 1855–79); *Cladoniæ Europææ* (380 species, 1860–63); *Algæ Europææ Exsiccatæ* (1,600 species, 1861–79); *Fungi Europæi Exsiccati* (2,600 species, 1861–79). D. at Meissen, Apr. 24, 1881. Charles E. Bessey.

Rabies: an extremely fatal infectious disease of many animals. In man it is generally called Hydrophobia (*q. v.*).

Rabshākeh [from the Assyrian *Rab-shākē*, chief of the officers]: a high officer in the Assyrian army, next in rank to the *tartan*, or field-marshal. At times he seems also to have been employed as interpreter and ambassador. It is he who carries on the negotiations with the officers of King Hezekiah of Judah (702 B. C.) before the walls of Jerusalem, during the campaign of Sennacherib. A similar officer is sent by Tiglath-Pileser II. on a mission to Tyre (734 B. C.). See Schrader, *Keilinschriften und das Alte Testament* (2d ed. Giessen, 1883, p. 319); Fried. Delitzsch, *The Hebrew Language* (London, 1883, p. 13); Thiele, *Babylonisch-Assyrische Geschichte* (Gotha, 1856, p. 497).
Richard Gottheil.

Rabulas (or, more correctly, **Rabbula**): Bishop of Edessa and the predecessor of Ibas. He is said to have governed his diocese with great authority, and succeeded in suppressing the various heretical sects which arose before the Nestorian controversy. D. at Edessa, Aug. 8, 435. Of his writings, some hymns and letters, the rules he drew up for the monks, and a sermon he delivered in Constantinople are still extant. They were edited by Overbeck (*Ephraemi Syri et Rabulæ Edessini Opera*, Oxford, 1865), and translated into German by Beckell in the *Kempten Bibliothek* of Church Fathers (1874).

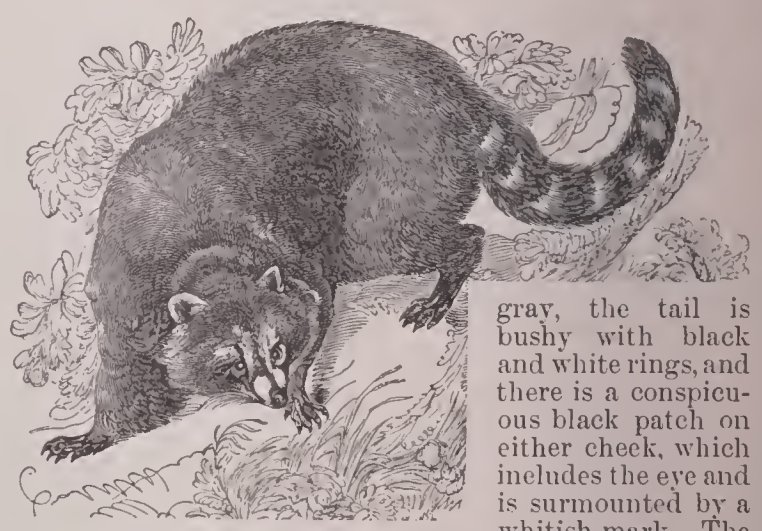
Racahout, răăk′a-hoŏt, or **Racahout des Arabes**: a starchy food prepared in Barbary from the acorns of *Quercus ilex* and *Q. ballota*, oaks of that region. It is flavored with herbs, and is sometimes prescribed for invalids. The racahout of confectioners is a compound of starch with chocolate, vanilla, etc., sold as a sweetmeat, or for making a beverage.

Racalmu′to: town of Sicily, province of Girgenti; on the left bank of an affluent of the Platani; about 15 miles N. E. of the town of Girgenti (see map of Italy, ref. 10–F). The neighboring country is very rich in grain, vines, olives, and fruits, and abounds in sulphur, saltpeter, and gypsum. Pop. 13,133.

Racan, răă′kaăn′, Honorat de Bueil, Marquis de: author: b. at La Roche Racan, Touraine, France, in 1589. In 1605 he became page at the court of Henry IV., and a few years later served a short time in the army, taking part in the siege of La Rochelle. He then withdrew to his estate and devoted himself to letters. D. in 1670. He stood under the influence of Malherbe, but was too indolent and negligent to reach his polish of language and style. His chief work is a pastoral drama, *Les Bergeries* (1618). He wrote also odes, sonnets, epigrams, and a paraphrase of the Psalms. He was one of the first members of the Academy. His *Œuvres complètes* were edited by de Latour (2 vols., Paris, 1857). A. G. Canfield.

Racconigi, răăk-kō-nee′jĕe: town of Northern Italy, province of Cuneo; on the right bank of the Maira; about 19 miles by rail S. of Turin (see map of Italy, ref. 3–B). It is a walled town, and the three old castles of Migliabruna, of Carpanetto, and of Bonavalle are in its remote neighborhood, but it is now chiefly known for the royal castle and park in its immediate vicinity. This castle was originally a fortress, was converted into something like a villa by E. Filiberto in 1681, and has been improved by successive princes until it is one of the most sumptuous of the Italian royal palaces. Pop. 7,875.

Raccoon, **Racoon**, or more often **Coon** [from Amer. Ind. *arrathkune*, whence Fr. *raton*, raccoon (in form adapted to *raton*, augment. of *rat*, rat]: the common name for a small carnivorous mammal, *Procyon lotor*, the best-known member of the family *Procyonidæ*, a group nearly related to the bears. The raccoon is about 2 feet long, without the tail; the body is stout, tail rather short and bushy; feet plantigrade, furnished with rather slender toes. The fore feet are well fitted for grasping, although none of the digits are opposable, and the animal climbs well. The general color is



The crab-eating raccoon.

gray, the tail is bushy with black and white rings, and there is a conspicuous black patch on either cheek, which includes the eye and is surmounted by a whitish mark. The raccoon dwells in hollow trees, and is nocturnal and omnivorous; though aquatic animals (fish, mollusks, and crawfish) form a large portion of its food. It is readily tamed, and is an amusing but mischievous pet, although like all carnivores subject to sudden outbreaks of temper. It has the peculiar habit of washing its food, whence the specific name of *lotor* (washer) and the German name, *Waschbär* (wash-bear). It is found throughout the greater part of the U. S., and a closely related species, *Procyon cancrivora*, the crab-eating raccoon or agonara, larger with shorter fur and more powerful dentition, is found in the northern parts of South America.
F. A. Lucas.

Raccoon Nation: See Iroquoian Indians.

Race, Cape: See Cape Race.

Race'mic Acid [*racemic* is from Lat. *race'mus*, bunch of grapes or fruit], also called **Paratartaric Acid** and **Uvic Acid** ($C_4H_6O_6$): an acid found with tartaric acid in grape-juice, and identical with it in composition, though differing from it in its action on polarized light and in some other characters. It was discovered by Kestner in wines of certain vintages. It may also be formed artificially. Racemic acid itself has no action on polarized light, but by certain treatment may be separated into two isomeric constituents, one of which is ordinary dextro-rotatory tartaric acid, and the other is lævo-rotatory, the two being called *dextro-tartaric* and *lævo-tartaric* acid. Pasteur found certain relations between the modifications of the crystals of the two acids and the action on polarized light, which have attracted much attention on account of a theory that has been proposed to account for them. See STEREO-CHEMISTRY.

Revised by IRA REMSEN.

Rachel [from Heb. *Rāchel*, liter., ewe]: a native of Northern Mesopotamia, younger daughter of Laban, favorite wife of Jacob, and mother of Joseph and Benjamin. Her tomb, about 4 miles from Jerusalem on the road to Bethlehem, though of modern construction, undoubtedly marks the site of her burial, described in Gen. xxxv. 19, 20.

Rachel, răă'shel', properly ÉLISA RACHEL FÉLIX: actress; b. at Mumpf, Switzerland, Feb. 28, 1820, daughter of a wandering Hebrew peddler. In Lyons, Paris, and other cities she, with her sister Sophia, afterward called Sarah, sang at the *cafés* and on the boulevards. Choron, teacher of singing at the Royal Institution, attracted by their voices, took them from the streets and gave them frec instruction. In 1833 they were admitted to the Conservatoire, where Élisa developed more dramatic talent than musical. In 1837 she made an unsuccessful *début* at the Gymnase, but in 1838 astonished and captivated Paris by her performance, at the Théâtre Français, of Camille in *Les Horaces*. Her fame and fortune were made. The classic tragedies of Racine, Corneille, and Voltaire were revived; her intensity, originality, naturalness, the singular expressiveness of her face, the skill of her declamation, made a new era in dramatic art. She played, also, with great power Jeanne d'Arc, Marie Stuart, Adrienne Lecouvreur (the play by that name was written for her by Legouvé and Scribe), and other characters. In 1855, in company with her brother, Raphael Félix, and her sisters, Sarah, Lia, and Dinah, she went to the U. S., but after she had played in a few cities failing health compelled her to desist. She returned to France, and died at Cannet, near Cannes, Jan. 3, 1858. See Janin, *Rachel et la Tragédie* (1858), and the *Life* by Mrs. Kennard (1885). Rachel was slender, graceful, not beautiful, and had a pale complexion, expressive features. brilliant eyes, and fascinating presence.—RAPHAEL FÉLIX became in 1868 director of the Théâtre Porte Saint-Martin; SARAH (d. 1877) was connected with the Gymnase, the Français, and the Odéon; LIA, devoted to high tragedy, distinguished herself at the Porte Saint-Martin; REBECCA died in 1854, having been five years at the Théâtre Français.

Rachmaninoff, SERGI W.: See the Appendix.

Racine: city (settled in 1836, incorporated in 1848); capital of Racine co., Wis.; on Lake Michigan, at the mouth of Root river, and the Chicago, Milwaukee and St. Paul and the Northwestern railways; 25 miles S. by E. of Milwaukee, 62 miles N. of Chicago (for location, see map of Wisconsin, ref. 7–F). It has one of the best harbors on Lake Michigan, is connected with the principal lake ports by steamboat and propeller lines, and has considerable shipping of its own. The city is laid out regularly on a plateau 40 feet above the level of the lake and 690 feet above that of the sea, is lighted with gas and electricity, and has a new system of water-works, which provides an abundant supply of water from the lake. There are 3 national banks with combined capital of $625,000, a State bank with capital of $100,000, and 2 daily, 5 weekly, a semi-monthly, and 2 monthly periodicals. The educational institutions include Racine College (Protestant Episcopal, chartered in 1852), St. Catharine's Academy (Roman Catholic, opened in 1866), the McMurphy Home School (Protestant Episcopal, opened in 1877), and Racine Academy (non-sectarian), and the benevolent institutions, St. Luke's Hospital and the Taylor Orphan Asylum. There are four libraries, High School, Racine College, Y. M. C. A., and McMurphy's Home School) which contain over 14,000 volumes. The census returns of 1890 showed that 190 manufacturing establishments reported. These had a combined capital of $11,533,207, employed 4,872 persons, paid $2,418,498 for wages and $4,340,308 for materials, and had products valued at $8,462,359. The principal industries were the manufacture of agricultural implements, which had 11 establishments, a capital of $5,573,207, and products valued at $1,979,613; of carriages and wagons, which had 5 establishments, a capital of $2,347,932, and products valued at $1,902,536; and of leather, trunks and valises, and malt liquors. Pop. (1880) 16,031; (1890) 21,014; (1900) 29,102.

Racine, răă'scen', JEAN BAPTISTE: dramatic poet; b. at La Ferté-Milon, Aisne, France, Dec. 22, 1639. He studied first at the College of Beauvais, then at Port-Royal, where he underwent the influence of its severe moral and religious ideas, and under such masters as Nicole, Lancelot, and Hamon became an eager and proficient student of the classic literatures, especially that of Greece; finally at the Collège d'Harcourt, at Paris, where he was fascinated by the gayety and elegance of social life. He remained at Paris after his studies were finished, mixing with men of letters and giving himself freely to the pleasures and dissipations of the capital. His first literary venture, *Les Nymphes de la Seine*, an ode on the marriage of Louis XIV. (1660), brought him some praise and a royal gift of 100 louis. His habits gave concern to his family, and he was sent to an uncle, vicar at Uzès, in Languedoc, to study theology and qualify himself to receive a benefice. The efforts of his uncle to secure a benefice for him met with repeated failure, and he lost patience and in 1662 was again in Paris, where he offended his friends of Port-Royal still further by the manner of his life, and yielded fully to his inclinations for the theater, which they were then condemning. In his first tragedies, *La Thébaïde* (1664) and *Alexandre* (1665), his original genius is less conspicuous than the influence of Rotrou, Corneille, and Quinault. In his next play, *Andromaque* (1667), he achieved a new and original type of tragedy, which finds the constant motive of conduct in the passion of love taken at a moment of crisis, and seeks the dramatic interest entirely in the conduct of its characters under the play of this motive. This type is the perfection of French classic tragedy, and reappears in the six plays that followed: *Britannicus* (1669); *Bérénice* (1670); *Bajazet* (1672); *Mithridate* (1673); *Iphigénie* (1674); and *Phèdre* (1677). In all he follows the working of violent passion, especially in his heroines, with great psychological penetration. To these plays, to which an excellent comedy, *Les Plaideurs* (1668), must be added, he gave a rare perfection of form by an exquisite polish of language and an unequaled harmony of versification. The intrigues of jealous rivals, culminating in the apparent failure of *Phèdre*, powerfully seconded by a recoil in his moral attitude toward the ideas of Port-Royal, led Racine to abandon the theater. This recoil amounted to a conversion, and he even thought of becoming a Carthusian monk. In the same year he was married, and, with Boileau, was appointed royal historiographer. At the prayer of Madame de Maintenon he wrote for her schoolgirls of St.-Cyr two biblical tragedies with chorus, *Esther* (1688) and the masterpiece *Athalie* (1691), which keep the qualities of his earlier works, except that passions of another order are substituted for that of love. After this he wrote only letters, epigrams, some religious verse, and a short *Histoire de Port-Royal*. D. Apr. 21, 1699. He had entered the Academy in 1673. The best edition of his works is that of P. Mesnard in the *Collection des Grands Écrivains de la France* (8 vols. and 2 albums, Paris, 1865–73). See P. Robert, *La Poétique de Racine* (Paris, 1890); P. Stapfer, *Racine et Victor Hugo* (Paris, 1887); F. Brunetière, *Les Époques du théâtre français* (Paris, 1892).

A. G. CANFIELD.

Racine, LOUIS: author; son of Jean Baptiste Racine; b. in Paris, Nov. 2, 1692. His education was directed by Boileau and Rollin, and he grew up with the religious sentiments of Port-Royal. He wrote memoirs on his father's life, and religious and didactic poems which possess grace and elegance, but lack spirit and interest. The most important are *La Grâce* (1720), in four cantos, and *La Religion* (1742), in six cantos. D. in Paris, Jan. 29, 1763.

A. G. C.

Racing: See HORSE-RACING.

Rack: a kind of liquor. See ARRACK.

Rack: a certain gait of a horse. See GAITS.

Rack [M. Eng. *racke*; cf. Dutch *rek*, *rek-bank*; Germ. *reck*, *reck-bank*, rack; *recken*, stretch + *bank*, bench]: an engine of judicial torture formerly much employed in Europe to compel accused persons to plead guilty and to ob-

tain satisfactory testimony from recusant witnesses. It was introduced into England in 1447 by the Duke of Exeter as constable of the Tower of London. In 1628 it was pronounced illegal by the courts. The victim was stretched upon a platform of wood; cords were attached to his limbs, and then strained by pulleys until the sufferer yielded or had his joints dislocated.

Rackarock: See EXPLOSIVES (*The Chlorates*).

Rackets, or **Racquets** [from O. Fr. *rachette* > Fr. *raquette*, from Span. *raqueta*, racket, battledore, palm of the hand (tennis being originally played with the palm of the hand), perhaps from Arab. *rāhat*, palm of the hand]: a game originally similar to tennis, now played with ball and racket-bat in a closed court, about 60 feet long and 30 wide. The front wall has two lines marked on it, the first (play-line) 2 feet from the floor and the second (service-line) 8 feet. The half of the floor-space farthest from the front wall is marked off into two courts by a line midway between the side walls. One player stands in each court. The first serves the ball so that it may rebound from the front wall above the service-line and strike in the opposite court, the second returns it above the play-line, and so on. The server is allowed one "fault"; i. e. if on his first attempt the ball strikes between the two lines, or rebounds to a part of the floor not his opponent's court, and the second player declines to return it, he may serve again. If the second player fails to return the ball properly the first scores one; if the server fails, his "hand is out" and his opponent serves. The one who first scores fifteen wins.

Radbertus, PASCHASIUS: one of the most prominent ecclesiastical writers of the Carolingian age; b. toward the close of the eighth century; entered the monastery of Corbie, in Picardy, in 814. The favorite pupil of Abbot Adalbard, a relative of Charlemagne, Radbertus became teacher in the cloistral school, and in 844 he was elected abbot, but, being unable to maintain discipline in the monastery, he resigned in 851. A complete and critical edition of his extant works was published by Sirmond (Paris, 1618) and reprinted in Migne, *Patrol. Latin.* By far the most interesting is his *De Corpore et Sanguine Domini*, in which he exposed the doctrine of the Roman Catholic Church on the Eucharist. This book became famous because of the controversies it gave rise to in the following century, when Hrabanus Maurus, Ratramnus, Scotus Erigena, and others opposed certain of its tenets, but their opposition was based on a misunderstanding of the text. See Wetzer and Welte, *Kirchenlexikon*, and Ebert, *Geschichte der Literatur des Mittelalters*, vol. ii., p. 230. The best text of this little work is in Martène and Durand, *Amplissima Collectio* (vol. ix., Paris, 1723).

Revised by J. J. KEANE.

Radcliffe, ANN (*Ward*): novelist; b. in London, England, July 9, 1764; married in 1786 William Radcliffe, subsequently editor of *The English Chronicle*; published several romances notable for their wild and fantastic plots, of which *The Mysteries of Udolpho* (1794) is the only one remembered. Others once popular were *The Sicilian Romance* (1790), *The Romance of the Forest* (1791), and *The Italian* (1797). D. in London, Feb. 7, 1823. Her writings had considerable influence upon the literature of the time, and even Byron was among her imitators. A *Memoir* by Talfourd appeared in 1826, introducing the posthumous romance *Gaston de Blondville*, and a collection of her poems was issued in 1834. Revised by H. A. BEERS.

Radcliffe, CHARLES BLAND, M. D., F. R. C. P.: physician; b. at Brigg, Lincolnshire, England, June 2, 1822; M. B., London University, in 1845 and M. D. in 1851; became physician to the Westminster Hospital in 1857 and to the National Hospital for the Paralyzed and Epileptic in 1863; was lecturer on botany in the medical school of Westminster Hospital 1850–54, and lectured on materia medica 1854–60; was Gulstonian lecturer in 1860 and Croonian lecturer in 1873 of the Royal College of Physicians. He was joint editor of *Rankin's Abstract of the Medical Sciences* from 1852–64. Among his published works are *Proteus, or the Law of Nature* (London, 1850); *The Philosophy of Vital Motion* (London, 1851); *Epilepsy and other Affections of the Nervous System* (London, 1854); *Dynamics of Nerve and Muscle* (London, 1871); and articles in *Reynolds's System of Medicine*. D. June 18, 1889. S. T. ARMSTRONG.

Radcliffe College: See HARVARD UNIVERSITY.

Radetzky, răă-det'skĕĕ, JOHANN JOSEPH WENZEL ANTON FRANZ KARL, Count: soldier; b. at Trzebnitz, Bohemia, Nov. 2, 1766; entered the Austrian army in 1784; fought with distinction at Aspern and Wagram in 1809, and at Kulm and Leipzig in 1815; was made commander-in-chief of the Austrian troops in Italy in 1831, and field-marshal in 1836; put down the revolution in Milan and Venice in 1848, though then over eighty years old; won the victories at Custozza and Novara over the Piedmontese, and governed the Austrian possessions in Italy to Feb. 28, 1857, when he resigned. D. at Milan, Jan. 5, 1858. See Radetzky's *Denkwürdigkeiten in Mittheilungen des kaiserlichen Kriegsarchivs* (1887), and Kunz, *Die Feldzüge des Feldmarschalls Radetzky in Oberitalien* (1890).

Radiata [from Lat. *radia'tus*, having spokes or rays, perf. partic. of *radia're*, furnish with spokes or rays, deriv. of *ra'dius*, spoke]: one of the four great groups or branches into which Cuvier divided the animal kingdom, and which included those forms in which the parts radiated from a central axis like the spokes from the hub of a wheel. It included, as limited by him, the Cœlenterates, Ctenophores, Gephyrea, Polyzoa, Protozoa, and Parasitic Worms of later zoölogists. It was soon found that some of these forms had other affinities, and the clear definition by Leuckart of the *Cœlenterata* and *Echinodermata* gave the death-blow to the ill-assorted group, which disappeared from European works about the middle of the nineteenth century, but lingered in the U. S. for twenty years more. J. S. KINGSLEY.

Radiation: See the Appendix.

Radical Axis: a line related to two circles and determined by the condition that the tangents from any point upon it to the circles are equal in length. If the circles intersect it is their common chord. S. N.

Radicals [from Lat. *radica'lis*, deriv. of *ra'dix*, root, origin, foundation], in chemistry sometimes called **Radicles**: a term applied to a group of elements that can pass unchanged through a series of compounds by chemical reactions. Thus in the salts formed by ammonia with acids the presence of the hypothetical radical *ammonium*, NH_4, is assumed. So, too, in all cyanogen compounds the group CN is assumed. Among the compounds of carbon such groups are very common, so much so that Liebig proposed the name chemistry of the compound radicals for organic chemistry. Thus ALCOHOL (*q. v.*) is a compound of the group or radical ethyl, C_2H_5, with the group or radical hydroxyl, OH. Or alcohol is the hydrate of this radical; ether is the oxide, $(C_2H_5)_2O$; chlorethane the chloride, C_2H_5Cl, etc. Some of these organic radicals are called *residues* or *rests*. Thus ethyl, C_2H_5, is the *residue* or *rest* of ethane, C_2H_6. It is that which is left after one atom of hydrogen has been removed. The theory of radicals played an extremely important part in the development of the science of chemistry. I. R.

Radiograph: See *X*-RAYS.

Radiola'ria [Mod. Lat., from Lat. *radius*, a ray]: a subclass of Rhizopodous Protozoa which occur in the sea, at times extremely abundant. They have the body divided into two portions, inner and outer, by a perforated membrane. In the inner portion is the nucleus, while the outer contains no nuclei, but gives rise to numerous radiating filaments of protoplasm (*pseudopodia*). There is in addition, frequently, a skeleton, either horny or siliceous, and often of extreme beauty. The central protoplasm alone is concerned in reproduction, and in it are found flagellate spores which in turn develop into *Actinophrys*-like embryos. (See HELIOZOA.) Haeckel, in his great monograph of the Radiolaria collected by the Challenger expedition, recognizes 739 genera and 4,318 species of these pelagic organisms. Many forms are interesting from the fact that they contain "yellow cells" which are known to be unicellular algæ living symbiotically with the Radiolarians. See SYMBIOSIS. J. S. KINGSLEY.

Radiom'eter [from Lat. *ra'dius*, ray, *radia're*, radiate + Gr. μέτρον, measure]: in physics, any instrument for the detection and measurement of radiant heat. One of the earliest forms was the differential thermometer of Leslie, which consisted of two glass bulbs, the necks of which were joined. The air contained within these bulbs is separated by means of a column of liquid. In order to prevent liquid from collecting in the bulbs the tube which joins the two is generally bent twice at right angles, and the instrument is mounted so that the bulbs are uppermost. (See Fig. 1.) One of these bulbs being subjected to the radiant heat while the other was protected, the expansion of the atmosphere in the heated bulb served to drive the liquid column along the tube,

bringing it to rest in some position other than that which the liquid would occupy when the temperatures of the two bulbs were the same. By means of this simple device Leslie discovered many of the important facts concerning radiant energy.

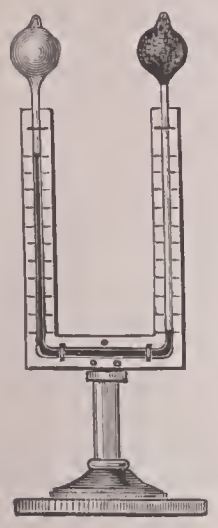


Fig. 1.

The Thermopile (*q. v.*), which in the hands of Melloni yielded such remarkable results, is also to be classified as a radiometer. It is, indeed, with the possible exception of the Bolometer (*q. v.*), the most important instrument for the study of radiation. Whether the thermopile, which enables us to measure radiant energy by means of the electromotive force which is generated by the difference of temperature between its junctions, or the bolometer, an instrument which indicates temperature through the variation in the electrical resistance of a wire or strip of metal which is exposed to the rays, the intensity of which it is desired to measure, is the more sensitive is as yet an open question. The bolometer has, however, one very great advantage over the thermopile in that its mass may be reduced to an exceedingly small quantity. Possessing small mass, it is susceptible to very rapid fluctuations of temperature, and is capable of following sudden changes much more accurately than can be done by means of the ordinary form of thermopile.

Many other forms of radiometer have been described, for some of which a degree of delicacy surpassing that attainable with either of the instruments just mentioned is claimed. The best known of these are the thermo-galvanometer of d'Arsonval, the tasimeter of Edison, and the selenium cell. The thermo-galvanometer, which, under the name of the radio-micrometer, has been developed and utilized by Boys, consists of a very small light thermo-couple of bismuth and antimony closed upon itself so as to form a complete circuit. (See Fig. 2.) The same is suspended in a strong magnetic field by means of a quartz-fiber. When one of the bismuth-antimony junctions is exposed to radiation differences of potential arise, and since the circuit is of low resistance a considerable current flows. In consequence of this current the suspended thermo-element tends to turn in the field, and the movement is noted by means of a very small light mirror and a telescope and scale.

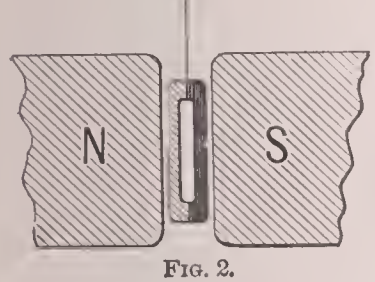

Fig. 2.

The tasimeter depends for its action upon the change of contact resistance of carbon with change of pressure. A vulcanite strip is so placed that one end of it rests upon a microphone button. Vulcanite possesses a large coefficient of expansion. When subjected to radiation its elongation is sufficient to materially compress the carbon button, reducing the resistance of the same and thereby increasing the flow of the current through a galvanometer in circuit with the latter. Neither of these forms has been found to be so serviceable as the bolometer or the thermopile, although an almost incredible sensitiveness has been claimed for both.

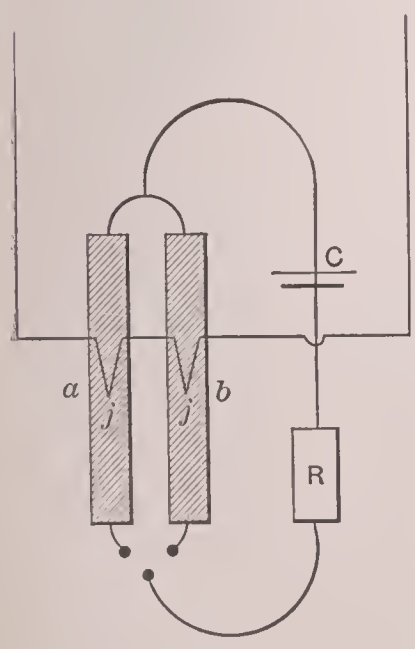

Fig. 3.

A method for the measurement of radiant heat was described by Knut Ångström in 1893 (see *Physical Review*, vol. i., p. 365), which, although not of exceeding sensitiveness, affords a very accurate means of comparing radiant intensities. Ångström's instrument takes advantage of the principles of both bolometer and thermopile. It consists of two similar strips of metal (*a* and *b*, Fig. 3), one of which is exposed to radiation, while the other is shielded. These strips are in contact with the opposite junctions of a thermo-element, *j*, which is placed in circuit with a sensitive galvanometer. By means of the heating action of an electric current generated in the battery, C, the temperature of the protected strip is brought into equilibrium with that of the exposed strip, a condition which is indicated by the reduction of the galvanometer deflection to zero.

A very sensitive radiometer is that which is based upon the remarkable changes in the conductivity of selenium when this substance is exposed to light. The selenium radiometer has been found a very unsatisfactory instrument, however, on account of the uncertainty of its action. Its sensitiveness to radiation depends upon instability of molecular structure. Like all other changes which consist in the breaking down of molecular arrangement, this is of great irregularity, and beyond accurate control.

The instrument with which the name radiometer is most generally connected is, in the strict sense of the word, not a radiometer at all. The apparatus in question is Crookes's radiometer (Fig. 4). It consists of a set of four mica-veins mounted at the ends of arms and revolving upon a needle-point. The arrangement is inclosed in a glass bulb from which the air has been exhausted by means of the mercury-pump. Crookes found that when the atmosphere reached a certain degree of attenuation these mica-veins began to revolve under the action of light. The phenomenon attracted great attention and many investigations concerning it were made. The result of these studies has been to show that the instrument is entirely unfitted for use as a measurer of radiant energy. The phenomena which the instrument presents are in themselves, however, of great interest.

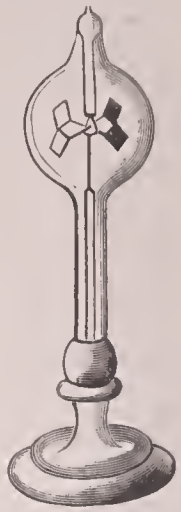

Fig. 4.

For a description of Crookes's radiometer, see Crookes, *Quarterly Journal of Science* (1876); Schuster, *Proc. Royal Society* (1876); Stoney, *Phil. Mag.* (1876). E. L. Nichols.

Radish [from O. Fr. *radis*, radish, Lat. *ra'dix*, root, whence O. H. Germ. *rātih* (> Mod. Germ. *rettich*) and O. Eng. *rādic*, radish]: the *Raphanus sativus*, a cruciferous plant, a native of Asia, cultivated for its root, and used as a table relish. The root is stimulant, diuretic, and antiscorbutic. The seeds of some varieties yield an oil almost identical with rape and colza oil.

Radium: See the Appendix.

Radius [Lat. *ra'dius*, spoke, ray]: the outer bone of the forearm, on the same side with the thumb. It is parallel with the ulna, which is larger than the radius, and enters much more closely into the formation of the elbow-joint, while the radius forms the joint with wrist-bones.

Radnorshire: a county of South Wales, adjoining two English counties—Shropshire on the N. and Hereford on the E. Area, 432 sq. miles. The surface is irregular and mountainous, reaching an altitude of 2,163 feet in Radnor Forest; more than half of the soil is bog and moorland. Of the latter, however, the larger part has been reclaimed, and is under cultivation. The valleys afford rich pasturage for large herds of cattle. Barley, oats, and potatoes are grown; cattle and sheep are reared. Principal towns, Presteign and New Radnor. Radnorshire returns one member to Parliament. Pop. (1891) 21,791.

Radowitz, raa'dō-wits, Joseph Maria, von: soldier and statesman; b. at Blankenburg, Brunswick, Germany, Feb. 6, 1797; received his military education at Paris and Cassel; fought in the campaigns of 1813 and 1815; taught mathematics at the military school of Cassel: removed in 1823 to Prussia, and held high military and diplomatic positions, and for a short time in 1850 was Minister of Foreign Affairs. He was a member of the Frankfort Parliament in 1848, and on its dissolution was the chief agent in bringing about the union of the three kingdoms, an attempt to found a united German state under the leadership of Prussia. D. in Berlin, Dec. 25, 1853. His *Gespräche aus der Gegenwart über Staat und Kirche* (Stuttgart, i., 1846; ii., 1851) and *Gesammelte Schriften* (5 vols., Berlin, 1852–53) derive their principal interest from the friendship and community of ideas between the author and Frederick William IV.

Rădulescu, Ioan Eliade: See Héliade, Jean.

Rae, John, M. D., LL. D.: Arctic explorer; b. in the Orkney islands (1813); studied medicine at Edinburgh; entered the service of the Hudson Bay Company as a surgeon 1833: for ten years lived at Moose Factory; made a boat journey (1846) along Hudson Bay to Repulse Bay; surveyed (1847) 700 miles of new coast-line, connecting surveys of Ross in Boothia with those of Parry at Fury and Hecla Strait. The only book he published was an account of this expedition, *Narrative of an Expedition to the Shores of the Arctic Sea* (1850). He took part in the expedition (1848) down the Mackenzie river in search of Sir John Franklin, and explored the whole coast of the Arctic Sea between the Mackenzie and the Coppermine rivers. He explored and mapped 700 miles of coast (1851), the south shores of Wollaston Land and Victoria Land. He proved the insular character of King William Land (1853), elicited from the Eskimos the first information obtained of Sir John Franklin's fate, and secured many relics of that party. For this discovery he received the admiralty grant of $50,000. He was a gold-medalist of the Royal Geographical Society, and attributed his success in Arctic travel to his ability to live in Eskimo fashion. D. in England, July, 1893. Revised by C. C. Adams.

Raff, Joseph Joachim: composer; b. at Lachen, Switzerland, May 27, 1822; owing to poverty was able to study music only at intervals; supported himself by teaching till he was twenty-four years of age, and then on the advice of Mendelssohn joined his class; but the death of Mendelssohn occurring soon after altered his plans. He had many struggles, and encountered much opposition, but force of character, persistency, and real musical talent enabled him to overcome them and to gain an eminent place in the ranks of composers. He was director of the conservatory at Frankfort-on-the-Main from 1877 till his death June 25, 1882. His works include eleven symphonies, including *Im Walde*, one of the best of modern works, an oratorio, *Das Weltgericht*, several operas and cantatas, very many sonatas for piano, for violin, and other instruments, much chamber music, songs, and many other pieces. His numbered works run up to Opus 216. He was a vigorous writer as well as composer, and contributed many articles to the German papers advocating the Wagner school. D. E. Hervey.

Raffles, Sir Thomas Stamford: administrator and ethnologist; b. at sea off Point Morant, Jamaica, July 5, 1781; son of a sea-captain in the West India trade; obtained at the age of fifteen an assistant-clerkship in the East India House. In 1805 he was appointed assistant secretary to the government of Pulo Penang (Prince of Wales island), and in 1807 he was made principal secretary. He soon became a leading authority upon the ethnology of the Indian Archipelago. He was secretary to the Governor-General of India, Lord Minto, during the expedition against Java 1811; was made lieutenant-governor of the newly acquired colony, and administered that important island and its dependencies with great judgment for five years. Returning to England on account of ill health, he was knighted in 1817, and published his *History of Java* (2 vols., 1817). Java having been restored to the Dutch, Raffles was in 1818 made lieutenant-governor of the settlement at Fort Marlborough, Bencoolen, on the coast of Sumatra. While in Sumatra he emancipated the slaves, formed the new British settlement of Singapore (1819), endowed there a college for the study of Malay and Chinese literature, and published *Malayan Miscellanies* (2 vols., Bencoolen, 1820–22). He returned to England in 1824, and founded the Zoölogical Society of London, of which he was the first president. D. in London, July 5, 1826. See the *Memoir* by his widow (1830).

Raffle'sia [Mod. Lat., named for its discoverer, Sir T. Stamford Raffles (1781–1826)]: a genus of plants of the family *Rafflesiaceæ*, natives of Sumatra and Java, and parasitic upon stems and roots of *Cissus*. They are greatly degraded, and are nearly stemless, rootless, and leafless, being little more than mere flowers, with a few scales for leaves; the seeds are rudimentary, and the embryo small and few-celled. The plant has a fungus-like, fleshy appearance, and a strong odor of carrion. *R. arnoldi* is considered the largest flower in the world. It is 3 feet in diameter, and has been known to weigh 15 lb. It is worshiped by the Javanese. *R. patma* has strong styptic power. *R. horsfieldii* is but 3 inches across. Revised by Charles E. Bessey.

Rafinesque, Constantine Samuel: naturalist; b. of French-German parents at Galata, Constantinople, in 1784. His mother's name being Schmaltz, he took for a time the name Rafinesque-Schmaltz. He was sent to the U. S. in 1802, landing at Philadelphia; he soon developed a fondness for natural history; made many excursions for collecting botanical specimens; went to Leghorn 1805, and thence to Sicily, where he resided ten years, and published (in Italian) several scientific works; sailed for New York 1815; lost by shipwreck on the coast of Long Island all his effects, including valuable books, manuscripts, and collections; was for some years Professor of Botany in Transylvania University, Lexington, Ky.; traveled and lectured in other States; settled finally at Philadelphia: wrote many monographs in various branches of natural history, especially *Ichthyologia Ohioensis* (Lexington, 1820); published *Annals of Kentucky* (1824), *The American Florist* (1832), *Atlantic Journal and Friend of Knowledge* (8 numbers, 1832–33), *The American Nations* (2 vols., 1836), *Medical Flora of the United States* (2 vols., 1828–30), *A Life of Travel and Researches* (1836), and other works. D. in Philadelphia, Sept. 18, 1842. The *Writings of S. C. Rafinesque on Recent and Fossil Conchology* was edited by W. G. Binney and G. W. Tryon, Jr. (Philadelphia, 1864). See *An Eccentric Naturalist* in *Science Sketches* by Jordan. Rafinesque was a man of large learning, quick insight, and great energy, but all his work is vitiated by an insatiate desire for novelties and a lack of recognition of the value of exact statement.
Revised by D. S. Jordan.

Rafn, Carl Christian: scholar; b. at Brahesborg, island of Fünen, Denmark, Jan. 16, 1795; studied at the University of Copenhagen; was appointed librarian of the university in 1821; and founded in 1825 the Society of Northern Antiquities. D. in Copenhagen, Oct. 20, 1864. Besides a number of critical editions, like *Krákumál* (1826), *Fornaldar Sögur* (3 vols., 1829), *Færeyinga Saga* (1832), and parts of *Fornmanna Sögur* (12 vols., 1828, *seq.*), and minor essays, he wrote *Antiquitates Americanæ* (1837), *Grönlands historiske Mindesmærker* (3 vols., 1838–45), and *Antiquités russes et orientales* (3 vols., 1850-54). In his *Antiquitates Americanæ* he gave the first popular account of the Norse discovery of America. Revised by D. K. Dodge.

Raglan, Fitzroy James Henry Somerset, Baron: son of the fifth Duke of Beaufort; soldier; b. in England, Sept. 30, 1788; educated at Westminster School; entered the army 1804; accompanied the Duke of Wellington in the Spanish Peninsula as a member of his staff, rising to the position of aide-de-camp and military secretary 1807; was wounded at Busaco 1810; distinguished himself at Badajoz 1812: was wounded in the battle of Waterloo; was knighted and made colonel; was secretary of embassy at Paris 1816–19; entered Parliament as a Conservative 1818 and 1826; was appointed master-general of the ordnance Sept., 1852; was made Baron Raglan Oct., 1852; commanded the British expedition to the Crimea, with the rank of general, Mar., 1854: defeated the Russians at the battle of the Alma Sept. 20; fought the battles of Balaklava, Oct. 25, and Inkermann, Nov. 5, and was made field-marshal Nov., 1854. The criticisms which were made on his command, on account of the sufferings of the troops, and the fearful repulse he suffered on June 18 weighed upon his mind, and he died in the camp before Sebastopol on June 28, 1855. His military papers formed a part of the material for Kinglake's *History of the Crimean War*.

Ragnarok [Icel. *ragna rökr* (translated into Germ. as *götterdämmerung*), the twilight of the gods]: in Scandinavian mythology, the final dissolution of the cosmic world, when gods and giants and men destroy each other in an internecine feud. Depravity and strife in the world proclaim the approach of the great event, which is preceded by a fall of snow from the four corners of the world, cold, piercing winds, tempestuous weather, the absence of summer, and convulsions of nature. Kindred slay each other for mere gain. The Fenris-wolf is freed from his chains, and the Midgard-serpent gains land. The heavens are rent in twain, and the sons of Muspel come riding through the opening in brilliant array to the battle-field called Vigrid. Thither repair also the Fenris-wolf, the Midgard-serpent, and all the forces of evil. The gods, who assemble without delay, arm themselves with speed, and sally forth to the battle-field, led by Odin. Odin is swallowed by the Fenris-wolf, and the wolf is killed by Vidar. Thor kills the serpent, but falls suffocated by its venom. Finally the earth, consumed by fire, sinks beneath the sea. After Ragnarok there is a new green earth, and there comes a new golden age in

which all will be good and happy. Then comes the Mighty One, he who is from everlasting to everlasting, and establishes peace and good will among gods and men. See SCANDINAVIAN MYTHOLOGY. RASMUS B. ANDERSON.

Raguet, ra-gā', CONDY, LL. D.: merchant and lawyer; b. in Philadelphia, Pa., Jan. 28, 1784; was educated at the University of Pennsylvania, and studied law; engaged in commercial pursuits; went to St. Domingo as supercargo of a vessel 1804; returned there 1805; published two small books giving an account of the state of that island and a history of the massacre of the planters; went into business on his own account 1806; accumulated a fortune; took an active part in several useful corporations and mercantile associations, and in taking measures for the defense of the city against an expected attack by a British fleet 1812; served in both branches of the Legislature; became in 1822 consul at Rio de Janeiro, Brazil; negotiated a commercial treaty with that country, to which, in 1825, he was appointed the first *chargé d'affaires*; returned in 1827, and wrote much in periodicals, especially in *The Portfolio*, in favor of free trade. D. in Philadelphia, Mar. 22, 1842. Author of *Principles of Free Trade* (1835); *On Currency and Banking* (1839); and other works; editor of *Free Trade Advocate* (2 vols., 1829); *Examiner* (2 vols., 1834–35); and *Financial Register* (2 vols., 1837–39).

Ragusa: town of Austria, in Dalmatia, on the Adriatic; picturesquely built in terraces along the side of Monte Sergio (see map of Austria-Hungary, ref. 10–F). It was the capital of a mediæval aristocratic republic, and during centuries the chief city on the eastern Adriatic. It rivaled Venice in activity and wealth and Florence in literary life, being commonly called the Slavic Venice. Its land-trade also was enormous; frequent caravans brought raw materials for export and manufacture, and took manufactured goods away. In 1364 it made a treaty of alliance with Murad I., the first concluded between a Christian state and the Ottomans; in 1421 it obtained from the Holy See special privileges or a sort of monopoly of trade with the Mussulmans; after 1453 it paid a small tribute to the Ottomans, but was always favored and protected by them; was twice almost destroyed by earthquake—in 1634 and 1667, when 5,000 persons perished. Napoleon suppressed the republic in 1808. In 1815 it was ceded to Austria; it had then 44,000 inhabitants. The doges' palace, library, and hospital are fine buildings. Grass grows in the principal streets, and the city is in full decay. Of its two harbors, Porto Cassonne is used only by fishing-boats, but Gravosa, 2 miles N., is the finest port on the Dalmatian coast, accommodating the largest men-of-war. Pop. (1891) 7,143. Seven miles S. are the ruins of Ragusa Vecchia, the ancient Epidaurus, destroyed by the Slavs in the seventh century. E. A. GROSVENOR.

Ragusa: town of Southeastern Sicily; in the province of Syracuse (see map of Italy, ref. 10–F). It is of very ancient origin; it sided with Syracuse against the Romans, and was by them made a colony. In 844 it was sacked by the Saracens. It has suffered greatly from earthquakes, being almost destroyed in 1693. In the city and immediate vicinity are remains of mediæval buildings, ancient tombs, and cisterns and caves in the rocks. Count Cabrero (d. 1423), who claimed the Sicilian crown, is buried here. The city consists of two distinct parts, each having its own municipal organization—Ragusa Superiore, pop. 24,183, and Ragusa Inferiore, pop. 6,260. E. A. GROSVENOR.

Rahbek, KNUD LYNE: poet and critic; b. in Copenhagen, Denmark, 1760. After studying theology and law he devoted himself to literature. In 1785 he published a volume of *Prosaiske Forsög* (Prose Attempts). In 1788 he delivered the first course of lectures on æsthetics ever given in Denmark, and in 1790 was appointed to the new chair of æsthetics at the University of Copenhagen. Besides *Minerva*, he edited alone *Den Danske Tilskuer* (The Danish Spectator, 1791–1808), the more general character of whose articles gave it an even greater influence than the earlier periodical. In Aug., 1798, he married Karen Margrete Heger, famous in Danish social and literary history as Kamma Rahbek. Besides editing a vast number of works of earlier and contemporary writers, among the former Holberg, he published *Dansk Læsebog* (Danish Reader, 1799), the first of its kind; *Ludwig Holberg som Lystspildigter* (Ludwig Holberg as Writer of Comedies, 1815–17); and many dramas and occasional poems, several of the latter of which still retain their popularity. Though only a second-rate writer and thinker, Rahbek exercised a greater influence upon his time than many of his more gifted contemporaries. For this he was in no slight degree indebted to his wife, whose wit and culture attracted to their home, Bakkehus, all that was best in the intellectual life of the capital. D. Apr. 1, 1830. D. K. DODGE.

Rahway: city; Union co., N. J.; on the Rahway river, and the Penn. Railroad; 19 miles S. W. of New York (for location, see map of New Jersey, ref. 3–D). Direct water-communication with New York is afforded by the river, which is here navigable for vessels of light draught. The city is tastefully laid out, and contains the residences of many people doing business in New York. There are 10 churches, a public high school, 4 grammar schools, a public library with over 10,000 volumes, a Y. M. C. A. building containing baths, gymnasium, bowling alley, and reading, social, and recreation rooms, a State bank with capital of $50,000, a savings-bank, and 2 weekly newspapers. The industries comprise a large printing and bookbinding house, printing-press manufactory, railway-signal works, woolen-mills, and carriage, hub, and spoke factories. Pop. (1880) 6,455; (1890) 7,105; (1900) 7,935.

Rai'æ [Mod. Lat., from Lat. *ra'ja*, ray, skate]: according to some authors an order, and to others a sub-order, of the class of elasmobranchiates, including the rays, torpedoes, and related types. The pectoral fins are much developed, produced from the anterior margins forward, and are connected with the rostral cartilages, thereby constituting an integral part of the form, and are not abruptly differentiated from the body, as in the sharks and all true fishes; the branchial openings are in two converging rows of five each on the inferior surface of the body; spiracles are well developed behind the eyes. In other respects the order essentially agrees with the *Squali*, and the two form a common super-order or sub-class—the *Plagiostomi*. The form varies considerably in the several members of the order; on the one hand, the sawfishes have an outline much like that of the sharks, and with a long caudal portion; and on the other hand, the eagle-rays and certain sting-rays have a disk extremely wide —much wider than long—and the caudal portion is reduced to a whip-like appendage. Revised by F. A. LUCAS.

Rai'idæ: a family of the order *Raiæ*, including the common skates or rays. In all these the disk is broad and sub-rhomboid, and the tail slender, but fleshy, and rather longer than the disk; the skin covered with radiated spines or asperities; the head well defined, and with a pointed snout; the internasal region furnished with a broad velum; the mouth transverse; the teeth small, generally varying according to the sex; the dorsals two in number, small and situated on the terminal half of the tail; the caudal reduced to a narrow seam. The female is oviparous, laying eggs provided with parchment-like cases furnished at each angle with a filamentous extension; these cases are known popularly as sailor's-purses, and are often found on the seashore. Between thirty and forty species are known. Some inhabit all seas, but they are more numerous in the northern than the southern hemisphere. Five species are found along the east coast of the U. S. (*Raia erinacea*, *R. ocellata*, *R. radiata*, *R. eglanteria*, and *R. lævis*), and several others on the west coast, *R. binoculata* being the most common.

Raikes, FRANCIS WILLIAM: See the Appendix.

Raikes, ROBERT: originator of Sunday-schools; b. at Gloucester, England, Sept. 14, 1735; succeeded his father as editor and publisher of the Gloucester *Journal*; founded a system of Sunday-schools for poor children in 1781, and witnessed its extension to most of the towns of England. D. Apr. 5, 1811. See the *Lives*, by Gregory (London, 1877) and Eastman (London, 1880), and SUNDAY-SCHOOLS.

Rail [from O. Fr. *raale* (> Fr. *râle*), deriv. of *raller*, have a rattling in the throat]: a popular name for any member of the *Rallidæ*, a family of marsh-haunting birds, having stout legs, long slender toes, weak wings, a compressed body, and, usually, a rather long bill. Rails are widely distributed throughout the world, and range in size from little larger than a sparrow to about 15 inches in length, or, if the COURLAN (*q. v.*) be counted a rail, 2 feet. They fly poorly, but run among the reeds with ease. They nest on the ground, and lay a number of cream or buff colored eggs with brown markings; the young run about as soon as hatched. Rails feed on all manner of small aquatic animals, such as snails and worms, and, to some extent, also on seeds. The common rail of Europe is *Rallus aquaticus*; the common species of the U. S. are the Virginia rail (*Ral-*

lus virginianus) and the sora, or ortolan (*Porzana carolina*). Both are found over the greater part of temperate North America, and are especially abundant during the fall migrations in the marshes and rice-fields of the Southern Atlantic States. F. A. Lucas.

Railways, or **Railroads**: roads with parallel lines of rails, upon which the (usually flanged) wheels of vehicles may run. The term *railways* is exclusively used in Great Britain, and is gaining ground in the U. S. Some writers confine the meaning of the term "railway" to the superstructure upon which the carriages run, the "railroad" being regarded as the formation of earthworks or other material upon which the "railway" itself rests. This distinction, however, is more fanciful than real, and the terms may properly be used synonymously.

General History.—The precise date of the first use of railways can not be ascertained. The plan of facilitating the draught of carriages by forming a hard continuous surface for the wheels to run upon is old and simple, and the successive adaptations of flagstones, pieces of timber, and finally strips of iron fastened to the top of the timbers, are the several improvements it has undergone. The use of iron was found to reduce the friction very sensibly, and to increase more than fourfold the amount which the horses could draw from the mines, where such tracks were mostly in use; a ledge or flange on the inner, or in some cases the outer, edge of the plate of iron forming the rail enabled the ordinary wagon to keep on the rails without difficulty. This kind of track was long in use, and was known as a tramway. The next improvement, growing out of the necessity for increased strength in the rails, was the introduction of the edge-rail, formed by setting up a bar of cast or rolled iron in the form of a T. This required special supports called "chairs," spiked to the timber-rails or to cross-supports of timber called "ties," or at intervals to stone blocks. In this rail the flange, which in the tramway was necessary to prevent the wheels from leaving the track, was removed, and in lieu of it a flange was cast on the inner edge of the wheel-tires. Railways constructed upon this principle were in operation in the principal collieries in Great Britain and Germany toward the close of the eighteenth century, used for the transportation of coal or ores from the pit to the port of shipment, sometimes by the force of gravity; and where the acclivity had sufficient steepness the loaded wagons in descending drew up the empty wagons by means of an endless rope passing around a pulley at the summit of the incline; in others, horse or steam power was used.

From the date of the application of the edge-rail—about the year 1790—in lieu of the timber-rail, with its strip of flat iron permitting but a limited speed, the additional strength thereby conferred on the railway proper naturally led those interested to seek a means of propulsion more effective than horse-power, and so the progress and extension of railways became intimately connected with the improvements in the locomotive engine.

The advantages of the low-pressure condensing steam-engine, as demonstrated by James Watt, led to the neglect of the high-pressure principle, although the high-pressure engine, from its comparative lightness, dispensing with the cumbrous apparatus necessary for condensation, is alone applicable to locomotive purposes on land.

Richard Trevithick in 1802 was the first person to take out a patent for a high-pressure engine adapted to motion on roads; his engine was first tried on common roads, but subsequently applied to colliery railways. Improvements made by him were the subject of a patent in 1804, and as early as this steam was used as a means of propulsion on some of these roads, but the speed was not greater than that of horses, owing to the imperfect construction of the boilers of the engines; and on grades as low as 18 feet per mile they required to be assisted by auxiliary power of some sort. The progress of improvement in the engine used for roads was much retarded for many years by an imaginary difficulty which it would seem a single experiment would have sufficed to remove. This was in the opinion that the friction, or the adhesion of the driving-wheels of an engine to the rails, did not offer sufficient resistance to slipping to allow of the power of the engine being applied to the axles so as to produce locomotion. As late as 1811 Blinkinsop obtained a patent for the application of a rack-rail, laid on one side of the railway, into which a cog-wheel on the axles of the driving-wheels worked. Other patents are on record as late as 1815, seeking to overcome this fictitious difficulty—some by means of chains extending the whole length of the road between the rails, and others by means of jointed levers worked by steam. It was at about this date that the discovery was made that the adhesion of the wheels of the engine to the rails furnished a sufficient fulcrum for the action of the propelling power, thus dispensing with all the cumbersome contrivances of racks and chains.

In 1814 George Stephenson built an engine for the Killingworth colliery. The boiler was a flue-boiler, and as it did not make steam enough for a speed of more than 3 miles per hour, it would have been condemned as useless had not Stephenson applied the steam-blast to it, which increased its speed to full 6 miles per hour. It is in the accounts of the day that this application was accidental; the noise of the escape steam was complained of as a nuisance, and to avoid it Stephenson turned the escape-pipe into the chimney, thus creating a draught.

Notwithstanding the efforts made by Stephenson to bring his engines into general use, the opinions of some able engineers of that day were that they did not possess the advantages which the inventor had anticipated. Their use was extending, however, in the neighborhood of the collieries for the transport of coal from the mines, although still supplemented on some of the inclines by horse-power, and on others by rope and stationary engines.

The Stockton and Darlington Railway, 37 miles in length, intended originally for the transport of coal alone, was opened in 1825. It had been the intention to operate it with horses, but Stephenson soon succeeded in introducing the use of locomotives. Engines and tenders weighing 12 tons drew loads of 92 tons upon that road, which has an average grade of 21 feet per mile, some places being level and others having a grade of 53 feet per mile; on the steeper grades 37 tons were taken up at a speed of 4 miles per hour, 6 miles per hour being the speed on other parts of the road; but a speed of from 7 to 8 miles per hour was attained under favorable circumstances. Increased commerce between Manchester and Liverpool, much hampered by the excessive tolls and uncertain movements on the canal between these points, led to chartering the Liverpool and Manchester Railway in 1828, its main object being the transport of merchandise between the two places, but by horse-power. The engineer, George Stephenson, however, advocated the use of steam exclusively. The directors of the road were induced to offer a reward for a locomotive engine which should be able to take three times its own weight on a level road at a speed of 10 miles per hour. In Oct., 1829, the Rocket, an engine built by Robert Stephenson, Jr., a nephew of George Stephenson, more than performed all the stipulated requirements; weighing but $7\frac{1}{2}$ tons, it drew 44 tons at the rate of 14 miles an hour. The effect of this announcement was electrical, and was felt in every civilized country in the impulse given to railway construction.

The first railway built in the U. S. was from the granite-quarries of Quincy, Mass., to tide-water, length 5 miles; begun in 1826 and completed in 1827, it was built to supply the granite for the Bunker Hill Monument, and made of wooden rails laid on granite sills, with a strap-rail of rolled iron. The second road was begun in Jan., 1827, and completed in May of the same year, extending from the coal-mines to the Lehigh river at Mauch Chunk, Pa.—a distance of 9 miles. The loaded cars passed down the inclined planes by gravity, and the empty cars were drawn up by mules. The rails were of timber covered with a strap of iron. In 1828 the Delaware and Hudson Canal Company constructed a railway from its coal-mines to Honesdale, the termination of the canal, to transport the anthracite coal to tide-water. The Baltimore and Ohio and the South Carolina railroads were begun, the latter in 1830. By the close of the year 1830 the following railways had advanced in construction as shown below:

NAME.	Projected, miles.	Completed, miles.
Quincy	5	5
Mauch Chunk	9	9
Delaware and Hudson Canal Company	16	16
Baltimore and Ohio	250	60
Mohawk and Hudson	16	12
South Carolina R. R. (Charleston and Augusta)	135	20
Camden and Amboy	50	constructing.
Ithaca and Owego	29	"
Lexington and Ohio	75	"

All these roads, with a single exception to be noted subsequently, were built for and operated by horse-power. The

first number of *The Railroad Journal* (from which the above list is taken) contains also a list of the railway companies then petitioning the Legislature of the State of New York for charters, the aggregate capital reaching the sum of $43,000,000; this prior to 1831. The roads mentioned in the table, it will be observed, were chartered before the experiment of the Rocket at Liverpool had indicated the most advisable power for operating railways.

In Jan., 1828, Horatio Allen, of the Delaware and Hudson Canal Company, went to England, charged with the duty of procuring the iron rails for that company's road, and also, at his discretion, to order three locomotive engines. He accordingly ordered one engine from the works of Foster, Rastrick & Co., of Stourbridge, and two engines from the works of R. Stephenson at Newcastle. These orders were given in the early summer of 1828, and the engines were received in New York in the following winter (1828–29). The burning of anthracite coal in the furnaces of engines was the point to be demonstrated by the Delaware and Hudson Canal Company, whose extensive mines were waiting a demand on the part of the public, the total consumption of anthracite coal having reached but about 80,000 tons yearly. In the spring of 1829 one of these three engines was ordered to be sent by river and canal to Honesdale, Pa., the initial point of the company's railway. The accident which sent the Stourbridge engine rather than either of the other two has not been accounted for. The other two engines were precise counterparts, and identical in boiler, engine, plan, and appurtenances with the Rocket, by the same maker, which subsequently startled the world by its performances at Liverpool. The Stourbridge Lion, as the engine was named, was put upon the track—built of hemlock timbers and strap-rails, with timber trestles 35 feet in height, and curves of 720 feet radius—and Mr. Allen ran the engine himself for some 6 miles at good speed amid the cheers of the incredulous spectators. No load was attached, as it was feared that it would prove too severe for the road, but it was the first trip ever made on a railway by a locomotive engine in America. It is true it was a foreign-built engine, but its plan had been selected by an American engineer many months before there existed any acknowledged standard by which such machines were to be judged; and there are few bolder achievements of the civil engineer on record than this trip for the first time with an engine between 8 and 9 tons weight at full speed upon such a road. The experiment was successful in exhibiting the value of anthracite coal as a fuel for steam purposes.

Horatio Allen had been appointed chief engineer of the South Carolina Railroad (not then constructed) at the date of his experimental trip with the Stourbridge Lion; and, entering upon his duties a short time subsequently, he reported his views as to the power which he considered it advisable to adopt for its operation in a paper dated Sept., 1829, strenuously urging, for reasons stated at length, the employment of steam as the locomotive power. This report, submitted to the board of directors and unanimously adopted and placed on record Jan. 14, 1830, was the first act by a corporate body, either in the U. S. or elsewhere, adopting the locomotive engine as the tractive power on a railway for general passenger- and freight-transport. Accordingly, in pursuance of that resolution, in Mar., 1830, E. L. Miller, on the part of the South Carolina Railroad Company, contracted with the West Point Foundry Company for a locomotive engine. This was the first locomotive engine built for railway service in the U. S., and was first put upon the road Nov. 2, 1830.

A second locomotive was also built at the West Point Foundry works for the same railway company, and from designs of the chief engineer. In 1830 trials of a small steam-engine built by Peter Cooper were made by the Baltimore and Ohio Railroad, which, however, continued to be operated by horse-power till 1832. The engine was placed on a platform-car.

The improvements made in the locomotive engine became so numerous that it is difficult to determine the precise value of their respective claims. Their effect upon the extension of railways was most marked, and projects and charters were multiplied, not unfrequently much in advance of the wants of the locality. The flat rail—or strap-rail, as it was called—was soon abandoned; the New Orleans and Lake Pontchartrain Railroad was the first to adopt the T-rail (1830–31), Gen. J. G. Swift being the engineer.

Between the years 1828 and 1833 the present system of railway communication in the U. S. may be said to have been begun by the commencement of the Baltimore and Ohio, the Baltimore and Susquehanna, the Camden and Amboy, the New Castle and Frenchtown, the Hudson and Mohawk, the Charleston and Augusta, the Boston and Providence, the Boston and Lowell, and other roads. If we except the Baltimore and Ohio, it will be seen that there was little foresight of a future great connecting system; and it may be said that in general the great lines of communication with the Mississippi valley and the States W. of it are made up of parts originally having little reference to each other. Indeed, the roads in the U. S. have been gradually called into existence to supply a need which they themselves have created, and which did not in the beginning exist. The Baltimore and Ohio and (at a later date) the Pennsylvania roads, connecting the Ohio with Baltimore and Philadelphia, the Mobile and Ohio, connecting that river with the Gulf, may be called the first through lines. The necessity of connecting the newly developed Pacific States with the older body gave rise to the most extended system of reconnoissance and survey through a vast expanse of mountain-chain and desert for the determination of practicable routes, and finally to the rapid construction of the most remarkable through line of railway in the world. The Union Pacific Railway (completed 1869) was built, many parts of it, at the unprecedented rate of a mile a day, but even this is regarded as slow, and the reports of the Canadian Pacific Railway (completed 1885) for the year 1883 show a progress for the entire working season, from Apr. 18 to Nov. 21, of 2·4 miles of completed track laid for every working day.

Following the history of railways to the present day, it will be in order to consider briefly some of the principles to be considered in their construction. The principles of the construction of the accessory works of a railway, such as embankments, bridges, tunnels, etc., differ in no essential save dimensions from those required for first-class turnpike-roads; but the location of the *curves*, or horizontal deviations from a right line; the *grades*, by which we understand the rise or fall in the direction of the length of the road; and the *gauge*, or width between the rails of the track, are the elements which determine the capacity or classification of a railway as a means of transport, and are matters requiring careful study.

Curves.—The amount of resistance to locomotion occasioned by curves in a road is partly due to the effect of centrifugal force, causing the flange of the outer wheel of the cars to press against the rail; partly to the dragging of the wheels, which, being necessarily fixed on the axle, are obliged to perform an equal number of revolutions whether on the inner and shorter, or outer and longer rail of the track; and partly to the axles being *fixed* parallel. In practice, curves of a mile radius offer but little impediment to rapid motion. The necessities of the locality very frequently call for curves of much less radius than this, and the expense of maintenance of both road and machinery is thereby much enhanced unless the curves be traversed at a reduced speed.

It is customary to reduce the rate of inclination on the portions of such parts of the road as are curved at the rate of ·05 feet per 100 for every degree of curvature, as also to raise the outer rail of the track a height proportioned to the speed of the trains. It has also been customary to make the tread of the wheels a conic surface, that in traversing a curve the wheels on the outer rail may run on a longer diameter and so cover a greater length of the track than those on the inner rail, and thus assist the movement around the curve; but this method has been found to produce much oscillation and concussion on the straight portions of the track, and has in a great measure been discontinued—at least to the extent originally thought necessary—although a coning of the wheels to the extent of $\frac{1}{16}$ inch is occasionally practiced. The action of the edge of the rail upon the wheel tends to wear the base of the cone into a groove, as it were, and what at first was thought a notable device for facilitating the movement of the vehicles around a curve is found in practice to be of no value, and in the U. S. the tread of the wheels is now made cylindrical. In European practice the coning of the wheels is still followed to a considerable extent, and the rails are inclined inward at an angle of from 1 in 20 to 1 in 24 in order to allow the rail-head to fit the wheel.

The velocity of the train being an element in the calculation for the super-elevation of the outer rail of the track, what would be suitable for one speed of train would be unsuitable for another; hence a compromise has to be made,

and the average speed of passenger-trains is usually taken from which to calculate this super-elevation:

Theoretically, if v = speed of train in feet per second,
r = radius of curve, in feet,
g = gauge of track, in inches,

then $g \times \frac{v^2}{32{\cdot}2r}$ = elevation in inches to be given to the outer rail of the track. In practice it is customary to disregard the speed and elevate the rail $\frac{1}{2}$ inch per degree of curvature for ordinary-gauge tracks. When the term "degree of curvature" is mentioned in speaking of curves, it is to be understood as the number of degrees subtended by a 100-foot chord. Thus a $\frac{1}{2}°$ curve is one of about 2 miles radius; a 1° curve is of about a mile radius; a 2° is of about a half-mile radius, or, more accurately—

Radius, feet.	Curvature, degrees.	Radius, feet.	Curvature, degrees.
22,918	½	2,292	2½
11,459	¾	1,910	3
7,639	¾	1,433	4
5,730	1	1,146	5
3,820	1½	955	6
2,865	2		

Hence the super-elevation to be given to the outer rail would be, in inches, for a 1° curve, ½; for a 2°, 1; for a 3°, 1½; for a 4°, 2; for a 5°, 2½ inches, and so on, which according to Trautwine is sufficient for speeds as high as 40 miles per hour. The modern refinement of the introduction of transition-curves, by which the point of tangency is virtually thrown back a considerable distance on the tangent, and the curve thus eased on its approach to the latter, gives the opportunity for availing earlier of the super-elevation of the outer rail. This results in a smoother motion when the cars take the curve, very perceptible in comparison with the older methods of change of direction.

Grades.—The additional resistance to motion occasioned by the various grades or inclinations in a road is susceptible of precise calculation, and is a constant quantity for the same inclination, let the state of the road or the machinery be what it may. It is as the sine of the angle of inclination; or, virtually, it is that fraction of the weight which is represented by dividing the height of a given inclination by its length. For instance, in a rise of 22 feet per mile it would be represented by $\frac{22}{5280} = {\cdot}004$, which is 8 lb. for a ton of 2,000 lb., or $\frac{1}{250}$th of the weight. The relative capacity of roads for traffic is therefore limited by their grades—that is to say, since only a certain number of trains can pass over the road yearly, that if the grades are such as to limit the load of the engine to a certain amount, the yearly tonnage, which is the total number of trains multiplied by the load of each, is limited in the same proportion. The capacity of railways is a subject of but little popular appreciation, but one of great importance in projecting new lines of roads.

The principle which obtains in calculating the effect of grades on the movement and weight of trains is briefly illustrated as follows: If a locomotive engine be prevented from advancing on the track, and at the same time the proportions of the machinery be such that upon the application of the power to the wheels the latter will revolve by slipping on the rails (as is usually the case), the engine is said to work up to its adhesion, and the latter becomes the limit of its tractive force. This adhesion varies, in different states of the rail-surface, from one-third to one-tenth of the weight on the driving-wheels, and may be taken ordinarily at one-sixth of the insisting weight. If, then, we know the amount of this and of the resistance to motion occasioned by the friction at the axles of the wheels of the engine and train, as also of the rolling of their surfaces on the rails, we may calculate the weight which the engine will draw on a level under the assumed condition of the rails and the machinery. Thus if it be found that 8 lb. per ton of the weight of the engine and train represents the resistance to motion on a level occasioned by all impediments to motion of whatever kind, disregarding the speed, then by dividing the adhesion expressed in pounds by 8 we obtain the gross weight in tons which the engine will draw upon a level; but where the train ascends a grade there will be, in addition to the resistance of friction on the level, the resistance arising from the gravity of the engine and its load, or its tendency if unresisted to move down the slope, explained above.

The resistance of gravity is the same on a given plane at all speeds, but is overcome twice as fast at 20 miles per hour as at 10 miles, and hence is said to vary with the speed. Friction varies with the load of the train and slightly with the velocity; concussion or resistance of the curves varies both with the weight and speed of the train. Atmospheric resistance varies with the speed and bulk of the train, but its value is not well established and has been estimated as dependent upon the area of the frontage of the train rather than its bulk. If we disregard for the present the various resistances in detail occasioned by curves, concussions, and that of the atmosphere, and consider them as included in a single factor per ton of train, the formula expressing the power of an engine on different grades is very simple and sufficiently accurate for relative comparison. Let E represent the weight on the driving-wheels of an engine in pounds; and let R represent the rise in feet per mile of a given grade; then the gross load, including engine and tender, in tons of 2,000 lb., which the engine will take up that grade will be represented by $\frac{{\cdot}2E}{{\cdot}3787R+8}$, the adhesion being one-fifth of the weight of the engine on the drivers. The following table shows the gross load, in tons of 2,000 lb., which, by the above formula, an ordinary freight-engine weighing 66,000 lb., 40,000 lb. on the driving-wheels, may be estimated to move on different grades in a good condition of the rails:

ON A LEVEL.	20 feet per mile.	30 feet.	40 feet.	50 feet.	60 feet.	80 feet.	100 feet.	150 feet.	200 feet.	250 feet.
1,000 ...	513·8	413·2	345·6	290·3	260·4	208·9	174·4	123·4	95·5	78·0

The most simple formula for the resistance of a train—for purposes of general comparison sufficiently accurate—is that of D. K. Clark, which is, where R is the resistance in pounds per ton (2,240 lb.) of engine, tender, and train, and V the velocity in miles per hour,

$$\frac{V^2}{171} + 8 = R.$$

The following table shows the resistance in pounds per ton (2,240 lb.) for different velocities, according to Clark's formula:

At 10 miles per hour.....	8·6 lb.	At 40 miles per hour.....	17·3 lb.
At 12 " "	8·8 lb.	At 50 " "	22·6 lb.
At 15 " "	9·3 lb.	At 60 " "	29·0 lb.
At 20 " "	10·3 lb.	At 80 " "	45·4 lb.
At 25 " "	11.7 lb.	At 100 " "	66·4 lb.
At 30 " "	13·3 lb.		

The resistance to motion as affected by the grade alone is had by multiplying the load by the rise in feet and dividing the product by the length also in feet. The following table shows by inspection the resistance in pounds on different grades, of loads varying from 1 to 500 tons:

GRADE IN FEET PER MILE.	1 ton.	50 tons.	75 tons.	100 tons.	250 tons.	500 tons.
10	4	212	318	424	1,061	2,121
20	8	424	636	848	2,121	4,242
30	13	636	955	1,273	3,182	6,363
40	17	848	1,273	1,697	4,242	8,484
50	21	1,061	1,591	2,121	5,303	10,606
60	25	1,273	1,909	2,545	6,364	12,727
70	30	1,485	2,227	2,970	7,424	14,848
80	34	1,697	2,545	3,394	8,485	16,969
100	42	2,121	3,182	4,242	10,606	21,212

The tractive or drawing power of an engine, called its *traction*, is directly as the diameter of the steam-cylinders, the steam-pressure, and the stroke of a piston, and inversely as the diameter of the driving-wheels; therefore we increase the tractive power of an engine by increasing either the diameter of cylinders, the steam-pressure per square inch, or the stroke, or by decreasing the diameter of the driving-wheels. The formula expressing this is as follows:

If d = diameter of a cylinder, in inches,
p = mean effective pressure of steam per square inch on the piston,
s = length of stroke, in inches,
D = diameter of the driving-wheels in inches,
then $\frac{d^2ps}{D}$ = tractive power.

This is upon the supposition that the adhesion of the wheels to the rails, taken at one-sixth of the weight in pounds upon the drivers, is in excess of the tractive power as above determined, the adhesions varying from as high as one-fourth to less than one-tenth of the weight on the driver. Thus the tractive power, with an effective pressure of steam on the piston of 80 lb., the stroke being 22 inches,

and the diameter of the cylinder being 16 inches, and diameter of wheel 60 inches, would be

$$\frac{16 \times 16 \times 80 \times 22}{60} = 7509{\cdot}8 \text{ lb.}$$

Therefore, if the weight of the engine on the driving-wheels is in excess of six times this, or = 45058·8. the engine would be said to work up to its adhesion, and locomotion would ensue.

Inclined Planes.—Before the locomotive had been perfected, and before even the question of locomotive- *vs.* stationary-engine power had been settled, it is not surprising that recourse was had to inclined planes (which were in fact the first form the railway assumed) for overcoming abrupt changes of level. Hence we find several examples, as that on the Mohawk and Hudson (Albany and Schenectady) road. The Columbia road (Philadelphia to the Susquehanna) had one at each end. The Alleghany Portage road, connecting two sections of the Pennsylvania Canal, had a number. The South Carolina road (Charleston to Augnsta) had one near the latter place, and the Baltimore and Ohio had one at Parr's Ridge, Md. On the Liverpool and Manchester road there were two, on the railway near Liège, Belgium, was one, and others existed elsewhere in Europe; but the neeessity of admitting much higher grades than had been supposed admissible and of overcoming them by locomotive power was speedily felt. The Baltimore and Ohio road was constructed to admit grades of 116 feet, and even heavier grades, though unadvisable, are yet to be found. All of the inclined planes above enumerated are now operated by the more modern locomotive engine. The grade of 116 feet per mile on the Baltimore and Ohio road is operated by two engines each 62 tons weight, which take a load of 600 tons, exclusive of the weight of engine and tender, up this incline at the rate of 15 miles per hour. For temporary purposes the engines have taken loads of 40 tons, exclusive of their own weight, up grades of over 500 feet to the mile. See INCLINED PLANE and MOUNTAIN-RAILWAYS.

Gauge.—It is not known what, if any, principle governed the determination in the first instance of the gauge between the rails of 4 ft. 8½ in. It was adopted in the roads from the collieries in the north of England, and believed to have arisen from the colliery-wagons in use on common roads having an outside width of axle of 5 feet; for as the tramroads had the flange on the outer edge of the rail these ordinary wagons could be used on them, and when the tramway was replaced by an edge-rail the same width of track was continued, but, measured from the inner edge of the rail, resulted in the 4 ft. 8½-inch gauge. Another reason, given by an authority, is that the tramways were 5 feet wide including the rails, and as the later edge-rails were 1¾ inches wide they practically determined the gauge at 4 ft. 8½ in. as soon as they were introduced. Be this as it may, Mr. Stephenson, engaged in these collieries, was selected to build the Liverpool and Manchester road, and seeing no reason to change the gauge with which he was familiar, it was adopted there. When once established on a line of road looking to future extension, it was apparent that unless some special advantage called for a change there was a manifest propriety in continuing its use; accordingly, the success of the Liverpool and Manchester road led to the general adoption of this gauge. As the weight of traffic increased, and a corresponding increase of power was called for in the locomotive engine, the impression prevailed that this could be best arrived at by increasing the space within which the machinery was placed, and an increase in the width of track on many roads was the consequence. In 1846 the inconvenience resulting from this lack of uniformity in the width of the railways in England led to the matter being brought before Parliament, and an inquiry was instituted as to the respective merits of the various proposed widths of tracks. The commotion which followed, known as the "battle of the gauges," led to experiments, investigations, and reports by a committee of Parliament, and every effort possible was made to arrive at a just conclusion in the premises, and the subject was exhaustively considered. The result was, that while Parliament declined to enact a law compelling all roads to adopt the narrow gauge, yet the evidence went to show that although for main-trunk lines of great traffic a wider gauge than the prevailing one of 4ft. 8½ in. would probably prove advantageous, yet the advantages were not then so apparent as were the disadvantages resulting from a lack of uniformity with the prevailing gauge of the kingdom; and the public mind settled generally to this belief. In the U. S. there were five different widths of track—from 4 ft. 8½ in. to 6 feet—and the advantages of uniformity of track again forcing itself upon the attention of railway proprietors resulted in the triumph of the 4 ft. 8½ in.; and for the same reasons as formerly, not its mechanical superiority to any other, but the expediency of its adoption in view of the extent of roads in operation of that width of gauge.

As before remarked, the grades, curves, and gauge of a railway are the elements of its capacity for transport. The relative effects of the first two are measurably well understood, but the precise value of the latter still remains a mooted question among engineers, although the general adoption of the standard gauge of 4 ft. 8½ in. in the U. S. has rendered such investigation of little practical interest.

Drainage.—The expense of the maintenance on any line will, other things being equal, vary very nearly in the proportion in which its drainage is good or otherwise. Water lying or running on the surface soaks and softens the road-bed, washes away the earth, and chokes the ditches. When saturated with water the road-bed loses its firmness, and the bottom sinks and deranges the tracks, thus adding to the shocks of the train and to the wear and tear of both the machinery and the track. The surface-drainage of the slopes of excavations is equally important, to prevent the velocity of running water from tearing up the soil and choking the ditches, which should be kept open and of a sufficient depth to drain the bottom of the ballast.

The cross-ties, upon which the rails rest, are generally of oak, chestnut, or other hard and durable wood, from 6 to 8 inches in depth, from 8 to 10 wide, and 8 feet in length, and are laid usually upon the road-bed at intervals of about 2 feet between centers. The ballast, or material upon which the ties rest, should be broken stone or gravel mixed with coarse sand free from loam or clay, and should extend to a depth of at least 18 inches below the bottom of the ties, and the space between the latter should be filled in nearly to the level of the bottom of the rail. The effect of this, besides securing the cross-ties and rails in their places, permits by its porosity the thorough drainage of the track, resists sinking of the ties, and enables them to be readily packed up, while it gives a proper amount of elasticity to the track, more conducive to durability than the plasticity of earth or the rigidity of rock, and secures them against the heaving action of the frost.

Rails and Cross-ties.—The early forms of strap-rails soon gave way to east-iron bars about 6 feet long, called fish-bellied rails, and these in turn were replaced by wrought-iron forms. The first steel rails were rolled in England in 1857, and the introduction of the Bessemer process (patented in 1856) produced a marked influence in cheapening the cost of construction of railways.

In Great Britain and on the continent of Europe it has been customary to make the rail double-headed, and when worn on one edge to reverse it, and thus double its duration; but this method, besides rendering an expensive cast-iron chair necessary, with its complication of fastenings (this item alone being estimated in Great Britain as amounting to over 1,000,000 tons), is of doubtful expediency, as the effect of the chair is in many cases to indent the lower face of the rail, which is subsequently liable to fracture. This has led to the use of the "bull-head" non-reversible rail, the lower head being only large enough to secure the rail in the chair. The system universally pursued in the U. S. of dispensing entirely with a chair, and making the base of the rail some five inches in width, resting on the timber cross-ties without other support, and secured to the latter by brad-headed spikes, is gradually gaining ground elsewhere as the most simple and efficient method of securing the rail.

For some years the use of steel cross-ties has been gaining ground, and is now advocated as conferring the requisite elasticity of track with economy of maintenance; and, what is very remarkable, as it is well known that rails subjected to the rolling traffic of the road do not deteriorate by rust, while a rail lying unused by the roadside is soon destroyed by rust, so it is found that the metal sleeper, or cross-tie of rolled iron or steel, while in use under the rails, does not suffer loss by rust to any appreciable extent, and does not require renewal from this cause. The extent of metal track in the world up to 1892 is shown in the following table (from official sources); it is scarcely to be regarded as experimental in countries where from scarcity of timber, climatic, or other considerations, the use of metal for the

support of the rails became almost a matter of necessity. This table also gives the miles of railway up to 1892:

COUNTRY.	Metal track, miles.	Total track, miles.	Per cent. of metal track.
Europe	10,400	135,000	7·70
Africa	1,330	5,300	25·09
Australasia	200	10,740	1·86
Asia	9,800	21,425	45·74
South America, Central America, West Indies, Mexico	3,850	21,000	18·33
U. S	20	171,000	.....
Canada	.....	14,635	.....
Totals	25,600	379,100	6·75

The average number of ties obtained from one acre of forest is 100, so that for new track with 2,640 ties per mile about 26½ acres of forest must be cleared to supply ties for each mile of track. The annual consumption of timber for railway purposes in the U. S. is about 365,000,000 cubic feet for ties, and 60,000,000 cubic feet for bridge and trestle construction of sawed material; so that the annual consumption of 500,000,000 cubic feet of wood in the shape of forest-grown (round) timber for railway purposes may be taken as a reasonable figure.

The first rails of rolled iron were not above 3 feet in length, while steel rails have been rolled over 80 feet in length. Common rails are rolled in lengths of about 30 feet, and the joints are secured by fish-plates—plain plates of rolled iron placed under the head of the rail, and secured to both rails by bolts—or by angle-plates, having the general sectional form of the rail and its flange, and secured in the same way by bolts. The joint being considered the weakest point of the track, every effort was made to stiffen it by clustering the ties near it, and making the joint-tie broader and heavier than elsewhere. Against this it was urged that the joint became stiffer than the remainder of the rail and to that extent objectionable, and the joint was then suspended by resting the angle-bar at each end on a tie, and dispensing with the support afforded by a tie immediately under the joint, thus giving elasticity to the joint. Each method has its advocates, and innumerable patents claiming to make a perfect joint have been issued. The rails are secured to the angle-plates by bolts passing through holes made oblong to permit the expansion and contraction of the rail occasioned by change of temperature. In the climate of the U. S. it is estimated that this variation in the length of a 30-foot rail will amount to $\frac{7}{16}$ of an inch. At or near the center of each rail the spikes are passed through nicks in the flange of the rail, instead of outside the flange as elsewhere, thus fastening each rail near the center of its length to the down grade by the action of the driving-wheels of the engines. The thorough draining and ballasting the track, it will be perceived, is relied upon to render the above precautionary measures of any service. Constant increase in the weight of rails has been going on for some years. Steel rails 6 inches high and of the same width of flange, and weighing 120 lb. to the yard, are now proposed, and 100-lb. rails are not uncommon. The main tracks of all the chief railways of the U. S. are of steel.

Electric Railways.—With the exception of variations in the width of gauge and weight of rail, and the details of the rolling stock, the railways of the U. S. present great uniformity of plan. To this statement an exception must be made in the case of the roads operated by electricity; for although the consideration of the motive power to be used on railways is in a measure foreign to the purpose of this article, yet the use of electricity has rendered some changes in the construction of the rail track essential, and still greater changes may be anticipated in the future.

The electrically operated railways have thus far been confined to the streets of cities and towns, and, as with other municipal roads, neither its construction nor its operation is embodied in the tabular statements herewith appended. See Electric Railways.

Statistics.—Nearly one-half of the railway mileage of the U. S. has been constructed since 1880. This great increase has been largely in the Southern and Western States. But this has been eclipsed by the increase in the magnitude of operations. The gross earnings of 1893 were $1,208,641,498, of which $808,494,668 were from freight, $311,978,347 from passengers, and $88,168,488 from miscellaneous sources. The net earnings were $358,648,918.

In addition to the cost of construction of new roads, a large amount of fresh capital is yearly expended on old lines; so that for many years past there has been expended upon railways over $1,000,000 for every working day in the year. Should much of the cost of new lines be lost to shareholders, the republic is undoubtedly the richer to a very large extent, possibly approximating the expenditure, from the incidental advantages growing out of opening new and extensive tracts of rich lands for settlement, and bringing within reach of markets products which would otherwise have had no commercial value. These railways during 1893 transported 757,464,480 tons of freight, an equivalent of 90,552,087,290 tons moved one mile, at an average charge of 0·89 cents per ton per mile; and passengers 628,965,973, equivalent to 15,246,711,952 persons carried one mile, at a charge of 2·05 cents per passenger per mile, the number of passengers carried equaling nearly nine times the entire population of the U. S. This is exclusive of elevated-railway travel in the cities. The value of the freight carried, at $25 per ton, would equal nearly $19,000,000,000.

Since the opening of the Liverpool and Manchester Railway (1831) there have been built about 400,000 miles of railway, at an estimated cost of $40,000,000,000. The railway may therefore justly claim to be one of the most signal instruments—perhaps the most signal instrument—of civilization yet developed. J. W. Adams.

Railway Equipment: The track, shops, stations, and rolling stock of railways. The total railway mileage of the world has 74 per cent. of standard gauge (4 ft. 8½ in. in the clear between the heads of the rails), 12 per cent. of broader gauges, and 14 per cent. of narrower gauges.

Track.—The visible portion of the road-bed, consisting of rails and cross-ties, constitutes the track, which usually rests on a foundation of broken stone or gravel. About 90,000,000 of timber cross-ties are annually used on the railways of the U. S. Preserving wooden ties is commonly practiced in Europe, and to some extent in the U. S. The principal processes are as follows: Kyanizing (corrosive sublimate), burnettizing (chloride of zinc), Boucherie (sulphate of copper), Wellhouse (chloride of zinc and tannin), and vulcanizing (heating under pressure). Metal tie-plates are often used under T-rails to protect the wood. Metal ties are used very little in the U. S., but extensively in other countries.

The two forms of rails in most general use are shown in Fig. 1. The flange or T-rail was invented in 1830 by Col. Robert L. Stevens, of the U. S., for the Camden and Amboy Railroad. In Europe it is called the Vignoles rail, having been reinvented in England in 1836 by C. H. Vignoles. It is used exclusively in the U. S. and largely in other countries, and is fastened to the cross-ties by bolts, screws, or spikes. The bull-head rails used in Europe are secured by wooden or iron wedges or "keys" to cast-iron chairs fastened to the ties. Modern track is laid with steel rails, which resist strains and shocks far better than iron rails and have greater endurance, and in 1891 the railways of the U. S. had 82 per cent. of their mileage laid with rolled steel

rails, and the balance with iron. The first steel rails were laid at Derby, England, in 1857. Rails for main track weigh 70 to 90 or even 100 lb. per yard, and are usually 30 feet long. The average life of good steel rails is about 150,000,000 to 200,000,000 tons of traffic. For rail-joints short splice-plates or fish-plates were used in 1831 on the Camden and Amboy Railroad, and in 1847 the fish-plate joint was invented in England by W. Bridges Adams. The angle-bar now generally used is a development of the fish-plate, and is 20 to 48 inches long, with four or six bolts. Since 1890 there has been a growing tendency to use a "bridge-plate" under the rail ends to prevent the deflection which (and not the space between the ends) causes the shocks to car-wheels. The most approved form of switch is the split switch (Fig. 2), in which the switch-rails are planed to a taper, so that

Fig. 1.—Rails: *a*, T-rail; *b*, bull-head rail.

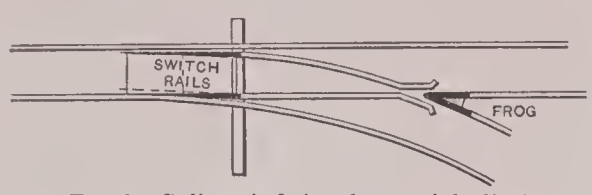

Fig. 2.—Split switch (set for straight line).

the ends will fit closely against the main or stock rails. This type was used in England before 1830. In the stub-switch (Fig. 3), still used in the U. S., the switch-rails are shifted

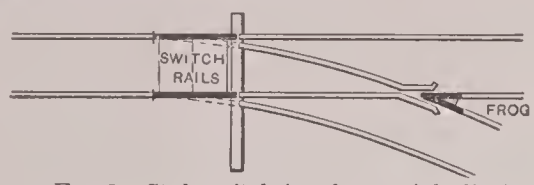

Fig. 3.—Stub-switch (set for straight line).

into line with those of one or other of the diverging tracks. The frog is placed at the intersection of the rails, and allows wheels to pass on either track.

Maintenance of Way.—Traffic causes wear and disturbance of the track; and climate and weather tend to rot the ties, shift the ballast, fill up the ditches, etc. The expense of maintenance is many times greater in the U. S. than in Europe, where, as a general thing, the roads are completed before being opened for use. Maintenance includes the periodical renewals of rails, ties, etc., and also the daily work of repairs and general attention to details. The work is of great importance to the safety and economy of traffic. A railway is divided into "sections" of 4 to 7 miles in length for single track, or 3 to 5 miles for double track, each section having a foreman and gang of 4 to 6 men, and the section is gone over daily from end to end to see that it is in good and safe condition.

Signals and Interlocking.—About 1841 the semaphore signal was introduced in railway service by C. H. Gregory in England, and it is almost universally used, although disks, etc., are used to some extent. It consists essentially of a post carrying a pivoted arm. When horizontal the arm indicates "track blocked" or "stop." When lowered to a vertical or inclined position it indicates "track clear" or "go on." Colored glasses attached to the arm move in front of a fixed lamp for the night-signals. Signals are of two classes: 1, those dividing the railway into sections or "blocks"; 2, those indicating the position of switches, drawbridges, etc. With block-signals a "distant signal" indicates the position of the "home-signal," but if the former is at "stop" a train may pass it, being prepared to stop at the home-signal if the latter has not in the meantime been lowered. A home-signal at "stop" must never be passed if the "absolute block" system is used, but with the inferior "permissive block" the train may pass after a certain interval, proceeding with caution. Block-signals are operated by wires, compressed air, etc., from towers placed at distances apart varying with the amount of the traffic. There is telegraph (and sometimes telephone) communication between the towers, and in the lock-and-block system invented in England in 1874 the apparatus of each tower is electrically interlocked with those of other towers, so that the signalman can not move the signals or switches until certain electrical operations have been performed by the other signalmen to release or unlock the levers for the movement he has notified them that he wishes to make. Automatic signals, worked electrically from track-connections by the trains, are used to a greater extent in the U. S. than in any other country, but are inferior to the lock-and-block system. The Westinghouse and Hall automatic systems are those most used. By a combination of the manual and automatic systems the signal is set at "stop" by the train, but must then be lowered by the signalman, who can not do so, however, until the train has passed the next signal. In 1843 the apparatus of a junction in England was so interlocked that conflicting signals could not be given. In 1856 John Saxby, of England, applied his invention of interlocking combined with the concentration of the operating levers, and in 1874 Mr. Stevens, of England, invented the interlocking by tappets, which is now generally used. In an interlocking plant the operating levers are connected to a series of bars or rods having notches and projections which engage with each other, and are so arranged that when switches and signals are set for a particular train movement no levers can be moved for any conflicting signal or switch. The first interlocking plant in the U. S. was used in 1874 by the New York Central Railroad, and in 1875 the Pennsylvania Railroad imported a Saxby machine from England. Such machines are now in extensive use at terminals, junctions, and track crossings. By Dec. 31, 1892, the railways in Great Britain had 97 per cent. of their switch and signal plant interlocked.

Water and Coal Stations.—The engine-tenders are generally supplied with water from a wooden or iron tank (one or more according to the number of engines) supported upon a stone, iron, or timber tower about 12 feet high. A hinged pipe at the base of the tank leads the water to the tender-manhole. A water-crane or column is an upright pipe beside the track with a swinging horizontal pipe to reach across to the tender-manhole, the water being taken from an underground pipe. It is very important to use good water. A plan for filling the tender-tank while the engine is running, invented by John Ramsbottom, of England, in 1861, is extensively used in Great Britain and the U. S. An iron track-tank about 18 inches wide, 6 inches deep, and 1,200 to 1,500 feet long is laid between the rails. In the tender-tank is an upright pipe, extended downward through the bottom and fitted with a movable curved end or "scoop." When running over the track-tank the scoop is lowered into it, and the motion forces the water up the pipe into the tender. Coal is loaded by shoveling, by cars or buckets, or from a coal-tipple, which is a structure fitted with rows of coal-bins at an elevation above the track. When an engine is under or alongside the tipple, gates are opened allowing the contents of the bins to flow down a chute into the tender. Coal is generally used for fuel, sometimes in the form of anthracite dust. Oil-fuel and bricks of pulverized coal mixed with tar or other cementing material are considerably used in Europe.

Stations and Shops.—The size of a station and the passenger accommodation and freight facilities provided depend upon the importance of the town and the traffic. Large stations generally have a train-shed covering the tracks and platforms, and at important terminals handsome buildings are frequently erected, containing the station and railway company's offices, hotel accommodations, etc. Union stations are for the use of two or more railways. At terminals and important stations extensive yards and side-tracks are required, and freight-sheds, warehouses, grain-elevators, stockyards, etc., must be provided according to the nature and extent of the traffic. In Europe hydraulic power is largely used for handling cars and freight at terminals. Some railways build locomotives and cars, and have therefore extensive works. Repair-shops for locomotive- and car-work, however, are required at different points on all roads. Engine-sheds in Europe are usually rectangular, but in the U. S. they are usually "roundhouses" of circular, annular, or segmental plan, with tracks radiating from a central turntable. Among the extra equipment required at terminal

and divisional points are the following, not all, however, being established at any but very important places: Repair-shops, engine- and car-sheds, storerooms for engine-supplies, sand-house (sand for engines), ice-house (ice for water-coolers, dining-cars, and refrigerator-cars), oil-house (for lamp-supply), gas or electric plant for car-lighting (where either system is used), coal- and water-supply, offices, rooms for employees, storerooms for parlor and sleeping-car supplies; side-tracks for storing, cleaning, inspecting, and repairing cars; turn-table or transfer-table, ash-pit, etc. The greatest terminal yards in the world are those at Buffalo, N. Y., which have about 100 miles of main track and 400 miles of side-track.

Cars.—The first passenger-cars resembled stage-coach bodies on four-wheel platforms, but as early as 1831 the American style of long car with trucks, or "bogies," end doors, central aisle, and seats all facing the same way, was introduced. In Europe the cars are generally short and light, divided into compartments having side doors, the passengers sitting face to face and knee to knee, but within recent years improvements have been made in introducing larger cars on trucks, and also parlor, dining, and sleeping cars. The smaller cars have four or six wheels, and are 26 to 34 feet long, while the larger ones on trucks are from 42 to 56 feet long. American cars are 50 to 80 feet long, wider and higher than European cars, and generally of stronger and heavier construction. The vestibule connections, or inclosed-end platforms, were used on mail-cars about 1852, and were first used on passenger-cars in 1886. They make a train practically one long articulated car, and afford increased safety in case of accident. Dining, sleeping, and parlor cars are run on most important trains, and are very luxuriously and elaborately finished and equipped. The first sleeping-car in the U. S. was run on the Cumberland Valley Railroad (Pennsylvania) in 1836–37. In 1856–57 Thomas L. Woodruff built a sleeping-car, and he was followed by Webster Wagner. In 1859 George M. Pullman began making improvements, and in 1864 he built for the Chicago and Alton Railroad the first real Pullman sleeping-car. European freight-cars are generally 12 to 18 feet long, with four wheels, weigh 11,200 to 18,000 lb., and carry 18,000 to 23,000 lb. Larger cars are used to some extent for coal, ore, etc. In the U. S. freight-cars are 30 to 36 feet long, with two four-wheel trucks, weigh 20,000 to 30,000 lb., and carry 40,000 to 60,000 lb. Refrigerator-cars for carrying meat, fruit, etc., have the sides, roof, and floor insulated by air-spaces, felt packing, etc., and are fitted with ice-chambers. Iron and steel are being largely used in freight-car construction, especially for the frames. The number of cars in the U. S. in 1891 was as follows:

CLASS OF SERVICE.	Total.	With train brake.	With automatic coupler.
Passenger	27,949	27,246	26,692
Freight	947,300	108,132	107,795
Company's	35,185	2,438	1,057
Fast freight	51,787	4,777	8,597
Total owned	1,062,221	142,593	144,141
Total leased	153,390	22,645	23,202
Grand total	1,215,611	165,228	167,343

Locomotives.—British practice in the design and construction of locomotives is still mainly followed by all countries except the U. S. and Canada. North American practice employs bar-frames, outside cylinders, trucks, equalized springs, eight-wheel-tenders, and large cabs fitted with seats. European practice employs plate-frames (invariably), inside cylinders, rigid axles and unequalized springs (generally), and four or six wheel tenders, while the men have to stand up in cabs affording little shelter. North American engines are equally well adapted for light and rough track, and the best and heaviest track, and many features of American practice are widely adopted in Europe, while locomotives are extensively exported from the U. S. The truck, or "bogie," was invented by John B. Jervis, of the U. S., in 1831, and first used on an engine ordered by him from the Stephenson works in England. The North American "eight-wheel" type of engine (having four coupled driving-wheels and a four-wheel leading truck) was patented in 1836 by H. R. Campbell, of Philadelphia, and is extensively used in Europe as well as in the U. S. British express-engines have often but one pair of driving-wheels, 7 feet to 8 feet diameter, and have never more than two pairs, while in the U. S. they have never less than two pairs, and often three pairs for the heavy express-trains characteristic of North American railways. Freight-engines in Europe have generally six wheels, all coupled, while in the U. S. they have from eight to twelve wheels, with six to ten wheels coupled. In 1891 there were in the U. S. 32,139 locomotives, of which 8,901 were passenger, 16,696 freight, 4,321 switching, and 2,221 unclassified and leased. Of this total, 23,094 were fitted with train-brakes. In the compound locomotive the expanded steam from the high-pressure cylinder flows to a larger low-pressure cylinder, where it expands further before escaping to the atmosphere. This gets more work out of the steam, and effects an economy of 10 to 20 per cent. in fuel, the best results being obtained at moderate speeds. The invention dates from 1834, but the first practical engines were built in 1875 to the designs of A. Mallet, of France. Engines on the Mallet system have two cylinders, and can be run at will as simple engines by admitting steam direct to both cylinders. In the Worsdell (England) and von Borries (Germany) two-cylinder engines, live steam is only admitted to the low-pressure cylinder at starting, and is then shut off by an automatic intercepting valve. Four-cylinder compounds may be arranged with one pair of cylinders to each of two driving-axles (generally European), or with two cylinders on each side acting together in the same way as the usual single cylinder. Engines with two, three, and four cylinders are in service throughout the world, and in 1892 there were about 2,500 compound locomotives in use, of which over 500 were in the U. S., where they were more extensively used than in any other country. These U. S. engines are of various designs, but all with two or four cylinders, giving them extra power in starting, and on heavy grades, and are generally arranged to be run as simple engines at will. They are of all types and are used in every class of service. See LOCOMOTIVE.

Brakes.—In the U. S. hand-brakes have been almost entirely superseded on passenger-cars, and to a considerable extent on freight-cars, by continuous power brakes applied by the engineman to all the wheels of a train simultaneously. Power-brakes have been operated by air-pressure, vacuum, steam, hydraulic power, weights, springs, and electricity, but the two former are most generally used, and so applied as to act automatically in case of rupture of the hose connecting the train-pipes of the cars. The Westinghouse air-brake was first patented in 1869, and is universally used in the U. S. and largely in other countries. The vacuum-brake, dating from 1871, is used in many foreign countries, and is efficient, but is slower in action than the Westinghouse, and therefore not so well adapted for long, heavy, or fast trains. The Eames vacuum-brake is used on elevated railways in New York and Brooklyn, and air- and vacuum-brakes have been applied to horse-, cable-, and electric-cars. In 1887 George Westinghouse perfected his quick-acting freight-train brake, which will stop a fifty-car train at 30 miles an hour in 320 to 350 feet. Passenger-trains at 40 to 60 miles an hour may be stopped in 600 feet for the

former and 900 to 1,000 feet for the latter speed. In Feb., 1893, the U. S. Congress passed a law compelling the use of power-brakes and automatic couplers on freight-cars. Brakes are generally applied to the driving- and tender-wheels of American locomotives, and sometimes also to the engine-truck wheels. With the Westinghouse brake the engine has an air-pump, main reservoir, and engineman's valve ; and each car has a smaller reservoir, triple valve, and a horizontal brake-cylinder having two pistons connected by a spiral spring. A pressure of 70 to 80 lb. is maintained in the reservoir and train-pipe, the brake-cylinder being empty and the brakes off. When the pressure in the train-pipe is reduced (purposely or by a broken hose connection), the greater pressure in each car-reservoir moves the triple valve, opening a passage by which the air rushes to the brake-cylinder and forces the pistons apart, thus applying the brake-shoes forcibly to the wheels by means of a system of rods and levers. To release the brakes, air is admitted by the engineman's valve from the main reservoir to the train-pipe, moving the triple valves back, recharging the car-reservoirs, and opening an escape for the air from the cylinders, the pistons being then drawn back by the spring. With the vacuum-brake there is a steam-ejector and a brake-cylinder on the engine, and a vertical brake-cylinder and ball-valve on each car. A vacuum is maintained in the train-pipe and cylinders by the ejector, the piston then being at the bottom of the cylinder and the brake off. When air is admitted (purposely or by a ruptured hose), its rush moves the ball-valve, thus closing the pipe to the top of the cylinder, and the air-pressure therefore passes to the bottom, forcing the piston up and applying the brakes. When air is again drawn from the pipes and cylinders by the ejector, the ball-valve returns to its position, allowing the air to escape, and the brakes then come off by their own weight and that of the descending piston.

Car-couplers (Fig. 4).—The common form of coupling used in the U. S. is the "link and pin," consisting of a link with its ends resting in the hollow ends of the drawbars of the two cars, and held in place by a vertical pin through each drawbar. Coupling and uncoupling by hand is dangerous work, and in the year ending June 30, 1892, about 378 men were killed and 10,319 injured in it. Passenger-cars are generally fitted with the automatic coupler invented by Ezra Miller in 1863, and have also spring buffers, safety-platforms, and safety-chains. The Janney automatic coupler for passenger and freight cars was adopted by the Master Car-builders' Association in 1887. Each coupler has a vertical claw-shaped end with a movable knuckle, and when pushed together the knuckles interlock, and can not be pulled apart unless a vertical locking-pin is withdrawn, which can be done by a handle at the side of the car. The Miller hook-coupler is uncoupled by shifting the hooked drawheads sideways by a lever on the car-platform. In Feb., 1893, the U. S. Congress passed a law that by Jan., 1898, all freight-cars must be equipped with automatic couplers. In Europe passenger-cars generally have hooked drawbars connected by chains which are drawn tight by a screw, bringing into contact the long spring buffers at the ends of the cars. Freight-cars have either a similar coupling or a loose chain.

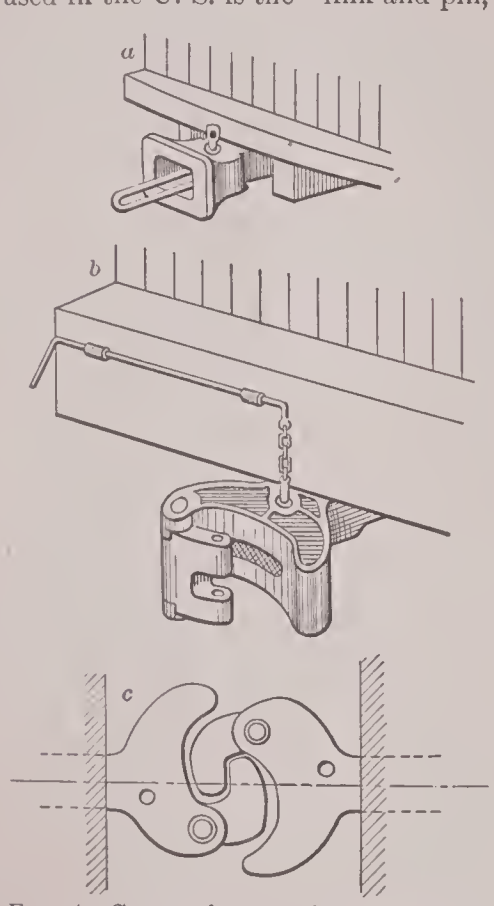

FIG. 4.—Car-couplers: *a*, link-coupler; *b*, Janney automatic coupler; *c*, top view of automatic couplers when coupled.

Car-lighting and heating.—Mineral-oil lamps are most used in the U. S., oil of 300° F. fire-test being the safest. In Europe vegetable oils are used, owing to the high price of kerosene, but they are inferior to the latter, and the cars are in general poorly lighted. Compressed oil-gas is extensively used in the U. S. and many other countries. The oil is distilled and vaporized in retorts, and the gas is forced into storage-tanks by compressor-pumps. It is then piped to the car-reservoirs, which usually hold 212 cubic feet at 150 lb. pressure, or enough for twelve lamps for sixteen hours. Gasoline-gas is used to a limited extent in the U. S. Electricity has been extensively experimented with, and is in use, but is expensive. It may be operated by storage-batteries, by a dynamo driven from a car-axle (with storage-batteries for use when the train stops), or by a separate engine and dynamo in one car. The ordinary stove has caused many fires in trains by being upset, especially in train-accidents, and in the U. S. its use is prohibited in some States. Improved stoves, with hot-water pipes, are used considerably, but the most approved system is that of leading steam from the engine through pipes in the cars, and it is very extensively used. In Europe stoves and steam and hot-water heating are used to a limited extent; but in Great Britain the primitive and inefficient plan of portable foot-warmers filled with hot water is the most common. The ventilation of American cars, especially sleeping-cars, is generally very poor, but in Europe fans and mechanical ventilators are largely used to draw out the foul air.

E. E. RUSSELL TRATMAN. A. M. WELLINGTON.

RAILWAY OPERATION: the conduct of the business of a railway, together with the methods and results of economic management. In all countries the government exercises the right to grant or refuse permission for the construction and operation of railways. The government may build and operate railways, as in France, Belgium, Germany, Australia, and South Africa, private lines being also generally permitted in the European countries. It may build and own the railways, but contract with private companies for their operation, as in France and Italy. It may own the railways, but allow private companies to construct and operate them, as to some extent in India. It may permit private companies to build, own, and operate railways, itself exercising a greater or lesser degree of control, as in the U. S., Great Britain, Canada, and many other countries. Railway companies claim that railways are purely private enterprises, but the courts in most countries have recognized them as being public highways, differing only in degree from roads or canals, the fact of a railway having its own equipment and using its collected tolls or rates for its exclusive use, not affecting the principle. The government assistance by land-grants, bonds, etc., is made in recognition of the railway as an improved highway. Abuses of railway management in the U. S. led to the "granger" movement in 1871, through which the granger or farmer element of the Northwestern States secured the passage of laws adverse to the railway companies, limiting rates and prohibiting discrimination. The resulting litigation led to an investigation by Congress, and in 1887 the Interstate Commerce Act was passed to regulate rates, prevent discrimination, etc., through the Interstate Commerce Commission. The principal executive head of a railway is the general manager, next to whom come the general superintendent (traffic), the chief engineer (civil engineering), and the superintendent of motive power (locomotives and cars), with their staffs of assistants. These attend to the handling of the business which is obtained through the general passenger agent and the general freight agent. In 1891 there were in the U. S. 784,285 railway employees (one man in 82, or over 1 per cent. of the entire population), exclusive of baggage-men and car-porters.

Traffic and Rates.—The relative importance of the passenger- and freight-traffic varies in different countries. Thus in Great Britain the proportion of freight to passenger earnings is about as 5 to 4, while in the U. S. it is about as 20 to 7. The following table, for 1890, gives the data from which this proportion is computed:

KIND OF EARNINGS, ETC.	United States.	United Kingdom.
Passenger earnings	$1,368,320,000	$171,640,000
Freight earnings	3,701,875,000	216,100,000
Miscellaneous earnings	360,000,000	17,000,000
Total earnings	5,430,195,000	404,740,000
Average rate per passenger	2·18 cts. per mile.	2·33 cts. per mile.
Average journey per passenger	24·18 miles.	7·20 miles.

There has been since about 1870 a steady reduction in rates in the U. S., due to the increasing competition, and in order to enable the railways to make a profit on their business the cost of transportation has had to be correspondingly reduced. This has been by (1) consolidation of railways and consequent lessening of expenses; (2) increase of locomotive power and mileage of each engine; (3) increase of capacity of freight-cars and decrease of proportion of dead load of trains; (4) improvements to track, terminals, etc. Passenger traffic does not show a similar reduction, owing largely to the increased weight of cars without increase in capacity. The following table may be instanced:

NEW YORK CENTRAL RAILROAD.	1875.	1891.
Rate per passenger mile.....cents	2·14	1·96
Expenses per passenger mile..... "	1·36	1·49
Rate per ton-mile..... "	1·27	0·74
Expenses per ton-mile..... "	0·90	0·57

Until about 1875 the railways made rates at their pleasure, making high rates on lines without competition to compensate for low rates on lines having competition, and discriminating between towns and individuals by special rates. This led to the enactment of the interstate commerce law (see INTERSTATE COMMERCE), which among other things prohibited pooling and discrimination. A pool is a combination of railways engaged in competitive traffic to maintain rates by suspending competition. The famous "long and short haul" clause forbids the practice of giving lower rates between certain widely separated points than are given to intermediate points, which are of course nearer together. Cheaper articles and the necessities of life must be carried at lower rates than expensive articles and luxuries, for the reason that the rates are necessarily based upon (1) cost of transportation (which varies with distance); (2) terminal charges (which are fixed rates); (3) market value of the freight. The reduction of passenger- or freight-rates does not necessarily mean a reduction of earnings, as the reduced rates may encourage additional traffic. The only correct basis of estimating the cost of railway service is the cost per passenger-mile and per ton-mile (or of hauling one passenger or one ton a mile), since it makes practically all the difference in cost of service whether they are hauled 1 mile or 100 miles. The car-mile may be used instead of the ton-mile. The zone-tariff system introduced in Hungary in 1890 divides the country into a series of belts or zones, with a uniform rate for each. Thus a person may travel a short or a long distance within any one zone for the same fare, but if his journey extends beyond its limits he must pay the rates for the two zones. It has caused a great reduction in rates and increase in traffic.

Train-dispatching.—This is the system of directing traffic most used in the U. S., by which the dispatcher at the principal station sends telegraphic orders to the agents or operators at the several stations. The operator writes out the order and hands a copy to the engineman or conductor of the specified train. The operator at the next stopping-place is notified to expect the train, and receives orders for its next movement. The principle is simple, but with heavy traffic, late trains, extra trains, etc., the operation is very intricate, and accidents are constantly occurring through carelessness, natural mistakes, or misunderstanding of orders. For the block system, see above (*Signals and Interlocking*); also the article BLOCK SYSTEM.

Loads and Speed of Trains.—Many of the long-distance express-trains in the U. S. are of very great weight, owing to the number of sleeping-cars, and such trains, with nine to twelve cars, weigh from 700,000 lb. to 950,000 lb. Short-distance expresses of four to six cars weigh from 280,000 lb. to 600,000 lb. Both light and heavy trains attain speeds of 45 to 60 miles per hour. In Great Britain the heavy trains of ten to fifteen cars weigh from 300,000 to 537,000 lb., while the lighter trains of about five cars weigh 168,000 lb. In other countries the train-loads resemble those of British trains, both in passenger- and freight-service. In the U. S. the freight-trains have from twenty-five to fifty large cars, and one of the heaviest trains ever hauled (Aug., 1892) consisted of forty cars carrying 2,640,000 lb. of grain. This train was 1,602 feet long and weighed 4,030,000 lb., including the engine, tender, and caboose. Trains of "fast-freight-line" cars with perishable freight are often run at as high speeds as passenger-trains, and the introduction of continuous freight-train brakes enables freight-trains to be run safely at much higher speeds than when hand-brakes alone had to be relied on, as is still generally the case in other countries. The highest records of express-train speed are held by the U. S., but the average speed (except on some of the principal lines) ranks below that of British express-trains, which have only to consider the signals and regular stops, while American trains have frequently to slow up for grade-crossings, etc. The fastest trains in the world are the Empire State Express and the Exposition Flyer, both of the New York Central Railroad, weighing about 140 net tons and 200 net tons respectively. The former runs daily between New York and Buffalo, 440 miles, in eight hours forty minutes, making four stops, or at an average speed of 51 miles per hour for the entire run. The latter ran daily between New York and Chicago during the summer of 1893, making the 980 miles in twenty hours, or at the rate of 49 miles per hour for the entire distance. Allowing for stops, slackening speed, etc., it is evident that very much higher rates of speed must be maintained in order to keep up the average, and 60 to 70 miles per hour are frequently made. With the former train in 1893 speeds were attained equivalent to 112 and 102 miles per hour; that is, a few miles were run in thirty-two and thirty-five seconds per mile. In the U. S. and Great Britain speeds of 50 to 60 miles per hour are of every-day occurrence, but in other countries the speeds are in general very much slower, and 50 miles per hour is a maximum very rarely attained on the Continent of Europe.

TABLE OF HIGHEST SPEEDS ON RAILWAYS.

RAILWAY.	Date.	Seconds per mile.	Equivalent to miles per hour.	No. of cars.	WEIGHT OF TRAIN IN LB.

Accidents.—In proportion to the extent of railway traffic, that is, the number of trains and passengers, the accidents are comparatively few. In the U. S. the train-dispatcher method of operation (the block system being but slowly introduced) is responsible for many accidents, great and small, particularly on railways having heavy traffic. In 1892 there were 2,327 train accidents, of which 1,062 were collisions, 1,165 were derailments, and 100 were from miscellaneous causes. The traffic that year amounted to 870,000,000 train-miles, and the number of persons killed on the railways was less than 1 for every 1,000,000 miles run by trains. The steady increase in the use of power-brakes and automatic couplers on freight-trains will tend to reduce very considerably the number of accidents to trains and to employees, and good discipline among the employees aids very materially in keeping down the number of accidents.

In Great Britain the train accidents have been reduced to a minimum by the enforced adoption of the block system, interlocking signals, and power-brakes, but, as in the U. S., many of the employees are killed in coupling and uncoupling cars. The following table shows the comparison between railway accidents of 1892 in the U. S. and Great Britain:

CLASS OF PERSONS.	Total number.	Number killed.	Number injured.	Killed, 1 in	Injured, 1 in
United States:					
Passengers.....	560,958,211	376	3,227	1,491,910	173,833

Total.....	.....	1,204	10,476	.....	.....

Relative Operating Expenses.—The following table, taken from Wellington's *Economic Theory of Railway Location*, was deduced by an analysis of the accounts of a large number of representative roads of the U. S. The various items of operating expense are expressed as percentages of the cost of running a train 1 mile, or a "train-mile," and the

table furnishes a good basis for comparisons irrespective of volume of business:

RELATIVE COST OF THE VARIOUS ITEMS OF OPERATING EXPENSES IN PERCENTAGES OF COST OF A "TRAIN-MILE."

				Per cent.
Train expenses, 47·0 per cent.	Engines, 18·0 per cent.	Road engines, 14·4 per cent.	Fuel	7·6
			Water	0·4
			Oil, etc	0·8
			Repairs	5·6
		Switching engines		3·6
	Train wages and supplies, 17·0 per cent.	Switching eng. wages		1·6
		15·4 per cent.	Eng. wages	6·4
			Car wages	8·5
			Car supplies	0·5
	Cars, 12·0 per cent.	Repairs and renewals		10·0
		Mileage (a practical equivalent for repairs)		2·0
Maintenance of way, 23·0 per cent.	Track between stations, 8·0 per cent.	Renewals of rails		2·0
		Adjusting track		6·0
	Road-bed, 7·0 per cent.	Renewing ties		3·0
		Earthwork, ballasting, etc.		4·0
	Yards and structures, 8·0 per cent.	Switches, frogs, and sidings		2·5
		Bridges and masonry		3·5
		Station and other buildings		2·0
Total of "line" or transportation expenses				70.0
Station, terminal, and general expenses and taxes				30·0
Total operating expenses				100·0

If $1 be assumed as the cost of a train-mile (i. e. 70 cents per train-mile transportation expenses proper), then these percentages will represent the cost of the various items per train-mile in cents. For any other cost per train-mile, either actual or assumed, multiply the items by this cost for its value in cents.

Operating Statistics.—The following statistics show the results of the operation of railways of the U. S. in 1891:

Single track, miles	161,275
Second track, miles	8,866
Third and fourth tracks, miles	1,562
Yard and side tracks, miles	35,742
Total of all tracks, miles	207,445
Total railway capital (45·28 per cent. stock, 49·24 per cent. funded debt, 5·48 per cent. other forms of indebtedness	$9,829,475
Passengers carried, number	531,183,998
Passengers carried 1 mile	12,844,243,881

E. E. RUSSELL TRATMAN.

Raimon'di, ANTONIO: geographer and naturalist; b. at Milan, Italy, in 1825. He went to Peru in 1850, and during the suceeeding twenty years visited every part of the republic, studying its geography, geology, and zoölogy; his last journey was through the region of the upper Amazon to the confines of Brazil. In 1873 he published a valuable account of the department of Ancach, dwelling particularly on its mineral riches. The Peruvian Government then engaged him to prepare a great work on the geography and natural history of Peru; three volumes on the geography, entitled *El Perú*, appeared in 1874, 1876, and 1880, and were to have been followed by others on botany, zoölogy, and ethnology; but the work was interrupted by the Chilian war, and when Lima was taken the printed portion of the fourth volume was destroyed. After the war Dr. Raimondi resumed his labors, but so much had been lost that there was much delay, and before new matter was ready for the press the author died at Lima, Dec., 1890. His manuscripts, maps, collections, etc., are in the possession of the Lima Geographical Society. HERBERT H. SMITH.

Raimondi, MARCANTONIO: engraver; b. at Bologna, Italy, 1488. He studied drawing in the school of Francesco Francia, and thus acquired the name of *Marcantonio del Francia*. He went to Venice as soon as he had acquired some proficiency in his art, and there he spent his savings in buying some plates after Albert Dürer, which he imitated so perfectly that his copies were taken for originals. Marcantonio then went to Rome and engraved a *Lucrezia* after Raphael, who got him to engrave, under his directions, the *Massacre of the Innocents*, *St. Cecilia*, and other works which brought him into great renown. Under Raphael's protection he founded a school for engraving. In 1527, during the sacking of Rome, he managed to save his life by giving up everything to the soldiers. A little before this he escaped another danger. For having engraved Giulio Romano's drawings illustrating the obscene sonnets of Aretino, Clement VII. had him put in prison, and only liberated him on account of his great talents. He then engraved for Baccio Bandinelli the *Martyrdom of San Lorenzo*. He is supposed to have been assassinated in Bologna in 1546. He engraved several Madonnas after Raphael, the *Life of the Virgin* in seventeen plates after Albert Dürer, the *Passion of our Lord*, *St. Paul preaching in Athens*, and many other biblical, historical, and mythological subjects, the greater part from drawings of Raphael. W. J. STILLMAN.

Raimundus Lullius: See LUL, RAIMON.

Rain: water falling in drops from clouds to the earth's surface. Rainfall, including rain, snow, hail, etc., depends on certain physical conditions and processes that are illustrated in a large way in the atmosphere. The amount of water-vapor that may exist in the atmosphere depends on the temperature of the vapor, and this depends, in turn, on the temperature of the air with which the vapor is mixed. It is therefore customary to speak of the *capacity* of the air for vapor. The capacity is small at low temperatures and rapidly increases in geometrical ratio at higher temperatures, doubling for a rise of about 18° F. at ordinary temperatures. When the capacity for vapor is satisfied, the air is said to be *saturated*. Saturation may be produced by the continual addition of vapor to a mass of air; and this condition is almost reached naturally in the excessively damp lower air of the doldrums or equatorial calms at sea; but as water-vapor slowly spreads or diffuses itself through the air, saturation is not usually attained in this way. It is more commonly attained by a reduetion of the temperature of a mass of air, already containing some vapor, until the capacity falls to equality with the amount of vapor present. The temperature then reached is called the *dew-point*, because any further cooling will eause the condensation of some of the vapor. Recent experiments, chiefly by Aitken, demonstrate that the condensation of vapor from damp air is favored, if not controlled, by the presence of excessive minute suspended particles, to which the term dust is rather inappropriately applied. Such particles are always present in the atmosphere. If condensation takes place above 32° F., the cloud-particles are minute droplets of water; if below 32°, they are spicules or crystals of snow. Much snow formed in the upper part of storm-clouds is melted into rain before reaching the ground. When a large mass of air is cooled, and a great cloud is formed, the initial cloud-particles may serve as centers of further condensation, or the smaller particles may coalesce to form larger ones. As snow-crystals appear to form by continual condensation of vapor about a single nucleus, it seems probable that rain-drops are likewise chiefly enlarged by continued condensation instead of by collision of separate droplets. As the cloud-particles fall, at first slowly, but faster as they grow still larger, they at last descend through and beneath the cloud-mass, and appear as rain or snow. There are various natural processes by which the air is cooled sufficiently to produce clouds and rain.

Mechanical Cooling of Air-currents by Expansion during Ascent.—Whenever a mass of air rises, either vertically or along an inclined path, the pressure upon it decreases; it expands and cools (see HEAT) at the rate of 1·6° F. for every

300 feet of vertical ascent. It is true that the capacity of the ascending and expanding air increases with gain of volume; but this is overcome by loss of capacity caused by decrease of temperature; hence if the ascent is carried far enough, clouds must be formed. When an ascending current of air becomes cloudy, the further cooling progresses at a slower rate than before, being retarded by the latent heat liberated from the condensed vapor. In this way the production of clouds and rainfall promote the ascent of the currents in which they are formed. Espy was the first to give this cause of rain its proper emphasis. The ascensional movement by which the air is cooled may be variously caused. It may be a spontaneous convectional ascent, dependent on the warmth and moisture of the lower air, and to this origin are ascribed the thunder-storms and violent cyclones of the torrid zone. The thunder-storms on land-areas of the temperate zone on summer afternoons are also convectional overturnings, their instability being generally dependent on warm southerly winds that flow obliquely toward the areas of low pressure (cyclonic storms) as well as on direct sunshine. It is chiefly in these summer storms that hail is formed, the freezing of the pellets being explained by the cooling of the active ascensional currents by which rain-drops are borne to a great altitude. The diurnal breezes that ascend mountain-slopes in fair summer weather frequently form clouds that grow to thunder-storms; thus many of the showers that are felt on the plains near the base of the Rocky Mountains are formed about the peaks of the front range.

The ascent of air-masses may in many cases be a constrained or driven ascent. Driven ascending currents are found where a general wind passes a mountain-range; hence mountainous districts are often rainy while the surrounding lowlands are dry (see DESERTS, PLATEAU, and SAHARA); hence the windward slopes of mountains receive a greater rainfall than the leeward slopes, as is illustrated in many parts of the world. (See chart of rainfall, article CLIMATE.) In the torrid zone, where the winds are prevalently from the east, the eastern coasts and mountain-slopes are well watered, as in Mexico and Brazil; but in the Indian monsoon region the western coasts are watered. (See WINDS.) In temperate latitudes, where the winds are prevalently from the west, the western mountainous coasts receive greater rainfall than the interiors, as on the Pacific coast of the U. S., British Columbia, and Alaska, compared to the interior of the continent; as on the Chilian slope of the Andes compared to the Argentine slope. The highlands of Western England receive more rainfall than the eastern lowlands; Norway is better watered than Sweden. Inasmuch as the general winds possess something of an eddy-like circulation around each of the several oceans, especially apparent in summer, and moving from left to right in this hemisphere, it follows that the southern coast of the U. S. receives the moist winds from the Gulf of Mexico, while in the Old World it is the northern slopes of the Pyrenees and the Atlas Mountains that receive the most rain.

The rainfall of the temperate zones that is received from cyclonic storms (areas of low pressure on the weather-maps) gives one of the most important examples of precipitation resulting from driven ascensional movements, according to the theory of the origin of these storms now generally accepted. They possess inflowing spiral winds beneath, outflowing clouds aloft, and heavy cloud-masses at intermediate altitudes from which much rain or snow is delivered. Hence an oblique whirling ascent of the inflowing surface winds is inferred about the central region. But as these storms occur in winter more frequently, and with greater strength, than in summer, they can not be well ascribed to spontaneous convectional overturnings like the tropical cyclones. They are better explained as gigantic driven eddies, resulting from the uneven flow of the general circulation of the atmosphere around the poles. On the lands, cyclonic storms are particularly rainy among mountains; indeed, it is generally only with the assistance of these stormy winds that the general winds are provoked to yield rainfall.

There is a certain altitude on mountain-slopes, varying with the season, at which the rainfall is heavier than either above or below. In the Alps, where the winter clouds hang low, the precipitation is greatest about 3,000 or 4,000 feet above sea-level in the colder season; but the mountains are not high enough to enable one to detect the altitude of greatest fall in summer. In the southern ranges of the Himalayas, on the other hand, the summer is the damper season; then the altitude of maximum rainfall is about 4,000 feet; while in the relatively dry winters it is estimated at about 20,000 feet.

An interesting contrast between the rainfall produced by the constrained ascent of air-currents over mountains and that caused by overturnings or eddies in the free atmosphere is that the first cause acts only over a rather definite and restricted area, while the second produces a trail of rainfall for hundreds or perhaps thousands of miles, as the storm-clouds are borne along in the general aërial currents. Thus the rains of wet-weather spells in the temperate zone may ordinarily be traced on the weather-maps while traveling from place to place, generally yielding greater rainfall over the ocean or along mountains than in the interiors or on lowlands, but continuing to water the surface more or less freely as they advance, as long as their commotion lasts. It may be seen from this that prognostics of rainfall based on the phases of the moon, or on the positions of the planets, which are the same for all parts of the world, can not have just application to a process that may be in operation in one place while absent from another.

In contrast to the cooling of ascending currents by expansion, there is the warming of descending currents by compression. Hence descending currents are prevailingly dry. Such are the anticyclonic weather-areas (areas of high pressure on the weather-maps), although local convectional showers may occur within them in summer. Such are the cold northern continental interiors of winter, in which the snowfall is very moderate, occurring only when a passing cyclone invades the region. Such are leeward mountain-slopes, where the air descends, clear and dry, after a cloudy and rainy ascent on the windward slope; as on many islands of the trade-wind zone, on the western slope of the equatorial Andes, the interior slope of the Sierra Nevada of California, and the southern slope of the Pyrences. Such are the tropical belts of high pressure, much interrupted by the lands, but more or less continuous around the oceans about latitude 30° or 35° in either hemisphere, although here local convectional action and passing cyclones may produce occasional rainfall.

Poleward Winds.—Air-currents flowing toward the pole generally become cloudy and rainy, as a result of cooling as they enter latitudes where sunshine is shorter and weaker, and where the surface of land or water over which they advance is colder than their source. The cloudiness and rainfall of poleward winds is especially favored in winter, when the poleward weakening of sunshine is rapid; it is favored when they blow from a warm sea over a cold land, as from the Gulf of Mexico or the adjacent Atlantic over the central or eastern parts of the U. S. in winter. On the other hand, this cause is weakened when poleward winds blow over warm summer lands, as the Mississippi valley in summer; for the lands may be for a certain distance warmer than the sea which the winds have left, and during a considerable distance of poleward advance the diurnal supply of sunshine may increase instead of diminishing. (See *Solar Climate*, under article CLIMATE.) It is noteworthy that nearly all poleward winds that yield rainfall are members of cyclonic storms, and hence that this cause of rainfall is for the most part only supplementary to the one already considered. On the other hand, equatorward winds are prevailingly dry, and the regions where they prevail, or the weather periods in which they occur, are comparatively rainless. Hence in the U. S. the dryness of the northerly winds which blow in the after part of the cyclonic areas, although flurries of rain or snow are often formed in them to leeward of the Great Lakes. Hence the dryness of the trade-wind belts, as long as the winds are not constrained to rise over mountains; hence the belts of greater salinity in the oceans (see OCEAN) and the deserts of the torrid zone are thus determined. Hence the aridity of coastal lands that are situated under the equatorward members of the wind-eddies that blow around the several oceans, as Lower California and Northern Chili, in spite of their being near the sea.

Mixture of Two Air-masses.—It is possible to produce condensation of vapor by mixing two masses of air, both saturated, but of unlike temperatures. The cause of rainfall was suggested by Hutton in the eighteenth century, but it is now regarded as ineffectual. It is true that some condensation must result from such a process, but the process must be of rare occurrence, because when two air-masses of different temperatures are brought together it is extremely improbable that they will both be saturated. If one wind be relatively dry, mixture may even result in dissolving the clouds of the other wind. Moreover, under the most

favorable assumptions, this process can not account for the large amount of rainfall frequently yielded from cyclonic areas in the U. S.; the part it plays in rain-making must be subordinate. Indeed, when it is remembered that damp winds are brought to saturation not by the addition of water-vapor, but more generally by some process of cooling, it is more reasonable to ascribe nearly all rainfall to a continuation of the processes of cooling, which are effective in producing clouds and rainfall as long as they last, instead of ascribing it to mixture, which can cause but little condensation at best, and whose cause of condensation ceases as soon as the mixture is completed.

Measurement and Record of Rainfall.—Rainfall is collected and measured by the rain-gauge, a cylindrical vessel of diameter advisedly not less than 6 inches, having a sharp upper rim and a vertical interior surface, converging below to a funnel, beneath which the gathered fall is protected from loss by evaporation. The gauge should be placed in open ground, removed from trees and buildings by a distance at least as great as their height. It should be securely fastened to avoid being overturned by the wind. Much care should be taken to select a place for the gauge where its surroundings will remain long unchanged. The rainfall is poured from the gauge into a vessel of smaller diameter, so that its depth is increased; it is then measured by a slender rod, properly graduated. Self-recording gauges are made, by which record is kept of the time and rate of fall of every shower. Snow is difficult to measure, as it is liable to gain or loss by drifting. The gathered snow is melted by adding a known amount of warm water, the total then being measured as before.

A hundredth of an inch or more of rainfall is taken to define "a rainy day." The total rainfall and the number of rainy days in each month and the year, the date of the first and last snow, and the amount of snow on the ground at the end of each month, are desired for rainfall records. Rainfall records vary greatly. Certain regions, like Arizona, may have no rain for months; others, like Western Scotland, may have many rainy days all through the year. In high latitudes the rate of fall is moderate; in hot regions excessive falls occur within brief periods, extreme falls being known as "cloud-bursts." Heavy falls cause great destruction by flooding rivers, as in Pennsylvania, May 30–June 1, 1889, when 8 inches fell over an area of 12,000 sq. miles. In Northern India, Sept. 17–18, 1880, 10 inches fell over an area of 10,000 sq. miles. In regions having under 18 inches of rainfall annually agriculture can not be safely practiced without irrigation; in such regions the fluctuation of the amount of rainfall from year to year is a large part of the total, thus giving rise to serious disasters or famines.

The distribution of rainfall over the world is illustrated in a map under the article CLIMATE (*q. v.*); it may be briefly classified as follows: First, a strong contrast between the torrid zone and the polar regions, the latter having a lighter fall because of the slow loss of capacity when air cools at low temperatures. Second, a contrast between continental borders and interiors, in favor of the former. Third, a contrast between high and low lands, with greater rainfall on the former. Fourth, a contrast between the windward and leeward mountain and continental slopes, the latter being drier. In all this it is perceived that the distribution of rainfall is not a fortuitous matter, but that it is closely dependent on the fixed order of nature. This is still better seen when comparing the distribution of rainfall and the general circulation of the winds. Around the belt of equatorial calms there is a plentiful rainfall, usually in the form of late diurnal showers or thunderstorms. The trade-wind belts are prevailingly dry, except where the winds rise over mountains, then giving what is called a tropical rainfall, as on the mountains of Brazil and Guiana. A supplementary cause of rainfall in this belt is found in the tropical cyclones that traverse it in the late summer. The stormy westerly winds have frequent showers or spells of rainy or snowy weather from passing storms, the amount decreasing toward the poles and toward continental interiors, and locally increasing on the windward mountain slopes. In consequence of the annual march of the sun and the associated shifting of the wind-system, the above simple scheme of rainfall may be further subdivided: First, the equatorial rain-belt travels N. and S. after the sun, thus extending its influence over a sub-equatorial belt. Along the axis of this belt there are two rainy and two dry seasons each year, as at Quito and in the Gulf of Guinea, but this subdivision is not apparent all around the world. Near the margin of the sub-equatorial belt there is a single rainy season followed by a longer dry season. Thus the equatorial forests of Africa and South America with plentiful rainfall lie between belts of more open country having a wet and dry season, and these open belts gradually merge into the deserts of the trade-winds so conspicuous in the Sahara. The annual overflow of the Nile depends on the northward march of the equatorial rains into the mountains of Abyssinia; the wet season of the llanos of Venezuela depends on the northward march of the rains from the Amazon valley. Second, the vague division between the trade-winds and the westerly winds, known as the horse-latitudes on the oceans, or the meteorological tropics all around the world, migrates N. and S. over a belt of variable width, called the sub-tropical belt; here the summers, chiefly under the control of the steady trades, are dry, while the winters have a sufficient rainfall from the passing cyclonic storms of the westerly winds. The winter rains of California, Spain, and the Mediterranean countries in the Northern Hemisphere, and of Chili, South Africa, and Southern Australia in the Southern Hemisphere, are all of this character. It is thus seen that the Sahara has rain on its northern and southern margins in winter and summer; the intermediate belt of absolutely no rain is very narrow, if existing at all. Finally, the rainfall of the westerly winds is greater on the western coasts in winter, when the cyclonic storms are stronger, but greater on the interiors in summer, when local convectional storms are more active. Thus Norway and British Columbia have more rain in winter, but Nebraska and Russia have more in summer. Florida is peculiar in lying in the latitude of the subtropical belt, but in having rainy summers, as if by local convectional action.

Rain-making.—The great loss to agricultural interests occasioned by droughts, and the limit set to agricultural occupation by the insufficient rainfall of arid regions, has at various times given rise to speculations and experiments concerning the artificial production of rain. It is unfortunate that the net result of all these efforts leads only to the conclusion that the order of nature can not be changed by any such means as have been proposed. The experiments may be divided into two classes—the first, including those which look for immediate results; the second, those which hope for a gradual but permanent improvement of the climate.

Under the first heading are fires and explosions. Fires were suggested by Espy as a means of establishing an updraught by which a more general convectional overturning of the air might be excited, and thus clouds and rain produced. It may, perhaps, be admitted that at times when the processes of nature are about to begin this operation it might be locally hastened by a considerable conflagration; but there is no reason to expect that combustible material can be supplied in sufficient amounts to produce valuable results. The favorable examples quoted by Espy would long ago have been repeated if the gain of the experiments had been more than their cost.

Explosions of cannon, dynamite, oxyhydrogen balloons, etc., have been proposed as a means of provoking rainfall, because battles have often been followed by rain-storms. This theory had been advocated particularly by Powers, and has thus secured congressional aid in the U. S. The relation of rainfall to battles appears to be highly fortuitous; no valid argument can be based on the facts as now reported. No shadow of evidence has been presented to show that the rain that occurred a day or two after a battle had its beginning over an area in any way related to the battle-field; indeed, the presumption is strongly in favor of the rain having begun at some indeterminate distance away from the battle-ground, perhaps even before the battle, and having reached the battle-field after the fight fortuitously, on its drifting course.

Other fanciful speculations might be quoted. There is no physical reason for thinking that explosions can cause the condensation of water-vapor into clouds and rain. The governmental experiments carried on in Texas by Dyrenforth in 1891, by which governmental science was seriously discredited, caused an excessive noise, but produced only a few drops of rain, and that only when rain-clouds previously formed drifted over the place of firing. Not the least care was taken by the experimenters to determine the place and time of beginning and subsequent movement of the rain-storms that in a few cases visited the field of experiment after firing had been many hours or days in progress.

The chief process by which a permanent improvement of an arid climate is hoped for is tree-planting. The belief in the efficacy of this process appears to be based on the misinterpretation of various facts concerning the relation of forests and rainfall. For example, the greater population of certain arid districts bordering on the Mediterranean has been ascribed to a formerly better climate, and the change from the former to the present time has been attributed to the deforesting of the region. There is, however, in the first place, no sufficient proof that the region has ever been seriously deforested by man; and no proof, in the second place, that the injurious change of climate has not been a natural one, under which the former tree-growth as well as the former greater population has naturally and gradually decreased. Again, excessive tree-cutting, as in Savoy and elsewhere, has allowed the rainfall to wash the soil from the mountain-slopes into the valleys, greatly to the injury of plant-growth in both places; it has also caused an excessive variation of stream-volume, between sudden floods at times of rain and dwindling streams in drier spells and seasons; but it is not shown that the destruction of trees has decreased the rainfall. There are indeed very few accurate records which can be appealed to in evidence of any such connection, and no decisive results can be claimed in any case. It is, therefore, premature to conclude that the climate of a region can be changed by planting trees, even in great numbers; but, on the other hand, it is highly probable that whatever rain falls would be better saved for springs and streams in a region with a good proportion of forest than in a barren region; and that the injurious action of hot winds and droughts, such as afflict the western part of the Mississippi basin, would be diminished if trees could be induced to grow there in abundance; but this need not be expected in a naturally semi-arid and treeless region, unless by aid of extensive irrigation. W. M. Davis.

Rainbow [O. Eng. *regenboga*: Germ. *regenbogen*]: a well-known optical meteorological phenomenon consisting of an arch of concentric colored bands arranged in the prismatic order, violet being innermost. It is sometimes simple, and sometimes accompanied by an outer, secondary bow, which is broader and fainter than the primary, and has its colors in the reverse order. A rainbow occurs when the sun or moon, not far above the horizon, throws its beams upon a sheet of falling drops on the opposite side of the heavens. A beam of light from the sun S falls upon a raindrop obliquely at R (Fig. 1, *a*); a portion is reflected; the remainder,

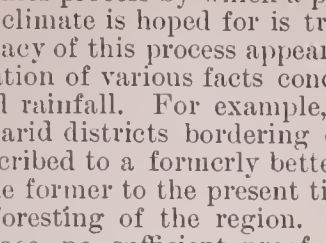

Fig. 1, *a*.

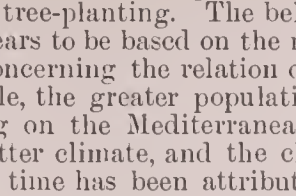

Fig. 1, *b*.

passing into a denser medium, is refracted toward the normal R C (see Refraction) and converged to a point; at A the portion not transmitted is reflected and diverges; at R' the beam is again refracted *from* the normal R' C, and reaches the eye at E. The rays of light emerging are usually so greatly dispersed as to be practically invisible. Calculation proves that for certain angles of incidence the emergent rays form a beam of rays distinctly visible; such rays are called effective rays. These rays emerge, not as white light, but they are spread out by the drop into their component colored rays. (See Light.) The angles of incidence and emergence vary for each color. After one internal reflection and two refractions the deviation of the violet ray forms an angle of 40° 13'. The deviation of the red from the same cause is 42° 39'.

Draw a line E D (Fig. 2) parallel to the sun's rays S A, S B, etc. (they being practically parallel with each other). Let the eye E take such a position that the angle A E D shall equal 40° 13'—the angle of deviation of the violet ray after two refractions and one internal reflection. S A E equals A E D, being alternate angles. The eye E therefore receives from the drop A a violet ray, while the other colors of the same dispersed ray fall below it. The angle of deviation of red is 42° 39'—2° 26' greater than violet. A drop B, 2° 26' above A, sends to E a red ray; all the effective intermediate rays produce the intermediate colors in their order. Every other drop in the sheet of falling water which has the same obliquity to the eye E as the drop A will also send to it a violet ray. The only drops which fulfill this condition are those which would define the base of a right cone whose apex is the eye, and the center of whose base is in a right line pass-

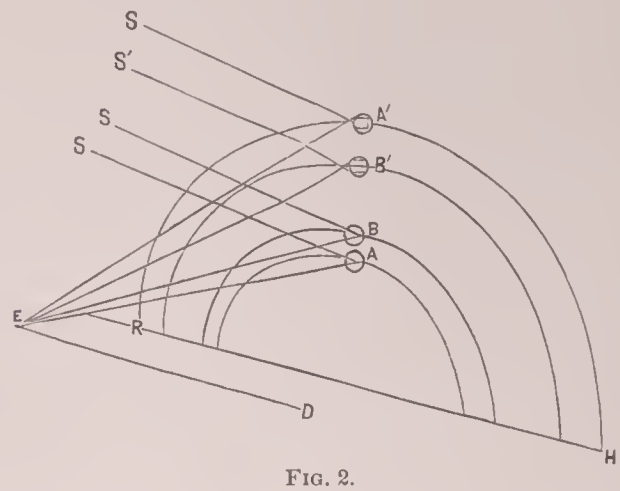

Fig. 2.

ing through the sun and the spectator's eye. The violet rays then, and all the other colors in their order concentrically arranged, form, when the sun is at the horizon, a semicircle, and when he is higher a proportionally smaller segment of a circle. The whole circle could be visible only to a spectator on the top of a very high and narrow peak, which elevated him while it did not obstruct the light. At a definite distance above the drop A and its series is another, B', at such an angle to the eye E that a red ray, after two refractions at R, R' and two reflections at A, A' (Fig. 1, *b*), is sent to E, and in the same way the other colors of the secondary bow. The angle of deviation of red, after two refractions and two reflections, is smaller than violet; red, therefore, is the innermost color of the secondary bow; the difference between the angles of the deviation of the extreme colors in this bow is greater than in the primary; it is therefore broader. The rays have been reflected one more time; it is therefore fainter. If the sun were a mere point, the primary bow would be 2° 26' wide from violet to red. The mean angular diameter of the sun is, however, 32', and each ray of light proceeding from it forms a separate bow, which partially overlaps, the violet apparently projecting 16' beyond the inner and the red 16' beyond the outer edge. The colors, being intermingled in the myriads of superimposed bows, are much modified. Between the primary and secondary bows are sometimes seen concentric bands of red, growing fainter and narrower as they approach the secondary; this phenomenon is explained by interference. (See Interference.) The lunar bow is like the solar, except that the colors are less distinct—sometimes not at all distinguishable, when it appears as an arch of white light. See Halo.

Revised by R. A. Roberts.

Rainey's Corpuscles: elongate protozoans belonging to the *Sarcosporida* (see Sporozoa) which occur as parasites in the muscles of birds, the pig, rat, etc. They vary in length from individuals of microscopic size up to those an eighth or even half an inch in length. D. S. J.

Rainfall: See Rain and Climate.

Rain-gauge: See Rain (*Measurement and Record of Rainfall*).

Rainier, rā-neer', **Mount**: a volcanic peak standing alone on the western slope of the Cascade Range in the State of Washington. Within a small crater at the top there is some solfataric action, suggesting that the volcano may not be extinct; but the date of the principal eruptions is so remote that subsequent erosion has scored the sides of the cone with deep cañons. In these are a series of glaciers, the largest in the U. S. south of Alaska. The mountain rises about 9,000 feet above its base, and its summit is 14,400 feet above the sea. Its lower slopes are densely wooded. Vancouver, the navigator, named it in honor of Admiral Rainier, of the British navy. Current usage is divided between this name and Tacoma.

Rains, Gabriel James: See the Appendix.

Rains, George Washington: See the Appendix.

Rainy, Robert, D. D.: minister and professor; b. in Glasgow, Scotland, Jan. 1, 1826; was educated in Glasgow University and New College, Edinburgh; minister of Free church, Huntly, 1851–54; of Free High church, Edinburgh,

1854–61; since 1861 Professor of Church History in New College, and since 1873 principal. Besides pamphlets and contributions to periodicals, Dr. Rainy has published *Three Lectures on the Church of Scotland* (Edinburgh, 1872; several later editions); *The Delivery and Development of Christian Doctrine* (Cunningham Lectures, Edinburgh, 1874); *The Bible and Criticism* (London, 1878); and *The Epistle to the Philippians* in *The Expositor's Bible* (Edinburgh and New York, 1893). C. K. Hoyt.

Rainy Lake: a large lake on the boundary between Minnesota and Canada; receives the waters of the Nameken and many other rivers, and discharges its own waters through Rainy Lake river into Lake of the Woods. It is in a marshy region, with few inhabitants. It abounds in small islands, and contains a great supply of fish of several species. Elevation, 1,035 feet.

Raisins [from O. Fr. *raisin*, cluster of grapes, grape, raisin: Ital. *racemo*: Span. *racimo* < Lat. *race'mus*, cluster of grapes or fruit, whence Eng. *raceme*]: the dried fruits of the sweeter sorts of grapes, grown in warm climates, and mostly dried in the sun. As this requires a practically rainless period of several weeks, the production of raisins on a commercial scale is limited to a few specially favorable climatic regions —viz., the south of Spain, Asia Minor, Greece, a portion of Calabria and Sicily, Southern California, and Chili. Three kinds of grapes are commonly used in making the raisins of commerce. The large Spanish raisins are made chiefly from the white *Muscat* (Muscat of Alexandria), in the provinces of Malaga and Valencia. The medium-sized or small, light-colored, seedless raisins of commerce are the fruit of the prolific *Sultana* grape, grown in Asia Minor and the Ionian islands; while the smallest of all, the so-called currants (properly *Corinths*), are derived from a very small berried but large bunched grape, grown in the same region, of which there is a black and a white variety, the former being the one generally used; hence the "black currants" of Zante. Raisin-grapes must be pulpy, and should acquire not less than 28 to 30 per cent. of sugar in their juice.

Drying in the sun is sometimes begun on the vine, the stalk being half cut. Mostly the fully ripe bunches are cut and spread (in Spain) on gravel-beds sloping toward the sun, and covered over at night or in case of rain; they are turned from time to time, avoiding the abrasion of the "bloom" as much as possible. In California, trays of wood or felt, set on the ground during the day and "stacked" and covered at night or in case of rain, are used; turning is done by inverting the full tray, previously covered with an empty one. The drying is frequently finished, or at times even entirely done, in ventilated drying houses or chambers, of which the temperature can be accurately regulated. In Greece and Asia Minor the bunches are sometimes hung on lines or spread on platforms. After drying, the moisture-condition of the small and large berries is equalized by placing the bunches in "sweating-boxes" while still warm. As large, complete bunches bring the highest price, such are carefully picked out from the first, and sometimes placed singly in ornamental paper packages. The next quality is packed, while still warm, into the well-known boxes containing about 20 lb., forming the several grades of "London layers"; lower qualities are detached from the stems and packed as "loose raisins" in barrels or bags. When the color of the stems is dark instead of light cinnamon, rain has fallen on them during drying and the commercial value is much diminished. In Greece and Asia Minor the berries are sometimes dipped in weak lye to facilitate drying, and some salt and oil is mixed with the raisins, which are, of course, devoid of bloom.

The raisin-product of California in the year 1892 was about 60,000,000 lb., and the area of raisin-culture is increasing rapidly, while that of Spain is diminishing in consequence of the ravages of the phylloxera. E. W. Hilgard.

Rajah [from Hind. *rājā* < Sanskr. *rājan-*, king; cf. Lat. *rēx*, king]: a title of many princes in the East, assumed by many of the Rajput caste, and by the great landowners, even of low caste. Many princes have assumed the title *mahârâjâh*, or great rajah.

Rajmahal: See Dravidian Languages.

Rajputana [deriv. of Hind. *rāj-pūt*, prince, son of a rajah < Sanskr. *rāja-putra*; *rājan-*, king + *putra-*, son]: the collective name of twenty native states of India, under the protection of the Indian Government, ruled by rajahs, covering an area of 130,268 sq. miles, mostly desert or semi-arid plains; E. of the lower Indus and S. of the Punjaub. Through the east run the Aravalli Hills, and fertile districts watered by streams from these hills contain the two largest and finest towns, Jaipur and Jodpur. The Thar, or great sandy desert of North India, lies in the west. The southeastern region is the most fertile. The chief British agent regulating these states resides at Ajmere, a small territory under the direct rule of the viceroy. Nine-tenths of the people are Hindus, and the Rajputs among them number only about 800,000, but they are the ruling element, and give their name to the territory. Pop. (1901) 9,811,032. C. C. Adams.

Rákóczy, rā̆a-kōt'sĕĕ: a celebrated Hungarian family, extinct in the male line. Francis II., Prince of Transylvania, b. in 1676, was a son of Francis I. and Helena Zrinyi. The father, early elected Prince of Transylvania, never occupied the throne; he died a few months after the birth of his son. Francis II. was educated from 1688 at the Austrian court and in Prague by the Jesuits, but continued a Protestant. After his marriage with a daughter of the Landgrave of Hesse he lived on his estates in Upper Hungary, but, suspected of conspiring against the Austrian Government, he was carried to Vienna in 1701 and confined in a dungeon. He escaped, fled to Poland, and lived in retirement until in 1703 he joined the Hungarian revolutionists. He proclaimed the independence of Hungary, and was placed at the head of the Hungarian confederacy, but was defeated in 1708 and fled to Poland. The peace of Szathmár (1711) marked the overthrow of the revolution. Rákóczy refused to accept this peace, and in consequence was excluded from the amnesty. He lived for a few years in France, and then went to Turkey, where he died at Rodosto, Apr. 8, 1735. He wrote *Mémoires sur les Révolutions de Hongrie* (The Hague, 1738).

Rákóczy March: a national air of Hungary and Transylvania, by an unknown composer, named in honor of Francis Rákóczy II. It has played a similar *rôle* in the history of Hungary to that played in the history of France by the *Marseillaise*, the anthem of the French Revolution.

Rákos: See Budapest.

Râle, raal [= Fr., liter., a rattling in the throat]: the rustling sounds heard in the lungs in various diseases. They are whistling, cooing, or wheezing in character when they are caused by spasm or narrowing of the bronchial tubes or small bronchioles; and crackling, bubbling, or gurgling in character when there is liquid exudation in the air-passages.

Rale, raal, Sébastien: missionary; b. in Franche-Comté, France, in 1658; became a Jesuit and a teacher of Greek in a college at Nîmes; went to Canada as a missionary 1689; labored at the Abenaki mission of St. Francis, near the falls of the Chaudière, and among the Illinois Indians, and settled in 1695 at Norridgewock on the Kennebec river, Maine. He built a church, converted many of the Abenaki Indians, learned their language, and acquired so great an influence that he was believed by the English settlers to be the cause of the frequent border forays. A price was set on his head, and the Indian village of Norridgewock was several times attacked; Father Rale's church was burned by Capt. Hilton in 1705, and having been rebuilt, was again destroyed in 1722, when the missionary escaped to the woods, but his papers were carried off. A third expedition from Fort Richmond surprised Norridgewock Aug. 2, 1724, and Father Rale was shot. Among his papers carried off in 1722 was an Abenaki dictionary, preserved in the library of Harvard College, and edited with notes by John Pickering in the *Memoirs* of the American Academy of Arts and Sciences for 1833. A *Life* of Father Rale forms a part of vol. vii., series 2d, of Sparks's *American Biography*.

APPENDIX.

Opzoomer, op'zō-mer, CORNELIS WILLEM: philosopher and jurist; b. in Rotterdam, Holland, Sept. 20, 1821; studied jurisprudence in Leyden, and attracted, even while a young student, much attention by his *Letter to Da Costa* and *Examination of the Annals of Dutch Theology*, in which he attacked the so-called orthodox dogma; was appointed Professor of Philosophy at the University of Utrecht in 1846, and acted as a leader in all movements of reform and progress in politics, religion, and science. His principal works are *Wetenschap en Wijsbegeerte* (1857): *Het Wesen der Kennis* (1863; 2d ed. 1867); *De Godsdienst* (1864).

Orangeburg: city; capital of Orangeburg co., S. C. (for location, see map of South Carolina, ref. 6–E); on the North Edisto river, and the South Carolina and Georgia Railroad: 51 miles S. of Columbia, 80 miles N. W. of Charleston. It is in an agricultural region; is an important market for cotton, rice, turpentine, and lumber; has a variety of manufactories; and contains Claflin University (non-sectarian, founded on the national land grant, and chartered in 1872), the State Agricultural College, two State banks with combined capital of $136,032, a private bank, and two weekly newspapers. Pop. (1880) 2,140; (1890) 2,964; (1900) 4,455.

Orange City: town (founded in 1870); capital of Sioux co., Ia. (for location, see map of Iowa, ref. 2–C); on the Chi. and N. W. Railway; 42 miles N. of Sioux City. It is in an agricultural and hog-raising region, is the seat of the Northwestern Classical Academy (Reformed, chartered in 1882), and has a State bank with a capital of $75,000, 2 private banks, and 3 weekly newspapers. Pop. (1880) 320; (1890) 1,246: (1900) 1,457.

Orinoco River The U. S. ship Wilmington made a trip up the Orinoco early in 1899 in the interest of American commerce. A correct chart of the river for the uses of navigation was made from the bar off Barima Point to Ciudad Bolivar. The ship reported that no charts had been made of some of the delta streams, including the San Juan river, and that the ships and cargoes of business enterprises established there were consequently endangered. The Orinoco is 20 miles wide at its mouth, and flows over an immense bar which it took the Wilmington an hour to clear. There are no steering-marks, lights, or lighthouses on this part of the Venezuelan coast. Considerable American interests have been established on or near the Orinoco, such as the Imataca iron mines, on the Imataca river, 5 miles above its confluence with the Orinoco. The mines are rich in ore of excellent quality. At Santa Catalina, on the river of that name, 3 miles from the Orinoco, is the headquarters of a company having a concession from the Venezuelan Government authorizing it to exploit 20,000 sq. miles of territory in the Orinoco valley. Much research has been carried out, and various enterprises, including mining, will be undertaken. The main product as yet is balata, a substitute for rubber. Barrancas, half-way to Ciudad Bolivar, has become an assembling and shipping point for cattle, most of which are sent to Cuba. St. Felix, above Barrancas, is the point of departure from the river for miners bound for the El Callao gold district, 150 miles distant. More than $40,000,000 in gold has been shipped from St. Felix in recent years. In 1897 Major Stanley Paterson, of England, spent several months on the Orinoco and its tributaries above Ciudad Bolivar, studying commercial opportunities. He reported that the country is of great value. "The rich rolling savannas," he wrote, "will support countless herds of cattle and horses. The forests yield large quantities of natural products, such as rubber, quinine, and other commodities. The upper waters of the Guanimo tributary are so affected by the sarsaparilla growing profusely along the banks that the natives drink the water and bathe there to cure skin diseases." He named many varieties of commercial woods, including mahogany and cedar, and several varieties of plants yielding rubber. The Orinoco has one tributary, the Guaviare, with an extent of navigable waters at least equal to that of the main stream, which, with its affluents, presents a navigable highway from the Atlantic to the foot of the Andes. Minister Loomis wrote to the State Department from Caracas that the visit of the Wilmington would undoubtedly stimulate U. S. commerce on the Orinoco.

C. C. ADAMS.

O'Shea, M. VINCENT, B. L.: educator; b. in Le Roy, N. Y., in 1866; prepared for college in Le Roy Academic Institute; B. L., Cornell University, 1892; Professor of Physiology and Pedagogy, State Normal School, Mankato, Minn., 1892–95; Professor of Educational Psychology and Child-study, Teachers' College, Buffalo, N. Y., 1895–97; Professor of the Science and Art of Education, University of Wisconsin, 1897; author of numerous magazine articles.

Ostend Manifesto: a memorandum regarding the acquisition of Cuba, drawn up by the U. S. ministers to England, France, and Spain in 1854. By the early fifties the slavery controversy in U. S. history had reached an acute stage. The Whig party had broken up with Scott's defeat. The Free-soil party was comparatively small. The Republican party had not yet appeared. The Democratic party was already preparing for the Kansas-Nebraska affair, which was to lead to Democratic disruption and the civil war. Territory for slavery was and had been the great desideratum of the Southern statesmen. Toward the lands southward, Mexican, Central American, or insular, these statesmen east longing eyes. Various filibustering expeditions—all unsuccessful—to Cuba and Nicaragua characterize the decade 1850–1860. But a more direct stroke than a filibustering expedition was now contemplated. The South had a sympathizer in the White House, President Pierce. His minister to Spain, Pierre Soulé, of Louisiana, was a French refugee from the restoration period; he had adopted the extreme political views of the section in which he had settled, and he was now the soul of a conference of diplomatists summoned by the President to discuss the acquisition of Cuba. A recent expedition was fresh in mind. Fears existed that Cuba might develop into another Santo Domingo. And the political and commercial aspects were ever present. Soulé, with his associates, James Buchanan, minister to England, and John Y. Mason, minister to France, deliberated at Ostend and later at Aix-la-Chapelle. They signed a memorandum which embodied their views, and is known as the Ostend Manifesto. It was sent to Secretary of State Marcy, and several months later was transmitted to Congress and published. Its substance is: The ministers urge the purchase of Cuba from Spain for $120,000,000. The island is regarded as necessary to the U. S., and the sale as advantageous to Spain. If the offer is refused, then "self-preservation is the law of nature." It will be necessary to consider whether Cuba is not essential to the welfare of the U. S. If this question is answered in the affirmative, then the U. S. is "justified in wresting it [Cuba] from Spain."

The manifesto was sharply criticised in the U. S. and unfavorably noticed abroad, in the London *Times* and elsewhere. It was denounced in the first Republican national convention in 1856, and was not expressly made a party plank by the Democrats. Historically it may be viewed in two lights: as a link in the chain of the slave power, whose development so greatly antagonized the North, and as a bold step in the path of territorial expansion.

EDMUND K. ALDEN.

Otis, ELWELL S.: soldier; b. in Maryland, Mar. 25, 1838; educated at Rochester University; studied law at Harvard College, and had just been admitted to the bar when the

civil war broke out. He entered the army as a captain in 1862, and became lieutenant-colonel Dec. 23, 1863, participating in all the general engagements of the Fifth Corps of the Army of the Potomac from 1862 to 1864, and was mustered out Jan. 24, 1865. On Mar. 13, 1865, he was breveted colonel of volunteers for gallant and meritorious services in the battle of Spottsylvania, and brigadier-general of volunteers for gallant and meritorious services in the battle of Chapel House. On July 28, 1866, he was appointed lieutenant-colonel of the Twenty-second Infantry, and on Mar. 2, 1867, was breveted colonel. He served as acting inspector-general in the department of Dakota from Mar. 16, 1874, to Jan. 26, 1876. On Feb. 8, 1880, he was appointed colonel of the Twentieth Infantry. He served as commandant of the U. S. Infantry and Cavalry School from Nov. 14, 1881, to June 29, 1885. He was appointed brigadier-general Nov. 28, 1893, and was in command of the department of the Columbia 1894–98, when he took command of the department of the Colorado. On May 4, 1898, he was nominated major-general, and on July 15 sailed in command of the fourth Manila expedition. On Aug. 30, 1898, he assumed control of the department of the Pacific, and on Sept. 16 was made acting military governor of Manila. He was succeeded by Gen. McArthur Apr. 7, 1900, and was placed in command of the department of the Lakes, Chicago.

Ottawa University: an institution of learning in Ottawa, Kan.; incorporated in 1865 jointly by the Baptists of Kansas and the Ottawa Indians, who were at that time occupying a reservation of 12 miles square, and most of whom had been converted to Christianity and had adopted the dress and the pursuits of the whites. By an act of the Legislature, which set aside 20,000 acres of the reservation for purposes of the university, 4 members of the board of trustees were Indians and 2 were white men. This relation, however, proved unsatisfactory, and by a readjustment the institution passed, in 1873, into the sole control of the whites. The school has an endowment of $80,000. Instructors in 1900 for all departments, 20; attendance in all departments, 504. The library contains 3,000 volumes, in addition to which students have the use, at a nominal cost, of the city library. Both sexes are admitted. J. D. S. Riggs, Ph. D., is president.

Pachmann, Vladimir, de: pianist; b. in Odessa, Southern Russia, July 27, 1848, of German parents named Bachmann; studied in Vienna from 1866 to 1869. His first appearance in London in 1882 created a great sensation. He taught there some time, and married his pupil Margaret Okey, from whom he was afterward separated. Since then he has devoted himself entirely to concert work. His travels have been all over Europe, and include several visits to the U. S. He is considered one of the greatest living Chopin players. D. E. Hervey.

Pago Pago: a harbor on the south side of Tutuila island, Samoan group. It is regarded as the safest and best inlet of the Samoan islands, and it would probably have replaced Apia as a port if it had not been about 25 miles off the convenient route of vessels plying between Honolulu and New Zealand. Pago Pago was secured by the U. S. as a coaling station, and the Government is establishing a wharf and coal-sheds there.

Paine, Robert Treat: philanthropist: great-grandson of the R. T. Paine who signed the Declaration of Independence; b. in Boston, Oct. 28, 1835; graduated at Harvard in 1855, where he afterward studied law, and then traveled abroad; was admitted to the bar in 1859; retired from practice in 1870, devoting himself to humanitarianism, becoming prominent in organizing the Associated Charities of Boston, of which he was made president; founded the Wells Memorial Institute, completed in 1883; to endow a fellowship "for the study of the ethical problems of society, the effects of legislation, governmental administration, and private philanthropy, to ameliorate the lot of the mass of mankind," gave $10,000 to Harvard in 1887; in connection with his wife, founded and endowed a trust of about $200,000, called the Robert Paine Association, in 1890; for the exclusive benefit of workingmen, built about two hundred dwelling-houses, purchasable on easy terms; was elected president of the board of trustees of the Episcopal Theological School of Cambridge, Mass., and became president of the American Peace Society.

Palmer, George Herbert, A. M., LL. D.; educator and author; b. in Boston, Mass., Mar. 19, 1842; prepared for college at Phillips Academy, Andover, Mass.; A. B., Harvard, 1864; A. M., Harvard, 1867; at Andover Theological Seminary as a student 1865–67 and 1869–70, and at the University of Tübingen 1867–69; LL. D., University of Michigan, 1894; LL. D., Union College, 1895; Litt. D., Western Reserve University, 1898; submaster Salem high school 1864–65; tutor in Greek at Harvard 1870–72, and in philosophy 1872–73; curator of the Gray collection of engravings 1872–76; Assistant Professor of Philosophy 1873–83; Professor of Philosophy 1883–89; Alford Professor of Natural Religion, Moral Philosophy, and Civil Polity 1889; author of *The Odyssey of Homer* (books i.–xii., text and translation, 1884); *Odyssey* (books i.–xxiv., translation, 1891); *The New Education* (1887); *The Glory of the Imperfect* (1891); *Self-Cultivation in English* (1897); *The Antigone of Sophocles* (translation, with introduction); and of many magazine articles.

Paraguay: Previous to 1897 Paraguay suffered for seven years from droughts and the ravages of locusts. The small rivers were so low that craft could not be used to bring down to the Paraguay river the crops of yerba mate, the staple article of export, and it therefore could not be shipped to any extent, even to the Argentine Republic, which is the chief buyer. In 1897–98 the rainfall was plentiful, locusts did no serious harm, and the tobacco crop was excellent. The Government is encouraging immigration by paying the passage of immigrants from Buenos Ayres, and supplying oxen and farming tools to be paid for in produce or labor. There are now nine colonies. The most convenient districts for agricultural pursuits are along the Paraguay river, because they are near the boats that carry produce to Buenos Ayres and Montevideo; but the best lands are some distance back from the river. Timber is becoming, next to yerba, the most important industry. The hard woods compare favorably with any timber in the world for durability and strength. They are chiefly exported in the shape of squared logs, are sent down the rivers in rafts or barges, and find a ready market in Rosario, Buenos Ayres, Montevideo, and Europe, more especially in Germany, Belgium, and France. Mineral resources are important, but are not yet worked. The production of sugar has begun. The exports in 1899 were valued at $2,021,023 (gold): the chief articles were yerba mate, $718,292; tobacco, $112,488; hides, $441,308; timber, oranges, and hair, $595,550. The total imports were $2,147,838 (gold), and were chiefly textiles, wines, and rice. About half the imports come from Great Britain. Trade with the U. S. is small, but increasing, the imports being chiefly agricultural machinery, sewing-machines, lamps, and household utensils.

C. C. Adams.

Parker, Francis Wayland, A. M., LL. D.; educator; b. in Piscataquog, town of Bedford, N. H., Oct. 9, 1837; educated on the farm, in the country school, at Appleton's Academy, Mount Vernon, N. H., in Hopkinson Academy, and in the University of Berlin. After teaching in New England for several years, he was at the outbreak of the civil war principal of the school in Carrollton, Greene co., Ill. Being unable to enter the army in Illinois, he returned to New Hampshire and joined the Fourth New Hampshire Regiment at Manchester as a private. Before the company was mustered he was made first lieutenant, and in the following winter captain. The first three years of the war he spent on the South Atlantic coast, taking part in the siege of Charleston. In 1864 his regiment joined Gen. Butler's command at Bermuda Hundred. During the great campaign of 1864 Capt. Parker was in many severe battles. After the crater fight at Petersburg he was put in command of his regiment. At Deep Bottom, while in command of a brigade, he was severely wounded. Leaving the hospital in Oct., 1864, he stumped New Hampshire in the second Lincoln campaign. Promoted to lieutenant-colonel, he rejoined his regiment after the battle of Fort Fisher. He marched with his regiment across North Carolina to meet Sherman, was taken prisoner, and while with Gen. Johnston's army heard the news of Lee's surrender and witnessed the downfall of the Confederacy. On leaving the army, in spite of strong inducements to enter politics and business, he again took up teaching; was principal of the grammar school, Manchester, N. H., 1865–68; principal of grammar school, normal training-school, and assistant superintendent of schools, Dayton, O., 1868–71; studied at the University of Berlin for two and a half years; superintendent of schools, Quincy, Mass., 1875–80; one of the supervisors of schools, Boston, Mass., 1880–83. He was

BADGES AND ROSETTES OF PATRIOTIC SOCIETIES

1. Sons of the American Revolution. 2. Society of the Cincinnati. 3. Sons of the Revolution. 4. Society of Colonial Wars. 5. The Society of the War of 1812. 6. General Society of the War of 1812. 7. The National Society of the Colonial Dames of America. 8. Aztec Club of 1847. 9. Society of the Colonial Dames of America. 10. Daughters of the Revolution. 11. Naval Order of the United States. 12. Daughters of the American Revolution.

principal of the Cook County (now Chicago) Normal School 1883–99. In 1899 he was elected president of a new school of pedagogy founded by Mrs. Emmons Blaine in Chicago, Ill. Col. Parker's work in Quincy attracted wide attention; during the years 1878–80 more than thirty thousand visitors inspected the work of the Quincy schools. He has traveled and lectured very extensively. He aims to apply the principles of Comenius, Froebel, and Pestalozzi, making no pretension to any new methods of his own. All that he does is nevertheless not only forceful, but original, strongly marked by his own personality. He has written *Talks on Teaching*; *How to Study Geography*; *Outlines in Geography*; *Talks on Pedagogics*; *Uncle Robert's Geography*, etc.

C. H. Thurber.

Parker, Horatio Gilbert: author; b. in Addington, Ontario, in 1859; studied for the ministry, spending two years, 1883 to 1885, in Trinity University, Toronto. In 1886 he was compelled by ill health to go to Australia, where he became associate editor of the *Sydney Evening Herald*, and wrote several plays. Later he went to England and devoted himself to authorship. Among his published works are *A Lover's Diary*; *Pierre and His People*; *An Adventurer of the North*; *The Translation of a Savage*; *The Chief Factor*; *Mrs. Falchion*; *A Trespasser*; *The Trail of the Sword*; *When Valmond Came to Pontiac*; *The Seats of the Mighty*; *The Pomp of the Lavillettes.*

Parker, John Adams: artist; b. in New York city, Nov. 29, 1829; was educated at New York University: engaged in merchandising 1850–57, then studied art, exhibiting first at the National Academy in 1858, of which he became an associate in 1869; was one of the founders of the Brooklyn Art Club. His paintings, which chiefly portray mountain scenery, include *Twilight in the Adiroudacks*; *Winter Twilight*; *Landscape in the Adirondacks, Twilight*; *A Winter Evening*; *The Gothics—Adirondacks*; and *Close of a November Day.*

Parkes, Sir Henry, G. C. M. G.; statesman; b. in Stoneleigh, Warwickshire, England, in 1815; was apprenticed to learn a trade in Birmingham; in 1839 went to Sydney, New South Wales, in 1848 was active in the election of Mr. Robert Lowe (afterward Viscount Sherbrooke) as a member of the local legislature, and later established a daily newspaper, the *Empire*; was elected a member of the Parliament of New South Wales in 1854, was sent to England in 1861 as a commissioner for emigration, and soon after his return to the colony, in 1862, was again elected to Parliament. In Jan., 1866, he became colonial secretary, in which office he passed the Public Schools Act, under which he was president of the Council of Education 1867–70. In May, 1872, he became premier of the colony, and held the office until Feb., 1875; was again premier four times, 1877–78, 1878–83, 1887–89, and 1889–91. During his last ministry he actively promoted the cause of colonial confederation. In 1877 he received the rank of K. C. M. G., and in 1888 G. C. M. G. In 1882 King Humbert conferred upon him the dignity of Commander of the Crown of Italy in recognition of services in behalf of distressed Italian emigrants to Australia. Two volumes of his speeches have been published, and he is the author of *Fifty Years in the Making of Australian History* (1892). D. in Sydney, N. S. W., Apr. 26. 1896.

Parrish, Stephen: artist; b. in Philadelphia, Pa., July 9, 1846; after brief experience in mercantile life, studied art; exhibited at the Pennsylvania Academy in 1878, and at the National Academy of Design in 1879; studied etching, producing his first work in 1879; exhibited in both branches of art at many art-centers both in the U. S. and abroad; traveled extensively in Europe 1885–86. Among his etchings are *A Northern Moorland*; *Low Tide, Bay of Fundy*; *Coast of New Brunswick*; *Winter Evening*; *London Bridge*; and *A Gloucester Wharf.* His paintings include *November*; *In Winter Quarters*; *Low Tide, Evening*; *On the Rance, Brittany*; and *The Road to Perry's Peak.*

Parsons, Albert Ross: pianist; b. in Sandusky, O., Sept. 16, 1847: educated in Buffalo, N. Y. In 1863 the family moved to New York, where he studied until 1867, when he went to Leipzig. He continued his studies in Berlin in 1870, and returned to New York in 1872, where he has since remained. His compositions are in the fashionable form for piano, but his chief fame is as a teacher and his critical and pedagogical works are esteemed very valuable. He was president of the Music-teachers' National Association in 1890.

D. E. Hervey.

Parsons, Charles: artist; b. in Manchester, England, May 8, 1821; early removed to the U. S., and received education in the public schools of New York city; studied lithography and became an expert illustrator; was placed in charge of the art department of Harper & Brothers in 1861; is an associate of the National Academy of Design, a member of the New York Water-color Society, and has exhibited in both oil and water-color at the Academy, among his notable paintings being *An Old Orchard* and *Amagansett.*

Parton, Arthur: artist; b. in Hudson, N. Y., Mar. 26, 1842; removed to New York city in 1865, before which his first pictures had been exhibited in Philadelphia; has exhibited often at the National Academy, of which he became a member in 1884; traveled in Europe 1870–71, studying chiefly in Paris. His pictures include *Evening, After the Rain*, for which he received a medal from the American Art Association; *November*; *On the Road to Mt. Marcy*; *A Mountain Brook*; *Sycamores of Old Shokam*; *Nightfall*; *The Morning Ride*; and *Winter on the Hudson.*

Parton, Ernest: artist; brother of Arthur Parton; b. in Hudson, N. Y., Mar. 17, 1845; early began to paint, without having studied the art, and at the age of twenty took a studio in New York city; visited Europe in 1873, and after travel opened a studio in London, where he was encouraged to remain. Among his best-known paintings are *Morning Mist*; *Sunny September*; *The High Hall Garden*; *Au Bord de l'Eau*; *Waning of the Year*; *Silver and Gold*; *Falling Leaves and Fading Trees*; *Where Memory Dwells*; *Vale of Light*; and *The Last of October.*

Partridge, William Ordway: sculptor; b. in Paris, France, Apr. 11, 1861; graduated at Columbia College; studied art in Rome, Florence, and Paris; became Professor of the Fine Arts at Columbian University and lecturer before the National Social Science Association and Concord School of Philosophy. His principal sculptures are a statue of Shakespeare, now in Lincoln Park, Chicago; a bronze statue of Alexander Hamilton; a bust of Edward Everett Hale; a bust of Whittier, in the Boston Public Library; and a colossal bronze equestrian statue of General Grant, purchased by the Union League Club of Brooklyn. He has published *Art for America* (1894); *Song-Life of a Sculptor* (1894); and *The Technique of Sculpture* (1895).

Pascal, Jacqueline: Jansenist educator; younger sister of Blaise Pascal; b. in Clermont-Ferrand, France, Oct. 5, 1625. She early displayed remarkable intellectual qualities, with tendencies toward a religious life, and in 1652, on the death of her father, she retired to the convent of Port-Royal des Champs. In 1655 she was in charge of the education of the children in the convent. She died at the early age of thirty-six, on Oct. 4, 1661, partly, no doubt, from sorrow caused by the persecutions of her sect. Her chief claim to interest in the history of pedagogy is as the author of the *Regulations for the Girls' Schools at Port-Royal*, written in 1657. These rules are very austere; the Jansenists solved the problem of the education of girls in a far less satisfactory way than that of the education of boys.

C. H. Thurber.

Patriotic Societies in the United States: In recent years the remarkable development of an interest in genealogical matters has given rise to a large number of so-called patriotic-hereditary societies, in which membership is restricted to descendants of those who participated in some one of the great military events of the country, or to actual participants themselves. There are a few exceptions to this general rule, such as are shown by the Society of Mayflower Descendants or Order of the Descendants of Colonial Governors. Of these societies, the oldest is the Society of the Cincinnati. (See Cincinnati, Society of the.) It was organized at the close of the Revolution. The war of 1812, the war with Mexico, the civil war, and the war with Spain have given rise to similar bodies. Subsequent to the centennial celebrations of the events of the Revolution, a number of these societies were organized in which membership was restricted to men, and societies of patriotic women also were formed. Each of these societies has its distinctive insignia, including a badge and ribbon, together with a button or stick pin bearing the colors that belong especially to the order.

An act of Congress approved Sept. 25, 1890, permits the badge of the men's societies to be worn by officers and enlisted men of the U. S. army and navy on occasions of

ceremony. The anniversary of some historic event is chosen for the annual meetings, and dinners or functions are given in honor of some important historic occasion. The demand for the records of the soldiers of the Revolution has led to the publication of muster-rolls and similar documents in Connecticut, Massachusetts, New York, and other States, and much historical and genealogical information has been issued by the societies. Monuments and tablets marking historic sites have been erected through the efforts of these organizations. The name, date of formation, objects, eligibility, and number of members of the more important societies are herewith given :

Colonial Period.—The *Society of Mayflower Descendants* was organized in New York city Dec. 22, 1894. Its objects are to preserve the memory, the records, the history, and all facts relating to the Mayflower pilgrims, their ancestors, and their posterity. It admits to membership any lineal descendant, either man or woman, more than eighteen years old, of any passenger of the voyage of the Mayflower which terminated at Plymouth, Mass., in Dec., 1620, including all signers of the compact. State societies exist in New York, Pennsylvania, Massachusetts, Connecticut, Illinois, District of Columbia, and Ohio. The membership is 1,470, of which number 230 claim descent from Bradford, 208 from Mullens and Alden, 207 from Tilly and Howland, and 200 from Brewster.

The *Order of the Descendants of Colonial Governors* was founded in Covington, Ky., Jan. 1, 1896. It commemorates the services of those men who exercised supreme executive power in the American colonies, and laid in them the foundations of stable governments, and of that respect for civil laws and authority which made the maintenance of their future independence possible. It admits to membership male or female descendants of colonial governors who are members of the Society of Colonial Wars, Society of Colonial Dames, or Society of Mayflower Descendants. There are State societies in New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, District of Columbia, Louisiana, Kentucky, Ohio, Michigan, Missouri, Arkansas, Colorado, California, Oregon, and Canada. The membership is about 400.

The *Society of Colonial Wars* was instituted in New York city Aug. 18, 1892, and has for its object the perpetuation of the memory of those events, and of the men who, in military, naval, and civil positions of high trust and responsibility, by their acts or counsel, assisted in the establishment, defense, and preservation of the American colonies. Male descendants of such persons are eligible to membership. State societies exist in New York, Pennsylvania, Maryland, Massachusetts, Connecticut, District of Columbia, New Jersey, Virginia, New Hampshire, Vermont, Illinois, Missouri, Ohio, Nebraska, Minnesota, Kentucky, California, Colorado, Iowa, Georgia, Michigan, Wisconsin, Delaware, Rhode Island, Washington, and Maine. The membership numbers more than 2,500.

The *Order of the Founders and Patriots of America* was incorporated in New York city Mar. 18, 1896. It has among its objects to teach reverent regard for the names and history, character and perseverance, deeds and heroism of the founders of the U. S. and their patriot descendants. Its members, called associates, must be lineally descended in the male line of either parent from an ancestor who settled in any of the colonies now included in the U. S. from the settlement of Jamestown, May 13, 1607, to May 13, 1657, and whose immediate ancestors, at the call of its colonists, adhered as patriots to this cause through the Revolutionary war. There are State societies in New York, New Jersey, Connecticut, and Pennsylvania. The membership is 442.

The *National Society of Colonial Dames of America*, organized in New York city May 23, 1890, has among its objects to collect manuscripts, traditions, relics, and mementos of bygone days, for preservation, and to commemorate the success of the American Revolution. It admits to membership (on invitation only) women who are legitimately descended in their own persons from some ancestor of worthy life who came to reside in an American colony before 1776. This society has chapters in the cities of New York, Baltimore, Philadelphia, and Washington. The membership is about 300.

The *National Society of the Colonial Dames of America* was organized in Wilmington, Del., May 19, 1892. Its objects include the collection and preservation of manuscripts, traditions, relics, and mementoes of bygone days, the preservation and restoration of buildings connected with the early history of the country, and the creation of a popular interest in colonial history. Membership is limited to women (on invitation only) who are descended in their own right from some ancestor of worthy life who came to reside in an American colony prior to 1750. State societies exist in Pennsylvania, Maryland, New Jersey, Delaware, District of Columbia, Rhode Island, Massachusetts, New York, Virginia, South Carolina, Connecticut, Georgia, New Hampshire, and North Carolina, and in the non-colonial States of California, Illinois, Michigan, Minnesota, Iowa, Ohio, Colorado, Maine, Missouri, Wisconsin, Tennessee, Louisiana, Kentucky, Indiana, Alabama, Arkansas, West Virginia, Mississippi, Oregon, Vermont, Texas, and Florida, with a total membership of 3,370.

The *Society of Daughters and Patriots of America* was organized in Washington city June 7, 1898. Its objects are to preserve unwritten colonial and Revolutionary history, to furnish supplies for field hospitals in time of war, and to inculcate patriotism among American women. It admits to membership descendants in the direct paternal line of either father or mother from an ancestor who settled in the colonies before 1687, and through an ancestor who was faithful to the cause of the colonies through the Revolutionary war. Its membership is 23.

The *Order of the Old Guard* was organized in Chicago, Ill., Oct. 15, 1896. It has for its purpose the establishing of a military society, with State organization, to which any male descendant, of twenty-one years, of a patriot who served in the colonial war, in the Revolution, or in the war of 1812, is eligible. The object is to organize a three-company battalion, the first company of which will wear colonial uniforms, the second the uniform of the Revolution, and the third the uniform of the war of 1812. Its membership is 83.

The *Holland Society* was founded in New York city Apr. 6, 1885. It has for its objects the collection and preservation of information, history, genealogy, documents, etc., relating to the early settlement of the Dutch in America, including Huguenots and persons of other nationalities who found homes in Holland, the perpetuation of the memory, as well as the fostering and promotion of the principles and virtues of Dutch ancestors, and to provide for social intercourse among its members. It admits to membership male descendants in the direct male line of a Dutchman resident in America before 1675. Its membership is 843.

The *Daughters of the Holland Dames* was incorporated in New York city Dec. 9, 1895. Its objects are to collect genealogical records, arms and crests of its members, papers, letters, and documents, preserving and arranging the same, thereby securing a true history honoring the memory of those who made the history possible. Membership, which is limited to residents of New York city and the Hudson river valley, including Albany, and must not exceed 100, is restricted to women who are lineally descended from a Hollander resident of the Dutch or English colonies in America which were established in New York before 1700. The membership is less than 100.

Period of the Revolution.—The *Society of the Cincinnati*, founded in Newburg, N. Y., May 13, 1783, by American and foreign officers who served for three years in the Continental army, has for its object the perpetuation of the mutual friendships that were formed under the pressure of common danger in the Revolution. Membership descends to the eldest lineal male descendant, and in failure of a direct male descendant to male descendants through intervening female descendants. Of the original thirteen State societies all have been re-established, although those in Delaware, Georgia, New Hampshire, and North Carolina were only provisionally admitted to the general society in 1899. The membership is 580.

The *Society of the Sons of the American Revolution*, organized in San Francisco, Cal., Oct. 22, 1875 (as the *Sons of Revolutionary Sires*, which on Apr. 30, 1889, became one of the State societies of the *Sons of the American Revolution*), has State societies in Arizona, Arkansas, California, Colorado, Connecticut, Delaware, District of Columbia, Florida, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Montana, Nebraska, New Hampshire, New Jersey, New York, Ohio, Oregon, Pennsylvania, Rhode Island, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, Washington, West Virginia, Wisconsin, the Hawaiian islands, and France. Its chief object is to perpetuate the memory of the men who, by their services or sacrifices during the Revolution, achieved the independence of the American people. It ad-

mits to membership any lineal male descendant of an ancestor who was at all times unfailing in his loyalty to, and rendered actual service in, the cause of American independence. The membership is 9,690.

The *Society of the Sons of the Revolution* was organized in New York city Feb. 22, 1876. Its objects are to perpetuate the memory of the men in the military, naval, or civil service of the colonies, and of the Continental Congress, who, by their acts or counsel, achieved the independence of the country. Membership is permitted to any male person descended from one who as a military, naval, or marine officer, soldier, sailor, or marine, was in actual service under the authority of any of the thirteen colonies or States, or of the Continental Congress, and always loyal to such authority. There are State societies in New York, Pennsylvania, District of Columbia, Iowa, New Jersey, Georgia, Massachusetts, Colorado, Maryland, Minnesota, Ohio, California, Connecticut, New Hampshire, North Carolina, Illinois, Missouri, Florida, Alabama, West Virginia, Tennessee, South Carolina, Kentucky, Montana, Texas, Washington, Virginia, Indiana, Michigan, North Dakota, and Rhode Island, with a total membership of 5,950.

The *Naval Order of the United States* was organized in Boston, Mass., July 4, 1890. It has for its chief objects the encouragement of research and the publication of data pertaining to naval art and science, and to establish libraries in which to preserve all documents, rolls, books, portraits, and relics relating to the navy and its heroes at all times. The companions of the first class include commissioned officers who took part in the navy in the Revolution, in the war with France, in the war with Tripoli, in the war of 1812, in the war with Mexico, in the civil war, or in the war with Spain, also those participating in any war in which the U. S. navy may be engaged hereafter, or the eldest male lineal descendant of any such, or in default of a lineal descendant one collateral representative; and as companions of the second class enlisted men who have received the U. S. naval medal of honor for bravery in the face of the enemy. There are State commanderies in Massachusetts, Pennsylvania, New York, Illinois, and the District of Columbia. The membership is about 500.

The *Military Order of Foreign Wars* was instituted in New York city Dec. 27, 1894, as the *Military and Naval Order of the United States*, but on June 21, 1895, changed its name. It has for its objects the commemoration of the efforts of the forces in establishing and maintaining the principles contended for by the American colonies, and later by the U. S. in the Revolution, the war of 1812, the war with Tripoli, the Mexican war, and the war with Spain. It admits to membership commissioned officers who participated in any of these foreign wars as veteran companions, and direct lineal descendants in the male line of the foregoing as hereditary companions. Commanderies exist in New York, Pennsylvania, Connecticut, Illinois, California, Massachusetts, Florida, Maryland, District of Columbia, Vermont, Missouri, Virginia, and Ohio. The membership is nearly 1,300.

The *Society of American Wars* was founded in Minneapolis, Minn., Jan. 11, 1897. Its objects are the perpetuating among their descendants of the memory of the men who were instrumental in establishing the colonies of North America and were the founders of their nation: of the men who achieved American independence; and of the men who in military and naval positions of trust assisted in the preservation of the republic in the 1812, Mexican, and civil wars; collecting for preservation documents relating to those periods; providing suitable commemorations of the prominent events connected with those periods; and inspiring in its members the fraternal and patriotic spirit of their forefathers. It admits to membership, as companions, U. S. officers of the Mexican or the civil war, and lineal male descendants of colonial or Continental soldiers or civil officers prior to 1783, and of U. S. officers of the war of 1812, the Mexican war, or the civil war. The membership is 485.

The *Society of the Daughters of the American Revolution* was organized in Washington, D. C., Oct. 11, 1890. Its objects are to perpetuate the memory and spirit of the men and women who achieved American independence, by the acquisition and protection of historical spots and the erection of monuments, etc., and to carry out the injunction of Washington in his farewell address. Any woman who is of the age of eighteen years, and who is descended from a man or woman who with unfailing loyalty rendered material aid to the cause of independence, is eligible to membership. The membership is 27,432, distributed in the States and Territories of Alabama, Arkansas, California, Colorado, Connecticut, Delaware, District of Columbia, Florida, Georgia, Idaho, Illinois, Indiana, Indian Territory, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Montana, Nebraska, New Hampshire, New Jersey, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Carolina, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, Washington, Wisconsin, and Wyoming, each of which is under the jurisdiction of a State regent. There are also individual chapters in Canada, in the Hawaiian islands, and in Europe.

The *Daughters of the Revolution*, organized in New York city Aug. 20, 1891, has for its object to keep alive among the members and their descendants, and throughout the community, the patriotic spirit of the men and women who achieved American independence. It admits to membership any woman more than eighteen years old who is a lineal descendant of an ancestor who was loyal to the colonies and was in actual service during the Revolution. There are State societies in Colorado, Connecticut, Delaware, Indiana, Iowa, Kentucky, Maryland, Massachusetts, Minnesota, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Texas, Utah, Washington, West Virginia, and Wisconsin. The membership is 3,000.

The *Daughters of the Cincinnati* was incorporated in New York city Dec. 28, 1894. It has for its objects to renew and foster among its members the friendships formed and cemented amid the trying ordeals of the Revolution in the camp and on the battle-field, by their ancestors, who by wise leadership and study achieved the independence of the American colonies and established the government of the U. S. This society admits to membership (on invitation only) women who are direct lineal descendants of officers of the American army or navy who took part in the Revolutionary struggle with Great Britain, and who were entitled to original membership in the Society of the Cincinnati. Its membership is 90.

The *Dames of the Revolution* was organized in New York city June 25, 1896. It was established for the purpose of perpetuating the memory of those ancestors whose sacrifices and labors secured the existence of the republic, and to preserve the records of these men in the Revolution. It admits to membership any woman more than eighteen years old who is descended in her own right from an ancestor who, either as a military, naval, or marine officer, or official in the service of any one of the thirteen colonies, assisted in establishing American independence during the Revolution. The membership is about 50.

The *Society of the Children of the American Revolution* was organized in Washington, D. C., Apr. 5, 1895. Among its objects are the acquisition of knowledge of American history, the saving of the places made sacred by the American men and women who forwarded American independence, and the finding out and honoring of the lives of children and youth of the colonies and of the American Revolution. Membership is extended to any boy or girl who is descended from a man or woman who with unfailing loyalty rendered material aid to the cause of independence. There are 156 local societies, with a total membership of 4,250, distributed variously throughout the different States.

The *St. Nicholas Society of New York City*, organized in New York city Feb. 28, 1835, has for its objects to collect and preserve information respecting the history, settlement, manners, etc., of the city of New York, and to promote social intercourse among its native citizens. Membership is restricted to natives or residents of New York city who are descended from residents of New York prior to 1785. Descendants of members are preferred for membership, which is limited. The membership is 650.

Period of the War of 1812.—The *Society of the War of 1812*, instituted in New York city Jan. 30, 1826, has for its purpose the inspiration of the members and of the American people with the patriotic spirit of the men who, during the war of 1812, defended their country against hostile encroachments on its rights and interests. It admits to hereditary membership descendants of commissioned officers who actually served in the war of 1812. It absorbed the Veteran Corps of Artillery in 1848, and in 1892 adopted its present name. The membership is 100.

The *General Society of the War of 1812* was organized in Philadelphia, Pa., Jan. 8, 1891, by the Pennsylvania Asso-

eiation of the Defenders of the Country in the War of 1812 (organized in 1854) and the Association of the Defenders of Baltimore in 1814 (organized in 1842), and now includes State societies in Massaehusetts, Conneetieut, Ohio, District of Columbia, New York, and New Jersey. Its objeet is to perpetuate the memory and spirit of the men who completed the Revolution by the victories of the war of 1812. Membership is open to any male person above the age of twenty-one years who participated in or who is a lineal deseendant of one who served during the war of 1812. The membership is nearly 1,000.

The *Society of the United States Daughters, 1812*, was founded in Cleveland, O., Sept. 19, 1892, and has for its object to seeure the genealogies, facts, and traditions of the founders of Ameriea, where they came from, the vessels they arrived in, their deseendants, and reeord of serviee in the Freneh war, in the Revolution, and in the war of 1812. It admits to membership any woman more than eighteen years old who is a lineal descendant of an ancestor who assisted in establishing Ameriean independenee during the war of 1812. There are State societies in Maine, New Hampshire, Massachusetts, New York, Pennsylvania, Ohio, Miehigan, and Louisiana. Its membership is 479.

Period of the War with Mexico.—The *Aztec Club of 1847*, founded in the eity of Mexico, Oet. 13, 1847, has for its objeet to keep alive the traditions that eluster about the names of those offieers of the army and navy and marine eorps who took part in the Mexican war of 1846–48, and admits to membership as primary members offieers who participated in the war, and, as assoeiate members, sons or blood-relatives. Its membership is 235.

Period of the Civil War.—The *Military Order of the Loyal Legion* was organized in Philadelphia, Pa., Apr. 15, 1865. Its objeet is to hold in remembranee the sacrifiees made in eommon and the triumphs shared in maintaining the honor, integrity, and supremaey of the national Government at a critieal period of its history. Its membership is divided into companions of the first class, consisting of offieers who partieipated in the eivil war, and companions of the seeond class, consisting of the eldest sons of original companions. There are State eommanderies in Pennsylvania, New York, Maine, Massachusetts, California, Wiseonsin, Illinois, Distriet of Columbia, Ohio, Miehigan, Minnesota, Oregon, Missouri, Nebraska, Kansas, Iowa, Colorado, Indiana, Washington, and Vermont. Its membership is 9,071.

The *Grand Army of the Republic* was organized in Deatur, Ill., Apr. 6, 1866. Its principal objeets are to preserve and strengthen those kind and fraternal feelings whieh bind together the soldiers, sailors, and marines who united to suppress the rebellion, and to perpetuate the memory and history of the dead. It admits to membership any soldier or sailor of the U. S. army, navy, or marine eorps who served between Apr. 12, 1861, and Apr. 9, 1865, and who was honorably diseharged therefrom after sueh service, and of sueh State regiments as were called into active serviee and subjeet to the orders of U. S. general offieers between the dates mentioned. There are 7,213 Grand Army posts, contained in 45 departments, eaeh of whieh is a State or Territory, exeept in five eases where the department eonsists of two States or Territories, with a total membership of 305,603.

The *Woman's Relief Corps*, which is an auxiliary to the Grand Army of the Republie, was organized in July, 1883. Its objeets are to perpetuate the memory of the heroie dead, to extend needful aid to the widows and orphans, to eherish and emulate the deeds of the army nurses, and to ineulcate lessons of patriotism and love of eountry among the ehildren and in the eommunities. It admits to membership mothers, wives, daughters, and sisters of Union soldiers. The membership is 138,444, whieh is divided into 3,141 corps in 35 departments.

The *Sons of Veterans, U. S. A.*, was organized in Philadelphia, Pa., Sept. 29, 1879. It has for its objects the preservation of the memories of fathers and their sacrifiees for the Union in the eivil war, to aid members of the Grand Army of the Republie and members of the order, to assist in the observanee of Memorial Day, and to inculeate patriotism and a love of eountry among the people. It admits to membership any lineal deseendant more than eighteen years old of any honorably diseharged Union soldier, sailor, or marine, who served in the eivil war. The membership is about 30,000, divided among 1,017 eamps in 29 divisions, most of whieh have an area equal to that of a State or Territory.

The *Union Veteran Legion* was organized in Pittsburg in Mar., 1884. Its objects are the cultivation of true devotion to Ameriean government and institutions, and the preservation of friendly relations among those who fought for the safety of the Ameriean Union. It admits to membership any officer, soldier, sailor, or marine of the Union army, navy, or marine corps, during the civil war, who volunteered prior to July 1, 1863, for a term of three years, and was honorably diseharged, for any cause, after a service of at least two eontinuous years, or was at any time discharged by reason of wounds reeeived in line of duty; also those who volunteered for a term of two years prior to July 22, 1861; but no drafted person, no substitute, nor any one who has at any time borne arms against the U. S. is eligible. The membership is distributed among 152 encampments, whieh are organized in 21 States and the District of Columbia, and ineludes more than 20,000 veterans.

The *Ladies of the Union Veteran Legion*, which is auxiliary to the Union Veteran Legion, was organized in Newark, O., Feb. 20, 1890, and has for its objects the cultivation of trne fraternity and patriotism, and the moral, soeial, and intellectual development of its members, as well as the relief of its members, and of widows and orphans of members of the Union Veteran Legion and others in sickness and distress. It admits to membership the mothers, wives, widows, sisters, daughters, and granddaughters of soldiers, sailors, and marines of the Union army and navy who are eligible to membership in the Union Veteran Legion. Its membership is about 3,000.

The *Union Veterans' Union* was founded in Washington, D. C., in 1886. Its ehief objeets are to preserve and perpetuate, with firmness, but without animosity, the principles of the war for the preservation of the Union, contended for on many battlefields; to exact from the Government proper appreciation of the serviees of the Union soldier in the preservation of the integrity of the nation and just recognition of his claims, and effectively to eare for the members of the order and the widows and orphans of those deeeased. It admits to membership veterans who have served honorably in the army, navy, or marine eorps of the U. S., between Apr. 12, 1861, and Apr. 30, 1865, have participated in one or more engagements or battles, and have reeeived an honorable discharge. Its membership is 71,000.

The *United Confederate Veterans* was organized in New Orleans, La., June 10, 1889. Its ehief objects are to eneourage the writing of partieipants therein of accounts, narratives, memoirs, histories of battles, episodes, and oeeurrences of the war between the States; to gather authentie data, statisties, documents, reports, plans, maps, and other material for an impartial history of the Confederate side; to collect and preserve relics and mementoes of the war; and to make and perpetuate a record of the serviees of every member. It admits to membership any surviving soldier or sailor who served in the Confederate service during the civil war. The membership, whieh is nearly 50,000, is distributed among 1,250 eamps, whieh are organized in three departments, as follows: The Army of Northern Virginia Department, with divisions in Virginia, Maryland, North Carolina, South Carolina, Kentueky, and West Virginia; the Army of the Tennessee Department, with divisions in Georgia, Alabama, Tennessee, Mississippi, Louisiana, and Florida; and the Trans-Mississippi Department, with divisions in Missouri, Texas (Northwestern Texas, Southeastern Texas, Southwestern Texas, and Western Texas, subdivisions), Arkansas, Indian Territory, and Oklahoma.

The *United Sons of Confederate Veterans* was organized in Riehmond, Va., June 30, 1896. Its chief objects are to gather authentic data, statisties, documents, reports, plans, maps, and other material for an impartial history of the Confederate side; to eollect and preserve relies and mementoes of the war; to make and perpetuate a record of the services of every member of the United Confederate Veterans, and all living Confederate veterans, and, as far as possible, of those of their eomrades who have died. It admits to membership any male deseendant more than sixteen years old of those who served in the Confederate army or navy to the end of the war, or who died in prison or while in aetual service, or who were killed in battle, or who were honorably retired or diseharged. The society consists of 140 eamps, distributed so as to perpetuate the plan of the Confederate army, by being divided into three departments: Army of Northern Virginia Department, eonsisting of Virginia, Maryland, North Carolina, South Carolina, and Kentueky; Army of Tennessee Department, including Georgia, Tennessee, Mis-

sissippi, Louisiana, and Florida; Trans-Mississippi Department, including States west of the Mississippi, except Louisiana. The total membership is 8,000.

The *United Daughters of the Confederacy* was organized in Nashville, Tenn., Sept. 10, 1894. Besides cultivating ties of friendship among the women whose fathers, brothers, sons, and often mothers, shared common dangers, sufferings, and privations, as well as to perpetuate the honor, integrity, valor, and other noble attributes of true Southern character, this society has among its objects to instruct and to instill into the descendants of the people of the South a proper respect for and pride in the war history, with a veneration and love for the deeds of their forefathers, and to perpetuate a truthful record of the noble and chivalric achievements of their ancestors. It admits to membership the widows, wives, mothers, sisters, and lineal female descendants of those who served honorably in the army or navy of the Confederate States, or who served in the civil service of the Confederate States, or one of the Southern States, or gave personal services to the Confederate cause. There are 269 chapters, distributed in the following States and Territories: Alabama, Arkansas, California, District of Columbia, Florida, Georgia, Indian Territory, Kentucky, Louisiana, Maryland, Mississippi, Missouri, New York, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia (two divisions), and West Virginia, with a total membership of 14,186.

Period of the War with Spain.—The *Society of the Army of Santiago de Cuba* was organized in Santiago de Cuba July 31, 1898. It has for its object the recording of the history and conservation of the memory of the events of the campaign which resulted in the surrender on July 17, 1898, of the Spanish army in the city of Santiago de Cuba, and the military province to which it pertained. It admits to membership all officers and men (including acting assistant surgeons and volunteer aides) who participated worthily in the Santiago campaign at any time between June 14 and July 17, 1898. Its membership is about 500.

The *Naval and Military Order of the Spanish-American War* was organized in New York city Feb. 2, 1899. Its objects are to cherish the memories and associations of the war with Spain, to unite and promote the ties of fellowship formed by those who participated, and to advance the best interests of the sailors and soldiers of the U. S. It admits to membership any man who served on the active list or performed active duty as a commissioned officer, regular, or volunteer, during the war with Spain. Its membership is 270.

Miscellaneous.—The *Huguenot Society of America* was organized in New York city Apr. 12, 1883. It has among its objects to perpetuate the memory and to foster and promote the principles and virtues of the Huguenots; also to discover, collect, and preserve all existing documents, monuments, etc., relating to the genealogy or history of the Huguenots of America. It admits to membership all descendants in the direct male lines or through the female lines of the Huguenot families which emigrated to America prior to the promulgation of the Edict of Toleration, Nov. 28, 1787. Its membership is about 300.

The *National Society of New England Women* was organized in New York city Jan. 24, 1895. It has for its objects to promote social and intellectual intercourse among its members, and to offer advice and assistance to women of New England extraction residing in other parts of the U. S. It admits to active membership any woman more than eighteen years old who is a native of New England or one of whose parents and whose husband are or were natives of New England. Descendants of active members may become associate members. The membership is 586.

The *Order of the Indian Wars of the United States* was organized in Chicago, Ill., July 26, 1896. Its object is to perpetuate the memory of the services rendered by the American military forces in their conflicts and wars within the territory of the U. S., and to collect and secure for publication historical data relating to the instances of brave deeds and personal devotion by which Indian warfare has been illustrated. It admits to membership officers of the army, navy, and marine corps who have been or who hereafter may be engaged in the service of the U. S. in any grade in conflicts or actual field service against hostile Indians within the jurisdiction of the U. S. as first-class companions, and the sons of living members of the first-class companions as second-class companions. Its membership is 40.

Marcus Benjamin.

Patterson, Rev. George, LL. D.: historian; b. in Pictou, Nova Scotia, Apr. 30, 1824; entered the ministry in 1849. He received the degree of D. D. from Princeton Seminary, New Jersey, and that of LL. D. from Dalhousie College, Halifax. Among his writings are *History of the Country of Pictou*; *The Portuguese on the Northeast Coast of America*; *The Red Indians of Newfoundland*; *The Magdalen Islands*; *Sable Island, its History and Phenomena*.

Paur, Emil: conductor; b. in Czerowitz, Austria, July 29, 1855. His first musical studies were at home, next at the Vienna conservatory, where he graduated with high honors. He began conducting in Berlin, and when twenty-one years old was appointed court conductor in Cassel, going from there in 1880 to Königsberg, in 1891 to Leipzig as first conductor of the opera, and went to Boston to conduct the Boston Symphony Orchestra in 1893. In 1898 he was elected conductor of the New York Philharmonic Society to succeed the late Anton Seidl. He is also known favorably as a pianist, violinist, and composer.

D. E. Hervey.

Payne, Joseph: educator; b. in Bury St. Edmunds, England, Mar. 2, 1808. His opportunities for education were very limited, and at an early age he was under the necessity of supporting himself, relying partly on teaching, partly on newspaper writing, reading widely at the same time. At about twenty years of age he became private tutor in the family of Mr. David Fletcher, and succeeded so well that ultimately, in partnership with Mr. Fletcher, he founded and successfully carried on for some years the Denmark Hill Grammar School in Camberwell. In 1845 he set up a school of his own at Mansion House, Leatherhead, which he carried on for many years with great success. In 1872 the College of Preceptors in London took an important step in establishing the first English professorship of the Science and Art of Education, and to this chair Mr. Payne was called. He thus has the distinguished honor of being the first Professor of Education in England. At an early age Mr. Payne came under the influence of Jacotot, published an account of his system, and gave public lectures to arouse the teachers to a sense of its importance. To the enthusiasm inspired by Jacotot's methods he was always glad to attribute his intense and lasting interest in the science of teaching. He devoted the latter years of his life to the work of elevating the teacher's conception of his calling. D. Apr. 30, 1876. During his life he published little, but since his death two volumes, *Lectures on the Science and Art of Education* and *Lectures on the History of Education*, have been published, and have been recognized as forming an important contribution to educational literature.

C. H. Thurber.

Payne, William Henry: soldier; b. in Clifton, Fauquier co., Va., June 15, 1830; was educated at the University of Missouri, the Virginia Military Institute, and the University of Virginia; at the outbreak of the civil war, organized the Black Horse Cavalry for the Confederate service, and commanded that force as captain at the first battle of Bull Run, several weeks afterward being promoted to major; became lieutenant-colonel of the Fourth Virginia Cavalry in 1862, and colonel in 1863; advanced to brigadier-general in 1864, his brigade being composed of the 5th, 6th, 8th, 15th, and 36th Regiments of Virginia cavalry in Gen. Fitzhugh Lee's division; was three times seriously wounded in battle; became counsel for the Southern Railroad in 1898.

Peacock, Thomas Brower: poet; b. in Cambridge, O., Apr. 16, 1852; educated in Zanesville, O.; was for ten years associate editor of the Topeka *Democrat*. He is the author of *Poems* (1872); *The Vendetta, and other Poems* (1876); *The Rhyme of the Border War* (1880); and *Poems of the Plains and Songs of the Solitudes* (1888), the last-named volume being translated into German by Karl Knortz.

Pearl Harbor: an inlet on the south coast of Oahu, Hawaiian islands, 5 miles W. of Honolulu. By a convention between the U. S. and the King of the Hawaiian islands (1884), the king granted to the U. S. the exclusive right to establish and maintain at Pearl Harbor a coaling and repair station for the use of its naval vessels. U. S. war-ships made surveys of the harbor in 1873, 1875, 1887, and 1897, and from the standpoint of the navigator it is probably better known than any other harbor of no greater commercial importance. The depth of water is about 50 feet, but a bar running across the channel outside the entrance rises to within 10 feet of the surface. This obstruction has not been removed, and since the Hawaiian group was annexed

to the U. S. public attention has been less directed to Pearl Harbor, because the advantages sought there are present in a developed condition at Honolulu. C. C. Adams.

Pearse, Carroll Gardner: educator; b. in Tabor, Ia., Nov. 2, 1858; studied at Doane College, Crete, Neb.; superintendent of schools in Wilber, Kan., 1884–88; superintendent of schools in Beatrice, Neb., 1888–95; superintendent of schools in Omaha, Neb., since 1895; author of numerous occasional addresses.

Pearson, Sir Charles John, P. C., LL. D., D. L.: Scotch judge; b. in Midlothian, Nov. 6, 184–; educated at Edinburgh Academy and at Edinburgh and St. Andrews Universities, and afterward at Corpus Christi College, Oxford, at which last place he took high honors in Greek. He studied law at the Inner Temple, and was called to the Scotch bar as an advocate in 1870; took up the practice of his profession, in which he attained early eminence, and also devoted much attention to politics, in which he attained considerable prominence; was sheriff of chancery 1885–88, procurator of the Church of Scotland 1886–90, sheriff of Renfrew and Butte 1888, sheriff of Perthshire 1889. He was created queen's counsel and appointed solicitor-general for Scotland in 1890; was Conservative member of Parliament for Edinburgh and St. Andrews Universities 1890–96; was lord-advocate of Scotland 1891–92 and 1895–96, and also dean of the faculty of Advocates of Scotland 1892–95; and in 1896 was made judge of the Supreme Court of Scotland. His principal writings consist of addresses and a few essays. F. Sturges Allen.

Peary Land: the interior part of Northern Greenland, between 78° and 82° N. lat., explored and described by R. E. Peary, C. E., U. S. N., who crossed it four times, his first two transits being made in the spring and summer of 1892, and his last two in the spring and summer of 1895. His routes were over the compacted snow which has filled every valley and completely submerged every mountain, until the entire interior of Greenland is simply a huge snow dome, in places 10,000 feet high, absolutely devoid of life of any kind, and with a horizon as blank as that of mid-ocean. Over this frozen desert, at altitudes from 5,000 to 8,000 feet above sea-level, Peary traveled between the west and northeast coasts of Greenland. The region was named Peary Land by the Philadelphia Geographical Society. C. C. A.

Peck, William Henry: educator and author; b. in Augusta, Ga., Dec. 30, 1830; educated at Western Military Institute, Ky., and graduated at Harvard in 1853; was principal of a public school in New Orleans 1854–56, and Professor of Belles-lettres, History, and Elocution in the University of Louisiana 1856–58; after a brief residence in New York city, returned to Georgia and founded the *Georgia Weekly*, a literary publication; became president of the Masonic Female College in Greenville, where the *Georgia Weekly*, which had failed, was revived; was Professor of Languages in Le Vert Female College, Ga., to which place the *Weekly* was removed. He is the author of *The McDonalds, or the Ashes of a Southern Home* and *The Confederate Flag on the Ocean* (1867).

Peckham, Rufus William, LL. D.: lawyer; b. in Albany, N. Y., Nov. 8, 1838; received common-school education, and graduated at Union College. He took up the study of law in June, 1857, and was admitted to the bar, at the general term of the Supreme Court of New York, in Dec., 1859. He began the practice of law in Albany, where he was district attorney of Albany County, and later corporation counsel of Albany city; he was subsequently elected justice of the Supreme Court of the State of New York, and judge of the Court of Appeals of New York, which latter office he retained until he was appointed justice of the Supreme Court of the U. S. by President Cleveland. Justice Peckham is a brother of Wheeler H. Peckham, who was also nominated by President Cleveland prior to Justice Peckham's appointment, but whose nomination was not confirmed by the Senate. F. Sturges Allen.

Peckham, Stephen Farnum: chemist; b. near Providence, R. I., Mar. 26, 1839; after study and practice of chemistry at Brown University and at a laboratory in Providence, experimented with others in the manufacture of illuminating oils from petroleum; became hospital steward of the Seventh Rhode Island Regiment in 1862, continuing in military service until near the end of the civil war; had charge of the chemical department of the U. S. army laboratory in Philadelphia; served as expert for the California Petroleum Company, and prepared reports on the occurrence of petroleum for the Geological Survey of California, including an examination of the bitumen of that State; taught chemistry in Brown in 1867, and afterward in Washington and Jefferson College, the State Agricultural College of Maine, Buchtel College, and the University of Minnesota; was chemist to the Geological Survey of Minnesota; has devoted himself especially to the study of petroleum and its uses, writing much on that subject; was special agent for the national census 1880; wrote the article on *Petroleum* for the *Encyclopædia Britannica*, and is the author of *An Elementary Treatise on Chemistry* (1876).

Peckham, Wheeler Hazard: lawyer; b. in Albany, N. Y., Jan. 1, 1833; son of Hon. Rufus W. Peckham and brother of Rufus Wheeler Peckham, now (1899) justice of the U. S. Supreme Court; educated at Albany Academy and Union College, which he left owing to ill health; studied law and was admitted to the bar in the State of New York, taking up his residence in New York city in 1894; was one of the leading counsel in the Tweed prosecutions, and in various other important litigations, including the Bell telephone patent cases, and the Louisiana bond cases; was appointed district attorney of New York in 1884; was nominated by President Cleveland as justice of the Supreme Court in 1893, but his nomination was not confirmed by the Senate; was several times president of the Association of the Bar of New York City. F. Sturges Allen.

Peele, John Thomas: artist; b. in Peterborough, England, in 1822; early removed to the U. S. and began painting portraits; afterward devoted himself to genre work, especially the portrayal of children; opened a studio in New York city in 1846, and became an associate of the National Academy; finally returned to England in 1851. Among his paintings are *Children of the Wood*; *Music of the Reeds*; *A Highland Supper*; *The Little Laundress*; *Prayer for Health*; *Recitation for Grandpa*; *The Village School*; and *The Bird's Nest.*

Peffer, William Alfred: b. in Cumberland co., Pa., Sept. 10, 1831; at the age of fifteen, worked on his father's farm during the summer and taught school during the winter; removed to Indiana in 1853, to Missouri in 1859, and afterward to Illinois, where he enlisted for the civil war in 1862; was mustered out of service as a lieutenant in 1865, having studied law in leisure hours and acted as judge-advocate; practiced law in Clarksville, Tenn., in 1865, then removed to Kansas, where he founded the *Fredonia Journal* and the *Coffeyville Journal*, and was elected to the State Senate in 1874; was Republican presidential elector in 1880, editor of the *Kansas Farmer* in 1881, and was sent to the U. S. Senate in 1890 by the People's Party, his term of office expiring in 1897; was nominated for Governor of Kansas by the Prohibitionists in 1898. He has published *Myrioma*, a national poem (1869); *The Carpet-Bagger in Tennessee* (1869); *Geraldine, or What May Happen*, an historical story of Kansas (1882); *Peffer's Tariff Manual* (1888); *The Way Out* (1890); and *The Farmer's Side* (1891).

Penfield, Samuel Lewis, A. M.: mineralogist; b. in Catskill, N. Y., Jan. 16, 1856; graduated at the Sheffield Scientific School of Yale University in 1877. On the completion of his course he became one of the assistants in analytical chemistry, receiving more recently an appointment as Professor of Mineralogy in the university. His specialty is the chemistry of minerals, and in order to perfect himself in this branch he studied at the University of Strassburg in 1881, and at the University of Heidelberg in 1884. He received the honorary degree of A. M. from Yale in 1896. Prof. Penfield has made a high reputation for himself in his specialty, as is shown by the many papers on minerals that he has contributed to the *American Journal of Science*. He is also the author of *Determinative Mineralogy and Blowpipe Analysis* (New York, 1896).

Marcus Benjamin.

Penfield, Smith N.: musician; b. in Oberlin, O., Apr. 11, 1837, and after some study in New York continued in Leipzig and Paris. On his return he settled in Savannah, Ga., founded a conservatory of music there, and established and conducted for four years the Mozart Club. He finally settled in New York, and received the degree of Mus. Doc. from the University of New York. He was president of the Music Teachers' National Association in 1891 and also of the New York State Music Teachers' Association. He has com-

posed much good music, and as an organ-player he ranks very high. D. E. Hervey.

Penn College: an institution of learning in Oskaloosa, Ia. The predecessor of Penn College was Spring Creek Union College, incorporated in 1864. In 1866 the Friends united with the Spring Creek Union College Association, and acquired the right to nominate a part of the board of directors for the purpose of establishing a college to be conducted in accordance with the principles of the Society of Friends. Spring Creek Union College became Penn College in 1873, and the first college term was opened the same year. The institution has an endowment of $30,000. Four courses are offered—the classical, scientific, philosophic, and classical-biblical—which lead to the degrees of A. B., Ph. B., and S. B. Provision is also made for the degree of A. M. Of the 18 colleges comprised in the Iowa State Teachers' Association, Penn College is one of the six that rank highest for proficiency in instruction and standard of admission requirements to collegiate standing. The college has 14 instructors and about 400 students. Absalom Rosenberger is president.

Pennsylvania, Western University of: an institution of learning in Allegheny, Pa., founded in 1787 by the General Assembly of Pennsylvania as an academy or public school in the town of Pittsburg. It was the first school established by law W. of the Alleghany Mountains and N. of the Ohio river. In 1819 the Pittsburg Academy was reincorporated by the General Assembly as the Western University of Pennsylvania, and provision was made by the Assembly for its growth along university lines. The university building, with all its contents, was destroyed in the great fire that swept Pittsburg in 1845. On the destruction in 1849, by fire also, of the new building, which had been erected in another locality, instruction was suspended for five years. The institution is now prospering, its assets, including those of the affiliated schools, being very considerable. The instructors number more than 100 and the students nearly 800. Next to the University of Pennsylvania, Western University has the largest attendance of any institution of higher learning in the State. The university has departments of medicine, pharmacy, dental surgery, law, and mines and mining engineering, for which last the Legislature appropriated, in 1895, $50,000. W. J. Holland, D. D., LL. D., is chancellor.

Perfumery: perfumes in general; in commerce, substances either of animal or vegetable origin that are of value in consequence of the odor they impart. These substances by a natural process of slow evaporation or volatilization yield their perfume to the objects within reach, and so give to the person or surroundings an odor that is pleasing and agreeable to the cultivated taste. They have also some value as disinfectants, tending both to mask offensive odors and to oxidize deleterious organic compounds. Perfumes are either of animal or vegetable origin. Of the former, the ambergris from the spermaceti whale, the castor from the common beaver, the civet from the civet-cat, and the musk from the musk-deer are the most important. These four substances are commercial articles, and are made into extracts by treatment with alcohol, sometimes called *tincturation*, in which the crude substance is allowed to remain until all the odor has been taken up by the alcohol. These extracts are then sold in various degrees of dilution, and are also used in combination with other extracts to form perfumes. They are highly esteemed—not so much for their own odor as for the permanence which they yield to other compounds owing to their slight volatility and slow decomposition. Perfumes of vegetable origin include those from gums, such as myrrh and olibanum; from seeds, such as tonquin and vanilla; and from roots, such as orris; also the essential oils of all plants and trees, including those from flowers, as rose oil; from grasses, as lemon-grass oil; from leaves, as bay oil; and from wood, as cedar oil. The gums, roots, and seeds yielding solid perfumes are dried and ground into powder, and then made into incense, pastilles, sachets, and the like. The oils and volatile odors from plants and flowers are obtained by three principal methods—*distillation*, *enfleurage*, and *maceration*. In distillation the fragrant part of the plant is put into a still, covered with water, and then heated. The oily distillate, called *attar* or *otto*, passes over into a receiver, and is then condensed; thus rose-leaves, distilled, yield attar of roses and orange-flowers attar of neroli. As the attars are all slightly soluble in water, the distillate coming over contains a slight amount of perfume, and is known commercially as rose-water, orange-water, and the like. Enfleurage is used with flowers in which the odor is more volatile, and depends upon the fact that greasy bodies readily absorb and retain volatile odors which they will again readily yield when brought in contact with alcohol. The flowers from which it is desired to extract the odor are spread upon trays containing grease, or in some cases vaseline, and the spent flowers are replaced by fresh ones until the grease called *pomade* is considered saturated. Maceration is similar to the foregoing except that the grease is kept liquid by being heated over a water-bath. Sometimes both enfleurage and maceration are used, and at times only one process is desirable; thus tuberose and jasmine yield the better pomade by enfleurage, and rose, orange, and acacia give the better result by maceration; while the preferred jonquil and violet pomade is obtained by a combination of both—that is, enfleurage followed by maceration. The pomade when obtained by enfleurage is heated sufficiently to liquefy it, but not so hot as to destroy the odor, and then filtered through fine linen to remove any extraneous material into retainers, in which condition it is put upon the market. The final process is the making of the *essence*—as the commercial perfume is called. This is accomplished by dividing the solid pomade into small pieces and infusing it with strong alcohol until the odor has been entirely removed from the fat. These essences, combined in various proportions, yield the ordinary commercial product. The resources of modern chemistry have added to the compounds used by the perfumer, and synthetical products such as coumarin, nitro-benzol or false almond, and methyl protocatechnic aldehyde or vanillin now find extensive application in the art of perfumery. See Attar of Roses, Civet, Musk, etc. See the following books: *Perfumes and their Preparation*, by G. W. Atkinson; *A Comptete Practical Treatise on Perfumery*, by A. J. Cooley; *Manufacture of Perfumery*, by Dr. C. Deite; and *Art of Perfumery*, by C. H. Piesse.

Marcus Benjamin.

Perkins, Frederic Beecher: author; b. in Hartford, Conn., Sept. 27, 1828; studied at Yale, but left college in 1848 to study law; was admitted to the bar in 1851, afterward entering the Connecticut Normal School, where he graduated; became assistant editor of *Barnard's American Journal of Education*, and was made librarian of the Connecticut Historical Society, subsequently becoming secretary of the Boston Public Library, and in 1880 librarian of the San Francisco Free Public Library. Among his publications are *Scrope, or the Lost Library* (1874); *My Three Conversations with Miss Chester* (1877); *Charles Dickens, his Life and Works* (1877); and *Rational Classification of Literature for Shelving and Cataloguing Books in a Library* (1881–82). D. Jan. 27, 1899.

Perkins, George Henry, Ph. D.: naturalist; b. in East Cambridge, Mass., Sept. 25, 1844; graduated at Yale in 1867, and received the degree of Ph. D. there for post-graduate studies in 1869, when he was called to the chair of Natural History in the University of Vermont, and also became State entomologist of Vermont; has closely studied the archæology of the Champlain Valley, writing much on the subject for periodicals and scientific societies; has lectured on natural history. Reports of his published by the State of Vermont are *On the Injurious Insects of Vermont* (1876–78); *The More Important Parasites Infesting Man and the Lower Animals* (1880); and *The Flora of Vermont* (1882).

Perosi, Lorenzo: priest and composer; b. in Tortona, Piedmont, Italy, Dec. 20, 1872, the son of a village church organist. His first studies were with his father, then at the conservatory in Milan. At eighteen he was appointed organist at Monte Casino, and was subsequently musical director of the chapel at Imola, director of the Royal Chapel and organist of St. Mark's, Venice. He then took up the study of theology, and was ordained priest when twenty-three years old. The pope appointed him director of music in the Sistine Chapel, Rome. He has written four oratorios: *The Passion*, Sept., 1897; *The Transfiguration of Christ*, Feb., 1898; *The Resurrection of Lazarus*, Nov., 1898; and *The Resurrection of Christ*, Mar., 1899. *The Nativity of Christ* is still to be performed. His projected series of oratorios will cover the entire life of Christ, and will include twelve oratorios. The performance of these works in Italy, Paris, London, and New York aroused much enthusiasm. His style is that of Bach and Handel, modified by Italian melody. D. E. Hervey.

Perowne, John James Stewart, D. D.: Church of England, Bishop of Worcester; b. in Burdwan, India, Mar. 13, 1823; graduated B. A. at Cambridge 1845, and was elected fellow of Corpus Christi College; vice-principal of St. David's College, Lampeter, 1862–72; prælector in theology in Trinity College, Cambridge, 1872–78; Hulsean Professor of Divinity 1875–78. In 1878 he became Dean of Peterborough, and in 1891 was raised to the episcopate as Bishop of Worcester. He was a member of the Old Testament company of Bible revisers 1870–84, and of the royal commission on ecclesiastical courts 1881–83. He won great fame as a Hebrew scholar. Among his publications are *The Book of Psalms, a new translation with notes, critical and exegetical* (London, 1864–68, 2 vols.; 9th ed., in 1 vol., 1898); the Hulsean lectures on *Immortality* (1869); *The Remains, Literary and Theological, of Bishop Thirlwall* (1875–76, 3 vols.); *The Doctrine of the Lord's Supper* (1887); he edited *The Cambridge Bible for Schools* (1877, *sqq.*) and *The Cambridge Greek Testament for Schools and Colleges* (1887, *sqq.*). S. M. J.

Perry, Enoch Wood: artist; b. in Boston, Mass., July 31, 1831; after visiting New Orleans in 1848, went to Europe, studying in Düsseldorf and Paris 1852–53, subsequently going to Rome; was U. S. consul at Venice 1856–58, when he returned and settled in Philadelphia; went to the Sandwich islands in 1863, and in 1865 settled permanently in New York city; was recording secretary to the National Academy of Design 1871–73, holding the same position in the American Art Union; first exhibited at the National Academy in 1858, and became a member thereof in 1869. Besides many portraits, including those of Jefferson Davis, John Slidell, and John C. Breckinridge, he has painted *The Weaver*; *Lost Art*; *Thanksgiving Time*; *Young Franklin and the Press*; *The Sower*; *Mother and Child*; *Afternoon Nap*; *Solitaire*; *A Modern Eve*; *The Milkmaid*; *The Wicker-Workers*; and *The Cradle Song*.

Peru: The development of the rich part of Peru lying E. of the Cordilleras is likely to be hastened by communications now being established both with the Pacific and the Atlantic. A road is being constructed between the Oroya Railroad and the navigable Pichis river of the Amazon basin, by means of which a through route will be established across the continent from Callao to the mouths of the Amazon. This eastern part of Peru is rich in minerals, timber, and rubber, and has great agricultural possibilities. Its chief town is Iquitos, which is within reach of Atlantic commerce by the Amazon, and is 3,000 miles from Para. Water is abundant, and the climate is healthful, and is said to be sufficiently temperate at certain altitudes to encourage European immigration.

Peruvian cotton of the Pacific coast valleys is growing in importance as an article of export. It does not compete with American cotton, for it is used in the U. S. and elsewhere in manufactures for which the cotton staples of the Southern States are not suited. It is used by manufacturers of woolen goods, especially of underwear and hosiery. The staple is longer than that of U. S. upland or the Indian cotton, though shorter than sea-island or Egyptian. The total exports from New York to Peru in 1897 viâ the Straits of Magellan amounted to 15,612 tons. The principal U. S. articles sent to Peru are refined petroleum, lumber, railroad ties, and machinery. Two lines of steamers ply between New York and the western coast of South America. A line from San Francisco would increase the U. S. trade. Trade is now largely controlled by Europe. England sends more than a third of the imports, Germany about a sixth, France a ninth, and then follow Chile and the U. S. More than half the exports (sugar, cotton, wool, silver and copper and their ores, rubber, cocaine, and coca-leaves) go to England and a fourth to Chile. C. C. Adams.

Petersen, Dory: pianist; wife of Richard Burmeister (*q. v.*), to whom she was married in 1883; b. in Oldenburg, Germany, Aug. 1, 1860, and for seven years a pupil of Franz Liszt. She appeared at many concerts in European capitals, and since 1887 has been head of the musical department of the Woman's College of Baltimore, Md.

Petersilea, Carlyle: pianist; b. in Boston, Mass., Jan. 18, 1844, and at twelve years of age was considered a musical prodigy. His entire career has been spent in Boston and vicinity as a pianist, teacher, and composer. In addition to his musical works and studies, he has written two books entitled *The Discovered Country* and *Oceanides: a Psychical Novel*.

Phelps, Thomas Stowell: naval officer; b. in Buckfield, Me., Nov. 2, 1822. He was graduated at the Naval Academy in 1846, and was promoted to lieutenant in 1855. He saw service in the Mexican war; engaged in fighting Indians in Washington Territory 1855–56; was with the Paraguay expedition 1858–59; served in the relief expedition dispatched to Fort Sumter at the outbreak of the civil war; assisted in surveying and charting the Potomac river in 1861 for the defense of Washington; in the same year, operating in the secret-service division, he examined a number of North Carolina inlets, and buoyed the Hatteras inlet to aid expeditions into the waters of that State, during which service he had frequent skirmishes with Confederate gunboats; took part in several engagements with the Yorktown and Gloucester Point batteries, and was instrumental in destroying two Confederate vessels; by timely and well-planned movement he prevented the conjunction of a large body of Confederate troops with the main army at the battle of West Point, Va.; was advanced to lieutenant-commander 1862; examined and surveyed obstructions dangerous to U. S. blockading vessels 1863–64; in 1865 commanded the Juniata at the capture of Fort Fisher; became commander 1865, captain 1871, commodore 1879, rear-admiral 1884, and was retired 1885. He wrote *Reminiscences of Washington Territory* (1882). D. Jan. 10, 1901.

Philip, John Woodward: naval officer; b. in Kinderhook, N. Y., Aug. 26, 1840; graduated at the Naval Academy, Annapolis, in 1860; was commissioned midshipman the following year and attached to the frigate Constitution. He was commissioned lieutenant July 16, 1862, was made executive officer of the Chippewa, the Pawnee, and the Montauk of the South Atlantic blockading squadron, and was engaged in the bombardment of Fort Sumter and the siege of Charleston. He was executive officer of the Wachusett of the East Indian squadron 1865–67, being commissioned lieutenant-commander July 25, 1866; was ordered to the flag-ship Hartford in 1867 and to the Richmond in 1868, where he remained until Nov., 1871. In 1872 he again became executive officer of the Hartford, from which he was detached to command the Monocacy. In 1874 he had leave of absence to command one of the steamships of the Pacific Mail Company. He was commissioned commander Dec. 18, 1874, and in 1876 his leave of absence was revoked and he was put in command of the Adams. The following year he was granted leave of absence to conduct the Woodruff scientific exploring expedition around the world. On his return he was put in command of the Tuscarora, and was engaged in surveying expeditions. In 1884 he became lighthouse inspector for the twelfth district, and in 1887 was ordered to the command of the receiving-ship Independence at Mare island navy-yard. Here he remained till 1890, receiving the commission of captain Mar. 31, 1889. He was in command of the Atlanta for a year, and then was made general inspector of the New York, which was not finished till 1893, when he was put in command. He had charge of the Boston navy-yard 1894–97, when he was put in command of the Texas. In the war with Spain in 1898 his ship took an active part in the battle of July 3 off Santiago. He was commissioned commodore Aug. 10, 1898, was ordered to the command of the Brooklyn navy-yard Dec. 23 of the same year, and soon afterward became a rear-admiral. D. June 30, 1900.

Phil'ippine Islands (Spanish, *Islas Filipinas*), named in honor of King Philip II. of Spain: a large archipelago between the Pacific Ocean and the South China Sea, ceded (with the Sulu group) to the U. S. by the treaty with Spain, signed in Paris by the peace commissioners of the two countries Dec. 10, 1898, and ratified by the Senate of the U. S. on Feb. 6 and by the Queen Regent of Spain on Mar. 17, 1899. The northern limit of the ceded territory is Bashi Channel, S. of Formosa, lat. 21° 20′ N., the most northern lands being the Batan or Bashi group of small islands, embracing about 130 sq. miles. The southern limit is Sibutu island, the southernmost of the Sulu group, in lat. 4° 30′ N. The possessions of the U. S. thus extend N. and S. a distance of about 1,160 statute miles, and are connected with Formosa by the reefs and islets of the Batan group and with Borneo by the chain of the Sulu islands, and farther E. by the island chain of which Palawan island is the largest member. The widest part of the U. S. domain is in the S., where the scattered islands from Palawan and Balabac in the W. to Mindanao in the E. extend about 715 miles E. and W. Most of the land area is included between

BRADLEY & POATES, ENGRS., N.Y.

the meridians 120° and 125° E. from Greenwich. The northern limit at the Bashi Channel was established by Spain at an early day. The Sulu Archipelago came into the possession of Spain by treaty with the Sultan of Sulu signed Aug. 15, 1882, and thereafter formed an administrative province of the Philippines Government. Parts of it had been occupied by Spain in 1876. The boundary between the Philippines and British North Borneo in the region of the Palawan chain of islands was established Mar. 7, 1885, by a treaty between Great Britain, Spain, and the Netherlands, which provided that the islands Balanbangan, Banguey, and Malavalli, together with all islands within 3 geographical miles of the coast of British North Borneo, should be a part of that colony.

Area.—The Philippines are very imperfectly known. Not even the larger islands have been accurately surveyed, and considerable parts of the interior have not been explored, the largest unknown regions being in Mindanao. That many of the coasts have been surveyed is due to the energy of maritime nations, particularly Great Britain and the Netherlands. The number of islands is not known. Hundreds are very small, and recent estimates have varied from 600 to 2,000. It is possible that, counting every islet, the latter estimate may not be very excessive, though the question can not yet be determined. The largest island, Luzon, about 41,000 sq. miles, is the fourteenth, and Mindanao, about 37,500 sq. miles, the sixteenth largest island in the world. The other large islands in order of size, with approximate areas (including where specified some of the most important small islands near them), are: Palawan and Calamianes, 5,500 sq. miles; Samar, 5,200; Panay, 4,860; Negros, 4,700; Mindoro, with Marinduque and Lubang, 3,900; Leyte, 3,060; Cebu, with Bantayan, 1,800; Bohol, with Siquijor, 1,600; Sulu and Basilan (Sulu group), 1,450; Masbate and Ticao, 1,300. It is thus seen that the twelve largest islands with their main dependencies contain approximately about 111,870 sq. miles; and as it is estimated upon the best data now attainable that the total area of the land surface is not more than 115,000 sq. miles, it is evident that most of the large number of islands are very small. The estimates of area given above are based upon computations made in the Gotha Geographical Establishment, and are smaller than the Spanish estimates.

Distribution of Islands and Population.—The land area may be divided into six groups of islands: (1) The Luzon group, including the Batan islands, Luzon, and the islands Polillo and Catanduanes, E. of Luzon. (2) The Mindoro-Masbate group, including the islands Mindoro with Marinduque and Lubang, Romblon with Tablas and Sibuyan, Burias, Masbate, and Ticao. (3) Group of the Visayas islands, including the islands Samar, Leyte, Bohol with Siquijor, Cebu with Bantayan, Negros and Panay. (4) Mindanao. (5) Calamianes and Palawan. (6) Sulu islands, of which Basilan and Sulu or Jolo are most important. The latest census, for purposes of taxation and very imperfect, was taken in 1887, and indicated that the islands had a population of about 7,000,000. It is believed that the population in 1899 is between 7,000,000 and 8,000,000. The best data as to density of population indicate that the Visayas group is most thickly settled, with a density of 114 to the square mile. Then come Luzon and its dependencies, with a density of 85; Sulu group, 57; Mindoro-Masbate group, 39; Mindanao, 15; Calamianes and Palawan, 13. These figures are merely more or less valuable approximations accepted for the time while no satisfactory data exist. The known facts, however, show that the Philippines have a comparatively dense population, about 60 to the square mile, according to the estimates given.

Geology and Topography.—Little study has been given to the geology of the archipelago, and that chiefly to economic geology. Most of the islands appear to have been lifted above the sea at a comparatively recent epoch, as is shown by raised beaches and coral reefs, now a little inland, which contain shells similar to those of marine animals now living in those waters. Some islands, like Cebu, have a cap of limestone deposited when they were below sea-level. Underlying the sedimentary rocks, and also spread over large areas of the surface, schists, granite, gneiss, diabase, volcanic minerals, etc., have been traced. The development of railroad-building and mining will promote geological study by opening cuttings and excavations. The islands are connected with Borneo and Celebes by three ridges, partly submarine and partly emerged, forming island chains between the northern and southern lands. These three lines of ridges are continued N. through the Philippines, and form a large part of their relief, the whole orographic system of the islands coinciding with or being parallel to these lines. Mountains are the predominant topographic feature. Very few summits much exceed 8,000 feet in height, and the loftiest peaks yet known are Apo (more than 10,000 feet) and Malindang in Mindanao, Halcon in Mindoro, and Mayon in Luzon. The plains are alluvial districts on the middle and lower courses and at the mouths of the rivers. The alluvial districts are of considerable extent, particularly in Luzon, whose broad low plains N. of Manila, between the coast mountain ranges, are very productive. There is much tillable land in the valleys, but the total cultivable area is not more than a third of the land surface.

Volcanoes and Earthquakes.—The Philippines are a region of considerable igneous energy. Extinct craters are numerous, and seem to be disposed in regular axes coinciding with those of the islands. Most of these volcanoes are now extinct, and the three active volcanoes that attract most attention are in South Luzon. Bulusan (5,327 feet), at the southern end of Lusan, was long inactive, but has had periods of mild eruption since 1852. Mayon or Albay (7,786 feet), 27 miles N. of Bulusan, is the most active and destructive in the archipelago. It is an almost perfect cone, rises from a base covering 80 sq. miles, and no trace of a crater properly so called has been discovered. Forests cover its sides to a height of 2,000 feet, and the scoria above is difficult to scale. It ejects little lava, but enormous quantities of ashes. In the last century thousands of people have been killed and many villages destroyed by its eruptions, and the ejected matter has been blown as far away as Manila, 200 miles distant. Taal is 45 miles S. of Manila, only 850 feet above the sea, on an island on Bombom Lake, and its crater is about 800 feet deep and a mile in diameter. It was most active in the eighteenth century, but is still steaming, and the eruption of 1885 destroyed all vegetation on the island. There are smoking cones in the northern part of Luzon and on the islands farther N., and also on Negros and Mindanao. In spite of the vents afforded to the subterranean forces by active volcanoes, some part of the archipelago is almost continually in a state of tremor. The seismic vibrations normally run from W. to E., and nearly every year some disaster is caused by earthquakes. In 1880 the cathedral and other massive buildings in the old city of Manila were completely wrecked, but the effects of this shock were less disastrous than those of 1863, when nearly the whole of Manila was destroyed, with great loss of life. The liability to great damage has since been lessened by erecting buildings that can better withstand the shocks.

Drainage.—The islands are well supplied with rivers, smaller streams, and lakes. Many lakes are large. Laguna de Bay (Bay Lake), which nearly bisects Luzon, S.E. of Manila, is 25 miles long by 21 miles wide, covers an area of 350 sq. miles, and is a commercial convenience. Its outlet is the Pasig river, which enters Manila Bay through the city. The parallel mountain ranges give space for important rivers both in Luzon and Mindanao. The largest is the Cagayan or Rio Grande, which has a course of more than 200 miles and carries the drainage of Northern Luzon, between the coast cordilleras, to the northern coast. It has numerous affluents, and the system supplies the wide valleys with abundant water. South of this system the Abra and the Agno carry the rainfall of a large area to the China Sea, and the Pampangan, which traverses the vast plain of that name, empties into the northern side of Manila Bay, where its broad delta, with more than twenty mouths, projects beyond the old coast-line. These delta streams are much used to carry produce to market at Manila. All these lowlands are dotted with lakes. The Pasig is only 12 miles long. Small steamers ply on it between Bay Lake and the sea. The longest river of Mindanao flows N. in a wide valley between the mountain ranges. It is the Agusan or Batuan, and is navigable for a few miles. The Rio Grande is navigable for about 70 miles and flows S. and W. into the Celebes Sea. There are many crater lakes on this island.

Climate.—Though the Philippines are within the tropics, their north and south extension of nearly 1,200 miles, N. of the equator, and the differing altitudes, give them considerable variety of climate, which, however, is essentially tropical, the normally high temperature oscillating between narrow limits. The fact that the climate is also insular gives the island an advantage over continental areas within the tropics, and the nights often afford relief from the trying heat of the day by temperatures 10° to 20° cooler. Tem-

perature records have been kept only at the Meteorological Observatory in Manila, and these show that in that city the mean annual temperature is 80° F., and the extremes are 60° and 100°, or an annual range of 40°. The hottest season is from March to June, and the greatest heat is generally felt in May, when the maximum ranges from 80° to 100° in the shade. The maximum in every month of the year is 91° or more, but the records show no temperatures higher than 100°. The coolest weather is in December and January, when the temperature falls at night to 60° or 65° and seldom rises in the day above 75°. The cool season lasts from November to February inclusive, when the sky is bright, the atmosphere cool and dry, and the weather delightful. As, however, the temperature varies only by a few degrees from month to month, it is useless to distinguish seasons, and the year is divided into the wet and dry monsoons, the dry polar current from the N. E. prevailing from October to April and the moist southwest monsoon for the rest of the year. From July to October inclusive the rains are very heavy, and large tracts of lowlands are flooded. The mean annual rainfall at Manila is 75 inches, and the extremes of annual precipitation have ranged from 121 to 36 inches. The roads are almost impassable in the rainy season, and many forms of business are much retarded. Typhoons occur between May and November, but are most frequent in July, August, and September. They develop in the Pacific and sweep over the China Sea during the southwest monsoon. They affect the Philippines as far S. as Mindanao, wrecking vessels, destroying villages, and often killing hundreds of people. The most dangerous time at Manila is about the end of October. The typhoon which struck that city in 1882 was one of the most terrific on record, and its velocity was 140 miles an hour. Hongkong now gives cable notice of the approach of these storms, and much property is thereby saved. On the whole, the islands are, for a tropical region, considered healthful for people of the white race if the hygienic observances required in such regions, now fairly well understood, are observed.

Flora.—In 1882 botanists had already recognized 4,583 species of plants belonging to more than 1,200 genera. The forest growths are an important factor in the natural riches of the islands. They cover very large areas, but are unequally distributed, and Cebu and Panay have been nearly denuded of trees by the conversion of the land into farms. Many varieties of little-known trees are useful for many purposes, and ebony, cedar, ironwood, sapanwood, logwood, gum-trees, the cocoanut and areca palms, and the bamboo abound. Gutta-percha is found in some places. Every part of the cocoanut-palm is turned to account, and the oil expressed from the nut was the only substance used for lighting before the introduction of kerosene. There are numerous varieties of the bamboo, which grows profusely everywhere and serves a great many purposes. Among the particularly useful hard woods are the *molave*, a brown timber of great strength and hardness, which is proof against the attacks of the white ant; the *dongon* and the *ipil*, which are much used for buildings, vessels, and furniture. Nearly all tropical fruits are grown, but the orange, pineapple, banana, and some others are by no means of the best quality. The cacao-tree, the mango, and guavas flourish. The yam and sweet potato are everywhere raised; wheat is cultivated to some extent in the more elevated regions; maize is grown a little, but does not thrive; and the cucumber, onion, melon, pumpkin, and some other vegetables, introduced long ago by the Spanish priests, are now widely cultivated. White potatoes are beginning to be raised to a small extent.

Fauna.—There are no beasts of prey except the ngiao, a species of wild cat, and this is not very plentiful. The *Macacus cynomolgus* and other apes and monkeys are found, and also the wild East Indian buffalo, deer, and hogs, which probably have descended from domestic animals. Goats, sheep, dogs, and cats are numerous, and so are flying squirrels and very large bats. The tame buffalo, called the water-buffalo because it delights to wallow in mud and water, is used everywhere in agricultural work, and also as a pack and draught animal in freight transportation. It is the most useful domestic animal. Many cattle are raised in some islands for beef. All the venomous snakes are represented, crocodiles grow to enormous size, and white ants, mosquitoes, tarantulas, and other large spiders are among the insect pests. About 600 species of birds are known, and bird-life is very abundant. The surrounding seas abound with life and some of the rivers teem with fish.

Minerals.—Only about a score of islands are known to contain valuable minerals. Their geographical distribution is shown in the following table prepared by Mr. George F. Becker, of the U. S. Geological Survey. All the mineralogical data here given are taken from his report, which is the latest and fullest summary:

ISLAND.	Latitude (north end).		Character of mineral resources.
	°	′	
Luzon	18	40	Coal, gold, copper, lead, iron, sulphur, marble, kaolin.
Catanduanes	14	8	Gold.
Marinduque	13	34	Lead, silver.
Mindoro	13	32	Coal, gold, copper.
Carraray	13	21	Coal.
Batan	13	19	Coal.
Rapu-Rapu	13	15	Coal.
Masbate	12	37	Coal, copper.
Romblon	12	37	Marble.
Samar	12	30	Coal, gold.
Sibuyan	12	30	Gold.
Semarara	12	7	Coal.
Panay	11	56	Coal, oil, gas, gold, copper, iron, mercury (?).
Bilaran	11	43	Sulphur.
Leyte	11	35	Coal, oil, mercury (?).
Cebu	11	17	Coal, oil, gas, gold, lead, silver, iron.
Negros	11		Coal.
Bohol	10	10	Gold.
Panaon	10	10	Gold.
Mindanao	9	50	Coal, gold, copper, platinum.
Sulu Archipelago	6	30	Pearls.

The coal might better be characterized as a highly carbonized lignite. It may supplant imported coal for most purposes. The finest beds thus far found are in the small island of Batan, E. of the southern part of Luzon (lat. 13° 19′), the heating effect being about three-fourths that of Cardiff coal. Large deposits in Southern Mindoro and Semarara are said to be similar to those of Batan. The deposits thus far known in Masbate and Panay are not of much importance. A high quality is reported from Leyte. The maximum thickness of the seams on Cebu is 15½ feet, and ten analyses of Cebu coal indicate a caloric effect of two-thirds that of Cardiff coal. The occurrence of lignite along the entire eastern coast of Mindanao is probable, judging from the outcrops already known.

In Cebu petroleum has been found associated with coal at Toledo, on the west coast, and is also reported from Asturias, N. of Toledo, on the same coast, and from Alégria to the S. Natural gas is said to exist in the Cebu coal fields. On Panay, oil is reported at Janiuay, province of Iloilo, and also gas on the same island. Petroleum highly charged with paraffin is found on Leyte.

Gold is found at a vast number of places from North Luzon to Central Mindanao. It is usually detrital, and either in existing watercourses or in stream-beds now dry. In Mindanao some gravels are elevated and adapted to hydraulic mining. There are no data to determine decisively the value of these placers. They are washed by natives, largely with cocoanut-shells for pans. In Abra province, at the northern end of Luzon, are placers, and the gravel of the Abra river is auriferous. In Lapanto are gold-quartz veins as well as gravels. Gold is obtained in this province close to the copper mines. In Benguet the gravels of the Agno river carry gold. There is also gold in Bontoc province and in Nueva Ecija. The most important of the auriferous provinces is Camarines Norte. Here the townships of Mambulao, Paracale, and Labo are especially well known as gold-producing. Mr. Drasche, the German geologist, says 700 natives were at work on rich quartz veins at the time of his visit twenty-five years ago. Many other places in this province have been worked by the natives. At the south end of Panaon, just S. of Leyte, there are gold-quartz veins, one of which, 6 feet thick, has yielded from $6 to $7 to the ton. In Mindanao are two known gold-bearing districts, one in Surigao province and the other in the province of Misamis. Near Imponan and on the Gulf of Macajalar there are said to be many square miles of gravels carrying large quantities of gold, with which is associated platinum. The product of this district was estimated some years ago at 150 oz. per month, all extracted by natives.

Copper ores are reported from a great number of localities. Northern Luzon contains a copper region which is unquestionably valuable. The best-known part of this region lies about Mt. Data, lat. 16° 53′, long. 120° 58′ E. of Greenwich. Here copper ore has been smelted by the natives

from time immemorial. Reports indicate that there are copper mines in various parts of the Cordillera Central, but the only deposits examined with care are those at and near Mancayan (5 miles W. of Mt. Data). The deposits of Mancayan are described as veins of rich ore, reaching 23 feet in width and arranged in groups. Mean assays are said to show over 16 per cent. of copper, mainly as tetrahedrite and allied ores. The gangue is quartz. The country rock is described as a large quartzite lens embedded in a great mass of trachyte. An attempt has been made by white men to work these deposits, but without much success. The failure was not due to the quality or quantity of ore.

A lead mine has been partly developed near the town of Cebu. The most important deposit of argentiferous galena is said to be at Torrijos, on Marinduque. A metric ton, or 1,000 kilogrammes, is said to contain 96 grammes of silver, 6 grammes of gold, and 565·5 kilogrammes of lead. In Camarines, a province of Luzon, lead ores occur, but are worked only for the gold they contain.

There is iron ore in abundance in Luzon, Carabello, Cebu, Panay, and doubtless in other islands. In Luzon it is found in the provinces of Laguna, Pampanga, and Camarines Norte, but principally in Bulacan. The finest deposits are in the last-named province, near Camachin, where a small industry exists, wrought iron being produced in a sort of bloomery, and manufactured into plowshares. It would appear that charcoal pig iron might be produced to some advantage in this region. The lignites of the archipelago are probably unsuitable for iron-blast furnaces.

Sulphur deposits abound about active and extinct volcanoes. In Luzon the principal sulphur deposits are in Daclan, province of Benguet, and at Colasi, in Camarines. The finest deposit is said to be on the little island of Bilaran, N. E. of Leyte. Marble of fine quality occurs on the small island of Romblon (lat. 12° 37′). It is much employed in churches in Manila for baptismal fonts and other purposes. Marbles are also quarried at Montalban in Manila province, and at Binangonan in Marong province. There are concessions for mining kaolin at Losbanos in Laguna province. Pearl-fisheries exist in the Sulu Archipelago, and are said to form an important source of wealth.

Inhabitants.—All immigration into the islands in early times must have come from the W., and there is reason to believe that it was partly through a great emigration from the Philippines to the E. that the Polynesian islands were populated. Most of the native population is of Malay origin and may broadly be divided into three great groups: (1) Those who have become considerably advanced in civilization, and were called by the Spanish Indios or Indians, by which term they are distinguished from (2) the Moros or Moors, the name given by the Spanish to the Mohammedans who entered the archipelago from Borneo about four centuries ago, and occupy some of the southern islands; and (3) the savage or semi-savage tribes that have maintained their independence in the interior of Luzon and other islands, have never paid tribute to the Spaniards, still practice their pagan rites, and are called *Infieles* or Infidels. Besides these large groups is a small one, the Aetas or Negritos (Little Negroes), believed to be the remnant of the aboriginal inhabitants who were driven back or exterminated by the intruding Malays. The most potent forces in the development attained have been immigrants settling in the islands within a comparatively recent period, chiefly Spanish, Chinese, and traders of other nationalities.

There are perhaps 20,000 persons of pure Spanish blood, most of them in Manila and its neighborhood, though priests are widely scattered on their large land-holdings, and until after the Spanish-American war the Spanish official class represented the Government wherever Spain had acquired a foothold. The governmental and religious institutions had practically co-ordinate power. All inhabitants who could be reached by the tax-gatherer contributed to the revenues. Ports were opened to foreign trade only when the moral suasion of Europe compelled this step. The principal duty of the governors of the provinces was the collection of taxes, and the judicial machinery was so dilatory and inadequate as to give rise to complaints that justice could not be obtained in the courts. The Spanish Roman Catholic religious orders gained a large measure of control over the more advanced Filipinos, claimed some millions of converts, had enormous holdings of the finest lands which they leased to the natives on onerous terms, and while many of the clergy were men of excellent character and intentions, there were many others whose disreputable character and policy of oppression were detrimental to the natives. The chief reasons assigned by the Filipinos for their various revolts against Spanish rule were the oppression of the Church authorities, excessive taxation, and the injustice of the courts. Considerable Spanish capital is invested in sugar-raising and tobacco-manufactures, but the foreign trade of the islands except with Spain has been chiefly stimulated by British, German, and American merchants. The Spaniards have had no influence in improving the very backward position of agriculture. The descendants of Spanish fathers and native mothers are numerous, and many of the merchants and landed proprietors are of this class. The total European population is estimated at 25,000.

The Chinese are the most numerous among the foreigners in the Philippines. They number about 50,000, and in many of the towns most of the retail trade, banking, and money-lending is in their hands. Some of them also do a large wholesale business, sending agents through the country districts to collect produce which they export on their own account. Their persistent industry and economy have made them helpful to the natives and to business, and many of them have amassed considerable fortunes. Very few Chinese women go to the islands. Thousands of the native women have married Chinese, and their children, Chinese mestizos (half-breeds), numbering about 200,000 and inheriting to a large extent the excellent qualities of their fathers, are a most useful class. They share the business of their fathers, who, besides commercial pursuits, devote themselves to many trades.

The Indios or more or less civilized natives are divided into four groups, the Tagals, Vicols, Visayas, and Ilocanes. The Tagals, on the whole, are furthest advanced in civilization, number about 1,500,000, and the revolt against Spanish rule, and later against the U. S. Government in its efforts to restore order, has chiefly been confined to a part of them. Most of them live in Luzon in the low-lying plains, in the towns, and near the streams and sea. They are also found in Mindoro, Marinduque, and some smaller islands farther S. They are the chief native pioneers of civilization. Most of them live by raising rice and cattle, and by fishing. They are nominally Roman Catholics, are indolent like most tropical peoples, and welcome all the Church holy days as festive occasions. Physically they are well developed, and the Tagalog language is more widely spoken in the archipelago than any other. The Ilocanes, a comparatively small tribe, live in Northwestern Luzon, and differ from the Tagals chiefly in dialect. The Visayas, who give their name to the central group of islands, are estimated to number 2,500,000. The leading distinction between them and the other branches of the Malayan family in the archipelago is their language. The Vicoles occupy the Camarines peninsula, with the islands of Catanduanes, Burias, Ticao, and half of Masbate, greatly resemble the Tagals, and number about 400,000.

The Moros occupy the Sulu chain of islands and a large part of the coasts of Mindanao, Balabac, and the southern part of Palawan. They brought with them from Borneo their Mohammedan faith and social usages, have nothing in common with the peoples living farther N., have always resisted to the utmost the attempts of the Spaniards to convert them to Christianity, and formerly preyed severely upon the trade and natives of the northern islands until their reverses, due to primitive weapons and methods of warfare, restrained their piratical ardor. The work of keeping them in order and developing their islands appears practicable if no attempt is made to interfere with their religious belief.

The hill tribes and other wild tribes in parts of the interior of Luzon and a few other islands live as they did before the Spanish occupancy. They have many languages and dialects, probably number at least 500,000 souls, and Prof. Worcester and others who have visited some of the tribes found them quite simple and harmless, though others are warlike. They are most numerous in the interior of Mindanao. The Negritos are almost wholly confined to the higher mountain ranges in Luzon and Negros, are blacks, of almost dwarfish stature, and are likely to become wholly extinct. There is considerable admixture of blood among the Indios, the wild Malayan tribes, and the Negritos.

Agriculture.—Farming in the three centuries of the Spanish *régime* has been characterized by utter lack of

progress. Most of the people till the land as their ancestors did before the invasion from Europe. Only a ninth of the area is now cultivated, though agriculture is the chief industry. About 8,000,000 acres are under cultivation. The total production could be increased from ten to fifteen fold. There are scarcely any well-kept farms. Outside the hemp, coffee, sugar, and tobacco plantations tillage is confined to garden-patches around the huts, and the natives raise little more than their families require. A great part of the cultivated lands is owned by the religious corporations, Spaniards, and half-breeds, is usually worked on shares, and the produce of the plantations is sent direct to Manila, Iloilo, or Cebu. Much of the export products—hemp, sugar, coffee, and tobacco—is bought on the land by Chinese speculators, who ship it down the rivers or creeks in flat-bottomed canoes or barges. There is little agricultural machinery except sugar-mills and engines, and a sharpened stick often does duty as a plow. The most unique product, because it is a commercial success only in the Philippines, is Manila hemp (native name *abaca*), *Musa textilis*, a variety of the banana family, one of the most useful of fiber-plants, each plant yielding two qualities of fiber, one of which is the best material used for sail-cloths and cordage, and from the other is woven fabrics superior in softness and lightness to those made of the best Russian hemp. It produces under the best conditions as high as 3,000 lb. of fiber to the acre, most of which is exported, 6,528,965 bales having been sent abroad in ten years, the U. S. taking on an average 41 per cent. of the total exports. Rice, the staple food of the natives and of most of the Chinese, is grown in many varieties, some maturing within three months of planting, two crops being raised in a year. In some years, however, $2,000,000 worth of rice has to be imported, and most of it is brought from Cochin-China. The average annual production of rice is 36,000,000 bush. Sugar is grown very extensively, but most of it is poor and coarse and brings a low price because of slovenly cultivation and manufacture and lack of high-grade machinery. The sugar exports from Manila are mostly produced on Luzon, while those of the Visayas are for the most part shipped from Cebu. The best tobacco grows in the northern part of Luzon, in the provinces of Isabella and Cagayan, and is sent in covered boats down the Rio Grande to Aparri, and there shipped by steamer to Manila. The tobacco of Northwestern Luzon and the Visayas is of inferior quality, and has seldom been manufactured at Manila, but has usually been shipped to Spain. Manila cheroots and cigars are as famous and highly appreciated E. of the Cape of Good Hope as the Havana product is among Western nations. About 20,000 persons are employed in and near Manila in making cigars. The Philippine islands cotton staple is about an inch long, smooth, and of good color, but is not yet extensively raised. Coffee is grown, but has not had a fair trial, as the plantations are not well managed. The cocoa-palm attains perfection in these islands, and copra, one of its products, is exported in considerable quantity. The banana is most prolific and useful, yielding a larger amount of food from a given area than any other crop.

Manufactures.—Cigar-making at and near Manila is the largest industry. Small ships for the coasting trade are built to some extent. A cotton-mill costing $200,000, with 6,000 spindles, is an English enterprise at Manila, where there are also two sugar-refineries, some distilleries, a German cement-factory, Swiss umbrella and hat factories, carriage-factories, and ropewalks. In some villages of Luzon and Panay almost every family has a hand loom, and cotton and sail-cloths, quilts, coverlets, etc., are produced in considerable quantities. Cotton rugs of handsome designs are made in some of the islands, and fabrics of hemp, silk, and piña, the fiber of the pineapple-leaf, are also produced. There is room for splendid development in the island industries.

Commerce.—It was only after steam-navigation began, and particularly after the opening of the Suez Canal, that commerce developed in the Philippines. The export products have been mostly handled by large British, German, and Spanish houses and Chinese traders. These houses have usually advanced considerable money to producers in order to secure their crops, a procedure involving large capital and some risk, but very profitable. The British, Germans, and Belgians have sold a great deal of iron, zinc, machinery, guns, and hardware in the islands. Watches, cheap jewelry, shoes, oilcloth, varnishes, paints, and carriage fittings are among the articles in large demand. The following statistics show the amount and distribution of foreign commerce in the latest years reported:

COUNTRIES.	Imports from Philippines.	Exports to Philippines
Great Britain (1897)	$6,223,426	$2,063,598
France (1896)	1,990,297	359,796
Germany (1896)	223,720	774,928
Belgium (1896)	272,240	45,660
Spain (1895)	4,819,314	4,973,589
Japan (1897)	1,332,300	92,823
China (1897)	56,137	97,717
India (1896)	7,755	80,156
Straits Settlements (1896)	274,130	236,001
New South Wales (1897)	119,550	176,858
Victoria (1896)	180	178,370
United States (1897)	4,383,740	94,597
Total	$19,702,819	$9,174,093

The chief articles of export in 1897 were Manila hemp, $6,745,177, of which Great Britain took $3,694,214 and the U. S. $2,701,651; tobacco, $3,435,552, of which Spain took $2,533,150 and Great Britain $716,767; cocoanuts and copra, $2,009,602, of which France took $1,787,198; and sugar, $4,282,110, of which Great Britain took $1,512,703, Japan $1,156,411, the U. S. $1,199,202, and Spain $413,794. The principal imports were cotton manufactures, $1,524,622, of which Great Britain supplied $1,268,087; metals and metal manufactures, $337,216, of which Great Britain supplied $185,413; machinery, $191,269, of which Great Britain's share was $151,630; and provisions, $118,538. The total value of imports for the ten months ending October, 1900, was $20,143,152; of exports, $19,372,830.

Foreign commerce got a foothold in the Philippines in spite of long Spanish opposition. Foreign vessels were not permitted to enter Manila Bay nor foreign merchants to live in the city until the nineteenth century. The heavy protective tariff levied by Spain in 1891 diverted most of the trade to the home country, Manchester cottons being largely replaced by Barcelona goods. Later Great Britain regained the cotton trade, which is the most important feature of the imports. The trade of the U. S. with the islands fell off steadily during the last years of the Spanish occupancy. The import trade from the Philippines fell from $10,268,278 in 1888 to $4,383,740 in 1897; but it is now recovering.

Communications.—In 1899 Manila was in frequent but not regular communication with the U. S. by steamers. The only large line of ships connecting Manila with Europe is that of the Compañia Transatlantica, which has a monthly service to Liverpool, calling at Singapore, Colombo, Aden, Suez, Port Said, and Barcelona. Three steamship lines plying regularly between Australia, China, and Japan began calling at Manila in 1899. Several steamers under the British flag do a brisk business between Manila and Hongkong. A steamer runs to Singapore to meet the French mail-steamers, which carry the larger part of the Western mails. Manila is connected with the ports of the provinces by 35 steamers and a large number of small sailing vessels. The only railroad in operation is between Manila and Dagupan, 123 miles, connecting the capital with the rice-growing districts of Pangasinan. It is a single-track road, well and substantially built. The highways are very poor, and the streams are usually bridgeless. Travelers in the interior find no hotels, but every village has a public building, often a very rude structure, where free shelter may be had and food may be bought at a fixed scale of prices. Manila is connected with Hongkong by cable, and the U. S. is extending the land and cable lines on and between the islands.

Chief Ports.—The islands have an immense coast-line and a large number of good harbors, but the exclusive policy of Spain, which opened to foreign trade only five ports, has prevented the others from being well known except to coastwise traders. The treaty ports were Manila, Iloilo, Cebu, Sual, and Zamboanga. The last-named is on Mindanao and its trade is insignificant, and so is that of Sual. Manila Bay is one of the finest in the world, embraces 120 sq. miles, and the water is deep almost everywhere except in front of the city. The harbor works have not yet been completed, and one of the first needs is safe landing-places for the larger steamers, which now have to discharge part of their cargo by lighters. Manila's situation fits it to occupy a commanding position in Oriental trade. (See MANILA.) Iloilo, near the southeast end of Panay, is the second port in importance and is 250 miles from Manila. The approach to the harbor is a channel between a sandbank and Guimaras island, which is 2½ miles from the shore. The well-protected anchorage

is outside the Iloilo river, but small vessels enter and discharge their cargoes at the wharves. Cebu, on the island of the same name, formerly surpassed Iloilo in commercial importance, but for some years has held the third place. It chiefly exports sugar, hemp, tobacco, and sapanwood. Aparri, at the northern end of Luzon, the port from which the tobacco crop is shipped to the capital, is destined to become a place of large importance. A rich area is tributary to it, and it is 250 miles nearer Hongkong and 400 miles nearer San Francisco than Manila.

History.—The islands were discovered by the Portuguese sailor Ferñao de Magalhães (Magellan) in 1521, when he landed on the eastern coast of Mindanao. He then sailed to Cebu, where he was received in a friendly manner by the ruler and accompanied him on a war expedition in which the explorer was killed. Spain sent a number of expeditions to take possession of the islands, but all failed until 1565, when Philip II. sent Miguel de Legaspi to seize the islands, which had been named in his honor. Legaspi secured a foothold in Cebu, and later removed to Luzon, where Manila was founded in 1581. The coasts were gradually brought under the dominion of Spain, but the interior of the larger islands and some of the smaller ones were never subjected to her authority. For a long time the islands were attacked frequently by the Portuguese, who were jealous of the growing power of Spain in the Orient, and later by the Dutch, who wished to add the Philippines to their Eastern empire. None of these attacks, however, were of a formidable character, and Spain's most serious troubles with external enemies in the Philippines were the invasion of the Chinese pirate Li Ma Hong in 1754, when he attacked the Spanish with a powerful fleet of nearly 100 war-junks, but was finally defeated; and in 1762 when England captured Manila and held it with the surrounding country for two years, when, peace having been restored between the two countries, the territory was returned to Spain. The more civilized natives, including the half-breeds, were long greatly discontented with the government given them by Spain, and there were revolts from time to time, the most serious of which began in Aug., 1896, and continued, with one slight interruption, until the end of the Spanish rule. The capture of Aguinaldo March 23, 1901, was practically the end of the armed revolution, chiefly of the Tagals, against the American occupancy, which had been carried on with ever-decreasing success during 1899–1900. In March, 1900, President McKinley appointed a second commission, which arrived in Manila June 3, to organize the civil government of the islands. April 7, 1900, the Military Governor Major-General Otis was relieved at his own request. He was succeeded by Major-General MacArthur. On June 21 a proclamation of amnesty was issued, and in the following months many Filipinos took advantage of its provisions. On July 4, 1901, the military government was discontinued, excepting in such provinces as still remained in insurrection, and the Hon. William H. Taft, the president of the commission, appointed Civil Governor June 22, entered upon his duties.

C. C. Adams.

Phillips, Claude: lawyer and art critic; b. near Manchester, England, about 1855; received a school and university education, and after taking his degree of bachelor of arts studied law, and was called to the bar at the Inner Temple in 1883. He practiced his profession but little, giving his attention to art criticism and history. He was formerly art critic for the *Manchester Guardian*, and is now (1899) art critic for the *Daily Telegraph*; he is a frequent contributor to the *Fortnightly Review*, *Art Journal*, *Magazine of Art*, the *Quarterly Review*, *Edinburgh Review*, *Nineteenth Century*, *Portfolio*, *Gazette de Beaux-Arts* of Paris, and other periodicals; is now (1899) keeper of the Wallace Collection. He has published *Life of Sir Joshua Reynolds*; *Life of Frederick Walker*; *Life of Antoine Watteau*; *The Early Work of Titian* and *The Later Work of Titian*, and other art criticisms and writings.

F. Sturges Allen.

Phillips, John Arthur: author; b. in Liverpool, England, Feb. 25, 1842; began his literary work in 1865 as a journalist in New York. In 1870 he moved to Canada, where he has continued his journalistic work. He has written many short stories, among which are *Thompson's Turkey, and other Christmas Tales* (1873); *Hard to Beat* (1877); *Bad to Worse* (1877); *The Ghost of a Dog* (1885); *Out of the Snow, and other Stories* (1886).

Phororhach'idæ: a family of gigantic extinct South American birds, characterized by the great size and massive structure of the skull, and especially of the beak, which is high, compressed, and terminates in a sharp hook. The nostrils are high up in the basal portion of the beak; the mandible is truncated at the back and curved upward toward the front, this being a very uncommon thing in birds. The sternum is unknown, but well-formed wings were present, although far too small to have been of any use for purposes of flight. The legs were massive, comparing in this respect with Dinornis and Æpyornis (*qq. v.*), and the character of the caudal vertebræ indicates that there was no external tail. The size of the skull may be appreciated from the fact that the first specimen discovered, the anterior portion of a lower jaw, was believed to belong to some great extinct sloth. In the best-known species, *Phororhachos inflatus*, the cranium was 13 inches long and the beak 4 inches deep, while the skull of *P. longissimus* attained a length of 21 inches; a neck-vertebra of this last species has a width of 5 inches. *Brontornis*, whose entire skull has not been found, was a still more massively built member of the family, the bones of the leg having the following measurements: femur, 17 inches; tibia, 30 inches; tarsus, 16 inches; or a combined length of 5 ft. 3 in. The width of the tarsus at its upper end is 5¼ inches, the leg of this bird being thus much larger than that of a horse. The remains of these birds are found in Tertiary deposits in Patagonia, considered by Florentino Ameghino, by whom the birds were first described, as Eocene. Other authorities, however, consider them to be not later than Oligocene and more probably Miocene, a supposition borne out by the specialized structure of the birds, which, in spite of their great size, are in no way related to the ostriches. They were assigned by Ameghino to a special order called *Stereornithes*, on the supposition that they were totally different from any existing forms; but while their relationships are still uncertain, they present no characters entitling them to rank as an order, and have affinities with the herons, and probably with the trumpeters (*Psophia*). From the structure of their beaks it is possible that the *Phororhachidæ* were to some extent carnivorous, although this is purely a matter of conjecture, while a published figure of *Phororhachos* attacking a *Hadrosaurus* is entirely misleading, since the two forms were separated by an immense interval of time.

Skull of *Phororhachos longissimus*, ⅛ natural size.

F. A. Lucas.

Picking, Henry Forry: naval officer; b. in Somerset co., Pa., Jan. 28, 1840; graduated at the Naval Academy in 1861; served in the North Atlantic blockading squadron 1861–62; was commissioned lieutenant in 1862, and took part in the engagement with the Confederate ram Merrimac and the batteries at Sewell's Point; was made lieutenant-commander in 1866, commander in 1875; served on the Kearsarge 1879–81, and afterward commanded the Michigan; advanced to captain in 1889, commanding the

naval forces of the South Atlantic station, where he rendered notable service in obviating a rupture between the U. S. and Brazil, receiving the commendation of the President and of the State and Navy Departments for his judicious course, after which he was relieved, his term of service having expired; afterward served on various boards: became commodore in 1898, rear-admiral and commandant of the Boston navy-yard in 1899. D. Sept. 8, 1899.

Pictet, Raoul: physicist and engineer; b. in Geneva, Switzerland, in 1842; educated at the university of his native city and subsequently for many years Professor of Physics in its faculty. He is the author of numerous papers on scientific subjects, and is best known for his successful attempt to liquefy oxygen and nitrogen in the winter of 1877–78. This famous experiment was announced at the meeting of the Academy of Sciences in Paris, Dec. 24, 1877, at which meeting the French physicist Cailletet reported a similar result reached by him independently and by the use of an entirely different method. The priority in this matter was given to Cailletet because he had previously made a demonstration of his method privately before certain members of the Academy. (See Liquefaction of Gases; also Liquid Air, in the Appendix.) These researches led Pictet to the development of the industrial applications of his apparatus for the production of artificial cold, and he has thus become one of the chief authorities upon refrigerating machinery and upon all subjects relating to cryogenic processes. E. L. N.

Pinar del Rio: a western province of Cuba and the most famous tobacco-growing region of the world. The chief seat of its cultivation is along the southern slopes of the Cordillera de las Organos, the famous Vuelta Abajo region. This tobacco is usually bought up in advance by speculators, and the manufactured product is retailed at very high prices. The land on which this tobacco grows has been cleared of forests and is covered with siliceous alluvial deposits. The Western Railroad traverses the Vuelta Abajo tobacco district, and extends to the city of Pinar del Rio, which is 104 miles S. W. of Havana. Other products of the province are coffee, corn, cotton, sugar, rice, and fruits. Pop. (1899) province, 173,064; city, 8,880. C. C. Adams.

Pinchback, Pinckney Benton Stewart: politician; b. in Macon, Ga., May 10, 1837; of African descent; attended school in Cincinnati, O., in 1846; became a river boatman in 1848; ran the Confederate blockade at Yazoo City and reached New Orleans, then in possession of Union troops, in 1862; by authority of Gen. Banks, raised a company of colored cavalry. He was active in politics in 1867, and was made inspector of customs; was a member of the State constitutional convention in 1867, and State Senator in 1868; appointed by President Grant register of the land office of New Orleans in 1869; founded the New Orleans *Louisianian* in 1870; was appointed a school director for New Orleans in 1871, and in the same year was elected president *pro tempore* of the Senate and became Lieutenant-Governor; was acting Governor during the impeachment of Gov. Warmoth, 1872–73; elected to the U. S. Senate in 1873, but was never admitted; was appointed commissioner to the Vienna Exposition from Louisiana in 1873, and was made a member of the State board of education in 1877; elected a delegate to the constitutional convention of the State in 1879, appointed surveyor of customs at New Orleans in 1882, and was a trustee of the Southern University 1883–85; was admitted to the bar in 1886, having graduated in the law department of Straight University.

Pirbright, Henry de Worms, First Baron, D. L., F. R. S.: English lawyer and statesman; b. in Egham, England, in 1840; educated at King's College, London, of which he was made a fellow in 1863, in which year he was called to the bar at the Inner Temple. He took up the practice of his profession, but became prominent chiefly in political affairs, and especially in matters relating to the foreign policy of Great Britain. He was Conservative member of Parliament for Greenwich 1880–85, and for Liverpool 1885–95; was parliamentary secretary to the board of trade of Liverpool 1885–88, and Under-Secretary for the Colonies 1888–92; in 1888 was made British plenipotentiary and president of the conference on sugar bounties. He has published *England's Policy in the East*; *The Austro-Hungarian Empire*; *Memoirs of Count Beust*; and also some articles and brochures on scientific subjects, including *The Earth and its Mechanism*.
F. Sturges Allen.

Pitt-Lewis, George: English lawyer and law-writer; b. in Honiton, Dec. 13, 1845; received his early education from private instructors at Honiton grammar school, where his father was head master; obtained studentship of the Inns of Court 1869, and was called to the bar; was made queen's counsel in 1885; was Liberal member of Parliament for Devonshire 1885–86, and Liberal-Unionist 1886–92; retired from the Liberal-Union party organization in 1894. He is now (1899) recorder of Poole. He assumed the maternal name Pitt in 1876 by royal license, being descended on his mother's side from William Pitt. He has published several works on local practice, and is also the editor of the ninth edition of *Taylor on Evidence* (1895), and joint author of *The Insane and the Law* (1897), a compendious treatise on modern lunacy legislation. F. Sturges Allen.

Plaisted, Harris Merrill: soldier; b. in Jefferson, N. H., Nov. 2, 1828; graduated at Waterville College (now Colby University) in 1853, and at Albany Law School in 1855; admitted to the bar and began to practice in Bangor, Me., in 1856. He became lieutenant-colonel of a volunteer infantry regiment in 1861, was promoted colonel in 1862, and took part in the Peninsula campaign, the siege of Yorktown, the seven days' battles, and the battles of Williamsburg and Fair Oaks; commanded a brigade in the siege of Charleston, and served with Grant in the Richmond and Petersburg campaigns. He was breveted brigadier-general of volunteers in Feb., 1865, and major-general in March. In 1865 he resumed his law practice in Bangor. He was twice elected to the Legislature, was attorney-general of Maine 1873–75, and was elected to Congress in 1874 to fill an unexpired term, but declined a re-election. He was Governor of Maine 1881–83, after which he edited and published the *New Age*, a Democratic weekly, in Augusta, which is now controlled by his son. D. in Bangor, Jan. 31, 1898.

Platt, Charles Adams: artist; b. in New York city, Oct. 16, 1861; studied art at the National Academy of Design and in Paris, giving special attention to etching, in which branch of art his works include *Fishing-Boats*; *Provincial Fishing-Village*; *Old Houses near Bruges*; *Deventer, Holland*; and *Dieppe*. He has exhibited in oil and in water-color at the Paris Salon, the National Academy, and elsewhere.

Platt, William Henry, D. D., LL. D.: b. in Amenia, N. Y., Apr. 16, 1821; was admitted to the bar in 1840, practicing for four years in Alabama; was ordained deacon in the Protestant Episcopal Church in 1851, priest in 1852, and held rectorships in Selma, Ala., Petersburg, Va., Louisville, Ky., San Francisco, Cal., and Rochester, N. Y.; received the degrees of D. D. and LL. D. from the College of William and Mary in 1878. His publications include *Art Culture* (1873); *Influence of Religion in the Development of Jurisprudence* (1877); *After Death, What?* (1878); *Unity of Law, or Legal Morality* (1879); *God Out, and Man In*, a reply to R. G. Ingersoll (1883); and *The Philosophy of the Supernatural* (1884).

Platter (or **Plater**), Thomas: humanist educator; b. in a hamlet in the mountains of Valais in 1499. He spent his early days in tending the herds in the wild country around his home, but being intended by his mother for the priesthood, he was set to study with the local pastor. Soon, however, in order to pursue his studies further, he adopted the only course then open to him, and became a wandering scholar, joining himself to a cousin who was visiting his home at that time. With his cousin he went from town to town, leading the picturesque but wretched life of the wandering students of that day, called *bacchants*. These bacchants went from town to town, seeking alms, and not scrupling to steal if necessary. They took with them children whom they trained for mendicants, and who served them as a sort of fags. Platter's cousin was a bacchant and led his small relative a sorry life. Finally Thomas separated from his cousin, who made desperate efforts to recover so valuable a servant, but in vain. He was received into the school of Jean Sapidus at Schlestadt, where he studied Latin. Later he went to Zurich and studied with Myconius, at the same time learning the trade of rope-maker. By working at his trade he continued his studies, learning Greek and Hebrew. He settled at Bâle, worked some years at his trade, and then became proof-reader in a printing establishment, and in 1541 was nominated Professor of Greek in the gymnasium in that city, which position he filled until 1578. At the age of sixty-three he had written

his autobiography, addressed to his eldest son, Félix. This autobiography is a very interesting document for the history of education in the sixteenth century. The author tells with charming simplicity all his adventures and travels, and shows in all its detail the miserable life of the poor scholars at the time. This was first published in its original text in 1840. The story is told in brief but interesting fashion in Lagrange, *Les Écoles au moyen âge*. Platter is one of the most curious and interesting figures of the epoch of the Renaissance and the Reformation. D. in Bâle in 1582. C. H. Thurber.

Poland, John Scroggs: soldier; b. in Princeton, Ind., Oct. 14, 1836; graduated at the U. S. Military Academy in 1861, and appointed first lieutenant in the Second Infantry June 6, 1861. He served in the Army of the Potomac in the battle of Bull Run and until after the battle of Gettysburg, having meantime been promoted captain and breveted major and lieutenant-colonel, and was afterward engaged in the defenses of Washington. He was Assistant Professor of Geography, History, Ethics, and Drawing in the Military Academy 1865–69, and during the following ten years was employed principally in frontier duty. He became a major Dec. 15, 1880. He was chief of the law department of the U. S. Infantry and Cavalry School in Leavenworth, Kan., 1881–86, and also in charge of the department of military drawing 1881–83. On Mar. 1, 1886, he was made lieutenant-colonel of the Twenty-first Infantry. He published *Digest of the Military Laws of the United States from 1861 to 1868* (Boston, 1868) and *The Conventions of Geneva of 1864 and 1868*, and *St. Petersburg International Commission* (Leavenworth, 1886). D. in Asheville, N. C., Aug. 8, 1898.

Polar Research: The chief results of the three years' explorations of Mr. Frederick G. Jackson in Franz Josef Land in 1894–97 are that it is found to be an archipelago of comparatively small islands, there being no large land-masses; the discovery of a considerable number of islands and of Victoria Sea N. of the archipelago; proof that Gillis Land, if it exists, is not in the position where it has been shown on the maps; and the complete mapping of the western part of the region. In 1898 the party led by Mr. Walter Wellman, of Chicago, erected its house at Cape Tegetthoff, Franz Josef Land, within 594 geographical miles of the north pole, with the intention of advancing N. by sledge and boat in an effort to reach the pole. In June, 1899, the Duke of the Abruzzi, a prince of Italy, sailed from Norway with a well-equipped expedition. He returned Sept. 6, 1900, having reached 86° 33′ N. lat., the highest point then touched. In 1898 two expeditions, one American, led by Robert E. Peary, C. E., U. S. N., and the other Norwegian, led by Capt. O. N. Sverdrup, sailed up the west coast of Greenland, hoping to reach and define the northern coast of that island, to explore the islands near it, to make scientific observations, and to reach the pole. Hope for the safety of the Arctic aeronaut S. A. Andrée and his two companions not having been entirely abandoned, Prof. A. G. Nathorst and his expedition sailed from Stockholm on May 20, 1899, on the steamer Antarctic to search for the missing men on the east coast of Greenland between 73° and 76° N. lat., and also to carry out explorations there and make deep-sea investigations during the journey.

Some unusual achievements in Spitzbergen waters in 1898 were due largely to the remarkably favorable conditions for navigation. The prevailing western drift usually packs the ice solidly against the east coast, and it was not until about 1870 that the world learned something about the contour of that coast. In 1898 Prof. Nathorst, on the Antarctic, carried out two undertakings never before accomplished, circumnavigating Northeast Land, one of the largest islands of the Spitzbergen group, passing unimpeded through Hinlopen Strait, which is usually choked with ice, and then sailing completely around the entire Spitzbergen group. He made a survey of the coasts of the three King Charles islands, much of which had been shown by dotted lines on the maps, and also explored White island, 100 miles N., that had hitherto been marked "existence doubtful."

In 1895 and later the idea of renewing Antarctic exploration received much support from geographers, particularly those of Great Britain and Germany. It was urged that Antarctic research had been entirely neglected for about sixty years; that the known north polar area was as large in the seventeenth century as the known south polar area in the nineteenth; that the unknown Arctic was now only as large as European Russia, while the unknown Antarctic was twice as large as Europe; and that important problems of physical geography could not be solved until more study was given to the south polar regions. The agitation was promoted by the success of some ventures in Antarctic waters, notably the outlining of a part of the east coast of Graham Land by the sealer Jason, under command of Capt. C. A. Larsen, from Nov., 1893, to Jan., 1894; and the attainment of Victoria Land in Jan., 1895, by the steam-whaler Antarctic, the first time this most southern known land had been visited since its discovery by Sir James Ross in 1841. Mr. C. E. Borchgrevink and a party from the whaler were the first to land on the coast of the mainland. A Belgian expedition on the steamer Belgica has passed the first winter ever spent by men in the Antarctic regions. The party, which was commanded by Lieut. de Gerlache, was frozen in the Antarctic ice a full year, from Mar. 10, 1898, to Mar. 14, 1899, during which time the vessel drifted with the ice between 70° and 71° 36′ S. lat. and 85° and 103° W. lon. Before penetrating the ice the party had spent three weeks to the S. of the South Shetland islands and in the neighborhood of Hughes Gulf, where twenty landings were made and many specimens illustrating flora, fauna, and geology were collected. During the winter drift the ice-field extended from 50 to 60 miles N. of the vessel. South winds brought very cold clear weather. North winds, coming from the open sea, brought cloudy weather and frequent fogs, with temperatures rising to zero or even to the thawing-point. The ice was incessantly in slow motion, drifting with the wind. The prevailing direction of the wind was toward the W., and the Belgica emerged from the ice about 500 miles W. of the point where she had entered it. The drift to the S. under the propulsion of the north winds was as rapid as the drift to the N. when the south winds were blowing, from which fact, and also from the very deep soundings, it was inferred that if there is an Antarctic continent the vessel was far from its northern edge on the South American side of the polar area. The sun disappeared on May 17 and rose sixty-five days later, on July 21. High gales and heavy snowfalls were frequent, rendering work outside the ship impossible. The pack-ice felt the influence of the ocean swells as well as of the winds, and its aspect was constantly changing. The ice was generally compact, but sometimes there were wide areas of open water or long channels or narrow veins of water. When the openings closed by pressure, instead of freezing, ridges of hummocky ice marked the line of contact. In the openings of the ice seals and penguins appeared, particularly late in the winter, and they were a desirable addition to the bill of fare. The polar night was marked by more or less impairment of heart-action among the men, and Lieut. Danco succumbed to the malady. Collections were made of pelagic and deep-sea fauna and sediments. One of the sailors was accidentally drowned. The party, thus deprived of two of its members, reached Punta Arenas in Magellan Straits fourteen days after the vessel escaped from the ice.

On Aug. 22, 1898, the steamer Southern Cross, purchased and fitted by Sir George Newnes for polar work, sailed from London for Victoria Land in the Antarctic. The expedition is in charge of the young Norwegian C. E. Borchgrevink. The party of 11 men with their equipment, including 75 dogs, were landed on Feb. 28, 1899, on the shore of Victoria Land at Cape Adare, 71° 23′ S. lat. and 169° 56′ E. lon. The vessel was sent to Australia to winter. With the dawn of the Antarctic spring Borchgrevink intended to make a sledge-journey overland as far S. as possible. The vessel was to call for the party in the autumn and carry it home.

The German deep-sea expedition on the steamer Valdivia late in 1898 made an excursion into the Antarctic area S. of Africa, and skirting the edge of the pack-ice from W. to S. E. through 50° of longitude, where a submarine plateau was supposed to exist, took 14 soundings, 5 of which revealed depths of more than 18,000 feet, and others nearly reached this figure.

In 1899 Germany and England were preparing to send large expeditions to the south polar area. It was expected that the German expedition under the command of Dr. E. von Drygalski, the explorer of glacial phenomena in Southern Greenland, would start in the autumn of 1901, penetrate the polar area on the meridian of Kerguelen island, establish a station on Victoria Land, and spend a year in its work, which will include a sledge-journey to or toward the pole, the fixing of the location of the magnetic

pole, the exploration of the west coast of Victoria Land, and the making of scientific observations and collections. In 1899 the British and German Governments agreed to give large financial support to the expeditions of their respective countries, and it was expected that the necessary outlay for each of these enterprises would be more than $250,000. C. C. Adams.

Police Power: in law, a power inherent in every sovereignty or government to do and enact such things as may be necessary to the protection and preservation of the lives, well-being, and property interests of the members of the community and its own entity. The exact boundaries of the police power of a state can not be, or have never been, definitely marked, nor the limits of its exercise exactly prescribed; it is broadly defined and broadly exercised, and has been defined so as to include "the authority to establish such rules and regulations for the conduct of all persons as may be conducive to the public interest."

The police power of a state is distinguished from the broad rights of eminent domain and the right of taxation, although these are essentially based upon the necessity of the preservation of the state and its well-being. The now obsolete or obsolescent laws regulating the expenditures and apparel of private individuals, interfering with or prohibiting the worship or practices of religious or other sects, restraining or prohibiting speculation in the necessaries of life, and engrossing or forestalling the market, are all included under what is now recognized as the police power of the state, although the recognition of this power as such, and the development of the law upon it, belongs chiefly to the nineteenth century, and especially the period subsequent to 1840. The broad scope of the power and the nature of the occasions which justify its exercise are best shown by citing some of the specific instances of its application.

Under the name of "the law of overruling necessity," the police power of states was early exercised to destroy houses and other buildings to prevent the spread of fire. Its exercise here does not come under the right of eminent domain, but is broader and more absolute, and pertains, as in the following examples, to the preservation of the property, health, morals, and general well-being of the community. When its exercise requires the taking or destruction of private property, no right of compensation accrues to the person or party deprived of it, unless such right is expressly created by statute. The rights and privileges of private corporations are subject to reasonable regulation by the state under its police power, so long as no essential right or privilege conferred by the charter is taken away. Thus the speed at which trains may be run on a railroad, the grade of its crossings, the forbidding of unreasonable charges or discrimination, the requiring of employees to submit to examination as to fitness for their places where involving the public safety, as engineers or brakemen, the requiring of the redemption of tickets, etc., are all instances of the exercise of this power over corporations.

In its care over the health and morals of the community it may establish mortuary laws; may provide for and regulate the confinement and care of the pauper sick and the insane, require persons practicing professions, such as medicine, surgery, dentistry, midwifery, etc., affecting the public health and morals to pass examinations to prove their fitness and competency to carry on properly the practice of their profession; may prohibit the employment of children below a certain age, and regulate the hours of employment of women and children; may prohibit the carrying on of trades or manufactures in such a manner or in such a place as to be likely to injure the health of the community or to prove a public nuisance; may prohibit the sale, or even the manufacture, of liquors or poisons, or of adulterated or harmful foodstuffs, etc. Under this same power belongs the right to establish quarantine stations, to control and regulate navigable waters, enact game and fishing laws, require licenses from peddlers, regulate the use of the highways, and, in short, the right to do all those things necessary to the self-preservation of the body politic.

In the U. S. the exercise of this power by the individual States is limited by those powers the exercise of which has been exclusively vested in the Federal Government by the Constitution of the U. S. Where the Federal Government is vested with the power of co-ordinate control which becomes exclusive when exercised by it, as in the case of quarantine laws, the State may exercise its control until its legislation is superseded by that of the Federal Government. The vesting of control of any subject-matter in the Federal Government, however, does not deprive the States of the right to pass any laws whatever affecting the subject where such laws are necessary to the preservation of health, life, or safety of the inhabitants of the State; thus although the subject of interstate commerce is regulated by the Federal Government, the State, for the preservation of the existence and well-being of its members, may make laws indirectly affecting the subject-matter under federal control. But the State may not carry this to such a point as under cover of the police power to hinder or obstruct the exercise by the U. S. Government of the power vested in it by the Federal Constitution, nor may it in this way deprive any citizen of rights guaranteed to him by the Federal Constitution.

For a full exposition of the subject, see Cooley's *Constitutional Limitations*; Prentice on *Police Powers* (1894); Tiedeman's *Limitations of Police Power in the United States*; Thayer's *Cases on Constitutional Law* (1894–95). Compare also the articles on Taxation, Eminent Domain, and Lunacy Laws. F. Sturges Allen.

Polonium: a metallic element found in the mineral pitchblende by P. Curie and Mme. S. Curie. Its discovery was announced at a meeting of the French Academy of Sciences, July 18, 1898. The discoverers in studying this complex mineral, the analysis of which is somewhat difficult, owing to the many rare elements that it contains in small quantities, found a body that was exceedingly active from the point of view of the emission of the new rays described by Becquerel. In analyzing the mineral it was found that the active material referred to separated out with the bismuth; but as yet no means of separating it from that volatile element in the wet way has been found. But when heated *in vacuo* in a Bohemian glass tube to about 700° C. the active substance is deposited in the form of a black film in that portion of the tube which is between 250° and 300° C., while the bismuth sulphide remains in the warm part of the tube. By continuing this operation products were obtained of which the activity was found to be 400 times greater than that of uranium. As no known elements have any such activity, it is believed by the discoverers that the substance which they have isolated contains a hitherto unknown metallic element very similar to bismuth in its analytical properties. If the existence of this new metal be confirmed, it is proposed that it be called *polonium*, after the native country of one of its discoverers. Marcus Benjamin.

Polo y Bernabe, Luis: diplomat; b. in Spain in 1858; after receiving education, he accompanied his father to the U. S., in 1872, as *attaché* of the Spanish legation at Washington, his father, José Polo, being minister, upon whose retirement, in 1875, he was made third secretary of the legation, holding that position until 1881, when he was transferred to The Hague as second secretary, remaining there until 1885, when he was recalled to Madrid, serving in the foreign office, in charge of consulates and commercial affairs; later was sent to Cairo as minister resident in Egypt, afterward being transferred to Brazil and again recalled to Madrid; succeeded Enrique Dupuy de Lome as ambassador to the U. S. in 1898, but soon asked for his passports, in view of the impending war between the two countries, and went to Canada, where his presence was alike objectionable to the U. S. and to the British Government; on returning to Spain became under-secretary to the foreign office in Madrid.

Ponape Island: an island in the eastern part of the Carolines group; the largest and one of the most important of the islands. It has been of special interest to archæologists since the exploration in 1896 by Mr. F. W. Christian of the remarkable prehistoric works known to exist there. Mr. Christian found that columnar shafts of basalt, many weighing several tons each, were transported from 20 to 30 miles to build up defenses, tombs, and other structures. A still more remarkable fact is that the little islands off the east coast of Ponape, on which these structures were reared, are mainly artificial, having been built up out of the shallow waters of the lagoon by the heaping up of these shafts of basalt. These artificial islands cover an area of about 9 sq. miles and there are between 50 and 60 of them. No basalt is near them, but the explorer found the quarries whence it was obtained more than 20 miles away. Many of the shafts and blocks weigh at least 3½ tons. They may have been rolled with the aid of levers to the water's edge, but the means employed to place them on the rafts and to

lift many of them to a height of 20 or 30 feet to form the top of the walls on the islets has not been discovered. Mr. Christian traced the course of the rafts from the quarries to the stone islands by the blocks of basalt that are strewn over the bottom of the lagoon. They had evidently fallen from the rafts or sunk with them. The islands were reared above the water from 5 to 10 feet, and on this foundation great walls were erected, the largest of which is 30 feet high and 10 feet thick. The prisms of basalt were placed closely together, alternating lengthwise and crosswise. Many walls inclose large spaces, one of which is 185 by 115 feet. Tombs were found in some of them, and it is believed the inclosed spaces were used for tombs, treasure-chambers, and forts. The native tradition as to the origin of these structures is that they were built by all the tribes of the island at a time when it was much more populous than at present. Finally there was a great invasion of peoples from the S., who overturned a part of these artificial walls, killed all their defenders, and blotted out the ancient civilization. Other ruins, not so extensive, are found on some other islands of the group. The opinion is expressed by some that no people of the present race could have constructed these immense works. See Christian's report in *The Geographical Journal*, Feb., 1899. C. C. Adams.

Pond, Frederick Eugene (*Will Wildwood*): sporting author; b. in Packwaukee, Wis., Apr. 8, 1856; received a common-school education; was instrumental in organizing the National Sportsmen's Association, and active in forming the Wisconsin Sportsmen's Association for the protection of fish and game; was field editor of *Turf, Field, and Farm* 1881–86, associate editor of the *American Field* in 1883, and later conducted *Wildwood's Magazine*, in Chicago; besides edited Frank Forrester's *Fugitive Sporting Sketches* (1879), his *Sporting Scenes and Characters* (1880), and Isaac McLelland's *Poems of the Rod and Gun* (1886). He is the author of *A Handbook for Young Sportsmen* (1876); *Memoirs of Eminent Sportsmen* (1878); and *The Gun-Trial and Field-Trial Records of America* (1885).

Poore, George Vivian: English physician and professor of medical jurisprudence; b. in Andover, Sept. 23, 1843; was educated in the royal naval school at New Cross, and at University College, London; after graduating at the latter he took up the practice of medicine in London; was medical attendant to the late Prince Leopold, Duke of Albany, 1870–71, to the Prince of Wales 1872, and the Duchess of Cumberland; was made physician to the University College Hospital in 1876, in which year he was also appointed Professor of Medical Jurisprudence and Clinical Medicine in University College, and this position he still (1899) retains. He was honored with the Dannebrog for professional services to the Duchess of Cumberland in 1872; in 1891 was made secretary-general to the sanitary congress, besides which he has held numerous other positions of high professional standing. His publications include, besides works and papers of a purely professional nature, *Essays on Rural Hygiene* (2d ed. 1894). F. Sturges Allen.

Pope, Franklin Leonard: electrical engineer; b. in Great Barrington, Mass., Dec. 2, 1840; educated in his native town, and became a telegraph operator, and assistant engineer of the American Telegraph Company and the Russo-American Telegraph Company; in the latter capacity made with George Blenkinsop the first exploration, in 1866, of the region about the sources of the Skeena, Stickeen, and Yukon rivers, in British Columbia and Alaska; settled in New York city as an electrical engineer and expert. In 1870 he was associated with Thomas A. Edison in inventing the one-wire printing telegraph, known as the "ticker," that is used for telegraphing exchange quotations, etc. In 1872 he invented the rail circuit for automatic control of electric block signals on railroads, and he patented many other improvements for railroad and telegraph service. He also practiced as a patent attorney. In 1885 he was elected president of the American Institute of Electrical Engineers. Since 1884 he had been editor of the *Electrical Engineer*, and he wrote, besides many articles for periodicals, *Modern Practice of the Electric Telegraph* (1871) and *Life and Work of Joseph Henry* (1879). D. Oct. 13, 1895.

Port-Royal, Little Schools of: One feature of the counter-reformation, or the reaction against Protestantism, was the organization of the teaching congregations, namely, the Jesuits, the Brethren of the Christian Life, and the Jansenists. The Port-Royal schools represent the educational activities of the Jansenists in France. The foundation of the schools dates back as far as 1637, which marks the beginning of the celebrated community of recluses founded outside the monastery of Port-Royal. This community brought up in the knowledge of letters and Christian piety a few children of good birth, whom it wished to spare the dangers attending the usual college course, but the schools were not definitely organized until 1656, and they were finally closed by the king's command in Mar., 1661, having had a checkered and peripatetic existence, owing to the continued opposition of the Jesuits. The idea of the foundation of these schools belongs to the illustrious Duvergier de Hauranne, Abbé of Saint-Cyran. The attendance of the schools at their most flourishing period probably did not exceed fifty, and the entire number of children that passed through the schools was possibly not more than a hundred. Their influence is, however, not to be measured in this way. Compayré says of them: "Singular destiny that of those teachers, whom a relentless fate permitted to exercise their functions only for five years, yet who, through their works, have remained perhaps the best authorized exponents of French education!" Their most notable contribution to pedagogy is probably the introduction of the new system of teaching reading, which has become celebrated under the name of the Port-Royal method. The originator of this system seems to have been Pascal himself. For the first time in France they made the French language the subject of serious study. The discipline was mild, but gravity and dignity were enforced to the extent of producing a repellent formalism. The spirit of emulation was purposely suppressed. The general judgment of their work is thus summed up by Compayré: "Ardor and sincerity of religious faith; a great respect for the human person; the practice of piety held in honor, but kept subordinate to the reality of the inner feeling; devotion advised, but not imposed; a marked mistrust of nature, corrected by displays of tenderness and tempered by affection; above all, the profound, unwearied devotion of Christian souls who give themselves wholly and without reserve to other souls to raise them up and save them—this is what was done by the discipline of Port-Royal. But it is rather in the methods of teaching and in the administration of classical studies that we must look for the incontestable superiority of the Jansenists. The teachers of the Little Schools were admirable humanists, not of form, as the Jesuits were, but of judgment. They represent, it seems to us, in all its beauty and all its force, that intellectual education already divined by Montaigne, which prepares for life men of sound judgment and of upright conscience. They founded the teaching of the Humanities." Among the most noted of the authors connected with the Port-Royal schools, whose works influenced and continued to influence French education, are Nicole, one of the authors of the Port-Royal *Logic*, and author of *The Education of a Prince*; Lancelot, the grammarian; the great Arnauld; and, less well known, De Sacy, Guyot, Coustel, Varet, Jacqueline Pascal. See Compayré, *History of Pedagogy*; Cadet, *Port-Royal Education*; Cousin, *Jacqueline Pascal*; Sainte-Beuve, *Histoire de Port-Royal* (6 vols., 1871). C. H. Thurber.

Portugal is the part of the Iberian peninsula most favorably situated for foreign commerce, both on account of its large sea-frontage and also because, as a rule, its inland boundary crosses the Spanish rivers flowing to the Atlantic just at the point where they become navigable; still its resources are less developed than those of Spain. Its industries, formerly nearly stifled by importations from Great Britain, have advanced in several lines. The country is particularly weak in metal industries, while cotton, wool, and silk manufactures have considerable development. The principal manufacturing districts are Lisbon and Oporto. The exports to the U. S. in the year ending June 30, 1900, were valued at $3,743,216, and the largest items, in order of importance, were India-rubber (brought from the African colonies), corkwood, and port wine. The U. S. furnished 14 per cent. of the imports. The African colonies are making some commercial progress. A bank was discovered in 1897, about 50 miles S. of the Azores, over which the water is only 250 to 625 feet deep. It is remarkably rich in fish, and is likely to create a new industry for the Azores. The Portuguese colony of Macao, near Canton, has greatly declined in commercial importance. The port is now accessible only to small vessels, owing to sand-banks. Many of the inhabitants have removed to Hongkong and Chinese ports, where they have positions in foreign commercial houses.

The commerce of the Chinese living in Macao is fairly important, and in 1898 amounted to $18,330,043.

Powell, F. York: English lawyer and historical writer; b. in England about 1845; was educated at Rugby, and at Christ Church College, Oxford; then read law in the Middle Temple, where he was called to the bar in 1870. He has held consecutively the positions of tutor and law lecturer of Christ Church College, and historical lecturer at Trinity College, Oxford, and has been Regius Professor of Modern History at Oxford University since 1894. His publications include as editor, *An English History from Contemporary Writers*; as author, *Early England up to the Norman Conquest* (in *Epochs of English History*); *Alfred the Great and William the Conqueror*; *Old Stories from British History*; *History of England to 1509*; and other historical essays and pamphlets, including articles in the *Encyclopædia Britannica*, and in the *English Historical Review*, *National Observer*, *Manchester Guardian*, and other English journals, historical and literary. F. Sturges Allen.

Powell, Maud: violinist; b. in Peru, Ill., Aug. 22, 1868, and began the study of the violin in Chicago when eight years old. When twelve years old she was taken to Europe, spending a year each in Leipzig, Paris, Berlin, and London. Her first public appearance on her return was in New York at a Philharmonic Society concert, in Oct., 1885. Since then she has been constantly playing all over the U. S.
D. E. Hervey.

Power, Polyphase Transmission of: Power may be transmitted by the pumping of water, to be used for water-motors. By using great pressure, a given amount of power may be transmitted by a small quantity of water; to carry this small quantity of water small pipes suffice, and small pipes are cheap. Similarly, a given amount of power may be transmitted over a small wire carrying a small electric current under high electric pressure. The electrical problem is complicated, however, by the fact that the use of high electric pressures involves more or less risk to life and property, and it is therefore expedient to transform the transmitted electrical power so that the inexpert user may be supplied with large electric current at low pressure.

The advantage of alternating current for power transmission lies in the fact that the alternating-current machinery needed for the transformation of a given amount of power from small current and high pressure to large current and low pressure, or *vice versa*, is simpler and cheaper to construct and to operate than the machinery required to accomplish the same result with constant current, or direct current, as it is called. When the transmitted power is to be used solely for lighting, simple alternating current is entirely satisfactory. When the transmitted power is to be used wholly or in part for motive purposes, simple alternating current is not satisfactory, for the reason that a good self-starting motor using simple alternating current can not at present be made.

The employment of alternating current for motive purposes depends upon the use of the so-called *induction motor*. This type of motor needs to be supplied with two or more independent alternating currents transmitted over three or more distinct wires. The use of two or more independent alternating currents in this way is called *polyphase transmission*. When two alternating currents are so used the arrangement is called a *two-phase system*; when three alternating currents are so used the arrangement is called a *three-phase system*. The significance of the term phase will appear in the following discussion.

The Single-phase Alternator.—A dynamo for generating an alternating current is called an *alternator*. An alternator constructed to give a single alternating current is called a *single-phase alternator*; an alternator constructed to give polyphase alternating currents is called a *polyphase alternator*. The single-phase alternator consists of a multipolar electro-magnet (*the field-magnet*), of which the poles N S (Fig. 1) project inward toward the passing slots in an iron wheel, A (*the armature*), which is built up of sheet-iron stampings. An insulated wire is laid in these slots in such a way that an object moving along the wire would move up in one slot and down in the next (*up* and *down* being parallel to the shaft on which the armature rotates), and the ends of this wire are soldered to two insulated metal rings (*collecting rings*), which are fixed to the armature shaft at one end of the armature. Two metal springs (*brushes*) rub on these rings and keep the ends of the armature wire in permanent connection with the terminals of the outside circuit through which the alternating current is to be sent. The projecting poles (N S) of the field-magnet are wound with wire through which a constant current is sent from an auxiliary dynamo called the *exciter*.

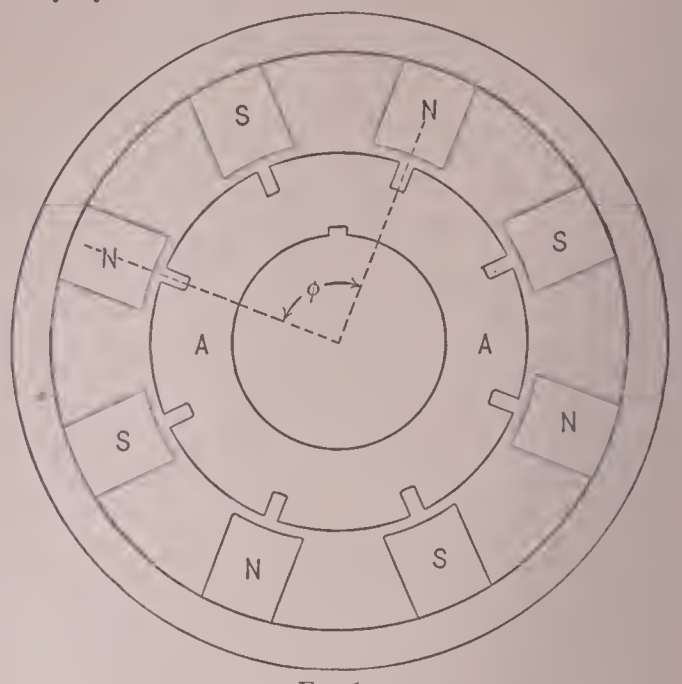

Fig. 1.

The Alternating Current.—Fix the attention on one slot of the armature (Fig. 1). As this slot passes a north pole of the field-magnet a momentary electric current is pushed in one direction through the circuit connected to the brushes; as this slot passes a south pole of the field-magnet a momentary electric current is pushed in a reverse direction through the circuit. Commercial alternators give from 50 to 300 of these reversals or alternations per second. The following geometric representation of an alternating current is useful in the discussion of polyphase systems:

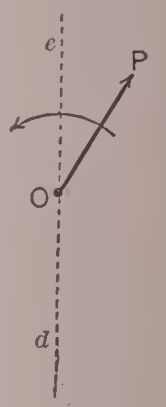

Fig. 2.

Representation of an Alternating Current.—A line, O P (Fig. 2), rotates at constant speed about the point O in the direction of the curved arrow. Consider the projection of O P on the fixed line *e d*. This projection changes value continually, being alternately up and down, or positive and negative, exactly as an alternating current. The rotating line O P thus represents an alternating current.

The Two-phase Alternator.—Consider two similar single-phase alternators, A and B, with their armatures mounted on one and the same shaft. Suppose the armature slots of A to be squarely under the field-magnet poles of this

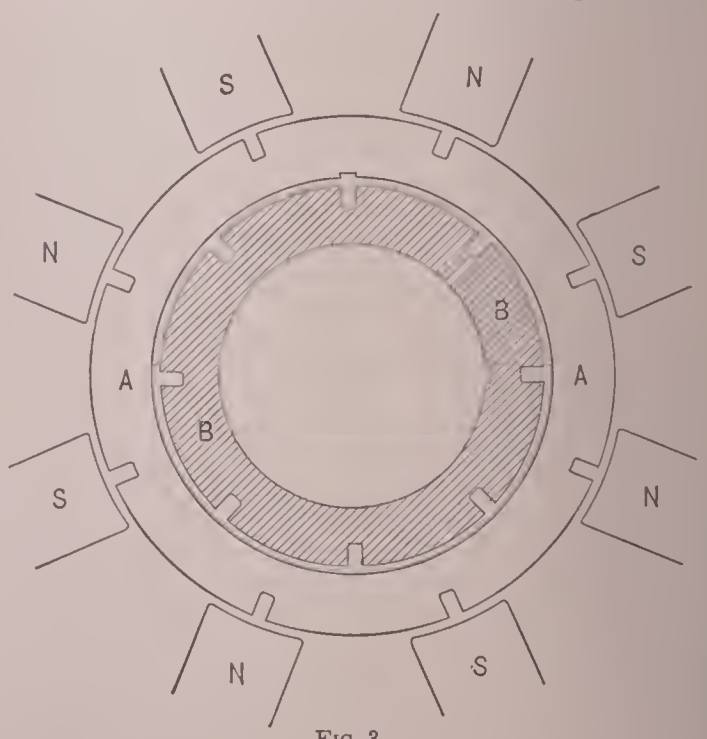

Fig. 3.

alternator when the armature slots of B are midway between the field-magnet poles of this alternator. This is shown in

Fig. 3, the armature B being drawn inside of the armature A for the sake of clearness. Under these conditions the alternating currents given by A and B are so related in their pulsations that the current from A is at its greatest value when the current from B is zero, and the current from B is at its greatest value when the current from A is zero. Two single-phase alternators connected mechanically as here described constitute a *two-phase alternator*. In practice the two-phase alternator is made by placing the armature wires of A and B in slots on one and the same armature. For this purpose the armature has twice as many slots as in Fig. 1, the A winding is placed in slots 1, 3, 5, 7, etc., and the B winding is placed in slots 2, 4, 6, 8, etc.

The four collecting rings are placed at one end of this compound armature, one pair of rings serving for terminals of winding A, and the other pair serving as terminals of winding B. The two-phase alternator has in general four collecting rings and four transmission lines. Fig. 4 is an

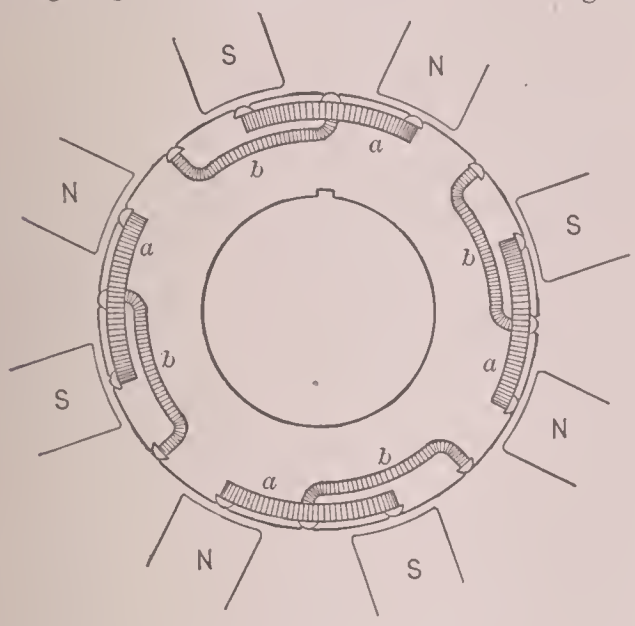

Fig. 4.

end view of a two-phase alternator showing armature windings in place. The two sets of windings are indicated by the letters *a* and *b*.

Representation of Two-phase Currents.—Two lines, O A and O B (Fig. 5), at right angles to each other, rotate at constant speed about the point O in the direction of the curved arrows. Consider the projections of O A and O B on the fixed line *e d*. The projection of O A is a maximum when the projection of O B is zero, and *vice versa*, exactly as the two alternating currents given by a two-phase alternator. The rotating lines O A and O B thus represent the two-phase currents.

The Three-phase Alternator.—Consider three similar single-phase alternators with their armatures mounted on one

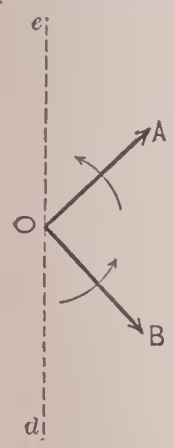

Fig. 5.

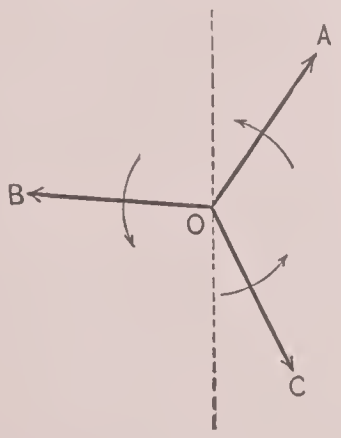

Fig. 6.

and the same shaft. Designate these alternators by the letters A, B, and C. Let ϕ be the angle at the center of the shaft subtending two slots, as shown in Fig. 1. Let the armature slots of each alternator be numbered 1, 2, 3, etc., in succession. Suppose slot No. 1 on B is $\frac{1}{3}\phi$ ahead of slot No. 1 on A, and that slot No. 1 on C is $\frac{2}{3}\phi$ ahead of slot No. 1 on A. Then the three alternators constitute a *three-phase alternator*, and the three alternating currents given by these three alternators will be represented by the projections on *e d* of the three lines O A, O B, and O C (Fig. 6), these lines being 120° apart, and all of them rotating at the same speed in the direction of the curved arrows. In practice the three-phase alternator is made by placing the windings of A, B,

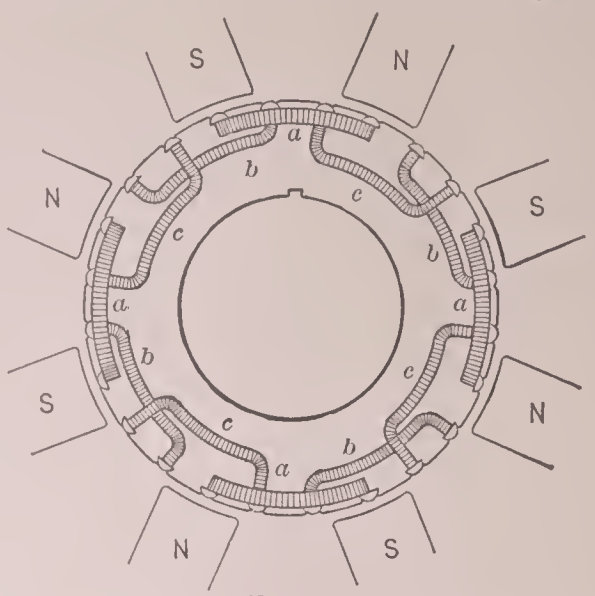

Fig. 7.

and C on one and the same armature body. This practical arrangement is shown in Fig. 7, in which the three sets of windings are indicated by the letters *a*, *b*, and *c*. Three collecting rings, three brushes, and three transmission lines are sufficient for the three-phase alternator, as shown in Figs. 8 and 9. In these figures A, B, and C represent the three armature windings and the points 1, 2, and 3 represent the three collecting rings. Fig. 8 shows what is called the Δ-scheme of connection, and Fig. 9 shows what is called the Y-scheme of connection. The Δ-scheme is clearly enough shown in Fig. 8. In the Y-scheme one end of each winding is connected to a collecting ring, and the other ends of the three windings are connected together as shown at *n*. Corresponding to these two schemes for connecting the three armature windings to the mains (connections made of course by means of brushes on the collecting rings) there are two schemes for connecting to the mains three circuits, A, B, and C, which are to receive current from three-phase mains. These two schemes for connecting receiving circuits are likewise indicated by Figs. 8 and 9.

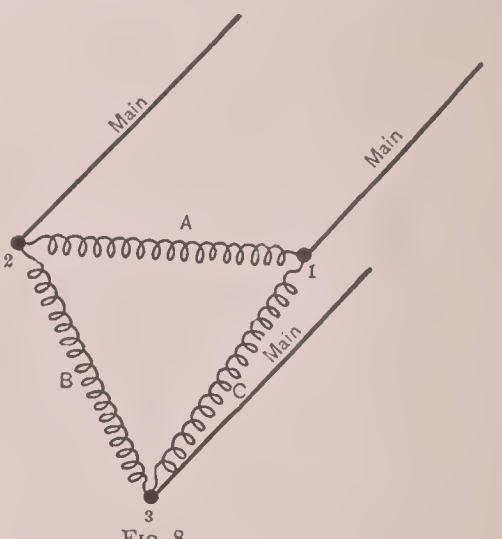

Fig. 8.

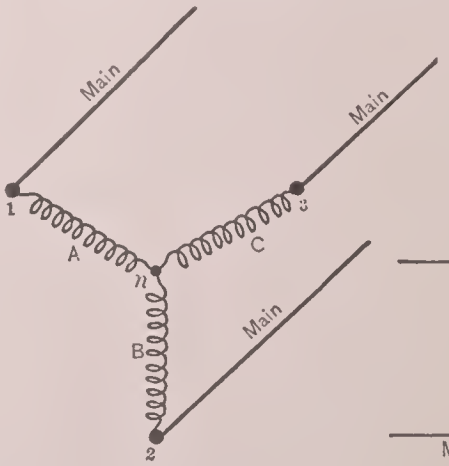

Fig. 9.

The Single-phase Transformer.—The single-phase transformer consists of two distinct and separate coils of wire, a primary and a secondary, wound on the same iron core. One

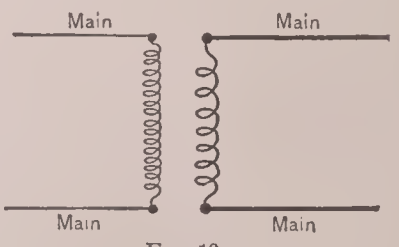

Fig. 10.

of these coils is made of many turns of fine wire, and the other of few turns of coarse wire. When a large alternating current is pushed through the coarse-wire coil by low electric pressure the fine-wire coil gives out a small alternating current at high electric pressure, or *vice versa*.

The actual power given out from the one coil is 97 per cent. or more of the power taken in at the other coil. In connection diagrams the single-phase transformer is indicated as in Fig. 10, in which the heavy lines represent the low-pressure mains and the fine lines represent the high-pressure mains.

Step-up and Step-down Transformers.—It is not convenient to generate in the polyphase alternator itself the very high electrical pressures used for long-distance transmission, on account of the difficulty of sufficiently insulating the armature windings. Polyphase generators are therefore usually constructed to give large currents at low pressures, and the power thus developed is transformed to small current at high pressure by means of the *step-up transformer*, and at the receiving-station the power is transformed from small current at high pressure to large current at low pressure by means of the *step-down transformer*, which is similar in every respect to the step-up transformer. The simplest arrangement is to transform each phase independently by means of a single-phase transformer. Thus Fig. 11 shows the arrangement of two single-phase transformers for step-up or step-down of two-phase currents. Fig. 12 shows the arrangement of three single-phase transformers for step-up or step-down of three-phase currents; A, B, and C are the three single-phase transformers, the points *h h h* are the three high-pressure mains, and the points L L L are the three low-pressure mains.

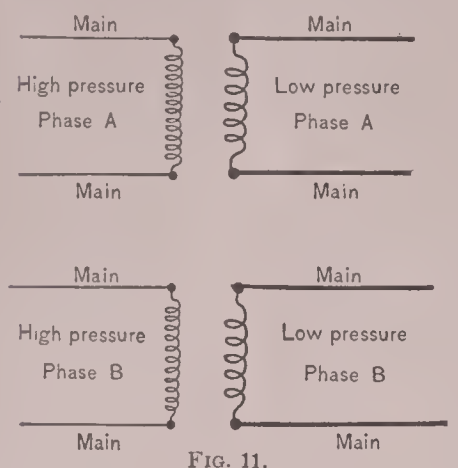

Fig. 11.

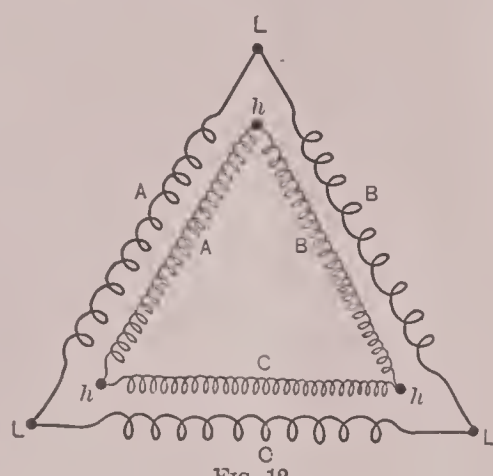

Fig. 12.

The Transmission Lines.—The electrical problems involved in the design and construction of transmission lines are comparatively simple. The larger the wire the greater the initial cost, and the smaller the wire the greater the continuous loss of power due to heating. The size of the wire is so determined that neither the cost nor the continued loss may be excessive. The line is insulated by supporting it on porcelain or glass insulators of large size and great thickness, or, if the line is to be laid underground, it is insulated by a rubber compound and incased in lead. The line is protected from lightning by much the same means as are employed for the protection of city lighting and power circuits. When the electrical pressure is raised to about 60,000 volts or more (this pressure is between the outgoing and incoming wires of each phase) considerable electrical leakage takes place from wire to wire through the air. This leakage produces a great loss of power.

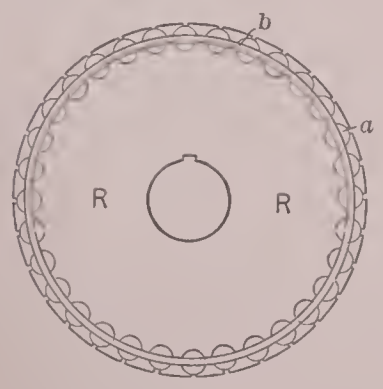

Fig. 13.

The Induction Motor.—It was pointed out in the introduction that the adaptation of alternating currents to motive purposes depends upon the use of the induction motor, and that it is the requirements of this motor that have led to the development of polyphase systems of transmission.

Consider an iron wheel (R R, Fig. 13) built up of circular disks of sheet iron. In this wheel a large number of holes (*a*, Fig. 13) are bored parallel to the shaft and near to the periphery. In these holes copper rods are inserted, and the ends of these rods on each side are soldered to massive copper rings (*b*). This arrangement is called a *squirrel-cage*, and it is the rotating part of the induction motor.

Fig. 14.

Imagine this squirrel-cage to be placed between the poles of a field-magnet, as shown in Fig. 14. If this magnet is set rotating in the direction of the curved arrows, electric currents are induced in the copper rods of the squirrel-cage, and by a sort of dragging action the cage is made to rotate with the field-magnet poles. As used in the induction motor the squirrel-cage is closely surrounded by an iron ring (F F, Fig. 15) which is built up of sheet-iron ring stamp-

Fig. 15.

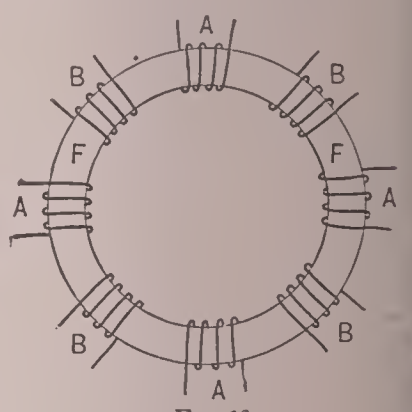

Fig. 16.

ings, and polyphase currents, passing through two or three sets of windings on F F, cause in this ring a *rotating state of magnetism*, which exactly reproduces the conditions represented in Fig. 14, and the squirrel-cage is made to rotate. The windings on F F are shown in Fig. 16. No electrical connections whatever are made with the squirrel-cage.

The following is a description of the windings on F F and of their action for the case of a four-pole two-phase induction motor. The arrangement of windings for three-phase currents does not differ materially from the windings here described.

The ring F F is wound with eight similar coils, each covering one-eighth of the circumference of the ring, as shown in Fig. 16. The four coils A are connected in series and supplied with one current of a two-phase system, and the four coils B are connected in series and supplied with the other current of the two-phase system. These coils in series are so connected that adjacent coils of one set magnetize the ring in opposite directions, as shown by the arrows in Figs. 17, 18, and 19. The manner in which the two-phase currents produce rotating magnetic poles in the iron ring F F is shown in Figs. 17, 18, and 19. Fig. 17 shows the state of affairs at the instant that the alternating current in coils A is at its maximum and the current in coils B is zero. A′ and B′ are the rotating lines of which the

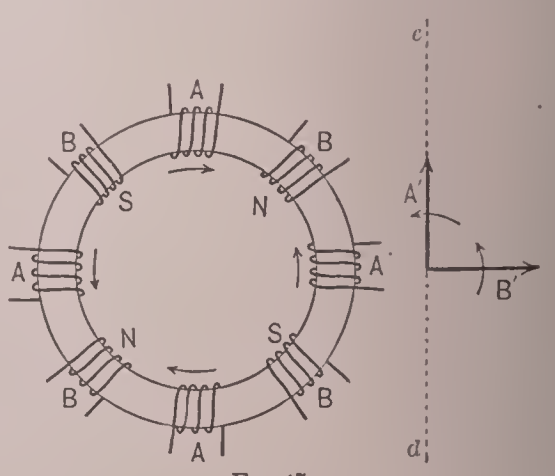

Fig. 17.

projections on the fixed line *e d* represent the varying values of the alternating currents in coils A and B respectively. Fig. 18 shows the state of affairs when the current in coils A has decreased in value and the current in coils B has increased to the same value. Fig. 19 shows the state of affairs when the current in coils A has become zero and the current in coils B has reached its maximum value, as shown by the positions of the lines A′ and B′.

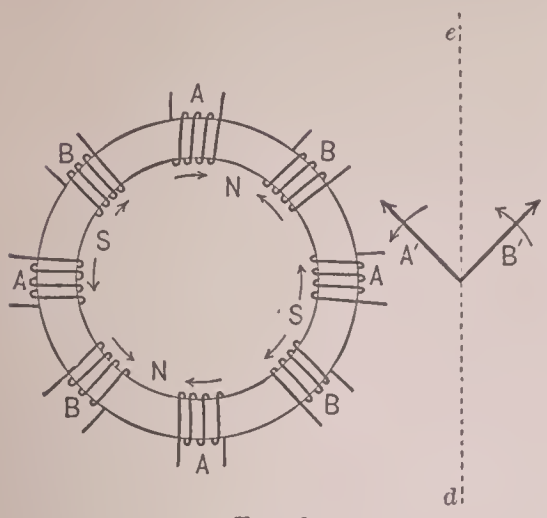

Fig. 18.

Thus from the state of affairs represented by Fig. 17 to the state of affairs represented by Fig. 19 the poles (N S) of the iron ring have moved over one-eighth of the circumference of the ring. An examination of intermediate stages would show that this movement of poles is continuous, and an examination of sueeeeding stages would show that the poles (in this case of two pairs of poles) move once around the entire circumference of the ring while the lines A′ B′ make two revolutions.

In the practical form of the induction motor the windings on the ring F F are imbedded in slots on the inner face of the ring, and instead of enveloping the ring the windings are arranged in a manner similar to the windings of a two-phase or three-phase alternate armature.

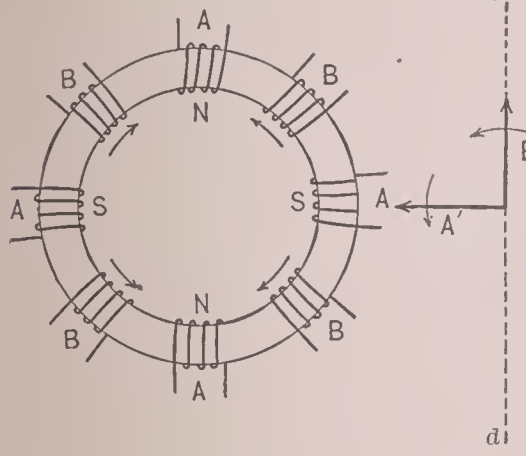

Fig. 19.

The Synchronous Motor.—Any alternating-current generator may be nsed as a motor, provided it is started by independent means, and its speed carefnlly adjusted until the pulsations of the current which it would produce as a generator are in exact unison, or synchronism with the pulsations of the supply-current,* before it is connected to the supply-mains. When once in action such a motor runs at invariable speed as its load is increased, frequency of supply-current being unchanged, and when it is overloaded to the slightest extent it comes to a standstill. A single-phase alternator may be used as a synchronous motor with single-phase current, and a polyphase alternator may be used as a synchronous motor with a supply of polyphase currents. The latter is the more satisfactory, inasmuch as the torque or turning effort is steady, while in the single-phase synchronous motor the turning effort pulsates with the supply-current. A further advantage is that with polyphase currents a small induction motor may be used to bring the synchronous motor up to speed in starting. In fact, the polyphase alternator is essentially an induction motor when running as a motor below synchronism, and will start itself, but not satisfactorily.

The Rotary Converter.—An ordinary direct-current dynamo may be made into a single-phase or polyphase alternator by providing the machine with collecting rings in addition to its regular commutator. Such a machine may be driven as a synchronous motor by supplying alternating current to the collecting rings, and its motor load may be provided by taking off direct current from the commutator. When used in this way the machine is called a *rotary converter.*

The Single-phase Rotary Converter.—Given a direct-current dynamo, bipolar or multipolar. Consider the commutator bars which, for any given position of the armature, lie midway under the north poles of the field-magnet. All of these bars are connected together, and to collecting ring No. 1; and the commutator bars which, for the given position of the armature, lie midway under the south poles of the field-magnet are connected together, and to collecting ring No. 2.

The Two-phase Rotary Converter.—Imagine the armature of a single-phase rotary converter to be turned until the commutator bars connected to collecting rings Nos. 1 and 2 are midway between the field-magnet poles. Then the collecting rings to be added to give a two-phase converter are connected—ring No. 3 to the commutator bars midway under north poles, and ring No. 4 to the bars midway under south poles of the field-magnet. Fig. 20 shows field-magnet,

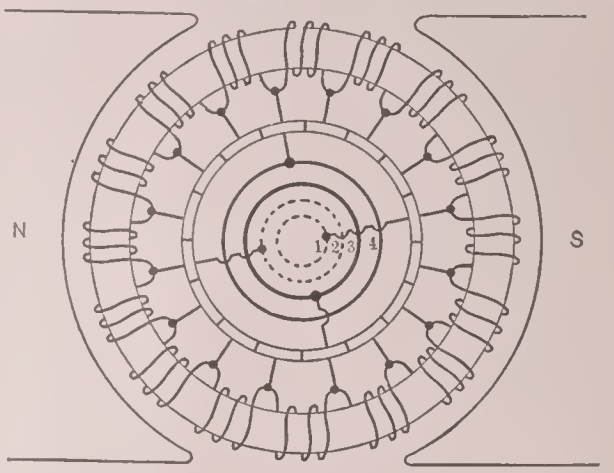

Fig. 20.

armature, and commutator of a two-pole direct-current dynamo, and indicates the connections to the four collecting rings, the addition of which to the machine adapts it for use as a two-phase rotary converter.

The Three-phase Rotary Converter.—Three collecting rings connected as follows to the commutator bars of a direct-current dynamo adapt the machine for use as a three-phase rotary converter. The commutator bars midway under N poles of the field-magnet (armature in any given position) are connected to ring No. 1. Let ϕ be the distance between adjacent bars of this set; then the bars $\frac{1}{3}\phi$ ahead of the first set are connected to collecting ring No. 2, and the bars $\frac{2}{3}\phi$ ahead of the first set are connected to collecting

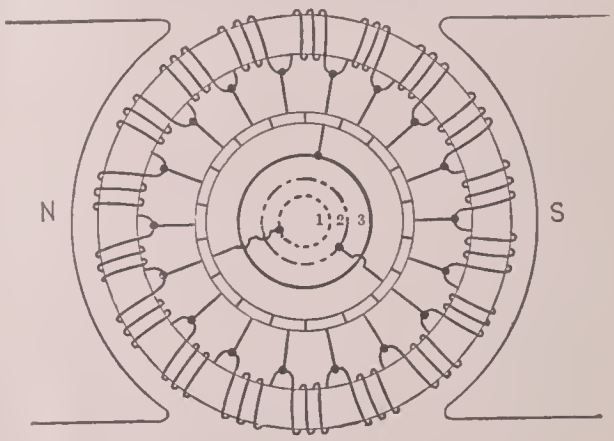

Fig. 21.

ring No. 3. This arrangement is shown in Fig. 21 for a two-pole machine.

The Use of the Rotary Converter.—The rotary converter may be used as an ordinary direct-current dynamo or motor or as an alternator or synchronous motor; or it may be run as a direct-current motor, the load being provided by taking alternating currents off the collecting rings; or it may be run as a synchronous motor, using alternating current, the load being provided by taking direct current off the commutator. This last is the principal use of the machine. Whenever power transmitted by the polyphase system is to be used in the form of direct current the rotary converter is used for bringing about the conversion. Thus in many extended electric-railway plants it is expedient to transmit power, high-pressure polyphase, from a central power-plant

* Further, the machine must be also adjusted until the *pulsations* of its E. M. F. are at each instant opposite to the pulsations of E. M. F. between the mains.

and step it down to rotary converters stationed along the line of the railway; these rotary converters supply direct current at medium low pressure to the trolley-wire.

The Phase Transformer.—In some power-plants the alternators generate two-phase currents, while for long-distance transmission three-phase currents require less copper, and are therefore preferable. In such case the step-up transformer may be arranged to take in two-phase currents at low pressure, and give out three-phase currents at high pressure. Such an arrangement is called a *phase transformer*. The following is a description of the essential features of a two-phase three-phase transformer. The lines A and B, Fig. 22, are the rotating lines of which the projections represent the alternating electromotive forces of the A and B phases of a two-phase alternator. These two electromotive forces act upon the respective primary coils of two transformers, X and Y, as shown in Fig. 23. Let the line E_1, Fig. 22, be the E. M. F. which is to act between Nos. 1 and 2 of the three-phase mains, E_2 the E. M. F. which is to act between mains No. 2 and No. 3, and E_3 the E. M. F. which is to act between mains No. 3 and No. 1. Break E_1 up into its components *a* and *b*, Fig. 22; the secondary coil *a*, Fig. 23, is wound with a number of turns sufficient to give the component *a*, Fig. 22, and the secondary coil *b* on the other transformer is wound with a number of turns sufficient to give the component *b*, Fig. 22. The coils *a* and *b* are connected in series between mains No. 1 and No. 2. Similarly the E. M. F.'s E_2 and E_3 may each be produced by a pair of secondary coils, one on each transformer.

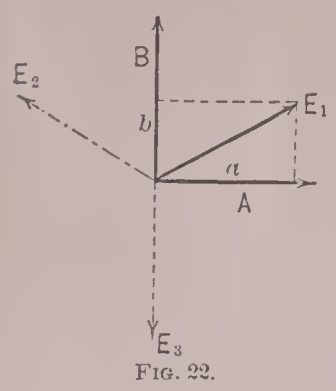

FIG. 22.

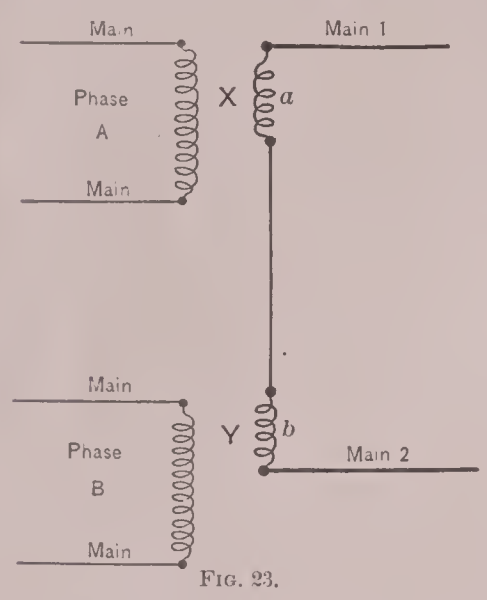

FIG. 23.

The Transmission Plant — Résumé. — The plant for long-distance transmission of power by polyphase currents consists of power-station, transmission line, and receiving-station. The power-station is provided with a prime mover, either water or steam, which drives one or more polyphase alternators, and also one or more small direct-current dynamos for exciting the field-magnets of the alternators. The alternators furnish large current at low pressure to the step-up transformers, which furnish small current at high pressure to the transmission lines. The step-up transformer may be a combination of single-phase transformers or it may be a two-phase three-phase transformer. At the receiving-station the high-pressure polyphase currents from the lines pass through the step-down transformers. These step-down transformers may supply current direct to the user at a pressure of a few hundred volts, or to a local distributing system at, say, 2,000 volts, from which individual users are supplied through additional step-down transformers.

The alternating currents furnished by these step-down transformers are at once available for glow-lamps for the manufacture of calcium carbide and carborundum; in short, for every purpose in which the heating action only of the current is important; and for driving induction motors, synchronous motors, and rotary converters. For arc-lamps, street-car service, storage-battery charging, and for chemical manufactures in general the direct current from the rotary converter is used.

W. S. FRANKLIN.

Princeton University (formerly the **College of New Jersey**): an institution of learning chartered in 1746 by the colony of New Jersey. Its first sessions were held in Elizabethtown in 1747, under President Dickinson. In 1748 it obtained a very liberal charter from Gov. Belcher, and was removed to Newark under the presidency of Aaron Burr (1748–57), who remained at its head until after the institution had been finally located at Princeton in 1757. The famous Jonathan Edwards was its president for part of the year 1758. There were two other presidents in the colonial period—Samuel Davies, who held the office for two years (1759–61), and Samuel Finley, for five years (1761–66). The troubled times of the Revolutionary period saw John Witherspoon in control (1768–94). The influence of this sturdy patriot was often felt in the councils of the struggling nation. He and two of the alumni of the college, Richard Stockton and Benjamin Rush, signed the Declaration of Independence. The next four presidents, Samuel Stanhope Smith (1795–1812), Ashbel Green (1812–22), James Carnahan (1823–54), and John Maclean (1854–68), represent another period in the history of the college as well as of the nation.

During this period Princeton was highly respected as an institution of learning. Its professors were men of sterling character and of wide reputation, and many of its alumni attained eminent positions in every sphere of life. These were the days when the college, as such, filled a high place in the educational system of the country.

The university spirit, however, was moving abroad at the close of this period, and contemporary Princeton felt its broadening influence first under the presidency of James McCosh (1868–88). Under his administration great strides were made in the development of the institution, both intellectually and materially. It was reserved for his successor, Francis Landey Patton, the present incumbent of the office of president, to realize what had been the ideal of his predecessor. On the occasion (1896) of the one hundred and fiftieth anniversary of its foundation, what was formerly the College of New Jersey became Princeton University.

Many munificent gifts, both by generous friends and alumni, have placed handsome buildings upon its campus, and have increased its corps of instructors and added to its appliances, until it represents a logical and healthful growth around the historic nucleus of the one handsome building which well fulfilled every need of the college in 1756.

The John C. Green School of Science and its associated buildings for the chemical and electrical departments provide for the work involved in technical training, as contrasted with the classical courses of the academic department. The main building provides accommodation for the physical, botanical, and engineering laboratories, as well as lecture-rooms for these departments and many others. Properly lighted rooms are secured for the classes in technical and free-hand drawing. The chemical department has recently been equipped with a building wholly devoted to its own uses. This laboratory was constructed after a careful study of the leading chemical laboratories of the world had been made, with a view to combining every advantage in structure to be derived from experience.

The electrical engineering department is provided with two buildings. One of these is devoted to the study of dynamos, their construction and application, and is connected with the machine-shop of the School of Science. The other, where the more technical and theoretical work is done, is located at a distance from all disturbing influences.

The academic and scientific courses of study are completed in four years, and lead to degrees in arts and letters, science, and engineering, both civil and electrical. The curriculum is arranged with the view of giving a broad liberal culture as a basis for any professional career. The graduate courses represent the university work of the institution, and lead to the higher degrees of master and doctor. The undergraduate years are occupied with required classroom work in the first portion. To these are added series of lecture courses, which gradually become so numerous as to afford large series of logically co-ordinated elective studies in the two closing years. At the present time there are in the academic department 42 required courses, 139 elective courses, 77 graduate courses, and 6 optional courses.

In the scientific department there are many courses of study, taken either with the academic classes or in parallel, and in addition there are 64 required technical courses, with 20 elective studies given only to scientific students. The course in electrical engineering is a graduate course occupying two years. At the present time (1899) there are 128 graduate students and 4 in electrical engineering. There are 633 academic and 334 scientific undergraduates, making a total enrollment of 1,099. In 1900, 1,302.

The governing body of Princeton is a self-perpetuating board of trustees, consisting of the Governor of the State, the president, and 25 members. The faculty, which has immediate control of the institution, consists (1900) of 59 professors and 9 assistant professors, together with 22 instructors and tutors and 13 fellows.

The expense of an education at Princeton ranges from $200 to $600. The institution possesses more than a hundred endowed scholarships and 11 fellowships, 6 of which are open to undergraduates, and, in addition, there are awarded each year 32 prizes for successful competition in various departmental examinations.

The library offers especial facilities for study. The Chancellor Green Library building has been refitted as a consulting library, where about 40,000 standard works, including the latest publications and periodicals, are accessible from 8 A. M. to 10 P. M. The new building has capacity sufficient to shelve 1,200,000 volumes, and includes the administration rooms, 15 rooms for seminary work, and a large room for the exhibition of rare books. The building is thoroughly equipped with all the latest modern improvements in heating, ventilation, stacks, elevators, telephones, etc. The general collection of books in this building consists of more than 110,000 volumes and 35,000 pamphlets, besides many special collections of great value. There are several technical libraries which are located in connection with the laboratories or observatories. These include books on astronomy, biology, botany, and geology. There are about 200,000 volumes in all, accessible to the students. There are three museums connected with the institution: (1) geological and archæological; (2) biological; (3) historic art. All of these have extensive collections which have been carefully arranged and are accessible at all times.

There are nine laboratories in which scientific work is done: (1) psychological; (2) physical; (3) electrical engineering; (4) chemical; (5) mineralogical; (6) histological; (7) biological; (8) paleontological; (9) civil engineering.

In addition to these there are two observatories. One of these is devoted to the work of investigation, mainly in the department of astronomical physics. It is furnished with an equatorial telescope of 23 inches aperture and 30 feet focal length, which is provided with all the usual micrometric and spectroscopic accessories. The other observatory is devoted to the purposes of instruction. It possesses an equatorial of 9½ inches aperture, a meridian circle, transit instruments, prime vertical, chronograph, two standard clocks, and all the subsidiary apparatus required for carrying out the work involved in the courses on practical astronomy.

There are 32 buildings on the campus of the university, which covers about a square mile of ground on the south side of the main street of the town near its central portion. Twelve of these buildings are dormitories, which, however, accommodate only about three-quarters of the students. Among the more noticeable of the remaining buildings are the following:

Alexander Hall, a very handsome building, is used for public exercises, lectures, and university gatherings of a general character. Both the exterior and interior of this structure are very ornate, being richly decorated with carvings and mosaic.

The infirmary was built to meet the demand for the proper care of the students who might be taken ill at any time. It contains all the modern arrangements of the best hospital construction. The building is under the charge of the sanitary committee of the university. The students pay a small fee, for which they obtain in all cases of ordinary sickness every needed care.

The Halls, under which name the two literary societies of the institution are generally known, originated early in the history of the university. They are conducted by the undergraduates, and occupy handsome marble buildings which are not only an ornament to the campus, but which serve the purpose of providing the necessary rooms for the meetings of the societies. Each hall possesses a valuable library of more than 10,000 volumes. They conduct courses of literary exercises, and award numerous prizes for orations, essays, and debates.

The religious interests of the institution are provided for by the chapel exercises and the meetings of the Philadelphian and St. Paul's Societies. A broad evangelical spirit is cultivated, and sectarianism is not favored. The Philadelphian Society was founded in 1825, and is therefore one of the oldest societies of this character in the U. S. It has a building of its own, containing a hall for general meetings and a reading-room.

The university athletic grounds are ample and complete in all their appointments. Within the inclosure are a large winter practice-house, a house containing the dressing-rooms, a large grand stand, besides a club-house for the use of the athletic teams. These grounds are used for intercollegiate games of all sorts, while the Brokaw field and its memorial building, containing a swimming-pool, serve as the general playground for the students.

The fortunate location of Princeton, midway between the great cities of New York and Philadelphia, in a town where everything is largely subordinate to the interests of the university, gives it exceptional advantages. While quite near enough to these cities to give easy access, none of their disturbing distractions are felt. In addition, the university is of necessity, from these same conditions, forced to be a cosmopolitan rather than a local center of learning.

WILLIAM LIBBEY.

Pritchett, HENRY SMITH, Ph. D.: astronomer; b. in Fayette, Mo., Ap. 16, 1857; educated at Pritchett College, Glasgow, Mo., and in 1876 went to Washington to continue mathematical and astronomical studies under Prof. Asaph Hall in the U. S. Naval Observatory. Two years later he was appointed assistant astronomer in the Naval Observatory, but resigned in 1880, and spent a year in the Morrison Observatory in Glasgow. In 1881 he was called to the chair of Astronomy in the Washington University, St. Louis, where he remained until his appointment as superintendent of the Coast and Geodetic Survey in 1898. He was a member of the party that went to Auckland, New Zealand, to observe the transit of Venus in 1882, and on the completion of that work he served as acting assistant on the Coast and Geodetic Survey, accompanying the party that visited Australia, Singapore, Japan, and elsewhere, sent to determine gravity with the Koter pendulums. In 1894 he visited Europe, and at that time received the degree of Ph. D. from the University of Munich. His scientific investigations have not been confined exclusively to astronomy, but he has also paid considerable attention to physics and geodesy. In connection with the latter he determined latitudes for the U. S. Geological Survey, and he also participated in the longitudinal determinations with parties from both the U. S. Geological and the U. S. Coast Surveys. Dr. Pritchett is a member of numerous scientific societies, and was in 1891 president of the St. Louis Academy of Sciences. He is the author of many scientific papers, the more important of which are the following monographs: *Determination of the Mass of Mars* (1878); *The Rotation Period of Jupiter* (1880); *A Formula for Predicting the Population of the United States* (1890); *Report on the Total Eclipse on Jan. 1, 1899* (1892); and *Eclipses of the Satellites of Saturn* (1899).

MARCUS BENJAMIN.

Private Road: a popular and quasi-legal designation for a roadway or passage overland for horses and teams which is open to the public, but the ownership of which is vested in private parties. Such private roads or streets are in general governed by the same laws which apply to any private property, except for the rights of the public arising from the fact that they are thrown open so as to give an implied invitation to the public to use them. As a result of this implied invitation, there may be implied duty upon the owners to keep it in reasonably safe condition for the public to use in the way in which it is apparently intended to be used, so that if this is not done any person receiving injury may have a right of action against the owner of the property for damages so sustained.

The matter is frequently regulated by public statute, providing for or requiring the erection of notices to the public that the road or street is a private road, in which case parties using it do so at their own risk of injury or damage. The government or municipality also has the power to regulate and control such roads, and may prescribe the way in which they shall be paved, sewered, and lighted, and impose upon the abutting owners the duty of complying with the regulations made for this purpose. Such a road may become a highway by use and occupation under the law of prescription, or by virtue of an expressed dedication, or by an implied dedication arising out of the manner in which the property is thrown open to the public and used by them. In the absence, however, of the enforcement of any such right by the public, such road may be closed or fenced in at the pleasure of the owner or owners, or parties having rights

or interest in it, in the same manner as any other private property. See Highways. F. Sturges Allen.

Probate Courts: This term is used to designate certain courts in England and in the U. S. which have jurisdiction and control, more or less extensive, of the probate of wills and the regulation of the management and settlement of the estates of decedents, and also the control of the estates of minors and other persons reckoned to be incompetent at law. In Great Britain, up to a very recent date, this jurisdiction was largely vested in the ecclesiastical courts, and was actually administered to a certain extent by the surrogate, or the deputy or substitute of the ecclesiastical judge, whence arises the American use of the term surrogate courts, to designate courts having essentially the same jurisdiction as those elsewhere called probate courts.

In England in 1857, by a statute (20 and 21 Vict., ch. 77), a new tribunal was established, called a court of probate, upon which was conferred the jurisdiction formerly exercised by the ecclesiastical and manorial courts over decedents' estates, and the ecclesiastical courts were deprived of their power to grant or revoke letters of administration. The new court of probate was given jurisdiction in testamentary cases, both in voluntary cases and in cases of legal contention, and had jurisdiction throughout all England. The law of England was further modified by the act of 36 and 37 Vict., ch. 66, of 1873, known as the Supreme Court of Judicature Act, which united and consolidated all the courts then existing so as to constitute one supreme court of judicature in England. By section 16 of this act the jurisdiction of the court of probate was transferred to the high court of justice, and this jurisdiction was declared to include all the jurisdiction which at the commencement of the act was vested in or capable of being exercised by the judges of the several courts of probate, sitting in court or in chambers or elsewhere, when acting as a judge or judges in pursuance of any statute, law, or custom; and they were declared to have the powers which were given to such court or to any such judge or judges by any statute, and also all ministerial powers, duties, and authorities incident to the jurisdiction conferred.

Where there is no dispute as to the grant of probate or letters of administration under the present law the grant is made in what is called "common form," either in the principal registry in London or in the district registries which were created throughout England and Wales. Where there is a contention the questions of probate or granting of letters of administration are determined judicially, in what is called "solemn form," in the court of probate, except where the estate does not exceed a certain amount, in which case the county courts have jurisdiction.

In the English colonies of America the probate jurisdiction of the ecclesiastical courts of England was vested in the minor civil courts, which followed the precedents and principles of the spiritual courts of England, modified by the special history or circumstances attending the formation of the colony. Thus in the colony of New York, which was Dutch in its origin, the probate jurisdiction of the courts was governed by the Dutch Roman law, the custom of Amsterdam, and the law of Aasdon, and was exercised by a tribunal of members of the colonial council; afterward, from 1653 to 1655, by the court of burgomasters and schoppens, and then by the court of orphan masters, and, after the occupation of the province by England, by the mayor's court. It was afterward vested in the court of common pleas, the successor of the mayor's court, and subsequently was, and now is, exercised by the surrogate's court, created by statute.

In England, and in many of the Eastern States of the U. S., each county has a court of probate; in other States, including Pennsylvania, in each county there is what is known as an orphans' court, while in other States, including Kentucky and some other Western and Southern States, the probate jurisdiction is vested in the county court. In still other States probate jurisdiction is vested in the clerks of the ordinary civil courts, either wholly, as in North Carolina, or during vacation, as in Indiana and elsewhere.

Generally speaking, the probate court has jurisdiction over the administration of an estate of the decedent if his domicile at the time of his death was within the limits of the jurisdiction of the court, the question of domicile here being a mixed question of fact and of law. (See Domicile.) For the purpose of such administration the decedent's estate is considered to be situated at the place of his domicile, but the control and administration of his estate is under the administration of the court within whose jurisdiction the estate is situated.

In England, prior to the act of 1857, above mentioned, a distinction was made between wills of personal and real property, it being held that wills of real property or both real and personal property must be probated, but that the probate of wills of personal property only was unnecessary and improper. Subsequent to the act of 1857, however, all papers of a testamentary character were required to be probated in England, as they are in the U. S., where no distinction is made between wills affecting personal and wills affecting real property. Papers not executed and attested according to law, such as letters, memoranda, etc., are not of a testamentary nature, and need not be probated: but where a paper is referred to in a properly executed will, and contains directions as to the disposition to be made of the executor's estate, it should be probated with the will. A properly executed paper merely appointing an executor, without making any disposition of the decedent's estate, is held to be a will, and is held to be proper and necessary to be probated.

The duties and privileges of executors, heirs, devisees, legatees, and other persons having rights under or by virtue of a will, and the procedure for the probate of wills and letters testamentary, is particularly regulated by statutes which should be consulted for their specific provisions.

Prothero, Rowland Edmund: English lawyer and historian; b. in Clifton-on-Terne, Sept. 6, 1852, son of Rev. Canon Prothero, of Whippingham; received his education at Marlborough and at Baliol College, Oxford; was fellow of All Souls College, Oxford, 1875–91, and proctor 1883–84; he studied law and was called to the bar, but has devoted himself chiefly to historical and critical literature, and he is now (1899) editor of the *Quarterly Review*. Besides numerous contributions to the reviews and monthly periodicals, he has published *Pioneers and Progress of English Farming* (1887); *Life and Correspondence of Dean Stanley* (1893); *Letters and Verses of Dean Stanley* (1895); *Letters of Edward Gibbon* (1896); revised Mr. Holmes's *Life of Queen Victoria* (1897); and *Letters and Journals of Lord Byron* (vols. i. and ii., 1898). F. Sturges Allen.

Prowse, Daniel Woodley, LL. D.: b. in Newfoundland in 1834; after a course of education at the Church of England Academy at St. Johns, Newfoundland, the collegiate school at Liverpool, England, and King's College, Windsor, Nova Scotia, he read law and was called to the bar of Newfoundland in 1858; was made queen's counsel in 1870; he was a member of the Legislature 1861–69 for Burgeo and La Poile; was appointed judge of the central district court in 1869, and served as a member of the commission for the consolidation of colonial laws; was chairman of the board of health 1893–96. He is chiefly known for his *History of Newfoundland* (1895), besides which he has written for the periodicals and also a *Manual for Magistrates in Newfoundland* (2d ed. 1898). F. Sturges Allen.

Prume, François Herin Jehin: violinist; b. in Spa, Belgium, Apr. 18, 1839, the son of a distinguished painter, and nephew of François Prume, violinist, and Joseph Prume, an artist of repute. He began his studies at the age of four years, from his uncle François. When twelve years old he took first prize at the Brussels conservatory for playing, and at fifteen he gained first prize for harmony. At sixteen he began his career as a virtuoso, and for many years had uninterrupted success in his concert tours. He followed Emperor Maximilian to Mexico in 1864, and then visited Cuba and the U. S. under the management of Strakosch, achieving great success in New York in 1865. He settled in Montreal, where he died May 29, 1899. D. E. Hervey.

Putnam, George Haven: publisher and author; b. in London, England, Apr. 2, 1844; studied at Columbia College in 1860 and in Göttingen 1861–62, leaving college to enter the U. S. army during the civil war, in which he became brevet major: was appointed deputy collector of internal revenue in 1866, and in the same year became a publisher in New York city, later becoming head of the firm of G. P. Putnam's Sons: has served on executive committees of the Free Trade League, the Reform Club, the Civil Service Reform Association, and as secretary of the American Publishers' Copyright League. He has published *Authors and Publishers* (1875); *Literary Property* (*Lalor's Cyclo-*

pædia, 1879); *Authors and their Public in Ancient Times* (1893); and edited *The Question of Copyright* (1891).

Pyle, Howard: artist; b. in Wilmington, Del., Mar. 5, 1853; studied art in Philadelphia, and after a brief residence in New York city returned to Wilmington, where he has since resided, being chiefly engaged in book and magazine illustration. Some of his publications, for which he made the drawings, are *The Merry Adventures of Robin Hood* (1883); *Pepper and Salt* (1885); *Within the Capes* (1885); *The Wonder Clock* (1887); *The Rose of Paradise* (1887); and *Otto of the Silver Hand* (1888).

Queens, Borough of: one of the boroughs of the city of New York as constituted under the charter of Jan. 1, 1898. It includes the former Long Island City, the former towns of Newtown, Flushing, and Jamaica, and part of the old town of Hempstead, which territory constitutes Queens County, that part of old Queens County not taken into the new city having been formed into the new Nassau County. Pop. (1900) 152,999. For the new government, see New York, City of, in the Appendix.

Quick, Robert Hebert, M. A.: educator; b. in London, Sept. 20, 1831. His father was a merchant of considerable fortune, so that the son did not have the stimulus of the knowledge that he must depend upon his own resources for a livelihood. He was fitted for the university mainly by private tutors, though he had a brief term at Harrow, and completed his education at Trinity College, Cambridge. He took orders and was for a time curate at St. Mark's, Whitechapel. He then studied in Germany. Returning, he took up his clerical duties again, but in another church. In 1858 he went again to Germany, and on his return, in May, took a position in the Lancaster grammar school. Early in 1859 he again went to Germany, and in the summer of that year accepted the mathematical mastership at Guilford grammar school. He taught in several other schools, and finally, in the autumn of 1869, accepted a mastership at Harrow, having in the meantime published his great work, *Educational Reformers*, in 1868. In 1874 he resigned his position at Harrow. In 1876 he started a school of his own at Orme Square. In 1879 he was appointed to give a course of lectures on the history of education for the Teacher's Training Syndicate at Cambridge. These lectures he continued until 1883. He was rather disappointed with them, and says that no one in the university had the slightest interest in the subject, or cared anything about it. His audience at his first lecture was made up mainly of young ladies from Newnham and Girton. In 1881 he gave up the day school in Orme Square and a little later started a private boarding-school at Guilford, the attendance at which never reached more than six. In 1883 he accepted the living at Sedbergh, where he remained until 1887. On resigning at Sedbergh, he settled at Redhill, near London, where he passed the remainder of his life. He died Mar. 9, 1891, while on a visit to his friend, Prof. Seeley, at Cambridge. Few books on education have been more widely read and more generally commended than his *Educational Reformers*, first published in 1868 and in a revised and enlarged edition twenty-five years later. The book achieved its first success in America. It was many years after publication before the English edition of five hundred copies was disposed of. For many years Mr. Quick was the most eminent authority on educational questions in England, and almost the only English writer on education in England of international reputation. His theories found wide acceptance, and he had special skill in interpreting the views of other writers on educational questions. It can not be said, however, that he was himself a successful teacher, a criticism which can be made on most of the educational reformers; but through his writings he probably did more than any one else to encourage the development of the professional spirit among English teachers. See *Life and Remains of the Rev. R. H. Quick*, edited by F. Storr (1899).

C. H. Thurber.

Rachmaninoff, Sergei Wassiliewitch: pianist; b. in Novgorod, Russia, in 1873, and a pupil of Arenski (theory) and Siloti (piano) in the Imperial Conservatory of Moscow, where he received the great gold medal. He belongs to the Neo-Russian school. Several of his compositions were played by Siloti in his tour of the U. S., in 1897–98. Besides works for the pianoforte, he has composed a trio in D minor dedicated to the memory of Tschaikowski. He made his first appearance as a pianist in London in the spring of 1899.

D. E. Hervey.

Radiation: the process by which energy in the form of wave-motion of the luminiferous ether is sent out from the surface of bodies. Radiation is the most important of the three ways in which heat energy is transferred from place to place (radiation, convection, and conduction). The fact is now completely established that the waves with which we have to deal in radiation are in all cases identical in character with those to which the phenomena of light are due. Light-waves and the so-called heat-waves travel at the same velocity and are equally capable of reflection, refraction, dispersion, polarization, diffraction, and interference. There is, indeed, no criterion by which these two classes can be separated one from another save that of wave-length. A certain group of waves only, the lengths of which lie between narrow and well-defined limits and are all contained within a single octave, are capable of affecting the retina, and thus arousing the sensation of light, but all waves in the ether require energy for their production, carry energy with them in their course through space, and when destroyed deliver energy at the point where the wave-motion ceases.

Units of Wave-length.—There are three distinct systems for the expression of wave-length in common use:

(*a*) Spectroscopists, who have to do, primarily, with the visible spectrum, adopt as their unit the *tenthmeter* or Ångström unit, which is 10^{-10} meters or 10^{-8} cm.

(*b*) Students of radiation in the broader sense usually express their results in microns (μ). The micron is one millionth of a meter or 10^{-4} cm. The change from one of these systems to the other is made by shifting the decimal point four places. Thus the wave-length of the yellow light of the sodium flame (D_1) is 5,896·0 Ångström units or 0·5896μ.

(*c*) Hertzian Waves (*q. v.*), which are identical with the waves with which we have to deal in the study of radiation, but of greater length, are usually expressed in centimeters.

In this article all wave-lengths will be given in microns.

The Range of Known Wave-lengths.—The waves which constitute the visible spectrum—i. e. which are capable of affecting the retina—all lie approximately between 0·39μ (extreme violet) and 0·77μ (extreme red). The shortest wave-length thus far actually measured is, however, only 0·1μ, while the longest is 61·0μ. There is every reason to believe that waves much shorter than these on the one hand and longer on the other exist. Becquerel rays* or Uranium Rays (*q. v.*) are very generally thought to be identical with the waves due to ordinary radiation, but of exceedingly short wave-length, and the Röntgen rays (or X-Rays, *q. v.*) are placed by many authorities in the same class. As regards long waves, it should be noted that Rubens and Nichols† predicted with confidence the existence of waves of much greater length than those measured by them (24μ), and indicated definitely the way in which they may be produced. At the time of writing their memoir, however (1897), they had not succeeded in isolating and identifying them. In 1899 Rubens and Aschkinass,‡ by a new and ingenious method to be described later, obtained these waves and found their length to be, as predicted, respectively 51μ and 61μ.

Hertz waves, to which reference has been made in a previous paragraph, and which owe their existence to electrical oscillations, depend as to wave-length upon the size of the apparatus. The mechanical difficulties in producing very short waves are great, but Ledebew§ has succeeded in reducing the wave-lengths to 0·3 cm. (3,000μ). Longer waves (up to wave-length = infinity as a limit) are readily producible at the will of the experimenter.

Of this great series of wave-lengths only those which lie between the narrow limits of the visible spectrum can be studied directly by optical methods. The far greater class, the wave-lengths of which exceed 0·77μ, can be detected most readily by means of their thermal action. The energy, fortunately for such investigations, increases rapidly with the wave-length, so that while it is exceedingly difficult to make thermal measurements in the neighborhood of the violet end of the visible spectrum, indications are more easily obtained in the red and in the infra-red. As for those wave-lengths which lie beyond the violet (the ultra-violet), the energy is almost without exception too small to be measured. There are, it is true, a few isolated instances

in which the heating effect of a very brilliant group of waves like those which are found in the spectrum of the arc-light have been shown by means of apparatus of extraordinary delicacy, but were our knowledge of this region confined to that which could be determined by the heating effect it would be very slight. Fortunately, these shortest waves are of great actinic power, so that the photographic plate enables us to study the ultra-violet spectrum in great detail.

It is not many years since the wave-lengths represented in ordinary radiation were divided into three distinct groups: the so-called actinic rays, the visible rays, and the dark-heat rays. It has only gradually been made evident that, as has already been stated in a previous paragraph, all radiation is a form of energy and capable of producing heat in proportion to its energy, and that the actinic and the optical phenomena which we take advantage of on account of the ease with which they enable us to study certain groups of waves do not indicate any difference excepting that of wave-length.

Character of the Ether-waves which Constitute Radiation.—The identity of all the waves emitted by a radiating body being established, we are able to take advantage of our very complete knowledge of the waves which constitute the visible spectrum (which knowledge is obtained by numerous optical experiments) to describe the character of them all. It may be stated in general that radiation is transmitted by means of the ether, and that it consists of transverse waves. These waves travel *in vacuo* with a velocity (the velocity of light) of 30,057,400,000 cm. (186,680 miles) per second; through space occupied by ordinary matter, such as the air, water, glass, etc., the velocity is somewhat reduced.

Production of Radiation.—Radiation depends, both as to amount and as to the character of the waves given off by the radiating body, upon the temperature of that body. Bodies at all temperatures send forth ether-waves. At low temperatures these waves are chiefly of great wave-length, and as the temperature rises shorter and shorter waves begin to show themselves. At the temperature called the red heat or temperature of incandescence—namely, about 500° C.—those waves which make up the visible spectrum begin to be present in sufficient intensity to affect the retina. The very first impression upon that organ is an exceedingly dim sensation of light unaccompanied by any color-impression. This, however, is speedily followed, as the intensity of the stimulus rises, by a recognition of the characteristic colors of a red-hot glowing surface. As the temperature continues to rise, shorter and shorter wave-lengths attain intensities sufficient to produce a physiological effect, and the color-sensation passes gradually from red and yellow into white.

Were radiation homogeneous as regards wave-length, it would be a comparatively simple matter to express the growth or rise of radiating power as a function of the temperature. Owing to the innumerable wave-lengths which are simultaneously given off by glowing bodies, the problem is a very complicated one. We have to consider the growth of each wave-length separately, and since with rising temperature the rate of increase of intensity varies with the wave-length, being greater for short than for long wave-lengths, a complete analysis involves a separation of radiation into its component parts, a study of each of these separately, and the recombination of the results by some process of integration.

The matter is further complicated by the existence of a distinct variety of radiation which is not primarily due to temperature, but to chemical action, the effect of light, exposure to kathode rays, or to any one of a variety of other causes. This type of radiation, which will be left out of account in the present article, is termed Luminescence (*q. v.*).

Methods of Studying Ether-waves.—Radiation belonging to the region of the visible spectrum is studied by means of a variety of optical instruments which are described at some length elsewhere. (See Spectrophotometer, Spectrum, Spectroscope, Telescope, etc.) In the study of waves belonging to the regions of the ultra-violet and the infra-red other means must be employed for detecting the presence of the waves and of measuring the wave-length and intensity.

In the ultra-violet two methods are used, namely photography, first employed by Becquerel* in 1842, and the use of the fluorescent screen. Photographs of the spectrum of the sun, taken under conditions which avoid as far as possible the absorption of the waves by passage through glass and other media, show the presence of radiation from this source extending to about wave-length 0·22μ, at which point the spectrum appears to cease rather abruptly. There is reason to believe that shorter waves are present in the sun, but that they are cut off in passing through the earth's atmosphere. When we substitute for sunlight the radiation from a source of light near at hand, so that the thickness of the layer of air to be traversed is reduced, still shorter waves manifest themselves by their effect upon the sensitive plate. Kayser and Runge,* for example, have been able to detect the presence of radiation, due to burning aluminium, the wave-length of which was 0·1852μ. Victor Schumann,† to eliminate still further the influence of absorbing media in the path of the ultra-violet rays, contrived a spectroscope with lenses and prism of fluorite, which material is even more transparent than quartz for extremely short waves. The apparatus was so constructed that the rays passed through a vacuum instead of air, and fell on a sensitive plate devoid of gelatin. In this way it was found possible to photograph the hydrogen spectrum as far as 0·1000μ.

The other method chiefly employed in the study of the ultra-violet consists in placing in the path of the rays some luminescent material, such as uranium glass, which possesses the property when exposed to radiation, particularly to ultra-violet rays, of emitting longer wave-lengths, some of which lie within the range of the visible spectrum. In this way the presence of the ultra-violet rays may be made evident to the eye, and the spectrum beyond the range of visibility may be explored. Stokes studied the spectrum of sunlight in this way at a very early day (1851), and picked out by means of fluorescent screens the numerous dark lines previously discovered by Becquerel.

The study of the solar spectrum by these two methods shows that it is filled with black lines due to the passage of the light through the incandescent vapors of iron, calcium, magnesium, aluminium, etc.; in short, that the ultra-violet spectrum is simply a continuation of the visible spectrum of the sun. If, on the other hand, we burn a metal such as iron and study the spectrum of the light which it emits, we find it made up of numerous bright lines corresponding to the bright lines of the visible spectrum of this substance.

In the study of the infra-red neither photography nor the use of the fluorescent screen would at first thought seem to be available, since it is to the shorter wave-lengths of the violet and ultra-violet chiefly that actinic action and the power of producing luminescence belong. Both of these methods have nevertheless been of great service in the study of the wave-lengths lying just outside the limits of the visible spectrum beyond the red; and while neither of them was the first method used, nor, on account of the rather narrow range through which they are applicable, can be regarded as the most important, we owe most of our detailed knowledge of these portions of the spectrum to them.

The existence of the infra-red spectrum was first demonstrated by William Herschel.‡ who placed a thermometer in the rays of the sun's spectrum and found an elevation of temperature increasing toward the red and even beyond that point, and presenting several regions of maximum and minimum after the limit of visibility had been passed. In 1840 his son, John Herschel,§ showed the presence of absorption bands or lines in the infra-red spectrum by the ingenious and very simple method of dipping smoked paper in alcohol or ether and placing it in the solar spectrum while still wet with its black face toward the light. The unequal evaporation due to the amount of heat produced in different portions enabled him to trace the lines on the reverse side of the paper and to locate them. It had already been shown by E. Becquerel‖ in the previous year (1839) that the invisible rays beyond the red were capable of affecting daguerreotype plates previously exposed to light, and this effect was utilized by J. W. Draper¶ in 1843 to obtain a photograph of the infra-red spectrum. He found three dark lines, which he designated by the Greek letters α, β, and γ.

E. Becquerel in 1842 noticed an interesting property of these rays—namely, that they were capable of destroying the luminescence of a phosphorescent substance previously exposed to light—and he made use of this property to obtain

reversed or negative pictures of the infra-red spectrum on such screens. Regions devoid of energy on account of absorption bands or lines, corresponding to the dark lines of Fraunhofer, continued to glow, while the intervening regions which were exposed to radiation were dark. This method of studying the infra-red spectrum by phosphorescence was later developed and used by his son, H. Becquerel,* who mapped the spectrum as far as wave-length 1·48μ. The younger Becquerel not only studied in detail the infra-red spectrum of the sun within these limits, but likewise mapped a considerable number of absorption spectra, including those of the rare earths. He likewise obtained impressions on the phosphorescent screen of lines due to sodium, potassium, calcium, magnesium, thallium, and silver. He showed by a comparison with the absorption spectrum of water that the three most prominent bands or line groups in the infra-red spectrum of the sun were in all probability due to the absorbing effect of the moisture in the air—a statement which is confirmed by the fact that these bands increase in depth as the sun approaches the horizon and appear of different intensities on different days. Fig. 1

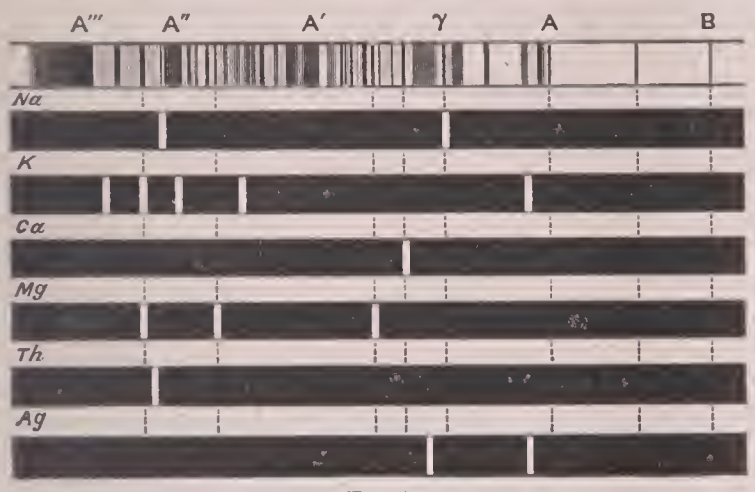

Fig. 1.

shows on a greatly reduced scale Becquerel's map of the infra-red solar spectrum, together with the bright-line spectra of several metals.

The photographic method, which had its origin in the observations of E. Becquerel (1839), that daguerreotype plates were sensitive by a sort of secondary action to exposure to infra-red, was developed by Vogel, by Waterhouse,† and chiefly by Abney,‡ who first succeeded in producing plates on which excellent photographs of the infra-red could be obtained as far as wave-length 1·0μ. Abney's photographic maps show a large number of lines corresponding to the dark lines of the Fraunhofer series within this region. There is considerable discrepancy in the assignment of wave-lengths between his values and those obtained by Becquerel, although both observers made use of the normal spectrum produced by a grating in the determination of the position of the principal lines on their maps. Lommel§ in 1890 made photographs of the infra-red spectrum by exposing a phosphorescent screen to the rays and subsequently placing it in contact face to face with a sensitive dry plate. Measurements of wave-length obtained in this way agree closely with those made by Abney.

The portion of the infra-red which is capable of investigation by these two methods lies within narrow limits—namely, between the red end of the spectrum and wave length 1μ. For the study of longer waves we must have recourse to their thermal action. In this field William Herschel's observation at the beginning of the century, to which reference has already been made, was the only important piece of work for many years. Fizeau and Foucault‖ in 1847 explored the heat spectrum by means of minute thermometers of extreme sensitiveness. Desains¶ (1868) made many explorations of the infra-red spectrum of the sun by means of the linear thermopile and noted the extreme variability of the solar spectrum with the condition of the earth's atmosphere and the height of the sun above the horizon. Similar observations were made by Lamansky* in 1871, and in 1879 Mouton† compared the sun's spectrum by this method with that of artificial sources of light. One of the most important steps in the study of the infra-red was the invention by Langley‡ of the bolometer, an instrument which, on account of its extraordinary sensitiveness, has in great measure displaced the thermopile, and has made it possible to obtain a detailed knowledge of the obscure heat-waves of great length.

The best known of the instruments used in the thermal study of radiation, such as the differential thermometer of Leslie (see Radiometer), the Pyrheliometer (*q. v.*) of Pouillet, the Thermopile (*q. v.*), the Bolometer (*q. v.*), and the compensated actinometer of Ångström (see Radiometer), have been briefly described elsewhere. Of these the most important are the bolometer and thermopile. By the use of them, in connection with that almost inconceivably delicate instrument the galvanometer, it has been found possible thus to explore the whole region of the infra-red, to verify the existence of the lines and absorption bands noticed by Becquerel, and to extend the investigation to wave-lengths far beyond those to which his fluorescent screen was sensitive.

With the bolometer, Langley§ determined the distribution of heat-energy in the spectrum of the sun at various times and at different heights above the sea. He likewise explored the heat-spectrum of various artificial sources, of the firefly, of the moon, etc. Brief reference is made to this work in the article Spectrum. For details concerning his measurements on solar radiation, see the remarkable memoir entitled *Researches on Solar Heat; a Report of the Mount Whitney Expedition.*‖

More recent measurements of solar radiation have been made on Teneriffe and in Switzerland by K. Ångström, using his apparatus mentioned in the previous paragraph; also by Homén¶ in Finland, who employed Ångström's method. Homén recorded the fluctuations in the radiant energy received from the sun and sky throughout the twenty-four hours of each day; also the returned radiation from the surface of the ground. He even followed the passage of the heat thus received by the soil as it slowly penetrated the earth's crust by conduction. The curve in Fig. 2 shows

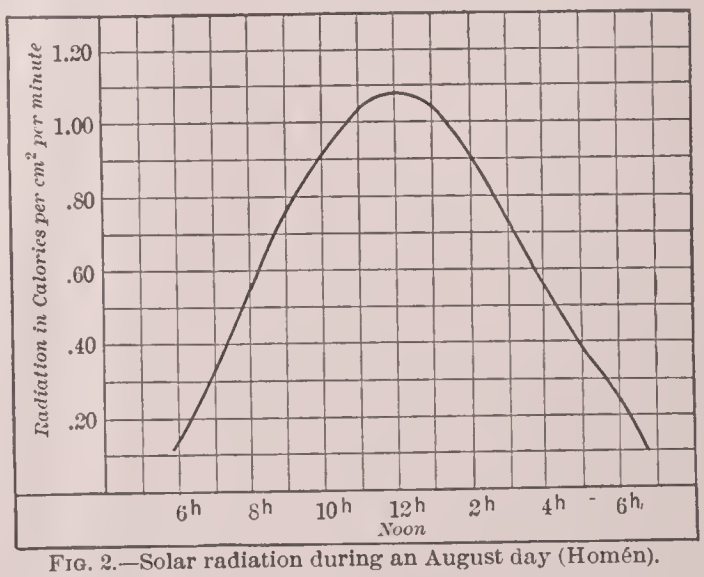

Fig. 2.—Solar radiation during an August day (Homén).

the rise and fall in the intensity of solar radiation during a bright day as determined from his experiments.

Snow** found it possible, by means of a bolometer, to explore the visible spectrum, picking up the Fraunhofer lines, and to obtain indications in the spectrum of the electric arc even from wave-lengths lying on the border-line of the ultra-violet. The region in which the greatest amount of energy was found was that occupied by the so-called hydrocarbon bands in the extreme violet of the arc spectrum, the second or outermost of which is scarcely visible to the eye.

The performance of such experiments depends upon the possession of galvanometers of the utmost sensitiveness, and

such instruments are subject to magnetic disturbances to a degree which makes their use trying under the most favorable circumstances. The natural fluctuations of the intensity of the earth's magnetic field, excepting during so-called magnetic storms, one can readily take account of and correct for, but, owing to the widespread use of the electric current in industrial life, the magnetic field in the locality of most laboratories is at the present day subject to sudden and uncontrollable artificial fluctuations, which makes the use of a galvanometer of the highest sensitiveness almost impossible. Fortunately, an instrument has been devised the performance of which, as regards sensitiveness, exceeds that of the best thermopile or bolometer, and which is not affected by fluctuations in the magnetic field. This instrument, which was invented by Ernest F. Nichols (1895), depends upon the principle discovered by Crookes, and exhibited by him in his radiometer. The Nichols radiometer, a diagram of which is given in Fig. 3, consists of two mica vanes, *a a*, blackened on the same side. These vanes are held together by thin fibers of glass, by which they are attached to a vertical glass rod of small diameter, which forms the axis of rotation. To the lower end of this rod a minute mirror, *s*, is attached. A very fine quartz fiber serves to suspend this arrangement within a hollow block of brass over which a bell jar, *b*, fits. By means of the neck of the bell jar the hollow chamber within the metal block is connected with a mercury air-pump. There are two openings: one, not shown, opposite the vanes, which is closed by means of a window, usually of fluorite or of some other substance pervious to the waves which are to be measured; and the other, *c*, of glass through which a beam of light can be sent to the mirror, and, after reflection, returned again to the telescope and scale. When the air has been sufficiently removed from around this suspension it becomes highly sensitive to radiation, and manifests a rotatory tendency like that of the mica vanes used by Crookes in his radiometers. (See RADIOMETER.) If one of the two vanes at *a* is exposed to radiation while the other is protected, they will take up a new position of equilibrium, with the quartz fiber twisted to such an extent as to counterbalance precisely the tendency to rotation. This deflection enables one to measure the energy of the radiation to which the vane is exposed. The instrument is at its maximum sensitiveness when the pressure is reduced to ·05 mm. Since the total weight of the suspension is only 7 milligrammes, its moment of inertia is exceedingly small, and the arrangement in the hands of the inventor has been found to give the highest known delicacy as an indicator of the presence of ether-waves and a means of measuring their intensity.

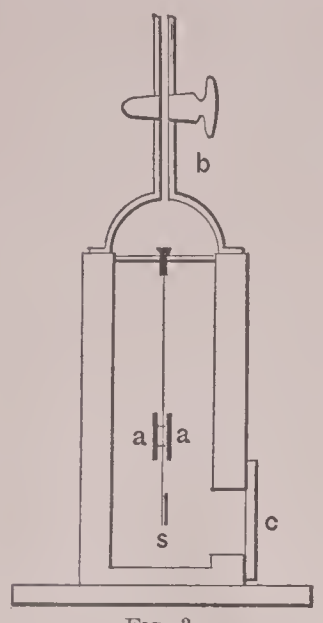

FIG. 3.

The Production and Isolation of the Longer Wave-lengths in the Infra-red.—The study of the longer wave-lengths emitted by radiating bodies is subject to certain difficulties. Glass prisms, which afford the best means of dispersion so far as the visible spectrum is concerned, disperse less and less as the wave-length increases, so that the entire spectrum lying between 3μ and infinity is scarcely separated at all. Glass, moreover, is opaque to all radiation the wave-length of which exceeds 3·5μ. Quartz, which, like glass, is transparent throughout the visible spectrum, in turn becomes opaque at 4·2μ. A favorite substance for prisms for work in this region has been rock salt, which remains pervious for much longer waves. These properties were known to the early students of the subject, Melloni, Tyndall, and others, and it was with rock-salt prisms that Langley's celebrated studies of the infra-red spectrum were made. This material becomes opaque to radiation at about wave-length 20μ.

Rubens, who, in collaboration with Nichols, Trowbridge, and Aschkinass, respectively, has succeeded in working with longer wave-lengths than any other observer, has carefully studied this peculiarity of rock salt and of the similar potassium salt (sylvine, KCl), found that while they transmit longer waves than any other material which has been used for prisms, not excepting fluorite, their use must finally be given up on account of the increasing opacity of the material. Fluorite was found to transmit no waves exceeding 9μ in length.

The regions in which water (and the same curve will apply to alcohol and to aqueous solutions of alums and of various other salts), glass, and quartz, all of which are quite transparent throughout the visible spectrum, begin to be

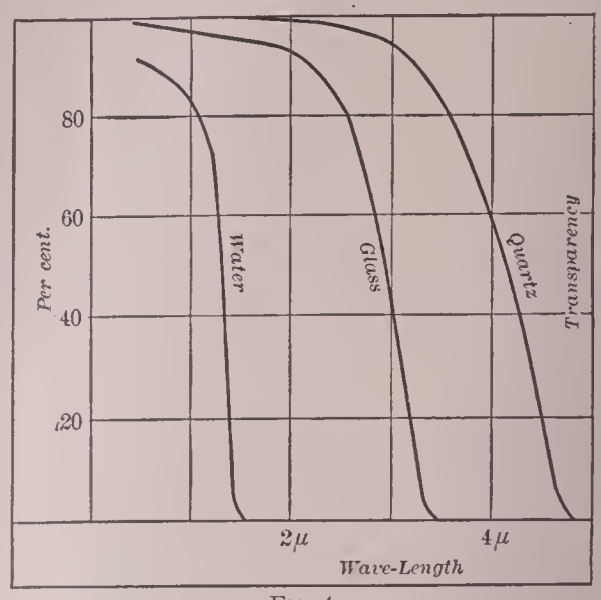

FIG. 4.

opaque, are shown graphically in Fig. 4. Ordinates are transmitting powers for radiation, abscissas are wave-lengths. Fig. 5, which comprises the region between 8μ and 25μ, shows the same property, according to the measurements of Rubens and Trowbridge,* in the case of fluorite ($CaFl_2$), rock salt (NaCl), and sylvine (KCl).

In order to obtain still longer waves than those which can be isolated by means of dispersion, the observers just referred to made use of an ingenious method for the isolation of homogeneous rays of great wave-length in sufficient quantity to make the determination of their wave-length possible. This method may be called the method of *successive reflections*, and is based upon the fact that substances like quartz and fluorite, which are transparent for certain portions of the spectrum, become opaque in others, and that

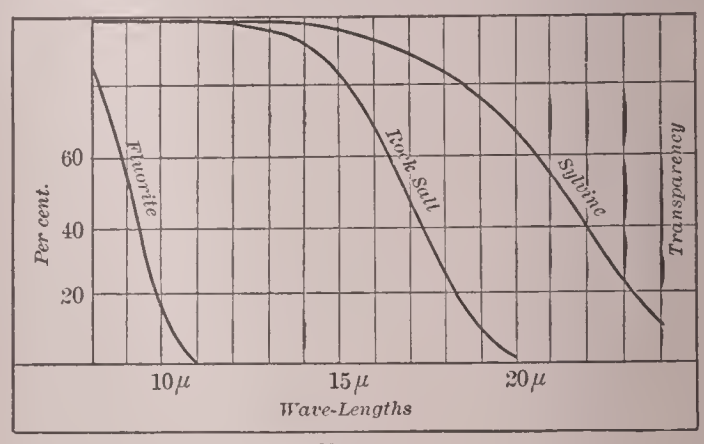

FIG. 5.

their reflecting power for the waves to which they are opaque is very great. By causing the radiation from the body which contains the wave-lengths to be investigated to be reflected from polished surfaces of quartz, fluorite, or rock salt respectively, those waves which are strongly reflected will be sifted out until after three or four reflections scarcely any others are left. The ray thus rendered almost homogeneous can then be measured as to its energy by means of the bolometer, and its wave-length can be determined.

A diagram of the apparatus used in this experiment by Rubens and Nichols † is shown in Fig. 6. Rays from a zircon lamp at *a*, which is at the principal focus of the concave mirror *b*, are sent successively to the three polished surfaces *p p p* by selective reflection, from which the desired wave-length is to be isolated. They are then received by the concave mirror *d*, and focused upon the slit (*s*) of a spectrometer. This instrument has mirrors (*e e'*) in place of collimator and object lenses, a grating (*g*) in place of a prism,

* Rubens and Trowbridge, *Wiedemann's Annalen*, vol. lx., p. 724.
† Rubens and Nichols, *l. c.*

and a radiometer in place of the eyepiece at h. By means of the diffraction of the rays at the grating, which consisted of a set of fine parallel wires, the wave-length is determined. With quartz used in this way, waves of the length of about 8·8μ are obtained; with fluorite the wave-length is very much greater, lying between 24 and 25μ. These waves are absorbed by nearly all known substances. A fluorite plate 2 mm. thick was found to absorb them completely, rock salt 5 mm. thick transmitted only about 3 per cent., and a sylvine plate of the same thickness about 5 per cent. Almost the only substance which does not absorb these waves strongly is the vitreous form of chloride of silver in thin plates, which in a thickness of half a millimeter was found to transmit about 70 per cent. of the rays.

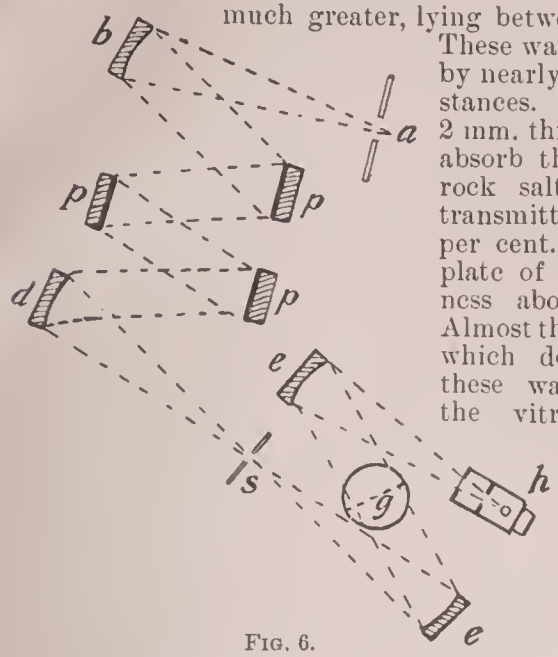

Fig. 6.

Lampblack was likewise found to be comparatively pervious to them. The smoking of the chloride of silver plate until the sun's disk could not be seen through it increased its absorbing power only about 5 per cent. The optical properties of rock salt and sylvine are such as to permit of the isolation, by the method of successive reflections, of waves having lengths equal to 51μ and 61μ.

So feeble are the waves of these lengths in the radiation of glowing bodies that it was impossible to detect them with the apparatus just described, and it was only by the discovery that quartz, which is opaque for all wave-lengths between 4·6μ and 24μ, transmits these still longer waves freely and with high dispersion, that Rubens and Aschkinass* were finally able (1899), by use of a prism of that substance, to isolate and measure them. It was computed that the intensity, which fell off very rapidly in the region explored (as shown by the curve in Fig. 7), was at wave-length 60μ only $\frac{1}{800000}$ as great as the intensity in the maximum of the spectrum at wave-length 1·5μ. It appears unlikely that it will be possible, with the means now at the command of physicists, greatly to extend the range of these explorations into regions of still longer wave-length.

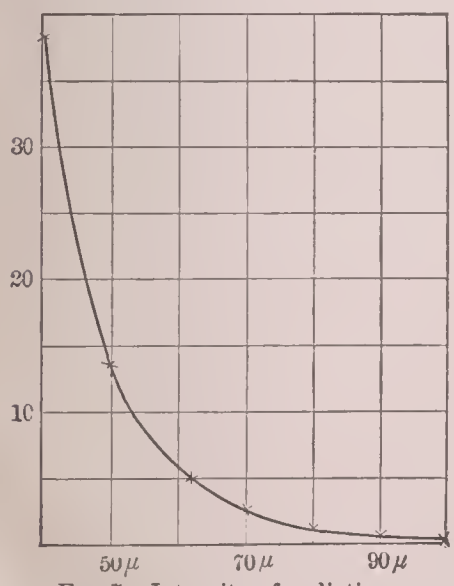

Fig. 7.—Intensity of radiation.

Dispersion in the Infra-red.—Our knowledge of the dispersion of the longer waves of the infra-red spectrum has likewise been notably increased of recent years (1894–99), and the results of the investigations of Rubens and his co-workers, and of Paschen, in this interesting domain have been most important. The variations in the index of refraction of rock salt, with increasing wave-length, which is shown graphically in Fig. 8, will serve to illustrate the nature of these results. The index of this material falls off rapidly within the limits of the visible spectrum, and it is to this change that its dispersing power is due. With increasing wave-length the dispersion decreases in marked degree as indicated by the trend of the curve toward the horizontal direction between 1μ and 4μ. It was commonly believed that the curve beyond the regions actually capable of measurement continued indefinitely in the general direction of the dotted line. Many of the wave-lengths given in the earlier memoirs, including those of Langley, were computed on the basis of that assumption. It was subsequently found, however, that the curve trends downward as shown in the diagram, so that the dispersion increases instead of diminishing, and that the former estimates of wave-length beyond 6μ were altogether at fault. The waves described by these observers were in fact very much shorter than they estimated them to be.

* See the various memoirs already cited.

The curve for rock salt is typical of all the optical materials thus far studied. All of them—i. e. sylvine, fluorite, quartz, and glass—show the same double inflection and the same tendency toward increasing dispersion. In the case of quartz it seems probable, according to the experiments of Ernest Nichols,* that in the neighborhood of 9μ, where the substance becomes opaque and assumes the properties of a metal, the index of refraction is less than unity. This means that in such regions anomalous dispersion occurs.

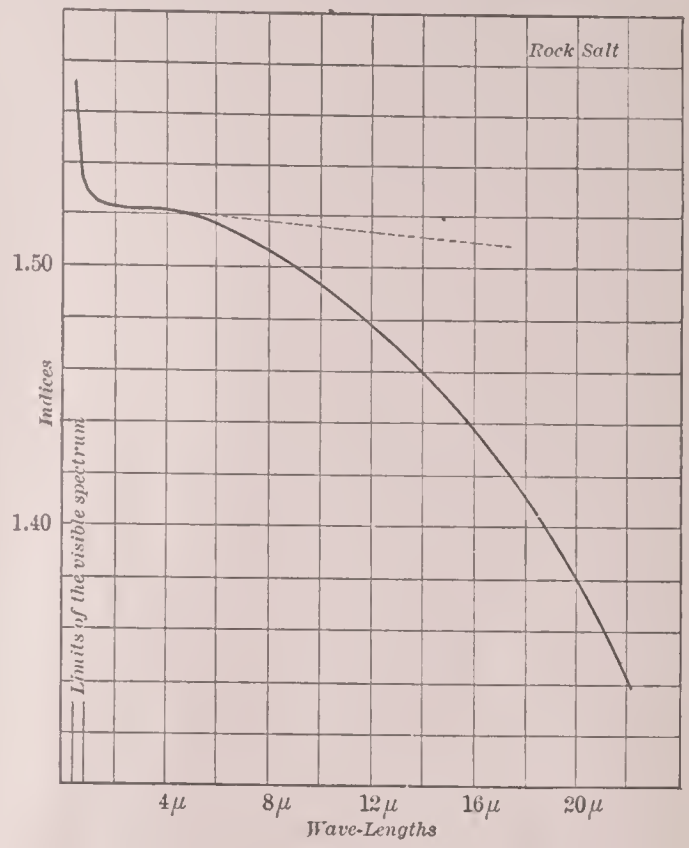

Fig. 8.

For the still longer waves measured by Rubens and Aschkinass, however, the index is 2.17—a value nearly identical with that computed from the dielectric constant for waves of infinite length.

Relation of Radiation to the Character of the Radiating Surface.—The amount and kind of radiation depends not only on the temperature of the radiating body, but likewise on the character of its surface. All bodies radiate in proportion to their absorbing power for radiation, and send out wave-lengths only which they are capable of absorbing. When ether-waves come in contact with a material surface they are either *reflected*, *transmitted* (in proportion as the body whose surface we are considering is transparent or pervious), or *absorbed*. A body reflecting none and transmitting none of the radiation falling on its surface would be a perfect absorber. Such bodies, which do not, strictly speaking, exist in nature, are termed *perfectly black bodies*. Lampblack, platinum black, and certain black pigments approximate so closely to the above definition that they may be regarded, so far as the visible spectrum is concerned, as completely fulfilling it. Lampblack and similar opaque bodies are, however, highly pervious to the longer waves of the infra-red, while, as we have already seen, all known transparent substances become opaque in certain regions.

Selective Absorption and Radiation.—Since the reflecting power and the transmitting power of all substances vary in marked degree with the wave-length, it follows that the absorbing power and radiating power of such substances will differ from that of a black body which absorbs completely waves of all wave-lengths. These phenomena are called respectively *selective absorption* and *selective radiation*. Gases and vapors possess these properties in the highest degree. They are entirely transparent to most waves,

* Nichols, *Physical Review*, vol. v., p. 297.

but opaque to certain ones. When heated to incandescence gases and vapors accordingly radiate those particular waves for which they are opaque, and no others. It is in consequence of this fact that we find the spectrum of gaseous substances to consist of bright lines, and the spectrum produced when light passes through vapors to consist of the continuous spectrum crossed with dark lines. Between this extreme and that of the radiation from a black body which contains all known wave-lengths there is an almost infinite variety.

Through the exhaustive investigations of Stefan,* Wien,† Lummer,‡ Paschen, § and others who have worked for years theoretically and experimentally upon the law of the variation of radiation with temperature, and through the researches of Langley,‖ K. Ångström,¶ and of Rubens and his various co-workers whose labors have been touched upon in this article, the exceedingly intricate problem of radiation is now well in hand. Few subjects are more important to the advancement of science, and few have taxed more severely the skill and patience of the physicist. To no scientific problem, perhaps, has a greater wealth of experimental ingenuity been applied and with greater result. For the details of the remarkable series of investigations to which our present knowledge is due, the reader is referred to the various memoirs cited in this article and in the articles Hertzian Waves, Kathode Rays, Luminescence, and Uranium Rays. E. L. Nichols.

Radium: a metallic element found by P. Curie, Mme. S. Curie, and G. Bemont in the mineral pitchblende. While studying the radio-activity of the constituents of this mineral, these investigators found subsequent to their discovery of the substance which they named Polonium (*q. v.*) a second substance also strongly radio-active and differing entirely from the first body in its chemical properties. The new substance has apparently the properties of almost pure barium. It is not precipitated by either hydrogen sulphide, ammonium sulphide, or ammonium hydrate; its sulphate is insoluble in water and acids; the carbonate is insoluble in water; the chloride is very soluble in water, but insoluble in concentrated hydrochloric acid and in alcohol. These investigators believe that this substance, which consists largely of barium, also contains a new element which gives to the substance its radio-activity and which is close to barium in its chemical properties. This belief is based largely on the fact that, as barium has no radio-active properties, these properties are due to some material present, which therefore must be a new element. Moreover, its spectrum shows a ray which does not appear to be due to any known element. The rays emitted by this new substance yield light, very faint, but functioning apparently without a source of energy. A new source of light has therefore been realized in this discovery. Marcus Benjamin.

Raikes, Francis William, LL. D.: English lawyer; b. in Chester, England, about 1840; educated at Shrewsbury school, Royal Academy at Gossport, and at Peterhouse, Cambridge University; subsequently he was three years at sea in the merchant service, and then entered the royal navy by open examination for navigating officers; served in the navy for about seven years, and then read law with Sir Richard Webster, and was called to the bar at the Inner Temple in 1873. He attained eminence for his intimate knowledge of the intricacies of English practice in admiralty and equity; was made judge of the county court of Hull circuit No. 16 in 1898. He has written numerous papers on maritime law, and translated and edited the maritime codes of the different nations of Europe, and has also published *Jurisdiction and Practice of County Courts in Admiralty* (joint author) and *The New Practice*. F. Sturges Allen.

Rains, Gabriel James: soldier; b. in Craven co., N. C., in June, 1803; graduated at the U. S. Military Academy in 1827, and was assigned to the infantry. He served in various campaigns against Indians, being promoted captain Dec. 25, 1837; brevetted major Apr. 28, 1840, having routed a superior force of Seminoles near Port King, Florida. On the opening of the Mexican war he was among the first engaged, being one of the defenders of Fort Brown in May, 1846. After the battle of Resaca de la Palma he returned to the U. S. on recruiting duty. He became a major on Mar. 9, 1851, and lieutenant-colonel on June 5, 1860, serving meanwhile on the Pacific coast against Indians, and having been in 1855 brigadier-general of Washington Territory volunteers. He resigned on July 31, 1861, and became a brigadier-general in the Confederate army. He commanded a division at Wilson's Creek, was engaged in the fighting at Shiloh and Perrysville, and turned the battle in favor of the Confederates by a flank movement at Seven Pines. He afterward was in charge of the conscript and torpedo bureaus at Richmond, and organized the system of torpedoes for protection of the harbors of Charleston, Savannah, Mobile, and other places. D. in Aiken, S. C., Sept. 6, 1881.

Rains, George Washington: soldier; b. in Craven co., N. C., in 1817; graduated at the U. S. Military Academy in 1842, and was appointed second lieutenant of engineers; transferred to the artillery in 1843. He was Professor of Chemistry, Mineralogy, and Geology at West Point 1844–46. During the war with Mexico he served on the staffs of Gens. Scott and Pillow, and was brevetted captain and major. In 1856 he resigned. He entered the Confederate army in 1861, was commissioned colonel, and built and equipped at Augusta, Ga., the Confederate powder-works, which at the close of the war were among the best in the world. He was made brigadier-general before 1865. In 1867 he became Professor of Chemistry and Pharmacy in the medical department of the University of Georgia, and was dean of the faculty until 1884. He published *Steam Portable Engines* (1860); *Rudimentary Course of Analytical and Applied Chemistry* (1872); *Chemical Qualitative Analysis* (1879). D. in Newburg, N. Y., Mar. 21, 1898.
