381 Properties of ſoda. Its properties, while pure, are preciſely the ſame with thoſe of potaſs, excepting only that its affinity for other bodies is not ſo ſtrong; it does not, therefore, require any particular deſcription. We ought to mention, however, that it differs from potaſs in one particular; potaſs attracts moiſture in the air, but ſoda parts with it, and when expoſed to the atmoſphere, ſoon crumbles down into a dry powder.

It is capable of combining with all the ſubſtances with which potaſs unites; but it forms compounds poſſeſſed, in general, of very different properties from thoſe of the compounds into which potaſs enters.

It

(N) If the glaſs be made with ſoda.

(O) But reddiſh if the glaſs be formed of ſoda. *Klaproth.*

(P) The λιτρον of the Athenians was evidently the ſame ſubſtance; and ſo was the נתר of the Hebrews.

It is reckoned more proper than potaſs for forming glaſs and ſoap.

Some chemiſts have ſuppoſed that it is compoſed of magneſia and azot; but their proofs are inſufficient.

The order of its affinities is the ſame with that of potaſs.

Sect. III. *Of Ammonia.*

382 Diſcovery of ammonia.

Ammonia (q), volatile alkali, or *hartſhorn*, as it is called in commerce, is mentioned as early as the 15th century. Both Baſil Valentine and Raymond Lully deſcribed the methods of procuring it. Dr Black was the firſt who diſtinguiſhed pure ammonia from the carbonat of ammonia, or ammonia combined with carbonic acid; and Dr Prieſtley firſt diſcovered the method of obtaining it in a ſtate of complete purity.

To obtain pure ammonia, mix common ſal ammoniac with three parts of ſlacked lime; apply heat; and receive the product in a veſſel filled with mercury ſtanding in a baſon of mercury. A gas comes over, which is pure ammonia[*]. This gas is tranſparent like common air, and is not condenſed by cold.

383 Its properties.

Its ſpecific gravity is 0,000732. It is to common air as 600 to 1000[†].

It has a very ſtrong, but not unpleaſant ſmell. Animals cannot breathe it without death. When a lighted candle is let down into this gas, it goes out three or four times ſucceſſively; but at each time the flame is conſiderably enlarged by the addition of another flame of a pale yellow colour, and at laſt this flame deſcends from the top of the veſſel to the bottom[‡].

Water abſorbs this gas with avidity. It diſappears almoſt inſtantly on the introduction of a little water. From an experiment of Dr Prieſtley, it appears that water ſaturated with this gas is of the ſpecific gravity 1,1435[§].

This water acquires the ſmell of ammonia. It has a very ſtrong diſagreeable taſte, and converts vegetable colours to a green.

Ammonia in the ſtate of gas has no effect upon ſulphur or phoſphorus. Carbon abſorbs it; probably becauſe it contains water. Neither hydrogen nor azot produce any alteration on it[||].

Alcohol and ether abſorb it in conſiderable quantity[¶].

384 Its component parts.

Dr Prieſtley diſcovered, that when electric exploſions were made to paſs through this gas, its bulk was gradually augmented to thrice the ſpace which it formerly occupied. It was then moſtly converted into hydrogen gas. He diſcovered, too, that heat produced the very ſame effect[*]. Theſe experiments prove that hydrogen enters as an ingredient into the compoſition of ammonia.

Mr Scheele obſerved, that when ammonia was treated with the oxides of mangareſe, gold, or mercury, the oxides were reduced; the ammonia diſappeared; and nothing remained but a quantity of azotic gas. Theſe facts induced Bergman to conjecture, that ammonia was compoſed of hydrogen and azot: a conjecture which has been fully confirmed by the experiments of Berthollet.

This ingenious chemiſt obſerved, that if oxy-muriatic acid and ammonia be mixed, an efferveſcence takes place; azot is diſengaged, a quantity of water formed, and the oxy-muriatic acid is converted into common muriatic acid. Now the ſubſtances mixed were ammonia and oxy-muriatic acid, which is compoſed of oxygen and muriatic acid; the products were, muriatic acid, azot, and water, which is compoſed of oxygen and hydrogen. The oxygen of the water was furniſhed by the acid; the other products muſt have been furniſhed by the ammonia, which has diſappeared. Ammonia, therefore, muſt be compoſed of azot and hydrogen. Mr Berthollet proved, that ammonia was compoſed of theſe ingredients by a number of other experiments. For inſtance, if the oxide of copper be heated in contact with ammoniacal gas, it is reſtored to the metallic ſtate; the ammonia diſappears, a quantity of water is formed, and azotic gas is diſengaged. It follows from Mr Berthollet's experiments, that ammonia is compoſed of 121 parts of azot and 29 of hydrogen[*]. According to Dr Auſtin, it is compoſed of 121 parts of azot, and 32 of hydrogen[†].

385 Formation of ammonia.

After the compoſition of ammonia had been thus aſcertained, it became a queſtion of ſome conſequence, Whether it could be formed artificially? Dr Auſtin accordingly mixed hydrogen and azotic gas together in the proper proportions, and endeavoured to make them combine by the application of heat, by electricity, and by cold; but he found, that while theſe two ſubſtances were in a gaſeous ſtate, they could not be combined by any method which he could deviſe. It could not be doubted, however, that the combination often takes place when theſe bodies are preſented to each other in a different form. Dr Prieſtley[‡] and Mr Kirwan[||] had actually produced it, even before its compoſition was known. Accordingly he found, that when tin is moiſtened with nitric acid, and after being allowed to digeſt for a minute or two, a little potaſs or lime is added, ammonia is immediately exhaled[§]. In that caſe, the nitric acid and the water which it contains are decompoſed; the oxygen of each unites with the tin, and reduces it to the ſtate of an oxide; and at the ſame time the hydrogen of the water combines with the azot of the acid, and forms ammonia, which is driven off by the ſtronger affinity of the potaſs or lime. Dr Auſtin ſucceeded alſo in forming ammonia by ſeveral other methods. He introduced into a glaſs tube filled with mercury a little azotic gas, and then put into the gas ſome iron filings moiſtened with water. The iron decompoſes the water and combines with its oxygen; and the hydrogen meeting with azot at the moment of its admiſſion, combines with it, and forms ammonia. This experiment ſhews, that the gaſeous ſtate of the azot does not prevent its combination with hydrogen.

336 Sulphuret of ammonia.

Ammonia may be combined with ſulphur by mixing together two parts of muriat of ammonia (ammonia combined with muriatic acid), two parts of lime, and one part of ſulphur, and diſtilling; a yellow liquor is obtained, which contains ſulphuret of ammonia. It is capable of cryſtallizing.

The phoſphuret of ammonia is unknown.

Ammonia is capable of combining with ſeveral of the metallic oxides, particularly copper.

It combines with fixed oils, and forms *ſoap*.

The order of its affinities is preciſely the ſame with that of the fixed alkalies.

CHAP. V. *Of* ACIDS.

387 Properties of acids. SUBSTANCES poſſeſſed of the following properties are denominated *acids*.

1. When applied to the tongue they excite that ſenſation which is called *ſour* or *acid*.

2. They change the blue colours of vegetables to a red. The vegetable blues employed for this purpoſe are generally tincture of litmus and ſyrup of violets or of radiſhes, which have obtained the name of *reagents* or *teſts*. If theſe colours have been previouſly converted to a *green* by alkalies, the acids reſtore them again.

3. They unite with water in almoſt any proportion.

4. They combine with all the alkalies, and moſt of the metallic oxides and earths, and form with them thoſe compounds which are called *neutral ſalts*.

It muſt be remarked, however, that every acid does not poſſeſs all theſe properties; but all of them poſſeſs a ſufficient number of them to diſtinguiſh them from other ſubſtances. And this is the only purpoſe which artificial definition is meant to anſwer.

388 Theories about the acid principle. Paracelſus believed that there was only one acid principle in nature, which communicated taſte and ſolubility to the bodies in which it was combined. Becher embraced the ſame opinion; and added to it, that this acid principle was a compound of earth and water, which he conſidered as two elements. Stahl adopted the theory of Becher, and endeavoured to prove, that his acid principle was ſulphuric acid; of which, according to him, all the other acids were mere compounds. But his proofs were only conjectures or vague experiments, from which nothing could be deduced. Nevertheleſs, his opinion, like every other which he advanced in chemiſtry, continued to have ſupporters for a long time, and was even countenanced by Macquer. At laſt its defects began to be perceived; Bergman and Scheele declared openly againſt it; and their diſcoveries, together with thoſe of the French chemiſts, notwithſtanding the ill-natured attempts of Monnet to ſupport it, demonſtrated the falſehood of both parts of the theory, by ſhewing that ſulphuric acid did not exiſt in the other acids, and that it was not compoſed of water and earth, but of ſulphur and oxygen.

The opinion, however, that acidity is owing to ſome principle common to all the ſalts, was not abandoned. Wallerius, Meyer, and Sage, had advanced different theories in ſucceſſion about the nature of this principle; but as they were founded rather on conjecture and analogy than direct proof, they obtained but few advocates.

389 Lavoiſier's theory. At laſt Mr Lavoiſier, by a number of ingenious and accurate experiments, proved, that ſeveral combuſtible ſubſtances when united with oxygen form acids; that a great number of acids contain oxygen; and that when this principle is ſeparated from them, they loſe their acid properties. He concluded, therefore, that the acidifying principle is oxygen, and that acids are nothing elſe but combuſtible ſubſtances combined with oxygen, and differing from one another according to the nature of the combuſtible baſe. This concluſion has been confirmed by every ſubſequent obſervation. All the acids hitherto analyſed contain oxygen, *one* perhaps excepted, *the Pruſſic acid*, which poſſeſſes properties ſo different from the reſt, that it might, without great impropriety, be placed in a diſtinct claſs. It is probable, therefore, that thoſe acids which it has not yet been poſſible to decompoſe conſiſt of oxygen combined with a combuſtible baſe: but till this analyſis has actually been accompliſhed, the theory of Mr Lavoiſier cannot be conſidered as completely demonſtrated (R).

390 Liſt of the acids. The acids at preſent known amount to about 39, moſt of which have been examined within theſe 30 years. Their names are as follows:

1. Sulphuric acid,
2. Sulphurous,
3. Nitric,
4. Nitrous,
5. Muriatic,
6. Oxy muriatic,
7. Phoſphoric,
8. Phoſphorous,
9. Boracic,
10. Fluoric,
11. Carbonic,
12. Acetic,
13. Acetous,
14. Oxalic,
15. Tartarous,
16. Citric,
17. Malic,
18. Lactic,
19. Saccholactic,
20. Gallic,
21. Benzoic,
22. Succinic,
23. Camphoric,
24. Suberic,
25. Laccic,
26. Pyromucous,
27. Pyrolignous,
28. Pyrotartarous,
29. Pruſſic,
30. Formic,
31. Sebacic,
32. Bombic,
33. Zoonic,
34. Arſenic,
35. Tungſtic,
36. Molybdic,
37. Chromic,
38. Platinic,
39. Stannic,

Theſe acids ſhall form the ſubject of the following ſections.

SECT. I. *Of Sulphuric Acid.*

SULPHUR combines with two different quantities of oxygen: with the ſmaller quantity it forms *ſulphurous acid*; with the larger *ſulphuric acid*. The laſt of theſe is the ſubject of the preſent ſection.

391 Diſcovery of ſulphuric acid. The ancients were acquainted with ſome of the compounds into which ſulphuric acid enters; *alum*, for inſtance, and *green vitriol*: but they appear to have been ignorant of the acid itſelf. It is firſt mentioned in the works of Baſil Valentine, which were publiſhed about the end of the 15th century.

It was for a long time obtained by diſtilling *green vitriol*, a ſalt compoſed of ſulphuric acid and green oxide of iron; hence it was called *oil of vitriol*, and afterwards *vitriolic acid*. Another method of obtaining it was by burning ſulphur under a glaſs bell; hence it was called alſo *oleum ſulphuris per campanam*. The French chemiſts in 1787, when they formed a new chemical nomenclature, gave it the name of *ſulphuric acid*.

392 Method of procuring it. At preſent it is generally procured by burning a mixture of ſulphur and nitre in chambers lined with lead. The theory of this proceſs requires no explanation. The nitre ſupplies a quantity of oxygen to the ſulphur,

---

(R) This theory has been carried ſo far by ſome chemiſts, that they have conſidered it as a concluſive proof that oxygen did not enter into the compoſition of a body, if they could ſhew that the body was not an acid. Thus, according to them, *water* cannot contain oxygen, becauſe water is not an *acid*.—But ſurely no theory, however ingenious and ſatisfactory, can for a moment be put in competition with experiment. The ways of Nature are not as our ways, nor her thoughts as our thoughts.

ſulphur, and the air of the atmoſphere furniſhes the reſt. The acid thus obtained is not quite pure, containing a little potaſs, ſome lead, and perhaps alſo nitric and ſulphurous acids. Theſe acids may be driven off by applying for ſome time a gentle heat, and afterwards the ſulphuric acid itſelf may be diſtilled over pure.

393 Its component parts.

It appears from an experiment of Mr Berthollet, that ſulphuric acid contains 63,2 parts of ſulphur, and 36,8 of oxygen. He aſcertained, in the firſt place *, that nitre is totally decompoſed by being heated with $\frac{1}{5}$th of ſulphur. He then mixed together 288 grains of nitre and 72 of ſulphur; and after expoſing them to a ſufficient heat, he found 12 grains of ſulphur ſublimed, and 228 grains of ſulphat of potaſs †. But the ſum of the ingredients was 360 grains; conſequently 120 grains have been diſſipated. All this loſs muſt have been ſuffered by the acid of the nitre, for the heat was too ſmall to ſeparate any of the alkali. According to Mr Kirwan, 288 grains of nitre contain 132,96 of alkali, and 155,04 of acid. 155,04 — 120 = 35,04 = quantity of oxygen furniſhed by the nitre to convert 60 grains of ſulphur into acid.

394 Its properties.

Sulphuric acid is a liquid, ſomewhat of an oily conſiſtence, tranſparent and colourleſs as water, without any ſmell, and of a very ſtrong acid taſte. When applied to animal or vegetable ſubſtances, it very ſoon deſtroys their texture.

It always contains a quantity of water; part of which, however, may be driven off by the application of a moderate heat. This is called *concentrating the acid*. When as much concentrated as poſſible, its ſpecific gravity is 2,000.

It changes all vegetable blues to a red, except indigo.

According to Erxleben, it boils at 546°; according to Bergman, at 572°.

395 Its cryſtals.

When expoſed to a ſufficient degree of cold, it cryſtallizes or freezes; and after this has once taken place, it freezes again by the application of a much inferior cold. Moreveau froze it at — 4°; it aſſumed the appearance of frozen ſnow. After the proceſs began it went on in a cold not nearly ſo intenſe. The acid melted ſlowly at 27,5°; but it froze again at the ſame temperature, and took five days to melt in the temperature of 43° ‡. Chaptal, who manufactured this acid, once obſerved a large glaſs veſſel full of it cryſtallized at the temperature of 48°. Theſe cryſtals were in groups, and conſiſted of flat hexahedral priſms, terminated by a ſix-ſided pyramid. They felt hotter than the ſurrounding bodies, and melted on being handled §. Chaptal has obſerved, that ſulphuric acid, in order to cryſtallize, muſt not be too concentrated. This obſervation has been extended a good deal further by Mr Keir. He found, that ſulphuric acid, of the ſpecific gravity of 1,780, froze at 45°; but if it was either much more or much leſs concentrated, it required a much greater cold for congelation *.

396 Its affinity for water.

Sulphuric acid has a very ſtrong attraction for water. Neumann found, that when expoſed to the atmoſphere it attracted 6,25 times its own weight. Mr Gould found, that 180 grains of acid, when expoſed to the atmoſphere, attracted 68 grains of water the firſt day, 58 the ſecond, 39 the third, 23 the fourth, 18 the fifth, and at laſt only 5, 4, 3, 4, 3, &c. The 28th day, the augmentation was only half a grain †. The affinity therefore between ſulphuric acid and water, as is the caſe in general with other ſubſtances, becomes weaker the nearer they approach to ſaturation. He does not ſpecify the ſpecific gravity of his acid; but as it only attracted 3,166 times its own weight, it could not have been very concentrated.

When ſulphuric acid is mixed with water, a great quantity of caloric is evolved. A mixture of equal parts of theſe liquids cauſes a heat almoſt equal to that of boiling water. Lavoiſier and De la Place found, that when 2,625 lbs. troy of ſulphuric acid, of the ſpecific gravity 1,87058, was mixed with 1,969lbs. troy of water, as much caloric was evolved as melted 4,1226 pounds troy of ice, or as much caloric as the acid and water would have given out had they been heated without mixture to 155,9° ‡. This caloric is owing chiefly, if not ſolely, to the increaſe of denſity in the water; for when equal quantities of ſulphuric acid and water are mixed together, the ſpecific gravity is much greater than the mean; and it has been formerly ſhewn, that whenever bodies become denſer they give out caloric.

397 Strength of ſulphuric acid of various denſities.

Since there is ſuch a ſtrong affinity between ſulphuric acid and water, and ſince the denſity of the mixture is different from the mean denſity of the ingredients, it becomes a problem of the greateſt importance to determine how much of the ſtrongeſt ſulphuric acid that can be prepared exiſts in any given quantity of ſulphuric acid of inferior ſpecific gravity, and which conſequently conſiſts of a determined quantity of this ſtrong acid diluted with water.

This problem has been ſolved by Mr Kirwan §. He took ſulphuric acid of the ſpecific gravity 2,000, which is the ſtrongeſt that can be procured, for his ſtandard, and the point was to determine how much of this ſtandard acid exiſted in a given quantity of acid of inferior denſity.

He concluded, from a number of experiments with ſulphuric acid, of the ſpecific gravities 1,8846, 1,8689, 1,8042, 1,7500 (for he could not procure an acid of the ſpecific gravity 2,000 at the temperature of 60°, in which his experiments were performed), that when equal parts of ſtandard acid and water are mixed, the denſity is increaſed by $\frac{1}{75}$th part of the whole mixture. Then, by applying a formula given by Mr Poujet (s), he calculated, that the increaſe of denſity, on mixing

§ Iriſh Tranſ. iv.

(s) Mr Poujet undertook the examination of the ſpecific gravity of alcohol mixed with different quantities of water. He took for his ſtandard alcohol whoſe ſpecific gravity was 0,8199, at the temperature of 65,75°. He then formed ten mixtures; the firſt containing nine meaſures of alcohol and one of water, the ſecond eight meaſures of alcohol and two of water, and ſo on, till the laſt contained only one meaſure of alcohol and nine of water. He took care that each of theſe meaſures ſhould contain equal bulks, which he aſcertained by weight, obſerving that a meaſure of water was to a meaſure of alcohol as 1 to 0,8199. Thus 10000 grains of water and 8199 of alcohol formed a mixture containing equal bulks of each. From the ſpecific gravity of each of theſe mixtures he diſcovered how much they had diminiſhed in bulk in conſequence of mixture, by the following method.

different quantities of ſtandard acid and water, was as in the following table:

Number of part of water.	Number of parts of ſtandard acid.	Augmentation of denſity.
5	95	0,0252
10	90	0,0479
15	85	0,0679
20	80	0,0856
25	75	0,0699
30	70	0,1119
35	65	0,1213
40	60	0,1279
45	55	0,1319
50	50	0,1333

The firſt 50 numbers of the following table were formed by adding theſe augmentations to the ſpecific gravity of the above mixture found by calculation, and taking the arithmetical mean for the intermediate quantities. The remaining numbers were formed from actual obſervation. He found by the firſt part of the table, that 100 parts of acid, of the ſpecific gravity 1,8472, contained 88,5 parts ſtandard, conſequently 400 grains of this acid contain 354 grains ſtandard. He took ſix portions of this acid, each containing 400 grains, and added to them as much water as made them contain reſpectively 48, 46, 44, 42, 40, 38 grains ſtandard. The quantity of water to be added in order to produce this effect, he found by the following method. Suppoſe $x =$ the quantity of water to be added to 400 parts of acid, that the mixture may contain 48 *per cent.* of ſtandard acid. Then $400 + x : 354 :: 100 : 48$, and conſequently $x = 337,5$. After finding the ſpecific gravity of theſe, the half of each was taken out, and as much water added; and thus the ſpecific gravities, correſponding to 24, 23, 22, 21, 20, 19, were found. Then ſix more portions, of 400 grains each, were taken, of the ſpecific gravity 1,8393, and the proper quantity of water added to make them contain 36, 34, 32, 30, 28, 26 *per cent.* of ſtandard. Their ſpecific gravities were found, the half of them taken out, and as much water added; and thus the ſpecific gravity of 18, 17, 16, 15, 14, and 13 found. Care was taken, after every addition of water, to allow the ingredient ſufficient time to unite.

The laſt 11 numbers were only found by analogy; obſerving the ſeries of decrement of the four laſt numbers before them.

TABLE

Calling A the real ſpecific gravity of any of the mixtures; B its ſpecific gravity found by calculation, ſuppoſing no diminution of bulk; n the number of meaſures compoſing the whole maſs; $n - x$ the number to which it is reduced in conſequence of mutual penetration—it is evident, ſince the increaſe of denſity does not diminiſh the weight of the whole maſs, that $n\,\mathrm{B} = \overline{n - x} \times \mathrm{A}$. Therefore $x = \frac{\mathrm{A} - \mathrm{B}}{\mathrm{A}} \times n$, or (making $n = 1$) $= \frac{\mathrm{A} - \mathrm{B}}{\mathrm{A}}$. $\frac{\mathrm{A} - \mathrm{B}}{\mathrm{A}}$ is therefore the diminution of volume produced by the mixture.

The following table contains the reſult of Mr Poujet's experiments, calculated according to that formula; the whole volume or n being $= 1$.

Meaſures of		Diminution of the whole volume = 1 by experiment.	By calculation.
Water.	Alcohol.		
1	9	0,0109	0,0103
2	8	0,0187	0,0184
3	7	0,0242	0,0242
4	6	0,0268	0,0276
5	5	0,0288	
6	4	0,0266	0,0276
7	3	0,0207	0,0242
8	2	0,0123	0,0184
9	1	0,0044	0,0103

It is evident, from this table, that the diminution of the bulk of the mixture follows a regular progreſſion. It is greateſt when the meaſures of water and alcohol are equal, and diminiſhes as it approaches both ends of the ſeries. Mr Poujet accounts for this by conceiving the alcohol to be diſſolved in the water, which retains a part of it in its pores, or abſorbs it. The quantity abſorbed ought to be in the ratio of that of the ſolvent and of the body diſſolved, and each meaſure of water will retain a quantity of alcohol proportional to the number of meaſures of alcohol in the mixture. Thus in a mixture formed of nine meaſures of alcohol and one of water, the water will contain a quantity of alcohol $= 9$; in one of eight meaſures of alcohol and two of water, the water will contain a quantity of alcohol $= 8$. Therefore the diminution of bulk in each mixture is in a ratio compounded of the meaſures of alcohol and water which form it; in the above table, as 1×9, 2×8, 3×7, 4×6, &c. And in general, taking the diminution of bulk when the meaſures of both liquids are equal for a conſtant quantity, and calling it c, calling the number of meaſures n, the number of meaſures of alcohol x, the increaſe of denſity

398 Quantity of real acid in ſtrong ſulphuric acid.

But we have no reaſon to ſuppoſe that ſulphuric acid, at the denſity 2,000, is free from all mixture of water; ſo far from that, we know for certain that it contains a conſiderable proportion; for when it is combined with other bodies, barytes, for inſtance, or potaſs, there is a conſiderable quantity of water which remains behind, and does not enter into the combination. Now, is it poſſible to determine what would be the denſity of ſulphuric acid, ſuppoſing it to be deprived of all water, or at leaſt of all water except what is neceſſary for its exiſtence as an acid? or to determine, how much real acid exiſts in a given quantity of ſtandard acid?

Homberg firſt attempted to anſwer this queſtion. It was afterwards undertaken by Bergman, and Wenzel, and Wiegleb. They do not inform us of the quantity of water contained in a given weight of acid, but they put it in our power to find it, by informing us how much real acid is neceſſary to ſaturate a given quantity of potaſs. Their reſpective experiments give the following numbers:

	Homb.	Berg.	Wenzel.	Wiegleb.
100 parts of potaſs require	38,3	78,5	82,63	101,92.

Homberg uſed carbonat of potaſs, and did not take into conſideration the carbonic acid driven off by the ſulphuric. When this is taken in, his number ſhould be 54 inſtead of 38,3.

Now to diſcover the quantity of real acid in any ſulphuric acid mixture, we have only to find out how much potaſs it would require for ſaturation. The differences between the above reſults are ſo great, that there was reaſon to ſuſpect their accuracy. Mr Kirwan therefore attempted to aſcertain the denſity of pure ſulphuric acid by another method, and he rated it at 4,226. As this method has been already deſcribed in the article Chemistry, *Encycl.* we cannot enter upon it here. At any rate, it would be unneceſſary, as many of the principles upon which Mr Kirwan went were erroneous, as Mr Morveau* and Mr Keir† have ſufficiently ſhewn; and Mr Kirwan, with his uſual candour, has accordingly abandoned it, and adopted another method which is not liable to the ſame exceptions. He diſſolved 1523,5 grains

denſity or diminution of bulk z; we ſhall have $c : z :: \frac{n}{2} \times \frac{n}{2} : \overline{n - x}, \times x$ and $z = \frac{4c}{n^2} \times \overline{nx - x^2}$, or (making $n = 1) = 4cx^2$.

The diminution of bulk, calculated according to this formula, make the laſt column of the above table. They correſpond very well with experiment, while the meaſures of alcohol are more than thoſe of water, but not when the reverſe is the caſe. This Mr Poujet thinks is owing to the attraction which exiſts between the particles of water, and which, when the water is conſiderable compared with the alcohol, reſiſts the union of the water with the alcohol.

By the formula $z = \frac{4cnx - 4cx^2}{n^2}$, the quantity of alcohol of the ſtandard may be determined in any mixture where the alcohol exceeds the water.

Let the number of meaſures, or the whole maſs - - - $= 1$
The meaſures of alcohol - - - - - - - - $= x$
The diminution of bulk at equal meaſures - - - - $= c$
The diminution of bulk of a mixture containing x meaſures of alcohol - $= 4cx - 4cx^2$
The ſpecific gravity of water - - - - - $= a$
The ſpecific gravity of the alcohol - - - - - $= b$
The ſpecific gravity of the unknown mixture - - - $= y$

grains of pure carbonat of potaſs, dried in a red heat, in diſtilled water. The whole weighed 4570 grains. He took 360 grains of this mixture, which contained 120 grains of carbonat of potaſs, and ſaturated it with pure ſulphuric acid of the ſpecific gravity 1,565, which, according to the above table, contained 61 *per cent.* of ſtandard acid. The acid required for ſaturating the ſolution of potaſs amounted to 130 grains, and contained therefore 79 of ſtandard. The carbonic acid diſengaged was 34 grains, and conſequently the quantity of alkali was 120 — 34 = 86 grains. The ſolution being turbid, was diluted with 3238 grains of water. Its ſpecific gravity was then 1,013 at the temperature of 60°. The weight of the whole was 3694 grains. Forty-five grains of ſulphat of potaſs (potaſs combined with ſulphuric acid), diſſolved in 1017 grains of diſtilled water, have the ſame ſpecific gravity at the ſame temperature; from whence it follows, that the proportion of ſalt in each was equal. But in the laſt ſolution the quantity of ſalt was $\frac{1}{23,6}$ of the whole; therefore the quantity of ſalt in the firſt was $\frac{3694}{23,6} = 159,52$ grs. Now of this weight 86 grains were alkali; the remainder, therefore, which amounts to 70,52 grains, muſt be acid. But the quantity of ſtandard acid employed was 79 grains; of this there were $8\frac{1}{2}$ grains which did not enter into the combination, and which muſt have been pure water: 79 parts of ſtandard acid, therefore, contain at leaſt 8,5 parts of water, and conſequently 100 parts of ſtandard acid contain 10,75 parts of water. It only remains now to conſider how much water ſulphat of potaſs contains. Mr Kirwan thinks it contains none, becauſe it loſes no weight in any degree of heat below ignition, and even when expoſed to a red heat for half an hour it hardly loſes a grain. This is certainly ſufficient to prove, at leaſt, that it contains very little water; and conſequently we may conclude, with Mr Kirwan, that 100 parts of ſulphuric acid, of the ſpecific gravity 2,000, are compoſed pretty nearly of 89,25 of pure acid and 10,75 of water. This method uſed by Mr Kirwan is nearly the ſame with that propoſed by Mr Keir *.

It ſeems even poſſible to obtain ſulphuric acid free from all the water that may not be neceſſary to its acid ſtate. When it is procured by diſtillation from green vitriol, if the receiver be changed after the proceſs has gone on for ſome time, a quantity of acid is obtained in a ſolid form, or cryſtallized. This, as Morveau has ſhewn, is ſulphuric acid deprived of the water with which it is uſually combined. When this *glacial* acid, as it has been called, is expoſed to the air, it riſes in white fumes, and is ſoon diſſipated. This ſingular effect is produced by its violent attraction for the water which exiſts in atmoſpheric air. When thrown into water, it ſeizes it with violence; a great deal of caloric is evolved, ſufficient, if the quantity of water be not too great, to elevate the whole in vapours *.

399 Action of this acid on other bodies.

Sulphuric acid is capable of decompoſing alcohol and oils; and when aſſiſted by heat, it decompoſes alſo ſome of the metallic oxides which contain the greateſt quantity of oxygen; as red oxide of lead, black oxide of manganeſe. It decompoſes likewiſe all the ſulphurets and phoſphurets which have an alkaline or earthy baſis.

It oxidates iron, zinc, and manganeſe, in the cold. By the aſſiſtance of heat it oxidates ſilver, mercury, copper, antimony, biſmuth, arſenic, tin, and tellurium. At a boiling heat it oxidates lead, cobalt, nickel, molybdenum. It does not act upon gold, platinum, tungſten, nor titanium.

It unites readily with all the alkalies, the alkaline earths, alumina, and jargonia, and with moſt of the metallic oxides, and forms ſalts denominated *ſulphats*. Thus the combination of ſulphuric acid and ſoda is called *ſulphat of ſoda*; the compound of ſulphuric acid and lime, *ſulphat of lime*, and ſo on. It does not act upon ſilica nor adamanta.

400 Its affinities.

Sect. II. *Of Sulphurous Acid.*

401
Component parts of ſulphurous acid.

Sulphurous acid is compoſed of ſulphur and oxygen combined: the proportions have not been aſcertained; but the fact itſelf, and that the quantity of oxygen is leſs than what enters into ſulphuric acid, has been proved beyond the poſſibility of doubt. Neither can it be doubted, though the fact has not been attended to, that in this acid the ſulphur and oxygen mutually ſaturate each other; and that ſulphuric acid is not compoſed of ſulphur and oxygen, but of ſulphurous acid and oxygen. Phoſphorus is capable of decompoſing ſulphuric acid by the aſſiſtance of heat, of ſeizing a quantity of its oxygen, and converting it into ſulphurous acid; but upon ſulphurous acid it has no effect whatever *. The affinity of phoſphorus therefore for oxygen is leſs than that of ſulphur; yet it is capable of taking oxygen from ſulphuric acid. Is it not evident from this, that ſulphuric acid is compoſed of ſulphurous acid and oxygen? and that ſulphur has a ſtronger affinity for oxygen than ſulphurous acid has? For if both the acids were compoſed directly of ſulphur and oxygen, it would follow from experiment, that the affinity of phoſphorus for oxygen was both ſtronger and weaker than that of ſulphur; which would be abſurd.

402
Its diſcovery.

Sulphurous acid has been known ſince the time of Stahl. Scheele firſt diſcovered the method of obtaining it in quantities; and Dr Prieſtley firſt procured it in a ſtate of purity; for Scheele's acid was diſſolved in water.

403
Method of procuring it.

Stahl's method of procuring ſulphurous acid was to burn ſulphur at a low temperature, and expoſe to its flames cloth dipped in a ſolution of potaſs. By this method he obtained a combination of potaſs and ſulphurous acid; for at a low temperature ſulphur forms by combuſtion only ſulphurous acid. On this ſalt Scheele poured a quantity of tartarous acid, and then applied a gentle heat. The ſulphurous acid is in this manner diſplaced, becauſe its affinity for potaſs is not ſo ſtrong as that of tartarous acid; and it comes over into the receiver diſſolved in water. It is now commonly procured by mixing with ſulphuric acid oil, greaſe, metals, or any other ſubſtance that has a ſtronger affinity for oxygen than ſulphurous acid, and applying a heat ſufficient to diſtil over the ſulphurous acid as it forms. Mr Berthollet has found, that ſugar is the beſt ſubſtance to employ for this purpoſe.

Dr Prieſtley poured a little oil on ſulphuric acid, applied heat, and received the product in a glaſs jar filled with mercury. It was ſulphurous acid free from all ſuperfluous water, and in a gaſeous form.

404
Its properties,

In this ſtate it is colourleſs and inviſible like common air. It is incapable of maintaining combuſtion; nor can animals breathe it without death. It has a ſtrong and ſuffocating odour. It is this odour which burning ſulphur exhales. Its ſpecific gravity, according to Bergman, is 0,00246 *; according to Lavoiſier, 0,00251 †. Clouet and Mongé found, that by the application of extreme cold it is converted into a liquid.

Dr Prieſtley diſcovered, that when a ſtrong heat is applied to this acid in cloſe veſſels, a quantity of ſulphur is precipitated, and the acid is converted into ſulphuric ‡. Berthollet obtained the ſame reſult: but Fourcroy and Vauquelin could not ſucceed §.

Water abſorbs this acid with avidity. According to Dr Prieſtley, 1000 grains of water, at the temperature 54,5°, abſorb 39,6 grains of this acid. The ſpecific gravity of water ſaturated with ſulphurous acid is 1,040 ||. Water in the ſtate of ice abſorbs it very rapidly, and is inſtantly melted. Water ſaturated with this acid can be frozen without parting with any of it. When water, which has been ſaturated with this acid at the freezing temperature, is expoſed to the heat of 65,25°, it is filled with a vaſt number of bubbles, which continually increaſe and riſe to the ſurface. Theſe bubbles are a part of the acid ſeparating from it. It freezes a few degrees below 32 ¶.

Sulphuric acid abſorbs it at zero; but allows great part of it to eſcape at 32 *.

It reddens tincture of turnſol; but deſtroys the colour of ſyrup of violets.

It is decompoſed by hydrogen and carbon, and ſulphurated hydrogen gas, when aſſiſted by heat †.

Oxygen gas gradually converts it into ſulphuric acid; but this change does not take place unleſs water be preſent.

It does not ſeem capable of oxidating any of the metals except iron, zinc, and manganeſe.

When in the ſtate of gas it is abſorbed by oils and ether.

When glaſs tubes, filled with ſulphurous acid in the ſtate of gas, are expoſed to a ſtrong heat, a quantity of ſulphur precipitates, and the reſt of the acid is converted into the ſulphuric.

405
Its combinations,

It combines with the alkalies, alkaline earths, and alumina, and many of the metallic oxides, and forms neutral ſalts, known by the name of *ſulphites*.

406
And affinities.

Its affinities, as far as they have been inveſtigated, are as follows ‡:

Barytes,
Lime,
Potaſs,
Soda,
Magneſia,
Ammonia,
Alumina,
Jargonia * ?
Metallic oxides,
Water.

Sect. III. *Of Nitric Acid.*

There are three different ſubſtances compoſed of azot and oxygen, *nitric acid*, *nitrous acid*, and *nitrous gas*. The firſt contains moſt oxygen; the laſt contains leaſt.

407
Diſcovery of nitric acid.

Nitric acid ſeems to have been firſt obtained in a ſeparate ſtate by Raymond Lully, who was born at Majorca in 1235. He procured it by diſtilling a mixture of nitre and clay. Baſil Valentine, who lived in the 15th century, deſcribes the proceſs minutely, and calls the acid *water of nitre*. It was afterwards denominated

‡ *Ibid.*

* *Vauquelin, Ann. de Chim.* xxii. 208.

ted *aqua fortis* and *ſpirit of nitre.* The name *nitric acid* was firſt given it in 1787 by the French chemiſts.

408
Method of procuring it.

Nitric acid is generally obtained in large manufactories by diſtilling a mixture of nitre (T) and clay; but the acid procured by this proceſs is weak and impure. Chemiſts generally prepare it by diſtilling three parts of nitre and one of ſulphuric acid in a glaſs retort. This method was firſt uſed by Glauber. When obtained in this manner it contains ſome nitrous acid, which may be expelled by the application of a very gentle heat *.

* *Scheele.*

Nitric acid is one of the moſt important inſtruments of analyſis which the chemiſt poſſeſſes; nor is it of inferior conſequence when conſidered in a political or commercial view, as it forms one of the moſt eſſential ingredients of gunpowder. Its nature and compoſition accordingly have long occupied the attention of philoſophers. We ſhall endeavour to trace the various ſteps by which its component parts were diſcovered.

400
Diſcovery of its component parts.

As nitre is often produced upon the ſurface of the earth, and never except in places which have a communication with atmoſpheric air, it was natural to ſuppoſe that air, or ſome part of the air, entered into the compoſition of nitric acid. Mayow having obſerved, that nitre and atmoſpherical air were both poſſeſſed of the property of giving a red colour to the blood, and that air was deprived of this property by combuſtion and reſpiration—concluded, that nitre *contained that part of the air which ſupported combuſtion, and was neceſſary for reſpiration.*

Dr Hales, by applying heat to nitric acid, and what he called *Walton mineral*, obtained a quantity of air poſſeſſed of ſingular properties. When atmoſpherical air was let into the jar which contained it, a reddiſh turbid fume appeared, a quantity of air was abſorbed, and the remainder became tranſparent again *. Dr Prieſtley diſcovered that this air could only be obtained from nitric (U) acid; and therefore called it *nitrous air.* He found that when this gas was mixed with oxygen gas, nitrous acid was reproduced. Here, then, we find, that oxygen is a part of the nitric acid, and conſequently that Mayow's affirmation is verified.

* *Veget. Statics,* ii. 284.

Dr Prieſtley, however, explained this fact in a different manner. According to him, nitrous gas is compoſed of nitrous acid and phlogiſton. When oxygen is added, it ſeparates this phlogiſton, and the acid of courſe is precipitated. This hypotheſis was adopted by Macquer and Fontana; and theſe three philoſophers endeavoured to ſupport it with their uſual ingenuity. But there was one difficulty which they were unable to ſurmount. When the two gaſes are mixed in proper proportions, almoſt the whole aſſumes the form of nitric acid; and the ſmall reſiduum ($\frac{1}{13}$th part), in all probability, or rather certainly, depends on ſome accidental impurity in the oxygen gas. What then becomes of the oxygen and phlogiſton? Dr Prieſtley ſuppoſed that they formed carbonic acid gas: but Mr Cavendiſh proved, that when proper precautions are taken, no ſuch acid appears †.

† *Phil. Tranſ.* 1784.

Dr Prieſtley had procured his nitrous gas by diſſolving metals in nitric acid; during the ſolution of which a great deal of nitrous gas eſcapes. He ſuppoſed that nitrous gas contained phlogiſton, becauſe the metal was oxidated (and conſequently, according to the then received theory, muſt have loſt phlogiſton) during its formation. Mr Lavoiſier proved that this ſuppoſition was ill-founded by the following celebrated experiment *: To 945 grains of nitric acid (ſpecific gravity 1,316) he added 1104 grains of mercury. During the ſolution 273,234 cubic inches of nitrous gas were produced. He then diſtilled the ſalt (oxide of mercury) which had been formed to dryneſs. As ſoon as it became red hot it emitted oxygen gas, and continued to do ſo till almoſt the whole of the mercury was revived: The quantity of oxygen emitted was 287,742 cubic inches. All that had happened, therefore, during the ſolution of the mercury, was the ſeparation of the acid into two parts; nitrous gas, which flew off, and oxygen, which united with the metal (X).

* *Mem. Par.* 1776, p. 673.

Mr Lavoiſier concluded, therefore, that the whole of the nitrous gas was derived from the nitric acid; that nitric acid is compoſed of oxygen and nitrous gas; and that the proportions are nearly 64 parts by weight of nitrous gas, and 36 of oxygen gas.

But there was one difficulty which Mr Lavoiſier acknowledged he could not remove. The quantity of oxygen obtained by decompoſing nitric acid was often much greater than what was neceſſary to ſaturate the nitrous gas. Mr De Morveau attempted to account for this; but without ſucceſs†. Nitrous gas itſelf was evidently a compound; but the difficulty was to diſcover the ingredients. Mr Lavoiſier concluded, from an experiment made by decompoſing nitre by means of charcoal, that it contained azot: and ſeveral of Dr Prieſtley's experiments led to the ſame reſult. But what was the other ingredient?

† *Encyc. Method. Chim. Acide Nitrique.*

Mr Cavendiſh had obſerved, while he was making experiments on the compoſition of water, that ſome nitric acid was formed during the combuſtion of oxygen and hydrogen gas, and that its quantity was increaſed by adding a little azot to the two gaſes before the exploſion. Hence he concluded that the formation of the acid was owing to the accidental preſence of azotic gas. To verify this conjecture, he paſſed an electrical ſhock through a quantity of common air encloſed in a glaſs tube: the air was diminiſhed, and ſome nitric acid formed. He repeated the experiment, by mixing together oxygen and azotic gas; and found that when they bore a certain proportion to each other, they were totally convertible into nitric acid. In one experiment, the proportion of azot to oxygen (in bulk) was as 416 to 914; in another, as 1920 to 4860 ‡.

‡ *Phil. Tranſ.* 1783.

Theſe experiments were immediately repeated by Meſſrs Van Marum and Van Trooſtwyk, and with nearly the ſame reſult.

The moſt convenient method of performing them is the following: Take a glaſs tube, the diameter of which

---

(T) Nitre is compoſed of nitric acid and potaſs.

(U) Or nitrous acid: for at the period of Dr Prieſtley's diſcovery (1772) they were not accurately diſtinguiſhed.

(X) We have already mentioned, in a preceding note, that this experiment was firſt made by Mr Bayen. See Part I. chap. iii. of this Article.

which is about the ſixth part of an inch, through the cork that ſhuts one end of which let a ſmall metallic conductor paſs with a ball at each end. Fill this tube with mercury, and plunge its open end into a baſon of mercury: then put into it a mixture of 0,13 of azotic and 0,87 of oxygen gas, till it occupies three inches of the tube; and introduce a ſolution of potaſs till it fill half an inch more. Then, by means of the conductor, make electrical exploſions (from a very powerful machine) to paſs through the tube till the air is as much diminiſhed as poſſible. Part of the potaſs will be found converted into nitre. Mr Cavendiſh actually ſaturated the potaſs with this acid. Mr Van Marum did not, though a good deal more gas had diſappeared than in the experiments of Mr Cavendiſh. This difference evidently depends on the quantity of potaſs contained in a given weight of the ſolution. The ſolution which Mr Van Marum uſed was no doubt ſtronger than that which Mr Cavendiſh employed.

Dr Prieſtley had obſerved, ſeveral years before theſe experiments were made, that atmoſpherical air was diminiſhed by the electric ſpark, and that during the diminution the infuſion of turnſol became red; but he concluded merely that he had precipitated the acid of the air. Landriani, who thought, on the contrary, that carbonic acid gas was formed, enounced the alteration of lime-water by it as a proof of his opinion. It was to refute this notion that Mr Cavendiſh undertook his experiments. He has ſince that time repeated them with the ſame ſucceſs *.

It cannot be doubted, then, that nitric acid is compoſed of azot and oxygen; for the objections of Dr Prieſtley have been conſidered while we were treating of water. Conſequently nitrous gas muſt alſo be compoſed of the ſame ingredients. According to Lavoiſier, nitric acid is compoſed of four parts, by weight, of oxygen and one part of azot.

410 Its properties.

Nitric acid is liquid, colourleſs, and tranſparent; but the affinity between its component parts is ſo weak, that the action of light is ſufficient to drive off a part of its oxygen in the form of gas; and thus, by converting it partly into nitrous acid, to make it aſſume a yellow colour. Its taſte is exceedingly acid and peculiar. It is very corroſive, and tinges the ſkin of a yellow colour, which does not diſappear till the epidermis comes off.

It has a ſtrong affinity for water, and has never yet been obtained except mixed with that liquid. When concentrated, it attracts moiſture from the atmoſphere, but not ſo powerfully as ſulphuric acid. It alſo produces heat when mixed with water, owing evidently to the concentration of the water.

411 Its ſtrength at different ſpecific gravities.

The ſpecific gravity of the ſtrongeſt nitric acid that can be procured is, according to Rouelle, 1,583; but at the temperature of 60°, Mr Kirwan could not procure it ſtronger than 1,5543.

Taking this acid for the ſtandard, Mr Kirwan has calculated how much of it exiſts in nitric acid of inferior denſity. His determination may be ſeen in the following Table, which was formed preciſely in the ſame manner as that formerly given of the ſtrength of ſulphuric acid.

100 parts, at the ſpecific gravity	Contain of ſtandard acid	100 parts, at the ſpecific gravity	Contain of ſtandard acid	100 parts, at the ſpecific gravity	Contain of ſtandard acid

1,4069	71	1,2687	45	1,1040	19

Now, how much water does nitric acid contain, the denſity of which is 1,5543?

412 Quantity of real acid contained in concentrated nitric acid.

Mr Kirwan dried a quantity of cryſtallized carbonat of ſoda in a red heat, and diſſolved it in water, in ſuch a proportion, that 367 grains of the ſolution contained 50,05 of alkali. He ſaturated 367 grains of this ſolution with 147 grains of nitric acid, the ſpecific gravity of which was 1,2754, and which, therefore, by the preceding table, contained 45,7 *per cent.* of acid ſtandard. The carbonic acid driven off amounted to 14 grains. On adding 939 grains of water, the ſpecific gravity of the ſolution, at the temperature of 58,5°, was 1,0401. By comparing this with a ſolution of nitrat of ſoda, of the ſame denſity, preciſely in the manner deſcribed formerly under ſulphuric acid, he found, that the ſalt contained in it amounted to $\frac{1}{16,901}$ of the whole. There was an exceſs of acid of about two grains. The weight of the whole was 1439 grains: The quantity of ſalt, conſequently, was $\frac{1439}{16,901} = 85,142$ grains. The quantity of alkali was $50,05 - 14 = 36,05$. The quantity of ſtandard acid employed was 66,7. The whole of which amounted to 102,75 grains; but as only 85,142 grains entered into the compoſition of the ſalt, the remaining 17,608 muſt have been pure water mixed with the nitric acid. But if 66,7 of ſtandard acid contain 17,608 of water, 100 parts of the ſame acid muſt contain 26,38 *.

One hundred parts of ſtandard nitric acid, therefore, is compoſed of 73,62 parts of pure nitric acid and 26,38 of water. But as Mr Kirwan has not proved that nitrat of ſoda contains no water, perhaps the proportion of

---

* *Phil. Tranſ.* 1788.

* *Iriſh Tranſ.* iv.

of water may be greater. He has rendered it probable, however, that nitrat of ſoda contains very little water.

413 Its action on other bodies,

Nitric acid is decompoſed by a great variety of ſubſtances. When poured upon oils, it ſets them on fire. This is occaſioned by a decompoſition both of the acid and oil. The oxygen of the acid combines with the carbon and with the hydrogen of the oils, and at the ſame time lets go a quantity of caloric. Hence we ſee that the oxygen which enters into the compoſition of the nitric acid ſtill contains a great deal of caloric; a fact which is confirmed by a great number of other phenomena. The combuſtion of oils by this acid was firſt taken notice of by Borrichius and Slare; but it is probable that Homberg communicated it to Slare. In order to ſet fire to the fixed oils, it muſt be mixed with ſome ſulphuric acid; the reaſon of which ſeems to be, that theſe oils contain *water*, which muſt be previouſly removed. The ſulphuric acid combines with this water, and allows the nitric acid, or rather the oil and nitric acid together, to act. The drying oils do not require any ſulphuric acid: they have been boiled, and conſequently deprived of all moiſture. It ſets fire alſo to charcoal, provided it be perfectly dry. This fact was firſt obſerved by Prouſt, and afterwards confirmed by the Dijon academicians. It ſets fire alſo to zinc, biſmuth, and tin, if it be poured on them in fuſion, and to filings of iron, if they be perfectly dry *. In all theſe caſes the acid is decompoſed. Sulphurated hydrogen gas alſo takes fire, and burns with a ſtrong flame by means of this acid †.

It is capable of oxidating all the metals except gold, platinum (x), and titanium. It appears, from the experiments of Scheffer, Bergman, Sage, and Tillet, that nitric acid is capable of diſſolving (and conſequently of oxidating) a very minute quantity even of gold.

414 Its combinations,

Nitric acid combines with alkalies, alkaline earths, alumina, and jargonia, and with the oxides of metals, and forms compounds which are called *nitrats*. It does not act upon ſilica nor adamanta.

415 And affinities.

The order of its affinities is as follows:

Barytes,
Potaſs,
Soda,
Strontites ‡,
Lime,
Magneſia,
Ammonia,
Alumina,
Jargonia § ?
Metallic oxides, in the ſame order as for ſulphuric acid.
Water.

SECT. IV. *Of Nitrous Acid.*

416 Component parts of nitrous acid.

If oxygen gas be mixed with nitrous gas, a quantity of red fumes appear, which are readily abſorbed by water. Theſe red fumes are *nitrous acid*.

If a glaſs veſſel containing nitric acid be inverted into another veſſel containing the ſame acid, and expoſed to the light, the inverted glaſs will become partly full of oxygen gas, and at the ſame time part of the nitric acid is converted into nitrous acid *. It follows, from this experiment, that nitrous acid contains leſs oxygen than nitric acid. Lavoiſier has calculated, that it contains ſomewhat leſs than three parts of oxygen to one of azot.

417 Its properties.

Nitrous acid is of a brown or red colour, exceedingly volatile, and emitting a very ſuffocating and ſcarcely tolerable odour. When to this acid, concentrated, a fourth part by weight of water is added, the colour is changed from red to a fine green; and when equal parts of water are added, it becomes blue †. Dr Prieſtley obſerved, that water impregnated with this acid in the ſtate of vapour became firſt blue, then green, and laſtly yellow. A green nitrous acid became orange-coloured while hot, and retained a yellow tinge when cold. A blue acid became yellow on being heated in a tube hermetically ſealed. An orange-coloured acid, by long keeping, became green, and afterwards of a deep blue; and when expoſed to air, reſumed its original colour. Theſe colours ſeem to depend upon the concentration of the acid.

Dr Prieſtley found that water abſorbed great quantities of this acid in the ſtate of vapour; and that when ſaturated, its bulk was increaſed one-third.

In the ſtate of vapour, it is abſorbed rapidly by oils. Whale oil, by abſorbing it, became green, thick, and heavier It gradually decompoſed the acid, retained the oxygen, and emitted the azot in the ſtate of gas ‡.

It is abſorbed by ſulphuric acid, but ſeemingly without producing any change; for when water is poured into the mixture, the heat produced expels it in the uſual form of red fumes §. The only ſingular circumſtance attending this impregnation is, that it diſpoſes the ſulphuric acid to cryſtallize ‖. This fact, firſt obſerved by Dr Prieſtley in 1777 (y), was afterwards confirmed by Mr Cornette.

Nitrous acid appears capable of combining with moſt of the bodies with which nitric acid unites. The ſalts which it forms are called *nitrites*.

Its affinities have never been accurately examined. Bergman ſuppoſes them the ſame with thoſe of nitric acid.

(x) Nitre, however, acts upon platinum, as Mr Tennant has proved. *Phil. Tranſ.* 1797. Morveau had made the ſame obſervation in the *Elemens de Chimie de l'Academie de Dijon.*

(y) Bernhardt, however, relates, in 1765, that once, when he was diſtilling a mixture of ten pounds of nitre with an equal quantity of calcined vitriol, which he had put into a retort, to which was fitted an adapter between the retort and the receiver, which contained a quantity of water—he obſerved a conſiderable quantity of a white cryſtalline ſalt formed in the adapter, while the liquid acid paſſed as uſual into the receiver. This ſalt was very volatile, ſmoked ſtrongly when it was expoſed to the air, and exhaled a red vapour; it burnt, to a black coal, wood, feathers, or linen, as ſulphuric acid does; and where a piece of it fell, it evaporated in form of a blood red vapour, till the whole of it diſappeared. Half an ounce of theſe cryſtals diſſolved in water with ſpurting and hiſſing, like that of a red-hot iron dipped in water, and formed a green nitrous acid. Some of this ſalt being put into a bottle, which was not well ſtopped, entirely vaniſhed. Theſe cryſtals were evidently the ſame with Dr Prieſtley's. See *Keir's Dictionary.*

Of Nitrous Gas.

418 Diſcovery of nitrous gas.

NITROUS gas was firſt obtained by Dr Hales, but its properties were diſcovered by Dr Prieſtley. It may be procured by diſſolving metals in nitric or nitrous acid, and catching the product by means of a pneumatic apparatus.

As nitrous acid is formed by combining nitrous gas and oxygen, it is evident that nitrous gas contains leſs oxygen than nitrous acid. According to Lavoiſier, it is compoſed of two parts of oxygen and one of azot.

419 Its properties.

Nitrous gas is elaſtic, and inviſible like common air. It extinguiſhes light, and inſtantly kills all thoſe animals that are obliged to breathe it. Its ſpecific gravity, according to Mr Kirwan, is 0,001458 *.

Dr Prieſtley found that water was capable of abſorbing about one-tenth of nitrous gas, and that by the abſorption it acquired an aſtringent taſte †. Water parts with all the nitrous gas it has imbibed on being frozen ‡.

Neither phoſphorus nor ſulphur ſeem capable of decompoſing nitrous gas.

Mr Linck, profeſſor at Roſtoc, found, that three parts of nitrous gas and two of hydrogen gas, obtained by ſulphuric acid and iron, are ſcarcely, or not at all, diminiſhed when expoſed to day-light over water. Common air is not more dminiſhed by this admixture kept a long time: but the mixture itſelf of theſe two gaſes is diminiſhed by the addition of new portions of nitrous gas. Mr Linck concludes, from this obſervation, that part of the oxygen of the nitrous gas combined with the hydrogen and formed water, and that the remaining oxygen and azot formed a mixture ſimilar to the air of the atmoſphere. Mr Vauquelin had previouſly made the ſame obſervation. The affinity of hydrogen, therefore, for oxygen is greater than that of azot §.

Oils imbibe nitrous gas with avidity, and decompoſe it.

Nitric acid abſorbs a vaſt quantity of it, and is by that means converted into nitrous acid.—Sulphuric acid alſo abſorbs it.

420 The eudiometer.

The moſt important property of nitrous gas is that of combining inſtantly with oxygen gas, and forming nitrous acid, which is inſtantly abſorbed by water. This property induced Dr Prieſtley to uſe nitrous gas as a teſt of the purity of common air. He mixed together equal bulks of theſe ſubſtances, and judged of the purity of the air by the diminution of bulk. The apparatus uſed for this purpoſe, which conſiſts of a graduated tube, has been called a *eudiometer*. This eudiometer has been greatly improved by Fontana, but it is ſtill liable to uncertainty in its application. Perhaps the beſt eudiometer is ſulphuret of potaſs, which, as Morveau has diſcovered, abſorbs, on the application of heat, the whole oxygen in a given bulk of air almoſt inſtantaneouſly.

Dr Prieſtley found that nitrous gas was decompoſed by paſſing electric exploſions through it.

Let us now conſider in what manner oxygen and azot are combined in the three ſubſtances which have been juſt deſcribed.

421 Manner in which azot and oxygen are combined.

It can hardly be conceived that azot is capable of combining with three different proportions of oxygen, and of being ſaturated with each: it is ſurely much more probable, that in nitrous gas the oxygen and azot ſaturate each other directly and completely; that nitrous acid is compoſed of nitrous gas and oxygen, and nitric acid of nitrous acid and oxygen. And this ſuppoſition is confirmed by conſidering that the ſtrength of affinity by which the oxygen is retained in each of theſe ſubſtances is very different. Some ſubſtances, as light, are capable of decompoſing nitric acid, by ſeizing ſome of its oxygen, and of converting it into nitrous acid; but they have no effect whatever upon nitrous acid or nitrous gas. Others, as biſmuth, copper, phoſphorus, and ſulphur, are capable of decompoſing both nitric and nitrous acids, but are incapable of altering nitrous gas: And others, again, as carbon, zinc, and iron, are capable of decompoſing all the three. Every body which is capable of decompoſing nitrous acid is capable alſo of decompoſing nitric acid; and every body that decompoſes nitrous gas is capable alſo of decompoſing the other two. But the reverſe of this is not true. The affinity of oxygen, then, for azot, nitrous gas, and nitrous acid, is different: oxygen has a ſtronger affinity for azot than it has for nitrous gas, and a ſtronger affinity for nitrous gas than for nitrous acid. But if all theſe bodies were direct combinations of azot and oxygen, how could this difference of affinity take place? Is it reaſonable to ſuppoſe that a ſubſtance has a ſtronger affinity for one proportion of any other body than for another proportion? or that, if ſuch a difference exiſted, the ſtrongeſt affinity ſhould not always prevail? Mix together nitric acid and nitrous gas in proper proportions, and the whole mixture is converted into nitrous acid: but mix nitrous and nitric acids together, and no change whatever is produced. In the firſt caſe, is it not evident that the affinity of nitrous gas for oxygen is greater than that of nitrous acid; that therefore it decompoſes the nitric acid, deprives it of oxygen, and leaves it in the ſtate of nitrous acid? But, in the ſecond caſe, no change can take place, becauſe nitric acid is compoſed of nitrous acid and oxygen; and it would be abſurd to ſuppoſe, that *nitrous acid* has a ſtronger affinity for oxygen than *nitrous acid* has. But were azot and oxygen capable of uniting in various proportions, why ſhould not a mixture of nitric and nitrous acids, or of nitrous gas and nitrous acid, form new ſubſtances? And why are the only ſubſtances which appear in decompoſitions nitrous acid and nitrous gas? Surely theſe reaſons are ſufficient to ſhew us, that theſe bodies are combined in the following manner:

Azot and Oxygen } form nitrous gas;
Nitrous gas and oxygen } form nitrous acid;
Nitrous acid and oxygen } form nitric acid.

Perhaps there may be even more links in the chain than we are aware of. The dephlogiſticated nitrous air of Dr Prieſtley, which Dieman and Van Trooſtwyck have lately proved to be compoſed of 37 parts of oxygen and 63 of azot, and of which little more is known than that it ſupports flame, is noxious to animals, abſorbed by water, and only obtained by means of ſubſtances capable of decompoſing nitrous gas—perhaps this *air* is compoſed directly of oxygen and azot, nitrous gas of this air and oxygen, and ſo on. There may be even links ſtill farther back than that.

SECT. V. *Of Muriatic Acid.*

422 Diſcovery of muriatic acid.

MURIATIC acid appears to have been known to Baſil Valentine; but Glauber was the firſt who extracted it

---

* *On Phlogiſton*, p. 28.

† *Prieſtley*, i. 365.

‡ *Ibid.* p. 407.

§ *Nicholſon's Jour.* ii. 72.

from common ſalt by means of ſulphuric acid. Common ſalt is compoſed of muriatic acid and ſoda, for which laſt ſubſtance ſulphuric acid has a ſtronger affinity. This acid was firſt called *ſpirit of ſalt*, afterwards *marine acid*, and now, pretty generally, *muriatic acid* *.

* From *muria.*

It is ſometimes prepared by mixing one part of common ſalt with ſeven or eight parts of clay, and diſtilling the mixture. The clay, in this inſtance, is ſuppoſed to act chiefly by means of the ſulphuric acid which it always contains (z): But this ſubject ſtill requires farther elucidation. By theſe proceſſes, muriatic acid is obtained diſſolved in water. Dr Prieſtley diſcovered, that by applying heat to this ſolution, and receiving the product in veſſels filled with mercury, a gas was procured; which gas is muriatic acid in a ſtate of purity.

423
Its properties.

Muriatic acid gas is inviſible and elaſtic, like common air. It deſtroys life and extinguiſhes flame. A candle, juſt before it goes out in it, burns with a beautiful green, or rather light blue flame; and the ſame flame appears when it is firſt lighted again †.

† *Prieſtley*, ii. 293.

The ſpecific gravity of muriatic acid in the ſtate of gas is, according to Mr Kirwan ‡, 0,002315, which is nearly double that of common air.

‡ *Iriſh Tranſ.* iv.

Water abſorbs this gas with avidity. Ten grains of water are capable of abſorbing ten grains of the gas. The ſolution thus obtained occupies the ſpace of 13,3 grains of water nearly. Hence its ſpecific gravity is 1,500, and the denſity of the pure muriatic acid in it is 3,03 § (A).

§ *Kirwan, Iriſh Tranſ.* vol. iv.

As muriatic acid can only be uſed conveniently when diſſolved in water, it is of much conſequence to know how much pure acid is contained in a given quantity of liquid muriatic acid of any particular denſity.

424
Quantity of it contained in acids of various denſities.

Now the ſpecific gravity of the pureſt muriatic acid that can eaſily be procured and preſerved, is 1,196; it would be needleſs, therefore, to examine the purity of any muriatic acid of ſuperior denſity. Mr Kirwan calculated that muriatic acid, of the denſity 1,196, contains $\frac{49}{100}$ parts of acid of the denſity 1,500, which he took for the ſtandard; then, by means of experiments, he formed the following Table:

100 parts, at the ſpecific gravity	Contain of ſtandard acid	100 parts, at the ſpecific gravity	Contain of ſtandard acid	100 parts, at the ſpecific gravity	Contain of ſtandard acid
1,196	49	1,147	37	1,1036	26
1,191	48	1,1414	36	1,0984	25
1,187	47	1,1396	35	1,0942	24
1,183	46	1,1358	34	1,0910	23
1,179	45	1,1320	33	1,0868	22
1,175	44	1,1282	32	1,0826	21
1,171	43	1,1244	31	1,0784	20
1,167	42	1,1206	30	1,0742	19
1,163	41	1,1168	29	1,0630	16
1,159	40	1,1120	28	1,0345	10
1,155	39	1,1078	27	1,0169	5
1,151	38				

Muriatic acid (for this ſolution of the acid in water is always called by that name) is generally of a pale yellow colour, owing, as Dr Prieſtley ſuppoſed, to ſome earthy matter diſſolved in it; but much more probably to its having abſorbed a quantity of oxygen, for which it has a ſtrong affinity. Indeed, that this is the cauſe appears evidently from Dr Prieſtley's own obſervations; for it was deſtroyed only by thoſe bodies which had a ſtronger affinity for oxygen. It is very volatile, as might be expected, conſtantly emitting white fumes of a peculiar and unpleaſant odour.

425
Its action on other bodies.

Muriatic acid is capable, by the aſſiſtance of heat, of oxidating the following metals: Iron, tin, lead, zinc, biſmuth, cobalt, nickel, mangaeſe, antimony, arſenic. Several of theſe, as iron, for inſtance, it oxidates even without the aſſiſtance of heat.

At a boiling heat, it oxidates ſilver and copper. It has no action on gold, platinum, mercury, tungſten, molybdenum, tellurium, titanium. Its action on uranium has not been tried.

In the ſtate of gas, it appears to decompoſe alcohol and oils by its affinity for water *.

* *Prieſtley*, ii. 281.

It is capable of diſſolving a little ſulphat and fluat † of lime, and arſeniat of mercury.

† See ſect. ix.

It combines with the alkalies, alkaline earths, alumina, and jargonia, and with moſt of the metallic oxides, and forms neutral ſalts, known by the name of *muriats*.

426
Deſtroys putrid miaſmata.

Morveau firſt ſhewed, that this acid, in the ſtate of gas, neutralized putrid miaſmata, and by that means deſtroyed their bad effects. In 1773, the cathedral of Dijon was ſo infected by putrid exhalations, that it was deſerted, after ſeveral unſucceſsful attempts to purify it. Application was made to Mr Morveau to ſee whether he knew any method of deſtroying theſe exhalations. He poured two pounds of ſulphuric acid on ſix pounds of common ſalt, contained in a glaſs capſule, which had been placed on a few live coals in the middle of the church. He withdrew precipitately, and ſhut all the doors. The muriatic acid gas ſoon filled the whole cathedral, and could even be perceived at the door. After 12 hours, the doors were thrown open, and a current of air made to paſs through to remove the gas. This deſtroyed completely every putrid odour ‡.

‡ *Jour. de Phyſ.* i. 436.

427
Its affinities.

The affinities of muriatic acid are as follow:

Barytes,
Potaſs,
Soda,
Strontites §,
Lime,
Magneſia,
Ammonia,
Alumina,
Jargonia ‖,
Metallic oxides as in ſulphuric acid,
Water.

§ *Dr Hope.*

‖ *Vauquelin, Ann. de Chim.* xxii. 208.

SECT. VI. *Of Oxy-muriatic Acid.*

428
Diſcovery and preparation of oxy-muriatic acid.

PUT into a glaſs retort one part of the black oxide of mangaeſe and three parts of muriatic acid; place it in a ſand-bath in ſuch a manner that the liquor which riſes up into the neck of the retort may fall back again into

---

(z) Morveau has ſhewn, that even alumina contains ſulphuric acid, provided a precipitation, on adding muriat of barytes, be a ſufficient teſt.

(A) For let D = the denſity of a mixture; *m* the weight of the denſer ingredient; *d* its denſity; *l* the weight of an into the veſſel; and apply a ſmall receiver, with a little water in it, luted to the retort merely by a fillet of brown paper. In about a quarter of an hour the receiver will appear filled with a yellow-coloured gas; it is then to be removed, and others applied ſucceſſively till the operation be finiſhed.

This gas is oxy-muriatic acid, firſt diſcovered by Scheele, while he was making experiments on mangaueſe, and called by him *dephlogiſticated muriatic acid*, becauſe he thought it muriatic acid deprived of phlogiſton. The French chemiſts called it *oxygenated muriatic acid*, which Dr Pearſon contracted into *oxy-muriatic acid*; and this laſt name we have adopted, becauſe it is ſhorter and equally diſtinct.

429
Its compoſition.

The true theory of the formation and compoſition of this acid, which was firſt given by Berthollet, will appear from the following facts: The *black* oxide of manganeſe is, during the proceſs, converted into *white* oxide, and muſt therefore have given out a quantity of oxygen. When oxy-muriatic acid diſſolved in water is preſented to the light in a veſſel half empty, oxygen gas is diſengaged and floats above, and the acid is converted into common muriatic acid: Conſequently oxy-muriatic acid is compoſed of muriatic acid and oxygen. Black oxide of mangaueſe is compoſed of white oxide and oxygen; muriatic acid has a ſtronger affinity for oxygen than the white oxide; during the diſtillation the black oxide is decompoſed, the oxygen combines with muriatic acid, and the product is oxy-muriatic acid gas.

430
Its properties.

Oxy-muriatic acid gas is of a yellow colour. It ſupports flame, but cannot be breathed without proving noxious. The death of the ingenious and induſtrious Pelletier, to whom we have ſo often referred, was occaſioned by his attempting to reſpire it. A conſumption was the conſequence of this attempt, which, in a ſhort time, proved fatal.

It does not unite readily with water. Scheele found, that after ſtanding 12 hours over water, $\frac{4}{5}$ths of the gas were abſorbed: the remainder was common air, which no doubt had been contained in the veſſel before the operation. Berthollet ſurrounded ſeveral bottles containing it with ice: as ſoon as the water in theſe bottles was ſaturated, the gas became concrete, and ſunk to the bottom of the veſſels; but the ſmalleſt heat made it riſe in bubbles, and endeavour to eſcape in the form of gas*. Weſtrum obſerved that it became ſolid when expoſed in large veſſels to the temperature of 40°; and that then it exhibited a kind of cryſtallization†. The ſpecific gravity of water ſaturated with this gas, at the temperature of 43°, is 1,003*. Water impregnated with it has not an acid, but an auſtere taſte†, unlike that of other acids.

It renders vegetable colours *white*, and not red, as other acids do; and the colour thus deſtroyed can neither be reſtored by acids nor alkalies. It has the ſame effects on yellow wax. If the quantity of vegetable colours to which it is applied be ſufficiently great, it is found reduced to the ſtate of common muriatic acid. Hence it is evident, that it deſtroys theſe colours by communicating oxygen. This property has rendered oxy-muriatic acid a very important article in bleaching.

Nitrous gas, hydrogen, ſulphur, ſulphurous acid, and phoſphorus, decompoſe this acid, by depriving it of its oxygen, and leaving the muriatic acid in a ſeparate ſtate. Phoſphorus, however, does not produce this effect ſo readily, except when aſſiſted by heat*.

431
Nitro-muriatic acid.

When muriatic acid is mixed with nitric acid, the compound has preciſely the ſmell and the qualities of oxy-muriatic. It can ſcarcely be doubted, therefore, that as far as it acts as an acid, different from the muriatic and the nitric, it is nothing elſe but oxy-muriatic acid.

This mixture of the two acids was formerly called *aqua regia*; but at preſent it is called by the French chemiſts *nitro-muriatic acid*. It is firſt mentioned by Iſaac the Hollander, and ſeems to have been known before the muriatic acid itſelf. It was prepared by pouring nitric acid on common ſalt. The nitric acid decompoſes the ſalt, and part of it unites with the muriatic acid thus ſet at liberty.

432
Its action on other bodies.

Oxy-muriatic acid oxidates all the metals (except, perhaps, titanium) without the aſſiſtance of heat.

It decompoſes red ſulphuret of mercury, or cinnabar, which neither ſulphuric nor nitric acid is able to accompliſh§.

All the ſubſtances placed before muriatic acid in the table of the affinities of oxygen, are capable of decompoſing this acid. Many of them, when plunged into it while in the ſtate of gas, actually take fire. Weſtrum obſerved, for inſtance, that when pieces of wood were plunged into this gas, they took fire; that arſenic burned with a blue and green flame; biſmuth, with a lively bluiſh flame; nickel, with a white flame, bordering on yellow; cobalt, with a white flame, approaching to blue; zinc, with a lively white flame; tin, with a feeble bluiſh flame; lead, with a ſparkling white flame; copper and iron, with a red flame: that powdered charcoal took fire in it at the temperature of 90°, and that ammonia produced with it a loud detonation‖.

* *Journ. de Phyſ.* 1785.

† *Journ. de Phyſique*, xxxvii. 382.

* *Berthollet, Journ. de Phyſ.* 1785.

† *Scheele.*

§ *Bergman.*

‖ *Journ. de Phyſique*, xxxvii. 385.

---

an equal bulk of water; and m', d', and l', the ſame elements of the rarer: Then $D = \frac{m + m'}{l + l'}$. In the above caſe, $m + m' = 20$, and $l + l' = 13{,}3$. Then $D = \frac{20}{13{,}3} = 1{,}5$. Now to find the ſpecific gravity of the condenſed muriatic acid gas, we have from the above equation $l = \frac{m + m' - l'D}{D} = \frac{5}{1{,}5} = 3{,}3$; and $d = \frac{m}{l} = \frac{10}{3{,}3} = 3{,}03$. *See Iriſh Tranſactions*, vol. iv.

This calculation, however, is formed upon the ſuppoſition that the water ſuffers no condenſation at all—a ſuppoſition certainly contradicted by every analogy, and which, as Mr Keir has ſhewn, the experiments mentioned in Mr Kirwan's firſt paper are inſufficient to prove.

With alkalies, earths, and metallic oxides, it is capable of combining and forming neutral ſalts, which have been called *oxy-mariats*.

433 Its affinities.

The affinities of this acid, according to Lavoiſier, are as follows:

Alumina,
Jargonia * ?
Ammonia,
Oxide of antimony,
——— ſilver,
——— arſenic,
Barytes,
Strontites?
Oxide of biſmuth,
Lime,
Oxide of cobalt,
——— copper,
——— tin,
——— iron,
Magneſia (B),
Oxide of mangane ſe,
——— mercury,
——— molybdenum,
——— nickel,
——— gold,
——— platinum,
——— lead,
Potaſs,
Soda,
Oxide of tungſten,
——— zinc (C).

434 Of the component parts of muriatic acid.

The component parts of muriatic acid are ſtill imperfectly known. Dr Girtanner pretended, about the year 1790, that he had decompoſed it; and that it conſiſted of hydrogen combined with a greater proportion of oxygen than enters into the compoſition of water. He paſſed electrical exploſions through muriatic acid, and obtained a quantity of oxygen and hydrogen gas. But a repetition of theſe experiments ſhewed, that the gaſes were owing, not to the decompoſition of the acid, but to that of the water with which the acid was combined.

The experiments of Mr Lambe (D) have lately opened a new and unexpected path, which ſeems to lead directly to the diſcovery of the component parts of this acid. He found, that when iron was acted upon by ſulphurated hydrogen gas, a ſubſtance was produced which poſſeſſed all the properties of oxy-muriat of iron (oxy-muriatic acid combined with iron). The ſulphurated hydrogen gas which he uſed was obtained from ſulphuret of iron, formed by fuſing equal parts of iron and flowers of ſulphur; and it was extricated by diluted ſulphuric acid. In a ſolution of this gas in diſtilled water, he digeſted iron filings, previouſly purified by repeated waſhings with diſtilled water. The bottle was filled with the ſolution, and corked. The iron was preſently acted upon; numerous bubbles aroſe, which drove the cork out of the bottle; they were ſtrongly inflammable, and probably, therefore, pure hydrogen gas. The liquor gradually loſt its odour of ſulphurated hydrogen gas, and after ſome days ſmelled very much like ſtagnant rain-water. As the bubbles ceaſed to be produced, it recovered its tranſparency. On evaporating a ſmall quantity of this ſolution in a watch-glaſs to dryneſs, a bitter deliqueſcent ſalt was left behind. On this ſalt a little ſulphuric acid was dropped, and paper moiſtened with ammonia was held over the glaſs; white vapours were immediately formed over the glaſs; and conſequently ſome volatile acid was ſeparated by the ſulphuric acid. Mr Lambe evaporated about eight ounce meaſures of the ſame liquor, and, as before, dropped a little ſulphuric acid on the reſiduum; a ſtrong efferveſcence was excited, very pungent acid fumes aroſe, which, from their ſmell, were readily known to be muriatic. The ſame truth was eſtabliſhed beyond a doubt, by holding a bit of paper moiſtened with water, which made the vapours viſible in the form of a grey ſmoke; a diſtinguiſhing characteriſtic, as Bergman has obſerved, of the muriatic acid.—When mangane ſe and mercury were diſſolved in ſulphurated hydrogen gas, the ſalts formed gave the ſame unequivocal marks of the preſence of muriatic acid *.

Shall we conclude from theſe facts, that the baſis of muriatic acid is ſulphurated hydrogen; that muriatic acid is ſulphurated hydrogen combined with oxygen; that this combination takes place during the ſolution of the iron; and that the eſcape of hydrogen is owing to the decompoſition of the water?

SECT. VII. *Phoſphoric Acid.*

435 Diſcovery of phoſphorus.

PHOSPHORUS is capable of forming combinations with two different quantities of oxygen; with the larger it forms phoſphoric; and with the ſmaller phoſphorous acid.

Phoſphoric acid was unknown till after the diſcovery of phoſphorus. Boyle is perhaps the firſt perſon who mentions it: he diſcovered it by allowing phoſphorus to burn ſlowly in common air. But Margraf was the firſt perſon who examined its properties, and diſcovered it to be a peculiar acid.

It may be procured by expoſing phoſphorus to a moderate heat: the phoſphorus takes fire, combines with oxygen, and is converted into an acid.

436 Method of preparing it.

It may alſo be prepared by expoſing phoſphorus during ſome weeks to the ordinary temperature of the atmoſphere, even in winter; when the phoſphorus undergoes a ſlow combuſtion, and is gradually changed into a liquid acid. For this purpoſe, it is uſual to put ſmall pieces of phoſphorus on the inclined ſide of a glaſs funnel, through which the liquor which is formed drops into the bottle placed to receive it. From one ounce of phoſphorus about three ounces of acid liquor may be thus prepared, called *phoſphoric acid by deliqueſcence.*

Scheele has contrived another mode of obtaining the phoſphoric

---

* *Vauquelin, Ann de Chim.* xxii. 208.

* *Lambe, ibid.*

(B) According to Trommſdorf, oxy-muriatic acid is incapable of combining with magneſia. *Ann. de Chim.* xxii. 218.

(C) This is the order of the affinities of nitro-muriatic acid. Many facts (ſome of which ſhall appear afterwards) concur to prove that the affinities of the oxy-muriatic acid are the ſame, and indeed that they are the ſame acids.

(D) Analyſis of the waters of two mineral ſprings at Leminton Priors. *Mancheſter Memoirs*, vol. V. part 1ſt.

phoſphoric acid from phoſphorus without combuſtion, by the mere action of the nitric acid on phoſphorus *. Mr Lavoiſier has repeated and deſcribed this proceſs †. He put two pounds of nitric acid, the ſpecific gravity of which was 1,29895, into a retort, the contents of which were equal to ſix or ſeven French pints, and to which a balloon was fitted. Having placed this retort in a ſand-bath, and brought the heat of the acid contained in it to $133\frac{1}{3}$ deg. he added ſucceſſively ſmall quantities of phoſphorus, about 10 or 12 grains at a time, until he had diſſolved $2\frac{3}{4}$ oz. At firſt the effervеſcence was great, but at laſt he was obliged to apply heat to effect the ſolution. The operation laſted 17 or 18 hours. A good deal of nitrous acid had paſſed into the receiver. He then poured the contents of the retort into a ſmaller retort, and evaporated by means of a ſtronger heat, until the phoſphoric acid began to diſtil in white vapours. The remaining acid was ſo thick that he could not pour it out of the retort, and therefore could not aſcertain its quantity; but he ſuppoſes it might be 8 or 9 ounces, in which he thinks there were about $2\frac{1}{2}$ ounces of phoſphorus; the remaining $\frac{1}{4}$ ounce being ſuppoſed to have evaporated. The quantity of oxygen imbibed he reckons at $3\frac{1}{2}$ ounces, and the quantity of water at about 2 ounces.

Lavoiſier computes that phoſphoric acid contains 100 parts of phoſphorus and 154 of oxygen.

437 Its properties.

The colour of this acid is white; it has no ſmell, has an acid taſte; but is not corroſive (E).

It is exceedingly fixed. When expoſed to the fire in a matraſs with a long neck, it loſes at firſt the greater part of its water; then an odour of garlic is felt, owing to ſome phoſphorus, from which it is exceedingly difficult to clear it entirely; there is likewiſe a ſmall quantity of the acid volatilized along with the water. The liquor then becomes thick and milky: ſmall luminous decrepitations take place from time to time, and they continue for ſome time after the veſſel is taken from the fire. If the matter be then put into a crucible, and placed among burning coals, it firſt boils violently, and gives out a vapour which tinges flame green, and is at laſt converted to a white tranſparent glaſs, inſoluble in water.

The ſpecific gravity of this acid in a ſtate of dryneſs is 2,687 ‡, that of phoſphoric acid by deliqueſcence 1,417 §. It is capable of cryſtallizing; its cryſtals are quadrangular priſms terminated by quadrangular pyramids.

Phoſphoric acid obtained by deliqueſcence, when mixed with an equal quantity of diſtilled water, acquired ſo little *heat* as to raiſe the thermometer only one degree, as Mr Sage obſerved.

Mr Lavoiſier raiſed Reaümur's thermometer from 8° to 14° or 15° by mixing phoſphoric acid boiled to the conſiſtence of a ſyrup, with an equal quantity of water; and from 8° to 32° or 33° when the acid was as thick as turpentine ‖.

438 Its action on other bodies.

Phoſphoric acid is capable of oxidating iron, tin, lead, zinc, antimony, biſmuth, mangaueſe. When fuſed with ſeveral of theſe metals, as tin, lead, iron, and zinc, it is converted into phoſphorus; a proof that they have a ſtronger affinity for oxygen.

It does not act upon gold, platinum, ſilver, copper, mercury, arſenic, cobalt, nickel. It appears, however, to have ſome action on gold in the *dry way*, as it is called; for when fuſed with gold-leaf it aſſumes a purple colour; a proof that the gold has been oxidated.

It is capable of combining with alkalies, alkaline earths, alumina, and metallic oxides; and of forming ſalts known by the name of *phoſphats*.

Phoſphoric acid, by the aſſiſtance of heat, is capable of decompoſing glaſs.

439 Its affinities.

Its affinities are as follows:

Lime,
Barytes,
Strontites*,
Magneſia,
Potaſs,
Soda,
Ammonia,
Alumina,
Jargonia †,
Metallic oxides as in ſulphuric acid,
Water.

440 Phoſphorous acid.

The Phosphorous Acid is formed when phoſphorus is expoſed to a ſlow ſpontaneous combuſtion at the temperature of the atmoſphere; but it gradually abſorbs more oxygen, and is converted into phoſphoric acid.

Concerning phoſphorous acid nothing of any conſequence is at preſent known, except that it contains leſs oxygen than phoſphoric acid.

Sect. VIII. *Boracic Acid.*

441 Borax.

The word *borax* firſt occurs in the works of Geber, an Arabian chemiſt of the 10th century. It is a name given to a ſpecies of white ſalt much uſed by various artiſts. Its uſe in ſoldering metals appears to have been known to Agricola.

Borax is found mixed with other ſubſtances in Thibet. It ſeems to exiſt in ſome lands adjacent to lakes, from which it is extracted by water, and depoſited in thoſe lakes; whence in ſummer, when the water is ſhallow, it is extracted and carried off in large lumps. Sometimes the water in theſe lakes is admitted into reſervoirs, at the bottom of which, when the water is exhaled by the ſummer's heat, this ſalt is found.—Hence it is carried to the Eaſt Indies, where it is in ſome meaſure purified and cryſtallized: in this ſtate it comes to Europe, and is called *tincal*. In other parts of Thibet, it ſeems, by accounts received from China, they dig it out of the ground at the depth of about two yards, where they find it in ſmall cryſtalline maſſes, called by the Chineſe *mi poun*, *boui poun*, and *pin poun*; and the earth or ore is called *pounxa* ‡.

442 Diſcovery of boracic acid.

Though borax has been in common uſe for nearly three centuries, it was only in 1702 that Homberg, by diſtilling a mixture of borax and green vitriol, diſcovered the *boracic acid*. He called it *narcotic* or *ſedative ſalt*, from a notion of his, that it poſſeſſed the properties indicated by theſe names In his opinion, it was merely a product of the vitriol which he had uſed; but Lemery the Younger ſoon after diſcovered, that it could likewiſe be obtained from borax by means of the nitric and muriatic acids. Geoffroi afterwards diſcovered, that

† *Vauquelin, Ann. de Chim.* xxii. 208.

‡ *Kirwan's Mineralogy*, ii. 37.

(E) We have obſerved, however, that when very much concentrated it deſtroyed the texture of vegetable ſubſtances, paper for inſtance, very completely.

that borax contained ſoda: and at laſt Baron proved, by a number of experiments, that borax was compoſed of boracic acid and ſoda; that it might be reproduced by combining theſe two ſubſtances—and that therefore the boracic acid was not formed during the decompoſition of borax, as former chemiſts had imagined, but was a peculiar ſubſtance which pre-exiſted in that ſalt.

443 Attempts to prove that it does not exiſt in borax;

This concluſion has been called in queſtion by Mr Cadet *, who affirmed that it was compoſed of *ſoda, the vitrifiable earth of copper, another unknown metal, and muriatic acid.* But this aſſertion has never been confirmed by a ſingle proof; Mr Cadet has only proved that boracic acid ſometimes contains copper; and Beaumé's experiments are ſufficient to convince us that this metal is merely accidentally preſent, and that it is probably derived from the veſſels employed in cryſtallizing borax: That boracic acid generally contains a little of the acid employed to ſeparate it from the ſoda, with which it is combined in borax: And that crude borax contains a quantity of earth imperfectly ſaturated with boracic acid:—All which may be very true; but they are altogether inſufficient to prove that boracic acid is not a peculiar ſubſtance, ſince it diſplays properties different from every other body.

444 And to prove that it is phoſphoric acid.

Meſſrs Exſchaquet and Struve have endeavoured, on the other hand, to prove that the phoſphoric and boracic acids are the ſame. But their experiments merely ſhew that theſe acids reſemble one another in ſeveral particulars; and though they add conſiderably to our knowledge of the properties of the phoſphoric acid, they are quite inadequate to eſtabliſh the principle which theſe chemiſts had in view; ſince it is not ſufficient to prove the identity of the two acids, to ſhew us a reſemblance in a few particulars, while they differ in many others. Boracic acid muſt therefore be conſidered as a diſtinct ſubſtance, the component parts of which are entirely unknown.

445 Method of procuring it.

The eaſieſt method of procuring boracic acid is the following one: Diſſolve borax in hot water, and filter the ſolution; then add ſulphuric acid, by little and little, till the liquor be rather more than ſaturated. Lay it aſide to cool, and a great number of ſmall, ſhining, laminated cryſtals will form. Theſe are the boracic acid. They are to be waſhed with cold water, and drained upon brown paper.

446 Its properties.

This acid has a ſouriſh taſte at firſt, then makes a bitteriſh cooling impreſſion, and at laſt leaves an agreeable ſweetneſs. Its cryſtals have ſome reſemblance to ſpermaceti, and it has the ſame kind of feel.

It changes vegetable blues to red; it has no ſmell; but when ſulphuric acid is poured on it, a tranſient odour of muſk is produced *. The air produces no change on it.

According to Reuſs, it is ſoluble in 20 parts of cold water, eight parts of warm water, and 2,5 of boiling water. According to Wenzel, 960 grains of boiling water diſſolve 434 of this acid. According to Morveau, one pound of boiling water diſſolves only 183 grains.

It is exceedingly fixed when not combined with water. When expoſed to a violent fire it is converted into a white tranſparent glaſs; which, however, is ſoluble in water, and produces the acid again by evaporation.

Boracic acid is alſo ſoluble in alcohol; and alcohol containing it burns with a green flame.

Its ſpecific gravity is 1,479 ‡.

Paper dipped into a ſolution of boracic acid burns with a green flame.

Though mixed with fine powder of charcoal, it is nevertheleſs capable of vitrification; and with ſoot it melts into a black bitumen-like maſs, which is, however, ſoluble in water, and cannot be eaſily calcined to aſhes, but ſublimes in part *.

With the aſſiſtance of a diſtilling heat it diſſolves in oils, eſpecially in mineral oils; and with theſe it yields fluid and ſolid products, which give a green colour to ſpirit of wine.

When boracic acid is rubbed with phoſphorus, it does not prevent its inflammation; but an earthy yellow matter is left behind †.

447 Its action on other bodies.

It is hardly capable of oxidating or diſſolving any of the metals except iron and zinc, and perhaps copper.

Boracic acid combines with alkalies, alkaline earths, and alumina, and moſt of the metallic oxides, and forms compounds, which are called *borats*.

448 Its affinities.

Its affinities are as follows:

Lime,
Barytes,
Strontites ‡,
Magneſia,
Potaſs,
Soda,
Ammonia,
Oxide of zinc,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,
——— nickel,
——— mercury,
Alumina,
Jargonia §,
Water,
Alcohol.

Sect. IX. *Fluoric Acid.*

449 Diſcovery of fluoric acid.

The mineral called *fluor* or *fuſible ſpar*, was not properly diſtinguiſhed from other ſpars till Margraf publiſhed a diſſertation on it in the Berlin Tranſactions for 1768. He firſt proved that it contained no ſulphuric acid, as had been formerly ſuppoſed; he then attempted to decompoſe it, by mixing together equal quantities of this mineral and ſulphuric acid, and diſtilling them. By this method he obtained a *white ſublimate*, which he ſuppoſed to be the fluor itſelf volatilized by the acid. He obſerved, with aſtoniſhment, that the glaſs retort was corroded, and even pierced with holes. Nothing more was known concerning fluor till Scheele publiſhed his experiments three years after; by which he proved that it was compoſed chiefly of lime and a particular acid, which has been called *fluoric acid*.

450 Method of obtaining it.

To obtain it, put eight ounces of finely powdered fluor into a retort, and pour on it an equal quantity of ſulphuric acid, and lute to the retort, as exactly as poſſible, a receiver containing eight ounces of water. Vapours immediately appear and darken the inſide of the veſſel: Theſe are the acid in the ſtate of gas. The diſtillation is to be conducted with a very moderate heat, not only to allow the gas to condenſe, but alſo to prevent the fluor itſelf from ſubliming. After the proceſs,

ceſs, a cruſt of white earth is found in the receiver, which has all the properties of ſilica.

Scheele ſuppoſed that the ſilica produced was formed of fluoric acid and water, and Bergman adopted the ſame opinion. But Wiegleb and Buccholz ſhewed, that the quantity of ſilica was exactly equal to what the retort loſt in weight; and Meyer completed the proof that it was derived from the glaſs, by the following experiment: He put into each of three equal cylindrical tin veſſels a mixture of three oz. of ſulphuric acid and one oz. of fluor, which had been pulverized in a mortar of metal. Into the firſt he put one oz. of pounded glaſs; into the ſecond, the ſame quantity of quartz in powder; and into the third, nothing. Above each of the veſſels he hung a ſponge moiſtened with water; and having covered them, he expoſed them to a moderate heat. The ſponge in the firſt cylinder was covered with the cruſt in half an hour; the ſponge in the ſecond in two hours; but no cruſt was formed in the third, though it was expoſed ſeveral days. In conſequence of this deciſive experiment, Bergman gave up his opinion, and wrote an account of Meyer's experiment to Morveau, who was employed in tranſlating his works, to enable him to correct the miſtake in his notes.

451 Attempts to diſprove its exiſtence. Soon after the diſcovery of this acid, difficulties and doubts concerning its exiſtence as a peculiar acid were ſtarted by ſome French chemiſts, diſguiſed under the name of Boulanger, and afterwards by Mr Achard and Mr Monnet. To remove theſe objections, Mr Scheele inſtituted and publiſhed a new ſet of experiments; which not only completely eſtabliſhed the peculiar nature of the fluoric acid, but once more diſplayed the unrivalled abilities of the illuſtrious diſcoverer. Theſe important particulars we paſs over thus ſlightly, becauſe they have been partly treated of already in the article CHEMISTRY, *Encycl.* 452 Refuted by Scheele, One experiment, however, we cannot omit, becauſe it is ſufficient of itſelf to deſtroy almoſt all the objections of his antagoniſts, which conſiſted in attempting to prove, that the fluoric acid was merely a modification of the acid employed to extract it. We ſhall give it in Mr Sheele's own words.

"I melted together (ſays he) in a crucible two ounces of finely pulverized fluor ſpar with four ounces of potaſs. As ſoon as they were melted, I poured out the maſs, rubbed it, when it was become cold, to a powder, and extracted the alkali from it again by lixiviation with water. I evaporated the lixivium to dryneſs; and threw away the remaining undiſſolved powder (which was only one of the component parts of the fluor, and which diſſolved readily, and with effervescence, in acids) from its ſolution, in which it may be precipitated by ſulphuric acid in the form of ſelenite (ſulphat of lime). Upon a little of the dried alkali, put into a ſmall retort, I poured ſome ſulphuric acid, fitted to it a receiver containing ſome water; and even before the retort was become hot, I obſerved this water to be covered over with a pellicle of ſiliceous earth: a certain proof that the alkali had extracted the acid from the fluor during its expoſure to the fire with it. Should Mr Achard, agreeably to the opinion which he has adopted, conclude from this experiment, that the alkali ſeparated the volatile earth from the fluor (F); ſtill he muſt certainly allow this earth of his to be of an acid nature, ſince the alkali is capable of diſengaging it from the calcareous earth.—The remaining portion of the dried alkali I diſſolved again in water, and ſaturated the ſuperfluous alkali with pure nitric acid. After expelling from this ſaturated ſolution, by means of heat, the carbonic acid gas, which in ſuch caſes is always retained in the liquor, I dropped ſome of it into lime-water; whereupon I obtained a white precipitate, which was a regenerated fluor. I now diſſolved ſome oxide of lead in vinegar, and continued to add to the ley, which had been ſaturated with nitric acid, as much of this ſolution as was requiſite, till all precipitation ceaſed. Thus I transferred the fluor acid from the alkali to the oxide of lead. After waſhing the precipitate in cold water, and drying it, I dropped upon a ſmall quantity of it a few drops of ſulphuric acid; a frothing up immediately enſued, accompanied with an extrication of fluor acid vapours. But perhaps, in this caſe, the volatile earth of fluor unites with the ſulphuric acid, and converts this fixed, or almoſt fixed acid into acid gas. I can eaſily make allowance to Dr Prieſtley for being inclined to draw ſuch a concluſion, ſince this celebrated philoſopher does not pretend to be a chemiſt (G). Being deſirous of ſeeing whether heat alone was capable of expelling this acid from the oxide of lead, I put a little of this fluorated oxide into a ſmall retort, the receiver to which contained ſome water. The oxide was melted; but I could not perceive any acid. The bottom of the retort was moreover quite corroded and diſſolved, ſo that the whole ran into the fire. Thus the oxide of lead retains this acid in the fire, and will not part with it, unleſs the oxide is combined with ſome other ſubſtance. I therefore rubbed the remainder of my fluorated oxide of lead with an equal quantity of charcoal powder, and diſtilled the mixture in an open fire in a ſmall glaſs retort, to which was adapted a receiver containing ſome water. As ſoon as the reduction of the oxide of lead took place, the neck of the retort became incruſted with a white ſublimate, and a ſiliceous pellicle appeared upon the water. The ſublimate had a ſour taſte, becauſe the ſiliceous earth of which it conſiſts is penetrated with fluoric acid; and the acid water in the receiver let fall, on the addition of volatile alkali, a ſiliceous earth *."

Sorry are we to add, that ſince the death of this admirable man, to uſe the words of Mr Kirwan †, a man as eminent in the chemical as Newton in the mathematical branch of natural philoſophy, Mr Monnet ‡ has thought proper to renew his attacks in a ſtyle of haughtineſs and acrimony that inſpires infinite diſguſt. The falacy of his reaſoning is ſufficiently expoſed by Mr Leonhardi, in the 6th volume of his late learned edition of Macquer's Dictionary. 453 And Leonhardi.

* *Crell's Journal*, i. 221. Eng. Tranſl.
† *Mineralogy*, i. 226.
‡ *Journ. de Phyſ.* xxx. 253.

454 Its properties. Fluoric acid may be obtained in the form of gas, by applying a moderate heat to ſulphuric acid and fluor ſpar, and receiving the product over mercury.

This gas is the acid in a ſtate of purity. It is inviſible and elaſtic like air; it does not maintain combuſtion,

---

(F) Mr Achard affirmed that fluor was compoſed of a peculiar volatile earth.

(G) Dr Prieſtley at firſt advanced this hypotheſis, but he afterwards gave it up.

tion, nor can animals breathe it without death. It has a pungent ſmell, not unlike that of muriatic acid.

It is heavier than common air. It corrodes the ſkin almoſt inſtantly. It combines rapidly with water; and if it has been obtained by means of glaſs veſſels, it depoſites at the ſame time a quantity of ſilica.

Water impregnated with this gas does not freeze at a higher temperature than 23° *.

455 Its action on other bodies.

In the ſtate of gas this acid does not act upon nitrous gas nor ſulphur Alcohol and ether abſorb it, but it does not alter their qualities †.

It is capable of oxidating iron, zinc, copper, and arſenic.

It does not act upon gold, platinum, ſilver, mercury, lead ? tin, antimony, cobalt.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms compounds denominated *fluats*.

It is capable, as we have ſeen, of diſſolving ſilica, which is inſoluble in every other acid; accordingly it corrodes glaſs. This property has induced ſeveral ingenious men to attempt, by means of it, to engrave, or rather etch, upon glaſs.

456 Its affinities.

The affinities of fluoric acid are as follows:

Lime,
Barytes,
Strontites ‡,
Magneſia,
Potaſs,
Soda,
Ammonia,
Oxide of zinc,

Alcohol.

SECT. X. *Of Carbonic Acid.*

CARBONIC acid is compoſed of carbon and oxygen. According to Lavoiſier's experiments, the proportions are 28 parts of carbon and 72 of oxygen. Mr Prouſt informs us that there is alſo a *carbonous acid* (H); but with this acid we are not at preſent acquainted, and cannot therefore deſcribe it.

457 Diſcovery of carbonic acid.

Paracelſus and Van Helmont were acquainted with the fact, that air is extricated from ſolid bodies during certain proceſſes, and the latter gave to air thus produced the name of *gas*. Boyle called theſe kinds of air *artificial airs*, and ſuſpected that they might be different from the air of the atmoſphere. Hales aſcertained the quantity of air that could be extricated from a great variety of bodies, and ſhewed that it formed an eſſential part of their compoſition. Dr Black proved, that the ſubſtances then called *lime*, *magneſia*, and *alkalies*, are compounds, conſiſting of a *peculiar ſpecies of air*, and pure lime, magneſia, and alkali. To this ſpecies of air he gave the name of *fixed air*, becauſe it exiſted in theſe bodies in a fixed ſtate. This air or gas was afterwards inveſtigated by Dr Prieſtley, and a great number of its properties aſcertained. From theſe properties Mr Keir * firſt concluded that it was an acid; and this opinion was ſoon confirmed by the experiments of Bergman, Fontana, &c. Dr Prieſtley at firſt ſuſpected that this acid entered as an element into the compoſition of atmoſpherical air; and Bergman adopting the ſame opinion, gave it the name of *aerial acid*. Mr Bewdly called it *mephitic acid*, becauſe it could not be reſpired without occaſioning death; and this name was alſo adopted by Morveau. Mr Keir called it *calcareous acid;* and at laſt Mr Lavoiſier, after diſcovering its compoſition, gave it the name of *carbonic acid gas*.

458 Theories about its compoſition.

The opinions of chemiſts concerning the *compoſition* of carbonic acid have undergone as many revolutions as its name. Dr Prieſtley and Bergman ſeem at firſt to have conſidered it as an element; and ſeveral celebrated chemiſts maintained that it was the acidifying principle. Afterwards it was diſcovered that it was a compound, and that oxygen gas was one of its component parts. Upon this diſcovery the prevalent opinion of chemiſts was, that it conſiſted of oxygen and phlogiſton; and when hydrogen and phlogiſton came (according to Mr Kirwan's theory) to ſignify the ſame thing, it was of courſe maintained that carbonic acid was compoſed of oxygen and hydrogen: and though Mr Lavoiſier demonſtrated that it was formed by the combination of carbon and oxygen, this did not prevent the old theory from being maintained; becauſe carbon was itſelf conſidered as a compound, into which a very great quantity of hydrogen entered. But after Mr Lavoiſier had demonſtrated that the weight of the carbonic acid produced was preciſely equal to the carbon and oxygen employed; after Mr Cavendiſh had diſcovered that oxygen and hydrogen when combined did not form carbonic acid, but water—it was no longer poſſible to heſitate that this acid was compoſed of carbon and oxygen. Accordingly all farther diſpute about it ſeems now at an end. At any rate, as we have already examined the objections that have been made to this concluſion, it would be improper to enter upon them here.

459 Its analyſis.

If any thing was ſtill wanting to put this concluſion beyond the reach of doubt, it was to *decompound* carbonic acid, and thus to exhibit its component parts by analyſis as well as ſyntheſis. This has been actually done by the ingenious Mr Tennant. Into a tube of glaſs he introduced a bit of phoſphorus and ſome

* Prieſtley, ii 362.

† Ibid.

§ Lavoiſier.

|| Vauquelin, Ann. de Chim. xxii. 208.

* Keir's Macquer, art. Air.

(H) When there are two acids having the ſame baſe, but containing different quantities of oxygen, they are diſtinguiſhed by their termination. The name of that which contains moſt oxygen ends in *ic*, the other in *ous*. Thus ſulphuric and ſulphurous acids, nitric and nitrous, phoſphoric and phoſphorous, carbonic and carbonous.

ſome carbonat of lime. He then ſealed the tube hermetically, and applied heat. Phoſphat of lime was formed, and a quantity of carbon depoſited. Now phoſphat of lime is compoſed of phoſphoric acid and lime; and phoſphoric acid is compoſed of phoſphorus and oxygen. The ſubſtances introduced into the tube were phoſphorus, lime, and carbonic acid; and the ſubſtances found in it were phoſphorus, lime, oxygen, and carbon. The carbonic acid, therefore, muſt have been decompoſed, and it muſt have conſiſted of oxygen and carbon. This experiment was repeated by Dr Pearſon, who aſcertained that the weight of the oxygen and carbon were together equal to that of the carbonic acid which had been introduced; and in order to ſhew that it was the carbonic acid which had been decompoſed, he introduced pure lime and phoſphorus; and inſtead of obtaining phoſphat of lime and carbon, he got nothing but phoſphuret of lime. Theſe experiments were alſo confirmed by Meſſrs Fourcroy, Vauquelin, Sylveſtre, and Broigniart (I) *.

* *Ann. de Chim.* xiii. 312.

Carbonic acid may be obtained by pouring ſulphuric acid upon chalk, and receiving the product in a pneumatic apparatus.

460 Its properties,

It is inviſible and elaſtic like common air. It extinguiſhes a candle, and is unfit for reſpiration. It has no ſmell.

Its ſpecific gravity is 0,0018 †; but this varies according to its dryneſs or moiſture.

† *Bergman*, i. 9.

It reddens the tincture of turnſole, but no other vegetable colour ‡.

‡ *Ibid.*

Atmoſpheric air contains about $\frac{1}{100}$ part of this gas (K).

Water abſorbs it by agitation, or by allowing it to remain long in contact with it. At the temperature of 41° water abſorbs its own bulk of this gas. The ſpecific gravity of water ſaturated with it is 1,0015. This water, at the temperature of 35°, has little taſte; but if it be left a few hours in the temperature of 88°, it aſſumes an agreeable acidity, and a ſparkling appearance §.

§ *Ibid.*

Ice abſorbs no carbonic acid; and if water containing it be frozen, the whole ſeparates in the act of freezing ‖.

‖ *Prieſtley*, i. 120.

This gas alſo ſeparates from water at the boiling temperature ¶.

¶ *Ibid.*

Alcohol and oil of turpentine abſorb double their weight of this gas; olive oil its own bulk. Ether mixes with it in the ſtate of gas *.

* *Bergman*, *ibid.*

Phoſphorus ſuffers no change in this gas except it contains a mixture of oxygen gas †. It has an affinity for common air. Bergman left a bottle of it uncorked, and found that in a few days it contained nothing but common air. Common air, indeed, has ſo ſtrong an affinity for this gas, that it attracts it from water, as Mr Welter has obſerved ‡.

† *Brugnatelli, Nicholſon's Journal*, i. 446.

‡ *Ann. de Chim.* iii. 91.

It is abſorbed by red hot charcoal, as Morozzo and La Metherie have ſhewn.

461 Compounds,

It is capable of combining with alkalies, alkaline earths, and alumina, and ſeveral metallic oxides, and of forming compounds known by the name of *carbonats*. It has no affinity for jargonia, according to Klaproth *; but, according to Vauquelin, it has †.

* *Journ. de Phyſ.* xxxvi. 186.

† *Ann. de Chim.* xxii. 204.

462 And affinities.

Its affinities, as arranged by Bergman, are as follows:

Barytes,
Lime,
Strontites ‡,
Potaſs,
Soda,
Magneſia,
Alumina,
Metallic oxides as in *ſulphuric acid*,
Oxygen gas §,
Water,
Alcohol.

‡ *Dr Hope.*

§ *Mr Welter.*

SECT. XI. *Of Acetous Acid.*

Acetous acid or vinegar was known many ages before the diſcovery of any other acid, thoſe only excepted which exiſt ready formed in vegetables. It is mentioned by Moſes, and indeed ſeems to have been in common uſe among the Iſraelites and other eaſtern nations at a very early period.

The methods of procuring, purifying, and concentrating this acid, have been already given in the articles CHEMISTRY, FERMENTATION, and VINEGAR, *Encycl.* and cannot therefore be repeated in this place.

It has been aſcertained beyond a doubt, that this acid is compoſed of carbon, hydrogen, and oxygen; but neither the manner in which theſe ſubſtances are combined, nor their proportions, have been accurately aſcertained.

463 Lowitz's method of obtaining pure acetous acid.

Acetous acid, as commonly prepared, is very fluid, has a pleaſant ſmell, and an acid taſte. It reddens vegetable colours. In this ſtate it is mixed with a great proportion of water; but Mr Lowitz of Peterſburg has diſcovered that it may be obtained in a ſolid cryſtallized form. Of this curious and inſtructive proceſs we ſhall tranſcribe his own account ‖.

‖ *Crell's Journal*, i. 242. Eng. Tranſl.

" I have long been accuſtomed (ſays he) to prepare concentrated vinegar by congelation in the following manner: I freeze a whole barrel of vinegar as much as poſſible, then diſtil the remaining unfrozen vinegar in a water-bath; by which means I at firſt eſpecially collect the ſpirituous ethereal part; the vinegar, which next comes over, I freeze again as much as poſſible, and afterwards purify it, by diſtilling it again with three or four pounds of charcoal powder. Thus I never fail to get a very pure, ſweet-ſmelling, highly concentrated vinegar; the agreeable odour of which, however, may be

---

(I) Count Muſſin-Puſchin having boiled a ſolution of carbonat of potaſs on purified phoſphorus, obtained carbon. This he conſidered as an inſtance of the decompoſition of carbonic acid, and as a confirmation of the experiments related in the text. See *Ann. de Chim.* xxv. 105.

(K) At leaſt near the ſurface of the earth. Lamanon, Mongez, and the other unfortunate philoſophers who accompanied La Perouſe in his laſt voyage, have rendered it not improbable that at great heights the quantity of this gas is much ſmaller. They could detect none in the atmoſphere at the ſummit of the Peak of Teneriffe. See ***Lamanon's Memoir at the end of La Perouſe's Voyage.***

ſtill improved by the addition of a proper quantity of the ethereal liquor collected at the beginning of the firſt diſtillation, but which muſt be previouſly dephlegmated by two or three rectifications.

“ After the diſtillation in the water-bath was over, that no vinegar might be loſt, I uſed to move the retort, with the charcoal powder which remained in it, to a ſand-bath; and thus I obtained, by means of a ſtrong fire, a few ounces more of a remarkably concentrated vinegar, which was of a yellow colour.

“ Having collected about ten ounces of this concentrated vinegar, I expoſed it laſt winter in the month of December to a cold equal to —22°; in which ſituation it ſhot into cryſtals from every part. I let what remained fluid drop away from the cryſtals into a baſon placed underneath, firſt in the cold air, and afterwards at the window within doors. There remained in the bottle ſnow-white finely foliated cryſtals, cloſely accumulated one upon the other, and which I at firſt took to be nothing but ice: on placing them upon the warm ſtove, they diſſolved into a fluid which was perfectly as limpid as water, had an uncommonly ſtrong, highly pungent, and almoſt ſuffocating acetous ſmell, and in the temperature of —37° immediately congealed into a ſolid white cryſtallized maſs, reſembling camphor.

“ After I had obſerved that vinegar in this ſtate is of ſuch an extraordinary ſtrength and purity as to he in its higheſt degree of perfection, I took all poſſible pains to find out a method of obtaining all the acetous acid in the ſtate of glacial vinegar.

“ To avoid circumlocution, I ſhall denote the ſtrength of each ſort of vinegar, which it was neceſſary for me to know in my experiments, by degrees, which I aſcertain in the following manner: *viz.* to one drachm of vinegar I add, drop by drop, a clear ſolution of equal parts of carbonat of potaſs and water, till all at once a cloudineſs or precipitation appears. Although, on the appearance of this ſign, the acid is already ſuperſaturated with the alkali, yet it ſeems to me to be a more accurate teſt for aſcertaining its ſtrength than the ceſſation of efferveſcence; for as the point of ſaturation approaches, the efferveſcence becomes ſo imperceptible, that it is almoſt impoſſible to determine with preciſion when it is really at an end. Now, every five drops of the alkaline ſolution, which I find it neceſſary to add to the vinegar till the precipitation takes place, I reckon as one degree. Thus, for example, if a determinate quantity of vinegar requires 25 drops for that effect, I denote its ſtrength by five degrees. This is about the ſtrength of good diſtilled vinegar.

“ I call that vinegar which, in conſequence of its concentration, is capable of cryſtallizing in a great degree of cold, *cryſtallizable vinegar;* the cryſtals of vinegar, ſeparated after the cryſtallization is completed from the remaining fluid portion, I call *glacial vinegar;* and, laſtly, to the fluid reſiduum I give the name of *mother-ley of vinegar.*

“ From a great number of experiments, I have found that vinegar muſt have at leaſt 24 degrees of concentration before it can be brought to cryſtallize by expoſure to the moſt intenſe cold. Vinegar muſt be of the ſtrength of 42 degrees at leaſt, in order to become glacial vinegar; *viz.* in this ſtate of concentration it has the property of cryſtallizing in a degree of cold not exceeding that in which water begins to freeze.

“ I have found that charcoal, on being diſtilled with vinegar in a water bath, poſſeſſes the ſingular and hitherto unknown property of imbibing a certain quantity of the acetous acid in a very concentrated ſtate, and of retaining it ſo ſtrongly, that the acid cannot be ſeparated from it again but by the application of a conſiderably greater degree of heat than that of boiling water. Upon this circumſtance is founded the new method which I have diſcovered of concentrating vinegar, ſo as to obtain all its acid in the pureſt ſtate, *viz.* that of a glacial vinegar.

“ Let a barrel of vinegar be concentrated by freezing in the manner above deſcribed, and let the concentrated vinegar thus obtained, free from all inflammable or ſpirituous parts, be put into two retorts: Add to each of them five pounds of good charcoal reduced to a fine powder, and ſubject them to diſtillation in a water-bath. When no more drops of vinegar come over, put the diſtilled liquor into two freſh retorts; and after adding five pounds of charcoal powder to each, proceed as before to the diſtillation in a water-bath. In the mean while, the two firſt retorts are to be placed in a ſand-bath, that, by means of a briſk fire, the cryſtallizable vinegar, which is retained in the apparently dry charcoal powder, may be expelled from it. The heat muſt be ſtrong enough to make the drops follow one another every two ſeconds; and when, in this degree of heat, 20 ſeconds intervene between each drop, the vinegar which has been collected muſt be removed; for what follows is hardly any thing elſe but mere water. In this manner about ſix ounces and a half of cryſtallizable vinegar, which is generally of the ſtrength of between 36 and 40 degrees, may be collected from each retort. As ſoon as the diſtillation by the water-bath in the two retorts is over, the diſtilled liquor is to be poured back again into the firſt retorts upon the charcoal powder, which remains in them, and which has been already uſed; and from each of theſe retorts the remaining cryſtallizable vinegar (which generally amounts to as much as the firſt quantity) is to be abſtracted by diſtillation in a ſand-bath. Theſe operations may be alternately repeated till all the acid of the vinegar which had been concentrated by freezing is converted into cryſtallizable vinegar; or until the diſtilled liquor, conſtantly becoming weaker and weaker at every repetition of the diſtillation, comes over at length in the ſtate of mere water, which, with the above mentioned quantity of charcoal powder, generally happens at the fourth or fifth diſtillation. Now, in order to obtain the greateſt part of the pure acid contained in the cryſtallizable vinegar in the form of glacial vinegar, it muſt be ſet to cryſtallize in a great degree of cold; and the mother-ley muſt be afterwards thoroughly drained from the glacial vinegar, by letting it drop from the cryſtals, firſt in the cold, and then in the room before the window. The mother-ley may be rendered further cryſtallizable by diſtilling it with a little charcoal powder; the weaker part, which comes over firſt, being put aſide. But if a perſon wiſhes to keep the cryſtallizable vinegar for other purpoſes, and without ſeparating any glacial vinegar from it, he muſt diſtil the whole of it again with charcoal powder in a ſand-bath.

“ I have found by accurate experiments, that, by means of this curious proceſs, ten pounds of vinegar, concentrated by freezing to the 90th degree, may be made

made to yield 38 ounces of cryſtallizable vinegar, from which 20 ounces of glacial vinegar may be obtained.

“ What conſtitutes the excellence of this method is, that the concentration and purification are effected by one and the ſame medium, viz. the charcoal powder; in conſequence of which, both intentions are fulfilled at the ſame time.

“ Laſt year, after much reflection, I was ſo happy as to find out another very effectual method of ſeparating the acetous acid from the other ſubſtances combined with it, ſo as to obtain it at once in the ſtate of a glacial vinegar of the greateſt poſſible ſtrength. The ſeparating medium which I thought of is ſulphat of potaſs ſuperſaturated with ſulphuric acid; a ſalt in which, conformably to my purpoſe, the ſulphuric acid exiſts in a perfectly dry and dephlegmated ſtate.

“ By means of this ſalt a highly concentrated glacial vinegar may be obtained in the following manner:

“ Let three parts of acetated ſoda, prepared with vinegar diſtilled over charcoal, and evaporated to perfect dryneſs, be melted in a ſtrong heat; then pour it out, and rub it to a very fine powder. Mix this powder very accurately with eight parts of ſuperſaturated ſulphat of potaſs that has been previouſly well dried, and in like manner reduced to a fine powder; put the whole into a retort, and diſtil with a gentle heat, in ſuch manner that, along with the drops, ſome vapours alſo may be perceived to come out of the neck of the retort; but by no means ſo that the receiver ſhall be filled with theſe vapours. Notwithſtanding the moderate heat, the vinegar comes over very faſt, and the quantity of glacial vinegar, of the ſtrength of 54 degrees, which is thus obtained, amounts to nearly two parts.”

464 Action of acetous acid on other bodies.

Acetous acid is capable of oxidating iron, zinc, lead, nickel, tin, copper.

It does not act upon gold, ſilver, platinum, mercury, biſmuth, cobalt, antimony, arſenic.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms compounds known by the name of *acetites*.

465 Its affinities.

Its affinities are as follows:

Barytes,
Potaſs,
Soda,
Strontites?
Lime,
Magneſia,
Ammonia,
Oxide of zinc,
——— mangaueſe,
——— iron,
——— lead,
——— tin,

——— ſilver,
——— gold,
——— platinum,
Alumina *,
Jargonia †?
Water,
Alcohol,

Sect. XII. *Of Acetic Acid.*

If acetite of copper be diſtilled, an acid comes over of a more pungent ſmell than acetous acid, capable of cryſtallizing, and having a ſtronger affinity for other bodies than acetous acid. It is called *acetic acid*, and is ſuppoſed to contain a larger proportion of oxygen than acetous acid. This additional doſe it is ſuppoſed to receive from the oxide of copper, which during the proceſs is reduced to the metallic ſtate. It can hardly be doubted that the glacial vinegar of Lowitz, deſcribed in the preceding ſection, is really acetic acid, though it would perhaps be difficult to explain its formation. Its affinities are the ſame with thoſe of the acetous acid.

Sect. XIII. *Of Oxalic Acid.*

Sugar, a well-known ſubſtance extracted from the ſugar-cane, appears to have been uſed in the Eaſt at a very early period; but it made its way weſtward very ſlowly. As a medicine, it is mentioned by Dioſcorides; but it was not in common uſe in Europe till after the 14th century.

466 Compoſition of ſugar.

It has been proved that ſugar is compoſed of oxygen, carbon, and hydrogen. Lavoiſier concluded, from a long ſeries of delicate experiments, that it conſiſts of 8 parts of hydrogen, 64 of oxygen, and 28 of carbon.

467 Diſcovery of oxalic acid.

From ſugar, by a particular proceſs, an acid has been obtained called *oxalic acid*, becauſe it exiſts ready formed, as Scheele has proved, in the *oxalis acetoſella*, or wood ſorrel. At firſt, however, it was called the *acid of ſugar*, or the *ſaccharine acid*.

As the earlieſt and beſt account of the oxalic acid was publiſhed by Bergman, he was for a long time reckoned the diſcoverer of it; but Mr Ehrhart, one of Scheele's intimate friends, informs us, that the world is indebted for its knowledge of this acid to that illuſtrious chemiſt *, and Hermſtadt and Weſtrum aſſign the diſcovery to the ſame author †. The aſſertions of theſe gentlemen, who had the beſt opportunity of obtaining accurate information, are certainly ſufficient to eſtabliſh the fact, that Scheele was the real diſcoverer of oxalic acid.

468 Method of procuring it.

Bergman gives us the following proceſs for obtaining this acid. “ Put one ounce of white ſugar powdered into a tubulated retort, with three ounces of ſtrong nitric acid, the ſpecific gravity of which is to that of water as 1,567. When the ſolution is over, during which many fumes of the nitrous acid eſcape, let a receiver be fitted, and the liquor made to boil, by which abundance of nitrous gas is expelled. When the liquor in the retort acquires a reddiſh brown colour, add three ounces more of nitric acid, and continue the boiling till the fumes ceaſe, and the colour of the liquor vaniſhes. Then let the contents of the retort be emptied into a wide veſſel; and upon cooling, a cryſtallization will take place of ſlender, quadrilateral priſms, which are often affixed to each other at an angle of 45°. Theſe cryſtals, collected and dried on blotting paper, will be found to weigh 1½ dr. 19 gr. By boiling the remaining lixivium with two ounces of nitric acid in the retort, till the red fumes almoſt diſappear, and by repeating the cryſtallization as before, ½ dr. 13 gr. of ſolid acid will be obtained. If the proceſs be repeated

---

* *Lavoiſier.*
† *Vauquelin, Ann. de Chim.* xxii. 208.

* *Elwart's Magazine for Apothecaries*, 1785, Part i. p. 54.
† *Keir's Dictionary.*

once more upon the reſiduum, which has now a glutinous conſiſtence, with the ſucceſſive additions of ſmall quantities of nitric acid, amounting in all to two ounces, a ſaline brown deliqueſcent maſs will be formed, weighing half a dram, of which about a half will be loſt by a farther purification. The cryſtals obtained thus at different times may be purified by ſolution and cryſtallization, and by digeſting the laſt lixivium with ſome nitric acid, and evaporation with the heat of the ſun."

By the ſame proceſs Bergman obtained it from gum arabic, alcohol, and honey: Scheele, Hermſtadt, Weſtrum, Hoffman, &c. from a great variety of other vegetable productions; and Berthollet from a great number of animal ſubſtances.

It is of great conſequence not to uſe too much nitric acid, otherwiſe the quantity of oxalic acid will be diminiſhed; and if a very great quantity of nitric acid be uſed, no oxalic acid will be obtained at all *. On the contrary, if too ſmall a quantity of nitric acid be uſed, the acid obtained will not be the oxalic, but the tartarous †. We think we have obſerved, that a conſiderably larger proportion of oxalic acid may be obtained by pouring nitric acid on ſugar, and allowing theſe ſubſtances to act upon each other while cold. When the proceſs is conducted in that manner, hardly any thing ſeparates but nitrous gas.

469
Its properties.

Oxalic acid is capable of cryſtallization, or rather it is generally obtained in that ſtate. Its cryſtals are quadrilateral priſms, the ends of which often terminate in ridges ‡.

They are ſoluble in their own weight of boiling water: water at the temperature of 65,7° diſſolves half its weight of them. The ſpecific gravity of the ſolution is 1,0593 ‖. One hundred parts of boiling alcohol diſſolve 56 parts of theſe cryſtals; but at a mean temperature only 40 parts §. They are not eaſily ſoluble in ether. Fixed and volatile oils diſſolve them, and they may be again obtained by gentle evaporation. Too violent a heat would ſublime the acid itſelf.

Oxalic acid has a very acrid taſte when it is concentrated, but a very agreeable acid taſte when ſufficiently diluted with water ¶.

It changes all vegetable blues except indigo to a red. One grain of cryſtallized acid, diſſolved in 1920 grains of water, reddens the blue paper with which ſugar loaves are wrapt: one grain of it, diſſolved in 3600 grains of water, reddens paper ſtained with turnſole *. According to Morveau, one part of the cryſtallized acid is ſufficient to communicate a ſenſible acidity to 2633 parts of water †.

Its fixity is ſuch, that none of it is ſublimed when water containing it in ſolution is raiſed to the boiling temperature.

When this cryſtallized acid is expoſed to heat in an open veſſel, there ariſes a ſmoke from it, which affects diſagreeably the noſe and lungs. The reſiduum is a powder of a much whiter colour than the acid had been. By this proceſs it loſes $\frac{3}{10}$ths of its weight; but ſoon recovers them again on expoſure to the air. When diſtilled, it firſt loſes its water of cryſtallization, then liquifies and becomes brown; a little phlegm paſſes over, a white ſaline cruſt ſublimes, ſome part of which paſſes into the receiver; but the greateſt part of the acid is deſtroyed, leaving in the retort a maſs $\frac{1}{50}$th of the whole, which has an empyreumatic ſmell, blackens ſulphuric acid, renders nitric acid yellow, and diſſolves in muriatic acid without alteration. That part of the acid which ſublimes is unaltered. When this acid is diſtilled a ſecond time, it gives out a white ſmoke, which, condenſing in the receiver, produces a colourleſs uncryſtallizable acid, and a dark coloured matter remains behind *. During all this diſtillation a vaſt quantity of elaſtic vapour makes its eſcape. From 279 grains of oxalic acid, Bergman obtained 109 cubic inches of gas, half of which was carbonic acid and half hydrogen. Fontana from an ounce of it obtained 430 cubic inches of gas, one-third of which was carbonic acid, the reſt hydrogen. From theſe facts, it is evident that oxalic acid is compoſed of oxygen, hydrogen, and carbon; but the proportions are ſtill unknown.

When nitric acid is frequently diſtilled off oxalic acid, acetous acid is produced †. The ſulphuric acid, when concentrated, ſeems to produce the ſame effect. Muriatic and acetous acids diſſolve oxalic acid, but without altering it ‡.

470
Its action on other bodies.

Oxalic acid is capable of oxidating lead, copper, iron, tin, biſmuth, nickel, cobalt, zinc, mangaueſe.

It does not act upon gold, ſilver, platinum, mercury, arſenic?

Oxalic acid combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms ſalts known by the name of *oxalats*.

471
Its affinities.

Its affinities, according to Bergman, are as follows:

Lime,
Barytes,
Strontites §,
Magneſia,
Potaſs,
Soda,
Ammonia,
Alumina,
Jargonia ‖ ?
Metallic oxides as in *ſulphuric acid*,
Water,
Alcohol.

SECT. XIV. *Of Tartarous Acid.*

472
Diſcovery of tartarous acid.

TARTAR, or *cream of tartar* as it is commonly called when pure, has occupied the attention of chemiſts for ſeveral centuries. Duhamel and Groſſe, and after them Margraf and Rouelle the Younger, proved that it was compoſed of an acid united to potaſs: but Scheele was the firſt who obtained this acid in a ſeparate ſtate. He communicated his proceſs for obtaining it to Retzius, who publiſhed it in the Stockholm Tranſactions for 1770. It conſiſted in boiling tartar with lime, and in decompoſing the tartrite of lime thus formed by means of ſulphuric acid.

473
Its properties.

This acid, by a gentle evaporation, yields cryſtals ſo irregular in their figure, that every chemiſt who has treated of this ſubject has given a different deſcription of them. According to Bergman, they generally conſiſt of divaricating lamellæ *; according to Van Packen, they aſſume ofteneſt the form of long pointed priſms †; Spielman and Corvinus ‡ obtained them in groups, ſome of them lance-ſhaped, others needle-formed, others pyramidal. Morveau obtained them needle-form §. They do not experience any change in the air;

heat decompoſes them. In the open fire they burn without leaving any other reſiduum than a coal, which generally contains a little lime [*]. In cloſe veſſels, the product is carbonic acid and hydrogen gas [†]. If the proper quantity of nitric acid be diſtilled off the cryſtals, they are converted into oxalic acid, and the nitric acid, as uſual, paſſes into the nitrous acid [‡]. Hence it is evident that tartarous acid alſo, like the four former, is compoſed of oxygen, hydrogen, and carbon; but the proportions are equally unaſcertained.

This acid, when in cryſtals, diſſolves readily in water. Bergman obtained a ſolution, the ſpecific gravity of which was 1,230 [§]. Morveau obſerved, however, that cryſtals formed ſpontaneouſly in a ſolution, the ſpecific gravity of which was 1,084.

474
Its action on other bodies.

It has a very ſharp acid taſte, and reddens vegetable blues.

Tartarous acid does not oxidate gold, ſilver, platinum, lead, biſmuth, nor tin, and hardly antimony and nickel.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms ſalts known by the name of *tartrites*.

475
Its affinities.

The order of its affinities is the ſame as that given for oxalic acid; except that, according to Lavoiſier, the oxide of ſilver comes before that of mercury.

SECT. XV. *Of Citric Acid.*

476
Method of obtaining citric acid.

CHEMISTS have always conſidered the juice of oranges and lemons as a peculiar acid. This juice contains a quantity of mucilage and water, which render the acid impure, and ſubject to ſpontaneous decompoſition. Mr Georgius took the following method to ſeparate the mucilage. He filled a bottle entirely with lemon-juice, corked it, and placed it in a cellar: in four years the liquid was become as limpid as water, a quantity of mucilage had fallen to the bottom in the form of flakes, and a thick cruſt had formed under the cork. He expoſed this acid to a cold of 23°, which froze a great part of the water, and left behind a ſtrong and pretty pure acid [‖]. It was Scheele, however, that firſt pointed out a method of obtaining this acid perfectly pure. He ſaturated lemon-juice with lime, edulcorated the precipitate, which conſiſted of citric acid and lime, ſeparated the lime from it by diluted ſulphuric acid, cleared it from the ſulphat of lime by repeated filtrations and evaporation; then evaporated it to the conſiſtence of a ſyrup, and ſet it by in a cool place: a quantity of cryſtals formed, which were pure citric acid [¶]. It exiſts ready formed alſo in the juices of the following berries: *Vaccinium occicoccos, vaccinium vitis idæa, prunus padus, ſolanum dulcamara, roſa canina* [*], *cherries* [†].

Scheele adviſes the uſe of an exceſs of ſulphuric acid, in order to enſure the ſeparation of all the lime; but according to Dizé, this exceſs is neceſſary for another purpoſe [‡]. A quantity of mucilage ſtill adheres to the citric acid in its combination with lime, and ſulphuric acid is neceſſary to decompoſe this mucilage, which, as Fourcroy and Vauquelin have proved, it is capable of doing. His proof of the preſence of mucilage is, that when the ſolution of citric acid in water, which he had obtained, was ſufficiently concentrated by evaporation, it aſſumed a brown colour, and even became black towards the end of the evaporation. The cryſtals alſo were black. By repeated ſolutions and evaporations, this black matter was ſeparated, and found to be carbon. Hence he concluded that mucilage had been preſent; for mucilage is compoſed of carbon, hydrogen, and oxygen; ſulphuric acid cauſes the hydrogen and oxygen to combine and form water, and the carbon remains behind. It is not certain, however, as Mr Nicholſon remarks very juſtly [*], that the ſulphuric acid may not act upon the citric acid itſelf, and that the carbon may not proceed from the decompoſition of it; at leaſt the experiments of Mr Dizé are inſufficient to prove the contrary. In that caſe the ſmaller the exceſs of ſulphuric acid uſed the better.

477
Its properties.

The cryſtals of citric acid are rhomboidal priſms, the ſides of which are inclined to each other in angles of about 120 and 60 degrees, terminated at each end by four trapezoidal faces, which include the ſolid angles [†]. They are not altered by expoſure to the air.

An ounce of diſtilled water, at the temperature of the atmoſphere, diſſolves one ounce and two drams of cryſtallized citric acid; and during the ſolution the temperature is lowered 29,75°. Boiling water diſſolves twice its weight of this acid [‡].

Citric acid has a very acid taſte; it turns vegetable blues to a red.

478
Its action on other bodies.

It is capable of oxidating iron, zinc, tin. It does not act upon gold, ſilver, platinum, mercury, biſmuth, antimony, arſenic.

It combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms ſalts known by the name of *citrats*.

Fire decompoſes this acid, converting it into an acidulous phlegm, carbonic acid gas, and carbonated hydrogen gas. Its ſolution in water is alſo gradually decompoſed, if acceſs of air be permitted. It is evident, therefore, that this acid is alſo compoſed of oxygen, hydrogen, and carbon.

Scheele ſaid that he could not convert it into oxalic acid by means of nitric acid, as he had done ſeveral other acids; but Weſtrum affirms, that this converſion may be effected; and thinks that Scheele had probably failed from having uſed too large a quantity of nitric acid, by which he had proceeded beyond the converſion into oxalic acid, and had changed the citric acid into vinegar; and in ſupport of his opinion, he quotes his own experiments: from which it appeared that, by treating ſixty grains of citron acid with different quantities of nitric acid, his products were very different. Thus with 200 grains of nitric acid he got 30 grains of oxalic acid; with 300 grains of nitric acid he obtained only 15 grains of the oxalic acid; and with 600 grains of nitric acid no veſtige appeared of the oxalic acid. On diſtilling the products of theſe experiments, eſpecially of the laſt, he obtained vinegar mixed with nitric acid.

479
Its affinities.

The affinities of this acid are as follows [§]:

Lime (L),
Barytes,
Strontites [‖],

Sect. XVI. *Of Malic Acid.*

480 Diſcovery of malic acid.

Scheele diſcovered a peculiar acid in the juices of ſeveral fruits, which, becauſe it is found moſt abundantly in apples, has been called *malic acid.*

481 Method of obtaining it.

He obtained it by the following proceſs: Saturate the juice of apples with potaſs, and add to the ſolution acetite of lead till no more precipitation enſues. Waſh the precipitate carefully with a ſufficient quantity of water; then pour upon it diluted ſulphuric acid till the mixture has a perfectly acid taſte, without any of that ſweetneſs which is perceptible as long as any lead remains diſſolved in it; then ſeparate the ſulphat of lead, which has precipitated, by filtration, and there remains behind pure malic acid ‖.

This acid is contained in the berries of the *barberis vulgaris*, the *ſambucus nigra*, the *prunus ſpinoſa*, the *ſorbus aucuparia*, and the *prunus domeſtica* ¶.

If nitric acid be diſtilled with an equal quantity of ſugar, till the mixture aſſumes a brown colour (which is a ſign that all the nitric acid has been abſtracted from it), this ſubſtance will be found of an acid taſte; and after all the oxalic acid which may have been formed is ſeparated by lime-water, there remains another acid, which may be obtained by the following proceſs: Saturate it with lime, and filter the ſolution; then pour upon it a quantity of alcohol, and a coagulation takes place. This coagulum is the acid combined with lime. Separate it by filtration, and edulcorate it with freſh alcohol; then diſſolve it in diſtilled water, and pour in acetite of lead till no more precipitation enſues. The precipitate is the acid combined with lead, from which it may be ſeparated by diluted ſulphuric acid. It poſſeſſes all the properties of malic acid *. This acid, therefore, may be obtained from ſugar; and it may be converted into oxalic acid, by diſtilling off it the proper quantity of nitric acid †.

482 Its properties.

This acid bears a ſtrong reſemblance to the citric, but differs from it in the following particulars:

1. The citric acid ſhoots into fine cryſtals, but this acid does not cryſtallize.

2. The ſalt formed from the citric acid with lime is almoſt inſoluble in boiling water; whereas the ſalt made with malic acid and the ſame baſis is readily ſoluble by boiling water.

3. Malic acid precipitates mercury, lead, and ſilver, from the nitrous acid, and alſo the ſolution of gold when diluted with water; whereas citric acid does not alter any of theſe ſolutions.

3. Malic acid ſeems to have a leſs affinity than citric acid for lime; for when a ſolution of lime in the former acid is boiled one minute with a ſalt formed from volatile alkali and citric acid, a decompoſition takes place, and the latter acid combines with the lime and is precipitated.

483 Its combinations.

The malic acid combines with alkalies, alkaline earths, and alumina, and metallic oxides, and forms ſalts known by the name of *malats*.

Its affinities have not yet been aſcertained.

Sect. XVII. *Of Lactic Acid.*

If milk be kept for ſome time it becomes ſour. The acid which then appears in it was firſt examined by Scheele, and found by him to have peculiar properties. It is called *lactic* acid. In the whey of milk this acid is mixed with a little curd, ſome phoſphat of lime, ſugar of milk, and mucilage. All theſe muſt be ſeparated before the acid can be examined. Scheele accompliſhed this by the following proceſs:

484 Method of obtaining lactic acid.

Evaporate a quantity of ſour whey to an eighth part, and then filtrate it: this ſeparates the cheeſy part. Saturate the liquid with lime-water, and the phoſphat of lime precipitates. Filtrate again, and dilute the liquid with three times its own bulk of water; then let fall into it oxalic acid, drop by drop, to precipitate the lime which it has diſſolved from the lime-water: then add a very ſmall quantity of lime-water, to ſee whether too much oxalic acid has been added. If there has, oxalat of lime immediately precipitates. Evaporate the ſolution to the conſiſtence of honey, pour in a ſufficient quantity of alcohol, and filtrate again; the acid paſſes through diſſolved in the alcohol, but the ſugar of milk and every other ſubſtance remains behind. Add to the ſolution a ſmall quantity of water, and diſtil with a ſmall heat, the alcohol paſſes over, and leaves behind the lactic acid diſſolved in water *.

485 Its properties.

This acid is incapable of cryſtallizing: when evaporated to dryneſs, it deliqueſces again in the air †.

When diſtilled, water comes over firſt, then a weak acid reſembling the tartarous, then an empyreumatic oil mixed with more of the ſame acid, and laſtly carbonic acid and hydrogen gas—there remains behind a ſmall quantity of coal ‡.

486 Combinations,

The combinations which this acid forms with alkalies, earths, and metallic oxides, are called *lactats*.

487 And affinities.

Its affinities, according to Bergman, are as follows:

Barytes,
Potaſs,
Soda,
Ammonia,
Lime,
Magneſia,
Alumina,
Jargonia § ?
Metallic oxides as in *ſulphuric acid*,
Water,
Alcohol.

Sect. XVIII. *Of Saccholactic Acid.*

488 Sugar of milk.

If a quantity of freſh whey of milk be filtrated, and then evaporated by a gentle fire till it is of the conſiſtence of honey, and afterwards allowed to cool, a ſolid maſs

maſs is obtained. If this be diſſolved in water, clarified with the white of eggs, filtrated, and evaporated to the conſiſtence of a ſyrup, it depoſites on cooling a number of brilliant, white, cubic cryſtals, which have a ſweet taſte, and for that reaſon have been called *ſugar of milk.* Fabricius Bartholet, an Italian, was the firſt European who mentioned this ſugar. He deſcribed it in his *Encyclopædia Hermetico dogmatica*, publiſhed at Boulognia in 1619; but it ſeems to have been known in India long before that period.

489 Method of obtaining ſaccholactic acid.

After Mr Scheele had obtained oxalic acid from ſugar, he wiſhed to examine whether the ſugar of milk would furniſh the ſame product. Upon four ounces of pure ſugar of milk, finely powdered, he poured 12 ounces of diluted nitric acid, and put the mixture in a large glaſs retort, which he placed in a ſand-bath. A violent efferveſcence enſuing, he was obliged to remove the retort from the ſand-bath till the commotion ceaſed. He then continued the diſtillation till the mixture became yellow. As no cryſtals appeared in the liquor remaining in the retort, after ſtanding two days he repeated the diſtillation as before, with the addition of eight ounces of nitric acid, and continued the operation till the yellow colour, which had diſappeared on addition of the nitrous acid, returned. The liquor in the retort contained a white powder, and when cold was obſerved to be thick. Eight ounces of water were added to dilute this liquor, which was then filtrated, by which the white powder was ſeparated; which being edulcorated and dried, weighed 7½ dr. The filtrated ſolution was evaporated to the conſiſtence of a ſyrup, and again ſubjected to diſtillation, with four ounces of nitric acid as before; after which, the liquor, when cold, was obſerved to contain many ſmall, oblong, four cryſtals, together with ſome white powder. This powder being ſeparated, the liquor was again diſtilled with more nitric acid as before; by which means the liquor was rendered capable of yielding cryſtals again; and by one diſtillation more, with more nitrous acid, the whole of the liquor was converted into cryſtals. Theſe cryſtals, added together, weighed five drams; and were found, upon trial, to have the properties of the oxalic acid.

Mr Scheele next examined the properties of the white powder, and found it to be an acid of a peculiar nature; he therefore called it the *acid of ſugar of milk.* It is now called the *ſaccholactic acid.*

490 Its properties.

According to Scheele, it is ſoluble in 60 parts of its weight of boiling water; but Meſſrs Hermſtadt * and Morveau † found, that boiling water only diſſolved $\frac{1}{80}$th part: it depoſited about ¼th part on cooling in the form of cryſtals ‡.

The ſolution has an acid taſte, and reddens the infuſion of turnſole §. Its ſpecific gravity, at the temperature of 53.7°, is 1,0015 ||.

Phyſ. Chem.
Encyc. Method. i. 90.
Scheele.
Id.
Morveau, id.

When diſtilled, it melts very readily, becomes black, and frothes; a brown ſalt ſublimes into the neck of the retort, which has the odour of a mixture of amber and benzoin, having an acid taſte, eaſily ſoluble in alcohol, with greater difficulty in water, and burning in the fire with a flame. There paſſes into the receiver a brown liquid, having ſome of this ſalt diſſolved in it: There remains behind a coal *, which Hermſtadt found to contain a ſmall quantity of lime. Concentrated ſulphuric acid diſtilled on this ſalt becomes black, frothes, and decompoſes it †.

* *Scheele, ibid.*
† *Id. ibid.*

491 Hermſtadt attempts to diſprove its exiſtence.

Mr Hermſtadt of Berlin had made ſimilar experiments on ſugar of milk at the ſame time with Scheele, and with ſimilar reſults; but he concluded that the white powder which he obtained was nothing elſe than oxalat of lime with exceſs of acid, as indeed Scheele himſelf did at firſt. After he became acquainted with Scheele's concluſions, he publiſhed a paper in defence of his own opinion; but his proofs are very far from eſtabliſhing it, or even rendering its truth probable. He acknowledges himſelf, that he has not been able to decompoſe this ſuppoſed ſalt: he allows that it poſſeſſes properties diſtinct from the oxalic acid; but he aſcribes this difference to the lime which it contains; yet all the lime which he could diſcover in 240 grains of this ſalt was only 20 grains; and if the alkali which he employed was a carbonat (as it probably was), theſe 20 muſt be reduced to 11. Now Morveau has ſhewn, that oxalic acid, containing the ſame quantity of lime, exhibits very different properties. Beſides, this acid, whatever it is when united with lime, is ſeparated by the oxalic, and muſt therefore be different from it, as it would be abſurd to ſuppoſe that an acid could diſplace itſelf ‡. The ſaccholactic acid muſt therefore be conſidered as a diſtinct acid, as it poſſeſſes peculiar properties.

‡ *Morveau, Encyc. Method.* i. p. 291.

492 Its compounds and affinities.

Its compounds with alkalies, earths, and metallic oxides, are denominated *ſaccholats.*

Its affinities, according to Bergman, are as follows:

Lime,
Barytes,
Magneſia,
Potaſs,
Soda,
Ammonia,
Alumina,
Jargonia §?
Metallic oxides as in *ſulphuric acid,*
Water,
Alcohol.

§ *Vauquelin, Ann. de Chim.* xxii. 208.

SECT. XIX. *Of Gallic Acid.*

493 Nut-galls.

THERE is an excreſcence, known by the name of *nut-gall*, which grows on ſome ſpecies of oaks. This ſubſtance contains a peculiar acid, called from that circumſtance *gallic acid*, the properties of which were firſt examined with attention by the commiſſioners of the academy of Dijon; and the reſult of their experiments was publiſhed in 1777, in the third volume of their Elements of Chemiſtry. In theſe experiments, however, they employed the infuſion of galls, in which the acid is combined with the tanning principle (M). It was reſerved for Scheele to obtain it in a ſtate of purity.

He

(M) A ſubſtance lately diſcovered by French chemiſts, which exiſts alſo in oak-bark, and every other body which may be ſubſtituted for that bark in the operation of tanning. It reſembles the reſins in many properties; but its diſtinguiſhing property is that of forming with glue a compound inſoluble in water. When a little of the decoction of glue is dropped into an infuſion of nut-galls, a white curdy precipitate is inſtantly ſeen: This is the tanning principle combined with glue. The name *tanning principle* has been applied to it, becauſe *tanning* conſiſts in combining this principle with *ſkins*, by which they are converted into leather.

494 Diſcovery of gallic acid.

He obſerved, in an infuſion of galls made with cold water, a ſediment, which proved on examination to have a cryſtalline form and an acid taſte. By letting an infuſion of galls remain a long time expoſed to the air, and removing now and then the mouldy ſkin which formed on its ſurface, a large quantity of this ſediment was obtained; which being edulcorated with cold water, rediſſolved in hot water, filtrated, and evaporated very ſlowly, yielded an acid ſalt in cryſtals as fine as ſand*.

There is a ſhorter method of obtaining this acid in a ſtill purer ſtate than Scheele obtained it.

495 Method of obtaining it.

Pour ſulphuric ether on a quantity of powdered galls, and allow it to remain a few hours; by which time it becomes coloured. Put this tincture into a retort, and diſtil off the ether with a ſmall heat. The reſiduum poſſeſſes the colour and brittleneſs of a reſin, and has all the characters of Rouelle's reſiduous-extract; it does not attract moiſture from the atmoſphere. Diſſolve it in its own weight of water, and add ſulphuric acid, drop by drop, till the liquor has become of a manifeſtly acid taſte. It cauſes a white precipitate, which becomes coloured, and is immediately rediſſolved. At the end of ſome hours a reſinous matter will have precipitated. Decant off the fluid, dilute it with half its weight of water, filtrate and evaporate it to ¾ths in a moderate heat; add pure barytes till the liquor is no longer capable of decompoſing muriat of barytes; then filtrate it again; and on evaporation in a moderate heat ſmall white priſmatic cryſtals of gallic acid are formed on the ſides of the veſſel †.

It appears from the experiments of Deyeux, that the ſubſtance extracted from nut-galls by ether does not differ much from the extract by water ‡. Probably, then, the only reaſon for employing ether is the ſmall heat neceſſary for evaporating it.

There is ſtill another method of obtaining this acid. Diſtil nut-galls in a ſtrong heat, a white ſubſtance ſublimes, which cryſtallizes in the form of needles: This is gallic acid. If the cryſtals are impure, they may be purified by a ſecond ſublimation: but the heat muſt not be too violent, otherwiſe the cryſtals will melt into a brown maſs §. This proceſs was diſcovered by Scheele.

496 Prouſt's method.

But the moſt elegant method of obtaining gallic acid is that of Mr Prouſt. When a ſolution of muriat of tin is poured into an infuſion of nut-galls, a copious yellow precipitate is inſtantly formed, conſiſting of the tanning principle, combined with the oxide of tin. After diluting the liquid with a ſufficient quantity of water to ſeparate any portion of this precipitate which the acids might hold in ſolution, the precipitate is to be ſeparated by filtration. The liquid contains gallic acid, muriatic acid, and muriat of tin. To ſeparate the tin, a quantity of ſulphurated hydrogen gas is to be mixed with the liquid. Sulphuret of oxide of tin is precipitated under the form of a brown powder. The liquid is then to be expoſed for ſome days to the light, covered with paper, till the ſuperfluous ſulphurated hydrogen gas exhales. After this, it is to be evaporated to the proper degree of concentration, and put by to cool. Cryſtals of gallic acid are depoſited. Theſe are to be ſeparated by filtration, and waſhed with a little cold water. The evaporation of the reſt of the liquid is to be repeated till all the gallic acid is obtained from it‖.

497 Its properties.

The gallic acid thus obtained has a very acid taſte, and reddens vegetable colours. It is ſoluble in 1½ parts of boiling water, and in 12 parts of water at the temperature of the atmoſphere. Alcohol diſſolves one-fourth of its weight of this acid at the temperature of the atmoſphere. When boiling hot it diſſolves a quantity equal to its own weight.

When placed upon burning coals, gallic acid takes fire, and at the ſame time diffuſes a very ſtrong odour, which has ſomething aromatic in it. When ſtrongly heated, it melts, boils, becomes black, is diſſipated, and leaves a quantity of charcoal behind it. When diſtilled, a quantity of oxygen gas is diſengaged, an acid liquor is found in the receiver, with ſome gallic acid not decompoſed, and there remains in the retort a quantity of carbon. If what has paſſed into the receiver be again diſtilled, more oxygen gas is obtained, ſome gallic acid ſtill ſublimes, and a quantity of carbon remains in the retort. By repeated diſtillations the whole of the acid may be decompoſed. This decompoſition may be more eaſily accompliſhed by diſtilling repeatedly a ſolution of gallic acid in water. The products are oxygen gas, charcoal, and an acid liquor.

498 Its compoſition.

From theſe experiments, Mr Deyeux, who performed them, has concluded, that gallic acid is compoſed of oxygen, and a much larger proportion of carbon than enters into the compoſition of carbonic acid. But this concluſion is not warranted by the analyſis; for Mr Deyeux did not find that the quantity of oxygen gas and carbon obtained was equal to that of the gallic acid decompoſed: and in the acid liquor which came over, there evidently exiſted a quantity of water, which doubtleſs was formed during the diſtillation. Scheele, by treating gallic acid with nitric acid in the uſual manner, converted it into oxalic acid. Now it is certain that oxalic acid contains hydrogen as well as carbon. It cannot be doubted, then, that gallic acid is compoſed of oxygen, hydrogen, and carbon, in proportions not yet aſcertained. But Mr Deyeux has proved, that the quantity of carbon is very great, compared with that of the hydrogen.

Gallic acid combines with alkalies, earths, and metallic oxides, and forms compounds known by the name of *gallats*.

Its affinities have not yet been determined; but oxide of iron ſeems to have a ſtronger affinity for it than for any other ſubſtance; for gallic acid is capable of taking it from every other acid. In conſequence of this property, the infuſion of galls is employed to detect the preſence of iron in any liquid. As ſoon as it is poured in, if iron be preſent, a black or purple colour is produced.

Sect. XX. *Of Benzoic acid.*

499 Benzoin.

Benzoin or *benjamin* (as it is ſometimes called) is a kind of reſin brought from the Eaſt Indies; obtained, according to Dr Dryander, from the ſtyrax benzoe, a tree which grows in the iſland of Sumatra. This ſubſtance conſiſts partly of a peculiar acid, deſcribed as long ago as 1608 by Blaiſe de Vigenere, in his Treatiſe on Fire and Salt, under the name of *flowers of benzoin*, becauſe it was obtained by ſublimation. This acid, which is now called *the benzoic acid*, may be ſublimed from benzoin by heat; or it may be obtained by Scheele's

---

* *Stockholm Tranſ.* 1786.

† *Mr J. J. Dizé Jour. de Phyſ.* Dec. 1791.

‡ *Ann. de Chim.* xvii. 8.

§ *Ibid.*

‖ *Ibid.* xxv. 225.

Scheele's proceſs, which has been deſcribed in the article CHEMISTRY, *Encycl.*

500 Properties of benzoic acid.

Benzoic acid has little or none of the peculiar odour which diſtinguiſhes benzoin. Its taſte is not acid, but ſweetiſh, and very pungent *. It hardly affects the infuſion of violets; but it reddens that of turnſole, eſpecially if that infuſion be hot †. Heat volatilizes this acid, and makes it give out a ſtrong odour, which excites coughing. When expoſed to the heat of the blow-pipe in a ſilver ſpoon, it melts, becomes as fluid as water, and evaporates without taking fire. It only burns when in contact with flame, and then it leaves no reſiduum behind. When thrown upon burning coals, it riſes in a white ſmoke. When allowed to cool after being melted, it hardens, and a radiated cruſt forms on its ſurface ‡.

It ſuffers no other alteration in the air than loſing the little of the odour of benzoin which remained to it §.

Cold water diſſolves no ſenſible quantity of it; but it is ſoluble enough in hot water: 480 grains of boiling water diſſolve 20 grains of it; 19 of theſe are depoſited, when the water cools, in long, ſlender, flat, feather-like cryſtals ‖.

Concentrated ſulphuric acid diſſolves it without heat or any other change except becoming ſomewhat brown: when water is poured into the ſolution, the benzoic acid ſeparates and coagulates on the ſurface without any alteration ¶. Nitric acid preſents preciſely the ſame phenomena, and alſo the ſulphurous and nitrous acids. Neither the muriatic, the oxy-muriatic, nor the phoſphoric acids diſſolve it. The acetous, formic, and ſebacic acids, when hot, diſſolve it preciſely as water does; but it cryſtallizes again when theſe acids cool *.

Alcohol diſſolves it copiouſly, and lets it fall on the addition of water †.

Little is known reſpecting its baſe.

501 Its combinations and affinities.

It combines with alkalies, earths, and metallic oxides, and forms ſalts known by the name of *benzoats*.

Its affinities, from the experiments of Trommſdorf, appear to be as follows:

White oxide of arſenic,
Potaſs,
Soda,
Ammonia,
Barytes,
Lime,
Magneſia,
Alumina,
Jargonia ‡?
Water,
Alcohol.

SECT. XXI. *Of Succinic Acid.*

502 Amber.

AMBER is a well-known brown, tranſparent, inflammable body, pretty hard, and ſuſceptible of poliſh, found at ſome depth in the earth, and on the ſea-coaſt of ſeveral countries. It was in high eſtimation among the ancients both as an ornament and a medicine.—When this ſubſtance is diſtilled, a volatile ſalt is obtained, which is mentioned by Agricola under the name of *ſalt of amber;* but its nature was long unknown. Boyle was the firſt who diſcovered that it was an acid §. From *ſuccinum*, the Latin name of amber, this acid has received the appellation of *ſuccinic acid.*

503 Method of obtaining ſuccinic acid.

It is obtained by the following proceſs: Fill a retort half way with powdered amber, and cover the powder with a quantity of dry ſand; lute on a receiver, and diſtil in a ſand-bath without employing too much heat. There paſſes over firſt an inſipid phlegm; then a weak acid, which, according to Scheele, is the acetous *; then the ſuccinic acid attaches itſelf to the neck of the retort; and if the diſtillation be continued, there comes over at laſt a thick brown oil, which has an acid taſte.

The ſuccinic acid is at firſt mixed with a quantity of oil. Perhaps the beſt method of purifying it is that recommended by Pott, to diſſolve it in hot water, and to put upon the filter a little cotton, previouſly moiſtened with oil of amber; this ſubſtance retains moſt of the oil, and allows the ſolution to paſs clear. The acid is then to be cryſtallized by a gentle evaporation. And this proceſs is to be repeated till the acid be quite pure.

504 Its properties,

The cryſtals are white, ſhining, and of a foliated triangular priſmatic form: they have an acid taſte, but are not corroſive: they redden tincture of turnſole, but have little effect on that of violets.

They ſublime when expoſed to a conſiderable heat, but not at the heat of a water-bath. In a ſand bath they melt, and then ſublime and condenſe in the upper part of the veſſel; but the coal which remains ſhews that they are partly decompoſed †.

One part of this acid diſſolves in 96 parts of water at the temperature of 50°, according to Spielman ‡, in 24 parts at the temperature of 52°, and in 2 parts of water at the temperature of 212°, according to Stockar de Neuforn §; but the greateſt part cryſtallizes as the water cools. According to Roux, however, it ſtill retains more of the acid than cold water is capable of diſſolving ‖.

240 grains of boiling alcohol diſſolve 177 of this acid; but cryſtals again ſhoot as the ſolution cools ¶.

505 Combinations and affinities.

The combinations of this acid are called *ſuccinats*.

Its component parts are ſtill unknown.

Its affinities, according to Morveau, are as follows:

Barytes,
Lime,
Potaſs,
Soda,
Ammonia,
Magneſia,
Alumina,
Jargonia *?
Metallic oxides as in *ſulphuric acid,*
Water,
Alcohol.

SECT. XXII. *Of Camphoric Acid.*

506 Camphor.

CAMPHOR is a well-known white cryſtalline ſubſtance, of a ſtrong taſte and ſmell, obtained from a ſpecies of laurel in the Eaſt Indies; and Mr Prouſt has ſhewn that ſeveral volatile oils contain a conſiderable quantity of it †. It is ſo volatile, that it cannot be melted in open veſſels, and ſo inflammable that it burns even on the ſurface of water.

When camphor is ſet on fire in contact with oxygen gas, it burns with a very brilliant flame; much caloric is diſengaged, water is formed, the inner ſurface of the veſſel is covered with a black matter, which is undoubtedly carbon, and a quantity of carbonic acid gas is alſo produced ‡. Hence it follows, that it is compoſed of hydrogen and carbon, at leaſt principally.

---

† *Ann. de Chim.* iv. 179.

‡ *LaGrange, ibid.* xxiii. 153.

If one part of camphor and ſix parts of pulveriſed clay be mixed together, by means of alcohol, in a mortar, the mixture made up into balls, and when dry put into a retort, and diſtilled by a moderate heat—a quantity of oil comes over, and there remains in the retort a black ſubſtance, which conſiſts of the clay intimately mixed with a quantity of carbon. If the fire be not cautiouſly managed, a quantity of camphor alſo ſublimes. By this proceſs camphor is decompounded, and ſeparated into oil and carbon.

122,248 parts of camphor
produced 45,856 parts of oil
and 30,571 of carbon.

Total 76,427
Loſs 45,821

Carbonated hydrogen gas and carbonic acid were alſo formed *.

* Ann. de Chim. xxiii. 153.

The oil obtained has the following properties:

507 Oil of camphor. It has a ſharp cauſtic taſte, and leaves upon the tongue a ſenſe of coldneſs. It has an aromatic odour, approaching to that of thyme or roſemary. Its colour is a golden yellow.

When expoſed to the air, it partly evaporates, and there remains a thick brown matter with a ſharp bitteriſh taſte, which at laſt alſo evaporates.

With alkalies, it forms a ſoap, which poſſeſſes all the characters of ſoaps made with volatile oils.

Alcohol diſſolves it entirely; and when water is added to the ſolution it becomes milky, but no precipitate is produced †.

† Ibid. 159.

Theſe properties ſhew that this is a volatile oil, and conſequently it is probable that camphor is compoſed of volatile oil and carbon.

508 Camphoric acid. Mr Koſegarten, by diſtilling nitric acid off camphor eight times ſucceſſively, obtained an acid in cryſtals ‡, to which the name of *camphoric acid* has been given.

‡ Koſegarten, de Camphora, &c. 1785.

His experiments have been repeated by Mr Bouillon La Grange. He mixed together 122,284 parts of camphor with 489,136 parts of nitric acid of the ſpecific gravity 1,33, and diſtilled them. Much nitrous and carbonic acid gas were diſengaged, and part of the camphor was ſublimed; but part was converted into an acid. He returned the ſublimed camphor into the retort, poured on it the ſame quantity of nitric acid as at firſt, and diſtilled again. This proceſs he repeated till the whole camphor was acidified §. The quantity of camphoric acid obtained amounted to 53,498. The quantity of nitric acid was 2114.538.

§ Ann. de Chim. ibid.

509 Its properties. Camphoric acid thus obtained is in ſnow-white cryſtals, of the form of parallelopipedons ‖.

‖ Koſegarten.

Theſe cryſtals effloreſce in the air ¶.

¶ La Grange.

Camphoric acid has a ſlightly acid bitter taſte, and ſmell like that of ſaffron.

It reddens vegetable colours.

It is ſoluble in 200 parts of cold water, according to Koſegarten; in 96 parts of water at the temperature of 60°, according to La Grange. Boiling water diſſolves $\frac{1}{12}$th of its weight *.

* Koſegarten.

According to Koſegarten, it is inſoluble in alcohol; according to La Grange, alcohol diſſolves it, and when the ſolution is left in contact with the air of the atmoſphere, the acid cryſtallizes. It is not precipitated from its ſolution in alcohol by the addition of water †.

† Bouillon La Grange, Ann. de Chim xxvii. 40.

When this acid is placed on ignited coals, it emits a denſe aromatic fume, and is entirely diſſipated. By a gentler heat, it melts, and is ſublimed. If it be put into a heated porcelain tube, and oxygen gas be paſſed through it, the acid does not undergo any change, but is ſublimed.

By mere diſtillation, it firſt melts and then ſublimes; by which proceſs its properties are in ſome reſpect changed. It no longer reddens the tincture of turnſole, but acquires a briſk aromatic ſmell; its taſte becomes leſs penetrating, and it is no longer ſoluble either in water or the ſulphuric and muriatic acids. Heated nitric acid turns it yellow and diſſolves it. Alcohol likewiſe diſſolves it; and if this ſolution be left in contact with the air of the atmoſphere, it cryſtallizes.

Camphoric acid does not produce any change in ſulphur; alcohol and the mineral acids totally diſſolve it; and ſo likewiſe do the volatile and the fat oils.

Camphoric acid does not precipitate lime from limewater. It produces no change on the ſolution of indigo in ſulphuric acid.

510 Its combinations and affinities. It forms combinations with the alkalies, earths, and metallic oxides, which are called *camphorats*.

Its affinities, as far as aſcertained by La Grange, are as follows *:

Lime,
Potaſs,
Soda,
Barytes,
Ammonia,
Alumina,
Magneſia.

* Ann. de Chim. xxvii. 21.

Sect. XXIII. *Of Suberic Acid.*

511 Diſcovery of ſuberic acid. Cork, a ſubſtance too well known to require any deſcription, is the bark of a tree which bears the ſame name. By means of nitric acid, Brugnatelli converted it into an acid †, which has been called the *ſuberic acid*, from *Suber*, the Latin name of the cork-tree. Several chemiſts affirmed that this acid was the oxalic, becauſe it poſſeſſed ſeveral properties in common with it. Theſe aſſertions induced Bouillon la Grange to undertake a ſet of experiments on ſuberic acid. Theſe experiments, which have been publiſhed in the 23d volume of the *Annales de Chimie*, completely eſtabliſh the peculiar nature of ſuberic acid, by ſhewing that it poſſeſſes properties different from thoſe of every other acid.

† Crell's Annals, 1787.

512 Method of preparing it. To prepare it, a quantity of ſound cork grated down ſmall is to be put into a retort, ſix times its weight of nitric acid of the ſpecific gravity 1,261 poured upon it, and the mixture diſtilled by means of a gentle heat. Red vapours are immediately diſcharged; the cork ſwells up and becomes yellow, and as the diſtillation advances, it ſinks to the bottom, and its ſurface remains frothy. If that froth does not form properly, it is a proof that ſome part of the cork has eſcaped the action of the acid. In that caſe, after the diſtillation is pretty far advanced, the acid which has paſſed into the receiver is to be poured back into the retort, and the diſtillation continued till no more red vapours can be perceived; and then the retort is to be immediately taken out of the ſand-bath, otherwiſe its contents would become black and adhere to it. While the matter contained in the retort is hot, it is to be poured into a glaſs veſſel, placed upon a ſand-bath over a gentle fire, and conſtantly ſtirred with a glaſs rod. By this means it becomes gradually

gradually thick. As ſoon as white vapours, exciting a tickling in the throat, begin to diſengage themſelves, the veſſel is removed from the bath, and the maſs continually ſtirred till it is almoſt cold.

By this means an orange-coloured maſs is obtained of the conſiſtence of honey, of a ſtrong and ſharp odour while hot, but having a peculiar aromatic ſmell when cold.

On this maſs twice its weight of boiling water is to be poured, and heat applied till it becomes liquid; and then that part of it which is inſoluble in water is to be ſeparated by filtration (N). The filtered liquor becomes muddy; on cooling it depoſites a powdery ſediment, and a thin pellicle forms on its ſurface. The ſediment is to be ſeparated by filtration, and the liquor reduced to a dry maſs by evaporating in a gentle heat. This maſs is *ſuberic acid*. It is ſtill a little coloured, owing to ſome accidental mixture, from which it may be purified either by ſaturating it with potaſs and precipitating it by means of an acid, or by boiling it along with charcoal powder.

513 Its properties.

Suberic acid thus obtained is not cryſtallizable, but when precipitated from potaſs by an acid, it aſſumes the form of a powder; when obtained by evaporation it forms thin irregular pellicles.

Its taſte is acid and ſlightly bitter; and when diſſolved in a ſmall quantity of boiling water it acts upon the throat, and excites coughing.

It reddens vegetable blues; and when dropped into a ſolution of indigo in ſulphuric acid (*liquid blue*, as it is called in this country), it changes the colour of the ſolution, and renders it green.

Water at the temperature of 60° or even 70° diſſolves only $\frac{1}{57,6}$ part of its weight of ſuberic acid, and if the acid be very pure, only $\frac{1}{112}$th part: boiling water, on the contrary, diſſolves half its weight of it.

When expoſed to the air, it attracts moiſture, eſpecially if it be impure.

When expoſed to the light of day, it becomes at laſt brown; and this effect is produced much ſooner by the direct rays of the ſun.

When heated in a matraſs, the acid ſublimes, and the inſide of the glaſs is ſurrounded with zones of different colours. If the ſublimation be ſtopped at the proper time, the acid is obtained on the ſides of the veſſel in ſmall points formed of concentric circles. When expoſed to the heat of the blow-pipe on a ſpoon of platinum, it firſt melts, then becomes pulverulent, and at laſt ſublimes entirely with a ſmell reſembling that of ſebacic acid (O).

It is not altered by oxygen gas:—the other acids do not diſſolve it completely. Alcohol developes an aromatic odour, and an ether may be obtained by means of this acid.

It converts the blue colour of nitrat of copper to a green; the ſulphat of copper alſo to a geen; green ſulphat of iron to a deep yellow; and ſulphat of zinc to a golden yellow (P).

514 Its action on other bodies.

It has no action either on platinum, gold, or nickel; but it oxidates ſilver, mercury, copper, lead, tin, iron, biſmuth, arſenic, cobalt, zinc, antimony, manganeſe, and molybdenum.

With alkalies, earths, and metallic oxides, it forms compounds known by the name of *ſuberats*.

515 Its affinities.

Its affinities are as follows (Q):

Barytes,

(N) When this ſubſtance is put into a matraſs, water poured on it, and heat applied, it melts; and when the veſſel is taken from the fire and allowed to cool, one part of it, which is of the conſiſtence of wax, ſwims on the ſurface of the water, and another part precipitates to the bottom of the veſſel, and aſſumes the appearance of a whitiſh magma. When this magma is ſeparated by filtration, and waſhed and dried, a white taſteleſs powder is obtained, mixed with ligneous threads, ſoluble in acids and alkalies.

(O) An acid which ſhall be afterwards deſcribed.

(P) Owing perhaps to the preſence of a little iron in the ſulphat.

(Q) The place which the ſuberic acid occupies in the affinities of the alkalies, earths, and metallic oxides, as far as this ſubject has been inveſtigated by Bouillon La Grange, will appear by the following Tables:

516 Its compoſition.

Mr Bouillon La Grange, to whom we are indebted for all the facts relative to this acid, ſuppoſes that it is compoſed of oxygen, hydrogen, and carbon: but Mr Jameſon, in conſequence of the reſult of a ſeries of experiments which he made on charcoal, has been led to ſuſpect that it conſiſts entirely of carbon and oxygen. He found, that by the action of nitric acid upon charcoal, a brown, bitter, deliqueſcent maſs was formed, ſoluble in water, alcohol, and alkalies, and which emitted, particularly when heated, a very fragrant odour. This matter was more or leſs ſoluble in water according to the time that it had been expoſed to the action of the acid. When the nitric acid uſed was concentrated, and conſiderable in quantity, part of the charcoal was converted into an acid, which poſſeſſed the characters of the ſuberic †.

† *Jameſon's Mineralogy of Shetland and Arran*, p. 167.

Theſe facts are curious, and may extend our knowledge of the nature of vegetable acids, but they are inſufficient to prove the abſence of hydrogen in ſuberic acid, becauſe charcoal cannot eaſily be procured perfectly free from hydrogen, and becauſe ſeveral of the properties of ſuberic acid indicate the preſence of hydrogen in it, its becoming brown, for inſtance, when expoſed to the light. Mr Jameſon has obſerved, that the acid which exiſts ready formed in peat poſſeſſes the properties of ſuberic acid.

Sect. XXIV. *Of Laccic Acid.*

517 Diſcovery of white lac.

About the year 1786, Dr Anderſon of Madras mentioned, in a letter to the governor and council of that place, that neſts of inſects, reſembling ſmall cowry ſhells, had been brought to him from the woods by the natives, who eat them with avidity. Theſe ſuppoſed neſts he ſoon afterwards diſcovered to be the coverings of the females of an undeſcribed ſpecies of coccus, which he ſhortly found means to propagate with great facility on ſeveral of the trees and ſhrubs growing in his neighbourhood (r).

On examining this ſubſtance, which he called *white lac*, he obſerved in it a very conſiderable reſemblance to bees wax; he noticed alſo, that the animal which ſecretes it provides itſelf by ſome means or other with a ſmall quantity of honey, reſembling that produced by our bees; and in one of his letters he complains, that the children whom he employed to gather it were tempted by its ſweetneſs to eat ſo much of it as materially to reduce the produce of his crop. Small quantities of this matter were ſent into Europe in 1789, both in its natural ſtate and melted into cakes; and in 1793 Dr Pearſon, at the requeſt of Sir Joſeph Banks, undertook a chemical examination of its qualities, and his experiments were publiſhed in the Philoſophical Tranſactions for 1794.

518 Its analyſis.

A piece of white lac, from 3 to 15 grains in weight, is probably produced by each inſect. Theſe pieces are of a grey colour, opaque, rough, and roundiſh. When white lac was purified by being ſtrained through muſlin, it was of a brown colour, brittle, hard, and had a bitteriſh taſte. It melted in alcohol, and in water of the temperature of 145°. In many of its properties it reſembles bees wax, though it differs in others; and Dr Pearſon ſuppoſes that both ſubſtances are compoſed of the ſame ingredients, but in different proportions.

Two thouſand grains of white lac were expoſed in ſuch a degree of heat as was juſt ſufficient to melt them. As they grew ſoft and fluid, there oozed out 550 grains of a reddiſh watery liquid, which ſmelled like newly baken bread (s). To this liquid Dr Pearſon has given the name of *laccic acid* *.

* *Pearſon's Tranſl. of the Chemical Nomenclature.*

It poſſeſſes the following properties:

519 Properties of laccic acid.

It turns paper ſtained with turnſole to a red colour.

After being filtered, it has a ſlightly ſaltiſh taſte with bitterneſs, but is not at all ſour.

When heated, it ſmells preciſely like newly baken hot bread.

On ſtanding, it grows ſomewhat turbid, and depoſites a ſmall quantity of ſediment.

Its ſpecific gravity at the temperature of 60° is 1,025.

A little of it having been evaporated till it grew very turbid, afforded on ſtanding ſmall needle-ſhaped cryſtals in mucilaginous matter.

Two hundred and fifty grains of it were poured into a very ſmall retort and diſtilled. As the liquor grew warm, mucilage-like clouds appeared; but as the heat increaſed they diſappeared again. At the temperature of 200°, the liquor diſtilled over very faſt: A ſmall quantity of extractive matter remained behind. The diſtilled liquor while hot ſmelled like newly baken bread, and was perfectly tranſparent and yellowiſh. A ſhred of paper ſtained with turnſole, which had been put into the receiver, was not reddened; nor did another which had been immerſed in a ſolution of ſulphat of iron, and alſo placed in the receiver, turn to a blue colour upon being moiſtened with the ſolution of potaſs (t).

Oxide of Iron.	Oxide of Bismuth.	Oxide of Arsenic.
* * *	* * *	* * *
Sulphuric,	Muriatic,	Nitric acid,
Suberic.	Suberic.	Suberic.

Cobalt and Zinc the ſame with arſenic.

(r) The Chineſe collect a kind of wax, which they call *pe-la*, from a coccus, depoſited for the purpoſe of breeding on ſeveral ſhrubs, and manage it exactly as the Mexicans manage the cochineal inſect. It was the knowledge of this that induced Dr Anderſon to attempt to propagate his inſect.

(s) The ſame liquid appears on preſſing the crude lac between the fingers; and we are told, that when newly gathered it is replete with juice.

(t) A proof that the acid was not the pruſſic.

About one hundred grains of this diſtilled liquid being evaporated till it grew turbid, after being ſet by for a night, afforded acicular cryſtals, which under a lens appeared in a group not unlike the umbel of parſley. The whole of them did not amount to the quarter of a grain. They taſted only bitteriſh.

Another 100 grains being evaporated to dryneſs in a very low temperature, a blackiſh matter was left behind, which did not entirely diſappear on heating the ſpoon containing it very hot in the naked fire; but on heating oxalic acid to a much leſs degree, it evaporated and left not a trace behind.

Carbonat of lime diſſolved in this diſtilled liquid with effervſcence. The ſolution taſted bitteriſh, did not turn paper ſtained with turnſole red, and on adding to it carbonat of potaſs a copious precipitation enſued. A little of this ſolution of lime and of alkali being evaporated to dryneſs, and the reſiduum made red hot, nothing remained but carbonat of lime and carbonat of potaſs.

This liquid did not render nitrat of lime turbid, but it produced turbidneſs in nitrat and muriat of barytes.

To five hundred grains of the reddiſh-coloured liquor obtained by melting white lac, carbonat of ſoda was added till the effervſcence ceaſed, and the mixture was neutraliſed; for which purpoſe three grains of the carbonat were neceſſary. During this combination a quantity of mucilaginous matter, with a little carbonat of lime, was precipitated. The ſaturated ſolution being filtrated and evaporated to the due degree, afforded on ſtanding deliqueſcent cryſtals, which on expoſure to fire left only a reſiduum of carbonat of ſoda.

Lime-water being added to this reddiſh-coloured liquor produced a light purple turbid appearance; and on ſtanding there were clouds juſt perceptible.

Sulphuret of lime occaſioned a white precipitation, but no ſulphurated hydrogen gas was perceptible by the ſmell.

Tincture of galls produced a green precipitation.

Sulphat of iron produced a purpliſh colour, but no precipitation; nor was any precipitate formed by the addition firſt of a little vinegar, and then of a little potaſs, to the mixture.

Acetite of lead occaſioned a reddiſh precipitation, which rediſſolved on adding a little nitric acid.

Nitrat of mercury produced a whitiſh turbid liquor.

Oxalic acid produced immediately the precipitation of white acicular cryſtals, owing probably to the preſence of a little lime in the liquid.

Tartrite of potaſs produced a precipitation not unlike what takes place on adding tartarous acid to tartrite of potaſs (u); but it did not diſſolve again on adding potaſs.

Such were the properties of this acid diſcovered by Dr Pearſon. Its deſtructibility by fire, and its affording carbon, diſtinguiſh it from all the acids deſcribed in this article before the acetous; and its peculiar ſmell when heated, its precipitating tartrite of potaſs without forming tartar, its bitteriſh taſte, and its being converted into vapour at the temperature of 200°, diſtinguiſh it from all the acids hitherto examined *.

Sect. XXV. *Of Pyromucous Acid.*

520 Method of obtaining pyromucous acid.

Pyromucous (v) acid is procured by diſtilling ſugar or any of the ſweet juices. As they foam very much, the retort ſhould be large, and ſeven-eighths of it empty. A prodigious quantity of carbonic acid and carbonated hydrogen gas is diſengaged: A very thin light coal remains behind in the retort. Morveau found the glaſs of the retort attacked. The quantity of ſugar diſtilled was 2304 grains; the coal weighed 982 grains. There were 428 grains of a brown liquor in the receiver, conſiſting moſtly of an acid phlegm. This rediſtilled gave 313 grains of a liquor almoſt limpid, the ſpecific gravity of which was 1,0115 at the temperature of 77°. It reddened blue paper. This acid may be concentrated by freezing, or by combining it with ſome baſe, potaſs, for inſtance, and decompoſing the compound by a ſtronger acid, as, for example, the ſulphuric.

521 Its properties,

It has a very ſharp taſte. When expoſed to heat in open veſſels, it evaporates, leaving a brown ſpot. Diſtilled in cloſe veſſels, it leaves charcoal behind it.

It does not diſſolve gold as Schrickel and Lemery and ſeveral other chemiſts affirmed.

It does not attack ſilver nor mercury, nor even their oxides †. It corrodes lead, and forms ſtyptic and long cryſtals. Copper forms with it a green ſolution: With iron it forms green cryſtals; with antimony and zinc greeniſh ſolutions.

522 Combinations, and affinities.

The compounds which it forms are called *pyromucites*. Its affinities, according to Morveau, are as follows:

Potaſs,
Soda,
Barytes,
Lime,
Magneſia,
Ammonia,
Alumina,
Jargonia ‡.
Metallic oxides as in *ſulph. acid*,
Water,
Alcohol.

Sect. XXVI. *Of Pyro-lignous Acid.*

523 Method of obtaining pyro-lignous acid.

It is well known that the ſmoke of burning wood is exceedingly offenſive to the eyes: And chemiſts have long ago obſerved, that an acid might be obtained by diſtilling wood.

It is to Mr Goettling, however, and to the Dijon academicians, who repeated his experiment, that we are indebted for what knowledge we poſſeſs of the peculiar properties of this acid, which, becauſe it is obtained from wood by means of fire, has been called *the pyro-lignous acid* (w). It appears to be the ſame from what ever kind of wood it is obtained.

Mr Goettling filled an iron retort with pieces of birch tree bark, and obtained by diſtillation a thick, brown, very empyreumatic acid liquor. This liquor he allowed

---

* *Phil. Tranſ.* 1794, p. 383.

† *Schrickel.*

‡ *Vauquelin, Ann. de Chim.* xxii. 208.

(u) On this addition, tartar, or acidulated tartrite of potaſs, is formed, which precipitates, becauſe it is very little ſoluble in water. The addition of potaſs diſſolves it again.

(v) Morveau called this acid *ſyrupous* acid.

(w) Goettling called it *ligneous acid.*

allowed to remain at reſt for three months, and then ſeparated from it a quantity of oil which had riſen to the top. By diſtilling this liquor again, and then ſaturating it with potaſs, and evaporating to dryneſs, he obtained a brown ſaline maſs; which, by being rediſſolved in water, and evaporated, yielded greyiſh white cryſtals: Theſe cryſtals were compoſed of pyro-lignous acid and potaſs. He poured upon them, by little and little, a quantity of ſulphuric acid; and by applying a gentle heat, the pyro-lignous acid came over in conſiderable purity *.

The Dijon academicians obtained this acid from beech wood: by diſtilling 55 ounces, they procured 17 ounces of acid; which, when rectified by a ſecond diſtillation, was of the ſpecific gravity 1,02083.

524 Its properties, combinations, and affinities.

It reddens vegetable colours: when expoſed to a ſtrong heat, it takes fire and is deſtroyed. It unites very well with alcohol.

Its compounds are called *pyro-lignites*.

Its affinities, as fixed by Mr Eloy Bourſier de Clervaux and Mr de Morveau, are as follows:

Lime,
Barytes,
Potaſs,
Soda,
Magneſia,
Ammonia,
Oxide of zinc,
——— manganeſe,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,
——— nickel,
——— arſenic,
——— biſmuth,
——— mercury,
——— antimony,
——— ſilver,
——— gold,
——— platinum,
Alumina,
Jargonia † ?

Sect. XXVII. *Of Pyro-tartarous Acid.*

An acid may alſo be obtained by diſtilling tartar; it is called *pyro-tartarous acid.*

525 Properties of pyro-tartarous acid.

It has an empyreumatic taſte and odour; reddens the tincture of turnſole; but has no effect on that of violets. Little is known concerning this acid, except that many of its properties are the ſame with thoſe of the pyro-lignous; and Morveau conjectures that, if properly purified, it would probably be diſcovered to be the ſame with it.

The compounds which it forms are called *pyro-tartrites*.

Its affinities are unknown. Morveau ſuppoſes that they are the ſame with thoſe of the pyro-lignous acid.

526 Vegetable acids,

The 18 preceding acids are all (except the lactic and ſaccholactic) denominated *vegetable acids*, becauſe they are obtained from vegetable ſubſtances. We have placed the lactic and ſaccholactic acids in the ſame claſs; becauſe they bear a ſtrong reſemblance to vegetable acids, and becauſe they are evidently compoſed of the ſame ingredients with them.

527 Deſtroyed by fire.

Vegetable acids are diſtinguiſhed from all the acids deſcribed in the beginning of this chapter, by their deſtructibility by fire.

528 Convertible into each other.

There is no circumſtance in chemiſtry which has attracted greater attention than the poſſibility of converting the various vegetable acids into each other by means of different proceſſes. To explain what paſſes during theſe proceſſes, it would be neceſſary to know exactly the component parts of every vegetable acid, the manner in which theſe acids are combined, and the affinities which exiſt between each of their ingredients. This, however, is very far from being the caſe at preſent. Though a vaſt number of experiments have been made on purpoſe to throw light on this very point, the difficulties which were to be encountered have been ſo great, that no accurate reſults have yet been obtained.

529 Inquiry into the proportions of their ingredients.

It follows from theſe experiments, that all the vegetable acids are compoſed, chiefly at leaſt, of oxygen, hydrogen, and carbon; but that the proportions differ in every individual acid. We ſay chiefly, becauſe it has been ſuſpected from ſome phenomena, that one or two of theſe acids contain beſides a little azot. Let us take a view of what is at preſent known of the compoſition of theſe acids in their order.

1. As to carbonic acid, its compoſition has been aſcertained with tolerable accuracy; it conſiſts of about 28 parts of carbon and 72 of oxygen.

2. By diſtilling 7680 grains of acetite of potaſs, Dr Higgens obtained the following products *:

Potaſs, - - - - -	3862,994 grains.
Carbonic acid gas, - -	1473,564
Carbonated hydrogen gas, -	1047,6018
Reſiduum, conſiſting of carbon, -	78,0000
Oil, - - - - - -	180,0000
Water, - - - -	340,0000
Deficiency (x), - - -	726,9402

This deficiency Dr Higgens found to be owing to a quantity of water and oil which is carried off by the elaſtic fluids, and afterwards depoſited by them. He calculated it, in the preſent caſe, at 700 grains of water and 26,9402 grains of oil. Now, ſince acetite of potaſs is compoſed of acetous acid and potaſs, and ſince the whole of the potaſs remained unaltered, it follows that the acetous acid was converted into carbonic acid gas, carbonated hydrogen gas, carbon, oil, and water; all of which are compoſed of oxygen, hydrogen, and carbon.

Now 1473,564 gr. of carbonic acid gas are compoſed of 1060,966 gr. of oxygen, and 415,598 gr. of carbon.

1047,6018 grains of carbonated hydrogen gas, from a compariſon of the experiments of Dr Higgens and Lavoiſier, may be ſuppoſed to conſiſt of about 714,6008 grains of carbon, and 333,0010 of hydrogen.

200,9402 grains of oil contain 163,4828 grains of carbon and 43,4574 grains of hydrogen.

1040 grains of water contain 884 grains of oxygen and 156 grains of hydrogen.

Therefore

---

* Crell's Journal, 1779.

† Vauquelin, Ann. de Chim. xxii. 208.

* Higgens on Acetous Acid, p. 26.

(x) For 29,1 grains of oxygen gas had alſo diſappeared from the air of the veſſels.

Therefore 3817,006 grains of acetous acid are compoſed of 1944,966 — 29,1 = 1915,866 grains of oxygen, 532,4584 grains of hydrogen, and 1368,6816 grains of carbon. Conſequently 100 parts of acetous acid are compoſed of

50,19 oxygen,
13,94 hydrogen,
35,87 carbon.

100,00

Theſe numbers can only be conſidered as approximations to the truth; for the object of Dr Higgens was not to aſcertain the proportions of the ingredients which compoſe acetous acid; and therefore his experiments were not conducted with that rigid accuracy which would have been neceſſary for that purpoſe.

It is extremely probable, that during the acetous fermentation, or the converſion of alcohol into acetous acid, a quantity of water is formed *; and it is certain that oxygen is abſorbed. It follows from this that acetous acid contains more carbon and leſs hydrogen than alcohol. Now we have reaſon, from Lavoiſier's experiments, to believe that alcohol is formed of

51,72 oxygen,
18,40 hydrogen,
29,88 carbon.

Lavoiſier ſuppoſes that this acid contains alſo azot.

3. Acetic acid is ſuppoſed to conſiſt of the ſame baſe with acetous acid, combined with a larger proportion of oxygen; we would rather ſay, that it is acetous acid combined with oxygen.

4. When oxalic acid is diſtilled with ſix times its weight of ſulphuric acid, the products are acetous acid, ſulphurous acid, carbonic acid gas, and ſulphuric acid remains in the retort †. Hence it follows, that oxalic acid contains more carbon than acetous acid; but that it is compoſed of the ſame ingredients. It has been ſuppoſed that oxalic acid is compoſed of ſugar and oxygen. Now ſugar, according to Lavoiſier, is compoſed of

Hydrogen, - - - -	8
Oxygen, - - - -	64
Carbon, - - - -	28

Theſe proportions are rather unfavourable to that notion; at leaſt if any dependence can be put in the compoſition of acetous acid as deduced from the experiments of Dr Higgens.

5. Hermſtadt diſſolved four ounces of tartarous acid in 16 ounces of water, and kept the ſolution in a veſſel covered with paper in a warm place. In three months the taſte of the ſolution was changed, and the air in the upper part of the veſſel was found to be carbonic acid. In ſix months the ſolution was converted into acetous acid. It follows from this experiment, that tartarous acid contains more carbon than acetous acid, and that their ingredients are the ſame. If any doubts ſhould remain, the following experiment is ſufficient to remove them. Weſtrum mixed ſtrong ſulphuric acid with tartarous acid, and added mangneſe; acetous acid was produced, and a great quantity of carbonic acid gas was diſengaged. When nitric acid is diſtilled off tartarous acid, it is converted into oxalic acid, as Scheele firſt proved. Hence it has been ſuppoſed by ſome, that oxalic acid differs from tartarous merely in containing more oxygen: but this is very far indeed from being proved. According to Haſſenfratz, tartarous acid contains a conſiderable quantity of azot.

6. When citrat of lime is allowed to remain in a bottle ſlightly corked along with a little alcohol, the citric acid is gradually converted into acetous acid *. Weſtrum converted it into oxalic acid by means of nitric acid.

7. Malic acid was converted into oxalic by means of nitric acid by Scheele. It has been ſuppoſed to contain more oxygen than oxalic acid. Some of it is always formed during the common proceſs of converting ſugar into oxalic acid. Were we to judge from an experiment, which, however, was not performed with ſufficient accuracy, we would conclude that the baſe of malic acid is gum; for by diſtilling two parts of weak nitric acid off one part of gum in a very ſmall heat, we obtained a quantity of acid more in weight than the gum, which exhibited ſeveral of the diſtinguiſhing properties of malic acid. It was exceedingly light, white, and ſpongy, and attracted water very quickly from the atmoſphere, and could not afterwards be brought by evaporation to its former ſtate.

8. Scheele converted lactic acid into acetous by mere expoſure to the atmoſphere, and found that a quantity of carbonic acid was diſengaged. Hence this acid is merely the acetous with a ſmaller proportion of carbon.

9. The gallic acid, we have ſeen, contains more carbon than any of the others.

10. Nothing is known concerning the compoſition of the benzoic and ſuccinic acids. Hermſtadt ſays he converted benzoic acid to oxalic by means of nitric acid: but Morveau did not obſerve that any change was produced.

11. The baſe of camphoric is probably camphor.

Though theſe eighteen are the only acids which have hitherto been examined with attention, it cannot be doubted that the number of vegetable acids, either exiſting naturally, or at leaſt capable of being formed by art, is conſiderably greater. Morveau has lately aſcertained, that the red colours of flowers are owing to acids: This had already been conjectured by Linnæus.

Sect. XXVIII. *Of Pruſſic Acid.*

530 Diſcovery of Pruſſian blue.

About the beginning of the preſent century, Dieſbach, a chemiſt of Berlin, wiſhing to precipitate a ſolution of cochineal mixed with a little alum and ſulphat of iron, borrowed from Dippel ſome potaſs, from which that chemiſt had *diſtilled* ſeveral times his *animal oil*. On pouring in the potaſs, Dieſbach was ſurpriſed to ſee, inſtead of the red precipitate which he had expected, a beautiful blue powder falling to the bottom of the veſſel. By reflecting on the materials which he had employed, he eaſily diſcovered the method of procuring the blue powder at pleaſure †. This powder was called *Pruſſian blue*, from the place where it was diſcovered. It was announced in the Berlin Memoirs for 1710; but the proceſs was concealed, becauſe it had become a lucrative article of commerce. A method of preparing it, however, was publiſhed by Woodward in the Philoſophical Tranſactions for 1724, which he ſaid he had got from one of his friends in Germany. This method was as follows: Detonate together 4 ounces of nitre and as much tartar, in order to procure an extemporaneous alkali; then add 4 ounces of dried bullock's blood, mix the

531 Method of preparing it.

---

* Hermſtadt, Crell's Annals, 1786.

† Crell, Jour. de Phyſ. 1785.

* Stahl.

† Stahl's 300 Experiments.

the ingredients well together, and put them into a crucible covered with a lid, in which there is a ſmall hole; calcine with a moderate fire till the blood emits no more ſmoke or flame capable of blackening any white body expoſed to it: increaſe the fire towards the end, ſo that the whole matter contained in the crucible ſhall be moderately but ſenſibly red. In this ſtate throw it into two pints of water, and boil it for half an hour. Decant off this water, and continue to pour on more till it come off inſipid. Add all theſe liquids together, and boil them down to two pints. Diſſolve two ounces of ſulphat of iron and eight ounces of alum in two pints of boiling water; mix this with the former liquor while both are hot. An effervеſcence takes place, and a powder is precipitated of a green colour mixed with blue. Separate this precipitate by filtration, and pour muriatic acid upon it till it becomes of a beautiful blue; then waſh it with water and dry it.

Different explanations were given of the nature of this precipitate by different chemiſts. All of them acknowledged that it contained iron, but to account for the colour was the difficult point. Brown, and Geoffroy, and Neumann, diſcovered in ſucceſſion, that a great many other animal ſubſtances beſides blood communicated to alkalies the property of forming Pruſſian blue. Macquer undertook an examination of this ſubſtance, and publiſhed the reſult of his experiments in the Memoirs of the French Academy for 1752.

532 Its compoſition diſcovered by Macquer.

He obſerved that, when alkali is added to a ſolution of iron in any acid, the iron is precipitated of a yellow colour, and ſoluble in acids; but if iron be precipitated from an acid by an alkali prepared as above deſcribed, by calcination with blood (which has been called a *Pruſſian alkali)*, it is of a green colour. Acids diſſolve only a part of this precipitate, and leave behind an inſoluble powder which is of an intenſe blue colour. The green precipitate therefore is compoſed of two different ſubſtances, one of which is Pruſſian blue; the other, as he aſcertained by experiment, is the brown or yellow oxide of iron: and the green colour is owing to the mixture of the blue and yellow ſubſtances. When heat is applied to the inſoluble precipitate, its blue colour is deſtroyed, and it becomes exactly ſimilar to common oxide of iron. It is compoſed therefore of iron and ſome other ſubſtance, which heat has the property of driving off. If this inſoluble precipitate be boiled with a very pure alkali, it loſes its blue colour alſo, and at the ſame time the alkali acquires the property of precipitating of a blue colour ſolutions of iron in acids, or it has become preciſely the ſame with the Pruſſian alkali. Pruſſian blue, therefore, is compoſed of iron and ſomething which a pure alkali can ſeparate from it, ſomething which has a greater affinity for alkali than for iron. By boiling a quantity of alkali with Pruſſian blue, it may be completely ſaturated with this ſomething, which we ſhall call *colouring matter*, and then it has loſt all its alkaline properties. No acid can ſeparate this colouring matter from iron after it is once united with it. When iron diſſolved in an acid is mixed with an alkali ſaturated with the colouring matter, a double decompoſition takes place, the acid unites with the alkali, and the colouring matter with the iron, and forms Pruſſian blue. The reaſon that, in the common method of preparing Pruſſian blue, a quantity of yellow oxide is precipitated, is, that there is not a ſufficient quantity of colouring matter (for the alkali is never ſaturated with it) to ſaturate all the iron diſplaced by the alkali; a part of it therefore is mixed with Pruſſian blue. Muriatic acid diſſolves this oxide, carries it off, and leaves the blue in a ſtate of purity. Such were the concluſions which Macquer drew from his experiments; experiments which not only diſcovered the compoſition of Pruſſian blue, but threw a ray of light on the nature of affinities, which has contributed much towards the advancement of that important branch of chemiſtry.

The nature of the colouring matter, however, was ſtill unknown. Macquer himſelf ſuppoſed that it was pure phlogiſton; but the opinion was untenable. He had ſhewn that it poſſeſſed the property of forming neutral ſalts, and therefore Bergman and Morveau ſuſpected that it was an acid.

Scheele undertook the taſk of examining its nature, and publiſhed the reſult of his experiments in the Stockholm Tranſactions for 1782.

He obſerved that the Pruſſian alkali, after being expoſed for ſome time to the air, loſt the property of forming Pruſſian blue; the colouring matter muſt therefore have left it.

533 Decompoſed by Scheele.

He put a ſmall quantity of it into a large glaſs globe, corked it up, and kept it ſome time; but no change was produced either in the air or the Pruſſian alkali. Something muſt therefore diſplace the colouring matter when the alkali is expoſed to the open air, which is not preſent in a glaſs veſſel. Was it carbonic acid gas? To aſcertain this, he put a quantity of Pruſſian alkali into a glaſs globe filled with that gas, and in 24 hours the alkali was incapable of producing Pruſſian blue. It is therefore carbonic acid gas which diſplaces the colouring matter. He repeated this experiment with this difference, that he hung in the globe a bit of paper which had been previouſly dipped into a ſolution of ſulphat of iron, and on which he had let fall two drops of an alkaline lixivium, in order to precipitate the iron. This paper was taken out in two hours, and became covered with a fine blue on adding a little muriatic acid. Carbonic acid, then, has the property of ſeparating the colouring matter from alkali without decompoſing it.

534 The colouring matter ſeparated.

He found alſo that other acids produced the ſame effect. The colouring matter then may be obtained perhaps in a ſeparate ſtate. He accordingly made a number of attempts to procure it, and at laſt diſcovered the following proceſs: He boiled together for ſome minutes two ounces of Pruſſian blue in powder, one ounce of the red oxide of mercury, and ſix ounces of water; then paſſed the whole through a filter, and waſhed the reſiduum with two ounces of boiling water. The oxide of mercury has a greater affinity for the colouring matter than the oxide of iron; it therefore unites with it, and forms with it a ſalt ſoluble in water. The iron remains behind upon the filter, and the liquid is a ſolution of the colouring matter combined with mercury. He poured this ſolution upon half an ounce of pure iron-filings, and added at the ſame time three grains of ſulphuric acid. The iron ſeparates the oxygen from the mercury, in order to combine with the ſulphuric acid; the mercury is precipitated in its metallic ſtate, and leaves behind it a quantity of ſulphat of iron and of colouring matter diſſolved in water, but not combined, as the colouring matter is unable to ſeparate the iron from the acid *.

He then diſtilled in a gentle heat; the colouring mat-

ter

---

* *Berthollet Ann. de Chimie*, i. 30.

ter came over by the time that one-fourth of the liquor had paſſed into the receiver. It was mixed, however, with a ſmall quantity of ſulphuric acid; from which he ſeparated it by diſtilling a ſecond time over a quantity of carbonat of lime. The ſulphuric acid combines with the lime and remains behind, which the colouring matter cannot do, becauſe carbonic acid has a ſtronger affinity for lime than it has. Thus he obtained the colouring matter in a ſtate of purity.

535 Its component parts. It remained now to diſcover its component parts. He formed a very pure Pruſſian blue, which he diſtilled, and increaſed the fire till the veſſel became red. The ſmall quantity of water which he had put into the receiver contained a portion of the blue colouring matter and of ammonia; and the air of the receiver conſiſted of azot, carbonic acid gas, and the colouring matter. He concluded from this experiment, that the colouring matter was compoſed of ammonia and carbon. He mixed together equal quantities of pounded charcoal and potaſs, put the mixture into a crucible, and kept it red hot for a quarter of an hour: he then added a quantity of ſal ammoniac in ſmall pieces, which he puſhed to the bottom of the melted mixture, kept it in the fire for two minutes till it had ceaſed to give out vapours of ammonia, and then threw it into a quantity of water. The ſolution poſſeſſed all the properties of the Pruſſian alkali. Thus Mr Scheele ſucceeded in forming the colouring matter; and it was conſidered as proved that it was compoſed of ammonia and carbon.

But after the publication of Scheele's experiments, it was diſcovered that ammonia itſelf is compoſed of azot and hydrogen. It became therefore a queſtion, Whether ammonia entered into the compoſition of this ſubſtance, or merely its ingredients? Whether it was compoſed of ammonia and carbon, or of azot, hydrogen, and carbon combined in a different manner? This point has been decided by the following experiments: Mr Clouet made a quantity of ammoniacal gas paſs through a red hot porcelain tube filled with charcoal, and by this proceſs formed a quantity of the colouring matter *. Here the temperature was ſo high that the ammonia muſt have been decompoſed: and the colouring matter cannot be formed by combining ammonia and charcoal except at a temperature equally high. There is reaſon therefore to ſuppoſe that the ammonia is decompoſed. When oxy-muriatic acid is mixed with the colouring matter, it communicates to it a quantity of oxygen, and cauſes it in conſequence to aſſume very different properties. When a fixed alkali or lime is added to it in this ſtate, it is immediately decompoſed, and converted into ammonia and carbonic acid gas. The colouring matter in this ſtate contains all the ingredients neceſſary to form theſe two ſubſtances, namely, azot, hydrogen, carbon, oxygen: but in order to induce the ingredients to form theſe two compounds, the aſſiſtance of an alkali or lime to combine with the carbonic acid is neceſſary; juſt as ſulphur combines more eaſily with oxygen when united with an alkali or with iron than when ſeparate †.

* *Ann. de Chim.* xi.

† *Berthollet, ibid.* i.

The colouring matter, then, which we ſhall henceforth call the *Pruſſic acid*, is compoſed of azot, hydrogen, and carbon; but the proportions of theſe ingredients have not yet been determined. It is conſidered as an acid, though the preſence of oxygen has not been proved, becauſe it has the property of forming neutral ſalts with the ſame baſes as other acids.

536 Properties of Pruſſic acid. The Pruſſic acid is exceedingly volatile, and evidently capable of exiſting in a gaſeous ſtate. It has a peculiar odour, not diſagreeable, and which has been compared to the flowers of the peach. It has a ſweetiſh and ſomewhat hot taſte, and excites cough *.

It has no affinity for alumina nor for alcohol †.

* *Scheele.*

† *Morveau.*

This ſubſtance differs exceedingly in its action from all other acids.

537 Its action on other bodies. It is capable of combining, like them, with earths, alkalies, and metallic oxides, and of forming compounds which have been denominated *Pruſſiats*. But it enters much more readily into triple compounds with alkalies or earths, and metallic oxides, than into combinations with earths or alkalies ſeparately; and though its affinity appears to be greater for alkalies and earths than for metallic oxides, yet when in a free or gaſeous ſtate it does not enter into combinations with earths or alkalies without difficulty, and it is ſeparated from them much more eaſily than from metallic oxides. Mere expoſure to the light of the ſun, or to a heat of 110°, is ſufficient for that purpoſe.

538 Its affinities. Its affinities are ſuppoſed to be as follows:

Potaſs,
Soda,
Ammonia,
Lime,
Barytes,
Magneſia,
Oxide of zinc,
——— iron,
——— mangane ſe,
——— cobalt,
——— nickel,
——— lead,
——— tin,
——— copper,
——— biſmuth,
——— antimony,
——— arſenic,
——— ſilver,
——— mercury,
——— gold,
——— platinum (Y).

Sect. XXIX. *Of Formic Acid.*

539 Diſcovery of formic acid. In the 15th century ſeveral botaniſts obſerved, with aſtoniſhment, that the flower of ſuccory, when thrown into an ant hill, became as red as blood: But it was Mr S. Fiſher who firſt diſcovered that ants poſſeſſed a peculiar acid, which he obtained by diſtilling theſe animals. His experiments were publiſhed in the Philoſophical Tranſactions for 1670. Though Hoffman afterwards

---

(Y) We ſuſpect that this is not the real order of the affinities of this acid; the metallic oxides ought probably to be placed before the alkalies and earths, and the metallic Pruſſiats ought to occupy the place which is at preſent filled by the metallic oxides. The reaſons for this conjecture will appear afterwards. See Part III. chap. ii. ſect. 23. of this article.

repeated his proceſs, little was known concerning the nature of this acid till Margraf undertook its examination, and publiſhed his experiments in the Berlin Memoirs for 1749.

The ſpecies of ants from which the formic acid is obtained is the *formica rufa*, which reſide moſt commonly in woods, or at leaſt in elevated and dry places. They have been found to contain the greateſt quantity of acid in the months of June and July. If at that ſeaſon one of theſe animals be preſſed upon paper tinged with turnſole, it changes the colour of it to a moſt lively red: they even ſometimes ſtain it merely by crawling over it.

540
Methods of obtaining it.

There are two methods of obtaining the formic acid, diſtillation and lixiviation.

When the firſt method is to be employed, the ants are to be waſhed clean, dried with a gentle heat, put into a retort, and diſtilled with a moderate heat, gradually increaſed till all the acid has come over. It is mixed with an empyreumatic oil, from which it is ſeparated by paſſing it through a ſtrainer previouſly moiſtened with water. By this proceſs Meſſrs Ardviſſon and Oehrn obtained from a pound of ants 7½ ounces of acid, the ſpecific gravity of which, at the temperature of 60°, was 1,0075 [*]. Morveau obtained from 49 ounces of ants 23 ounces of pretty ſtrong acid [†]. Margraf added a quantity of water; but it is evident that this ſerves merely to weaken the acid.

When the other method is preferred, the ants are to be waſhed in cold water, put upon a clean linen cloth, and boiling water poured on them repeatedly till it can extract no more acid. The linen is then to be ſqueezed, and the ſeveral liquors mixed and filtrated. This method was firſt uſed by Ardviſſon and Oehrn: they obtained from a pound of ants an acid liquor which had more ſpecific gravity than common vinegar. It is to be purified from the oil which adheres to it by repeated diſtillations. After four diſtillations the empyreumatic oil ſtill manifeſts its preſence by its ſmell, but this ſmell vaniſhes if the acid be expoſed for ſome time to the air; a quantity of eſſential oil, however, ſtill remains, which cannot be ſeparated. The ſpecific gravity of the acid thus rectified is 1,0011 [‡].

Hermſtadt employed a third method. He expreſſed the juice of dry ants, and by this means obtained from 2 lbs. of theſe animals 21 oz. 2 dr. of juice, which on diſtillation yielded a clear pure acid, equal in ſtrength to very concentrated vinegar [§].

541
Its properties.

This acid ſeems to be capable of aſſuming a gaſeous form; at leaſt Hermſtadt obſerved, that when he put ſome of it into a bottle with a glaſs ſtopper, the ſtopper was frequently raiſed by an elaſtic fluid making its eſcape, and that after ſome days it had loſt its ſmell [||]. When this acid is boiled with nitric acid, a gas is extricated, which renders lime-water turbid, and has a very pungent odour [¶].

This acid has a ſtrong but not unpleaſant ſmell, a cauſtic taſte, and when much diluted a pleaſant acidity. When moſt concentrated, its ſpecific gravity is 1,0453 [*].

One part of this acid, mixed with 75 parts of water, gives a faint red to ſyrup of violets; mixed with 430 parts of water, it reddens paper coloured with turnſole; mixed with 1300 parts of water, it produces no effect on the infuſion of turnſole [†]. It mixes readily with alcohol.

It unites readily with the other acids. When boiled with ſulphuric acid, it becomes black. White acrid vapours riſe when the mixture becomes hot; and when it boils, a gas riſes which unites with difficulty to water and lime-water; the formic acid is again obtained, but its quantity is diminiſhed [*].

Nitric acid decompoſes it altogether, and is itſelf converted into nitrous acid. Muriatic acid does not alter it. Oxy-muriatic acts like nitric acid [†].

542
Its compounds and affinities.

Its compounds are called *formiats*.

Its affinities are the ſame with thoſe given above for the Pruſſic acid.

SECT. XXX. *Of Sebacic Acid.*

543
Diſcovery of ſebacic acid.

CHEMISTS had long ſuſpected that an acid could be obtained from tallow, on account of the acrid nature of the fumes which it emitted at a high temperature; but it was M. Grutzmacher who firſt demonſtrated this acid in a diſſertation *De Oſſium Medulla*, publiſhed in 1748 [‡]. Mr Rhodes mentioned it in 1753, and Segner publiſhed a diſſertation on it in 1754, and Crell examined its properties very fully in two diſſertations publiſhed in the Phil. Tranſ. for 1780 and 1782. It was called at firſt *acid of fat*, and afterwards *ſebacic acid*.

It may be procured by heating together a mixture of ſuet and lime. Sebat of lime is formed, which may be purified by ſolution in water. It is then to be put into a retort, and ſulphuric acid poured on it. Sebacic acid paſſes over on the application of heat.

544
Its properties,

Sebacic acid has an acid, ſharp, bitteriſh taſte, and a very pungent ſmell. It reddens tincture of litmus.

Heat cauſes it to aſſume a yellow colour.

It oxidates ſilver, mercury, copper, iron, lead, tin, zinc, antimony, mangaueſe.

It does not act upon biſmuth, cobalt, nickel. When mixed with nitric acid it diſſolves gold.

545
Compounds and affinities.

Its compounds are called *ſebats*.

Its affinities, according to Morveau, are as follows:

Barytes,
Potaſs,
Soda,
Lime,
Magneſia,
Ammonia,
Alumina,
Jargonia [§],
Oxide of zinc,
——— mangaueſe,
——— iron,
——— lead,
——— tin,
——— cobalt,
——— copper,
——— nickel,
——— arſenic,
——— biſmuth,
——— mercury,
——— antimony,
——— ſilver.

SECT. XXXI. *Of Bombyc Acid.*

546
Diſcovery of bombyc acid.

MR BOISSIER DE SAUVAGES obſerved, that the juice of the ſilkworm, in the diſeaſe called in France *muſcadine*, was acid; and Chauſſier remarked, that the ſilkworm, after being converted into a butterfly, gives out a

a liquor which turns vegetable blues to a red. He found, that during the time that the animal was forming its cocon, the acid was depoſited in a reſervoir near the anus. By means of a pair of ſciſſars he collected ſome which reddened blue paper, united with alkalies with effervеſcence, and even attacked the ſciſſars. He afterwards collected it by infuſing the chryſalids in alcohol, which diſſolved the acid, but left the impurities untouched.

This acid has never been examined with attention; ſo that almoſt all its properties are unknown.

Sect. XXXII. *Of Zoonic Acid.*

547 Method of obtaining zoonic acid. Mr Berthollet has obtained a peculiar acid by diſtilling vegetable and animal ſubſtances, to which he has given the name of the *zoonic acid* *. He procured it by diſtilling the gluten of wheat, the yeſt of beer, bones, and woollen rags; and concludes, therefore, that it may be produced by the diſtillation of all animal ſubſtances.

To obtain this acid pure, he mixed lime with the diſtilled liquid, after having ſeparated the oil, which it always contains (for the product of the diſtillation of animal ſubſtances is chiefly oil and carbonat of ammonia.) He boiled this mixture till the carbonat of ammonia was exhaled: he then filtered it, added a little more lime, and boiled it again till the ſmell of the ammonia had gone off entirely. The liquor, which now contained only zoonat of lime, he filtered again, and then added a little water impregnated with carbonic acid, in order to precipitate any lime which might happen to be diſſolved in the liquid without being combined with the zoonic acid.

After concentrating the zoonat of lime, he mixed it with phoſphoric acid, and diſtilled it in a retort. At a heat nearly equal to that of boiling water, the zoonic acid paſſes over in a ſtate of purity.

548 Its properties. The zoonic acid has an odour like that of meat when frying, and it is actually formed during that proceſs. It has an auſtere taſte.

It gives a red colour to paper tinged with turnſole.

With alkalies and earths it produces ſalts, which do not appear capable of cryſtallizing.

It forms a white precipitate in the ſolutions of acetite of lead and nitrat of mercury.

Part of the zoonic acid ſeems to be deſtroyed by the action of heat during the diſtillation of the zoonat of lime with phoſphoric acid: for the liquor, which is in ebullition, becomes brown, and grows black at the end of the operation; hence Mr Berthollet concludes that the zoonic acid contains carbon. The zoonat of ſilver, when kept, becomes gradually brown; hence he concludes that the acid contains hydrogen. Theſe concluſions he draws from a very ingenious theory of his, which has been already deſcribed in the article Bleaching in this *Supplement* †.

549 Animal acids. The five preceding acids have obtained the name of *animal acids*, becauſe they are all obtained from the animal kingdom. It can ſcarcely be doubted that a more accurate examination of animal ſubſtances will add conſiderably to the number of theſe acids.

Sect. XXXIII. *Of Arſenic Acid.*

Arsenic acid, which was firſt diſcovered by Scheele, may be produced by ſimply mixing the white oxide of arſenic with oxy-muriatic acid, and applying a heat ſufficient to ſublime the muriatic acid. The theory of this operation is evident: the white oxide has a greater affinity for oxygen than muriatic acid has; of courſe it combines with it, and is thus converted into arſenic acid, and the muriatic acid is eaſily ſublimed by applying heat. Method of obtaining arſenic acid.

Landriani has informed us, that this acid may be alſo formed by ſubliming ſeveral times ſucceſſively the white oxide of arſenic, and taking care every time to renew the air. This proceſs is equally ſimple; the oxide combines at a high temperature with the oxygen of the atmoſphere.

551 Its properties. This acid is exceedingly fixed. When expoſed to the air it attracts humidity, and at laſt becomes liquid. At the temperature of 60° it diſſolves in two-thirds of its weight of water. Its ſolution may be evaporated to dryneſs, and even converted into a glaſs, which attracts moiſture from the air, and acts powerfully on the crucible.

It is poiſonous as well as the white oxide of arſenic *.

When expoſed to a red heat, it is partly decompoſed and converted into white oxide of arſenic †.

It does not act upon gold, platinum, ſilver, mercury.

It oxidates copper, iron, lead, tin, zinc, biſmuth, antimony, cobalt, nickel, manganeſe, and arſenic, and in a very ſtrong heat, mercury and ſilver.

According to Berthollet's experiments, arſenic acid is compoſed of eight parts of white oxide of arſenic and one part of oxygen.

552 Its compounds and affinities. Its compounds are called *arſeniats.*

Its affinities are as follows:

Lime,
Barytes,
Magneſia,
Potaſs,
Soda,
Ammonia,
Oxide of zinc,
———— manganeſe,
———— iron,
———— lead,
———— tin,
———— cobalt,
———— copper,
———— nickel,
———— biſmuth,
———— mercury,
———— antimony,
———— ſilver,
———— gold,
———— platinum,
Alumina,
Jargonia ‡?
Water.

Sect. XXXIV. *Of Tungſtic Acid.*

553 Properties of tungſtic acid. Tungstic acid, or oxide of tungſten, was firſt diſcovered by Scheele; but the acid which he examined was not pure, being compoſed, as Mr Luyart has ſhewn, of nitric acid, ammonia, and tungſtic acid. The real acid is inſoluble in water, taſteleſs, and incapable of turning vegetable blues red till it has been firſt rendered

---

† Berthollet, Ann. de Chim. xxvi.

* Scheele.

† Id.

‡ Vauquelin, Ann. de Chim. xxii. 208.

ſoluble by being partly combined with ammonia. It is of a beautiful yellow colour, which becomes blue when expoſed to the light, or heated violently in cloſe veſſels. It does not recover its yellow colour except by calcination in the open air, and then increaſes in weight. When put into muriatic acid along with tin, zinc, or iron, the liquor becomes blue *. Treated with acetous acid, it becomes blue. When reduced to a glaſs with phoſphat of ſoda, the blue colour appears and diſappears according as the blue or yellow part of the flame is directed to it, as happens to manganeſe. Probably this blue ſubſtance is an oxide of tungſten with a ſmaller quantity of oxygen.

554
Its compounds and affinities.

Its compounds are called *tungſtats*.

Its affinities are as follows † :

Lime,
Barytes,
Magneſia,
Potaſs,
Soda,
Ammonia,
Alumina,
Jargonia ‡ ?

Sect. XXXV. *Of Molybdic Acid.*

555
Properties of molybdic acid.

Concrete molybdic acid, firſt diſcovered by Scheele, is white, and has an acid but metallic taſte. Its ſpecific gravity is 3,75 §. It is not altered in the air. When heated in a crucible till it is beginning to melt, it experiences no alteration. It remains fixed even in a great fire as long as the crucible is covered ; but the moment it is uncovered the acid riſes unaltered in a white ſmoke. It diſſolves in 570 parts of water. The ſolution reddens turnſole ; nitric acid does not affect it, but ſulphuric and muriatic acids diſſolve it by the aſſiſtance of heat.

It may be prepared by treating the ore of molybdenum with nitric acid, and waſhing the acid when formed in water.

When combined with potaſs, it forms a colourleſs ſalt.

Mixed with filings of tin and muriatic acid, it immediately becomes blue, and precipitates flakes of the ſame colour, which diſappear after ſome time, if an exceſs of muriatic acid has been added, and the liquor aſſumes a browniſh colour.

With the ſolution of nitrat of lead it forms a white precipitate, ſoluble in nitric acid.

When mixed with a little alcohol and nitric acid, it does not change its colour.

With a ſolution of nitrat of mercury, or of nitrat of ſilver, it gives a white flaky precipitate.

With the nitrat of copper it forms a greeniſh precipitate.

With ſolutions of ſulphat of zinc, muriat of biſmuth, muriat of antimony, nitrat of nickel, muriats of gold and platinum, it produces white precipitates when theſe ſolutions do not contain an exceſs of acid.

When melted with borax, it gives it a bluiſh colour.

Paper dipt in this acid becomes in the ſun of a beautiful blue colour ‖.

Sulphur is capable of partly decompoſing it by heat.

Its compounds are called *molybdats*.

Its affinities are unknown.

Sect. XXXVI. *Of Chromic Acid.*

556
Analyſis of the red lead of Siberia,

In the year 1770, Mr Pallas diſcovered in the gold mine of Bereſof, near Ekaterimbourg in Siberia, a mineral of a red colour, with a ſhade of yellow, cryſtallized in ſmall acute angled quadrangular priſms, ſometimes ſmooth, ſometimes longitudinally ſtreaked, and often hollow. Mr Macquart, profeſſor of medicine at Paris, who in 1783 had been ſent to the north by the French government in order to collect mineralogical information, brought with him a quantity of this mineral, which has been diſtinguiſhed by the name of *red lead ore of Siberia*, and in 1789 analyſed four ounces of it along with Mr Vauquelin. They found it to contain,

Lead	$36\frac{1}{9}$
Oxygen	$37\frac{5}{9}$
Iron	$24\frac{8}{9}$
Alumina	2
	$100\frac{5}{9}$

and a little ſilver *.

Mr Bindheim of Moſcow analyſed it ſoon after, and found it to contain,

Lead	60
Molybdic acid	11,66
Nickel	5,66
Oxide of iron	1
Air and water	5
Silica	4,5
	87,82

and a little copper and cobalt †.

Vauquelin examined it again in 1797, and found that all the former analyſes were inaccurate.

A hundred parts of this mineral, reduced to a fine powder, were mixed with 300 parts of the ſaturated carbonat of potaſs, and about 4000 parts of water ; and this mixture was expoſed for an hour to a boiling heat. He obſerved, 1ſt, that when theſe matters began to act upon each other there was produced a ſtrong efferveſcence, which continued a long time ; 2d, that the orange colour of the lead became a brick red ; 3d, that at a certain period the whole matter ſeemed to diſſolve ; 4th, that in proportion as the effervefcence advanced the matter reappeared under the form of a granulated powder of a dirty yellow colour ; 5th, that the liquor aſſumed a beautiful golden yellow colour. When the effervefcence had entirely ſubſided, and appeared to have no longer any action on the ſubſtances, the liquor was filtered, and the metallic duſt collected on the paper. After being waſhed and dried, it weighed no more than 78 parts: the potaſs, therefore, had taken from it 22 parts.

He poured upon the 78 parts juſt mentioned ſome of the nitric acid, diluted in 12 parts of water, which produced a briſk effervefcence. The greater part of the matter was diſſolved : the liquor aſſumed no colour, and there remained only a ſmall quantity of powder of an orange-yellow colour. The liquor of the reſiduum was ſeparated by the help of a ſyphon, the matter waſhed ſeveral times, and the waſhings united with the firſt liquor. This reſiduum, dried, weighed no more than 14 parts ; from which it follows, that the nitric acid had diſſolved 64.

He again mixed theſe 14 parts with 42 parts of the carbonat of potaſs and the neceſſary quantity of water, and

† *Berl. Beob* iv. 2911.

and then treated them as before, and the phenomena were the ſame. The liquor, after being filtered, was united to the former; and the reſiduum, waſhed and dried, weighed no more than two parts, which were ſtill red lead, and therefore thrown away.

The two nitric ſolutions, united and evaporated, produced 92 parts of nitrat of lead, cryſtallized in octahedra, perfectly white and tranſparent. Theſe 92 parts of nitrat of lead, diſſolved in water, were precipitated by a ſolution of the ſulphat of ſoda. This produced 81 parts of the ſulphat of lead, which were equivalent to 56,68 of metallic lead.

557 And diſcovery of chromic acid. The alkaline liquors were found to contain a ſalt compoſed of potaſs combined with a peculiar acid, which Mr Vauquelin afterwards called *chromic acid.*

Theſe liquors, ſubjected to evaporation until a ſaline pellicle was formed on their ſurface, produced, on cooling, yellow cryſtals; among which there was a carbonat of potaſs, not decompoſed. Theſe cryſtals, diſſolved in water, and the ſolution united with the mother-water, the whole was mixed with weak nitric acid until the carbonat of potaſs was ſaturated. The liquor then had a very dark orange-red colour. Being united with a ſolution of the muriat of tin, newly made, it firſt aſſumed a brown colour, which afterwards became greeniſh. Mixed with a ſolution of the nitrat of lead, it immediately produced the red lead. Laſtly, evaporated ſpontaneouſly, it produced ruby-red cryſtals, mixed with cryſtals of the nitrat of potaſs. Ninety-eight parts of this mineral, decompoſed as above-mentioned, having produced 81 parts of the ſulphat of lead, 100 parts would have given 82,65, which are equivalent to 57,1 of metallic lead. " But admitting, as experiment proves (ſays Mr Vauquelin), that 100 parts of lead abſorb, in combining with acids, 12 parts of oxygen, the 57,1 of metallic lead ought to contain in the red lead 6,86 of this principle, and we ought to have for the mineralizing acid 36,4.

558 Its properties. Chromic acid cryſtallizes in the form of elongated priſms of a ruby colour.

When mixed with filings of tin and the muriatic acid, it becomes at firſt yellowiſh brown, and afterwards aſſumes a beautiful green colour.

When mixed with a little alcohol and nitric acid, it immediately aſſumes a bluiſh green colour, which preſerves the ſame ſhade even after deſiccation. Ether alone gives it the ſame colour.

With a ſolution of nitrat of mercury, it gives a precipitate of a dark cinnabar colour.

With a ſolution of nitrat of ſilver, it gives a precipitate, which, the moment it is formed, appears of a beautiful carmine colour, but becomes purple by expoſure to the light. This combination, expoſed to the heat of the blow-pipe, melts before the charcoal is inflamed. It aſſumes a blackiſh and metallic appearance. If it be then pulveriſed, the powder is ſtill purple; but after the blue flame of the lamp is brought in contact with this matter, it aſſumes a green colour, and the ſilver appears in globules diſſeminated throughout its ſubſtance.

With nitrat of copper, it gives a cheſnut red precipitate.

With the ſolutions of ſulphat of zinc, muriat of biſmuth, muriat of antimony, nitrat of nickel, and muriat of platinum, it produces yellowiſh precipitates when theſe ſolutions do not contain exceſs of acid. With muriat of gold, it produces a greeniſh precipitate.

When melted with borax or glaſs, it communicates to them a beautiful emerald green colour.

Paper impregnated with chromic acid aſſumes in the light a greeniſh colour.

When mixed with muriatic acid, the mixture was capable of diſſolving gold like aqua regia; when this mixture of the two acids is diſtilled, oxy-muriatic acid is diſengaged, and the liquor aſſumes a very beautiful green colour.

Sulphuric acid, while cold, produces no effect upon it; but when warmed, it makes it aſſume a bluiſh green colour, probably by favouring the diſengagement of oxygen.

When this acid is heated along with charcoal, it is reduced to the metal called *chromum.* It is therefore compoſed of this metal and oxygen. From Vauquelin's experiments, it appears to contain one part of chromum and two parts of oxygen.

Such are the properties of this acid, as far as they have hitherto been diſcovered. Vauquelin is the only chemiſt who has examined it; and from his memoir the above account has been taken *.

The four laſt deſcribed acids are called *metallic acids,* becauſe they are compoſed of metals and oxygen.

559 Metallic acids. It is believed that moſt of the metals, we would rather ſay of the metallic oxides, are capable of being converted into acids by being combined with oxygen. It is certain that this is the caſe with platinum; and Hermſtadt, by diſtilling nitric acid off tin, converted it into a white maſs, ſoluble in three parts of water, which has been called *ſtannic acid* †. Several more of the metallic oxides act the part of acids: But no complete ſet of experiments on this important ſubject has yet appeared.

Chap. VI. *Of* Affinity.

560 Importance of affinity. The meaning of the word *affinity* has been already explained; and it muſt appear evident, from the uſe which has been made of it in this article, that the conſideration of the nature of affinity is the moſt important part of chemiſtry. While its laws are unknown, chemiſtry is not a ſcience, but a wilderneſs of facts without beauty or regularity: every thing is equally perplexing and incomprehenſible. The chemiſt, inſtead of being able to trace the operations of Nature, is loſt in an endleſs maze of uncertainty, without a guide to conduct him, or a ray of light to illuminate his ſteps. It is the knowledge of affinity which diſpels the darkneſs, removes the confuſion, ſhews us the order which ſubſiſts in all the phenomena of nature, points out their dependence on one another, and enables us to direct them as we think proper, to make them ſubſervient to the improvement of the arts, and thus to render them the miniſters of our comforts and enjoyments.

561 It unites bodies, particle to particle. 1. When two bodies are united together by affinity, how ſmall a portion ſoever of the compound we examine, we ſhall always find it to contain both of the ingredients. From this it is evident, that affinity combines bodies, particle with particle.

By *particles* we do not mean what philoſophers have called *atoms,* or the ſmalleſt parts into which it is poſſible to divide matter; but the ſmalleſt parts which make

---

* *Ann. de Chim.* xxv. 114. and *Philoſophical Magazine,* i. 279. and 361.

† *Ann. de Chim.* iv. 162.

make an integrant of any ſubſtance. Water, for inſtance, conſiſts of oxygen and hydrogen; but when we ſpeak of a particle of water, we do not mean the oxygen or the hydrogen ſeparately, but the ſmalleſt poſſible quantity of theſe combined in ſuch a manner as to form water. It is the *integrant particles* of bodies which are united by affinity. Thus ſulphuric acid is compoſed of ſulphur and oxygen combined together; and ammonia, of hydrogen and azot combined in the ſame manner. Now when ſulphuric acid and ammonia combine, it is not their elements, ſulphur, oxygen, azot, and hydrogen, which unite together, particle with particle, but the particles of the acid and the alkali as integrants. This is evident; becauſe if theſe ſubſtances be ſeparated from each other by means of a ſtronger affinity, they are found preciſely in the ſame ſtate as before they entered into combination.—When the ſubſtances which combine are *ſimple*, the ultimate and integrant particles are the ſame: But we are not certain that any of the bodies with which we are acquainted is ſimple, in the ſtrict and proper ſenſe of the word.

562
Opinions of the older chemiſts about affinity.

2. What is this *affinity* which unites bodies together? The older chemiſts thought that all ſolvents, or ſubſtances capable of diſſolving others, were compoſed of particles which had the form of wedges or hooks; that ſolution conſiſted in the inſinuation of theſe wedges or hooks between the particles of the bodies to be diſſolved; and that chemical combination was merely the linking of the different particles together by means of holes in one ſet of particles, into which the hooks or the wedges of the other ſet were thruſt. Such explanations, abſurd as they may appear, were faſhionable among chemical philoſophers till the days of Sir Iſaac Newton, who firſt aſcribed the chemical union of bodies to an *attraction* between the particles themſelves. This explanation, after a violent ſtruggle on the part of the chemiſts, has been at laſt unanimouſly adopted.

563
It is an attraction between the particles of bodies.

Affinity, then, is an *attraction* between the particles of different bodies, by which they are *drawn* towards one another, and kept united. This we take for granted, and conſider as a *fact*, without pretending to explain *how* they come to be poſſeſſed of this power, or *how* they exert it; both of which are evidently beyond the reach of the human underſtanding.

But though we cannot diſcover the manner in which affinity acts, we can ſee, at leaſt, that it follows certain laws, and that they are invariable; for ſimilar phenomena always occur when the circumſtances are the ſame.

564
Whether the ſame with gravitation.

Now what are the laws which affinity follows? There is a ſpecies of attraction which matter poſſeſſes, called *gravitation*, the laws of which were inveſtigated by Sir Iſaac Newton. Is affinity the *ſame* with gravitation, or does it follow different laws?

Upon a ſlight view of theſe two attractions, their phenomena appear very different. Gravitation acts at very great diſtances; affinity not until the bodies are mixed together: Gravitation acts on the whole maſs; affinity only on the particles: Bodies gravitate to one another directly as their maſſes, and inverſely as the ſquares of their diſtances. But how can affinity follow theſe laws, when it does not act till the bodies are apparently in contact? or ſuppoſing that it does act, how can they account for the phenomena of affinity? If barytes be preſented to a compound of ſulphuric acid and potaſs, the acid immediately leaves the alkali and combines with the earth: But had gravitation been the only power acting, ought not the barytes to have united with the ſulphat of potaſs without producing any decompoſition?

Theſe ſtriking differences have convinced many philoſophers, as they ſeem to have done Newton himſelf, that gravitation and affinity are different ſpecies of attraction. Let us not, however, embrace this concluſion vaguely, or without affixing a preciſe meaning to our words.

565
No poſitive proof that it is different.

Gravitation and chemical affinity are ſaid to be different ſpecies of attraction. But what is attraction? It is merely a general *fact*, or that tendency which is *obſerved* among all the portions of matter towards each other, but which exhibits very different appearances under different circumſtances. The tendency of matter towards matter at *ſenſible* diſtances is called *gravitation*, and its laws have been completely inveſtigated; but neither that tendency, nor theſe laws, have been, or can be, ſhewn to be *eſſential* to the exiſtence of matter. Chemical affinity is the tendency of particles towards each other at *inſenſible* diſtances, or when theſe particles are mixed together; and this tendency appears to be regulated by laws different from thoſe of gravitation. Like gravitation, it is merely an *obſerved fact*; and however different theſe facts may appear to be, they are probably both brought about by the ſame forces. It is indeed true, that gravitation is directly as the maſſes of matter, and inverſely as the ſquares of the diſtances of theſe maſſes; while the attraction, which is called *chemical affinity*, ſeems to obſerve very different rules. But we have ſhewn elſewhere (ſee OPTICS, nº 62—68, *Encycl.*; and BOSCOVICH in this *Suppl.*), that the ſame forces repel at one diſtance and attract at another; and that they may produce all the various phenomena of chemical affinity.

The difficulties to be accounted for in chemical affinities are their intenſity, their different degrees of ſtrength, and their being elective, or, which is the ſame thing, the capacity which one body has of diſplacing another.

How come affinities, it may be aſked, to differ in intenſity? Perhaps we might with propriety refer this queriſt to the ſtudy of Boſcovich's curve; but as our modern chemiſts are not generally verſant in ſuch ſtudies, we beg leave to obſerve, in this place, that we have no proof whatever of abſolute contact between bodies. On the contrary, it is highly probable, we had almoſt ſaid demonſtrable, that particles are in every inſtance at ſome diſtance from one another. For, on the ſuppoſition that two bodies were in actual contact, their attraction for each other would not only be as great as poſſible, but as great as the attraction of any other body for either of them *could poſſibly* be: Conſequently, it neceſſarily follows, that, ſince bodies chemically combined *can* be ſeparated, they are not in actual contact (A); but if they are not in contact, their diſtance from one another

---

(A) Perhaps the following demonſtration, which we borrow from the ingenious Mr Broughman, will render this more evident. In fig. 7. let the body A have for P an attraction which at the diſtance of AP is proportional

Plate XVII.

another *may* vary in different caſes, and the force of affinity will vary with the diſtance. Here then is a reaſon why the affinity of different bodies varies in ſtrength. Sulphuric acid, for inſtance, has a ſtronger affinity for barytes than for lime; becauſe when the combinations are formed, the diſtance between the acid and barytes is not ſo great as that between the acid and lime.

But why do the diſtances differ? If affinity be the ſame with gravitation, it muſt tend to bring the particles nearer one another: And what then prevents the lime from approaching as near the acid as the barytes does? We reply, *the figure of its particles*. This anſwer was firſt given to the queſtion by Buffon, and it is fully adequate to ſolve the difficulty. The particles of bodies, indeed, are a great deal too minute for us to diſcover their figure by actual inſpection; but the phenomena of cryſtallization ſhew us that this difference actually exiſts.

The cryſtals of every body aſſume a peculiar figure. Now as theſe cryſtals are all formed in the ſame manner, and by the ſame law, it is impoſſible to conceive any other reaſon for their variety but the difference in the form of the particles which compoſe them.

But why does one body diſplace another? When a particle of barytes is brought within a certain diſtance of a particle of ſulphuric acid and lime combined together, affinity acts and draws them nearer to one another; and the barytes, from its figure, approaches nearer the acid than the lime could, and forms with it a compound, the figure of which is ſuch, relatively to that of the lime, that they cannot approach within a ſmall enough diſtance of each other to counteract the attraction of the earth. Accordingly no compound is formed; for all that is meant by two particles having formed a compound, is, that their attraction for each other is greater than the attraction of the ſurrounding bodies for either.

566
Conſequently it ought to be conſidered as the *ſame*.

Having thus ſeen that none of the phenomena of *affinity* are inconſiſtent with their reſulting from the forces which bring about the phenomena of gravitation, we have a right to conclude, that it is at leaſt highly probable, that all the motions of the corporeal world are produced by the ſame power which, though not eſſential to matter, was impreſſed upon every atom of it by the Great Creator when he formed this univerſe; and that as the effects of this power are modified according to the ſituation of the bodies on which it acts, they are known by the different names of *gravity*, *adheſion*, *coheſion*, and *affinity*.

Gravity is the attraction between bodies ſo diſtant, that the maſſes alone influence the reſult, and that the power may be conſidered as placed in the centre of the attracting bodies.

Adhesion ſuppoſes a diſtance too ſmall for our ſenſes. It has been demonſtrated to be proportional to the number of touching points, which depends upon the figure of the particles that form the bodies.

Cohesion takes place only between particles of the ſame nature. Theſe, inſtead of touching only in one ſuperficies, as in adheſion, touch in every point where their figure will allow contact: conſequently the force of coheſion alſo muſt depend upon the figure of the particles.

Affinity unites bodies of a different nature, not merely by one ſuperficies, as *adheſion* does, but particle to particle, like *coheſion*; and the moſt perfect contact is formed that the figure of the particles will admit. Therefore, in this caſe alſo, the intenſity depends upon the figure of the particles.

567
Saturation explained.

3. If we make the attempt, we ſhall find that water will not diſſolve any quantity of common ſalt that we pleaſe. Water which refuſes to take up any more is ſaid to be *ſaturated* with ſalt. Neither can we combine *any* quantity of potaſs with a given portion of ſulphuric acid: we may add as much of it as we pleaſe, indeed; but if we evaporate the liquid, in order to obtain the ſalt in cryſtals, we ſhall find that only *part* of the potaſs has united with the acid, and that the reſt has cryſtallized ſeparately. From theſe examples, it muſt appear evident, that bodies combine with one another by affinity only in certain proportions; or, which is the ſame thing, that a determinate number of particles of each of the ingredients goes to the formation of an integrant particle of the compound, and that into this integrant *no additional particles* of either ingredient *can* be admitted. Let us ſuppoſe, for inſtance, that the particles of ſulphuric acid are tetrahedrons, and that the particles of potaſs are of ſuch a form, that one of them can attach itſelf to each of the ſides of the acid particle: In that caſe an integrant particle of ſulphat of potaſs would be compoſed of five particles, one of acid and four of alkali; for it is evident, that juſt four particles of potaſs would combine with every particle of acid, and that the acid would then be ſaturated, or, which is the ſame thing, would be incapable of receiving any more alkaline particles into combination with it. Let us ſuppoſe now, that there is juſt as much potaſs as ſaturates the acid; if more acid be poured in, it cannot enter into combination with the potaſs, becauſe all the potaſs is already combined with acid.

Thus it appears evident, from the nature of affinity, that the ingredients in every combination muſt mutually *ſaturate* each other, and that no more of either can be

---

tional to PM; then let P move towards A, ſo as to come to the ſituation P', and let the attraction here be $P'M'$; as it is continual during the motion of P to P', MM' is a curve line. Now in the caſe of the attraction of bodies for one another, PM is leſs than $P'M'$; and conſequently MM' does not ever return into itſelf, and therefore it muſt go *ad infinitum*, having its arc between AB and AC, to which it approaches as aſymptotes, the abſciſſa always repreſenting the diſtance, and the ordinate the attraction at that diſtance. Let P' now continue its motion to P'', and M' will move M''; and if P'' meets A, or the bodies come into perfect contact, $P''M''$ will be infinite; ſo that the attraction being changed into coheſion will be infinite, and the bodies inſeparable, contrary to univerſal experience; ſo that P can never come nearer to A than a given diſtance. *Nicholſon's Journal*, I. 555.

be admitted into the compound than what is neceſſary to produce this ſaturation. It follows equally, that there can be *no union* without ſaturation, except there be a deficiency in ſome one of the ingredients: For ſuppoſing that there is a ſufficient number of particles of potaſs, and that every particle of ſulphuric acid requires four of them, as before, for ſaturation, the very ſame cauſe that produces the union of one, two, or three particles of potaſs with a particle of acid, muſt produce the union of all the four.

Even when there is a deficiency of one of the ingredients, ſaturation muſt equally take place; for thoſe particles of acid that happen to be neareſt the alkali muſt ſtill be ſaturated; becauſe the affinity of all the acid particles for alkali was originally equal, and the difference of the diſtance muſt give the ſuperiority to thoſe that are neareſt; and thoſe particles of acid that are once ſaturated with potaſs cannot be deprived of it by any of the other particles, otherwiſe the affinity of ſome particles of ſulphuric acid for potaſs would be greater than that of others; which is abſurd.

It will no doubt be objected to all this that there are innumerable inſtances of additional portions of ſome one of the ingredients being received into a compound after ſaturation, and that ſome ſubſtances ſeem to be equally well ſaturated with different doſes of another. Oxygen, for inſtance, combines with azot in three different proportions, and forms nitrous gas, nitrous acid, and nitric acid. The metals, too, form, in the ſame manner, different oxides; and a great many inſtances of the ſame kind occur among the neutral ſalts.

But it ought to be remembered, that the concluſions againſt which theſe objections are urged, are conſequences deduced, we think fairly, from a propoſition which we conſider as demonſtrated, that *affinity is a ſpecies of attraction* (B). Theſe phenomena cannot therefore be admitted as valid objections, except it can be ſhewn that they are really *incompatible* with theſe concluſions. Now that this is not the caſe, has been ſhewn, in the moſt ſatisfactory manner, by Morveau*. Theſe apparent exceptions are owing to an affinity which exiſts between the compound as an integrant and one of its ingredients, and are not inſtances of various degrees of ſaturation, but of the formation of new compounds. According to this very ingenious idea, which, we believe, firſt originated with Bergman, and was firſt ſeen in its full extent by Morveau, we have formerly explained in what manner the various metallic oxides are formed: the firſt oxide is a compound of the metal and oxygen; the ſecond, of the firſt oxide and oxygen; the third, of the ſecond oxide and oxygen; and ſo on. In the ſame manner we have explained the various combinations of azot and oxygen: and the explanation may eaſily be extended to every other caſe. Theſe apparent objections, then, are not incompatible with the above concluſions, but perfectly conſiſtent with them; and conſequently they cannot be admitted as of any force.

* Encyc. Method. i. 560.

There is one phenomenon, indeed, which proves, independent of theſe concluſions, that theſe combinations are actually formed in the manner we have ſuppoſed, and which therefore merits particular attention. The phenomena is, that the affinity between the two ſimple ſubſtances is *almoſt always greater* than that between the compound and any of its ingredients. The affinity, for inſtance, between azot and oxygen is greater than that between nitrous gas and oxygen; and the affinity between nitrous gas and oxygen greater than that between nitrous acid and oxygen: For if nitrous gas be mixed with nitric acid, the whole is converted into nitrous acid; but no change whatever is produced when nitric and nitrous acids, or nitrous gas and nitrous acid, are mixed: and every ſubſtance which is capable of decompoſing nitrous gas is capable alſo of decompoſing nitrous and nitric acids; but many ſubſtances are capable of decompoſing nitrous and nitric acids which have no effect upon nitrous gas. In the ſame manner, the affinity between ſulphur and oxygen is greater than that between ſulphurous acid and oxygen: for when ſulphur is mixed with ſulphuric acid, the whole is converted into ſulphurous acid; but no change takes place when ſulphur and ſulphurous acid, or ſulphurous and ſulphuric acids are mixed together. A great many inſtances of the ſame kind might eaſily be produced, if theſe were not ſufficient to eſtabliſh the point. This curious fact affords a very ſtrong proof that the baſes, as well as the quantity of oxygen, is different in almoſt all the vegetable acids. Did the tartarous, oxalic, and acetous acids, for inſtance, conſiſt of the ſame baſe with various doſes of oxygen; were the tartarous compoſed of the baſe and oxygen; the oxalic, of tartarous acid and oxygen; the acetous, of oxalic acid and oxygen—in that caſe, a mixture of acetous and tartarous acids ought to form oxalic acid: but that this does not happen, any one may convince himſelf by actual experiment.

We do not mean to affirm that this fact, though it is certainly very often true, holds in all caſes; in ſome, perhaps, the reverſe may be true, though we do not recollect at preſent any inſtance of that kind.

568 Of the ſtrength of affinity.

4. Since the affinity of almoſt every two bodies for each other differs *in ſtrength* from that between every other two, it becomes an important problem *to determine the ſtrength of every affinity in numbers*. The ſolution of this problem would give a clearneſs and preciſion to chemiſtry equal to that of any other branch of natural philoſophy whatever, and enable it to advance with a degree of rapidity hitherto thought unattainable. No wonder, then, that this problem has occupied the attention of ſome of the moſt eminent philoſophers who have dedicated their time to chemiſtry.

569 Attempts to aſcertain it.

If the obſervations formerly made, in order to ſhew that

(B) Were any farther proof of this propoſition required, we would obſerve, that *coheſion* acts as an antagoniſt to affinity, and may be often rendered ſo ſtrong as to prevent affinity from acting with efficacy. Thus alumina and jargonia, when ſufficiently heated, become inſoluble in acids, without undergoing any other alteration than that of an increaſe of coheſion by their particles being brought nearer each other; for deſtroy this coheſion, and they become as ſoluble as ever. Now it follows from this, that if coheſion be *attraction*, ſo muſt *affinity*. The experiments of Morveau, to be afterwards mentioned, demonſtrate, that *adheſion* and *affinity* are produced by the ſame cauſe: Conſequently, if adheſion be attraction, ſo muſt affinity.

that the difference in the ſtrength of affinities depends upon the different forms of the particles which have an affinity for each other, be concluſive, it is evident that the certain method of learning the ſtrength of affinities would be to diſcover the forms of the parricles of all bodies. But no method has hitherto been diſcovered by which it is poſſible of becoming acquainted with the figure of the particles of bodies. The experiments indeed of the Abbé Hauy (afterwards to be deſcribed) point out a method by which the primary figure of cryſtals may be inveſtigated with a good deal of plauſibility; but this leaves the knowledge of the figure of the particles which compoſe theſe cryſtals ſtill uncertain.

As nobody, therefore, has attempted to take this road, in order to calculate the ſtrength of affinities, let us at preſent conſider the different methods which have been propoſed for that purpoſe, that we may ſee whether any of them will anſwer the end intended.

570 By Wenzel, Wenzel ſuppoſed that the time taken by one body to diſſolve another is a meaſure of the affinity which ſubſiſts between them. But the hypotheſis of that ingenious philoſopher will not bear the teſt of examination; for the *time* of ſolution evidently depends upon circumſtances unconnected with affinity. The coheſion of the body to be diſſolved, and the nature of the compound formed, muſt occaſion very great differences in the time of ſolution of different bodies, even on the ſuppoſition that their affinities were all the ſame.

571 Fourcroy, Fourcroy propoſed to meaſure the affinity of bodies by the difficulty of ſeparating them after they are combined: but we have no method for meaſuring this difficulty. Lavoiſier and De la Place, indeed, propoſed *caloric* for this purpoſe; but there are many compounds which caloric cannot ſeparate; and it never produces a ſeparation except by means of its affinity for one or other of the ingredients of the compound. Before caloric, therefore, could be employed as a meaſure, it would be neceſſary to know exactly the ſtrength of its own affinity for every other ſubſtance; which is juſt a caſe of the problem to be reſolved.

572 Macquer, Macquer ſuppoſed that the affinity of bodies for one another was in the compound ratio of the facility of their union and the difficulty of their ſeparation: But as we are in poſſeſſion of no method of aſcertaining either of theſe, it is evident that this theory, even allowing it to be juſt (which it certainly is not), could be of no uſe for aſſiſting us to calculate the force of affinities.

573 Morveau, Another method has been propoſed by the diſtinguiſhed philoſophical chemiſt Mr de Morveau (c).

In 1713 Dr Brook Taylor made ſome experiments on the adheſion of ſurfaces; and concluded from them, that the force of adheſion might be determined by the weight neceſſary to produce a ſeparation. But in 1772, Meſſrs La Grange and Cigna, obſerving that the ſurfaces of water and oil adhere together, and taking it for granted that theſe two liquids *repel* each other, concluded, in conſequence, that their adheſion was not owing to *attraction*; and hence inferred, that *adheſion*, in general, is always owing to the preſſure of the atmoſphere. This concluſion induced Morveau to examine the ſubject: he found that adheſion was *not affected* by the preſſure of the atmoſphere; for it required the ſame weight to ſeparate a diſk of glaſs (30 lines in diameter) from the ſurface of mercury in the open air, and under an exhauſted receiver. He obſerved that the ſame diſk adhered to water with a force of 258 grains, and to the ſolution of potaſs, though denſer, only with a force of 210. This reſult not only proved that adheſion was owing to attraction, but made him conceive the poſſibility of applying this method to the calculation of affinities: For the force of adheſion being neceſſarily proportional to the points of contact, and this being the caſe alſo with affinity, it is evident that the adheſion and the affinity between the ſame ſubſtances are proportional, and that therefore the knowledge of the one would furniſh us with the ratio of the other.

Struck with this idea, he conſtructed cylinders of different metals, perfectly round, an inch in diameter and the ſame in thickneſs, and having a ſmall ring in their upper ſurface, by which they might be hung exactly in equilibrium. He ſuſpended theſe cylinders, one after another, to the beam of a balance; and after counterpoiſing them exactly, applied them to a quantity of mercury placed about two lines below them, making them ſlide along its ſurface, to prevent any air from lodging between them and the mercury. He then marked exactly the weight neceſſary to overcome their adheſion, taking care to change the mercury after every experiment. The table of the reſults is as follows:

Gold adheres to mercury with a force of	446 gr.
Silver, - - - - - - -	429
Tin, - - - - - - -	418
Lead, - - - - - - -	397
Biſmuth, - - - - - -	372
Platinum, - - - - - -	282 *
Zinc, - - - - - - -	204
Copper, - - - - - -	142
Antimony, - - - - - -	126
Iron, - - - - - - -	115
Cobalt, - - - - - - -	8

* *Morveau, Ann de Chim.* xxv. 10.

The differences of theſe reſults cannot be owing to the preſſure of the air, which was the ſame in all; nor do they correſpond to the denſities of the metals; nor can they be owing to accidental differences in the poliſh of the cylinders, for a plate of rough iron adheres more ſtrongly to mercury than one of the ſame diameter exquiſitely poliſhed;—but they follow preciſely the order of affinity, and therefore may be conſidered as the meaſure of the ſtrength of the affinity between theſe different metals and mercury. They furniſh us alſo with a convincing proof that *affinity* is *attraction*, and the ſame ſpecies of attraction with *adheſion*; and that therefore, if the one be reducible to *gravitation*, ſo muſt the other.

Mr Achard, convinced of the importance of Mr Morveau's obſervations, made a great many experiments on *adheſion*, and publiſhed the reſult of them in 1780. He

---

(c) Now Mr Guyton: we have uſed the old name all along in the text to avoid ambiguity.

proved that the force of adheſion was not affected by alterations in the height of the barometer, but that its force became weaker as the heat of the fluid increaſed (D); and that the temperature remaining the ſame, the force of adheſion increaſed in the ſame ratio with the ſurfaces of the adhering bodies. He made about 600 experiments on the adheſion of different ſolids and fluids, proved that the force of adheſion did not depend on the denſities of the adhering bodies, nor on the different coheſive force of the fluids; and, after a laborious calculation, concluded that it depended on the figure of the particles of the adhering fluid and ſolid.

Theſe experiments and calculations of Mr Achard are certainly of importance; and we would have given them here, had not the objects of them been ſubſtances which can furniſh but few data for calculating the force of affinities.

This method of meaſuring the force of affinities ſeems to be an accurate one, and if it could be applied to every caſe of affinity, would, in all probability, enable us to ſolve the problem which we are now conſidering: But, unfortunately, its application is very limited, being confined to thoſe caſes alone in which one of the bodies can be preſented in a fluid, and the other in a ſolid ſtate. Nor can it be applied indiſcriminately to all thoſe caſes; for whenever the coheſion of any liquid is much inferior to the force of its adheſion to any ſolid, the ſeparation takes place in the particles of the liquid itſelf, and conſequently we do not obtain the meaſure of its adheſion to the ſolid, but of its own coheſion, and that, too, imperfectly. Thus, for inſtance, Mr Achard found that ſealing-wax adhered to water with a force of 92 grains, and to alcohol only with a force of $53\frac{3}{4}$ths; yet we know that ſealing-wax has a greater affinity for alcohol than for water; becauſe alcohol diſſolves it, which water is incapable of doing. The difference in the reſult in this inſtance was evidently owing to the ſmaller coheſion of alcohol. Mr Morveau's method muſt therefore be confined to thoſe caſes in which the coheſion of the liquid is ſtronger than its adheſion to the ſolid, which may be known by the ſurface of the ſolid not being moiſtened; and to thoſe in which the coheſion is not much inferior to the adheſion; for then, it is evident, that the force of coheſion will be increaſed as the force of adheſion. Let us ſuppoſe, for inſtance, that two ſolids, A and B, are made to adhere to the ſurface of a liquid, and that A can only form an adheſion with 50 particles of the liquid, whilſt B adheres to 100; it is evident that a much ſmaller force will deſtroy the coheſion of the 50 particles to which A adheres with the reſt of the liquid, than what will be required to deſtroy the coheſion of the 100 particles united to B with the ſame liquid *.

The method of Mr Morveau, then, may be applied with accuracy in both caſes; and *when* they occur can only be determined by experiment. It cannot, however, be applied indiſcriminately even then; for unleſs the ſolid and the fluid be preſented in ſuch a ſtate that no gas is extricated when the adheſion takes place, an accurate judgment cannot be formed of the force of adheſion. When marble (carbonat of lime), for inſtance, is applied to the ſurface of ſulphuric acid, there is an extrication of gas, which very ſoon deſtroys the adheſion, and prevents an accurate reſult. Were it poſſible to employ quicklime inſtead of marble, this would be prevented; or if this cannot be accompliſhed, why might not lime be employed, united with ſome acid that would not aſſume a gaſeous form, and at the ſame time has a weaker affinity than ſulphuric acid for lime? Why might not the phoſphat of lime, for inſtance, be uſed, which may be reduced to a ſtate of hardneſs ſufficiently great for the purpoſe? The extrication of gas, during the application of metals to the ſurfaces of acids, might be prevented by oxidating their ſurfaces. It is true, indeed, this could not be done with all the metals, on account of the nature of the oxide, but it might with ſeveral; copper, for inſtance, and ſilver. It cannot be doubted, that by theſe methods, and other contrivances that might be fallen upon, a ſufficient number of reſults might be obtained to render this method of the greateſt importance. It is rather ſurpriſing, therefore, that it has never been proſecuted.

574
And Kirwan.

Mr Kirwan has propoſed another method of ſolving the problem. While he was engaged in his experiments on the ſtrength of acids, he obſerved that the quantity of real acid neceſſary to ſaturate a given quantity of each of the baſes, was inverſely as the affinity between the reſpective baſes and the acid; and that the quantity of each of the baſes neceſſary to ſaturate a given quantity of acid was directly as the affinity between the baſe and the acid. Thus 100 grains of each of the acids require more alkali for ſaturation than lime, and more lime than magneſia, as may be ſeen in the following table:

100 grains of	Potaſs.	Soda.	Lime.	Amm.	Mag.	Alum.
Sulphuric acid	215	165	110	90	80	75
Nitric acid	215	165	96	87	75	65
Muriatic acid,	215	158	89	79	71	55

He concluded, therefore, that the affinity between acids and their baſes may be eſtimated by the quantity of baſes neceſſary for ſaturation. Thus the affinity between potaſs and ſulphuric acid is 215, and that between nitric acid and lime 96 *.

We have mentioned formerly, that the principle on which Mr Kirwan calculated the ſtrength of the acids was founded on a miſtake. It muſt follow of courſe, therefore, that the numbers which reſult from it muſt alſo be wrong. This Mr Kirwan has acknowledged, and ſeems to have given up all thoughts of aſcertaining the ſtrength of affinities by this method. But before it be abandoned altogether we wiſh the following obſervations were conſidered.

575
Attempt t
remedy th
defects of
his method

Bergman long ago eſtabliſhed as a principle, under the name of a chemical paradox, that *the ſtronger any ſalt was, the leſs of any other it required for ſaturation.* Thus, according to him,

100

* *Morveau, Encyc. Method. Chim.* art. *Adheſion.*

* *Phil. Tranſ.* 1783.

(D) Strictly ſpeaking, this is owing not ſo much to a decreaſe of the force of adheſion, as of that of the coheſion of the fluid itſelf.

100 parts of potaſs require	78,5	Sulphuric acid,
	64	Nitric,
	51,5	Muriatic,
	42	Carbonic,
100 parts of ſoda - -	177	Sulphuric,
	135,5	Nitric,
	125	Muriatic,
	80	Carbonic.

This propoſition, which has been admirably illuſtrated by Morveau *, evidently reſolves itſelf into the two following:

1. A *baſe* requires *the more* of an acid for ſaturation *the ſtronger* its affinity for that acid is.

2. An *acid* requires *the more* of any baſe for ſaturation *the greater affinity* it has for that baſe.

In order to judge of the truth of the firſt of theſe propoſitions, let us examine the following table, drawn up from the experiments of Bergman, Wenzel, and Kirwan.

	BERGMAN.			WENZEL.			KIRWAN.		
100 parts of	Sulphuric.	Nitric.	Muriatic.	Sulphuric.	Nitric.	Muriatic.	Sulphuric.	Nitric.	Muriatic.
Barytes	15,4		30,8						
Potaſs	78,6	64	51,5	82,4	107,7	54	81,8	87,1	78,2
Soda	175	135,5	125	125,8	166,6	83	129,4	136,1	114,2
Lime	143,7	134,4	70,45	147,74	195,6	103,6	141	180	86
Magneſia	173,67	159,25	82,92	181,8	257,15	122,27	170,5	255	104,275
Ammonia				142,42	201,22	96,25	187,5	233	116
Alumina	211,11		220,2	77,7	68,7	38,6			

It is evident at firſt ſight, that Bergman's experiments correſpond exactly with the propoſition. To ſaturate, according to him, 100 parts of potaſs, requires 78,6 of ſulphuric acid, 64 of nitric, and 51,5 of muriatic acid. There is only one deviation from the propoſition in the whole table, and this regards barytes, which, according to him, is ſaturated with 15,4 of ſulphuric and 30,8 of muriatic acid. But Mr Morveau has ſhewn, by ſeveral accurate experiments, that barytes requires much more ſulphuric acid for ſaturation than Bergman ſuppoſed *. And Klaproth has ſhewn, that 100 parts of barytes require 49,2 of ſtrong ſulphuric acid for ſaturation †. And Dr Withering's calculation ‡ agrees almoſt exactly with this; nor does that of Fourcroy differ much from it §. Inſtead of 15,4 of ſulphuric acid, therefore, which, according to Bergman, are neceſſary to ſaturate 100 of barytes, it ſhould be 42,8.

The firſt and laſt columns of Wenzel and Kirwan's experiments agree equally well with the propoſition, but the ſecond deviates from it completely. Wenzel probably might have been miſled by the manner of performing his experiments; but the ſame objection does not ſeem to lie againſt thoſe of Kirwan.

It can ſcarcely be doubted, however, to whatever cauſe the error is to be imputed, that the numbers in the ſecond column of Mr Kirwan's table are too large. The following experiment of Morveau is ſufficient to ſhew this.

According to Mr Kirwan's experiments, the proportions of acid and alkali in the four following ſalts are as under:

Sulphat of potaſs { Acid 100
Potaſs 108,7

Sulphat of lime { Acid 100
Lime 80,6

Nitrat of potaſs { Acid 100
Potaſs 83,33

Nitrat of lime { Acid 100
Lime 34,4.

Now when ſulphat of potaſs and nitrat of lime are mixed together, a double decompoſition takes place, and ſulphat of lime and nitrat of potaſs are formed. Let theſe two ſalts be mixed together; let the quantity of ſulphat of potaſs be ſuch, that the acid contained in it amounts to 100; and let a more than ſufficient quantity of nitrat of lime be added, to ſaturate the ſulphuric acid with lime. It is evident that for that purpoſe 80,6 of lime muſt be preſent; and the quantity of nitric acid combined with theſe 80,6 muſt be 234,4. This quantity would require for ſaturation 195,32 of potaſs, but there are only 108,7 in the mixture; conſequently there ought to exiſt in the mixture, after the mutual decompoſition of the ſalts, 64,87 of nitric acid in a ſtate of liberty. Such would be the reſult, provided Mr Kirwan's numbers were accurate; but the fact is, that no ſuch exceſs of acid exiſts in the mixture †; and conſequently the quantity of nitric acid contained in nitrat of lime is ſtated too high by Mr Kirwan. Although therefore Mr Kirwan's tables do not coincide with the propoſition which we are conſidering, this is not to be conſidered as a proof of its falſehood; as there is reaſon, from the experiment above deſcribed, to ſuſpect ſome error in the data from which Mr Kirwan calculated the ſtrength of the acids.

The truth of the ſecond propoſition may be judged of by the following Tables:

---

* Encyc. Method. Chim. i. 597.

* Encyc. Method. Chim. i. 591.

† Chim. Ann. ii. 1785.

‡ Phil. Tranſ. 1784.

§ Ann. de Chim. iv. 65.

† Ann. de Chim. xxv. 295.

According to BERGMAN.

100 parts of	Baryt.	Potaſs.	Soda.	Lime.	Magn.	Amm.	Alum.
Sulp. acid	646	127,5	56,5	69,5	578	42	473
Nitric acid		148,4	74,4	74,4	62,8		
Mur. acid	324,7	194	78	141,9	120,5		40

According to WENZEL.

100 parts of	Byryt.	Potaſs.	Soda.	Lime.	Magn.	Amm.	Alum.
Sulp. acid		120,8	79,16	67,2	55	70,2	128
Nitric acid		92,7	60	51,1	38,8	49,7	147,8
Mur. acid		183,8	119,2	96,5	81,7	103,9	259

According to KIRWAN.

100 parts of	Baryt.	Potaſs.	Soda.	Lime.	Magn.	Amm.	Alum.
Sulp. acid		122,2	77,2	70,4	57,3	53,3	
Nitric acid		112	73,8	55,5	39,2	44,8	
Mur. acid		168,6	133	112,7	89,9	78,5	

It appears that all the table of Bergman agrees with the propoſition except the numbers which correſpond to ſulphat of ſoda, ſulphat of alumina, nitrat of lime, and muriat of ſoda, which the late experiments of Mr Kirwan have ſufficiently ſhewn to be inaccurate.

Wenzel's table correſponds exactly, except the columns under ammonia and alumina, which Morveau has proved to be inaccurate.

Kirwan's table correſponds exactly, except with regard to the quantity of ammonia neceſſary to ſaturate muriatic acid, which does not appear to have been accurately determined by experiment.

Let us therefore take the truth of theſe two propoſitions for granted, and let us conſider every deviation from them as an error; and let us ſee whether they will enable us to diſcover the abſolute affinity of ſulphuric, nitric, and muriatic acids, for their reſpective baſes.

TABLE I. *Quantity of Baſe neceſſary to Saturate* 100 *Parts of the three Acids.*

100 parts	Baryt.	Potaſs.	Soda.	Lime.	Magn.	Amm.
Sulph. acid	233,3	123,3	78,7	68,3	56,8	49,3
Nitric acid	258,4	148,4	95,6	74,4	62,8	54,8
Muriat. acid	324,7	188,8	126,1	116,7	97,3	78,5

TABLE II. *Quantity of Acid neceſſary to Saturate* 100 *Parts of the ſix Baſes.*

100 parts	Sulph. acid.	Nitric acid.	Mur. acid.
Barytes	42,8	38,7	30,8
Potaſs	81	64	52,9
Soda	126,7	101,4	79
Lime	145,7	134,4	87,5
Magneſia	176,2	159,25	105,4
Ammonia	202,6	182,4	127,25

The firſt of theſe tables repreſents the affinity between the ſame acid and its various baſes; and the ſecond that of the baſes for the different acids. If it were required to know the ratios of the affinity which different baſes have for any particular acid, the firſt table, ſuppoſing it accurate, would give it exactly. In like manner, if it were required to know the ratios of the affinity of the acids for the various baſes, we would find them in the ſecond table.

576
And to conſtruct tables of affinity.

But if we wiſhed to know what was the affinity between one acid and baſe, compared with that between another acid and a different baſe; or if we wanted to have not the relative but the abſolute affinity between two bodies—it is plain that we could not find it in either of the tables; for the abſolute affinity muſt conſiſt of two things, the affinity which the acid has for the baſe, and the affinity which the baſe has for the acid. Now the firſt table gives us the one of theſe, and the ſecond the other; ſo that in order to repreſent affinity in abſolute numbers, the two tables muſt be multiplied into one another. This was the miſtake into which Mr Kirwan fell. His method conſiſted merely in conſtructing a table like our firſt, which (ſuppoſing the numbers accurate) gave only the affinity between the baſes and the ſame acid, but left out the affinity between the different acids and the ſame baſe; conſequently the different columns could not be compared with each other.

It is evident, however, that if the tables were multiplied together in their preſent ſtate, they could not poſſibly give an accurate table of affinities. For that purpoſe, it is neceſſary to put the ſame number in the firſt column of each table, and then to ſubſtitute other numbers in the remaining columns, having the ſame ratio to one another with the numbers in the original columns. This is done in the following Tables:

TABLE I. *Ratios of the Affinity of ſix Baſes for three Acids.*

	Barytes.	Potaſs.	Soda.	Lime.	Magn.	Amm.
Sulph. acid	100,00	52,85	33,73	29,27	24,34	21,12
Nitric acid	100,00	57,43	36,98	28,77	24,28	19,59
Mur. acid	100,00	58,11	38,81	35,70	29,94	24,15

TABLE

TABLE II. *Ratios of the Affinity of three Acids for ſix Baſes.*

	Sulph. acid.	Nitric acid.	Mur. acid.
Barytes	100,00	90,42	74,54
Potaſs	100,00	79,01	65,30
Soda	100,00	80,03	62,35
Lime	100,00	92,24	60,05
Magneſia	100,00	90,34	59,68
Ammonia	100,00	90,02	62,77

TABLE III. *Affinity between three Acids and ſix Baſes in Abſolute Numbers.*

	Sulph. acid.	Nitric acid.	Mur. acid.
Barytes	10000	9042	7454
Potaſs	5285	4537	3794
Soda	3373	2969	2419
Lime	2927	2653	2143
Magneſia	2434	2193	1786
Ammonia	2112	1763	1515

On the ſuppoſition that the two propoſitions mentioned above were ſtrictly true, and that the numbers which we fixed upon were preciſely the quantities of acid and baſe neceſſary to ſaturate each other reciprocally, this laſt table would repreſent accurately in numbers the ſtrength of the affinities of the three acids for each of the ſix baſes reſpectively.

We muſt acknowledge, however, that the truth of theſe propoſitions has not hitherto by any means been ſufficiently proved; but a great number of facts concur to render them exceedingly probable, and highly worthy of the attention of chemical philoſophers. And we hope that the method propoſed by Morveau, and which had been previouſly practiſed by Richter, of verifying theoretical calculations of the compoſition of the ſalts, by mixing together two ſalts which mutually decompoſe each other, and aſcertaining whether the reſult correſponds with calculation, will be followed out, and that it will be the means of enſuring more accuracy than it has hitherto been poſſible to obtain.

No one will ſuſpect that any thing which has here been ſaid is meant as a reflection on the ingenious chemiſts who have attempted to ſolve this moſt difficult of all chemical problems, the proportion of the ingredients which enter into the compoſition of the ſalts. Mr Kirwan, in particular, is entitled to the greateſt praiſe for the perſevering induſtry with which he has proſecuted the ſubject, for the candour which he has diſplayed, and for the new rout which he has opened to the chemical philoſopher. Though this problem has not hitherto been ſolved, and though the difficulties which ſurround it are almoſt inſurmountable, we may hope much from the general ſenſe which is at preſent entertained of its importance, and from the zeal and abilities of thoſe philoſophers who have particularly turned their attention to it.

In the mean time, the following Table of the ſtrength of affinities by Morveau, though the numbers be arbitrary, will be found of very great uſe *.

* Encyc. Method. Chim. i. 773.

577
Morveau's table of affinity.

	Sulph. acid	Nitric acid.	Muriat. acid	Acetous acid.	Carbonic acid.
Barytes	66	62	36	28	14
Potaſs	62	58	32	26	9
Soda	58	50	31	25	8
Lime	54	44	24	19	12
Ammonia	46	38	21	20	4
Magneſia	50	40	22	17	6
Alumina	40	36	18	15	2 (D)

5. Although every chemical combination is produced by the ſame general law, yet as their phenomena vary ſomewhat according to circumſtances, affinities have, for the ſake of greater perſpicuity, been divided into claſſes. Theſe claſſes may be reduced to *three*—*ſimple*, *compound*, and *diſpoſing* affinities.

578
Three claſſes of affinity.

The *firſt claſs* comprehends all thoſe caſes in which only *two bodies combine* together; as, for inſtance, ſulphuric acid and potaſs, oxygen and carbon. The affinities which belong to this claſs are known by the name of *ſimple* or *ſingle affinities*. Although one of the ſubſtances to be combined happens to be already united with another body, the combination is ſtill reckoned a caſe of ſingle affinity. Thus ſuppoſe the ſulphuric acid previouſly combined with magneſia, and forming with it the ſalt called *ſulphat of magneſia*, as ſoon as potaſs is preſented, the acid leaves the earth (which is precipitated), and unites with the alkali. Even when three bodies combine, it often happens that the union is produced merely by ſingle affinity. Thus, when ſome potaſs is dropped into tartarous acid, part of the acid unites with the alkali, and forms tartrite of potaſs; after this the remainder of the acid combines with the tartrite juſt formed, and compoſes a new ſalt known by the name of *acidulous tartrite of potaſs*, or *tartar*. This is evidently nothing elſe than two inſtances of ſimple affinity immediately following each other.

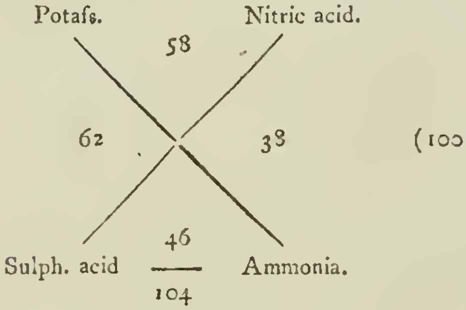
579
Viz. ſimple affinity,

When more than three bodies are mixed, decompoſitions and new combinations often take place, which could

580
Compound affinity,

(D) This table, however, does not correſpond quite accurately to all the phenomena. For inſtance, according to it, ſulphat of barytes is not decompoſed by carbonat of ſoda, although the contrary takes place in fact.

could not have been produced had the bodies been preſented in a different ſtate. If, for inſtance, into a ſolution of ſulphat of potaſs there be poured nitric acid, no decompoſition is produced, becauſe the ſulphuric acid has a ſtronger affinity for potaſs than nitric acid has. For the very ſame reaſon, ammonia may be poured into the ſolution without producing any change. But if nitrat of ammonia be poured in, a decompoſition inſtantly takes place, and two new bodies, *ſulphat of ammonia* and *nitrat of potaſs*, are formed. Such caſes of decompoſition form the *ſecond claſs of affinities*. They were called by Bergman caſes of *double elective attraction*; a name which is exceedingly proper when there are only four bodies concerned. But as there are often more than four, it is neceſſary, as Mr Morveau has obſerved, to employ ſome more comprehenſive term. We ſhall therefore call the affinities belonging to this claſs *compound affinities* (E); and comprehend under the term all caſes where more than three bodies are preſent, and produce combinations which would not have been formed without their united action. In theſe caſes the affinity of all the various bodies for each other acts, and the reſulting combination is produced by the action of thoſe affinities which are ſtrongeſt. The manner in which theſe combinations and decompoſitions take place, was firſt clearly explained by Dr Black. Let the affinity between potaſs and ſulphuric acid be = 62; that between nitric acid and ammonia = 38; that between the ſame acid and potaſs = 58; and that between the ſulphuric acid and ammonia = 46. Now, let us ſuppoſe that all theſe forces are placed ſo as to draw the ends of two cylinders croſſing one another, and fixed in the middle in this manner,

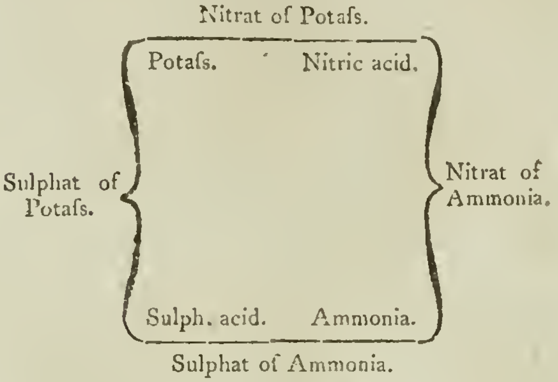


It is evident, that as 58 and 46 = 104, are greater than 62 + 38 = 100, they would overcome the other forces and ſhut the cylinders. Juſt ſo the affinity between potaſs and nitric acid, together with that between ſulphuric acid and ammonia, overcomes the affinity between potaſs and ſulphuric acid, and that between nitric acid and ammonia, and produces new combinations.

In all caſes of compound affinity, there are two kinds of affinities to be conſidered; 1*ſt*, Thoſe affinities which tend to preſerve the old compound, theſe Mr Kirwan has called *quieſcent* affinities; and thoſe which tend to deſtroy them, which he has called *divellent* affinities.

Thus, in the inſtance above given, the affinity between potaſs and ſulphuric acid, and that between nitric acid and ammonia, are quieſcent affinities, which endeavour to preſerve the old compound; and if they are ſtrongeſt, it is evident that no new compound can take place. On the contrary, the affinity between potaſs and nitric acid, and that between ſulphuric acid and ammonia, are divellent affinities; and as they are in this caſe ſtrongeſt, they actually deſtroy the former combinations and form new ones.

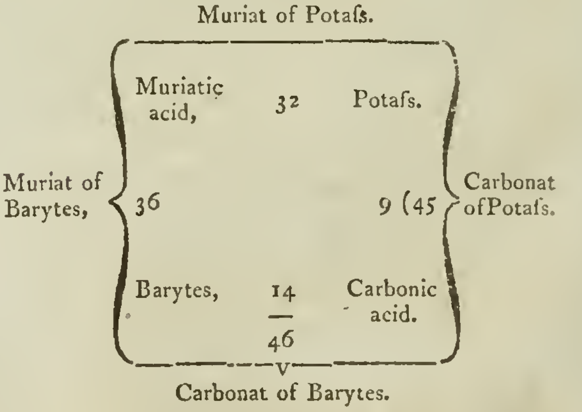
Bergman, who publiſhed a great many caſes of compound affinities, employed to explain them a method ſomewhat different from this. He would have repreſented the above caſe in the following manner:



At the four corners of an imaginary ſquare are placed the four ſubſtances, ſo that one acid ſhall be diagonally oppoſite to another. On the right and left ſide of the ſquare are placed the old compounds, each on the ſide of its own ingredients, and above and below are placed the new compounds.

Mr Elliot improved this method of Bergman, by adding numbers expreſſive of the affinity of the various ſubſtances. It is in caſes of compound affinity that the ratios of affinities, if we were poſſeſſed of them, would be peculiarly uſeful. For it is evident, that if we knew the ſtrength of affinities in abſolute numbers, we would be able to determine before hand all the caſes of compound affinity.

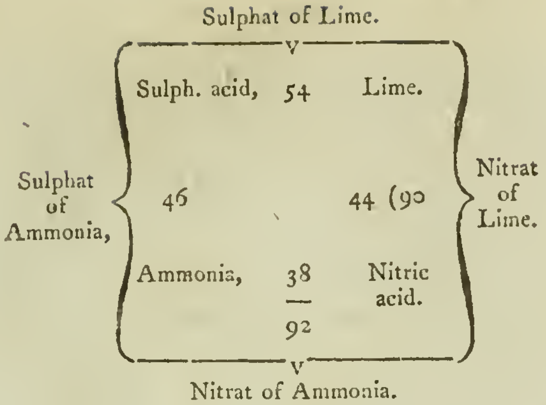
If we knew, for inſtance, that the affinity between the muriatic acid and barytes were = 36; that between the ſame acid and potaſs = 32; the affinity between potaſs and carbonic acid = 9; and that between the ſame acid and barytes = 14;—we would be certain, previous even to experiment, that when muriat of barytes and carbonat of potaſs are mixed, a double decompoſition would take place; which we know from experiment to be actually the caſe.



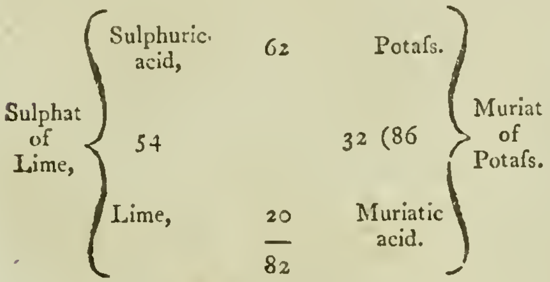
Another inſtance of decompoſition by compound affinities.

Sulphat

(E) Morveau called them *affinité par concours.*

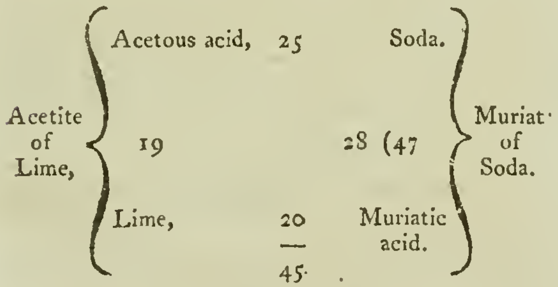


Suppoſing Morveau's numbers exact, it follows alſo, even prior to experiment, that no decompoſition takes place when ſulphat of lime and muriat of potaſs are mixed;



for the quieſcent affinities are 86, and the divellent only 82.

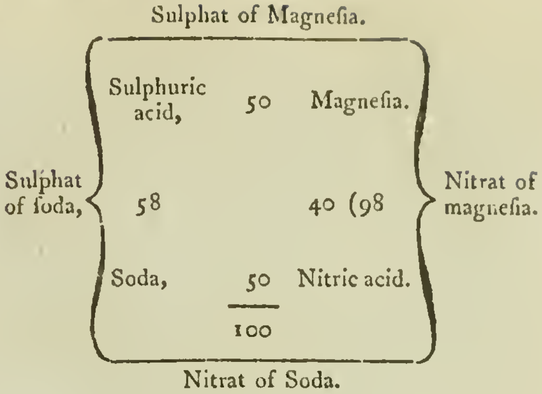
Nor when acetite of lime and muriat of ſoda are mixed;



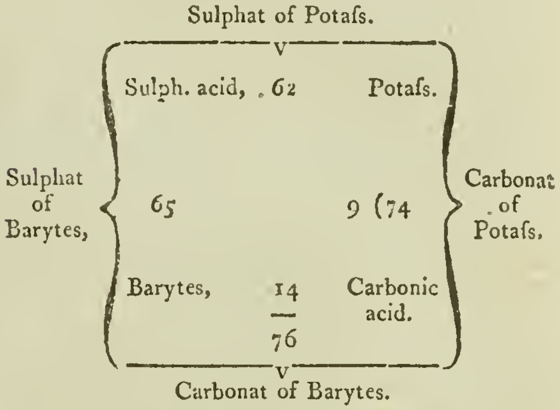
becauſe the quieſcent affinities are 47, and the divellent only 45. Theſe caſes where no decompoſition takes place have been called by Morveau caſes of *inverſe* compound affinity.

Morveau has propoſed the following improvements in repreſenting theſe caſes of compound affinities*.

When decompoſition does not take place, nothing is to be written above and below the ſquare, as in the two laſt examples. When a new compound remains diſſolved, a ſtraight line is to be placed between it and the ſquare, as in the following ſcheme.



When a new compound is precipitated, a line bent downwards in the middle is to be placed between it and the ſquare, as in the following ſcheme:



When a new compound is ſublimed, the line between it and the ſquare is to be pointed upwards in the middle, thus ⌐——^——¬.

When a new compound is partly diſſolved and partly precipitated, the line placed between it and the ſquare is to aſſume the following ſhape: ——⌐——¬.

When it is partly diſſolved and partly ſublimed, the following is the line to be uſed: ——⌄——¬.

581 And diſpoſing affinity.

The third claſs of affinities has been called by Mr Morveau *diſpoſing affinities*, becauſe they *diſpoſe* ſubſtances to combine that would not otherwiſe have done it. Suppoſe, for inſtance, that ſulphur is preſented to oxygen gas, it does not manifeſt any affinity for it; but combine it previouſly with potaſs, and it unites with oxygen with avidity. Its previous union with potaſs, in this caſe, *diſpoſed* it to unite with oxygen. The cauſe of this curious affinity is not yet well underſtood. If we conſider what it was that prevented the ſulphur and oxygen from combining, we ſhall find that it can only be its own attraction of coheſion, and the affinity between the oxygen and caloric which are combined. Whatever then diminiſhes this attraction of coheſion, or of *aggregation* as it has been called, muſt facilitate the union of

---

* Encyc. Method. Chim. i. 555.

of the ſulphur with oxygen. This is done in ſome meaſure by the potaſs. Beſides, if affinity depends upon the figure of particles, it is evident that there muſt be an affinity between the new compound and oxygen: but the moment the oxygen approaches within a certain diſtance of the ſulphur, it unites with it, as its affinity is much greater for that ſubſtance than for the compound.

The following is another inſtance of this curious affinity: Sugar, as Lavoiſier has proved, is compoſed of oxygen, hydrogen, and carbon: Now if concentrated ſulphuric acid be poured upon ſugar, the oxygen and hydrogen combine, and form water, which unites with the acid, and the carbon is precipitated. In this caſe, the preſence of the acid *diſpoſed* the oxygen and hydrogen to combine. In what manner this new combination is produced, it would not be eaſy to explain: not by weakening the attraction of coheſion; for we do not ſee how the acid could produce that effect. The only explanation that can be given, is to ſuppoſe that the ſulphuric acid, when it approaches within a certain diſtance of the oxygen and hydrogen, attracts them; and that this attraction, together with the affinity between the oxygen and hydrogen, is greater than that which produces the combination between the ingredients of the ſugar themſelves: the conſequence of which muſt be decompoſition.

582
Why bodies require different temperatures to unite,

6. We come now to one of the moſt difficult queſtions in chemiſtry—Why do bodies require different temperatures in order to unite? and why does the preſence of caloric in many caſes favour or rather produce union, while it prevents or deſtroys it in others?

Theſe queſtions were propoſed at the end of the ſecond Chapter of this article; and we reſerved them for this place, not becauſe we hoped to be able to anſwer them in a ſatisfactory manner, but becauſe no intelligible anſwer could be given till the nature of affinity had been previouſly conſidered. Some ſubſtances, phoſphorus for inſtance, combine with oxygen at the common temperature of the atmoſphere; others, as carbon, require a higher temperature; and others, as hydrogen and azotic gas, do not combine except at a very high temperature. To what are theſe differences owing?

In anſwer to this queſtion, we obſerve, that the attraction of *coheſion* evidently oppoſes that of *affinity.* Thoſe bodies which we preſent to combine together are generally aggregates, or, which is the ſame thing, conſiſt of many ſimilar particles united by coheſion: for we have no method of ſeparating bodies into their integrant particles, except *affinity.* Now we can conceive the attraction of coheſion between the particles of a body to be ſo great as to prevent them altogether from obeying the impulſe of affinity. That this actually happens in ſome caſes cannot be doubted: for if pure alumina be formed into a paſte, and heated ſufficiently, it becomes ſo hard that no acid can act upon it; yet its nature is not in the leaſt changed: by proper trituration, it may be again rendered ſoluble; and when precipitated from this new ſolution, it has recovered all its original properties. The effect of the fire, then, was merely to increaſe the coheſion, by ſeparating all the water, and allowing the particles to approach nearer each other.

It is evident, that whatever diminiſhes the coheſion which exiſts between the particles of any body, muſt tend to facilitate their chemical union with the particles of other bodies. This is the reaſon that bodies combine more eaſily when held in ſolution by water, or when they have been previouſly reduced to a fine powder. Now caloric poſſeſſes the property of diminiſhing coheſion. And one reaſon why ſome bodies require a high temperature to cauſe them to combine is, that at a low temperature the attraction of *coheſion* is in them ſuperior to that of affinity; accordingly, it becomes neceſſary to weaken that attraction by caloric till it becomes inferior to that of affinity. The quantity of caloric neceſſary for this purpoſe muſt vary according to the ſtrength of the coheſion and of the affinity; it muſt be inverſely as the affinity, and directly as the coheſion. Wherefore, if we knew preciſely the force of the coheſion between the particles of any body, and of the affinity between the particles of that body and of any other, we could eaſily reduce the temperature neceſſary to calculation.

That caloric or temperature acts in this manner cannot be doubted, if we conſider that other methods of diminiſhing the attraction of coheſion may be ſubſtituted for it with ſucceſs. A large lump of charcoal, for inſtance, will not unite with oxygen at ſo low a temperature as the ſame charcoal will do when reduced to a very fine powder; and charcoal will combine with oxygen at a ſtill lower temperature, if it be reduced to its integrant particles, by precipitating it from alcohol, as Dr Prieſtley did by paſſing the alcohol through red hot copper. And to ſhew that there is nothing in the nature of oxygen and carbon which renders a high temperature neceſſary for their union, if they be preſented to each other in different circumſtances, they combine at the common temperature of the atmoſphere; for if nitric acid, at the temperature of 60°, be poured upon charcoal powder, well dried in a cloſe crucible, the charcoal takes fire, owing to its combining with the oxygen of the acid *: And in ſome other ſituations carbon is ſo completely divided, that it is capable of combining with the oxygen of the atmoſphere, or, which is the ſame thing, of catching fire at the common temperature. This ſeems to be the caſe with it in thoſe pyrophori that are formed by diſtilling to dryneſs ſeveral of the neutral ſalts which contain acetous acid †. Theſe obſervations are ſufficient to ſhew that caloric is in many caſes neceſſary in order to diminiſh the attraction of *coheſion.*

But there is a difficulty ſtill remaining, How comes it that certain bodies will combine with oxygen without the aſſiſtance of any foreign heat, provided the combination be once begun, though a quantity of caloric is neceſſary to begin the combination? and that other bodies require to be ſurrounded by a great quantity of caloric during the whole time of their combining with oxygen? Alcohol, for inſtance, if once kindled, burns till it is quite conſumed; and this is the caſe with oils alſo, provided they be furniſhed with a wick.

We muſt obſerve, in the firſt place, that we would err very much, were we to ſuppoſe that a high temperature is not as neceſſary to theſe ſubſtances during the whole of their combuſtion as at the commencement of it; for Mr Mongé found, on making the trial, that a candle would not burn after the temperature of the air around it was reduced below a certain point.

All ſubſtances which continue to burn after being once kindled are *volatile*, and they burn the eaſier in proportion

---

* *Prouſt and Morveau, Encyc. Methad Chim.* i. 474.

† *Morveau, ibid.*

proportion to that volatility. The application of a certain quantity of caloric to alcohol volatilizes part of it; that is to ſay, diminiſhes the attraction of its coheſion ſo much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol; which combines with oxygen in its turn; more heat is given out; and thus the proceſs goes on. Oils and tallow exhibit the very ſame phenomena; only as they are leſs volatile, it is neceſſary to aſſiſt the proceſs by means of the capillary attraction of the wick, which confines the action of the caloric evolved to a ſmall quantity of oil, and thus enables it to produce the proper effect. In ſhort, then, every ſubſtance which is capable of continuing to burn, after being once kindled, is volatile, or capable of being converted into vapour by the degree of heat at firſt applied. The reaſon that a live coal will not burn when ſuſpended inſulated in the air, is not, as Dr Hutton ſuppoſed*, becauſe its *light* is diſſipated; but becauſe the coal cannot be converted into vapour by the degree of heat which it contains, and becauſe the coheſion of its particles is too great to allow it to combine with oxygen without ſome ſuch change. There are ſome coals, however, which contain ſuch a quantity of bitumen that they will burn even in the ſituation ſuppoſed by Dr Hutton, and continue to burn, provided they be furniſhed with any thing to act as a wick. It is needleſs to add, that bitumen, like oil, is eaſily converted into vapour.

* On *Light* and *Heat.*

But this explanation, inſtead of removing our difficulties, has only ſerved to increaſe them: For if caloric only acts by diminiſhing the attraction of coheſion, and converting theſe ſubſtances into vapour, why do not all elaſtic fluids combine at once without any additional caloric? why do not oxygen and hydrogen, when mixed together in the ſtate of gas, unite at once and form water? and why do not oxygen and azot, which are conſtantly in contact in the atmoſphere, unite alſo and form nitrous gas? Surely it cannot be the attraction of coheſion that prevents this union. And if it be aſcribed to their being already combined with caloric, how comes it that an additional doſe of one of the ingredients of a compound decompoſes it? Surely, as Mr Mongé has obſerved, this is contrary to all the other operations in chemiſtry.

That the particles of fluids are not deſtitute of an attraction for each other, is evident from numberleſs facts. The particles of water draw one another after them in caſes of capillary attraction; which is probably owing to the attraction of coheſion. It is owing to the attraction of coheſion, too, that ſmall quantities of water form themſelves into ſpheres: Nor is this attraction ſo weak as not to be perceptible. If a ſmall plate of glaſs be laid upon a globule of mercury, the globule, notwithſtanding the preſſure, continues to preſerve its round figure. If the plate be gradually charged with weights one after another, the mercury becomes thinner and thinner, and extends itſelf in the form of a plate; but as ſoon as the weights are removed, it recovers its globular figure again, and puſhes up the glaſs before it. Here we ſee the attraction of coheſion, not only ſuperior to gravitation, but actually overcoming an external force*. And if the workman, after charging his plate of glaſs with weights, when he is forming mirrors, happen to remove theſe weights, the mercury which had been forced from under the glaſs, and was going to ſeparate, is drawn back to its place, and the glaſs again puſhed up. Nor is the attraction of coheſion confined to ſolids and liquids; it cannot be doubted, that it exiſts alſo in gaſes; at leaſt it is evident, that there ſubſiſts an attraction between gaſes of a different kind: for although oxygen and azotic gas are of different gravities, and ought therefore to occupy different parts of the atmoſphere, we find them always mixed together; and this can only be aſcribed to an attraction. And were we to allow, with Humbolt and ſeveral other chemiſts, that theſe two gaſes are chemically combined in atmoſpherical air, an opinion contradicted by a late experiment in France (F); ſtill the exiſtence of carbonic acid gas in every part of the atmoſphere can only be aſcribed (if the inaccuracy of the expreſſion may be tolerated) to a kind of coheſion. And whoever has been accuſtomed to pneumatic experiments, muſt have obſerved that ſmall portions of *air*, as well as water, form themſelves into ſpheres, and that the attraction of coheſion is ſo ſtrong in gaſes, that large globules of them often adhere by a ſingle point to the bottom of veſſels filled with heavy fluids: whereas, had there been no attraction of coheſion, every part of the globule ought to have aſcended to the ſurface of the fluid, except the particles immediately in contact with the veſſel. Allowing, then, that there is an attraction of coheſion between the particles of gaſes, let us ſee whether that will not aſſiſt us in removing the difficulty.

* *Morveau, Affinité,* p. 543.

583 Explained.

It ſeems evident, in the firſt place, that the affinity between the baſes of the gaſes under conſideration and oxygen is greater than their affinity for that doſe of caloric which produces their elaſtic form; for when they are combined with oxygen, the ſame doſe will not ſeparate them again. Let us take hydrogen for an inſtance: The affinity of hydrogen is greater for oxygen than for the caloric which gives it its gaſeous form; but the oxygen is alſo combined with caloric, and there exiſts an attraction of coheſion between the particles of the hydrogen gas; the ſame attraction ſubſiſts between thoſe of oxygen gas. Now the ſum of all theſe affinities, namely, the affinity between hydrogen and caloric, the affinity between oxygen and caloric, the coheſion of the particles of the hydrogen, and the coheſion of the particles of oxygen—is greater than the affinity between the hydrogen and oxygen; and therefore no decompoſition can take place. Let the affinity between

Oxygen and caloric be	50
Hydrogen and caloric	50
Coheſion of oxygen	4
Coheſion of bydrogen	2
Sum of quieſcent affinities,	106
The affinity of oxygen and hydrogen,	105

The quieſcent affinities being greater than the divellent affinities, no decompoſition can take place.

(F) Air brought by means of a balloon from a great height in the atmoſphere was found to contain leſs oxygen gas than the ſame quantity of air near the ground.

Let now a quantity of caloric be added to the oxygen and hydrogen gas, it has the property of expanding them, and of courſe of diminiſhing their coheſion; while its affinity for them is ſo ſmall that it may be neglected. Let us ſuppoſe that it diminiſhes the coheſion of the oxygen 1, and of the hydrogen alſo 1, their coheſion will now be 3 and 1; and the quieſcent affinities being only 104, while the divellent are 105, the decompoſition would of courſe take place, and a quantity of caloric would thus be ſet at liberty to produce the ſame effects upon the neighbouring particles.

Thus, then, caloric acts only by diminiſhing coheſion: And the reaſon that it is required ſo much in gaſeous ſubſtances, and in thoſe combinations into which oxygen enters, is the ſtrong affinity of oxygen and the other baſes of the gaſes for caloric; for, owing to the repulſion which exiſts between the particles of that ſubtile ſubſtance, an effect is produced by adding large doſes of it, contrary to what happens in other caſes. The more of it is accumulated, the ſtronger is the repulſion between its particles; and therefore the more powerful is its tendency to fly off: and as this tendency is oppoſed by its affinity for the body and the coheſion of its particles, it muſt diminiſh both theſe attractions.

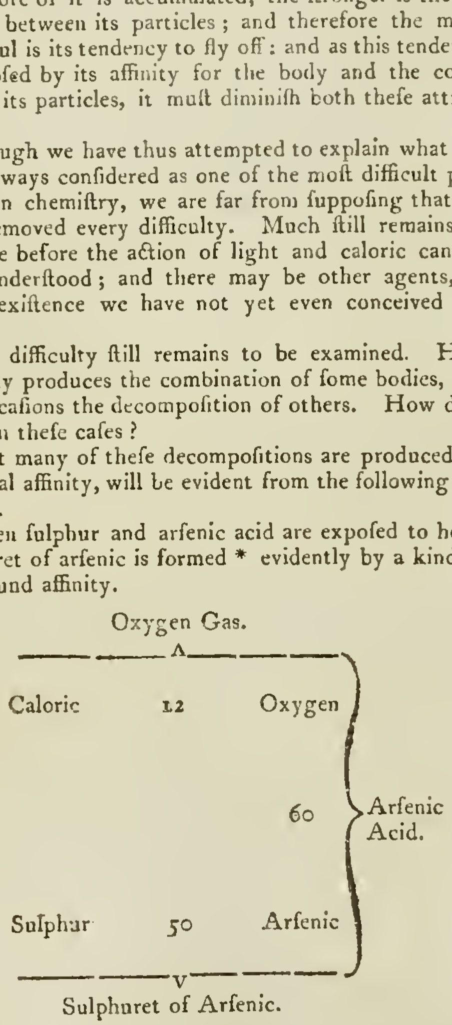
Though we have thus attempted to explain what has been always conſidered as one of the moſt difficult problems in chemiſtry, we are far from ſuppoſing that we have removed every difficulty. Much ſtill remains to be done before the action of light and caloric can be fully underſtood; and there may be other agents, of whoſe exiſtence we have not yet even conceived the idea.

One difficulty ſtill remains to be examined. Heat not only produces the combination of ſome bodies, but alſo occaſions the decompoſition of others. How does it act in theſe caſes?

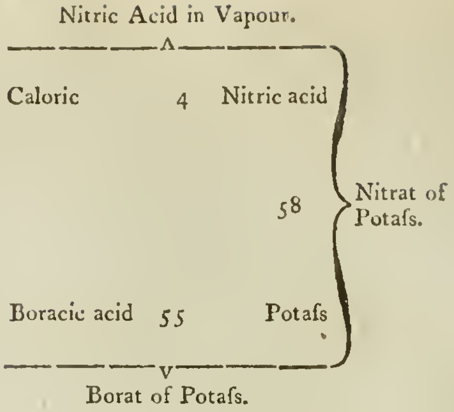
584 How heat decompoſes bodies.

That many of theſe decompoſitions are produced by chemical affinity, will be evident from the following examples.

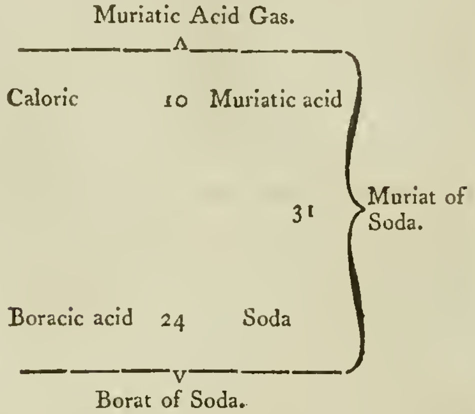
When ſulphur and arſenic acid are expoſed to heat, ſulphuret of arſenic is formed * evidently by a kind of compound affinity.



In the ſame manner, when nitrat of potaſs and boracic acid are expoſed to heat, the nitric acid is volatilized, and borat of potaſs is left behind.



By the ſame compound affinity boracic acid and heat decompoſes muriat of ſoda.



In the ſame manner, it would be eaſy to explain how all the decompoſitions by the *dry way*, as it is called, are produced.

But how comes caloric to decompoſe water after having produced the union of oxygen and hydrogen? The union, we have ſeen, was probably brought about by the play of oppoſite affinities; but in the ſeparation, caloric ſeems to act by its peculiar power, or the repulſion which exiſts between its particles. When caloric combines with an integrant particle of water, this repulſion muſt ſeparate the component parts ſomewhat from one another; conſequently it muſt weaken their affinity; for every increaſe of diſtance produces that effect. Now let us ſuppoſe that the affinity between oxygen and hydrogen is 105, and that the affinity between caloric and each of theſe bodies is 50: as ſoon as the particles of oxygen and hydrogen are ſo far ſeparated from each other that their affinity is leſs than 100, they will unite with caloric in preference, becauſe the ſum of their affinities for caloric is equal to 100; conſequently, whenever that takes place water will be decompoſed. Hence we ſee the reaſon why more heat is always neceſſary to produce the decompoſition of bodies than what produced their union.

Caloric poſſeſſes another ſingular property, that of changing the compound affinities of bodies, even when it

---

* *Pelletier.*

it does not appear to enter as an ingredient. What we mean will appear evident from the following examples:

Muriat of ammonia, }
Carbonat of magneſia, } decompoſe each other at the ordinary temperature of the atmoſphere, and form muriat of magneſia and carbonat of ammonia: but, on the contrary,

Muriat of magneſia, and }
Carbonat of ammonia, } decompoſe each other at a high temperature; for inſtance, at 212°. The products are muriat of ammonia and carbonat of magneſia *.

Again, if muriat of ſoda and ſulphat of magneſia be mixed together at a low temperature, for inſtance at zero, they decompoſe each other, and muriat of magneſia and ſulphat of ſoda are formed; but no decompoſition takes place at a temperature above 32°.—Muriat of ſoda, and ſulphat of alumina, exhibit preciſely the ſame phenomena †.

Laſtly, ſulphat of magneſia and carbonat of ammonia decompoſe each other at the ordinary temperature; but at 212° the carbonic acid flies off, and the remaining ſubſtances form a triple ſalt ‡.

The laſt of theſe phenomena appears owing to the affinity between carbonic acid and caloric, and the two firſt to the affinity between muriat of ammonia and caloric, for that ſalt is volatilized.

It would not be ſo eaſy to explain the mutual decompoſition of muriat of ſoda and ſulphat of magneſia at a low temperature. It is probably connected with the alterations in the diſtance of the ingredients of chemical compounds, which are produced by the preſence and abſence of caloric.

585 f Count umford's pinion re- ecting af- nity.

From the important part which caloric acts in chemical combinations, Count Rumford has been lately induced to ſuſpect that this ſubtile fluid is the *only agent* by which they are produced.

That caloric is a *neceſſary* agent in all chemical decompoſitions and new combinations, we very readily allow; becauſe we know no other cauſe except caloric to prevent the particles of bodies from actual contact; in which caſe decompoſition would be impoſſible: and if this be the ſenſe in which that ingenious philoſopher aſcribes chemical combinations to caloric, we very readily agree with him; but if he ſuppoſes that caloric is the *agent* by which the particles of bodies are brought near each other, and the *force* by which they adhere to one another, we cannot help thinking that he is miſtaken: For that bodies, chemically combined, are kept near each other by ſome force, cannot poſſibly be denied. Now, what is that force? We have ſaid, after Newton, an *attraction between the particles themſelves*; acknowledging, at the ſame time, that we are unable to explain what that is.

Count Rumford ſeems to ſuppoſe that there is no ſuch thing as attraction between the particles themſelves, but that caloric is the agent which keeps them together. If ſo, how does caloric perform this office? For our part, we do not pretend to underſtand it any more than the nature of attraction; nor do we ſee that it is poſſible to render it more intelligible. But there is another queſtion of ſtill greater importance, What are the proofs that caloric is the only agent in all caſes of chemical combinations? For our part, we can think of no proof that can render this opinion in the ſmalleſt degree plauſible.

Has this celebrated and candid philoſopher conſidered this ſubject with his uſual accuracy? If heat be a body, it cannot ſurely be the cauſe of affinity, unleſs it be poſſeſſed of properties which, ſo far from being proved, have not even been ſuſpected. On the contrary, if it be a property of matter, what property is it? If it be a peculiar motion, as Count Rumford ſuſpects, we would aſk if it be poſſible for any motion whatever, independent of attraction, to produce the permanent union of two bodies?

PART III. OF DOUBLY COMPOUND BODIES.

THE bodies which conſiſt of combinations of thoſe ſubſtances that have been denominated *compound*, and which, for that reaſon, we have ventured to call *doubly compound bodies*, may be reduced to three claſſes:

Soaps,
Neutral ſalts,
Hydroſulphurets.

Theſe ſhall form the ſubject of the three following Chapters; and we ſhall finiſh this part of the article with ſome obſervations on *cryſtallization*.

CHAP. I. *Of* SOAPS.

THE compounds into which *oils* enter without decompoſition have been denominated *ſoaps*.

Oils are capable of combining with alkalies, earths, and metallic oxides; they are capable alſo of combining with ſeveral of the acids. There are therefore two claſſes of ſoaps; 1. Alkaline, earthy, and metallic ſoaps, which, for the ſake of brevity, we ſhall call *alkaline ſoaps*; and, 2. Acid ſoaps. Theſe two claſſes form the ſubject of the two following Sections.

SECT. I. *Of Alkaline Soaps.*

As there are a great number of oils, all or moſt of which are capable of combining with alkalies, earths, and oxides, it is natural to ſuppoſe that there are as many genera of alkaline ſoaps as there are oils. That there are differences in the nature of ſoaps correſponding to the oil which enters into their compoſition, is certain; but theſe differences are not of ſufficient importance to require very particular deſcription. We ſhall therefore deſcribe all the alkaline ſoaps together, and notice, as we go along, ſome of the moſt important differences reſulting from the oily ingredients.

586 Common hard ſoap.

1. Soap of ſoda, or common ſoap. The word *ſoap* (*ſapo*, σαπων) firſt occurs in the works of Pliny and Galen, and is evidently derived from the old German word *ſepe* (G). Pliny informs us, that ſoap was firſt diſcovered by the Gauls; that it was compoſed of tallow and

---

(G) *Beckmann's Hiſtory of Inventions*, III. 239.—A ſimilar word is ſtill uſed by the common people of Scotland.

and aſhes; and that the German ſoap was reckoned the beſt *.

587 Method of forming it.

Soap may be prepared by the following proceſs. A quantity of the ſoda of commerce, which is a carbonat of ſoda, and which is often called *barilla* from the name of a plant, by burning which it is procured in great quantities in Spain, is pounded and mixed in a wooden veſſel, with about a fifth part of its weight of lime, ſlacked and paſſed through a ſieve immediately before. Upon this mixture a quantity of water is poured, conſiderably more than what is ſufficient to cover it, and allowed to remain on it for ſeveral hours. The lime attracts the carbonic acid from the ſoda, and the water becomes ſtrongly impregnated with the pure alkali. This water is then drawn off by means of a ſtop-cock, and called the *firſt ley*. Its ſpecific gravity ſhould be about 1,200.

Another quantity of water is then to be poured upon the ſoda, which, after ſtanding two or three hours, is alſo to be drawn off by means of the ſtop-cock, and called the *ſecond ley*.

Another portion of water is poured on; and after ſtanding a ſufficient time, is drawn off like the other two, and called the *third ley*.

Another portion of water may ſtill be poured on, in order to be certain that the whole of the ſoda is diſſolved; and this weak ley may be put aſide, and employed afterwards in forming the firſt ley in ſubſequent operations.

A quantity of oil, equal to ſix times the weight of the ſoda uſed, is then to be put into the boiler, together with a portion of the *third* or *weakeſt ley*, and the mixture muſt be kept boiling, and agitated conſtantly by means of a wooden inſtrument. The whole of the third ley is to be added at intervals to the mixture; and after it is conſumed, the *ſecond ley* muſt be added in the ſame manner. The oil becomes milky, combines with the alkali, and after ſome hours it begins to acquire conſiſtence. A little of the *firſt ley* is then to be added, not forgetting to agitate the mixture conſtantly. Portions of the firſt ley are to be added at intervals; the ſoapy ſubſtance acquires gradually greater conſiſtency, and at laſt it begins to ſeparate from the watery part of the mixture. A quantity of common ſalt is then to be added, which renders the ſeparation much more complete. The boiling is to be continued ſtill for two hours, and then the fire muſt be withdrawn, and the liquor muſt be no longer agitated. After ſome hours repoſe the ſoap ſeparates completely from the watery part, and ſwims upon the ſurface of the liquor. The watery part is then to be drawn off; and as it contains a quantity of carbonat of ſoda, it ought to be reſerved for future uſe.

The fire is then to be kindled again; and, in order to facilitate the melting of the ſoap, a little water, or rather weak ley, is to be added to it. As ſoon as it boils, the remainder of the firſt ley is to be added to it at intervals. When the ſoap has been brought to the proper conſiſtence, which is judged of by taking out ſmall portions of it and allowing it to cool, it is to be withdrawn from the fire, and the watery part ſeparated from it as before. It is then to be heated again, and a little water mixed with it, that it may form a proper paſte. It is then to be poured into the veſſels proper for cooling it; in the bottom of which there ought to be a little chalk in powder, to prevent the ſoap from attaching itſelf to it. In a few days the ſoap will have acquired ſufficient conſiſtence to be taken out, and formed into proper cakes (H).

The uſe of the common ſalt in the above proceſs is to ſeparate the water from the ſoap; for common ſalt has a ſtronger affinity for water than ſoap has.

Olive oil has been found to anſwer beſt for making ſoap, and next to it perhaps tallow may be placed: but a great variety of other oils may be employed for that purpoſe, as appears from the experiments of the French chemiſts above quoted. They found, however, that lintſeed oil and whale oil were not proper for making *hard ſoaps*, though they might be employed with advantage in the manufacture of *ſoft ſoaps*. Whale oil has been long uſed by the Dutch for this laſt purpoſe.

Soap may alſo be made without the aſſiſtance of heat; but in that caſe a much longer time and a larger proportion of alkali is neceſſary.

588 Its ſophiſtication.

Manufacturers have contrived various methods of ſophiſticating ſoap, or of adding ingredients which increaſe its weight without increaſing its value. The moſt common ſubſtance uſed for that purpoſe is water; which may be added in conſiderable quantities, eſpecially to ſoap made with tallow (the ingredient uſed in this country), without diminiſhing its conſiſtency. This fraud may be eaſily detected, by allowing the ſoap to lie for ſome time expoſed to the air. The water will evaporate from it, and its quantity will be diſcovered by the diminiſhing of the weight of the ſoap. As ſoap ſophiſticated in this manner would loſe its water by being kept, manufacturers, in order to prevent that, keep their ſoap in ſaturated ſolutions of common ſalt; which do not diſſolve the ſoap, and at the ſame time, by preventing all evaporation, preſerve, or rather increaſe, the weight of the ſoap. Meſſrs Darcet, Lelievre, and Pelletier, took two pieces equal in weight of ſoap ſophiſticated in this manner, and placed the one in a dry place in the open air, and the other in a ſaturated ſolution of common ſalt. After a month, the firſt had loſt $\frac{56}{100}$ of its weight, the other had gained about $\frac{10}{100}$ parts *. Various other methods have been fallen upon to ſophiſticate ſoap; but as they are not, we hope, generally known, it would be doing an injury to the public to deſcribe them here.

589 Proportion of its ingredients.

Different chemiſts have analyſed ſoap, in order to aſcertain the proportions of its ingredients; but the reſult of their experiments is various, becauſe they uſed ſoap containing various quantities of water. From the experiments of Darcet, Lelievre, and Pelletier, it appears that ſoap newly made and expoſed to ſale contains

9,75 Oil,
1,37 Alkali,
4,87 Water.

Soap is ſoluble both in water and in alcohol. Its properties as a detergent are too well known to require any deſcription.

It

* *Pliny*, lib. xviii. c. 51.

* *Ann. de Chim.* xix. 336.

(H) See the *Memoir of Darcet, Lelievre*, and *Pelletier*, in the *Ann. de Chim.* XIX. 253.

It is decompoſed by lime, and by compound affinity (1) by ſulphat of lime, nitrat of lime, muriat of lime, and probably all the ſalts which contain lime.

590 Soft ſoap. 2. Soap of potaſs.—Potaſs may be ſubſtituted for ſoda in making ſoap, and in that caſe preciſely the ſame proceſs is to be followed. It is remarkable, that when potaſs is uſed, the ſoap does not aſſume a ſolid form; its conſiſtence is never greater than that of hog's lard. This is what in this country is called *ſoft ſoap*. Its properties as a detergent do not differ materially from thoſe of *hard ſoap*, but it is not nearly ſo convenient for uſe. The alkali employed by the ancient Gauls and Germans in the formation of ſoap was potaſs: hence we ſee the reaſon that it is deſcribed by the Romans as an unguent.

Some perſons have affirmed that they knew a method of making hard ſoap with potaſs. Their method is this: After forming the ſoap in the manner above deſcribed, they add to it a large quantity of common ſalt, boil it for ſome time, and the ſoap becomes ſolid when cooled in the uſual way. That this method may be practiſed with ſucceſs has been aſcertained by Meſſrs Darcet, Lelievre, and Pelletier; but then the hard ſoap thus formed does not contain potaſs, but ſoda: for when the common ſalt (muriat of ſoda) is added, the potaſs of the ſoap decompoſes it, and combines with its muriatic acid, while at the ſame time the ſoda of the ſalt combines with the oil, and forms hard ſoap: and the muriat of potaſs formed by this double decompoſition is diſſolved in the water, and drawn off along with it*.

* *Ann. de Chim.* xix. 321.

Chaptal has lately propoſed to ſubſtitute wool in place of oil in the making of ſoap. The ley is formed in the uſual manner, and made boiling hot, and ſhreds of woollen cloth of any kind are gradually thrown into it; they are ſoon diſſolved. New portions are to be added ſparingly, and the mixture is to be conſtantly agitated. When no more cloth can be diſſolved, the ſoap is made†. This ſoap is ſaid to have been tried with ſucceſs. It might doubtleſs be ſubſtituted for ſoap with advantage in ſeveral manufactures, provided it can be obtained at a cheaper rate than the ſoaps at preſent employed.

† *Ibid.* xxi. 27.

Fiſh, too, have been lately ſubſtituted for oil with equal ſucceſs. The only diſadvantage which ſoap made in this manner is liable to, is a diſagreeable ſmell, from which it cannot eaſily be freed.

591 Soap of ammonia. 3. Soap of ammonia.—This ſoap was firſt particularly attended to by Mr Berthollet. It may be formed by pouring carbonat of ammonia on ſoap of lime. A double decompoſition takes place, and the ſoap of ammonia ſwims upon the ſurface of the liquor in the form of an oil; or it may be formed with ſtill greater eaſe by pouring a ſolution of muriat of ammonia into common ſoap diſſolved in water. We have formed it often by mixing cauſtic ammonia and oil‡.

‡ *Berthollet, Mem. Par.* 1780, or *Nicholſon's Journal*, i. 170

It has a more pungent taſte than common ſoap. Water diſſolves a very ſmall quantity of it; but it is eaſily diſſolved in alcohol. When expoſed to the air, it is gradually decompoſed.

592 Soap of lime. 4. Soap of lime.—This ſoap may be formed by pouring lime-water into a ſolution of common ſoap. It is inſoluble both in water and alcohol. Carbonat of fixed alkali decompoſes it by compound affinity*. It melts with difficulty, and requires a ſtrong heat.

* *Thouvenel.*

593 Soap of magneſia, 5. Soap of magneſia.—This ſoap may be formed by mixing together ſolutions of common ſoap and ſulphat of magneſia.

It is exceedingly white. It is unctuous, dries with difficulty, and preſerves its whiteneſs after deſiccation. It is inſoluble in boiling water. Alcohol and fixed oil diſſolve it in conſiderable quantity. Water renders its ſolution in alcohol milky. A moderate heat melts it; a tranſparent maſs is formed, ſlightly yellow, and very brittle†.

† *Berthollet, ibid.*

594 Of alumina, 6. Soap of alumina.—This ſoap may be formed by mixing together ſolutions of alum and of common ſoap. It is a flexible ſoft ſubſtance, which retains its ſuppleneſs and tenacity when dry. It is inſoluble in alcohol, water, and oil. Heat eaſily melts it, and reduces it to a beautiful tranſparent yellowiſh maſs‡.

‡ *Ibid.*

595 Of barytes, 7. Soap of barytes reſembles almoſt exactly the ſoap of lime§.

§ *Ibid.*

596 Of mercury, 8. Soap of mercury.—This ſoap may be formed by mixing together a ſolution of common ſoap and of corroſive muriat of mercury. The liquor becomes milky, and the ſoap of mercury is gradually precipitated. This ſoap is viſcid, not eaſily dried, loſes its white colour when expoſed to the air, and acquires a ſlate colour, which gradually becomes deeper, eſpecially if expoſed to the ſun or to heat. It diſſolves very well in oil, but ſparingly in alcohol. It readily becomes ſoft and fluid when heated‖.

‖ *Ibid.*

597 Of zinc, 9. Soap of zinc.—This ſoap may be formed by mixing together a ſolution of ſulphat of zinc and of ſoap. It is of a white colour, inclining to yellow. It dries ſpeedily, and becomes friable¶.

¶ *Ibid.*

598 Of cobalt, 10. Soap of cobalt.—This ſoap, made by mixing nitrat of cobalt and common ſoap, is of a dull leaden colour, and dries with difficulty, though its parts are not connected.

599 Of nickel, Mr Berthollet obſerved, that towards the end of the precipitation there fell down ſome green coagula, much more conſiſtent than ſoap of cobalt. Theſe he ſuppoſed to be a ſoap of nickel, which is generally mixed with cobalt*.

* *Ibid.*

600 Of tin, 11. Soap of tin.—It may be formed by mixing common ſoap with a ſolution of tin in nitro-muriatic acid. It is white. Heat does not fuſe it like other metallic ſoaps, but decompoſes it†.

† *Ibid.*

601 Of iron, 12. Soap of iron.—Formed by means of ſulphat of iron. It is of a reddiſh brown colour, tenacious, and eaſily fuſible. When ſpread upon wood, it ſinks in and dries. It is eaſily ſoluble in oil, eſpecially of turpentine. Berthollet propoſes it as a varniſh‡.

‡ *Ibid.*

602 Of copper, 13. Soap of copper.—Formed by means of ſulphat of copper. It is of a green colour, has the feel of a reſin, and becomes dry and brittle. Hot alcohol renders its colour deeper, but ſcarcely diſſolves it. Ether diſſolves it, liquefies it, and renders its colour deeper and more beautiful. It is very ſoluble in oils, and gives them a pleaſant green colour§.

§ *Ibid.*

603 Of lead, 14. Soap of lead.—It may be formed by means of acetite

---

(1) In this and the following chapter, *compound affinity* is not taken always in its ſtrict and proper ſenſe, but is applied to all thoſe decompoſitions in which the affinities of more than three bodies *act*.

acetite of lead. It is white, tenacious, and very adheſive when heated. When fuſed, it is tranſparent, and becomes ſomewhat yellow if the heat be increaſed*.

604 Of ſilver, 15 Soap of ſilver.—It may be formed by means of nitrat of ſilver. It is at firſt white, but becomes reddiſh by expoſure to the air. When fuſed, its ſurface becomes covered with a very brilliant iris; beneath the ſurface it is black †.

605 Of gold, 16. Soap of gold.—It is at firſt white, and of the conſiſtence of cream. It gradually aſſumes a dirty purple colour, and adheres to the ſkin ſo that it is difficult to efface the impreſſion ‡.

606 And of mangaueſe. 17. Soap of mangaueſe.—It is at firſt white, but it aſſumes in the air a reddiſh colour, owing evidently to the abſorption of oxygen. It ſpeedily dries to a hard brittle ſubſtance, and by liquefaction aſſumes a brown blackiſh colour §.

We owe the following reſinous ſoaps to Mr Mezaize.

607 Soap of turpentine and potaſs. 18. Soap of turpentine and potaſs.—576 grains of turpentine were diſſolved in 9216 grains of alcohol, and then 576 grains of potaſs were added. The alcohol was diſtilled off at a boiling water heat. There remained in the retort 648 grains of a browniſh ſoapy matter, which when ſpread on glaſs appeared tranſparent. There remained alſo nearly the ſame quantity of potaſs diſſolved in water. This ſoap was put in a veſſel for ſix weeks; during which time 72 grains of ſolution of potaſs ſeparated from it. It had aſſumed the conſiſtence of honey. Its colour was browner. It was completely ſoluble in water: the ſolution was milky. It diſſolved alſo in alcohol. It had no diſagreeable taſte. Vinegar decompoſed it.

608 Soap of benzoin, 19. Soap of benzoin and potaſs.—By treating 9216 grains of alcohol, 1728 grains of benzoin, and 576 grains of potaſs, as above, 1728 grains of a ſoap were obtained, browner than that of turpentine, of an odour a little aromatic. When left in a cellar for ſix weeks, it became ſolid. Its ſolution in water was yellowiſh. Vinegar decompoſed it. This compound is the ſame with Starkey's ſoap.

609 Of balm of Peru, 20. Soap of balm of Peru and potaſs—1152 grains of balm, 2304 grains of potaſs, and 9216 grains of alcohol, produced a ſoap of a reddiſh colour, and pretty conſiſtent.

610 Of guaiac, 21. Soap of guaiac and potaſs.—1728 grains of guaiac was diſſolved in 18648 grains of alcohol, and the ſolution filtered, and to this 1728 grains of potaſs were added, and the ſoap obtained as above. It was ſolid, of a brown colour at firſt, which afterwards became green on the ſurface, but remained unaltered within. Its ſolution in water was greeniſh. It had no diſagreeable taſte. It diſſolved in alcohol, and formed a green tincture. Vinegar decompoſed it.

611 And of ſcammony. 22. Soap of ſcammony and potaſs.—By the above proceſs a ſoap was obtained with ſcammony pretty conſiſtent, of a brown colour, ſoluble in water, and not decompoſed by the water of pits from which ſelenites is obtained. It has no diſagreeable taſte. Its ſolution in alcohol is of a deep amber colour ‖.

Sect. II. *Of Acid Soaps.*

612 Method of forming acid ſoaps. Sulphuric acid may be combined with oils in the following manner: Put two ounces of it into a glaſs mortar, and add, by little and little, three ounces of the oil nearly boiling hot, triturating it conſtantly. A ſubſtance is obtained of the conſiſtence of turpentine. Diſſolve it in about ſix ounces of boiling water, and the ſoap will unite into a maſs as the water cools If it ſtill contain an exceſs of acid, diſſolve it again in boiling water, and continue this proceſs till the ſoap is perfectly neutralized.

613 Acid ſoap of lintſeed oil, 1. Soap of ſulphuric acid and lintſeed oil.—It diſſolves entirely in water. The ſolution is opaque, of a bluiſh white colour, viſcid, and frothes when agitated. Alcohol diſſolves it. The ſolution is tranſparent and brown. Potaſs decompoſes it, forming ſulphat of potaſs. The oil ſwims on the top, of the conſiſtence of wax. Ammonia decompoſes it; and if too much be added it forms ſoap of ammonia. Magneſia, lime, nitric acid, and muriatic acid, alſo decompoſe it. Diſtilled, it yielded a few drops of water and an oil, which coagulated, and was of the conſiſtence of wax.

614 Of almond oil. 2. Soap of ſulphuric acid and oil of almonds.—Soluble in water; ſolution milky. Frothes. Soluble in alcohol; ſolution brown and tranſparent. Potaſs, lime, nitric acid, muriatic acid, ſulphurous acid (the oil ſeparated aſſumed the conſiſtence of turpentine), tartar, acidulous oxalat of potaſs, ſal ammoniac, muriat of lead and zinc decompoſe it. It is not decompoſed by vinegar, boracic acid, acetite of ammonia, borax, copper, tin, nor lead. When diſtilled, there paſſed over a little water and an oil, which coagulated and ſmelt very rancid: there remained behind a coal.

615 Of olive oil, 3. Soap of ſulphuric acid and olive oil.—It is brown, and of the conſiſtence of wax. Solution in hot water white, opaque, viſcid; frothes. Solution in alcohol tranſparent and brown. Potaſs, ammonia, magneſia, nitric acid, muriatic acid, vinegar, nitre, ſal ammoniac, acetite of lead and white oxide of lead, decompoſe it.

616 Of butter of cocao, 4. Soap of ſulphuric acid and butter of cocao.—It is hard, and marbled like Venice ſoap. Solution in water grey, opaque, viſcid; frothes. Solution in alcohol yellow and tranſparent. Potaſs, ammonia, nitric, muriatic, and acetous acids, tartar, ſal ammoniac, tartrite of potaſs, acetite of lead, and zinc in powder, decompoſe it. When diſtilled, there came over water, an oil that coagulated, and a few drops of a black oil, which alſo congealed: both were rancid.

617 Of wax, 5. Soap of ſulphuric acid and wax.—It is white, and becomes very hard. Its ſolution in water is white, and opaque, and frothes: Its ſolution in alcohol is yellow and tranſparent. Potaſs, ammonia, nitric and muriatic acids, decompoſe it.

618 Of ſpermaceti, 6. Soap of ſulphuric acid and ſpermaceti.—It is brown. It diſſolves in water: the ſolution is milky, viſcid, and frothes on agitation. It diſſolves in alcohol; the ſolution is tranſparent and yellow. It is decompoſed by as much alkali as ſaturates the acid: if more be added, it unites with the oil, and forms a new ſoap. Lime and magneſia decompoſe it. The oil is alſo ſeparated, and appears in the form of a coagulum on adding to the ſolution nitric acid, muriatic acid, tartar, nitre, nitrat of ſoda, common ſalt, and zinc in powder; but not on adding vinegar, tin, lead.

619 Of oil of eggs, 7. Soap of ſulphuric acid and oil of eggs.—Its ſolution in water is white, opaque, viſcid; frothes: that in alcohol yellow and tranſparent. Alkalies decompoſe it; but if too much be added a new ſoap is formed. Nitric and muriatic acids ſeparate the oil of the conſiſtence of wax,

---

* *Berthollet, ibid.*

† *Ibid.*

‡ *Ibid.*

§ *Ibid.*

‖ *Jour. de Phyſ.* xv. 441.

wax, the firſt yellow, the laſt a deep brown. Nitre, ſal ammoniac, acetite of lead, iron filings, zinc powder, decompoſe it; vinegar, borax, filings of lead do not.

To unite this acid with the eſſential oils, three ounces were put into a glaſs mortar, and four ounces of the oil were added drop by drop, and care taken to prevent its becoming hot: equal parts of water were then poured on, and the whole heated ſlowly nearly to the temperature of boiling water: on cooling, the ſoap united into a brown maſs.

620 Of turpentine, 8. Soap of ſulphuric acid and turpentine. It is brown, and of the conſiſtence of ſoft wax. Its ſolution in water is grey, opaque, viſcid; frothes: Its ſolution in alcohol is brown and tranſparent. Alkalies decompoſe it: with too much it forms at the boiling heat a new ſoap.

Nitric and muriatic acids ſeparated the oil thickened, as did alſo white oxide of lead, muriat of lead, muriat of ſoda and iron filings; but acetous acid, boracic acid, tartrite of potaſs, and tin filings, produced no ſuch effect.

621 And of amber oil. 9. Soap of ſulphuric acid and amber oil.—Its ſolution in water and alcohol as in the laſt ſoap. Alkalies, magneſia, and lime, decompoſed it. Nitric and muriatic acids ſeparated the oil of the conſiſtence of wax. Tartar, ſal ammoniac, muriat of antimony, acetite of lead, iron filings, decompoſed it; vinegar, acetite of ammonia, and lead did not.

Mr Achard, to whom we owe theſe ſoaps *, could not ſucceed in his attempts to form ſoaps with nitric and muriatic acids.

* *Journ. de Phyſ.* xvi. 109.

CHAP. II. *Of* NEUTRAL SALTS.

622 Salt explained. THE word *ſalt* has been uſed in chemiſtry in a very extenſive, and not very definite ſenſe. Every body which is ſapid, eaſily melted, ſoluble in water, and not combuſtible, has been called a *ſalt*.

Salts were conſidered by the older chemiſts as a claſs of bodies intermediate between earths and water. Many diſputes aroſe about what bodies ought to be comprehended under this claſs, and what ought to be excluded from it. Acids and alkalies were allowed by all to be ſalts; but the difficulty was to determine concerning earths and metals. Several of the earths poſſeſs all the properties which have been aſcribed to ſalts; and the metals are capable of entering into combinations which poſſeſs ſaline properties. It is needleſs for us to enter into this diſpute at preſent, as we have taken the liberty, in imitation of ſome of the beſt modern chemiſts, to expunge the claſs of ſalts altogether, and to arrange thoſe ſubordinate claſſes, which are uſually referred to it, under diſtinct heads.

623 Neutral ſalt explained. The word *neutral ſalt* was originally applied excluſively to combinations of acids and alkalies, which were conſidered as ſubſtances poſſeſſing neither the properties of acids nor alkalies, but properties intermediate between the two. But the word is now always taken in a more extenſive ſenſe, and ſignifies all compounds formed by the combination of acids with alkalies, earths, or metallic oxides. In theſe compounds, the earth, alkali, or oxide, is denominated the *baſe*. Each order of ſalts is denominated after the acid which enters into its compoſition; and every individual ſalt is diſtinguiſhed by ſubjoining the name of its baſe. Thus all the ſalts into which ſulphuric acid enters are called *ſulphats*, and the ſalt formed by the combination of ſulphuric acid and potaſs is called *ſulphat of potaſs*.

It is evident, then, that there muſt be as many orders of neutral ſalts as there are acids; and as many ſalts in each order as there are alkalies, earths, and metallic oxides, ſuppoſing every acid capable of combining with every one of theſe ſubſtances. But beſides theſe ſimple combinations of one acid and one baſe, there are others more complex, compoſed of two acids combined with one baſe, or two baſes combined with one acid, or a neutral ſalt combined with an acid or a baſe. Theſe combinations have been called *triple ſalts*; and they increaſe the number of neutral ſalts very conſiderably.

In the following ſections we ſhall take a ſhort view of the properties of the principal neutral ſalts at preſent known; for this wide and important region of chemiſtry is ſtill very far from being completely explored.

SECT. I. *Of Sulphats.*

SULPHURIC acid is capable of combining with all the alkalies, with alkaline earths, alumina, jargonia, and the greater number of the metallic oxides. The principal neutral ſalts which it forms are as follows:

624 Sulphat of potaſs. 1. Sulphat of potaſs.—This ſalt may be formed by ſaturating diluted potaſs with ſulphuric acid, and then evaporating the ſolution gently till cryſtals are formed. It ſeems to have been known at a very early period by chemiſts, and a great variety of names were given to it, according to the manner of forming it, or the fancy of the operator. Some of theſe names were, *ſpecificum purgans*, *nitrum fixum*, *arcanum duplicatum*, *panacea holſatica*, *ſal de duobus*, *ſal polychreſt glaſeri*, &c.; but it was commonly known by the name of *vitriolated tartar* till the French chemiſts called it *ſulphat of potaſs*, when they formed their new nomenclature in 1787 (K).

615 Its properties. When the ſolution of ſulphat of potaſs is ſufficiently diluted, it affords by evaporation hexahedral pyramids, or ſhort hexangular priſms, terminated by one or more hexangular pyramids. But theſe cryſtals vary much in their figure, according to the care with which they are prepared.

It has a very diſagreeable bitter taſte. Its ſpecific gravity is 2,298 *.

* *Briſſon.*

It is ſoluble in the temperature of 60° in 16 times its weight of water; in a boiling heat, it is ſoluble in 5 times its weight †.

† *Bergman.*

According to Bergman, it is compoſed of 40 parts of acid, 52 parts of alkali, and 8 of water; but according to Kirwan, whoſe experiment has been already deſcribed, it is compoſed of 45 parts of acid and 55 of alkali.

It ſuffers no alteration in the air.

When placed upon burning coals, it breaks into pieces with a noiſe reſembling a number of ſmall exploſions ſucceeding each other at ſhort intervals (L), but ſuffers no other alteration. In a red heat it melts.

It has hitherto been applied to little uſe. It is a

purgative,

(K) Bergman called it *alkali vegetabile vitriolatam*, and Morveau *vitriol of potaſs*.

(L) This is called *decrepitation*.

purgative, but its diſagreeable taſte prevents it from being much employed for that purpoſe.

It often has an exceſs of acid, owing, as Mr Bergman and Morveau have very ingeniouſly explained, to an affinity which exiſts between this ſalt and ſulphuric acid.

It is decompoſed by compound affinity by the following ſalts :

Nitrat of ſoda (M),
———— lime,
———— barytes*,
———— ſtrontites †,
———— ammonia,
———— magneſia,
———— mercury,

Nitrat of ſilver,
———— lead,
Acetite of barytes,
Muriat of lime ‡,
———— lead §,
———— magneſia?
———— ſoda ||.

It is ſometimes luminous in the dark, as Mr Giobert has obſerved ¶.

626 Sulphat of ſoda.

2. Sulphat of ſoda.—This ſalt was firſt diſcovered by Glauber a German chemiſt, and for that reaſon was long known by the name of *Glauber's ſalt*. He himſelf called it *ſal mirabile*. It may be prepared by ſaturating ſoda with ſulphuric acid, but is more uſually obtained by decompoſing common ſalt in order to procure muriatic acid.

Its cryſtals are tranſparent, and when formed by ſlow evaporation, are ſix-ſided priſms terminated by dihedral ſummits.

Its taſte at firſt has ſome reſemblance to that of common ſalt, but ſoon becomes very diſagreeably bitter.

It is ſoluble in 2,67 times its weight of water at the temperature of 60°, and in 0,8 of boiling water.

It is compoſed, according to Bergman, of 27 parts of acid, 15 of alkali, and 58 of water ; but, according to the experiments of Kirwan, of 22 parts of acid, 17 of alkali, and 61 of water.

When expoſed to the air, it loſes great part of its water, and falls into a white powder (N).

When expoſed to heat, it firſt undergoes the *watery fuſion* (O), then its water is evaporated, it is reduced to a white powder, and at laſt in a red heat it melts. Mr Kirwan has obſerved, that part of the acid, as well as the water, is driven off by the application of a ſtrong heat *.

This ſalt is uſed as a purgative.

It often combines with an exceſs of acid.

It is decompoſed by compound affinity, by the following ſubſtances :

Nitrat of lime,
———— magneſia,
Muriat of potaſs,
———— ſoda,
———— magneſia,
———— lime †,

Acetite of barytes,
———— potaſs,
———— lime,
Carbonat of barytes,
———— potaſs.

617 Sulphat of ammonia.

3. Sulphat of ammonia.—This ſalt was diſcovered by Glauber, and called by him *ſecret ſal ammoniac*. It was alſo called *vitriolated ammoniac*. It may be prepared by ſaturating ammonia with ſulphuric acid.

Its cryſtals are generally ſmall ſix-ſided priſms, whoſe planes are unequal, terminated by ſix-ſided pyramids.

It has a ſharp bitter taſte.

It is ſoluble in twice its own weight of water at the temperature of 60°, and in its own weight of boiling water.

According to Mr Kirwan, it is compoſed of 29,7 of alkali, 55,7 of ſulphuric acid, and 14,16 of water *.

When expoſed to the air, it ſlowly attracts moiſture.

When heated, it firſt decrepitates, then melts, and in cloſe veſſels ſublimes, but with ſome loſs of its alkali †.

It has not hitherto been applied to any uſe.

It is apt to contain an exceſs of acid.

It is decompoſed by compound affinity by the following ſalts :

Nitrat of lime,
———— magneſia,
———— mercury?
Muriat of potaſs,
———— ſoda,
———— barytes,
———— lime,
———— magneſia,
———— mercury*,
Acetite of potaſs,

Acetite of ſoda,
———— barytes,
———— lime,
———— magneſia,
Carbonat of potaſs,
———— ſoda,
———— barytes,
———— lime,
———— magneſia,
Phoſphat of lime †.

628 Sulphat of barytes.

4. Sulphat of barytes.—This ſubſtance was firſt diſcovered by Scheele. It abounds in nature. It is generally in the form of a hard, very heavy, ſtone.

It is ſometimes found cryſtallized ; but the variety of forms is ſo great that they baffle all deſcription.

It is ſoluble in 43,000 times its weight of water at the temperature of the atmoſphere ||.

Sulphuric acid diſſolves it when concentrated and boiling, but it is precipitated by the addition of water.

When expoſed to heat it melts, and, if the heat be very ſtrong, gradually diſſipates.

629 Bologna ſtone.

After being heated red hot, it has the property of being luminous in the dark. This was firſt obſerved in a variety of this ſubſtance known by the name of Bologna ſtone. Lemery informs us, that this property was firſt diſcovered by an Italian ſhoemaker named Vincenzo Caſciarolo. This man found a Bologna ſtone at the foot of Mount Paterno, and its brightneſs and gravity made him ſuppoſe that it contained ſilver. Having expoſed it to the fire, doubtleſs in order to extract from it the precious metal, he obſerved that it was luminous in the dark. Struck with the diſcovery, he repeated the experiment, and it conſtantly ſucceeded with him.

From an experiment of Mr Klaproth, it appears to be compoſed of 33 parts of acid and 77 of barytes.

It is decompoſed by compound affinity by the following ſalts :

Nitrat of ſoda,
———— lime,
———— ammonia,

Nitrat of magneſia,
Carbonat of potaſs,
———— ſoda *.

630 Sulphat of lime.

5. Sulphat of lime.—This ſubſtance was well known to the ancients under the name *gypſum* ; but the compoſition of gypſum was not known till Margraf and Macquer analyſed it, and proved that it was compoſed of ſulphuric acid and lime. The artificial compound

(M) Moſt of theſe double decompoſitions in this and the following ſections are inſerted on the authority of Morveau. See his Table of *Affinity*, page 360 of this article.

(N) This is called *efflореſcing*.

(O) When ſubſtances melt by means of the water they contain on the application of heat, they are ſaid to undergo the watery fuſion.

pound formed by the union of theſe two bodies was formerly called *ſelenite*.

It is found cryſtallized in various forms, ſometimes tranſparent and ſometimes opaque; and when pure it is of a white colour.

It has a ſlightly nauſeous taſte, ſcarcely perceptible except by drinking a glaſs of water impregnated with it *.

It is ſoluble in 500 parts of water at the temperature o. 60°, but much more ſoluble in boiling water.

It is compoſed, according to Bergman, of 46 parts of acid, 32 of earth, and 22 of water: according to the late experiments of Mr Kirwan, when ſo far dried as ſtill to retain its glaſſy appearance, it contains 48 of acid, 34 of earth, and 18 of water; which differs very little from the determination of Bergman.

It is not affected by expoſure to the air.

It is ſoluble in ſulphuric acid.

When expoſed to heat, it undergoes a kind of watery fuſion, but afterwards it cannot be melted by the ſtrongeſt heat. In a clay crucible indeed it fuſes at 130° Wedgewood, owing evidently to the preſence of the clay.

631
Plaſter of Paris.

When heated red hot and cooled, it is called *plaſter of Paris*; a ſubſtance ſo uſeful for caſting moulds, &c. on account of its property of becoming ſolid almoſt immediately when reduced into a paſte with water.

By compound affinity it is decompoſed by the following ſubſtances:

Acetite of barytes,
——— potaſs,
Carbonat of barytes,

Carbonat of potaſs,
——— ſoda,
——— magneſia?
——— alumina †.

632
Sulphat of ſtrontites.

6. Sulphat of ſtrontites. This ſalt, firſt formed by Dr Hope, is a white powder deſtitute of taſte. It is ſoluble in 3840 parts of boiling water. Sulphuric acid diſſolves it readily when aſſiſted by heat, but it is precipitated by the addition of water to the ſolution ‡.

633
Sulphat of magneſia.

7. Sulphat of magneſia. This ſalt was firſt obſerved in the ſprings at Epſom in England by Grew in 1675; but Dr Black was the firſt who accurately aſcertained its compoſition. It has been called *Epſom ſalt*, *ſal catharticus amarus*, and *Seydler ſalt*.

It cryſtallizes in quadrangular priſms, whoſe plains are equal, ſurmounted by quadrangular pyramids.

It has an exceſſively bitter taſte.

At the temperature of 60° it is ſoluble in its own weight of water, and in $\frac{3}{4}$ths of its weight of boiling water. The volume of water is increaſed $\frac{1}{4}$th by adding the ſalt §.

It is inſoluble in alcohol.

It is compoſed, according to Bergman, of 19 parts of earth, 33 of acid, and 48 of water; according to Mr Kirwan, of 17 parts of earth, 29,46 of acid, and 53,54 of water.

When expoſed to the air it effloreſces, and is reduced to powder.

When expoſed to heat it undergoes the watery fuſion, and by increaſing the temperature its water is evaporated, but it cannot be decompoſed by means of heat.

It is ſometimes employed as a cathartic, but its chief uſe is to furniſh magneſia by its decompoſition.

It is decompoſed by compound affinity by the following ſalts.

Muriat of potaſs,
——— ſoda (P),
——— lime,
Acetite of barytes,
——— potaſs,

Acetite of lime,
Carbonat of barytes,
——— potaſs,
——— ſoda *,
——— ammonia (Q).

634
Sulphat of ammonia and magneſia.

8. Sulphat of ammonia and magneſia. This triple ſalt was diſcovered by Mr Fourcroy. Into the ſolution of 100 parts of ſulphat of magneſia in 500 parts of water, 12 parts of ammonia being poured, a very ſmall quantity of magneſia was precipitated, and a conſiderable quantity more on the addition of another doſe of ammonia; but farther additions had no effect. From the magneſia precipitated, it appeared that 38 parts of the ſulphat had been decompoſed. There remained, therefore, 62 parts in ſolution, mixed with a large quantity of ammonia. By evaporation, 92 parts of a white tranſparent rhomboidal ſalt were obtained, evidently compoſed of ſulphuric acid, ammonia, and magneſia, in the proportions that would have formed 62 parts of ſulphat of magneſia and 30 of ſulphat of ammonia, and probably conſiſting of a combination of theſe two ſulphats †.

635
Sulphat of alumina.

9. Sulphat of alumina. This ſalt may be formed by diſſolving alumina in ſulphuric acid. It has an aſtringent taſte, is very ſoluble in water, and cryſtallizes in thin plates which have very little conſiſtence ‡. Little attention has hitherto been paid to this ſalt, which was never properly diſtinguiſhed from *alum* till two memoirs, one by Vauquelin and another by Chaptal, on the nature of alum, made their appearance in the 22d volume of the *Annales de Chimie*. This ſalt generally contains an exceſs of acid, and is not neutralized without conſiderable difficulty §.

636
Alum.

10. Sulphat of alumina and potaſs, or alum. The στυπτηρια of the Greeks, and the *alumen* of the Romans, was a native ſubſtance, which appears to have been nearly related to *green vitriol* or *ſulphat of iron*; and which conſequently was very different from what we at preſent denominate *alum*. From the reſearches of Profeſſor Beckmann, it appears that we owe the diſcovery of alum to the Aſiatics; but at what period, or by what means, the diſcovery was made, is altogether unknown.

It continued to be imported from the Eaſt till the 15th century, when a number of alum works were eſtabliſhed in Italy. In the 16th century it was manufactured in Germany and Spain; and during Queen Elizabeth's reign an alum work was eſtabliſhed in England by Thomas Chalomer.

The alum of commerce is uſually obtained from earths containing ſulphur and clay, or ſulphuric acid and clay.

637
Its compoſition,

The compoſition of alum has been but lately under-

ſtood with accuracy. It has been long known, indeed, that one of its ingredients is ſulphuric acid (R); and the experiments of Geoffroy, Hellot, Pot, Margraf, and Macquer, proved inconteſtibly that alumina is another ingredient. But ſulphuric acid and alumina are incapable of forming alum: Manufacturers knew, that the addition of a quantity of potaſs, or of ammonia, or of ſome ſubſtance containing theſe alkalies, is almoſt always neceſſary; and it was proved, that in every caſe in which ſuch additions are unneceſſary, the earth from which the alum is obtained contained already a quantity of potaſs. Various conjectures were made about the part which potaſs acts in this caſe; but Chaptal and Vauquelin appear to have been the firſt chemiſts that aſcertained, by deciſive experiments, that alum was a triple ſalt, compoſed of ſulphat of alumina and of potaſs united together (S)

638 And properties.

Alum cryſtallizes in large octahedrons, compoſed of two tetrahedral pyramids, applied to each other at their baſes.

It has a ſweetiſh and aſtringent taſte, and always reddens the tincture of turnſole.

It is ſoluble at the temperature of 60°, in from 10[*] to 15[†] times its own weight of water, according to its purity; pure alum being moſt inſoluble. Seventy-five parts of boiling-water diſſolve 100 of alum[‡].

[*] Neumann and Chaptal.
[†] Kirwan and Chaptal.
[‡] Bergman.

A hundred parts of alum contain, according to Kirwan, 17,62 parts of acid, 18 of earth (and alkali), and 64,38 of water[§].

[§] Kirwan's Min. ii. 14.

When expoſed to the air it effloreſces ſlightly.

When expoſed to a gentle heat it undergoes the watery fuſion. A ſtrong heat cauſes it to ſwell and foam, and to loſe about 44 *per cent.* of its weight, conſiſting chiefly of water of cryſtallization[||]. What remains is called *calcined* or *burnt alum*, and is ſometimes uſed as a corroſive.

[||] Ibid.

Alum is of great importance as a mordant in dyeing, and is uſed alſo in ſeveral other arts.

By compound affinity it is decompoſed by the following ſalts.

Nitrat of ſoda,
——— lime,
——— ammonia,
——— magneſia,
Muriat of barytes,
——— potaſs,
——— ſoda,
——— lime,
——— ammonia,
——— magneſia,
Acetite of barytes,

Acetite of potaſs,
——— ſoda,
——— lime,
——— ammonia,
——— magneſia,
Carbonat of barytes,
——— potaſs,
——— ſoda,
——— lime,
——— ammonia,
——— magneſia.

639 Homberg's pyrophorus.

If three parts of alum and one of flour or ſugar be melted together in an iron ladle, and the mixture dried till it becomes blackiſh and ceaſes to ſwell; if it be then pounded ſmall, put into a glaſs phial, and placed in a ſand-bath till a blue flame iſſues from the mouth of the phial, and after burning for a minute or two be allowed to cool (T), a ſubſtance is obtained known by the name of *Homberg's pyrophorus*, which has the property of catching fire whenever it is expoſed to the open air, eſpecially if the air be moiſt.

This ſubſtance was accidentally diſcovered by Homberg about the beginning of the 18th century, while he was engaged in his experiments on the human fæces. He had diſtilled a mixture of human fæces and alum till he could obtain nothing more from it by means of heat; and four or five days after, while he was taking the reſiduum out of the retort, he was ſurpriſed to ſee it take fire ſpontaneouſly. Soon after Lemery the Younger diſcovered that honey, ſugar, flour, or almoſt any animal or vegetable matter, could be ſubſtituted for human fæces; and afterwards Mr Lejoy de Suvigny ſhewed that ſeveral other ſalts containing ſulphuric acid might be ſubſtituted for alum[*]. Scheele proved, that alum deprived of potaſs was incapable of forming pyrophorus, and that ſulphat of potaſs might be ſubſtituted for alum[†]. And Mr Prouſt has ſhewn, that a number of neutral ſalts, compoſed of vegetable acids and alkalies, or earths, when diſtilled by a ſtrong fire in a retort, left a reſiduum which took fire ſpontaneouſly on expoſure to the air.

[*] See Macquer's Dict.
[†] Scheele on Fire, and on Pyrophorus.

Theſe facts have thrown a great deal of light on the nature of Homberg's pyrophorus, and enabled us in ſome meaſure to account for its ſpontaneous inflammation. It has been aſcertained, that part of the ſulphuric acid is decompoſed during the formation of the pyrophorus, and of courſe a part of the alkaline baſe becomes uncombined with acid, and the carbon, which gives it its black colour, is evidently divided into very minute particles. It has been aſcertained, that during the combuſtion of the pyrophorus a quantity of oxygen is abſorbed, The inflammation ſeems to be owing to a *diſpoſing affinity*. Part of the carbon and of the ſulphur attract oxygen from the atmoſphere, in order to combine with the potaſs, and the caloric diſengaged produces a temperature ſufficiently high to kindle the reſt of the carbon.

Alum is capable of combining with alumina, and of forming what has been called *alum ſaturated with its earth*, which is an inſoluble, taſteleſs, earthy-like ſubſtance.

It is capable alſo, as Chaptal informs us, of combining with ſeveral other baſes, and of forming many triple ſalts, which have never yet been examined with attention[‡].

[‡] Ann. de Chim. xxii. 293.

11. Sulphat

(R) Some chemiſts have thought proper to call the ſulphuric acid, obtained by diſtilling alum, *ſpirit of alum*.

(S) This they did in the two memoirs above quoted, and which were firſt publiſhed in the 22d volume of the *Annales de Chimie*. An account of Vauquelin's memoir has been already given under the article ALUM in this *Supplement*. Chaptal's memoir is no leſs intereſting. This celebrated chemiſt appears, from the facts ſtated in the 23d volume of the *Annales*, p. 222. to have made his diſcovery before Vauquelin: who, however, was ignorant of what Chaptal had done, as he informs us in the *Ann. de Chim.* xxv. 107. that his paper was read to the Inſtitute a fortnight before that of Chaptal's came to Paris. He informs us, too, that Deſcroiſilles had long before made the ſame diſcovery, and that he had publiſhed it in Berthollet's *Art de la Teinture*.

(T) Care muſt be taken not to keep it too long expoſed to the heat.

640 Sulphat of jargonia.

11. Sulphat of jargonia (u). In order to combine jargonia with acids, they ſhould be poured upon it while it is yet moiſt, after being precipitated from ſome of its ſolvents; for after it is dry, acids do not act upon it without difficulty. By this method ſulphat of jargonia is eaſily formed. It is white, and without ſenſible taſte. Heat expels the acid from it, and the jargonia remains in a ſtate of purity. At a high temperature charcoal converts it into a ſulphuret, which is ſoluble in water, and which, by evaporation, furniſhes cryſtals of hydroſulphuret (t) of jargonia *.

Klaproth informs us, that with exceſs of acid ſulphat of jargonia forms tranſparent ſtelliform cryſtals, ſoluble in water, and having an aſtringent taſte †.

12. Sulphat of iron. There are two ſulphats of iron, which were firſt accurately diſtinguiſhed by Mr Prouſt. The one contains the green oxide, the other the red oxide of iron. We ſhall, in imitation of Mr Prouſt, denominate them from their colours.

641 Green ſulphat of iron.

The *green ſulphat of iron.*—This ſalt, which is compoſed of ſulphuric acid and green oxide of iron, is found native, and was known to the ancients. It is mentioned by Pliny under the names of *miſy*, *ſory*, *calchantum* ‡. It was formerly called *green vitriol.*

It is generally prepared by expoſing native ſulphuret of iron, a very abundant mineral, to air and moiſture.

Its cryſtals are of a light green colour, and in the form of rhomboidal parallelopipeds.

It has a ſharp aſtringent taſte.

It is ſoluble in ſix times its weight of water at the temperature of 60°, and in $\frac{3}{4}$ths of its weight of boiling water §.

It is inſoluble in alcohol.

According to Bergman, it is compoſed of 39 parts of acid, 23 of oxide, and 38 of water; but according to Mr Kirwan, of 26 parts of acid, 28 (v) of oxide, and 46 of water.

When expoſed to the air, it effloreſces; but if it be moiſtened, it is gradually converted into red ſulphat of iron.

When heated, it firſt aſſumes a yellow colour, loſes its water and its acid; if the heat be increaſed, nothing remains but a yellow powder.

The Pruſſic alkali precipitates from the ſolution of this ſalt a white powder, which gradually becomes blue by attracting oxygen *.

It is uſed in dyeing, and in making ink, &c.

It is decompoſed by compound affinity by

Nitrat of ſilver,
Muriat of ſoda †.

642 Red ſulphat of iron.

The *red ſulphat of iron* may be formed by expoſing a ſolution of green ſulphat to the air, or by treating it with nitric acid. It was formerly called *mother water of vitriol.*

Little is known of its properties, except that it is deliqueſcent, incryſtallizable, and ſoluble in alcohol.

It was firſt accurately examined by Mr Prouſt.

The green ſulphat of iron generally contains ſome of it, which may be ſeparated by means of alcohol.

It is alone capable of forming Pruſſian blue with the Pruſſic acid, and of ſtriking a black colour with the gallic acid ‡.

We have obſerved, that when it is diluted with water, and an exceſs of ſulphuric acid is poured in, it is again ſlowly converted into green ſulphat.

643 Sulphat of zinc.

13. Sulphat of zinc.—This ſalt, according to the beſt accounts, was diſcovered at Rammelſberg in Germany, about the middle of the 16th century. Many aſcribe

* *Vauquelin, Ann. de Chim.* xxii. 199.

† *Jour. de Phyſ.* xxxvi. 187.

‡ *Lib.* xxxiv. c. 12.

§ *Bergman.*

* *Prouſt.*

† *Ballen and Tutben, Ann. de Chim.* xi. 320.

‡ See *Prouſt's paper, Nicholſon's Journal*, i. 435.

(u) *Jargonia*, or, as the French chemiſts call it, *zirconia*, has been diſcovered in great abundance in France by Morveau, who found that the hyacinths of Expailly contained more than half their weight of it. From Vauquelin's analyſis they appear to be compoſed of

32	parts of ſilica,
64	jargonia,
2	oxide of iron.

Jargonia has been examined with great care by theſe two philoſophers, the experiments of Klaproth have been confirmed, and ſeveral new properties of it have been diſcovered. Perhaps a more detailed account than we have hitherto given of this new earth may not be unacceptable to our readers.

Jargonia is a white powder, its ſpecific gravity is conſiderable, it has a feel reſembling that of ſilica, it has no taſte, and is inſoluble in water. When ſeparated from its ſolutions by pure alkalies, it retains, when expoſed to the air to dry, a pretty conſiderable quantity of water, which renders it tranſparent, and gives it a reſemblance to gum arabic both in its colour and fracture.

When expoſed to the heat of the blow-pipe it does not melt; but Vauquelin melted it by expoſing it ſurrounded with charcoal in a porcelain crucible to an intenſe heat for an hour and a half. Its ſpecific gravity was then 4,35, its colour was grey, and its hardneſs ſuch that it was capable of ſcratching glaſs. It melts with borax, and forms a tranſparent and colourleſs glaſs; but phoſphat of ſoda and the fixed alkalies do not attack it.

It is inſoluble in the fixed alkalies, has very little affinity for carbonic acid, and is precipitated from its ſolutions together with iron by the Pruſſic alkali.

Its affinities, as far as they have been aſcertained by Vauquelin, are as follows:

Vegetable acids, order unknown,
Sulphuric acid,
Muriatic,
Nitric.

See upon this ſubject the Memoirs of Morveau and Vauquelin, *Ann. de Chim.* xxi. 72. and xxii. 179.

(t) Theſe curious ſalts form the ſubject of the next chapter.

(v) Perhaps the quantity of oxide is ſomewhat over-rated here; for before it was examined by Mr Kirwan, it had aſſumed a red colour: it muſt therefore have been converted into the brown or red oxide by attracting oxygen from the atmoſphere.

aſcribe the invention to Julius Duke of Brunſwick. Henkel and Neumann were the firſt chemiſts who proved that it contained zinc; and Brandt firſt aſcertained its compoſition completely *. It is generally formed for commercial purpoſes from ſulphuret of zinc or *blende*, as it is called. This ſalt is called alſo *white vitriol*.

* *Beckmann's Hiſt. of Inventions*, art. *Zinc.*

It is of a white colour, and its cryſtals are rhomboidal priſms, terminated by quadrangular pyramids: there is generally a ſlight defect in two of the oppoſite angles of the priſm, which produces a quadrangular ſection †. Its ſpecific gravity is 2,000.

† *Bergman*, ii. 327.

It has a ſharp ſtyptic taſte.

It is ſoluble in 2,28 parts of water at the temperature of 60°; but in a much ſmaller quantity of boiling water ‡.

‡ *Ibid.*

It is compoſed, according to Bergman, of 40 (v) parts of acid, 20 of oxide, and 40 of water: Kirwan ſuppoſes that it is compoſed of 12 parts of acid, 26,4 of zinc, 20 of oxide, 41,6 of water (w).

According to Bergman, this ſalt is not altered in the air; others affirm that it effloreſces. This, no doubt, depends upon the place where it is kept.

Heat decompoſes this ſalt.

644
Sulphat of manganeſe.

14. Sulphat of manganeſe.—This ſalt was firſt obtained by Scheele (x): It is compoſed of ſulphuric acid and white oxide of manganeſe.

Its cryſtals are oblique parallelopipeds; they are of a white colour, and very bitter §.

§ *Scheele*,

Theſe cryſtals are decompoſed by a ſtrong red heat, and the ſulphuric is converted into ſulphurous acid by the oxide attracting its oxygen, and being changed into black oxide ‖.

‖ *Id.*

645
Sulphat of nickel.

15. Sulphat of nickel.—This ſalt, which is compoſed of ſulphuric acid and oxide of nickel, was firſt deſcribed by Bergman. Its cryſtals are in the form of decahedrons, compoſed of two quadrangular truncated pyramids; they are of a green colour ¶.

¶ *Bergman*, ii. 268.

646
Sulphat of cobalt.

16. Sulphat of cobalt.—This ſalt was firſt mentioned by Mr Brandt. Its cryſtals are of a reddiſh colour; but if any nickel be preſent, they are green.

647
Sulphat of lead.

17. Sulphat of lead.—This ſalt has been long known: it is compoſed of ſulphuric acid and white oxide of lead. The cryſtals are white, ſmall, and moſt commonly needle-ſhaped: according to Sage, they are tetrahedral priſms.

It is ſoluble in 18 parts of water,

Heat decompoſes it.—It is very cauſtic.

18. Sulphat of tin.—Nothing is known concerning this ſalt, except that it cryſtallizes in fine needles interlaced with one another *.

* *Monnet.*

648
Sulphat of copper.

19. Sulphat of copper.—This ſalt appears to have been known to the ancients. It is generally obtained by evaporating thoſe waters which naturally contain it. It is called alſo *blue vitriol*.

Its cryſtals are of a deep blue colour; they are in the form of oblong rhomboids. Its ſpecific gravity is 2,230.

It has a very ſtrong ſtyptic taſte; and indeed is employed as a cauſtic.

It is ſoluble in four parts of water at the temperature of 60°; but in a much ſmaller quantity of boiling water *.

It is compoſed, according to Bergman, of 46 parts of acid, 26 of oxide of copper, and 28 of water. Kirwan ſuppoſes it to contain 27,68 of acid, 35 of oxide, and 37,32 of water †.

* *Bergman.*

† *Miner.* ii. 23.

When expoſed to the air, it effloreſces, and is covered with a yellowiſh grey powder.

It requires a very ſtrong heat to decompoſe it.

It has the property of communicating a green colour to flame.

It is uſed in the preparation of ſeveral paints, and for a variety of other purpoſes.

It is decompoſed by compound affinity by acetite of lead.

649
Sulphat of biſmuth,

20. Sulphat of biſmuth.—Little is known of this ſalt, except that it is with difficulty cryſtallized, and is very deliqueſcent.

650
Antimony,

21. Sulphat of antimony.—This ſalt does not cryſtallize. It is eaſily decompoſed by heat.

651
Arſenic,

22. Sulphat of arſenic.—This ſalt is ſcarcely known. It does not appear to be cryſtallizable. It is decompoſed by water.

652
White ſulphat of mercury.

23. White ſulphat of mercury.—This ſalt may be formed by boiling together two parts of mercury and three of concentrated ſulphuric acid, and ſtopping the proceſs whenever the mercury is converted into a white maſs. This maſs, in order to remove the exceſs of acid, is to be waſhed repeatedly with ſmall portions of water, till it ceaſes to redden turnſole. The ſulphat of mercury, thus obtained, is very white. Its cryſtals are either ſmall plates or priſms. Its taſte is not very cauſtic. It is ſoluble in 500 parts of water at the temperature of 55°, and in 287 parts of boiling water. It is compoſed of 83 parts of white oxide of mercury, 12 of ſulphuric acid, and 5 of water ‡. It is not altered by expoſure to the air. Heat decompoſes it.

‡ *Fourcroy, Ann. de Chim.* x. 299.

This ſulphat is capable of combining with a new portion of acid: It was in that ſtate before it was waſhed with water. This ſalt, which may be called *acidulous white ſulphat of mercury*, has a very cauſtic taſte, and is corroſive. It reddens vegetable blues. It is ſoluble in 157 parts of water at the temperature of 55°, and in 33 parts of boiling water §.

§ *Fourcroy, ibid.*

653
Yellow ſulphat of mercury.

24. Yellow ſulphat of mercury.—This ſalt may be obtained by continuing to boil the preceding mixture of mercury and ſulphuric acid till the mercury aſſumes a yellow colour. It appears to be compoſed of yellow oxide of mercury and a ſmall portion of ſulphuric acid. It is ſoluble in 2000 parts of water at the temperature of 55°, and in 600 parts of boiling water. The ſolution is colourleſs. It was formerly called *turbith mineral* ‖.

‖ *Fourcroy, ibid.*

654
Sulphat of ammonia and mercury.

25. Sulphat of ammonia and mercury.—This triple ſalt may be formed by pouring ammonia into a ſolution of ſulphat of mercury. If only a ſmall quantity of ammonia be uſed, a copious blackiſh precipitate takes place, part of which is converted into running mercury by expoſure to light; and conſequently is black oxide of mercury; the remaining part is the triple ſalt. If a large quantity of ammonia be uſed, only the black oxide is

---

(v) There is evidently ſome miſtake in this ſtatement; it does not correſpond with what he ſays elſewhere.

(w) *Mineralogy*, ii. 24. We do not underſtand this ſtatement.

(x) Weſtfield, indeed, obtained it; but he miſtook it for ſulphat of magneſia.

is precipitated; for the triple ſalt is rendered much more ſoluble by an exceſs of ammonia. As this exceſs evaporates, the ſalt cryſtallizes. The cryſtals are polygons, very brilliant and hard. It has a ſharp, auſtere, metallic taſte. It has no peculiar odour. It is ſcarcely ſoluble, except with exceſs of ammonia. It is compoſed, according to Fourcroy's analyſis, of 18 parts of ſulphuric acid, 33 of ammonia, and 39 of oxide of mercury. Heat decompoſes it. The products obtained by diſtilling it are, a little ammonia, azotic gas, a little pure mercury, ſome *ſulphite of ammonia*; and there remains yellow ſulphat of mercury *.

This triple ſalt may be formed alſo by pouring ammonia upon acidulous ſulphat of mercury, or on yellow ſulphat of mercury †.

655
Sulphat of ſilver.

26. Sulphat of ſilver.—This ſalt is formed by pouring ſulphuric acid on oxide of ſilver. Its cryſtals are ſmall needles. It melts when expoſed to a ſtrong heat, but does not ſublime.

It is decompoſed by muriat of lead ‡.

27. Sulphat of gold.—This ſalt is unknown.

28. Sulphat of platinum.—Unknown.

29. Sulphat of tungſten.—Probably no ſuch combination is poſſible.

30. Sulphat of molybdenum.—Probably impoſſible.

656
Sulphat of uranium,

31. Sulphat of uranium.—This ſalt was firſt formed by Mr Klaproth. He formed it by pouring ſulphuric acid on the oxide of uranium. Nothing farther is known of it, except that its cryſtals are ſmall, and of a yellow colour.

657
Titanium,

32. Sulphat of titanium.—This ſalt was firſt formed by Mr M'Gregor. It does not appear, from Klaproth's experiments, to be cryſtallizable.

658
Tellurium.

33. Sulphat of tellurium.—When one part of tellurium is mixed cold in a well-ſtopped veſſel with a hundred parts of concentrated ſulphuric acid, the latter gradually aſſumes a beautiful crimſon red colour: when a ſmall quantity of water is added, drop by drop, the colour diſappears, and the metal is precipitated in the form of black flakes. The ſolution is deſtroyed by heat, the colour diſappears, and the metal ſeparates in the ſtate of a white oxide. When ſulphuric acid is diluted with two or three parts of water, and a ſmall quantity of nitric acid is added, it diſſolves a conſiderable quantity of tellurium. The ſolution is tranſparent and colourleſs, and is not decompoſed by the addition of a larger quantity of water §.

SECT. II. *Of Sulphites.*

SALTS compoſed of ſulphurous acid united reſpectively with alkalies, earths, or oxides, are called *ſulphites*. Thoſe hitherto examined are the following:

659
Sulphite of potaſs.

1. Sulphite of potaſs.—This ſalt was firſt formed by Stahl; but was firſt accurately deſcribed by Berthollet, Fourcroy, and Vauquelin.

It may be formed by paſſing ſulphurous acid into a ſaturated ſolution of carbonat of potaſs till all efferveſcence ceaſes. The ſolution becomes hot, and cryſtallizes by cooling ‖.

Its cryſtals are white and tranſparent; their figure that of rhomboidal plates. Its cryſtallization often preſents ſmall needles diverging from a common centre ¶.

Its taſte is penetrating and ſulphurous. At the common temperature of the atmoſphere, it is ſoluble in its own weight of water, but much more ſoluble in boiling water.

When expoſed to the air, it effloreſces, becomes opaque and hard, and is gradually converted into *ſulphat of potaſs* by abſorbing oxygen.

When expoſed to a ſudden heat, it decrepitates, loſes its water: at a red heat ſome ſulphurous vapours are emitted; at laſt a portion of ſulphur ſeparates, and the reſiduum is ſulphat of potaſs, with a ſlight exceſs of alkali.

Nitric and oxy-muriatic acids convert it into ſulphat of potaſs by imparting oxygen.

It decompoſes the oxides of gold, ſilver, mercury, the red oxide of lead, the black oxide of mangaueſe, and the brown oxide of iron. When the green oxide of iron and the white oxide of iron are boiled with it in water, and an acid added, a precipitate takes place of theſe bodies united to ſome ſulphur, and the ſalt is converted into a ſulphat: at the ſame time ſulphurated hydrogen gas is emitted.

By compound affinity it is decompoſed by

All ſalts with baſe of ſoda, except the borat and carbonat;

All metallic ſalts except carbonats;

All neutral ſalts whoſe acid has a ſtronger affinity for potaſs than ſulphurous acid has *.

660
Sulphite of ſoda.

2. Sulphite of ſoda.—This ſalt was firſt accurately deſcribed by Fourcroy and Vauquelin.

It is white and perfectly tranſparent. Its cryſtals are four-ſided priſms, with two very broad ſides and two very narrow ones, terminated by dehedral pyramids.

Its taſte is cool and ſulphurous.

It is ſoluble in four times its weight of cold water, but it is more ſoluble in hot water.

It is compoſed of 18,8 parts of ſoda, 31,2 of acid, and 50 of water.

By expoſure to air, it effloreſces, and is ſlowly converted into a ſulphat.

When expoſed to heat, it undergoes the watery fuſion, and afterwards exhibits preciſely the ſame phenomena as the ſulphite of potaſs.

Metallic oxides and ſalts affect it preciſely as they do ſulphite of potaſs.

It is decompoſed by compound affinity by carbonat of potaſs, and the other ſalts which decompoſe ſulphite of potaſs †.

661
Sulphite of ammonia.

3. Sulphite of ammonia.—This ſalt was firſt deſcribed by Fourcroy and Vauquelin ‡.

It cryſtallizes in ſix-ſided priſms terminated by ſix-ſided pyramids.

Its taſte is cool and penetrating like that of the other ammoniacal ſalts, but it leaves a ſulphurous impreſſion in the mouth.

It is ſoluble in its own weight of cold water. Its ſolubility is increaſed by heat.

It is compoſed of 29,07 parts of ammonia, 60,06 of acid, and 10,87 of water.

When expoſed to the air, it attracts moiſture, and is ſoon converted into a ſulphat.

Heat volatilizes it without decompoſition.

Its habitudes with metallic oxides and ſalts are nearly the ſame with thoſe of the above deſcribed ſulphites, only it is capable of forming with ſeveral of them triple ſalts §.

662
Sulphite of barytes.

4. Sulphite of barytes.—This ſalt was firſt deſcribed by Berthollet ‖.

It is incryſtallizable; it has no perceptible taſte; and is perfectly inſoluble in water ¶.

It

§ Ibid.

‖ Ann. de Chim. ii. 57.

¶ Fourcroy and Vauquelin.

It is compoſed of 59 parts of barytes, 39 parts of acid, and 2 of water.

It does not eaſily change into a ſulphat by expoſure to air; but heat produces this effect *.

663 Sulphite of lime.

5. Sulphite of lime.—This ſalt was firſt deſcribed by Berthollet †.

Its cryſtals are ſix-ſided priſms, terminated each by a very long pyramid ‡.

It has ſcarcely any taſte; however, when kept long in the mouth, it communicates to the tongue a taſte which is manifeſtly ſulphurous.

It is very ſparingly ſoluble in water, except with exceſs of acid.

It is compoſed of 47 parts of lime, 48 of ſulphurous acid, and 5 of water.

By contact of air it is converted into a ſulphat, but very ſlowly.

Heat converts it into a ſulphat by depriving it of a portion of ſulphur.

It is decompoſed by compound affinity by

Carbonates of alkalies, Fluats of alkalies,
Phoſphats of alkalies, Moſt metallic ſalts §.

664 Sulphite of magneſia.

6. Sulphite of magneſia.—This ſalt was firſt deſcribed by Fourcroy and Vauquelin.

Its cryſtals are white and tranſparent, and in the form of depreſſed tetrahedrons.

Its taſte is mild and earthy at firſt, and afterwards ſulphurous.

It is ſparingly ſoluble in water, except when there is an exceſs of acid.

It is compoſed of 16 parts of magneſia, 39 of acid, and 45 of water.

It becomes opaque when expoſed to the air; is very ſlowly converted into a ſulphat.

By expoſure to heat, it ſoftens, ſwells up, and becomes ductile like gum; a ſtrong heat decompoſes it altogether.

It is decompoſed by

Alkaline ſalts,
Earthy ſalts, except thoſe of alumina ||.

665 Sulphite of alumina.

7. Sulphite of alumina.—Firſt formed by Berthollet.

It does not cryſtallize, but is converted into a ſoft ductile maſs. It is not ſoluble in water, but becomes abundantly ſo when there is an exceſs of acid.

It is compoſed of 44 parts of alumina, 32 of acid, and 24 of water.

Heat decompoſes it ¶.

666 Sulphite of iron

8. Sulphite of iron.—It was firſt formed by Berthollet.

Its cryſtals are white, and have but very little of the ſtyptic taſte of iron ſalts *.

Berthollet alſo formed the ſulphites of zinc and tin, but he has not deſcribed them.

Sect. III. *Of Nitrats.*

Those ſalts, in the compoſition of which the nitric acid forms one ingredient, are called *nitrats*.

667 Nitre.

1. Nitrat of potaſs, nitre, or ſaltpetre.—As this ſalt is produced naturally in conſiderable quantities, particularly in Egypt, it is highly probable that the ancients were acquainted with it; but ſcarcely any thing certain can be collected from their writings. If Pliny mentions it at all, he confounds it with ſoda, which was known by the names of *nitron* and *nitrum*. It is certain, however, that it has been known in the eaſt from time immemorial. Roger Bacon mentions this ſalt in the 13th century under the name of *nitre*.

It cryſtallizes in ſlender oblong hexagonal priſms, often ſtriated, terminated by hexagonal pyramids obliquely truncated. Its ſpecific gravity is 1,920.

Its taſte is ſharp, bitteriſh, and cooling.

It is ſoluble in ſeven times its weight of water at the temperature of 60°, and in nearly its own weight of boiling water *.

According to Bergman, it is compoſed of 31 parts of acid, 61 of potaſs, and 8 of water; but this proportion of acid is undoubtedly too ſmall. According to Mr Kirwan, it is compoſed of 41,2 of acid, 46,15 of alkali, and 12,65 of water †.

It is not altered by expoſure to the air.

When expoſed to a ſtrong heat, it melts; and congeals by cooling into an opaque maſs, which has been called *mineral cryſtal*. If the heat be continued, the acid is gradually decompoſed and driven off. When the ſolution of nitre is expoſed to a boiling heat, part of the ſalt is evaporated along with the water, as Wallerius, Kirwan, and Lavoiſier, obſerved ſucceſſively. When nitre is expoſed to heat along with many combuſtible ſubſtances, its acid is decompoſed; the combuſtible ſeizes the oxygen, and at the ſame time a lively white flame appears, attended with a decrepitation: this is called the *detonation of nitre*.

Nitre mixed with charcoal and ſulphur in proper proportions forms *gunpowder*.

Nitre is decompoſed by compound affinities by

Acetite of barytes.

668 Reproduction of nitre.

No phenomenon has excited the attention of chemical philoſophers more than the continual reproduction of nitre in certain places after it had been extracted from them. Prodigious quantities of this ſalt are neceſſary for the purpoſes of war; and as Nature has not laid up great magazines of it as ſhe has of ſome other ſalts, this annual reproduction is the only ſource from which it can be procured. It became, therefore, of the utmoſt conſequence, if poſſible, to diſcover the means which Nature employed in forming it, in order to enable us to imitate her proceſſes by art, or at leaſt to accelerate and facilitate them at pleaſure. Numerous attempts accordingly have been made to explain and to imitate theſe proceſſes.

Stahl, ſetting out on the principle that there is only one acid in nature, ſuppoſed that nitric acid is merely ſulphuric acid combined with phlogiſton; and that this combination is produced by putrefaction: he affirmed accordingly, that nitre is compoſed by uniting together potaſs, ſulphuric acid, and phlogiſton. But this opinion, which was merely ſupported by very far-fetched analogies, could not ſtand the teſt of a rigorous examination.

Lemery the Younger accordingly advanced another; affirming, that all the nitre obtained exiſts previouſly in animals and vegetables, and that it is formed in theſe ſubſtances by the proceſſes of vegetation and animalization. But it was ſoon diſcovered that nitre exiſts, and is actually formed, in many places where no animal nor vegetable ſubſtance has been decompoſed; and conſequently this theory was as untenable as the former. So far indeed is it from being true that nitre is formed alone by theſe proceſſes, that the quantity of nitre in plants has been found to depend entirely on the ſoil in which they grow ‡.

At

† Mineral. ii. 27.

‡ Bouillon

At laſt by the numerous experiments of ſeveral French philoſophers, particularly by thoſe of Thouvenel, it was diſcovered that nothing elſe is neceſſary for the production of nitre but a baſis of lime, heat, and an open but not too free communication with dry atmoſpheric air. When theſe circumſtances combine, the acid is firſt formed, and afterwards the alkali makes its appearance. How the air furniſhes materials for this production is eaſily explained, now that the component parts of the nitric acid are known to be oxygen and azot. But how lime contributes to their union it is not ſo eaſy to ſee. It is a diſpoſing affinity, which, like moſt others referred to that ſingular claſs, our preſent knowledge of the nature of affinity does not enable us to explain. The appearance of the potaſs is equally extraordinary. If any thing can give countenance to the hypotheſis, that potaſs is compoſed of lime and azot, it is this ſingular fact.

669 Nitrat of ſoda. 2. Nitrat of ſoda. This ſalt was called formerly *cubic nitre.*

It forms rhomboidal cryſtals. Its ſpecific gravity is 1,870.

It has a cool ſharp taſte, and is ſomewhat more bitter than nitre.

It is ſoluble in about three parts of water at the temperature of 60°, and is ſcarcely more ſoluble in boiling water.

It is compoſed, according to Bergman, of 43 parts of acid, 32 of ſoda, and 25 of water. From an experiment formerly deſcribed, Mr Kirwan concludes, that it contains 57,65 of acid, and 42,35 of alkali; but perhaps the proportion of acid may be ſomewhat over-rated, as no direct proof has been brought that the ſalt contains no water.

When expoſed to the air it rather attracts moiſture.

Its phenomena in the fire are the ſame with thoſe of nitre, only it does not melt ſo eaſily.

It is decompoſed by compound affinity by the following ſalts:

Sulphat of barytes,
——— potaſs,
——— alumina,
Muriat of barytes,
——— potaſs,
——— lime,

Muriat of ammonia,
Acetite of barytes,
——— potaſs,
Carbonat of barytes,
——— potaſs.

670 Nitrat of ammonia. 3. Nitrat of ammonia. This ſalt cryſtallizes with difficulty into regular needles. It was formerly called *nitrum ſemivolatile*, and *nitrum flammans.*

It has a ſharp, acrid, ſomewhat urinous taſte.

It is ſoluble in about half its weight of boiling water.

It is compoſed of 58 parts of acid, about 26 of alkali, and 16 of water*.

When expoſed to the air it deliqueſces.

When expoſed to heat, it firſt undergoes the watery fuſion, afterwards detonates, and is completely decompoſed. Berthollet has ſhewn, that this phenomenon is owing to the hydrogen of the alkali entering into combination with the oxygen of the acid, and forming water, while the acid flies off in a gaſeous form.

By compound affinity it is decompoſed by the following ſubſtances:

Sulphat of barytes,
——— potaſs,
——— alumina,

Acetite of barytes,
——— potaſs,
——— ſoda,

Acetite of lime
——— magneſia,
——— alumina,
Muriat of barytes,
——— potaſs,
——— ſoda,

Muriat of lime,
——— magneſia,
——— alumina,
Carbonat of barytes,
——— potaſs,
——— ſoda.

671 Nitrat of barytes. 4. Nitrat of barytes. This ſalt may be formed into hexagonal cryſtals, but it requires great addreſs to produce them.

It attracts moiſture from the atmoſphere.

Heat decompoſes it, and leaves pure barytes. The decompoſition of this ſalt by heat is the moſt convenient method of procuring pure barytes yet known. It was firſt propoſed by Mr Vauquelin.

By compound affinity it is decompoſed by
Alkaline carbonats,
Oxalat of ammonia*.

672 Nitrat of lime. 5. Nitrat of lime. This ſalt forms by cryſtallization ſix-ſided priſms, terminated by dehedral pyramids, but more commonly ſmall regular octahedral needles.

It has a ſharp bitteriſh taſte.

It is ſoluble in two parts of cold water, and in its own weight of boiling water.

Boiling alcohol diſſolves its own weight of it †.

According to Bergman, it is compoſed of 43 parts of acid, 32 of lime, and 25 of water. Kirwan has found, that 100 parts of lime require for ſaturation 180 parts of acid ‡.

Nitrat of lime deliqueſces when expoſed to the air.

Heat decompoſes it like all other nitrats.

By compound affinity it is decompoſed by

Sulphat of barytes,
——— potaſs,
——— ſoda,
——— ammonia,
——— alumina,
Muriat of barytes,
——— potaſs,
Acetite of barytes,

Acetite of potaſs,
Carbonat of barytes,
——— potaſs,
——— ſoda,
——— ammonia,
——— alumina,
——— magneſia,
Tungſtat of ammonia §.

673 Nitrat of ſtrontites. 6. Nitrat of ſtrontites. This ſalt, firſt formed by Dr Hope, cryſtallizes readily, but the cryſtals are very irregular in their ſhape: ſometimes they are hexagonal truncated pyramids; ſometimes octahedrons, conſiſting of two four-ſided pyramids united at their baſes.

It is ſoluble in its own weight of water, at the temperature of 60°, and in little more than half its weight of boiling water. It has a ſtrong pungent taſte.

In a dry air it effloreſces, but in a moiſt air it deliqueſces.

It deflagrates on hot coals. Subjected to heat in a crucible, it decrepitates gently, and then melts. In a red heat it boils, and the acid is diſſipated. If a combuſtible ſubſtance be at this time brought into contact with it, a deflagration with a very vivid red flame is produced ||.

674 Nitrat of magneſia. 7. Nitrat of magneſia. The compoſition of this ſalt was firſt aſcertained by Dr Black.

Its cryſtals are quadrangular priſms. It has a very bitter taſte. It is very ſoluble in water. Alcohol diſſolves $\frac{1}{9}$th of its own weight of it ¶.

One hundred parts of magneſia require 255 of nitric acid for ſaturation *.

It deliqueſces in the air, according to Bergman; but Dijonval affirms, that he has procured it in cryſtals which rather effloreſce.

It

It is decompoſed by heat.

By compound affinity it is decompoſed by

Sulphat of barytes,
——— potaſs,
——— ſoda,
——— ammonia,
——— alumina,
Muriat of barytes,
——— potaſs,
——— ſoda,

Muriat of lime,
Acetite of barytes,
——— potaſs,
——— ſoda,
——— lime,
Carbonat of barytes,
——— potaſs,
——— lime.

675 Nitrat of ammonia and magneſia. 8. Nitrat of ammonia and magneſia. This triple ſalt was diſcovered by Mr Fourcroy. Into a ſaturated ſolution of nitrat of magneſia, containing 73 grains of magneſia, he poured ammonia as long as any precipitate could be obtained. Twenty-one grains of magneſia were precipitated, 52 grains remained combined with the acid and the ammonia. He found that 52 grains of magneſia produced, when ſaturated with nitric acid, 288 grains of nitrat; and that the quantity of nitric acid neceſſary to ſaturate 21 grains of magneſia, when ſaturated with ammonia, produced 84 grains of nitrat of ammonia. He concludes, therefore, though the data are not quite ſatisfactory, that the triple ſalt is compoſed of 288 grains of nitrat of magneſia, and 84 of nitrat of ammonia *.

676 Nitrat of alumina. 9. Nitrat of alumina. This ſeems to have been firſt attended to by Beaumé.

Its cryſtals are pyramidal. It has a very aſtringent taſte. It is ſoluble in water, and deliqueſces in the air.

677 Nitrat of jargonia. 10. Nitrat of jargonia. This ſalt may be eaſily formed by pouring nitric acid on newly precipitated jargonia.

It always contains an exceſs of acid. By evaporation a yellowiſh tranſparent matter is obtained, exceedingly tenacious and viſcid, and which dries with difficulty. It has an aſtringent taſte, and leaves on the tongue a viſcid matter, owing to its being decompoſed by the ſaliva. It is only very ſparingly ſoluble in water; the greateſt part remains under the form of gelatinous and tranſparent flakes. Like all the other ſalts into which jargonia enters, it is decompoſed by heat. It is decompoſed alſo by ſulphuric acid, which occaſions a white precipitate, ſoluble in exceſs of acid; by carbonat of ammonia, which produces a precipitate ſoluble by adding more carbonat; and by an infuſion of nut-galls in alcohol, which produces a white precipitate, ſoluble in an exceſs of the infuſion; unleſs the jargonia contains iron; in which caſe the precipitate is a greyiſh blue, and part of it remains inſoluble, giving the liquor a blue colour. This liquor, mixed with carbonat of ammonia, produces a matter purple by tranſmitted light, but violet by reflected light. Gallic acid alſo precipitates nitrat of jargonia of a greyiſh blue, but the colour is not ſo fine. Moſt of the other vegetable acids decompoſe this ſalt, and form combinations inſoluble in water †.

678 Nitrat of iron. 11. Nitrat of iron. The green oxide of iron decompoſes, but does not combine with nitric acid. The brown oxide forms with it a red or brown ſolution, which by evaporation may be reduced to a jelly, but will not cryſtallize.

679 Nitrat of zinc. 12. Nitrat of zinc. The oxide of zinc combines with nitric acid, and forms with it a ſalt which cryſtallizes in compreſſed and ſtriated tetrahedral priſms, terminated by four-ſided pyramids.

Its ſolution is exceedingly cauſtic. When placed on burning coals it melts and detonates as it dries. It can ſcarcely be dried without being in ſome meaſure decompoſed.

It deliqueſces in the air *.

680 Nitrat of mangancſe. 13. Nitrat of mangancſe. This ſalt, compoſed of oxide of manganeſe and nitric acid, was firſt examined by Scheele. Its cryſtals are ſmall and ſhining, of a very bitter taſte, and ſoluble in water †.

681 Nitrat of cobalt. 14. Nitrat of cobalt. It is of a pale red colour, and cryſtallizes in needles. It deliqueſces when expoſed to the air. Heat decompoſes it. When nickel is preſent, this ſalt aſſumes a green colour.

682 Of nickel. 15. Nitrat of nickel. Its cryſtals are of a green colour, and in the form of rhomboidal cubes. They are deliqueſcent, and are gradually decompoſed when expoſed to the air, the acid leaving them ‡.

683 Of lead. 16. Nitrat of lead. Nitric acid combines with the white oxide of lead. The cryſtals of this ſalt are of a white colour; their form an irregular octagon, or rather truncated hexahedral pyramid. When expoſed to heat it decrepitates, and melts with a yellowiſh flame. By compound affinity it is decompoſed by

Muriat of potaſs,
——— ſoda,
——— ammonia,
Carbonat of ſoda §.

684 Of tin. 17. Nitrat of tin. Tin is converted into an acid by nitric acid: it is not probable, therefore, that any permanent nitrat of tin can be formed.

685 Of copper. 18. Nitrat of copper. This ſalt appears to have been firſt obtained by Macquer.

Its form, when properly cryſtallized, is an oblong parallelogram. It is of a fine blue colour. It is exceedingly cauſtic. It melts at 77° ||.

It is deliqueſcent in a moiſt air, but in a dry place is covered with a green effloreſcence. It is very ſoluble in water. Heat decompoſes it.

686 Of biſmuth. 19. Nitrat of biſmuth. This ſalt cryſtallizes in various forms. Fourcroy obtained it in flattened rhomboids. It effloreſces in the air. Water decompoſes it. It detonates in the fire.

687 Of antimony. 20. Nitrat of antimony. Little is known concerning this ſalt, except that it is very deliqueſcent, and is decompoſed by heat.

688 Of arſenic. 21. Nitrat of arſenic. With white oxide of arſenic nitric acid forms a ſalt which cryſtallizes. It is very deliqueſcent. It does not detonate.

689 Of mercury. 22. Nitrat of mercury. This ſalt may be formed by diſſolving mercury in nitric acid. It cryſtallizes in the cold in regular flat 14-ſided figures; but their form differs according to the manner in which the cryſtallization has been performed.

It is ſoluble in water.

This ſalt is exceedingly cauſtic. It detonates on coals. When heated in a crucible it melts, and is decompoſed. The oxide attracts oxygen from the acid, which flies off in the form of nitrous gas, and red oxide of mercury remains behind.

It is ſlowly decompoſed alſo in the air. It is decompoſed by compound affinity by

Sulphat of copper, and a great many other ſulphats,
Phoſphat of ſoda,
Borax.

690 Of ammonia and mercury, 23. Nitrat of ammonia and mercury. This triple ſalt may be formed by pouring ammonia into a ſolution

---

§ *Bergman.*

|| *Sage.*

Muriats.

of nitrat of mercury. If only enough of ammonia to ſaturate the acid be uſed, the triple ſalt precipitates in the form of a white powder; but with an exceſs of ammonia it remains diſſolved, and forms by evaporation very bright polyhedral cryſtals.

It has a very ſharp taſte. It is ſoluble in 1200 parts of water at the temperature of 55°. Hot water ſeparates a little ammonia, which renders it ſtill more inſoluble. It turns vegetable blues green. Muriatic acid diſſolves it.

According to Fourcroy's analyſis, it is compoſed of 68,20 parts of oxide of mercury, 16 of ammonia, and 15,80 of nitric acid and water.

When diſtilled it yields ammonia, azotic gas, oxygen gas, yellow oxide of mercury, and pure mercury *.

691 Nitrat of ſilver,

24. Nitrat of ſilver. This ſalt may be formed by diſſolving ſilver in nitric acid.

It forms flat tranſparent cryſtals compoſed of needles. It is exceedingly cauſtic. When melted it forms a grey maſs called *lapis infernalis*, from its great corroſiveneſs

It is very ſoluble in water. It is not altered by expoſure to the air. Light decompoſes it.

By compound affinity it is decompoſed by

The ſulphats,

The muriats.

692 Nitrat of uranium,

25. Nitrat of uranium. This ſalt was firſt formed by Klaproth. Its cryſtals are hexagonal plates of a greeniſh yellow colour. The largeſt were $\frac{1}{4}$ths of an inch in length and $\frac{1}{4}$th in breadth †.

693 Titanium,

26. Nitrat of titanium. It is capable of cryſtallizing.

694 Tellurium.

27. Nitrat of tellurium. The ſolution of tellurium in nitric acid is tranſparent and colourleſs. When concentrated, it produces in time ſmall white light cryſtals in the form of needles, which exhibit a dendritic aggregation ‡.

Sect. IV. *Of Nitrites.*

The ſalts which the nitrous acid forms with alkalies, earths, and metallic oxides, are denominated *nitrites*. Very few of them have been examined; we ſhall not therefore attempt a deſcription of them.

Sect. V. *Of Muriats.*

Salts into which the muriatic acid enters are called *muriats*.

695 Muriat of potaſs.

1. Muriat of potaſs. This ſalt was formerly called *febrifuge* or *digeſtive ſalt of Sylvius*, and *regenerated ſea ſalt*.

Its cryſtals are cubes, but rather irregular.

It has a diſagreeable bitter taſte. Its ſpecific gravity is 1,836 §.

It is ſoluble in three times its weight of water at the temperature of 60°, and in double its weight of boiling water ‖.

It is compoſed, according to Bergman, of 31 parts of acid, 61 of potaſs, and 8 of water. Kirwan has found it to contain 36 of acid, 46 of alkali, and 18 of water ¶.

It ſuffers little alteration from expoſure to the air.

When expoſed to heat, it firſt decrepitates, then melts, and at laſt is volatilized, but without decompoſition.

The following ſalts decompoſe it by compound affinity:

Sulphat of ſoda,
——— ammonia,
——— alumina,
Nitrat of ſoda,
——— lime,
Nitrat of ammonia,
——— magneſia,
——— alumina,
——— lead.

Muriats.

696 Muriat of ſoda.

2. Muriat of ſoda, common or ſea ſalt. This ſalt has been known, and in common uſe, from the earlieſt ages. It is ſometimes called alſo *ſal gem.*

Its cryſtals are cubes, but they often aſſume other forms. Its ſpecific gravity is 2,120 *.

Its taſte is univerſally known, and is what is ſtrictly ſpeaking denominated *ſalt*.

It is ſoluble in $2\frac{14}{17}$ times its weight of water at the temperature of 60°, and in $2\frac{13}{17}$ its weight of boiling water †.

According to Bergman, it is compoſed of 52 parts of acid, 42 of alkali, and 6 of water. According to the late experiments of Mr Kirwan, of 40 parts of acid, 35 of alkali, and 25 of water.

It is not affected by expoſure to the air. It ought to be obſerved, however, that the muriat of ſoda in common uſe contains, beſides other impurities, a quantity of muriat of magneſia, which renders it deliqueſcent.

When heated it decrepitates. Heat volatilizes, but does not decompoſe it.

The following ſalts decompoſe it by compound affinity:

Sulphat of ammonia,
——— alumina,
——— potaſs *,
——— iron †,
Nitrat of ammonia,
——— magneſia,
——— alumina,
——— lead ‡,
Nitrat of ſilver §,
Aceſite of barytes,
Pyrolignite of barytes ‖,
——— lead ‖,
Carbonat of potaſs (*a*),
Alum (*b*),
Red oxide of lead (*c*).

697 How decompoſed by red oxide of lead.

That the red oxide of lead decompoſes this ſalt is a well known fact, and it has been conſidered as contrary to the laws of affinity. Mr Haſſenfratz endeavoured to account for it by ſuppoſing that the oxide is combined with carbonic acid, and that therefore it is a caſe of compound affinity. Mr Curaudau has proved that carbonic acid, inſtead of promoting, impedes the decompoſition; and that, in fact, carbonat of lead is incapable of decompoſing muriat of ſoda. He concludes, therefore, that the phenomenon cannot be accounted for by the commonly received laws of affinity * We cannot, however, think that the phenomenon is ſo unaccountable as Mr Curaudau ſuppoſes; for muriatic acid is capable of decompoſing the red oxide of lead, of combining with part of its oxygen, and of being converted into oxy-muriatic acid. Now if oxy-muriatic and nitro-muriatic acids be merely the ſame ſubſtance in a different form, as there is the ſtrongeſt reaſon for ſuppoſing, the white oxide of lead has a ſtronger affinity for it than ſoda has, and ought therefore to decompoſe it.

698 Muriat of ammonia.

3. Muriat of ammonia, or ſal ammoniac. This ſalt was known to the ancients, and was called by them *ſal ammoniac*, becauſe it was found in great quantities near the temple of Jupiter Ammon in Africa †.

It aſſumes the form of plumoſe cryſtals. The individual cryſtals are long hexahedral pyramids. Its ſpecific gravity is 1,420 ‡.

It has an acrid, poignant, urinous taſte.

It diſſolves in about three times its weight of water at the temperature of 60°, and in a much ſmaller quantity of boiling water.

It is compoſed, according to Kirwan, of 35 parts of acid, 30 of alkali, and 45 of water §.

In its common form (which is an opaque maſs) it is not affected by the air, but its cryſtals are liable to deliqueſce.

‡ *Kirwan.*

§ *Kirwan's Mineral.* ii. 34.

Heat volatilizes without decompoſing it.

The following ſalts decompoſe it by compound affinity :

Sulphat of alumina,
Nitrat of ſoda,
——— lead,
Acetite of barytes,
——— potaſs,
——— ſoda,
——— lime,
Acetite of magneſia,
——— alumina,
——— lead,
Carbonat of barytes,
——— potaſs,
——— magneſia (Y)

When this ſalt is ſublimed with gold leaf, there is found in the neck of the retort an amethyſt coloured matter, bordering on purple, ſoluble in water, and forming a purple ſolution. When filtered there remains behind a purple powder. This ſalt ſeems from this to be capable of oxidating gold *.

099 Muriat of barytes, 4. Muriat of barytes. This ſalt was firſt deſcribed by Bergman, but it has been moſt particularly attended to by Dr Crawford.

It affords oblong ſquare cryſtals.

It has an unpleaſant aſtringent taſte.

It is not very ſoluble in water. It is ſoluble in alcohol.

It is not altered by expoſure to the air, nor does heat in all probability decompoſe it.

Dr Crawford wrote a treatiſe on it in 1790, in which he recommended its uſe internally for ſcrofulous complaints. Care ought to be taken not to give it in too large quantities, as, like the other compounds of barytes, it is poiſonous.

The following ſalts decompoſe it by compound affinity (Z) :

Sulphat of ſoda
——— ammonia,
——— magneſia,
——— alumina,
Nitrat of ſoda,
Nitrat of lime,
——— ammonia,
——— magneſia,
——— alumina,
Phoſphat of lime †.

700 Muriat of ammonia and barytes, 5. Muriat of ammonia and barytes. This triple ſalt was firſt diſcovered by Fourcroy. It may be formed by pouring a carbonat of ammonia into a ſolution of muriat of barytes. It is eaſily decompoſed by heat, but none of the alkalies nor their carbonats are capable of altering it ‡.

701 Muriat of lime, 6. Muriat of lime. This ſalt was formerly called *fixed ammoniac*, becauſe it was commonly obtained by decompoſing ſal ammoniac by means of lime.

Its cryſtals are four-ſided ſtriated priſms, terminated by a very ſharp pyramid ; but it is not eaſily cryſtallized.

Its taſte is very bitter.

It is ſoluble in about $1\frac{1}{2}$ parts of cold water, and in leſs than its own weight of boiling water. Alcohol diſſolves its own weight of it.

According to Bergman, it is compoſed of 31 parts of acid, 44 of lime, and 25 of water. According to Kirwan, 100 parts of lime require for ſaturation 86 parts of muriatic acid.

It very ſpeedily deliqueſces when expoſed to the air. By heat it melts into a very hard vitreform ſubſtance.

The following ſalts decompoſe it by compound affinity :

Sulphat of ſoda,
——— ammonia,
——— magneſia,
——— alumina,
Nitrat of ſoda,
——— ammonia,
——— magneſia,
——— alumina,
Carbonat of potaſs,
——— ſoda,
——— ammonia *,
——— barytes,
——— magneſia,
——— alumina,
Acetite of barytes,
——— potaſs,
——— ſoda.

702 Muriat of ſtrontites, 7. Muriat of ſtrontites. This ſalt was firſt formed by Dr Hope. Its cryſtals are very long, ſlender, hexagonal priſms. It has a peculiar, ſharp, penetrating taſte.

Three parts of theſe cryſtals are ſoluble in two parts of water at the temperature of 60°. Boiling water diſſolves any quantity of them whatever.

They contain 42 *per cent.* of water of cryſtallization.

They ſuffer no change when expoſed to the air except it be very moiſt ; in which caſe they deliqueſce.

When heated, they firſt undergo the watery fuſion, and are then reduced to a white powder. A very violent heat decompoſes this ſalt.

Muriatic acid precipitates this ſalt from its ſolution in water. That acid, therefore, has a ſtronger affinity for water than the ſalt has †.

703 Muriat of magneſia, 8. Muriat of magneſia. This ſalt abounds in ſea water.

It is not eaſily cryſtallized. Bergman's method was to evaporate it by a conſiderable heat to the proper degree of concentration, and then to expoſe it to a ſudden cold. By this method he obtained it in ſmall needles ‡.

It has a very bitter taſte. It is ſoluble in its own weight of water §, and in five parts of alcohol ||.

A ſaturated ſolution of it quickly forms a jelly ; on which if hot water be poured ſpongy maſſes are formed not even ſoluble in muriatic acid ¶.

It is compoſed, according to Bergman, of 34 parts of acid, 41 of earth, and 25 of water. According to Kirwan, 100 parts of magneſia require for ſaturation 104,275 of acid *.

It deliqueſces very ſpeedily when expoſed to the air.

A ſtrong heat decompoſes it. When dried in a high temperature, it is very cauſtic †.

The following ſubſtances decompoſe it by compound affinity :

Sulphat of ſoda,
——— ammonia,
——— alumina,
Nitrat of ammonia,
Acetite of potaſs,
——— ſoda,
——— ſilver ‡.

(Y) Only at the common temperature. At a high temperature carbonat of ammonia decompoſes muriat of magneſia. See *Weſtrum*, *Ann. de Chim.* ii. 118.

(Z) Bergman affirmed, that this ſalt decompoſed all the ſulphats, and propoſed it therefore as a certain means of diſcovering the preſence of ſulphuric acid, however combined in any ſolution ; for the ſulphat of barytes is almoſt entirely inſoluble in water. But Mr Piſſis has obſerved, that it does not decompoſe ſulphat of lime nor of potaſs. See *Ann. de Chim.* xv. 317.

Carbonat of barytes,
——— potaſs,

Carbonat of ſoda
——— ammonia (y).

704 Muriat of ammonia and magneſia,

9. Muriat of ammonia and magneſia. This triple ſalt was firſt mentioned, we believe, by Bergman. It may be formed by pouring ammonia into a ſolution of muriat of magneſia. Part of the magneſia is precipitated, but great part of it remains diſſolved, and combined with the acid and the ammonia. This triple ſalt is compoſed, according to Fourcroy, of 73 parts of muriat of magneſia and 27 of muriat of ammonia *.

* Ann. de Chim. iv. 222.

705 Muriat of alumina,

10. Muriat of alumina.—This ſalt cryſtallizes with difficulty. It has an aſtringent taſte. Its ſolution is gelatinous, and cannot be filtrated without much dilution in water. It is deliqueſcent. When evaporated to dryneſs, it forms a gummy maſs: in a ſtrong heat it is decompoſed.

The following ſalts decompoſe it by compound affinity:

Nitrat of ammonia,
Acetite of barytes,
——— potaſs,
——— ſoda,
——— lime,

Acetite of magneſia,
Carbonat of barytes,
——— potaſs,
——— ſoda,
——— ammonia.

706 Muriat of jargonia,

11. Muriat of jargonia.—This ſalt is eaſily formed by pouring muriatic acid on newly precipitated jargonia. It is colourleſs; its taſte is very aſtringent: by evaporation it furniſhes ſmall tranſparent cryſtals in needles, which loſe their tranſparence in the air. Muriat of jargonia is very ſoluble in water and in alcohol; to the flame of which it does not communicate any particular colour. Heat decompoſes it; and it is decompoſed likewiſe by the ſaliva when taken into the mouth.

When muriat of jargonia contains a little ſilica, it forms cubic cryſtals without conſiſtence, and reſembling a jelly. Theſe cryſtals, when expoſed to the air, gradually loſe their tranſparency, and diminiſh in volume, and there are formed in the middle of the ſalt white ſilky needle-ſhaped cryſtals.

Muriat of jargonia is decompoſed by ſulphuric acid; part of the ſulphat precipitates, and part remains diſſolved in the muriatic acid. When this acid is driven off by heat, the remainder of the ſulphat is gradually depoſited: if the evaporation be ſtopped before the maſs be reduced to dryneſs, it forms a kind of jelly when cold. It is alſo decompoſed by the phoſphoric, citric, tartarous, oxalic, and ſaccholactic acids, which form with jargonia inſoluble compounds that precipitate in white flakes.

The gallic acid poured into muriat of jargonia produces a white precipitate; but a green, bordering on grey, if the jargonia contain iron; and this laſt precipitate becomes, when dry, of a bright black colour, and reſembles China ink. The liquid preſerves a greeniſh colour; new portions of gallic acid produce no farther precipitation; but carbonat of ammonia ſeparates in great abundance a flaky matter of a purpliſh colour, not unlike that of the leys of wine. From theſe experiments it follows, that gallic acid has a greater affinity for jargonia than muriatic acid has; and that the gallats of jargonia and iron are ſoluble in muriatic acid.

Carbonat of potaſs decompoſes muriat of jargonia, and part of the carbonic acid combines with the earth, and renders it eaſily ſoluble in acids though dried.

Carbonat of ammonia occaſions a precipitate, which is moſtly diſſolved by adding more carbonat.

Pruſſiat of mercury produces an abundant precipitate, which is ſoluble in muriatic acid; and which conſequently is not muriat of mercury.

A plate of zinc, introduced into a ſolution of muriat of jargonia, occaſions a ſlight effervelcence; the liquor becomes milky, and in a few days becomes a white ſemitranſparent jelly.

Alumina decompoſes muriat of jargonia with the aſſiſtance of a ſlight heat: the alumina diſſolves, the liquor becomes milky, and aſſumes the form of a jelly. When the muriat contains iron, it remains in the ſolution, and the precipitated jargonia is quite pure. Here, then, is a method of freeing jargonia from iron *.

* Vauquelin, Ann. de Chim. xxii. 201.

707 Muriat of iron,

12. Muriat of iron.—Muriatic acid forms with the green oxide of iron a ſalt which cryſtallizes in flat needles. When expoſed to the air, they deliqueſce, and the green oxide attracts oxygen, and is gradually converted into a brown oxide. Heat decompoſes this ſalt.

708 Muriat of zinc,

13. Muriat of zinc.—This ſalt, procured by diſſolving zinc or its oxide in muriatic acid, does not cryſtallize. Its ſolution is colourleſs. When heated, it becomes of a blackiſh brown. By diſtillation, a part of the acid is ſeparated, and muriat of zinc remains behind of a milk-white colour, ſolid, and formed of ſmall radiated needles. It attracts moiſture in the air.

709 Muriat of mangaueſe,

14. Muriat of manganeſe.—Muriatic acid diſſolves the white oxide of manganeſe. Its ſolution affords by evaporation angular ſhining cryſtals †: They are deliqueſcent and ſoluble in alcohol ‡.

† Scheele on Manganeſe.

‡ Kirwan's Mineral. ii. 37.

710 Cobalt,

14. Muriat of cobalt.—The ſolution of oxide of cobalt in muriatic acid is of a pale red, except it be contaminated with nickel or iron, when it is greeniſh. It cryſtallizes in ſmall needles, which are very deliqueſcent. Heat decompoſes it.

711 Nickel,

16. Muriat of nickel.—This ſalt is deliqueſcent, and loſes its acid when expoſed to the air §.

§ Bergman, ii. 268.

712 Lead,

17. Muriat of lead.—Muriatic acid combines with oxide of lead eaſily enough: but this ſalt is more readily procured by pouring muriatic acid into a ſolution of nitrat of lead; the muriat immediately precipitates in the form of a white powder. It is ſoluble in 30 times its weight of boiling water; and the ſolution yields by evaporation ſmall, ſlender, brilliant needles in bundles.

It is ſomewhat deliqueſcent. When expoſed to heat, it melts into a brown maſs, formerly called *corneous lead*.

It is decompoſed by compound affinity by
Sulphat of ſilver ||,
Carbonat of ſoda.

|| Bergman

713 Tin,

18. Muriat of tin.—This ſalt may be formed by diſſolving tin in hot muriatic acid. By evaporation it affords needle-ſhaped cryſtals, which are deliqueſcent.

This ſalt has a ſtrong affinity for oxygen. It decompoſes oxy-muriatic, nitric, ſulphurous, arſenic, molybdic, and tungſtic acids, the red oxide of mercury, black oxide of manganeſe, oxide of antimony, zinc, ſilver,

---

(y) Only at a high temperature. See *Muriat of Ammonia*.

ver, and gold; and by that means is converted into oxy-muriat of tin. It even abſorbs oxygen when expoſed to the air *. Theſe compoſitions are doubtleſs produced by *diſpoſing affinity*.

714 Muriat of copper,

19. Muriat of copper.—This ſalt may be formed by diſſolving copper or its oxide in muriatic acid.

Its cryſtals are priſmatic. It is of a beautiful graſs green colour. It has a very aſtringent and cauſtic taſte. It deliqueſces when expoſed to the air. A moderate heat is ſufficient to melt it; and when cooled it congeals into a maſs. It requires a ſtrong heat to volatilize it.

It is decompoſed by nitrat of ſilver †.

715 Muriat of biſmuth,

20. Muriat of biſmuth.—This ſalt cryſtallizes with difficulty. By ſublimation it forms a ſoft fuſible ſubſtance, formerly called *butter of biſmuth*.

716 Antimony,

21. Muriat of antimony.—This ſalt is found native. It cryſtallizes in priſms. When heated it evaporates.

717 Arſenic,

22. Muriat of arſenic.—This ſalt cryſtallizes; it is very volatile, and not very ſoluble, in water ‡.

718 Mercury,

23. Muriat of mercury.—This ſalt may be prepared by pouring diluted muriatic acid into a diluted ſolution of nitrat of mercury: the muriat of mercury is immediately precipitated in the form of a white powder. Common ſalt may be uſed inſtead of muriatic acid. This ſalt was formerly called *white mercurial precipitate* and *calomel*.

It cryſtallizes; but the form of the cryſtals, which are very ſmall, has not been determined.

It has little taſte. It is almoſt inſoluble in water. It is uſed as a medicine.

It is decompoſed by ſulphat of ammonia §.

719 Muriat of ammonia and mercury,

24. Muriat of ammonia and mercury.—This triple ſalt was firſt diſcovered by Fourcroy. It may be formed by pouring ammonia into a ſolution of corroſive muriat of mercury. It has the appearance of a white powder. Its taſte is at firſt earthy, afterwards metallic. It is nearly inſoluble in water. According to Fourcroy's analyſis, it is compoſed of 81 parts of oxide of mercury, 16 of muriatic acid, and 3 of ammonia.

Heat decompoſes it; producing ammonia, azotic gas, and muriat of mercury.

Sulphuric, nitric, and muriatic acids decompoſe it ‖.

720 Muriat of ſilver,

25. Muriat of ſilver.—This ſalt may be formed by diſſolving oxide of ſilver in muriatic acid, or, which is better, by pouring muriatic acid into nitrat of ſilver; muriat of ſilver immediately precipitates. It is very little ſoluble in water; according to Monnet, one part of it requires 3072 parts of water.

When expoſed to a ſmall heat, it melts into a grey ſemitranſparent maſs, not unlike horn; hence it was formerly called *luna cornea*. A long continued heat decompoſes it. This ſalt is very cauſtic: it is employed as an eſcharotic under the name of *lunar cauſtic*.

721 Muriat of titanium.

26. Muriat of titanium has been formed by Mr Klaproth.

Sect. VI. *Of Oxy-muriats.*

Those ſalts, into which the oxy-muriatic acid enters as an ingredient, are called *oxy-muriats*. As we conſider the nitro-muriatic acid to be preciſely the ſame with the oxy-muriatic, its combinations of courſe muſt receive the ſame name.

722 Oxy-muriat of potaſs.

1. Oxy-muriat of potaſs.—This ſingular ſalt was diſcovered by Mr Berthollet in 1786. It may be formed by ſaturating a ſolution of potaſs with oxy-muriatic acid gas. By evaporating this ſolution in the dark, common muriat of potaſs is firſt obtained: When it is ſeparated, and the liquor allowed to cool, oxy-muriat of potaſs cryſtallizes.

Its cryſtals are rhomboids, of a ſilvery brilliancy.

It has an inſipid cooling taſte, reſembling that of nitre. It is ſoluble in 17 parts of water at the temperature of 60, and in 2½ parts of boiling water *. It does not deliqueſce in the air; but light converts it into common muriat by ſeparating oxygen. When heated, it melts, and gives out oxygen gas; and this is the beſt method hitherto diſcovered of obtaining that gas in a ſtate of purity. According to Mr Hoyle, it contains about half its weight of concrete oxygen †.

When mixed with charcoal, iron, and many other combuſtibles, and heated, it detonates with aſtoniſhing violence. This property induced the French chemiſts to propoſe it as a ſubſtitute for nitre in the preparation of gunpowder. The attempt was made at Eſſons in 1788; but no ſooner had the workmen begun to triturate the mixture of charcoal, ſulphur, and oxy-muriat, than it exploded with violence, and proved fatal to Mr Letors and Mademoiſelle Chevraud. The force of this gunpowder when it is prepared is much greater than that of the common ſort of powder; but the danger of preparing it, and even of uſing it after it is prepared, is ſo great, that it can hardly ever be ſubſtituted with advantage for common gunpowder.

Fourcroy and Vauquelin aſcertained by experiment, that this ſalt exploded when triturated with ſulphur, charcoal, antimony, arſenic, cinnabar, ſugar, gums, oils, alcohol, ether, and ſulphuret of iron. When theſe ſubſtances were mixed, and ſtruck with a hammer, the exploſion took place. The theory of theſe exploſions was firſt pointed out by Mr Berthollet. The oxygen of the oxy-muriatic acid combines with the combuſtible, and at the ſame time lets go a quantity of caloric; and trituration or percuſſion acts merely by bringing the particles which combine within the ſphere of each others attraction.

723 Oxy-muriat of ſoda,

2. Oxy-muriat of ſoda. This ſalt was diſcovered at the ſame time by Mr Berthollet. Its properties are the ſame with the laſt, except that it is too deliqueſcent to be uſed.

3. Oxy-muriat of ammonia.—This combination is impoſſible. The oxy-muriatic acid and ammonia decompoſe each other.

724 Oxy-muriat of barytes, lime, magneſia,

4. Oxy-muriat of barytes.
5. ——— ——— lime.
6. ——— ——— magneſia.

} Theſe ſalts were diſcovered by Berthollet alſo. They all poſſeſs the property of detonating with combuſtibles, and of being reduced by that means to the ſtate of common muriats. Mr Tennant has lately propoſed the oxy-muriat of lime as a ſubſtitute for the other ſubſtances formerly uſed in the new mode of bleaching; particularly for bleaching printed cottons: And, as far as we can learn, it anſwers the purpoſe remarkably well (z).

725 Oxy-muriat of mercury,

7. Oxy-muriat of mercury.—This ſalt was formerly called *corroſive ſublimate*, and afterwards *corroſive muriat of*

(z) We have been informed, that this ſalt had been uſed by bleachers in Scotland ſome years before Mr Tennant propoſed it.

* *Pelletier, Ann. de Chim.* xii. 225.

† *Bergman.*

‡ *Bergman,* ii. 293.

§ *Bergman.*

‖ *Fourcroy, Ann de Chim.* xiv. 47.

* *Hoyle, Nicholſon's Journal,* ii. 292.

† *Ibid.*

Oxy-muriat.

of mercury. Berthollet firſt pointed out the nature of its compoſition.

This ſalt was mentioned by Rhaſes in the 10th century; and it ſeems to have been known in the eaſt at a much earlier period (A). The methods of preparing it uſed by the older chemiſts were numerous, complicated, and generally concealed as ſecrets. We ſhall not attempt, therefore, to give any account of them; and the methods uſed by later chemiſts have been deſcribed at conſiderable length in the article CHEMISTRY (*Encycl.* n° 815.)

It may be prepared by diſſolving mercury in a ſufficient quantity of oxy-muriatic acid, or by diſſolving red oxide of mercury in common muriatic acid.

When carefully cryſtallized, this ſalt aſſumes the form of cubes or oblique parallelopipeds, or rather quadrangular priſms, with ſides alternately narrower, and terminated by two inclined planes meeting together.

It has an exceedingly diſagreeable metallic taſte.

It is ſoluble in 19 times its weight of water at the temperature of 50°*. Boiling water, according to Macquer, diſſolves half its weight of it. Alcohol, at the temperature of 70°, diſſolves $\frac{3}{8}$ths of its weight of this ſalt †.

* *Spielman.*

† *Macquer.*

It does not attract moiſture from the air.

It is ſoluble in ſulphuric, nitric, and muriatic acids.

When triturated with $\frac{3}{4}$ths of its weight of mercury and a little water, and then ſublimed, it forms a white inſipid ſalt, called formerly *calomel* or *ſweet mercury*: This, as Scheele has proved, is preciſely the ſame with common muriat of mercury.

The theory of theſe two preparations is now pretty obvious. The experiments of Adet and Pelletier have ſhewn, that oxy-muriatic acid may be obtained from corroſive muriat of mercury ‡. We may conclude, therefore, with confidence, that the ſalt is an oxy-muriat. It cannot be prepared by means of common muriatic acid, except with red oxide of mercury, or ſome other ſubſtance from which it may abſorb oxygen. When pure mercury is added to oxy-muriat, it ſeizes the oxygen from the oxy-muriat, and the whole is converted into common muriat.

‡ *Ann. de Chim.* i. 1. and xii. 225.

It is decompoſed by

Tartar,
Moſt metals.

726 Oxy-muriat of tin.

8. Oxy-muriat of tin. When an amalgam of tin is triturated with its own weight of corroſive muriat of mercury, and the mixture is diſtilled in a glaſs retort by means of a very gentle heat, there paſſes over a thick white ſmoke, which condenſes into a colourleſs liquor that emits copious fumes, and has been called, in conſequence, *ſmoking liquor of Libavius*. This liquor was examined by Mr Adet. He found, that when about $\frac{1}{3}$d part of water was added to this liquor, it ceaſed to fume, and aſſumed a cryſtalline form; that then it might even be made red hot without ſubliming. It therefore owes its volatility to want of water, or rather to a ſtrong attraction for water. He found that this ſubſtance was capable of diſſolving, and therefore of oxidating more tin, without the emiſſion of any hydrogen, and conſequently without the decompoſition of water; he concluded from this, that it was compoſed of oxy-muriatic acid and tin *. This has been completely proved by Mr Pelletier, who found that when oxide of tin was combined with oxy-muriatic acid, it formed a compound preciſely the ſame with the ſmoking liquor of Libavius †.

Phoſphats.

* *Ann. de Chim.* i. 3.

† *Ann. de Chim.* xiii. 225.

This ſalt may be prepared, as Pelletier has proved, by diſſolving tin in muriatic acid, and then ſaturating it with oxy-muriatic acid gas.

It is uſed in dyeing.

727 Oxy-muriat of iron.

9. Oxy-muriat of iron. This ſalt is deliqueſcent; colourleſs; of a pure bitter taſte, without any of the ſweet aſtringency of the common ſalts of iron ‡.

‡ *Lambe, Mancheſter Mem.* v. p. 1.

Few of the other oxy-muriats have been hitherto examined with attention: Many of the metals, indeed, have been diſſolved in aqua-regia; but in moſt of theſe ſolutions the ſalt produced is a common muriat. The nitric acid ſupplies oxygen, and the muriatic acid diſſolves the oxide.

SECT. VII. *Of Phoſphats.*

THOSE ſalts, into which phoſphoric acid enters as an ingredient, are called *phoſphats*. This claſs of ſalts was firſt diſcovered by Margraf.

728 Phoſphat of potaſs,

1. Phoſphat of potaſs. This ſalt cryſtallizes in ſhort tetrahedral priſms, terminated by quadrangular pyramids.

It is very ſoluble in cold water, and ſtill more ſo in hot water.

It decrepitates on ignited coals like common ſalt. When a very ſtrong heat is applied, it melts into an opaque vitreous maſs, ſtill ſoluble in water.

The following ſalts decompoſe it by compound affinity:

Sulphat of lime,
Nitrat of mercury,
Muriat of mercury,
Acetite of lead.

729 Phoſphat of ſoda,

2. Phoſphat of ſoda.—Dr Pearſon, who firſt formed this ſalt, gives the following proceſs for preparing it;

Diſſolve in a long-necked matraſs 1400 grains of cryſtallized carbonat of ſoda in 2100 grains of water at the temperature of 150°. Add gradually 500 grains of phoſphoric acid of the ſpecific gravity 1,85. Boil the liquor for ſome minutes; and while it is boiling hot, filtrate it, and pour it into a ſhallow veſſel. Let it remain in a cool place, and cryſtals will continue to form for ſeveral days. From the above quantities of materials he has obtained from 1450 to 1550 grains of cryſtals.

Its cryſtals are rhomboidal priſms, of which the acute angles are 60°, and the obtuſe angles 120°, terminated by a three-ſided pyramid.

Its taſte is almoſt the ſame with that of common ſalt.

It is ſoluble in water. When expoſed to the air it effloreſces.

This ſalt has been introduced into medicine as a purgative, and on account of its pleaſant taſte has of late been much uſed. It is uſually taken in broth, which it is employed to ſeaſon inſtead of common ſalt.

Hellot remarked a particular ſalt in urine, different from thoſe that had uſually been obſerved, in 1737. Haupt deſcribed it in 1740 under the name of *ſal mirabile*

(A) If we liſten to Junker, the ancients applied the name *mercurium* to this ſalt; mercury they called *argentum vivum*.

rabile perlatum, or *wonderful perlated ſalt*. It was called *perlated* from the grey, opaque, pearl-like colour which it aſſumed when melted by the blow-pipe. Margraf deſcribed it in 1745, and found it would not yield phoſphorus when treated with charcoal, as the other ſalts of urine did. Rouelle the Younger analyſed it in 1776, and concluded from his experiments that it was a compound of phoſphoric acid and ſoda; but Mr Prouſt, being unable to obtain phoſphorus from it, concluded, that it did not contain phoſphoric acid, but another acid analogous to the boracic. To this ſubſtance, which Mr Prouſt actually obtained, Bergman gave the name of *perlated acid*, and Morveau afterwards called it *ouretic acid*. But Mr Klaproth ſoon afterwards analyſed it, and proved that it conſiſted of ſoda ſuperſaturated with phoſphoric acid. Scheele ſoon after made the ſame diſcovery. This acid of Mr Prouſt, then, is merely phoſphat of ſoda combined with phoſphoric acid, or *acidulous phoſphat of ſoda*.

730 Phoſphat of ammonia,

3. Phoſphat of ammonia.—This ſalt forms oblong-pointed cryſtals, or, as Mr Lavoiſier affirms, cryſtals reſembling thoſe of alum.

It is ſoluble in water. Heat evaporates it ſo eaſily, that it is difficult to obtain it in cryſtals except by adding an exceſs of alkali.

Microcoſmic ſalt, or ſalt of urine, is merely a mixture of theſe two laſt deſcribed ſalts.

731 Of barytes,

4. Phoſphat of barytes.—This ſalt is inſoluble in water[*].

732 Of lime,

5. Phoſphat of lime.—This ſalt is taſteleſs, and almoſt perfectly inſoluble in water. It forms the baſis of bones, and is therefore often called *earth of bones*. Wenzel obſerved it cryſtallize when held in ſolution by phoſphoric acid.

It is decompoſed by ſulphat of ammonia[†].
Carbonat of potaſs[‡],
——— ſoda[§].

733 Of ſtrontites,

6. Phoſphat of ſtrontites.—This ſalt was firſt formed by Dr Hope. It is a white powder ſoluble in 1920 parts of boiling water[||].

734 Of magneſia,

7. Phoſphat of magneſia.—This ſalt does not cryſtallize except with exceſs of acid, and then the cryſtals are very ſmall. Somewhat longer cryſtals may be formed by dropping phoſphoric acid into acetite of magneſia. It moſt commonly forms by evaporation a gummy maſs. It is ſoluble in alcohol[¶].

It is inſoluble in nitric acid. It melts by a ſtrong heat into a porcelain-like ſubſtance[*].

735 Of alumina,

8. Phoſphat of alumina.—This is a ſaline powder, inſoluble in water. Diſſolved in phoſphoric acid, it yields a gritty powder, and a gummy ſolution, which by heat is converted into a tranſparent glaſs.

736 Of iron,

9. Phoſphat of iron.—This ſalt is merely a dry adheſive maſs, inſoluble in water, but ſoluble in acids. With exceſs of acid, it forms cryſtals which do not deliqueſce, and by heat are converted into a garnet-coloured glaſs[†].

737 Of zinc,

10. Phoſphat of zinc.—It does not cryſtallize, but when evaporated becomes a gummy maſs, which may be melted into a tranſparent glaſs[‡].

738 Of mangancſe,

11. Phoſphat of mangancſe.—The ſolution of the oxide of mangancſe in phoſphoric acid is reddiſh, but becomes white on expoſure to the air.

739 Of nickel,

12. Phoſphat of nickel.—It is greeniſh, and does not cryſtallize[§].

740 Of arſenic,

13. Phoſphat of arſenic.—It cryſtallizes in ſmall grains hardly ſoluble in water[*].

741 Of uranium,

14. Phoſphat of uranium.—Firſt formed by Klaproth. It does not cryſtallize, but aſſumes the appearance of yellowiſh white flakes, difficultly ſoluble in water.

742 James's powder.

15. Phoſphat of antimony and lime.—Dr Pearſon has diſcovered, that the well known medicine called *James's Powder* is a triple ſalt, compoſed of phoſphoric acid, oxide of antimony, and lime. It is very inſoluble in water.

The remaining phoſphats are ſcarcely known.

SECT. VIII. *Of Borats.*

THE compounds into which the boracic acid enters are called *borats*.

743 Borat of potaſs,

1. Borat of potaſs.—This ſalt, formed by combining boracic acid and potaſs, is very little known. Baron firſt formed it. Borat of potaſs cryſtallizes, is ſoluble in water, and may be melted into a vitreous maſs, ſoluble in water.

744 Of ſoda,

2. Borat of ſoda or borax.—This ſalt is brought from the Eaſt Indies in an impure ſtate under the name of *tinkal*. When purified in Europe, it takes the name of *borax*.

Its cryſtals are hexangular priſms, of which two ſides are much broader than the remainder, terminated by triangular pyramids. It is of a white colour. Its ſpecific gravity is 1,740.

Its taſte is ſtyptic and alkaline.

It is ſoluble in 18 times its weight of water of the temperature of 60°, and 6 times its weight of boiling water.

It is compoſed, according to Bergman, of 17 parts of ſoda, 39 of acid, and 44 of water.

When expoſed to the air, it effloreſces ſlowly and ſlightly.

When heated, it ſwells, loſes about four-tenths of its weight, becomes ropy, and then aſſumes the form of a light, porous, and very friable maſs, known by the name of *calcined borax*; it then melts into a tranſparent glaſs, ſtill ſoluble in water.

By compound affinity it is decompoſed by
Nitrat of mercury[†].

When two pieces of borax are ſtruck together in the dark, a flaſh of light is emitted[‡].

Borax has the property of facilitating the fuſion of a great number of bodies. This property renders it uſeful in glaſs-making, in aſſaying ores, and in ſoldering metals.

Borax turns ſyrup of violets green; it appears therefore to be ſuperſaturated with alkali.

The real borat of ſoda, or the ſalt in which boracic acid and ſoda ſaturate each other, has not yet been examined with attention. According to Dr Withering, ſoda requires twice its weight of boracic acid to ſaturate it.

745 Of ammonia,

3. Borat of ammonia.—This ſalt has been examined only by Mr Fourcroy.

Its cryſtals are polyhedral pyramids.

It has a poignant urinous taſte, and turns ſyrup of violets green. It diſſolves readily enough in water. When expoſed to the air, it gradually loſes its cryſtalline form and becomes brown[§].

4. Borat

Borats.

4. Borat of barytes.—Unknown.

746 Of lime,
5. Borat of lime.—It is difficultly ſoluble in water, and did not cryſtallize with Beaumé.

747 Of ſtrontites,
6. Borat of ſtrontites.—This ſalt was firſt formed by Dr Hope.—It is a white powder, ſoluble in about 130 parts of boiling water. The ſolution turns the ſyrup of violets green *.

* *Hope, Tranſ. Edin.* iv. 17.

748 Of magneſia,
7. Borat of magneſia.—It aſſumes the appearance of ſmall irregular cryſtals. It is ſoluble in acetous and formic acids. Alcohol decompoſes it. It melts eaſily in the fire without being decompoſed †.

† *Bergman*, ii. 386.

749 Of alumina,
8. Borat of alumina.—It does not cryſtallize, and is ſcarcely ſoluble in water.

750 Of iron,
9. Borat of iron.—Its cryſtals are of a yellow colour, but the ſalt has never been examined with attention.

751 Of zinc,
10. Borat of zinc.—This ſalt does not appear to be capable of cryſtallizing. By heat, it melts into a light green inſoluble ſlag ‡.

‡ *Reuſs.*

752 Cobalt,
11. Borat of cobalt.—When oxide of cobalt is melted with boracic acid, a bluiſh grey ſlag is produced. This, by lixiviation and evaporation, yields cryſtals of a reddiſh white colour and ramified form §.

§ *Id.*

753 Nickel,
12. Borat of nickel.—A ſaline ſubſtance difficultly ſoluble ‖.

‖ *Bergman.*

754 Lead,
13. Borat of lead.—When boracic acid and red oxide of lead are melted together, the product is a fine greeniſh yellow, tranſparent, hard, inſoluble glaſs ¶.

¶ *Reuſs.*

755 Tin,
14. Borat of tin.—When equal parts of boracic acid and tin filings are melted together, the product diſſolved in water yields by evaporation tranſparent white polygonous cryſtals.

756 Copper,
15. Borat of copper.—When borax is poured into a ſolution of ſulphat of copper, borat of copper is precipitated in the form of a pale light green jelly, which when dried is with great difficulty ſoluble in water. It eaſily melts into a dark red vitreous ſubſtance *. According to Palm, by long trituration of filings of copper and boracic acid in water, and then digeſting the mixture, it diſſolves, and cryſtals may be obtained from it.

* *Bergman.*

757 Biſmuth,
16. Borat of biſmuth.—A white powder, which melts into a white tranſparent permanent glaſs †.

† *Wenzel.*

758 Arſenic,
17. Borat of arſenic.—White oxide of arſenic and boracic acid form a ſalt ſoluble in water and cryſtallizable ‡.

‡ *Reuſs.*

Sect. IX. *Of Fluats.*

Those ſalts into which fluoric acid enters are called *fluats*. They were firſt formed by Scheele.

759 Fluat of potaſs,
1. Fluat of potaſs. It forms a gelatinous maſs almoſt without taſte.

It diſſolves readily in water. When expoſed to the fire it melts without any ebulition §.

§ *Scheele* on *Fluor.*

760 Soda,
2. Fluat of ſoda. This ſalt reſembles exactly the fluat of potaſs ‖.

‖ *Ibid.*

761 Ammonia,
3. Fluat of ammonia. It cryſtallizes in ſmall priſms. It is deliqueſcent, and is partly decompoſed by heat ¶. It is decompoſed by

Nitrat of mercury,
——— — ſilver,
——— — lead.

¶ *Wiegleb.*

762 Barytes,
4. Fluat of barytes. A powder which requires a large quantity of water to diſſolve it *.

* *Bergman.*

763 Lime,
5. Fluat of lime. This ſalt abounds in nature. It is known by the name of fluor ſpar.

It cryſtallizes moſt commonly in the form of cubes. It is taſteleſs and nearly inſoluble in water.

It is not altered by the air. Its ſpecific gravity is about 3,1.

When expoſed to a ſudden heat it decrepitates. A very violent heat melts it into a white opaque maſs.

When reduced to powder and heated it becomes phoſphoreſcent; but it loſes this quality altogether if it be heated red hot.

6. Fluat of ſtrontites. This ſalt was formed by Dr Hope: but its properties have not been examined.

764 Magneſia,
7. Fluat of magneſia.—It is not ſoluble in water except there be an exceſs of acid. In that caſe, by ſpontaneous evaporation, it forms hexagonal priſms, terminated by a low pyramid compoſed of three rhomboidal ſides.

These cryſtals are hardly ſoluble in water. Alcohol diſſolves a ſmall portion of them. Heat does not decompoſe them *.

* *Bergman*, ii. 384.

765 Alumina,
8. Fluat of alumina. A ſaline maſs; which is ſweetiſh, clammy, and gelatinous.

766 Silica,
9. Fluat of ſilica. Little is known concerning this ſingular combination, except that it can exiſt in a gaſeous form, and that it depoſites ſilica in cryſtals after a certain time.

10. Fluat of ſilica and potaſs or ſoda. This triple ſalt may be formed by pouring fixed alkali into a ſolution of fluat of ſilica. It contains an exceſs of acid. On evaporation it yields a kind of jelly, which when dry ſeparates into gritty particles like ſand. It is ſoluble in 96 parts of hot water. In the fire it readily melts into a white maſs. If the heat be continued the acid ſeparates, and there remains a tranſparent glaſs, which is ſoluble in water, and forms a *liquor ſilicum* †.

† *Scheele, Crell's Journal*, i. 207. Eng. Tranſl.

11. Fluat of iron. It is incryſtallizable; but when evaporated leaves a hard maſs.

12. Fluat of zinc. It reſembles that of iron.

767 Metallic fluats.
13. Fluat of manganeſe. It may be formed by pouring fluat of ammonia into a ſolution of oxide of zinc in any of the three mineral acids. It cryſtallizes.

14. Fluat of cobalt. A yellow gelatinous maſs.

15. Fluat of nickel. It affords green cryſtals.

16. Fluat of lead. A ſweet taſted powder.

17. Fluat of tin. A nauſeous taſted jelly.

18. Fluat of copper. Blue cryſtals; ſome of them oblong, others cubic.

19. Fluat of arſenic. Small cryſtals.

20. Fluat of mercury. A powder. Before the blowpipe it melts into a yellow glaſs, moſt of which evaporates by a continued heat ‡.

‡ *Scheele* on *Fluor.*

Sect. X. *Of Carbonats.*

The compounds into which the carbonic acid enters are called *carbonats*. They were firſt analyſed by Dr Black.

768 Carbonat of potaſs.
1. Carbonat of potaſs. This ſalt is formed by ſaturating potaſs with carbonic acid, which is beſt done by expoſing a ſolution of potaſs for a conſiderable time to carbonic acid gas.

It cryſtallizes, according to Bergman, in quadrangular priſms; the apexes of which are compoſed of two inverted triangles, converging like the roof of a houſe ‖. According to Pelletier they are tetrahedral rhomboidal priſms, with dihedral ſummits. The complete cryſtal has eight faces, two hexagons, two rectangles, and four rhombs ¶.

‖ *Bergman.*

* *Ann. de Chim.* xv. 39.

It

It has an alkaline, but not a cauſtic taſte.

It is ſoluble at the common temperature in about four times its weight in water *. Boiling water diſſolves $\frac{5}{6}$ths of its weight †. Alcohol, even when hot, does not diſſolve above $\frac{1}{1200}$ parts of it.

According to Bergman, it is compoſed of 48 parts of potaſs, 20 of acid, and 32 of water. According to Pelletier, of 43 parts of acid, 40 of potaſs, and 17 of water. Bergman under-rated the quantity of acid from not obſerving that the ſalt loſes part of its acid when heated. Even ſolution in hot water produces a ſeparation of ſome acid ‡.

It is not altered by expoſure to the air.

Heat deprives it of its water and part of its acid, but does not decompoſe it completely. The following ſalts decompoſe it by compound affinity :

Sulphat of lime,
——— barytes,
——— ſoda,
——— ammonia,
——— magneſia,
——— alumina,
Muriat of barytes,
——— lime,
——— ammonia,
——— magneſia,
——— alumina,
——— ſoda §,
Nitrat of lime,
Nitrat of barytes,
——— ſoda,
——— ammonia,
——— magneſia,
——— alumina,
Acetite of barytes,
——— lime,
——— ammonia,
——— magneſia,
——— alumina,
Oxy-muriat of mercury,
Phoſphat of lime ‖.

When potaſs is ſaturated with carbonic acid it always lets fall a quantity of ſilica. Mr Pelletier has propoſed this ſaturation as the beſt method of purifying potaſs from that earth.

769 Carbonat of ſoda,

2 Carbonat of ſoda. This ſalt may be formed in the ſame manner with carbonat of potaſs.

Its cryſtals are five-ſided priſms, with one of the angles frequently truncated, ſurmounted by dihedral pyramids with rhomboidal faces.

Its taſte is preciſely the ſame with that of carbonat of potaſs.

It is ſoluble in double its weight of cold water.

It is compoſed, according to Bergman, of 16 parts of acid, 20 of alkali, and 64 of water.

It effloreſces when expoſed to the air. Heat is incapable of decompoſing it completely ¶.

The following ſalts decompoſe it by compound affinity :

Sulphat of ammonia,
——— barytes,
——— lime,
——— magneſia‡,
——— alumina,
Muriat of barytes,
——— ammonia,
——— lime,
——— magneſia,
——— alumina,
Acetite of barytes,
——— ammonia,
——— lime,
——— magneſia,
——— alumina,
Nitrat of ammonia,
——— magneſia,
——— alumina,
——— lead*,
Phoſphat of lime †.

770 Carbonat of ammonia,

3. Carbonat of ammonia. This ſalt forms octahedral cryſtals, having for the moſt part their two oppoſite apexes truncated ‡.

Its taſte and ſmell, though much weaker, are the ſame with thoſe of pure ammonia. Like all the alkaline carbonats it converts vegetable blues to green, preciſely as pure alkalies do.

It is ſoluble in rather leſs than twice its weight of cold water. Hot water diſſolves its own weight of it.

According to Bergman it is compoſed of 43 parts of alkali, 45 of acid, and 12 of water.

When expoſed to the air it becomes ſomewhat moiſt.

The ſmalleſt heat is ſufficient to evaporate it.

The following ſalts decompoſe it by compound affinity:

Sulphat of alumina,
Nitrat of lime,
Muriat of lime,
——— magneſia,
——— alumina,
Acetite of barytes,
——— lime,
——— magneſia,
——— alumina.

771 Carbonat of barytes,

4. Carbonat of barytes. This ſalt has been found native.

Its cryſtals have been obſerved to aſſume four different forms; double ſix-ſided and double four-ſided pyramids, ſix-ſided columns terminated by a pyramid with the ſame number of faces, and ſmall radiated cryſtals $\frac{1}{2}$ an inch in length, and very thin, appearing to be hexagonal priſms, rounded towards the point.

Cold water diſſolves $\frac{1}{2304}$ part, and boiling water $\frac{1}{1304}$ part of this ſalt. Water ſaturated with carbonic acid diſſolves $\frac{1}{830}$th part*.

According to Dr Withering, who firſt diſcovered it native, it is compoſed of 80 parts of barytes and 20 of acid. Bergman informs us, that artificial carbonat is compoſed of 7 parts of acid, 28 of water, and 65 of earth †.

It is not altered by expoſure to the air.

It is decompoſed by the application of a very violent heat ‡.

By compound affinity it is decompoſed by the following ſalts :

Sulphat of ſoda,
——— lime,
——— ammonia,
——— magneſia,
——— alumina,
Nitrat of ſoda,
——— lime,
——— ammonia,
——— magneſia,
Nitrat of alumina,
Muriat of lime,
——— ammonia,
——— magneſia,
——— alumina,
Acetite of lime,
——— magneſia,
——— alumina.

772 Carbonat of lime.

5. Carbonat of lime. This ſubſtance, under the names of marble, chalk, lime ſtone, &c. exiſts in great abundance in nature, variouſly mixed with other bodies.

When pure, it is of a white colour, and has very little taſte.

It is inſoluble in pure water; but water ſaturated with carbonic acid diſſolves $\frac{1}{1500}$ part of it ; from this ſolution it gradually precipitates as the acid leaves it in the form of ſmall rhomboidal cryſtals §.

It is compoſed, according to Bergman, of 34 parts of acid, 11 of water, and 55 of lime.

It ſuffers little or no alteration by being expoſed to the air.

When expoſed to heat, it firſt loſes its water, and afterwards its acid ſeparates as the heat is increaſed : But to ſeparate the acid completely, a very ſtrong heat is required.

The following ſalts decompoſe it by compound affinity :

Sulphat of alumina,
——— copper.

773 Carbonat of ſtrontites,

6. Carbonat of ſtrontites. This ſalt, which was firſt examined by Dr Hope, is inſipid, and ſoluble in 1536

parts

† Bergman, i. 21.

‡ Dr Hope.

§ Bergman, i. 21.

parts of boiling water. It is compoſed of 30,2 parts of acid, 69,8 of ſtrontites. A violent heat decompoſes it *.

774 Carbonat of magneſia. 7. Carbonat of magneſia. This ſalt may be formed by ſaturating the common magneſia of the ſhops with carbonic acid gas.

It diſſolves in water ſaturated with carbonic acid; and forms by evaporation cryſtals, which are tranſparent hexagonal priſms, terminated by a hexagonal plane; theſe are partly in groups and partly ſolitary: their length is about ſix lines, their breadth two †. They were diſcovered by Mr Butini of Geneva.

Water at the temperature of 50 diſſolves $\frac{1}{18}$ part of its weight of this ſalt ‡. When in the ſtate of powder, and of courſe deprived of its water of cryſtallization, it is much more inſoluble; and what is very remarkable, it is more ſoluble in cold than in hot water, impregnated with carbonic acid §.

It is compoſed, according to Fourcroy, of 50 parts of acid, 25 of magneſia, and 25 of water.

When expoſed to the air, it effloreſces, and falls into powder ||.

When heated, it decrepitates, falls into powder, and is decompoſed ¶.

The following ſalts decompoſe it by compound affinity:

Sulphat of lime,
——— ammonia,
——— alumina,

Nitrat of lime,
Muriat of lime,
Acetite of lime.

775 Carbonat of alumina. 8. Carbonat of alumina. Carbonic acid is capable of diſſolving alumina; for if alum be decompoſed by an alkaline carbonat, ſome alumina remains diſſolved in the liquor, and may be precipitated by a heat ſufficient to drive off the carbonic acid *. It cannot be doubted, then, that there may be produced a carbonat of alumina; but the ſalt has never been examined with accuracy.

776 Metallic carbonats. 9. Carbonat of iron. Water ſaturated with carbonic acid diſſolves $\frac{1}{10500}$ part of its weight of iron, which gradually precipitates by expoſure to the air †. Ruſt of iron is a kind of carbonat, at leaſt it always contains carbonic acid.

10. Carbonat of zinc. Zinc is copiouſly diſſolved by water ſaturated with carbonic acid ‡. As the metallic oxides, when ſaturated with carbonic acid, do not differ materially in their appearance from pure oxides, we ſhall not attempt to deſcribe any of the metallic carbonats. We ſhall, however, preſent our readers with the following Table, exhibiting a view of the weight which metallic oxides gain by being ſaturated with this acid.

	By Bergman.	By Wenzel.
	Precipitated by	
	Carb. of Soda.	Carb. of Potaſs.
100 parts of	Weight.	Weight.
Oxide of zinc,	100,930	100,774
iron,	100,250	100,863
mangaueſe,	100,800	
cobalt,	100,600	
nickel,	100,350	
lead,	100,320	100,304
tin,	100,310	100,345
copper,	100,940	100,884
biſmuth,	100,300	100,224
antimony,	100,400	100,395

gold,	100,060	100,326

* Hope, Tranſ. Edin. iv. 5.

† Butini ſur la Magneſie.

‡ Fourcroy, Ann. de Chim. ii. 298.

§ Butini.

|| Fourcroy, ibid.

¶ Id. ibid.

* Bergman, i. 11.

† Bergman, i. 33.

‡ Ibid.

Quantity of loſs by driving off the gas by ſolution according to Wenzel:

Zinc,	0,137
Iron,	0,009
Cobalt,	0,352
Lead,	0,157
Tin,	0,000
Copper,	0,174
Biſmuth,	0,056
Antimony,	0,000
Mercury,	0,038
Silver,	0,158
Gold,	0,144

Theſe determinations differ too widely from each other to be exact. It is obvious that part of the weight muſt be owing to adhering water, and very probably triple ſalts are formed, which muſt render the determination ſtill more erroneous.

Sect. XI. *Of Acetites.*

The compounds which the acetous acid forms are called *acetites*.

777 Acetite of potaſs. 1. Acetite of potaſs. Pliny is ſuppoſed, but probably without any reaſon, to have been acquainted with this ſalt, becauſe he recommends a mixture of vinegar and vine aſhes as a cure for a particular ſpecies of tumor *. It was firſt clearly deſcribed by Raymond Lully. It has received a great number of names; as, for inſtance, *arcanum tartari*, *ſecret foliated earth of tartar*, *eſſential ſalt of wine*, *regenerated tartar*, *diuretic ſalt*, *digeſtive ſalt of Sylvius*.

Its cryſtals are very white, and aſſume the form of thin plates.

It has a ſharp warm taſte.

It is ſoluble in about ten times its weight of water at the temperature of 60° †. It is ſoluble alſo in alcohol.

According to Wenzel, 240 parts of acetous acid require for ſaturation $241\frac{4}{9}$ths of potaſs. And from the experiments of Dr Higgins, it appears that acetite of potaſs is compoſed of 61,5 parts of alkali and 38,5 of acetous acid and water ‡.

When expoſed to the air it is very deliqueſcent.—When heated, it melts as readily as wax; and if a very ſtrong heat be applied, the acid is decompoſed.

The following ſalts decompoſe it by compound affinity:

Sulphat of ſoda,
——— lime,
——— ammonia,
——— magneſia,
——— alumina,
Nitrat of ſoda,
——— lime,

Nitrat of ammonia,
——— magneſia,
——— alumina,
——— biſmuth,
——— mercury,
Muriat of ammonia,
——— alumina.

778 Acetite of ſoda. 2. Acetite of ſoda. This ſalt was firſt deſcribed by Mr Baron.

Its cryſtals are ſtriated priſms, not unlike thoſe of ſulphat of ſoda.

It has a ſharp taſte, approaching to bitter.

It is ſoluble in 2,86 parts of water at the temperature of 60° §.

According to Wenzel, 440 parts of acetous acid require for ſaturation $157\frac{1}{7}$ths of ſoda.

It is not affected by expoſure to the air.

When heated, it firſt loſes its water of cryſtallization;

* Plinii, l. xxiii. præmium.

† Bergman, v. 78.

‡ On Acetous Acid, p. 8.

§ Bergman, ibid.

in a ſtrong heat it melts; and in a ſtill ſtronger, its acid is deſtroyed. This ſalt can only be obtained in cryſtals when there is an exceſs of alkali in the ſolution.

The following ſalts decompoſe it by compound affinity :

Sulphat of ammonia,
——— alumina,
Nitrat of ammonia,
——— magneſia,
Nitrat of alumina,
Muriat of lime,
——— ammonia,
——— magneſia.

779
Acetite of ammonia.

3. Acetite of ammonia. This ſalt was formerly called *ſpirit of Mindererus*.

It is too volatile to be eaſily cryſtallized : It may, however, by gentle evaporation, be made to depoſite needle-ſhaped cryſtals. Mr de Laſſone cryſtallized it by ſublimation *. When the ſublimation is ſlow, it forms long, ſlender, flatted cryſtals, terminating in ſharp points, of a pearl white colour, and about an inch and eight-tenths in length †.

It impreſſes the tongue at firſt with a ſenſe of coldneſs, and then of ſweetneſs, which is followed by a taſte reſembling that of a mixture of ſugar and nitre, in which the ſweet does not predominate over the mawkiſh taſte of the nitre ‡.

According to Wenzel, 240 parts of acetous acid ſaturate 244 of ammonia.

It is very deliqueſcent. It melts at 170°, and ſublimes at about 250° §.

When a watery ſolution of this ſalt is diſtilled, there comes over firſt a quantity of ammonia, next a quantity of acetous acid, and at laſt of the neutral ſalt itſelf. No ſuch decompoſition takes place when the cryſtals are diſtilled by a moderate heat ‖.

The following ſalts decompoſe acetite of ammonia by compound affinity :

Sulphat of alumina,
Carbonat of potaſs,
Carbonat of ſoda,
Nitrat of ſilver ¶.

780
Acetite of barytes.

4. Acetite of barytes. This ſalt was firſt formed by Mr Morveau.

It is not eaſily cryſtallized. Morveau procured it in long priſms in groups.

It has a pleaſant, ſomewhat acid taſte, and always contains an exceſs of acid.

It is ſoluble in water, and does not deliqueſce when expoſed to the air *.

The following ſalts decompoſe it by compound affinity :

Sulphat of potaſs,
——— ſoda,
——— lime,
——— ammonia,
——— magneſia,
——— alumina,
Nitrat of potaſs,
——— ſoda,
——— lime,
——— ammonia,
——— magneſia,
Nitrat of alumina,
Muriat of potaſs,
——— ſoda,
——— lime,
——— ammonia,
——— magneſia,
——— alumina,
Carbonat of potaſs,
——— ſoda,
——— ammonia.

781
Acetite of lime.

5. Acetite of lime. This ſalt was firſt deſcribed accurately by Crollius. The ancients, however, uſed a mixture of lime and vinegar in ſurgery †.

It cryſtallizes in fine needles, of a gloſſy appearance like ſatin.

Its taſte is bitter and ſour, becauſe it has an exceſs of acid.

It is ſoluble in water.

According to Wenzel, 240 parts of acetous acid require for ſaturation 125 of lime : according to Maret, 100 parts of acetite of lime contain 50 of lime *. From the experiments of Dr Higgins, it follows, that acetite of lime is compoſed of 35,7 parts of lime and 64,3 of acetous acid and water †.

It is not altered by expoſure to the air ; at leaſt Morveau kept ſome of it for a whole year merely covered with paper, and even quite uncovered for a month, without its undergoing any alteration ‡.

Heat decompoſes it, and at the ſame time partly decompoſes its acid.

The following ſalts decompoſe it by compound affinity :

Sulphat of ſoda,
——— ammonia,
——— magneſia,
——— alumina,
Nitrat of ammonia,
——— magneſia,
——— alumina,
Muriat of ammonia,
Muriat of alumina,
Carbonat of barytes,
——— potaſs,
——— ſoda,
——— ammonia,
——— magneſia,
——— alumina.

782
Acetite of ſtrontites.

6. Acetite of ſtrontites. This ſalt was firſt formed by Dr Hope. It forms ſmall cryſtals, which are not affected by expoſure to the atmoſphere. 49 parts of it are ſoluble in 120 parts of boiling water : It ſeems to be nearly as ſoluble in cold water. It renders vegetable colours green §.

783
Acetite of magneſia.

7. Acetite of magneſia. This ſalt was firſt mentioned by Mr Wenzel.

It is not cryſtallizable ; but forms by evaporation a viſcid maſs ‖.

It has a ſweetiſh taſte ; leaving, however, a ſenſe of bitterneſs ¶.

It is very ſoluble both in water and alcohol *.

According to Wenzel, 240 parts of acetous acid require for ſaturation $123\frac{3}{4}$ths of magneſia.

When expoſed to the air, it deliqueſces. Heat decompoſes it.

The following ſalts decompoſe it by compound affinity :

Sulphat of ammonia,
——— alumina,
Nitrat of ammonia,
——— alumina,
Muriat of ammonia,
——— alumina,
Carbonat of barytes,
——— potaſs,
——— ſoda,
——— ammonia,
——— alumina.

784
Acetite of alumina.

8. Acetite of alumina. This ſalt can only be formed by digeſting acetous acid on alumina recently precipitated.

By evaporation needle-ſhaped cryſtals are obtained, which are very deliqueſcent. According to Wenzel, 240 parts of acetous acid require $20\frac{5}{7}$ths of alumina for ſaturation.

This ſalt is decompoſed by compound affinity by the following ſalts :

Nitrat of ammonia,
Muriat of ammonia,
Carbonat of barytes,
Carbonat of potaſs,
——— ſoda,
——— ammonia.

785
Acetite of jargonia.

9. Acetite of jargonia. This ſalt may be formed by pouring acetous acid on newly precipitated jargonia. It has an aſtringent taſte. It does not cryſtallize ; but when evaporated to dryneſs, it forms a powder, which does not attract moiſture from the air as acetite of alumina does †. It is very ſoluble in water and in alcohol.

hol. It is not ſo eaſily decompoſed by heat as nitrat of jargonia, probably becauſe it does not adhere ſo ſtrongly to water *.

786 Acetite of iron.

10. Acetite of iron.—This ſalt was mentioned by Schrœder and Juncker. It is compoſed of acetous acid and brown oxide of iron.

Its ſolution forms by gentle evaporation ſmall oblong cryſtals; but the greateſt part of the ſalt aſſumes the form of a gelatinous maſs †.

It has a ſweetiſh ſtyptic taſte.

According to Wenzel, 240 parts of acetous acid require for ſaturation $186\frac{1}{2}$ of iron.

Heat decompoſes this ſalt; and it ſeems alſo to be gradually decompoſed by expoſure to the air.

787 Acetite of zinc.

11. Acetite of zinc.—This ſalt was firſt mentioned by Glauber.

Its cryſtals are rhomboidal, and ſometimes hexagonal plates, of a white colour, and the appearance of talk.

It is ſoluble in water. According to Wenzel, 240 parts of acetous acid require for ſaturation $195\frac{5}{6}$ths of zinc.

It is not altered by expoſure to the air. Heat decompoſes it. When thrown upon burning coals, it explodes with a blue flame.

12. Acetite of mangaueſe.—This ſalt is not cryſtallizable; and when evaporated to dryneſs, it deliqueſces. Is it not an acetat?

788 Acetite of cobalt.

13. Acetite of cobalt.—This ſalt is deliqueſcent. Its ſolution is of a fine red colour while cold; but becomes blue by being heated, and it recovers its former colour on cooling. According to Wenzel, 240 parts of acetous acid require for ſaturation $241\frac{5}{7}$ths of cobalt.

789 Acetite of nickle.

14. Acetite of nickel.—This ſalt forms rhomboidal cubes of a green colour ‡: They are not deliqueſcent: Their taſte is ſweet §.

790 Acetite of lead.

15. Acetite of lead.—This ſalt is mentioned by Iſaac Hollandus and Raymond Lully. It is compoſed of acetous acid and white oxide of lead.

It was formerly called *ſugar of lead*, *ſugar of Saturn*, *ſalt of Saturn*, *vinegar of Saturn*, *extract of Saturn*, &c.

Its cryſtals are flat parallelopipeds, terminated by two inclined planes approaching each other.

It has a ſweet and ſomewhat aſtringent taſte.

It is not very ſoluble in water; but acetous acid diſſolves it abundantly.

According to Wenzel, 240 parts of acetous acid require for ſaturation 503 of lead.

When expoſed to the air it becomes yellow, but undergoes no other alteration.

Heat decompoſes it by deſtroying the acid. When diſtilled, the reſiduum takes fire ſpontaneouſly on expoſure to the air. Paper dipped into acetite of lead forms excellent matches, which are not ſubject to go out, and which burn very ſlowly.

The following ſalts decompoſe it by compound affinity:

Muriat of ammonia,	Phoſphat of ammonia,
Sulphat of copper,	Oxalat of potaſs ‖,
Phoſphat of ſoda,	Malat of potaſs ¶.

791 Acetite of tin.

16. Acetite of tin.—This ſalt was firſt deſcribed by Lemery.

Its cryſtals are priſmatic needles in groups *. According to Wenzel, 240 parts of acetous acid require for ſaturation $3\frac{5}{11}$ of tin.

792 Acetite of copper.

17. Acetite of copper.—This ſalt was known to the ancients, and various ways of preparing it are deſcribed by Pliny *. It was formerly known by the names of *cryſtals of Venus and verdigriſe*.

It is of a deep green colour. Its cryſtals are rhomboids.

It has a diſagreeable coppery taſte.

It is ſoluble in water and in alcohol.

According to Wenzel, 240 parts of acetous acid require $16\frac{1}{8}$th of copper for ſaturation.

It effloreſces when expoſed to the air. Heat decompoſes it. It is uſed in painting.

793 Acetite of biſmuth.

18. Acetite of biſmuth.—This ſalt ſeems to have been firſt mentioned by Geoffroi. He called it *ſugar of biſmuth*.

It is moſt eaſily procured by mixing together the ſolutions of nitrat of biſmuth and acetite of potaſs. It forms brilliant, talky, ſilvery cryſtals.

It has a ſweetiſh taſte. According to Wenzel, 240 parts of acetous acid require for ſaturation $15\frac{5}{7}$ths of biſmuth.

It does not deliqueſce when expoſed to the air. Heat decompoſes it.

794 Acetite of antimony.

19. Acetite of antimony.—It yields with difficulty ſmall cryſtals †. According to Wenzel, 240 parts of acetous acid require for ſaturation $1\frac{1}{3}$d of antimony.

795 Acetite of arſenic.

20. Acetite of arſenic.—This ſalt forms ſmall cryſtals in grains, hardly ſoluble in water ‡.

796 Acetite of mercury.

21. Acetite of mercury.—This ſalt is mentioned by Schrœder.

Its cryſtals are ſmall thin plates.

It has a diſagreeable taſte, and excites coughing.

It is hardly ſoluble in water. According to Wenzel, 240 parts of acetous acid require for ſaturation $240\frac{1}{7}$ths of mercury.

When expoſed to the air it becomes black, owing to the reduction of the oxide of mercury. Heat decompoſes it.

797 Acetite of ſilver.

22. Acetite of ſilver.—This ſalt was perhaps firſt deſcribed by Margraf.

It is beſt formed by dropping acetite of ſoda or potaſs into a ſaturated ſolution of nitrat of ſilver §.

It forms ſmall oblong cryſtals, eaſily diſſolved in water †. It has a ſharp taſte.

According to Wenzel, 240 parts of acetous acid require for ſaturation $101\frac{4}{9}$ths of ſilver.

Heat decompoſes it. It is decompoſed by muriat of magneſia ¶.

798 Acetite of gold.

23. Acetite of gold.—This ſalt is mentioned by Schrœder and Juncker.

799 Acetite of uranium.

24. Acetite of uranium.—This ſalt was firſt formed by Klaproth.

Its cryſtals are regular four-ſided ſlender priſms, terminated at both ends by regular quadrilateral pyramids: they are tranſparent, and of a beautiful topaz yellow colour.

Heat decompoſes them: and what is ſingular, if they be heated gradually red hot, the oxide which remains retains nearly the form of the cryſtals *.

800 Acetats.

The compounds into which the acetic acid enters are called *acetats*. They are ſo imperfectly known at preſent, that we ſhall not attempt a deſcription of them.

Sect. XII. *Of Oxalats.*

The compounds of which oxalic acid forms a part are

are known by the name of *oxalats*. They were firſt deſcribed by Bergman.

801 Oxalat of potaſs.

1. Oxalat of potaſs.—This ſalt cryſtallizes with difficulty. It is very ſoluble in water. When heated it falls to powder *.

802 Acidulous oxalat of potaſs.

2. Acidulous oxalat of potaſs.—The oxalic acid is alſo capable of combining with potaſs in exceſs, and forming another ſalt, called *acidulous oxalat* from its acid taſte; or, to ſpeak more accurately, this ſalt is formed by the combination of oxalat of potaſs with oxalic acid. This ſalt exiſts ready formed in *oxalis acetoſella* or woodſorrel; from which it is extracted in ſome parts of Europe in great quantities. Hence it was formerly called ſalt of wood ſorrel. It is mentioned by Duclos in the Memoirs of the French Academy for 1668. Margraf firſt proved that it contained potaſs; and Scheele diſcovered that its acid is the oxalic. A great many intereſting experiments had been previouſly made on it by Wenzel and Wiegleb.

It may be formed, as Scheele has ſhown, by dropping potaſs very gradually into a ſaturated ſolution of oxalic acid and water: as ſoon as the proper quantity of alkali is added, acidulous oxalat is precipitated. But care muſt be taken not to add too much alkali, otherwiſe no precipitation will take place at all.

Its cryſtals are ſmall opaque parallelopipeds †.

It has an acid, poignant, bitteriſh taſte.

It is ſoluble in about ten times its weight of boiling water, but much leſs ſoluble in cold water.

It is not altered by expoſure to the air. Heat decompoſes it.

This ſalt is ſold in this country under the name of *eſſential ſalt of lemons*.

803 Oxalat of ſoda.

3. Oxalat of ſoda.—This ſalt agrees very much with oxalat of potaſs. Its cryſtals are ſmall, and ſoluble in water.

From Bergman's deſcription, oxalic acid appears alſo capable of combining in exceſs with ſoda, and forming an acidulous oxalat.

804 Oxalat of ammonia.

4. Oxalat of ammonia.—Its cryſtals are four-ſided priſms, generally diverging from various points. They redden the infuſion of turnſole.

They are eaſily ſoluble in water, but not in alcohol ‡.

It is decompoſed by nitrat of barytes §.

805 Earthy oxalats.

5. Oxalat of barytes.—This ſalt does not cryſtallize except with exceſs of acid. The addition of potaſs, or even of water, deprives it of this exceſs, and then it crumbles into powder. It is inſoluble in water ‖.

6. Oxalat of lime.—This ſalt does not cryſtallize. It is inſoluble in water, but ſomewhat ſoluble in acids. It is compoſed of 48 parts of acid, 46 of lime, and 6 of water. Heat decompoſes it ¶.

7. Oxalat of ſtrontites.—This ſalt was firſt formed by Dr Hope. It is a white inſipid powder; ſoluble in 1920 parts of boiling water. Heat decompoſes it by deſtroying the acid *.

8. Oxalat of magneſia.—This ſalt is in the form of a white powder. It is ſcarcely ſoluble either in water or alcohol. It is compoſed of 35 parts of magneſia and 65 of acid and water. Heat decompoſes it †.

9. Oxalat of alumina.—It is uncryſtallizable; but furniſhes on evaporation a yellowiſh pellucid maſs. It is ſparingly ſoluble in alcohol. It has a ſweet aſtringent taſte. It is compoſed of 44 parts of alumina and 56 of acid and water. When expoſed to the air it deliqueſces; and if it has been previouſly well dried, its weight is increaſed by $\frac{2}{3}$. It reddens turnſole *.

806 Metallic oxalats.

10. Oxalat of iron.—This ſalt forms priſmatic cryſtals of a yellowiſh green colour.

It has an aſtringent and ſweet taſte. It is very ſoluble in water.

It is compoſed of 45 parts of green oxide, and 55 of acid and water. When expoſed to heat it falls to powder †.

From Bergman's deſcription, the brown oxide of iron appears alſo capable of combining with oxalic acid. The compound does not cryſtallize, and is nearly inſoluble in water ‡.

11. Oxalat of zinc.—It is hardly ſoluble in water.

It is compoſed of 75 parts of oxide and 25 of acid.

12. Oxalat of manganeſe.—It is compoſed of oxalic acid and white oxide of manganeſe. It appears capable of cryſtallizing §.

13. Oxalat of cobalt.—This is a roſe-coloured powder, inſoluble in water, but ſoluble in oxalic acid; and capable, by that means, of cryſtallizing ‖.

14. Oxalat of nickel.—This is a green coloured powder, hardly ſoluble in water. It is compoſed of two parts of acid and one of oxide ¶.

15. Oxalat of lead.—It forms ſmall cryſtalline grains. They are inſoluble in alcohol, and nearly inſoluble in water. They contain 55 parts of oxide and 45 of acid *.

16. Oxalat of tin.—This ſalt forms priſmatic cryſtals. It has an auſtere taſte. If the ſolution of this ſalt be quickly evaporated, it affords a maſs reſembling horn, and ſoluble in water †.

17. Oxalat of copper.—This ſalt is uncryſtallizable. It is a bluiſh powder, inſoluble in water, except with exceſs of acid. It is compoſed of 21 parts of copper and 29 of acid ‡.

18. Oxalat of biſmuth.—This ſalt may be formed by dropping oxalic acid into a ſolution of nitrat of biſmuth. It forms pellucid polygonous cryſtals. When oxide of biſmuth is diſſolved by oxalic acid, the reſult is a white powder, ſcarcely ſoluble in water §.

19. Oxalat of antimony.—This ſalt forms cryſtalline grains, with difficulty ſoluble in water †.

20. Oxalat of arſenic.—This ſalt is compoſed of oxalic acid and white oxide of arſenic. Its cryſtals are priſms very ſoluble in water and alcohol. It reddens turnſole.

Heat ſublimes it; and by a ſtrong heat it may be decompoſed ¶.

21. Oxalat of mercury.—A white powder, hardly ſoluble in water, except with exceſs of acid *.

22. Oxalat of ſilver.—This ſalt may be formed by pouring oxalic acid into a ſolution of nitrat of ſilver. It is a white powder, ſcarcely ſoluble in water, and not at all in alcohol; but ſoluble in nitric acid. It becomes black by being expoſed to the air, owing to the reduction of the oxide †.

23. Oxalat of platinum.—This ſalt affords yellow cryſtals.

SECT. XIII. *Of Tartrites.*

THE ſalts into which tartarous acid enters as an ingredient are known by the name of *tartrites*.

807 Tartar.

1. Acidulous oxalat of potaſs or tartar.—This ſalt, which is compoſed of potaſs and an exceſs of tartarous acid, or rather of tartrite of potaſs and tartarous acid, has

---

† *Ibid.*

Tartrites. has been long known. It is obtained in a ſtate of impurity at the bottom, and adhering to the ſides of caſks in which wine has fermented. It is called *tartar*, ſays Paracelſus, becauſe it produces the oil, water, limeſtone, and ſalt, which burn the patient as *Hell* does. According to him, it was the principle of every diſeaſe and every remedy, and all things contain the germ of it.

Margraf and Rouelle firſt demonſtrated that it contained potaſs ready formed: and Scheele firſt obtained tartarous acid from it in a ſtate of purity.

Its cryſtals are very ſmall and irregular. According to Montet, they are priſms, ſomewhat flat, and moſtly with ſix ſides. It has a ſtrong acid taſte. It is ſoluble in about 30 times its weight of boiling water*. According to Bergman, it contains 23 parts of alkali and 77 of acid.

It is not altered by expoſure to the air. Heat decompoſes it, and at the ſame time deſtroys the acid. It is capable of forming a great many compounds.

808 Tartrite of potaſs.

2. Tartrite of potaſs. This ſalt may be formed by ſaturating the laſt deſcribed ſalt with potaſs. It was formerly called *ſoluble tartar*, becauſe it is much more ſoluble in water than the acidulous tartrite of potaſs. It cryſtallizes moſt readily when there is a ſmall exceſs of alkali in the ſolution. Its cryſtals are ſmall oblongs.

It has an unpleaſant bitter taſte. It is ſoluble in 4 parts of water at the temperature of 40°.

3. Tartrite of ſoda. This ſalt has never been accurately examined.

809 Tartrite of potaſs and ſoda.

4. Tartrite of potaſs and ſoda. This triple ſalt, formerly known by the name of *ſalt of Seignette*, becauſe firſt formed by Mr Seignette apothecary at Rochelle, is made by ſaturating tartar with ſoda.

Its cryſtals are priſms of eight or ten unequal ſides, having their ends truncated at right angles. They are generally divided into two in the direction of their axes, and the baſe on which they ſtand is marked with two diagonal lines, ſo as to divide it into four triangles.

It has a bitter taſte. It is almoſt as ſoluble as tartrite of potaſs.

It effloreſces when expoſed to the air. Heat decompoſes it.

810 Tartrite of ammonia.

4. Tartrite of ammonia. The cryſtals of this ſalt are polygonous priſms, not unlike thoſe of the laſt deſcribed ſalt.

It has a cooling bitter taſte like that of nitre. It is eaſily ſoluble in water. Heat decompoſes it.

5. Acidulous tartrite of ammonia. This ſalt may be formed by pouring tartarous acid into a ſolution of tartrite of ammonia. Like acidulous tartrite of potaſs, it is very inſoluble in water.

6. Tartrite of potaſs and ammonia. This triple ſalt may be formed by pouring ammonia into acidulous tartrite of potaſs.

Its cryſtals, according to Macquer, are priſms with four, five, or ſix ſides: according to the Dijon academicians, parallelopipeds, with two alternate ſloping ſides.

It has a cooling taſte. It is ſoluble enough in water. It effloreſces in the air. Heat decompoſes it.

811 Earthy tartrites.

7. Tartrite of barytes. Unknown.

8. Tartrite of lime. This ſalt, firſt formed by Scheele, is a taſteleſs and almoſt inſoluble powder. By heat the acid is decompoſed, and the pure lime remains behind.

9. Tartrite of ſtrontites. This ſalt was firſt formed by Dr Hope. Its cryſtals are ſmall regular triangular tables, having the edges and angles ſharp and well defined. It is inſipid. It diſſolves in 320 parts of boiling water.

It is not altered by expoſure to the air. Heat decompoſes it by deſtroying the acid *.

10. Tartrite of magneſia. This ſalt is inſoluble in water except there be an exceſs of acid preſent. It then affords by evaporation ſmall cryſtals in the form of hexangular truncated priſms †.

It has a more ſaline taſte, and is more fuſible, than tartrite of lime ‡.

Heat firſt melts and afterwards decompoſes it.

11. Tartrite of alumina. This ſalt does not cryſtallize, but forms by evaporation a clear tranſparent gummy maſs. Its taſte is aſtringent. It is ſoluble in water. It does not deliqueſce in the air §.

12. Tartrite of potaſs and alumina. This triple ſalt is formed by ſaturating tartar with alumina. It bears a very ſtriking reſemblance to the laſt deſcribed ſalt.

812 Metallic tartrites.

13. Tartrite of iron. This is a grey powder. When tartarous acid is poured into a ſolution of ſulphat of iron, ſcaly cryſtals are formed by evaporation. Theſe cryſtals are doubtleſs compoſed of tartarous acid combined with ſulphat of iron. This triple ſalt might be called *tartro-ſulphat of iron*.

14. Tartrite of potaſs and iron. This triple ſalt was formerly called *tartariſed tincture of Mars*, *chalybeated tartar*, and *tartariſed iron*. It may be formed by boiling two parts of tartar and one of iron filings, previouſly made up into a paſte, in a proper quantity of water. The liquor by evaporation depoſites cryſtals, which form the ſalt wanted.

15. Tartrite of zinc. This ſalt is not eaſily ſoluble in water.

16. Tartrite of potaſs and zinc. This triple ſalt, formed by combining tartar and oxide of zinc, is very ſoluble in water ‖.

17. Tartrite of lead. This ſalt, which is compoſed of tartarous acid and white oxide of lead, is almoſt inſoluble in water. Nitric acid diſſolves it.

18. Tartrite of potaſs and lead. This ſalt, formed by combining white oxide of lead with tartar, is very ſoluble in water ¶.

19. Tartrite of tin. Unknown. The tartrite of potaſs and tin, compoſed of tartar and oxide of tin, is capable of cryſtallizing.

20. Tartrite of copper. This ſalt is beſt formed by pouring tartarous acid into the ſolutions of muriat or ſulphat of copper; it precipitates in the form of blue cryſtals *.

This ſalt forms the beſt kind of the pigment called *Brunſwick green* †.

21. Tartrite of potaſs and copper. This triple ſalt is alſo in the form of blue cryſtals.

22. Tartrite of biſmuth. Small cryſtalline grains ‡.

23. Tartrite of antimony. This ſalt has never been examined with attention.

24. Tartrite of potaſs and antimony, or tartar emetic. To this ſalt, which is perhaps the moſt powerful emetic known, a great deal of attention has been paid, and a vaſt number of methods have been tried to prepare it. Theſe methods have been already deſcribed in the Encyclopædia. It appears from the experiments of Mr Bindheim,

---

† *Leonhardi.*

‡ *Bergman.*

Bindheim, that if this ſalt be carefully prepared, the difference that reſults from the uſe of different oxides is not ſo great as might have been expected *.

It was firſt made known by Adrian in 1631. It is a triple ſalt, compoſed of tartar and white oxide of antimony.

It is of a white colour and tranſparent. Its cryſtals are trihedral pyramids.

It diſſolves in 60 parts of cold water, and in a ſmaller proportion of hot water. It is decompoſed by lime and alkalies, iron, &c. Care ought therefore to be taken to uſe only diſtilled water when it is adminiſtered as a medicine.

25. Tartrite of arſenic. This ſalt forms priſmatic cryſtals very like thoſe of oxalat of arſenic †.

26. Tartrite of mercury. A yellow powder.

27. Tartrite of potaſs and mercury. This triple ſalt cryſtallizes ‡.

Sect. XIV. *Of Citrats.*

The compounds into which the citric acid enters have been denominated *citrats*.

Theſe ſalts are at preſent very imperfectly known. Mr Dizé has promiſed ſoon to ſupply this defect §.

813 Alkaline citrats. 1. Citrat of potaſs. This ſalt does not cryſtallize. It has a cooling ſaline taſte, and deliqueſces when expoſed to the air.

2. Citrat of ſoda. This ſalt does not deliqueſce. It has a mild, pleaſant, cooling taſte ||. According to Scheele, it does not cryſtallize.

3. Citrat of ammonia. This ſalt cryſtallizes in thin needles. It has a cooling and moderately ſaline taſte ¶. The ammonia is ſeparated by the application of heat *.

814 Earthy citrats. 4. Citrat of barytes. This ſalt is ſcarcely ſoluble in water. It aſſumes the form of a white powder †. It is ſoluble in citric acid.

5. Citrat of lime. This is a white powder, ſcarcely ſoluble in water ‡.

6. Citrat of magneſia. Does not cryſtallize. It forms a gummy ſaline maſs very ſoluble in water §.

7. Citrat of alumina. This ſalt is ſcarcely ſoluble in water.

815 Metallic citrats. 8. Citrat of iron. A ſolution of a brown colour.

9. Citrat of copper. A green gummy maſs.

10. Citrat of mercury. This ſalt may be formed by pouring citric acid into nitrat or acetite of mercury. It is a flaky ſalt, of a brick-duſt colour, more or leſs red ||.

Sect. XV. *Of Malats.*

816 Malats. The compounds into which the malic acid enters are called *malats*. This claſs of ſalts was firſt diſcovered by Scheele. They are no better known than the citrats.

1. Malat of potaſs.
2. Malat of ſoda. } Theſe ſalts are deliqueſcent ¶.
3. Malat of ammonia.

4. Malat of lime. Small irregular cryſtals. They require a large quantity of boiling water for their ſolution. With exceſs of acid they are readily ſoluble in cold water †. They are inſoluble in alcohol ‡.

5. Malat of barytes. The properties of this ſalt reſemble pretty much thoſe of malat of lime §.

6. Malat of magneſia. Deliqueſcent ||.

7. Malat of iron. A brown ſolution, not cryſtallizable *.

8. Malat of zinc. This ſalt forms beautiful cryſtals †.

Sect. XVI. *Of Lactats.*

817 Lactats. The neutral ſalts formed by the combination of the lactic acid with various baſes are called *lactats*. They were firſt diſcovered by Scheele.

1. Lactat of potaſs. A deliqueſcent ſalt, ſoluble in alcohol ‡.

2. Lactat of ſoda. This ſalt does not cryſtallize. It is ſoluble in alcohol §.

3. Lactat of ammonia. Cryſtals which deliqueſce. Heat ſeparates a great part of the ammonia before deſtroying the acid.

4. Lactat of barytes.
5. Lactat of lime. } Theſe ſalts deliqueſce ||. The lactat of lime is ſoluble in alcohol ¶.
6. Lactat of alumina.
7. Lactat of magneſia. Small deliqueſcent cryſtals *.
8. Lactat of iron. A brown ſolution.
9. Lactat of zinc. Cryſtals †.

Theſe ſalts have a very ſtrong reſemblance to malats. The only difference which Scheele obſerved was, that the malat of lime was inſoluble in alcohol, while alcohol diſſolved lactat of lime.

Sect. XVII. *Of Saccholats.*

818 Saccholats. The compounds into which the ſaccholactic acid enters are called *ſaccholats*. They alſo were firſt diſcovered by Scheele.

1. Saccholat of potaſs. Small cryſtals, ſoluble in eight times their weight of boiling water ‡.

2. Saccholat of ſoda. The ſame; ſoluble in five times their weight of boiling water §.

3. Saccholat of ammonia. A ſalt which has a ſouriſh taſte. Heat ſeparates the ammonia ¶.

4. Saccholat of barytes.
5. Saccholat of lime. } Theſe ſalts are inſoluble
6. Saccholat of magneſia. } in water *.
7. Saccholat of alumina.

Sect. XVIII. *Of Gallats.*

819 Gallats. The compounds into which the gallic acid enters are denominated *gallats*. They were firſt attended to by the Dijon academicians and by Scheele.

1. Gallat of potaſs.
2. Gallat of ſoda. } We only know that theſe compoſitions are poſſible, and that their properties
3. Gallat of ammonia.

are different from thoſe of all other ſalts.

4. Gallat of barytes. } Theſe ſalts are ſoluble in wa-
5. Gallat of lime. } ter, eſpecially when there is

exceſs of acid.

6. Gallat of magneſia. This ſalt is a yellow powder, ſoluble in water and in alcohol *.

7. Gallat of alumina. This ſalt, according to Bartholdi, exiſts ready formed in nut galls. It is very ſoluble in water.

8. Gallat of iron. This ſalt, which Mr Prouſt has diſcovered to be formed of gallic acid and brown oxide of iron, is of a black colour, and does not ſeem capable of cryſtallizing. It is ſoluble in the three mineral acids, and by that means is deprived of its black colour. It is to this ſalt that ink partly owes its black colour. Gallat of iron is decompoſed by alkalies.

We ſhall not attempt any farther account of this claſs of

of ſalts. Scarcely any addition has yet been made to the experiments of Scheele which have been given already in the article Chemistry, *Encycl.*

Sect. XIX. *Of Benzoats.*

820 Alkaline benzoats.

The compounds into which the benzoic acid enters have been called *benzoats*.

1. Benzoat of potaſs. This ſalt forms pointed feathery cryſtals. It has a ſaline ſharp taſte. It is very ſoluble in water. It deliqueſces when expoſed to the air *.

2. Benzoat of ſoda. The cryſtals of this ſalt are larger, but its taſte is the ſame with that of benzoat of potaſs. It is alſo very ſoluble in water. It effloreſces in the air †.

3. Benzoat of ammonia. This ſalt cryſtallizes with difficulty. Its cryſtals are feather-ſhaped. It deliqueſces ‡.

821 Earthy benzoats.

4. Benzoat of lime. This ſalt forms white, ſhining, pointed cryſtals, of a ſweetiſh taſte, and not eaſily ſoluble in water §.

5. Benzoat of magneſia. Feather-ſhaped cryſtals, of a ſharp bitter taſte, and eaſily ſoluble in water †.

6. Benzoat of alumina, an aſtringent ſalt.

822 Metalline benzoats.

7. Benzoat of iron. This ſalt forms yellow cryſtals. It has a ſweet taſte. It is ſoluble in water and alcohol. It effloreſces in the air. Heat diſengages the acid ¶.

8. Benzoat of zinc. This ſalt forms arboreſcent cryſtals. It is ſoluble in water and alcohol. When expoſed to the air it is diſſipated. Heat decompoſes it *.

9. Benzoat of mangaueſe. This ſalt, which is formed of benzoic acid and white oxide of mangaueſe, cryſtallizes in ſmall ſcales. It diſſolves readily in water; with difficulty in alcohol. It is not altered by expoſure to the air †.

10. Benzoat of cobalt. Flat cryſtals ‡.

11. Benzoat of lead. Very white cryſtals, ſoluble in water and alcohol. They are not altered by expoſure to the air. Heat diſengages the acid §.

12. Benzoat of tin. This ſalt may be formed by pouring benzoat of potaſs into a ſolution of tin in the nitro-muriatic acid. The benzoat of tin is precipitated. It is ſoluble in hot water, but inſoluble in alcohol. Heat decompoſes it ‖.

13. Benzoat of copper. Small cryſtals of a deep green colour. They are with difficulty ſoluble in water, and not at all in alcohol ¶.

14. Benzoat of biſmuth. This ſalt forms white needle-ſhaped cryſtals. They are ſoluble in water, and in a very ſmall proportion in alcohol. They are not altered by expoſure to the air. Heat decompoſes them *.

15. Benzoat of antimony. Cryſtals which effloreſce in the air, and are decompoſed by heat †.

16. Benzoat of arſenic. Small feather-ſhaped cryſtals. It is ſoluble in hot water, but cryſtallizes in the cooling. A moderate heat ſublimes it; a ſtrong heat decompoſes it. Sulphur decompoſes it. It is not decompoſed by alkalies ‡.

17. Benzoat of mercury. A white powder. It is inſoluble in water, but diſſolves in a ſmall quantity in alcohol. It is not altered by expoſure to the air. A ſmall heat ſublimes it; a greater decompoſes it. It is decompoſed by ſulphur §.

18. Benzoat of ſilver. This ſalt is ſoluble in water, and alſo in a very ſmall proportion in alcohol. It is not altered by expoſure to the air, but the rays of the ſun render it brown. Heat diſengages its acid *.

19. Benzoat of gold. Small irregular cryſtals, not eaſily ſoluble in water; inſoluble in alcohol. It is not altered by expoſure to the air. Heat decompoſes it †.

20. Benzoat of platinum. This ſalt forms ſmall browniſh cryſtals, with difficulty ſoluble in water; not ſoluble in alcohol. When expoſed to heat, it is decompoſed, and there remains behind a brown powder ‡.

Sect. XX. *Of Succinats.*

The neutral ſalts, formed by the combination of the ſuccinic acid with various baſes, have been called *ſuccinats*.

We ſhall not deſcribe theſe ſalts, as we could not add much to the account given in the Appendix to the article Chemistry in the *Encycl.* That account was taken from Mr Kier's Chemical Dictionary, and that gentleman borrowed it from Leonhardi.

Sect. XXI. *Of Camphorats.*

The neutral ſalts into the compoſition of which camphoric acid enters, have been denominated *camphorats*. The only chemiſt who has hitherto examined them is Bouillon la Grange: his experiments have been publiſhed in the 27th volume of the *Annales de Chimie*.

823 Camphorat of potaſs.

1. Camphorat of potaſs. To prepare this ſalt, carbonat of potaſs is to be diſſolved in water, and the ſolution ſaturated with camphoric acid. When the efferveſcence is over, the liquor is to be evaporated by a gentle heat to the proper conſiſtence, and cryſtals of camphorat of potaſs will be depoſited when the liquor cools.

Camphorat of potaſs is white and tranſparent; its cryſtals are regular hexagons. Its taſte is bitteriſh and ſlightly aromatic.

Water at the temperature of 60° diſſolves $\frac{1}{102}$th part of its weight of this ſalt; boiling water diſſolves $\frac{1}{4}$th part of its weight.

It is ſoluble in alcohol, and the ſolution burns with a deep blue flame.

When expoſed to moiſt air, it loſes a little of its tranſparency, but in dry air it ſuffers no change.

When expoſed to heat it melts, ſwells, and the acid is volatilized in a thick ſmoke, which has an aromatic odour. Before the blow-pipe it burns with a blue flame, and the potaſs remains behind in a ſtate of purity.

By compound affinity this ſalt is decompoſed by

Nitrat of barytes,
All the ſalts whoſe baſe is lime,
Nitrat of ſilver,
Sulphat of iron,
Muriat of tin,
——— lead §.

824 Camphorat of ſoda.

2. Camphorat of ſoda. This ſalt may be formed preciſely in the ſame manner with the camphorat of potaſs.

It is white and tranſparent; its taſte is ſomewhat bitter; its cryſtals are irregular.

Water at the temperature of 60° diſſolves leſs than $\frac{1}{200}$th part of its weight of this ſalt; boiling water diſſolves $\frac{1}{8}$th of its weight.

It is alſo ſoluble in alcohol.

When expoſed to the air it loſes its tranſparency, and effloreſces

effloreſces ſlightly, but is never completely reduced to powder.

Heat produces the ſame effect upon it as on camphorat of potaſs: the acid burns with a blue flame, which becomes reddiſh towards the end.

By compound affinity it is decompoſed by

Nitrat of lime,
——— ſilver,
Muriat of magneſia,
——— barytes,
——— alumina,
Muriat of lime,
——— iron,
Sulphat of alumina,
——— iron: and many other ſalts with metallic baſes *.

825 Camphorat of ammonia.

3. Camphorat of ammonia. This ſalt may be prepared by diſſolving carbonat of ammonia in hot water, and adding camphoric acid ſlowly till the alkali is ſaturated. It muſt then be evaporated with a very moderate heat, to prevent the diſengaging of ammonia.

It is very difficult to obtain this ſalt in regular cryſtals. When evaporated to dryneſs, there is obtained a ſolid opaque maſs of a ſharp and bitteriſh taſte.

Water at the temperature of about 60° diſſolves nearly $\frac{1}{100}$th part of its weight of this ſalt; boiling water diſſolves $\frac{1}{3}$d of its weight: But this and the two ſalts above deſcribed are a good deal more ſoluble when there is exceſs of baſe.

It is entirely ſoluble in alcohol.

When expoſed to the air it attracts moiſture, but not in ſufficient quantity to enable it to aſſume a liquid form.

When expoſed to heat it ſwells, melts, and is converted into vapour; before the blow-pipe it burns with a blue and red flame, and is entirely volatilized.

Moſt of the calcareous ſalts form triple ſalts with camphorat of ammonia.

It decompoſes in part all the aluminous ſalts except the ſulphat of alumina †.

826 Camphorat of barytes.

4. Camphorat of barytes. In order to prepare this ſalt, barytes is to be diſſolved in water, and camphoric acid added to the ſolution; the mixture is then to be boiled, and afterwards filtered and evaporated to dryneſs.

Camphorat of barytes does not cryſtallize; when the evaporation is conducted ſlowly, the ſalt is depoſited in thin plates one above another, which appear tranſparent while immerſed in the liquor, but become opaque whenever they come into contact with the air.

It has very little taſte, though it leaves at laſt upon the tongue a ſlight impreſſion of acidity mixed with bitterneſs.

Water diſſolves only a very ſmall quantity of this ſalt, boiling water being capable of taking up only $\frac{1}{600}$th part of it.

It is not altered by expoſure to the air.

When expoſed to heat it melts eaſily, and the acid is volatilized. When the heat is conſiderable, the acid burns with a lively blue flame, which becomes red and at laſt white.

It is decompoſed by

Nitrat of potaſs, ſoda, lime, ammonia, and magneſia.
Muriat of lime, potaſs, alumina, and magneſia.
All the ſulphats.
Carbonat of potaſs and ſoda.
Phoſphat of potaſs, ſoda, and ammonia ‡.

827 Camphorat of lime.

5. Camphorat of lime. This ſalt may be prepared by dropping into lime-water cryſtallized camphoric acid. The mixture is then to be made boiling hot, paſſed through a filter, and evaporated to about $\frac{3}{4}$ths of its volume. On cooling, camphorat of lime is depoſited.

It has no regular ſhape; but if the evaporation has been properly conducted, it is in plates lying one above another. It is of a white colour, and has a taſte ſlightly bitter.

Water at the temperature of 60° diſſolves very little of this ſalt; boiling water is capable of diſſolving about $\frac{1}{200}$th part of its weight of it. It is inſoluble in alcohol.

It is compoſed of 43 parts of lime, 50 of acid, and 7 of water.

When expoſed to the air it dries and falls into powder.

When expoſed to a moderate heat it melts and ſwells up: when placed on burning coals, or when heated in cloſe veſſels, the acid is decompoſed and volatilized, and the lime remains pure.

When ſulphuric acid is poured into a ſolution of this ſalt, it produces an inſoluble precipitate; nitric and muriatic acids precipitate the camphoric acid.

It is decompoſed by compound affinity by

Carbonat of potaſs,
Nitrat of barytes,
Muriat of alumina,
Sulphat of alumina,
Phoſphat of ſoda *.

828 Camphorat of magneſia.

6. Camphorat of magneſia. This ſalt may be prepared by pouring water on carbonat of magneſia, and then adding cryſtallized camphoric acid: heat is then applied, the ſolution is filtrated, and evaporated to dryneſs. The ſalt obtained is diſſolved in hot water, paſſed through a filter, and evaporated by means of a moderate heat till a pellicle forms on the ſurface of the ſolution. On cooling, the ſalt is depoſited in thin plates. The ſecond ſolution is to remove any exceſs of magneſia that may happen to be preſent.

This ſalt does not cryſtallize. It is white, opaque, and has a bitter taſte.

It is ſcarcely more ſoluble in water than camphorat of lime.

Alcohol has no action on it while cold, but when hot it diſſolves the acid and leaves the magneſia; and the acid precipitates again as the alcohol cools.

When expoſed to the air it dries and becomes covered with a little powder; but this effect is produced ſlowly, and only in a warm place.

When this ſalt is placed on burning coals, the acid is volatilized, and the magneſia remains pure. Before the blow-pipe it burns like the other camphorats with a blue flame.

The nitrats, muriats, and ſulphats, do not completely decompoſe this ſalt, if we except the nitrat of lime and muriat of alumina †.

829 Camphorat of alumina.

7. Camphorat of alumina. To prepare this ſalt, alumina, precipitated by means of ammonia, and well waſhed, is to be mixed with water, and cryſtals of camphoric acid added. The mixture is then to be heated, filtered, and concentrated by evaporation.

This ſalt is a white powder, of an acid bitteriſh taſte, leaving on the tongue, like moſt of the aluminous ſalts, a ſenſation of aſtringency.

Water at the temperature of 60° diſſolves about $\frac{1}{200}$th part of its weight of this ſalt. Boiling water diſſolves it

---

* *Bouillon La Grange, Ann. de Chim.* xxvii. 26.

† *Ibid.*

‡ *Bouillon La Grange, ibid.* p. 28.

* *Bouillon La Grange, Ann. de Chim.* xxvii. 21.

† *Id. ibid.*

it in conſiderable quantities; but it precipitates again as the ſolution cools.

Alcohol, while cold, diſſolves it very ſparingly; but when hot it diſſolves a conſiderable quantity of it, which precipitates alſo as the ſolution cools.

This ſalt undergoes very little alteration in the air; but it rather parts with than attracts moiſture.

Heat volatilizes the acid; and when the ſalt is thrown on burning coals it burns with a blue flame.

It is decompoſed by the nitrats of lime and barytes *.

Sect. XXII. *Of Suberats.*

The ſalts formed by the ſuberic acid have obtained the appellation of *ſuberats*. They have hitherto been examined only by Bouillon la Grange.

830 Suberat of potaſs.

1. Suberat of potaſs.—This ſalt ought to be formed by means of cryſtallized carbonat of potaſs.

It cryſtallizes in priſms, having four unequal ſides. It has a bitter ſaltiſh taſte, and it reddens vegetable blues. It is very ſoluble in water. Caloric melts it, and at laſt volatilizes the acid.

It is decompoſed by moſt of the metallic ſalts, and by ſulphat of alumina, muriat of alumina, and of lime; nitrat of alumina and of lime; and phoſphat of alumina †.

831 Suberat of ſoda.

2. Suberat of ſoda.—This ſalt does not cryſtallize. It reddens the tincture of turnſole. Its taſte is ſlightly bitter. It is very ſoluble in water and in alcohol. It attracts moiſture from the air. Caloric produces the ſame effect on it that it does on ſuberat of potaſs.

It is decompoſed by the calcareous, aluminous, and magneſian ſalts ‡.

832 Suberat of ammonia.

3. Suberat of ammonia.—This ſalt cryſtallizes in parallelopipeds. Its taſte is ſaltiſh, and it leaves an impreſſion of bitterneſs: It reddens vegetable blues.

It is very ſoluble in water. It attracts moiſture from the air. When placed upon burning coals, it loſes its water of cryſtallization, and ſwells up; and before the blow-pipe it evaporates entirely.

It is decompoſed by the aluminous and magneſian ſalts §.

833 Suberat of barytes.

4. Suberat of barytes.—This ſalt does not cryſtallize. Heat makes it ſwell up, and melts it. It is ſcarcely ſoluble in water except there be an exceſs of acid.

It is decompoſed by moſt of the neutral ſalts, except the barytic ſalts and the fluat of lime ‖.

834 Suberat of lime.

5. Suberat of lime.—This ſalt does not cryſtallize. It is perfectly white: It has a ſaltiſh taſte: It does not redden the tincture of turnſole.

It is very ſparingly ſoluble in water except when hot; and as the ſolution cools moſt of the ſalt precipitates again.

When placed upon burning coals it ſwells up, the acid is decompoſed, and there remains only the lime in the ſtate of powder.

It is decompoſed by
The muriat of alumina,
The carbonats of potaſs and ſoda,
The fluat of magneſia,
The phoſphats of alumina and ſoda,
The borat of potaſs,
All the metallic ſolutions ¶.

835 Suberat of magneſia.

6. Suberat of magneſia.—This ſalt is in the form of a powder:. It reddens the tincture of turnſole. It has a bitter taſte: It is ſoluble in water, and attracts ſome moiſture when expoſed to the air.

When heated it ſwells up and melts: before the blow-pipe the acid is decompoſed, and the magneſia remains in a ſtate of purity.

It is decompoſed by
Muriat of alumina,
Nitrat of lime and alumina,
Borat of potaſs,
Fluat of ſoda,
Phoſphat of alumina *.

836 Suberat of alumina.

7. Suberat of alumina.—This ſalt does not cryſtallize. When its ſolution is evaporated by a moderate heat in a wide veſſel, the ſalt obtained is of a yellow colour, tranſparent, having a ſtyptic taſte, and leaving an impreſſion of bitterneſs on the tongue. When too much heat is employed it melts and blackens. It reddens the tincture of turnſole, and attracts moiſture from the air. Before the blow-pipe it ſwells up, the acid is volatilized and decompoſed, and nothing remains but the alumina.

It is decompoſed by
The carbonats of potaſs and ſoda,
The ſulphat of iron,
The muriat of iron,
The nitrats of ſilver, mercury, and lead †.

Suberic acid forms alſo compounds with the oxides of ſilver, mercury, lead, copper, tin, iron, biſmuth, arſenic, cobalt, zinc, antimony, manganeſe, and molybdenum; moſt of which are incryſtallizable, and have an exceſs of acid ‡.

Sect. XXIII. *Of Pruſſiats.*

The compounds into which the pruſſic acid enters are called *Pruſſiats*.

Theſe ſubſtances, the moſt important of which are triple ſalts, have ſomething very peculiar in their affinities. The pruſſic acid appears to have a ſtronger affinity for alkalies and earths than for metals, at leaſt theſe ſubſtances are capable of decompoſing metallic pruſſiats; yet acids ſcarcely decompoſe the metallic pruſſiats, while the weakeſt acid known decompoſes the pruſſiats of alkalies and earths. Theſe phenomena have not yet been ſatisfactorily accounted for.

837 Alkaline pruſſiats.

1. Pruſſiat of potaſs. }
2. Pruſſiat of ſoda. } Theſe ſalts were firſt obtained pure by Mr Scheele. They are ſoluble in water; but they are of little uſe, as mere expoſure to the air decompoſes them.

3. Pruſſiat of ammonia.—This ſalt has the ſmell of ammonia. It is very volatile and as eaſily decompoſed as the other two.

838 Earthy pruſſiats.

4. Pruſſiat of lime.—This ſalt is ſoluble in water. It is alſo decompoſed by expoſure to the air.

5. Pruſſiat of barytes. }
6. Pruſſiat of magneſia. } Theſe ſalts are alſo ſoluble in water, and decompoſed by all acids.

Pruſſic acid does not combine with alumina.

839 Pruſſian blue.

7. Pruſſiat of iron, or Pruſſian blue.—This ſubſtance is compoſed, as Mr Prouſt has ſhewn, of the pruſſic acid and brown oxide of iron. With the green oxide the pruſſic acid forms a white compound, which, however, becomes gradually blue when expoſed to the atmoſphere, becauſe the oxide abſorbs oxygen, and is converted into brown oxide §.

Pruſſiat of iron is a deep blue coloured powder. It

---

† Id. ibid.

‡ Id. ibid. p. 57.

§ Nicholſon's Jour. i. 453.

is inſoluble in water, and ſcarcely ſoluble in acids. It is compoſed, according to the moſt accurate experiments hitherto made, of equal parts of oxide of iron and pruſſic acid. It is not affected by expoſure to the air. Heat decompoſes it by deſtroying the acid, and the oxide of iron remains behind.

The Pruſſian blue of commerce, beſides other impurities, contains mixed with it a great quantity of alumina. Its uſe as a pigment, and the attempts which have been made to introduce it as a dye, are well known.

Pruſſiat of iron may alſo exiſt in another ſtate: It may have a ſuperabundance of oxide; its colour is then more or leſs yellow. To this ſtate it may be reduced by digeſting it with alkalies or any of the alkaline earths. Theſe ſubſtances deprive it of part of its acid, but not of the whole.

This yellow pruſſiat is ſoluble in acids.

840 Affinities of the pruſſic acid explained.

Were we to attempt an explanation of this, and the other phenomena which the pruſſic acid diſplays in its combinations, we would conjecture, that this yellow pruſſiat is the ſubſtance formed by the direct combination of brown oxide of iron and pruſſic acid, and that the blue pruſſiat is formed of the yellow pruſſiat combined as an integrant with pruſſic acid: That the affinity between the pruſſic acid and oxide of iron is much ſtronger than that between yellow pruſſiat of iron and pruſſic acid; that therefore alkalies and earths have a ſtronger affinity for pruſſic acid than the yellow pruſſiat has, but a much weaker affinity than oxide of iron, and perhaps every other oxide;—hence the apparent ſuperiority of alkalies and earths in ſome caſes, while in others they appear very inferior. We would ſuppoſe, then, that the pruſſic acid has a much ſtronger affinity for oxide of iron, and perhaps for all other oxides, than for other bodies; that the pruſſiats, thus formed, are capable of combining with pruſſic acid; but that their affinity for it is much leſs than that of the alkalies and earths. This conjecture is ſupported by all the phenomena at preſent known; it would remove all the apparent anomalies which the combinations of this ſingular acid preſent, and reduce the whole of them under the known laws of affinity.

841 Properties of Pruſſian alkali,

8. Pruſſiat of potaſs and iron, commonly called *Pruſſian alkali*, or *Pruſſian teſt*. This ſubſtance is a triple ſalt, compoſed of pruſſic acid, potaſs, and oxide of iron combined together. To chemiſts and mineralogiſts it is one of the moſt important inſtruments ever invented; as, when properly prepared, it is capable of indicating whether any metallic ſubſtance (platinum excepted) be preſent in any ſolution whatever, and even of pointing out the particular metal, and of aſcertaining its quantity: This it does by means of a compound affinity, which, after what has been ſaid above, may be eaſily underſtood. The Pruſſian alkali may be conceived to be a combination of two ſubſtances, pruſſiat of potaſs and blue pruſſiat of iron. Now every metallic oxide has a ſtronger affinity for pruſſic acid than potaſs has (and, in fact, ſeems to have a ſtronger affinity for it than for any other ſubſtance). If, therefore, there happen to be any oxide in the ſolution, it immediately ſeizes the pruſſic acid with which the potaſs is combined, and by that means decompoſes the triple ſalt. A pruſſiat of the particular metal is formed, and, as moſt pruſſiats of metals are inſoluble, it is precipitated; and it indicates by its colour the particular metal, and by its weight the quantity of metal that happens to be preſent. At the ſame time the blue pruſſiat of iron is alſo precipitated, and its weight muſt be deducted from the quantity of the precipitate.

In order to be certain of the accuracy of theſe reſults, it is neceſſary to have a Pruſſian alkali perfectly pure, and to be certain before hand of the quantity, or rather of the proportions of its ingredients. To obtain a teſt of this kind has been the object of chemiſts ever ſince the diſcoveries of Macquer pointed out its importance. It is to the uſe of impure teſts that a great part of the contradictory reſults of mineralogical analyſes by different chemiſts is to be aſcribed.

842 Liable to impurities.

There are two * ways in which this teſt may be rendered impure, beſides the introduction of foreign ingredients, which we do not mention, becauſe it is obvious that it muſt be guarded againſt. 1. There may be a ſuperabundance of alkali preſent, or, which is the ſame thing, there may be mixed with the Pruſſian teſt a quantity of pure alkali; or, 2. There may be contained in it a quantity of yellow pruſſiat of iron, for which pruſſiat of potaſs has alſo a conſiderable affinity.

If the Pruſſian teſt contain a ſuperabundance of alkali, two inconveniences follow. This ſuperabundant quantity will precipitate thoſe earthy ſalts which are liable to contain an exceſs of acid, and which are only ſoluble by that exceſs: Hence alumina and barytes will be precipitated. It is to the uſe of impure teſts of this kind that we owe the opinion, that barytes and alumina are precipitated by the Pruſſian alkali, and the conſequent theories of the metallic nature of theſe earths. This miſtake was firſt corrected, we believe, by Mr Klaproth.

Another inconvenience ariſing from the ſuperabundance of alkali in the Pruſſian teſt is, that it gradually decompoſes the blue pruſſiat which the teſt contains, and converts it into yellow pruſſiat. In what manner it does this will be underſtood, after what has been ſaid, without any explanation.

On the other hand, when the Pruſſian alkali contains a quantity of yellow pruſſiat of iron, as great inconveniences follow. This yellow pruſſiat has an affinity for pruſſic acid, which, though inferior to that of the potaſs, is ſtill conſiderable; and, on the other hand, the potaſs has a ſtronger affinity for every other acid than for the pruſſic. When, therefore, the teſt is expoſed to the air, the carbonic acid, which the atmoſphere always contains, aſſiſted by the affinity between the yellow pruſſiat and the pruſſic acid, decompoſes the pruſſiat of potaſs in the teſt; and the yellow pruſſiat is precipitated in the form of Pruſſian blue: And every other acid produces the ſame effect. A teſt of this kind, therefore, would indicate the preſence of iron in every mixture which contains an acid (for a precipitation of Pruſſian blue would appear); and could not, therefore, be truſted to with any confidence.

843 Klaproth's method of forming it.

We will not attempt to deſcribe the various methods which different chemiſts have adopted of preparing this teſt; but ſhall ſatisfy ourſelves with deſcribing the method of Klaproth, which anſwers the purpoſe completely. This we ſhall do nearly in the words of Mr Kirwan.

Prepare a pure potaſs, by gradually projecting into a large crucible heated to whiteneſs a mixture of equal parts of purified nitre and cryſtals of tartar; when the whole

is

---

* See *Kirwan's Min.* i. 487.

is injected, let it be kept at a white heat for half an hour, to burn off the coal.

Detach the alkali thus obtained from the crucible, reduce it to powder, ſpread it on a muffle, and expoſe it to a white heat for half an hour.

Diſſolve it in ſix times its weight of water, and filter the ſolution while warm.

Pour this ſolution into a glaſs receiver, placed in a ſand furnace, heated to 170° or 180°, and then gradually add the beſt Pruſſian blue in powder, injecting new portions according as the former becomes grey, and ſupplying water as faſt as it evaporates; continue until the added portions are no longer diſcoloured, then increaſe the heat to 212° for half an hour.

Filter the ley thus obtained, and ſaturate it with ſulphuric acid moderately diluted; a precipitate will appear; when this ceaſes, filter off the whole, and waſh the precipitate.

Evaporate the filtered liquor to about one quarter, and ſet it by to cryſtallize: after a few days, yellowiſh cryſtals of a cubic or quadrangular form will be found mixed with ſome ſulphat of potaſs and oxide of iron; pick out the yellowiſh cryſtals, lay them on blotting paper, and rediſſolve them in four times their weight of cold water, to exclude the ſulphat of potaſs.

7. Eſſay a few drops of this ſolution with barytic water, to ſee whether it contains any ſulphuric acid, and add ſome barytic water to the remainder if neceſſary: filter off the ſolution from the ſulphat of barytes, which will have precipitated, and ſet it by to cryſtallize for a few days; that the barytes, if any ſhould remain, may be precipitated. If the cryſtals now obtained be of a pale yellow colour, and diſcover no bluiſh ſtreaks when ſprinkled over with muriatic acid, they are fit for uſe; but if they ſtill diſcover bluiſh or green ſtreaks, the ſolutions and cryſtallizations muſt be repeated.

Theſe cryſtals muſt be kept in a well-ſtopped bottle, which to preſerve them from the air ſhould be filled with alcohol, as they are inſoluble in it.

Before they are uſed, the quantity of iron they contain ſhould be aſcertained, by heating 100 grains to redneſs for half an hour in an *open* crucible: the pruſſic acid will be conſumed, and the iron will remain in the ſtate of a reddiſh brown magnetic oxide, which ſhould be weighed and noted: This oxide is half the weight of the Pruſſian blue afforded by the Pruſſian alkali; its weight muſt therefore be ſubtracted from that of metallic precipitates formed by this teſt. Hence the weight of the cryſtals, in a given quantity of the ſolution, ſhould be noted, that the quantity employed in precipitation may be known. Care muſt be taken to continue the calcination till the oxide of iron becomes brown; for while it is black it weighs conſiderably more than it ſhould *.

9. Pruſſiat of ſoda and iron. The only diſcernible difference between this ſalt and the laſt is, that it cryſtallizes differently †.

844
Pruſſiat of ammonia and iron.

10. Pruſſiat of ammonia and iron. This triple ſalt has alſo been employed as a teſt; but it is not ſo eaſy to obtain it in a ſtate of purity as the other two. It was diſcovered by Macquer, and firſt recommended by Meyer.

It forms flat hexangular cryſtals, ſoluble in water, and deliqueſces in the air. Heat decompoſes it like the other pruſſiats ‡.

We ſhall not give any deſcription of the triple ſalts formed by digeſting the alkaline earths on pruſſiat of iron; they are ſufficiently known, and are not of any uſe except as teſts; and in that reſpect they are inferior to that above deſcribed. They are all ſoluble in water, and are moſt of them capable of cryſtallizing.

845
Pruſſiat of mercury.

11. Pruſſiat of mercury. This ſalt, which was firſt formed by Scheele, is compoſed of the pruſſic acid combined with the red oxide of mercury. It may be formed by boiling the red oxide of mercury with Pruſſian blue. It cryſtallizes in tetrahedral priſms, terminated by quadrangular pyramids, the ſides of which correſpond with the angles of the priſm.

This ſalt is capable of combining with ſulphuric and muriatic acids, and forming triple ſalts, which have not yet been examined *.

Sect. XXIV. *Of Formats.*

The compounds into which the formic acid enters are called *formats*. We ſhall not deſcribe them, as little has been added to the account already given in the Appendix to the article Chemistry in the Encyclopædia.

Sect. XXV. *Of Sebats.*

The compounds into which the ſebacic acid enters are called *ſebats*. For our knowledge of this claſs of ſalts we are chiefly indebted to the celebrated Crell, who publiſhed a diſſertation on the ſebacic acid and its combinations in the Philoſophical Tranſactions for 1780 and 1782.

846
Alkaline ſebats.

1. Sebat of potaſs. This ſalt is of a white colour. Its cryſtals are quadrangular pyramids, of which two oppoſite ſides are narrower than the others. It has a ſharp ſaline taſte like muriat of ammonia, but milder. It is ſoluble in water, inſoluble in alcohol, and does not deliqueſce when expoſed to the air. Heat decompoſes it.

2. Sebat of ſoda. This ſalt is white. Its cryſtals are pyramids, with three or four ſides: a very moderate heat melts them.

3. Sebat of ammonia. This ſalt in taſte and ſolubility reſembles muriat of ammonia, but it differs from it in not being capable of ſubliming iron.

847
Earthy ſebats.

4. Sebat of lime. The cryſtals of this ſalt are hexagons, terminated by a plane ſurface: they have a ſharp acrid taſte; are very ſoluble in water, but not in alcohol: they do not deliqueſce.

5. Sebat of magneſia. A gummy, ſaline, uncryſtallizable maſs.

6. Sebat of alumina. A gummy ſaline maſs, which does not cryſtallize, and has an auſtere aſtringent taſte.

848
Metallic ſebats.

7. Sebat of iron. Needle-ſhaped cryſtals, which deliqueſce.

8. Sebat of lead. Needle-ſhaped cryſtals, very ſoluble in water.

9. Sebat of tin. A white deliqueſcent ſalt.

10. Sebat of copper. This ſalt is capable of cryſtallizing, but is very deliqueſcent.

11. Sebat of antimony. A cryſtallizable ſalt, which does not deliqueſce.

12. Sebat of arſenic. Small cryſtals.

13. Sebat of mercury. A white powder, very difficultly ſoluble in water.

14. Sebat of gold. Yellow cryſtals.

15. Sebat of platinum. Browniſh yellow cryſtals.

The bombats or compounds which the bombic acid forms are ſtill unknown.

* *Berthollet.*

Sect. XXVI. *Of Arſeniats.*

The compounds formed by the combination of the arſenic acid with baſes are called *arſeniats*. This claſs of ſalts was firſt diſcovered by Macquer; but little accurate was known concerning it till Scheele made known the arſenic acid.

An abſtract of Scheele's experiments has been given in the article Chemistry, *Encycl.*

To his deſcription of arſeniats ſeveral additions might be made, but not of ſufficient conſequence to warrant a repetition of what has been given in that article; and without ſuch a repetition theſe additions would ſcarcely be intelligible.

Sect. XXVII. *Of Metallic Acid Salts.*

It has been conjectured that all metals may be converted into acids by combining them with a ſufficient quantity of oxygen. This conjecture has been verified in a conſiderable number of inſtances. We have ſeen the arſenic acid, the tungſtic acid, the molybdic acid, and the new metallic acid of Vauquelin. Berthollet has diſcovered that platinum becomes an acid; and the ſame thing has been aſcertained with regard to tin. Even thoſe metallic oxides which do not poſſeſs many of the characters of acids are capable of combining with alkalies and earths, and of forming peculiar neutral ſalts. Theſe oxides, therefore, perform the office of acids; and conſequently muſt be conſidered as partaking of their nature, or rather as a kind of intermediate ſubſtances between acids and thoſe bodies which unite only with acids.

Some of theſe neutral ſalts we ſhall proceed to enumerate.

849 Fulminating gold.

1. Aurat of ammonia, or fulminating gold. This ſalt is compoſed of the oxide of gold and ammonia. This compound may be formed by precipitating gold from nitro-muriatic acid by ammonia. The precipitate is fulminating gold. Bergman was the firſt who clearly demonſtrated that this powder is compoſed of oxide of gold and ammonia. When heated a little above the boiling temperature it explodes with aſtoniſhing violence. Chemiſts had made many attempts to explain the cauſe of this phenomenon, but without ſucceſs, till Mr Berthollet diſcovered the compoſition of ammonia. After making that diſcovery, he proved, by a number of delicate and hazardous experiments, that during the fulmination the ammonia is decompoſed, that its hydrogen combines with the oxygen of the oxide and forms water, while the azot flies off in a gaſeous form, and occaſions the exploſion.

850 Fulminating ſilver.

2. Argentat of ammonia, or fulminating ſilver. This ſubſtance was diſcovered by Mr Berthollet. It may be formed by diſſolving oxide of ſilver in ammonia. It is a black powder. It poſſeſſes the fulminating property much more powerfully than the laſt deſcribed ſubſtance. The ſlighteſt friction makes it explode with violence. This property, as Mr Berthollet has proved *, is owing to the ſame decompoſition of ammonia and formation of water that cauſes the exploſion of fulminating gold.

If a ſmall retort be filled with the liquor from which the fulminating ſilver has been precipitated, and be made to boil, ſome azot is diſengaged, and ſmall opaque cryſtals are formed conſiſting of the ſame ſubſtance; which explode when touched, though they be covered with water. Nitrat and muriat of barytes precipitate ſilver from this ſalt.

851 Mercuriat of lime and of ammonia.

3. Mercuriat of lime. Oxide of mercury boiled with lime-water forms, by evaporation, ſmall tranſparent yellow cryſtals *.

4. Mercuriat of ammonia. Oxide of mercury diſſolves in ammonia in large quantity; and by evaporation furniſhes a white ſalt †.

852 Cuprat of ammonia.

5. Cuprat of ammonia. Oxide of copper diſſolves in ammonia. Mr Sage has deſcribed its cryſtallization. It is decompoſed by lime and potaſs, and cuprat of lime and potaſs are formed.

853 Stannat of gold.

6. Stannat of gold. When gold is precipitated by tin it unites with it. Vogel and Beaumé firſt obſerved that the precipitate, which is purple, contained tin.

854 Plumbat of lime.

7. Plumbat of lime. Lime-water boiled on the red oxide of lead diſſolved it. This ſolution, evaporated in a retort, gave very ſmall tranſparent cryſtals, forming priſmatic colours, and not more ſoluble in water than lime. It is decompoſed by all the ſulphats of alkalies and by ſulphurated hydrogen gas. The ſulphuric and muriatic acids precipitate the lead. It blackens wool, the nails, the hair, white of eggs; but it does not affect the colour of ſilk, the ſkin, the yoke of eggs, nor animal oil. It is the lead which is precipitated on theſe coloured ſubſtances in the ſtate of oxide; for all acids can diſſolve it. The ſimple mixture of lime and oxide of lead blackens theſe ſubſtances; a proof that the ſalt is eaſily formed ‡.

855 Zincat of ammonia.

8. Zincat of ammonia. De Caſſone has publiſhed a great number of experiments on the property which ammonia has of diſſolving oxide of zinc. Lime-water and potaſs alſo diſſolve it §.

856 Antimoniat of potaſs.

9. Antimoniat of potaſs. When antimony is detonated with nitre in a crucible, part of its oxide unites with the potaſs of the nitre ‖.

Chap. III. *Of* Hydrosulphurets.

857 Properties of ſulphurated hydrogen gas.

Sulphurated hydrogen gas, which has been deſcribed in the firſt part of this article, poſſeſſes almoſt all the properties of acids. It combines with water, and the ſolution gives a red colour to vegetable blues. It decompoſes ſoaps and ſulphurets, and is capable of combining with alkalies, earths, and metallic oxides, and of forming compounds, to which Mr Berthollet, to whom we are indebted for diſcovering them, has given the name of *hydroſulphurets* ¶.

Before giving any account of theſe compounds, which we ſhall do from the paper of Berthollet juſt quoted, we beg leave to make a few previous obſervations, in order to rectify ſome inaccuracies into which we have fallen from not being acquainted with the experiments of that philoſopher.

858 Remarks on ſulphurets.

Sulphur is capable of combining with alkalies, earths, metals, and metallic oxides, and forming the compounds known by the name of *ſulphurets*. The alkaline, earthy, and even ſome of the metallic ſulphurets, can only exiſt in a ſtate of dryneſs: the inſtant they are moiſtened with water, a quantity of ſulphurated hydrogen gas is formed, which combines with the ſulphuret, and forms a new compound. To theſe triple compounds Mr Berthollet has given the name of *hydrogenous ſulphurets*. All ſolutions of ſulphurets in water are in fact hydrogenous ſulphurets. Were it not for the formation and combination of ſulphurated hydrogen, the alkaline ſulphurets would

---

* *Berthollet, Ann. de Chim.* i.

* *Id. ibid.*

† *Lavoiſier, ibid.*

§ *Id. ibid.* p. 42.

‖ *Id. ibid.*

¶ *Ann. de Chim.* xxv. 233.

would be completely decompoſed by water, and their ſulphur precipitated; for water has a ſtronger affinity for the alkalies than ſulphur has. This Berthollet proved by the following experiment: To a ſolution of ſulphuret of potaſs in water (that is, to hydrogenous ſulphuret of potaſs), a quantity of oxy-muriatic acid ſuperſaturated with potaſs was added, and the ſulphur was immediately precipitated. In this experiment the ſulphurated hydrogen was deſtroyed by the oxygen of the oxy-muriatic acid; and the precipitation of the ſulphur ſhews that its affinity for potaſs was not ſufficient to keep it diſſolved, or, which is the ſame thing, that its affinity for potaſs was inferior to that of water.

859 Hydrogenous ſulphuret of mercury. The ſubſtance which we deſcribed in Part I. chap. iii. ſect. 4. of this article, under the name of *Black Sulphuret of Mercury*, is a hydrogenous ſulphuret of mercury, and therefore differs from the red ſulphuret of mercury or cinnabar by containing a quantity of ſulphurated hydrogen. Potaſs has a ſtronger affinity for this laſt ſubſtance than the ſulphuret; potaſs therefore, by the aſſiſtance of heat, deprives the black or hydrogenous ſulphuret of its ſulphurated hydrogen, and reduces it to the ſtate of red ſulphuret. This explains the method of forming cinnabar deſcribed in the ſection above referred to, and points out a much eaſier proceſs for obtaining that uſeful pigment.

860 Method of forming hydroſulphurets. We ſhall now proceed to the method of forming the hydroſulphurets. Berthollet obtained ſulphurated hydrogen gas from ſulphuret of iron in the uſual manner, by means of ſulphuric acid. It was made to paſs thro' a veſſel filled with water before it entered that in which the combination was to take place. By this method a ſolution of potaſs was impregnated with ſulphurated hydrogen; and in order to be certain of ſaturating the alkali completely, the gas was added in exceſs, and the exceſs was afterwards driven off by means of heat. By this method hydroſulphurets of potaſs, ſoda, and ammonia, may be formed.

In order to form hydroſulphuret of lime, that earth was mixed with diſtilled water, and ſulphurated hydrogen gas paſſed into this mixture till a ſufficient quantity of hydroſulphuret was judged to be formed; the liquid, which contained it in ſolution, was poured off the undiſſolved lime, and ſaturated to exceſs with ſulphurated hydrogen, and this exceſs was afterwards driven off by means of heat.

Hydroſulphuret of magneſia may be formed by diſſolving magneſia in water impregnated with ſulphurated hydrogen gas.

If a ſolution of ſulphuret of barytes in water, or, more properly, if hydrogenous ſulphuret of barytes be evaporated, a great number of confuſed cryſtals are formed; if theſe be ſeparated quickly by filtration, and placed upon blotting paper to dry, a white cryſtalline ſubſtance is obtained, which is hydroſulphuret of barytes.

861 Affinities of ſulphurated hydrogen. The affinities of the alkalies and earths for ſulphurated hydrogen appear, from the experiments of Berthollet, to be as follows:

Barytes,
Potaſs,
Soda,
Lime,
Ammonia,
Magneſia,
Jargonia.

Almoſt all the metallic oxides have a ſtronger affinity for ſulphurated hydrogen than the earths have.

862 Properties of hydroſulphurets. When the hydroſulphurats are prepared with the neceſſary precautions to prevent the contact of atmoſpherical air, they are colourleſs, but the action of the air renders them yellow.

If they be decompoſed while they are colourleſs, by pouring upon them ſulphuric acid, muriatic acid, or any other acid which does not act upon hydrogen, the ſulphurated hydrogen gas exhales without the depoſition of a ſingle particle of ſulphur; but if the hydroſulphuret has become yellow, ſome ſulphur is always depoſited during its decompoſition, and the quantity of ſulphur is proportional to the deepneſs of the colour.

The yellow colour, therefore, which hydroſulphurets acquire by expoſure to the atmoſphere is owing to a commencement of decompoſition. Part of the hydrogen of the ſulphurated hydrogen abandons the ſulphur, combines with the oxygen of the atmoſphere, and forms water. By degrees, however, a portion of the ſulphur is alſo converted into an acid; and when the proportion of ſulphurated hydrogen is diminiſhed, and that of the ſulphur increaſed to a certain point, the ſulphur and the hydrogen combine equally with oxygen.

If ſulphuric or muriatic acids be poured upon a hydroſulphuret after it has been for ſome time expoſed to the air, a quantity of ſulphurated hydrogen gas exhales, ſulphur is depoſited, and after an interval of time ſulphurous acid is diſengaged. It is therefore ſulphurous, and not ſulphuric acid, which is formed while the hydroſulphuret ſpontaneouſly abſorbs oxygen. This acid, however, is not perceptible till after a certain interval of time when ſeparated from the hydroſulphuret by means of an acid; becauſe as long as it meets with ſulphurated hydrogen a reciprocal decompoſition takes place. The oxygen of the acid combines with the hydrogen of the gas, and the ſulphur of both is precipitated.

863 Metalline hydroſulphurets. Sulphurated hydrogen is capable of combining with ſeveral of the metals, mercury, for inſtance, and ſilver: it combines with the greater number of the metallic oxides, and forms hydroſulphurets, on which the alkalies have no action at the temperature of the atmoſphere: But concentrated acids combine with the oxides of theſe hydroſulphurets, and ſeparate the ſulphurated hydrogen in the form of gas.

In the greater number of theſe metallic oxide hydroſulphurets, the tendency which oxygen and hydrogen have to combine occaſions a partial decompoſition of the ſulphurated hydrogen, and brings the oxides nearer to the metallic ſtate. In ſome of theſe hydroſulphurets part of the ſulphur alſo combines with oxygen, and forms ſulphuric acid.

The alkaline hydroſulphurets precipitate all the metals from their combination with acids; they are therefore very valuable teſts of the preſence of metals in any ſolution, as they do not precipitate any of the earths except alumina and jargonia. The following Table exhibits a view of the effect of hydroſulphuret of potaſs, hydrogenous ſulphuret of potaſs, and water impregnated with ſulphurated hydrogen gas, upon various metallic ſolutions.

Metallic

Hydroſulphurets.

Metallic Solutions.	Solution of Hydrogenous Sulphuret of Potaſs.	Water impregnated with Sulphurated Hydrogen Gas.	Hydroſulphuret of Potaſs.
Green ſulphat of iron.	A black precipitate, which becomes yellow by the contact of the air.		A black precipitate. The potaſs ſeparated.
Red oxide of iron.		Becomes black. The liquor remains very deep coloured if there be an exceſs of ſulphurated hydrogen.	Becomes black.
Sulphat of zinc.	A white precipitate.	A white precipitate.	A white precipitate.
Acetite of lead.	A white precipitate, which by an addition becomes black.	A black precipitate.	A black precipitate.
Red oxide of lead.		Becomes black.	The potaſs ſeparated.
Nitrat of biſmuth.		A black precipitate.	A black precipitate.
Oxide of biſmuth.		Becomes black.	
Nitrat of ſilver.	A black precipitate.	A black precipitate.	A black precipitate.
Sulphat of copper.	A brown precipitate.	A black precipitate.	A black precipitate.
Green oxide of copper.		Becomes black.	Separation of the potaſs.
Nitrat of mercury.	In a great deal of water, a brown colour.	A browniſh black precipitate.	A browniſh black precipitate.
Oxy-muriat of mercury.	A white precipitate, which becomes black by addition.	A white precipitate, becoming black by an addition.	White, becomes black by addition.
Red oxide of mercury.		Blackiſh.	A heat produced which cauſed the hydroſulphuret to boil. The alkali ſeparated (A).
Muriat of tin.			A black precipitate.
Oxy-muriat of tin.	A precipitation of ſulphur, and of the oxide.	No change.	A precipitate of white oxide of tin, and a diſengagement of ſulphurated hydrogen gas.
White oxide of tin.		No change.	Diſengagement of ſulphurated hydrogen gas.
Sulphat of manganeſe.		No change.	A white precipitate.
Black oxide of manganeſe.		The odour diſappears. An exceſs of the water diſſolves the oxide.	Ammonia diſengaged. Heat. The liquor boils (A).
Nitrat of antimony.			A reddiſh orange precipitate.
Tartrite of antimony.	A yellow orange precipitate.	An orange colour, but no precipitate.	An orange red precipitate, rediſſolved by an exceſs of hydroſulphuret.
White oxide of antimony.		Becomes yellow after ſome ſeconds.	The liquor loſes its colour (A).

Metallic

(A) In theſe, hydroſulphuret of ammonia was uſed inſtead of hydroſulphuret of potaſs.

Table continued.

Metallic Solutions.	Solution of Hydrogenous Sulphuret of Potaſs.	Water impregnated with Sulphurated Hydrogen Gas.	Hydrofulphuret of Potaſs.
Oxide of antimony ſublimed.		Scarcely changes colour.	
Solution of oxide of arſenic.	Sulphuret decompoſed as by an acid.	Becomes ſomewhat muddy, and of a yellow colour.	A yellow colour, but no precipitate.
Sulphat of titanium.			A precipitate of a deep green.
Molybdic acid.		A brown precipitate.	A brown precipitate.

Chap. IV. *Of* Cryſtallization.

864 Cryſtals. The word *cryſtal*, in its ſtrict and proper ſenſe, ſignifies a tranſparent body poſſeſſed of a regular figure. But it is now uſed to denote a body which has aſſumed a regular figure whether it be tranſparent or not. *Cryſtallization* is the *act* by which this regular figure is formed.

As the greater number of cryſtals belong to the claſs of neutral ſalts, it may not be improper, before we conclude this part of the article, to make a few obſervations on the phenomena of cryſtallization.

As cryſtallization is confeſſedly nothing elſe than the regular arrangement of the particles of bodies, it is evident that before it can take place the particles of the body to be cryſtallized muſt be at ſome diſtance from each other, and that they muſt be at liberty to obey the laws of attraction. They may be put into this ſituation by three methods, ſolution, ſuſpenſion, and fuſion.

865 Formed by ſolution, 1. Solution is the common method of cryſtallizing ſalts. They are diſſolved in water: The water is ſlowly evaporated, the ſaline particles gradually approach each other, combine together, and form ſmall cryſtals; which become conſtantly larger by the addition of other particles till at laſt they fall by their gravity to the bottom of the veſſel. It ought to be remarked, however, that there are two kinds of ſolution, each of which preſents different phenomena of cryſtallization. Some ſalts diſſolve in very ſmall proportions in cold water, but are very ſoluble in hot water; that is to ſay, water at the common temperature has little effect upon them, but water combined with caloric diſſolves them readily. When hot water ſaturated with any of theſe ſalts cools, it becomes incapable of holding them in ſolution: the conſequence of which is, that the ſaline particles gradually approach each other and cryſtallize. Sulphat of ſoda is a ſalt of this kind. To cryſtallize ſuch ſalts, nothing more is neceſſary than to ſaturate hot water with them, and ſet it by to cool. But were we to attempt to cryſtallize them by evaporating the hot water, we ſhould not ſucceed; nothing would be procured but a ſhapeleſs maſs. Many of the ſalts which follow this law of cryſtallization combine with a great deal of water; or, which is the ſame thing, many cryſtals formed in this manner contain a great deal of water of cryſtallization.

There are other ſalts again which are nearly equally ſoluble in hot and cold water; common ſalt for inſtance. It is evident that ſuch ſalts cannot be cryſtallized by cooling; but they cryſtallize very well by evaporating their ſolution while hot. Theſe ſalts generally contain but little water of cryſtallization.

866 Suſpenſion, 2. It appears, too, that ſome ſubſtances are capable of aſſuming a cryſtalline form merely by having their particles ſuſpended in water, without any regular ſolution; at leaſt it is not eaſy, on any other ſuppoſition, to explain the cryſtallizations of carbonat of lime ſometimes depoſited by waters that run over quantities of that mineral.

867 And fuſion. 3. There are many ſubſtances, however, neither ſoluble in water, nor capable of being ſo minutely divided as to continue long ſuſpended in that fluid; and which, notwithſtanding, are capable of aſſuming a cryſtalline form. This is the caſe with the metals, with glaſs, and ſome other bodies. The method employed to cryſtallize them is *fuſion*, which is a ſolution by means of caloric. By this method the particles are ſeparated from one another; and if the cooling goes on gradually, they are at liberty to arrange themſelves in regular cryſtals. There are many ſubſtances, however, which it has been hitherto impoſſible to reduce to a cryſtalline form, either by theſe or any other method. Whether this be owing to the nature of theſe bodies themſelves, or to our ignorance of the laws by which cryſtals are formed, as is much more likely, cannot be determined.

868 Cryſtallization explained. The phenomena of cryſtallization ſeem to have attracted but little of the attention of the ancient philoſophers. Their theory indeed, that the elements of bodies poſſeſs certain regular geometrical figures, may have been ſuggeſted by theſe phenomena; but we are ignorant of their having made any regular attempt to explain them. The ſchoolmen aſcribed the regular figure of cryſtals to their ſubſtantial forms, without giving themſelves much trouble about explaining the meaning of the term. This notion was attacked by Boyle; who proved that cryſtals were formed by the mere aggregation of particles *. But it ſtill remained to explain, why that aggregation took place? and why the particles united in ſuch a manner as to form regular figures? Theſe queſtions were anſwered by Newton. According to him, the aggregation is produced by the attraction which he had proved to exiſt between the particles of all bodies, and which acts as ſoon as theſe particles are brought within a certain diſtance of each other by the evaporation of the liquid in which they are diſſolved. The regularity of their figures he explained by ſuppoſing, that while in a ſtate of ſolution they were arranged in the liquid in regular rank and file; the conſequence

---

* *Treatiſe on the Origin of Forms and Qualities.*

ſequence of which, as they are acted upon by a power which at equal diſtances is equal, at unequal diſtances unequal, will be cryſtals of determinate figures *.

This explanation, which is worthy of Newton, is now univerſally admitted as the true one, and has contributed much towards elucidating this important part of chemiſtry.

Still, however, there remain various phenomena relating to cryſtallization, which it is no eaſy matter to explain.

869 Salts do not eaſily cryſtallize in cloſe veſſels,

It has been obſerved, that thoſe ſalts which cryſtallize upon cooling, do not aſſume a cryſtalline form ſo readily if they are allowed to cool in cloſe veſſels. If a ſaturated ſolution of ſulphat of ſoda, for inſtance, in hot water be put into a phial, corked up cloſely, and allowed to cool without being moved, no cryſtals are formed at all; but the moment the glaſs is opened, the ſalt cryſtallizes with ſuch rapidity that the whole of the ſolution in a manner becomes ſolid. This phenomenon has been explained by ſuppoſing that there is an affinity between the ſalt and caloric, and that while the caloric continues combined with it the ſalt does not cryſtallize; that the caloric does not leave the ſalt ſo readily when external air is not admitted, as glaſs receives it very ſlowly and parts with it very ſlowly. In ſhort, the atmoſpherical air ſeems to be the agent employed to carry off the caloric; a taſk for which it is remarkably well fitted, on account of the change of denſity which it undergoes by every addition of caloric. This is confirmed by the quantity of caloric which always makes its appearance during theſe ſudden cryſtallizations. This explanation might be put to the teſt of experiment, by putting two ſolutions of ſulphat of ſoda in hot water in two ſimilar veſſels; one of glaſs, the other of metal, and both cloſed in the ſame manner. If the ſalt contained in the metallic veſſel cryſtallized, which ought to be the caſe on account of the great conducting power of metals, while that in the glaſs veſſel remained liquid, this would be a confirmation of the theory, amounting almoſt to demonſtration. On the contrary, if both ſolutions remained liquid, it would be a proof that the phenomenon was ſtill incompletely underſtood.

870 And why.

Not only ſalts, but water itſelf, which commonly cryſtallizes at 32°, may be made to exhibit the ſame phenomenon: it may be cooled much lower than 32° without freezing. This, as Dr Black has completely proved, depends entirely upon the retention of caloric.

871 Variety of forms in cryſtals accounted for.

If the regular form of cryſtals depends upon the aggregation of particles, and if during all cryſtallizations this aggregation goes on in the ſame manner, why have not all cryſtals the ſame form? Some have aſcribed theſe differences to a certain polarity which the particles of bodies are ſuppoſed to poſſeſs, and which diſpoſes each kind of particles to arrange themſelves according to a certain law. Sir Iſaac Newton appears rather to have aſcribed it to the forms of the particles themſelves †; and this ſeems to be the real ſolution of the problem. For ſuppoſing that all particles have the ſame form, they muſt of courſe poſſeſs the ſame polarity; and therefore every cryſtal muſt have the ſame form. It is impoſſible, then, to account for the different forms of cryſtals without ſuppoſing that the particles which compoſe them have alſo different forms. And if the particles of bodies have different forms, their regular aggregation muſt produce cryſtals of various ſhapes; and therefore their polarity, which is merely a ſuppoſition founded on this difference in the appearance of cryſtals, cannot be admitted. Suppoſe, for inſtance, that eight cubic particles were regularly arranged in water, and that by the gradual evaporation of the liquid were to approach, and at laſt to combine, it is evident that the cryſtal which they would produce would be a cube. Eight ſix-ſided priſms would alſo produce a ſix-ſided priſm; and eight tetrahedrons would form a very different figure.

But it will be aſked, if the figure of cryſtals depends entirely upon the form of the particles that compoſe them, how comes it that the ſame ſubſtance does not always cryſtallize in the ſame way, but preſents often ſuch a variety of forms that it is ſcarcely poſſible to reckon them? We anſwer, that theſe various forms are ſometimes owing to variations in the ingredients which compoſe the integrant particles of any particular body. Alum, for inſtance, cryſtallizes in octahedrons; but when a quantity of alumina is added, it cryſtallizes in cubes; and when there is an exceſs of alumina, it does not cryſtallize at all. If the proportion of alumina varies between that which produces octahedrons and what produces cubic cryſtals, the cryſtals become figures with fourteen ſides; ſix of which are parallel to thoſe of the cube and eight to thoſe of the octahedron; and according as the proportions approach nearer to thoſe which form cubes or octahedrons, the cryſtals aſſume more or leſs of the form of cubes or octahedrons. What is ſtill more, if a cubic cryſtal of alum be put into a ſolution that would afford octahedral cryſtals, it paſſes into an octahedron: and, on the other hand, an octahedral cryſtal put into a ſolution that would afford cubic cryſtals, becomes itſelf a cube *. Now, how difficult a matter it is to proportion the different ingredients with abſolute exactneſs, muſt appear evident to all.

Another circumſtance which contributes much to vary the form of cryſtals, is the different degree of concentration to which their ſolution has been reduced, and the rapidity or ſlowneſs with which they are formed. For it is too evident to require illuſtration, that when cryſtals are depoſited very rapidly they muſt obſtruct one another, and mix together ſo as very much to obſcure the natural regularity of their form.

Even the nature of the veſſel in which the cryſtallization is performed is not without ſome influence.

872 Hauy's theory of cryſtals.

But, independent of theſe accidental circumſtances, Mr Hauy has ſhewn that every particular ſpecies of cryſtals has a primitive figure, and that the variations are owing to the different ways in which the particles arrange themſelves. Of this theory, which is certainly exceedingly ingenious, and even ſatisfactory, we ſhall attempt to give a ſhort view.

Happening to take up a hexangular priſm of calcareous ſpar, or carbonat of lime, which had been detached from a group of the ſame kind of cryſtals, he obſerved that a ſmall portion of the cryſtal was wanting, and that the fracture preſented a very ſmooth ſurface. Let *abcde fgh* (fig. 8.) be the cryſtal; the fracture lay obliquely as the trapezium *psut*, and made an angle of 135°, both with the remainder of the baſe *abcsph* and with *tuef*, the remainder of the ſide *inef*. Obſerving that the ſegment *psutin* thus cut off had for its vertex *in*, one of the edges of the baſe *abcnih* of the priſm, he attempted to detach a

---

† Optics, p. 375.

* Le Blanc, Ann. de Chim. xiv. 149.

a ſimilar ſegment in the part to which the next edge *c n* belonged, employed for that purpoſe the blade of a knife, directed in the ſame degree of obliquity as the trapezium *p s u t*, and aſſiſted by the ſtrokes of a hammer. He could not ſucceed: But upon making the attempt upon the next edge *b c*, he detached another ſegment, preciſely ſimilar to the firſt, and which had for its vertex the edge *b c*. He could produce no effect on the next edge *a b*; but from the next following, *a h*, he cut a ſegment ſimilar to the other two. The ſixth edge likewiſe proved refractory. He then went to the other baſe of the priſm *d e f g h r*, and found, that the edges which admitted ſections ſimilar to the preceding ones were not the edges *e f*, *d r*, *g k*, correſponding with thoſe which had been found diviſible at the oppoſite baſe, but the intermediate edges *d e*, *k r*, *g f*. The trapezium *l q y v* repreſents the ſection of the ſegment, which had *k r* for its vertex. This ſection was evidently parallel to the ſection *p s u t*; and the other four ſections were alſo parallel two and two. Theſe ſections were, without doubt, the natural joinings of the layers of the cryſtal. And he eaſily ſucceeded in making others parallel to them, without its being poſſible for him to divide the cryſtal in any other direction. In this manner he detached layer after layer, approaching always nearer and nearer the axis of the priſm, till at laſt the baſes diſappeared altogether, and the priſm was converted into a ſolid OX (fig. 9.), terminated by twelve pentagons, parallel two and two; of which thoſe at the extremities, that is to ſay, ASRIO, IGEDO, BAODC at one end, and FKNPQ, MNPXU, ZQPXY at the other, were the reſults of mechanical diviſion, and had their common vertices O, P ſituated at the centre of the baſes of the original priſm. The ſix lateral pentagons RSUXY, ZYRIG, &c. were the remains of the ſix ſides of the original priſm.

By continuing ſections parallel to the former ones, the lateral pentagons diminiſhed in length; and at laſt the points R, G coinciding with the points Y, Z, the points S, R with the points U, Y, &c. there remained nothing of the lateral pentagons but the triangles YIZ, UXY, &c. (fig. 10.). By continuing the ſame ſections, theſe triangles at laſt diſappeared, and the priſm was converted into the rhomboid *a e* (fig. 11.).

So unexpected a reſult induced him to make the ſame attempt upon more of theſe cryſtals; and he found that all of them could be reduced to ſimilar rhomboids. He found alſo, that the cryſtals of other ſubſtances could be reduced in the ſame manner to certain primitive forms; always the ſame in the ſame ſubſtances, but every ſubſtance having its own peculiar form. The primitive form of fluat lime, for inſtance, was an octahedron; of ſulphat of barytes, a priſm with rhomboidal baſes; of field-ſpath, an oblique angled parallelopiped, but not rhomboidal; of adamantine ſpar, a rhomboid, ſomewhat acute; of blende, a dodecahedron, with rhomboidal ſides; and ſo on.

Theſe muſt be conſidered as the real *primitive forms* of the cryſtals; the other forms which they often aſſume may be called *ſecondary forms*.

The primitive cryſtals obtained by the above proceſs may be divided by ſections parallel to their different ſides: all the matter which ſurrounded this primitive cryſtal may alſo be divided by ſections parallel to the ſides of the primitive cryſtal. It follows from this, that the parts detached by means of theſe ſections are ſimilar, and differ from one another only in ſize, which diminiſhes in proportion to the length that the diviſion is carried. But the diviſion of the cryſtals into ſimilar ſolids has a term, beyond which we ſhould come to the ſmalleſt particles of the body, which could not be divided without chemical decompoſition. It is probable, therefore, that the form of the integrant particles of a body is the ſame with the primitive form of its cryſtals. Here, then, we have a method of diſcovering the form of the particles of bodies; and if this method could be applied to all ſubſtances whatever, it would enable us to aſcertain the affinity of all bodies for each other by accurate calculation. It muſt be allowed that ſeveral objections might be made to the concluſions of Mr Hauy; but his theory is, on the whole, ſo plauſible, that it would certainly be worth while to extend it, and apply it to the calculation of affinities as far as it is ſuſceptible of the application. If the cryſtals obtained by the above proceſs be the primitive forms, it becomes a queſtion of ſome conſequence to determine in what manner the ſecondary forms are produced.

According to Hauy, all the parts ſuperadded to the primitive cryſtals, in order to form the ſecondary cryſtal, conſiſt of plates, which decreaſe regularly by the ſubtraction of one or more rows of integrant particles, in ſuch a manner, that the number of theſe ranks, and conſequently the form of the ſecondary cryſtal, may be determined by theory (c).

To explain this, let us ſuppoſe that EP (fig. 12.) repreſents a dodecahedron, terminated by equal and ſimilar rhombs; that this dodecahedron is a ſecondary cryſtal, the primitive form of which is a cube: the ſituation of this cube in the dodecahedron may be conceived from fig. 13. The ſmaller diagonals DC, CG, GF, FD, of four ſides of the dodecahedron, united round the ſame ſolid angle L, form the ſquare CDFG. Now there are ſix ſolid angles, compoſed of four plains, to-wit, the angles L, O, E, N, R, P (fig. 12.); and conſequently, by making ſections through the ſmaller diagonals of the ſides that form theſe angles, ſix ſquares will be made apparent, which are the ſix ſides of the primitive cube, three of which are repreſented in fig. 13. CDFG, ABCD, BCGH.

This cube being compoſed of cubic integrant particles, each of the pyramids, LCDFG for inſtance (fig. 13.) which repoſe upon its ſides, muſt alſo, according to the theory, be compoſed of ſimilar cubic particles. To make this appear, let us ſuppoſe that ABFG (fig. 14.) is a cube compoſed of 729 ſmall cubes: Each of its ſides will conſiſt of 81 ſquares, being the external ſides of as many cubic particles, which together conſtitute the cube. Upon ABCD, one of the ſides of this cube, let us apply a ſquare lamina, compoſed of cubes equal to thoſe of which the primitive cryſtal conſiſts, but which has on each ſide a row of cubes leſs than the outermoſt layer of the primitive cube. It will of courſe be compoſed of 49 cubes, 7 on each ſide; ſo that its lower baſe *o n f g* (fig. 15.) will fall exactly on the ſquare marked with the ſame letters in fig. 14.

Above this lamina let us apply a ſecond *l m p u* (fig. 16.),

---

(c) The explanation of Bergman is not very different. See his *Opuſc.* vol. ii. diſſ. 1.

16.), compoſed of 25 cubes; it will be ſituated exactly above the ſquare marked with the ſame letters (fig. 14.) Upon this ſecond let us apply a third lamina *v x y z* (fig. 17.) conſiſting only of 9 cubes; ſo that its baſe ſhall reſt upon the letters *v x y z* (fig. 14.). Laſtly, on the middle ſquare *r* let us place the ſmall cube *r* (fig. 18.), which will repreſent the laſt lamina.

It is evident, that by this proceſs a quadrangular pyramid has been formed upon the face ABCD (fig. 14.), the baſe of which is this face, and the vertex the cube *r* (fig. 18.). By continuing the ſame operation on the other five ſides of the cube, as many ſimilar pyramids will be formed; which will envelope the cube on every ſide.

It is evident, however, that the ſides of theſe pyramids will not form continued planes, but that, owing to the gradual diminution of the laminæ of the cubes which compoſe them, theſe ſides will reſemble the ſteps of a ſtair. We can ſuppoſe, however (what muſt certainly be the caſe), that the cubes of which the nucleus is formed are exceedingly ſmall, almoſt imperceptible; that therefore a vaſt number of laminæ are required to form the pyramids, and conſequently that the channels which they form are imperceptible. Now DCBE (fig. 19.) being the pyramid reſting upon the face ABCD (fig. 14.), and CBOG (fig. 19.) the pyramid applied to the next face BCGH (fig. 14.), if we conſider that every thing is uniform from E to O (fig. 19.) in the manner in which the edges of the *laminæ of ſuperpoſition* (as the Abbé Hauy calls the laminæ which compoſe the pyramids) mutually project beyond each other, it will readily be conceived, that the face CEB of the firſt pyramid ought to be exactly in the ſame plane with the face COB of the adjacent pyramid; and that therefore the two faces together will form one rhomb ECOB. But all the ſides of the ſix pyramids amount to 24 triangles ſimilar to CEB; conſequently they will form 12 rhombs, and the figure of the whole cryſtal will be a dodecahedron, ſimilar to that repreſented in fig. 12. and 13.

If the decreaſe of the laminæ of ſuperpoſition took place according to a more rapid law, if each lamina had on its circumference two, three, or four rows of cubes leſs than the inferior lamina—in that caſe, the pyramids produced being lower, their adjacent faces would no longer form one plane; and therefore the ſurface of the ſecondary cryſtal would conſiſt of 24 iſoſceles triangles, all inclined towards each other.

In this manner Mr Hauy has ſhewn, that a variety of ſecondary cryſtals are formed, and that their forms vary by means of ſlight variations in the ratio of the *decrement*. Dodecahedral ſulphuret of iron, for inſtance, is formed from a cubic nucleus, by the addition of laminæ, decreaſing, as in the example given above, with this difference, that from every lamina laid upon the face ABCD (fig. 14.) only one row of cubes are ſubtracted at the ſides AD and BC reſpectively; whereas two rows are ſubtracted at each of the ſides AB and CD. The conſequence of this more rapid decrement on two parallel ſides than on the other two will be, that the pyramid raiſed on the face ABCD (fig. 14.), inſtead of terminating in a ſingle cube as in the example given above, will terminate in a range of cubes; or (ſuppoſing the cubes infinitely ſmall) inſtead of terminating in a point, it will terminate in a ridge. The pyramid will therefore have for its two ſides, contiguous to AB and DC, two trapeziums, and for its ſides, contiguous to AD and BC, two triangles. Let us ſuppoſe alſo, that with regard to the laminæ of ſuperpoſition which ariſe on the face BCGH (fig. 14.), the decrements follow the ſame law, and that each lamina decreaſes by two rows of cubes towards the lines BC and HG, and only by one row towards the lines CG, BH: The pyramid, in that caſe, will be placed in a direction oppoſite to the pyramid on ABCD, the ridge at the vertex of it running parallel to BC: the vertex of the pyramid raiſed upon CDFG muſt be parallel to CG: the pyramids on the three other ſides of the cube ought to ſtand each like that which ariſes on the oppoſite face.

The ſides of all the ſix pyramids thus formed amount to twelve trapeziums and twelve triangles. Every triangle is evidently contiguous and in the ſame plane with a trapezium of the neareſt pyramid; conſequently the ſecondary cryſtal thus formed conſiſts of twelve ſides, each of which is a pentagon.

Several other examples have been given by Mr Hauy; but theſe are ſufficient to ſhew in what manner the various ſecondary forms of cryſtals are conſtructed, according to the theory of that ingenious philoſopher.

In his reſearches on this ſubject, Mr Hauy perceived, that ſome cryſtals aſſumed ſecondary forms which could not be accounted for by any decrement whatever along the edges. Thus, for inſtance, ſome bodies, the primary form of which is cubic, are ſometimes found cryſtallized in regular octagons. Mr Hauy explains the formation of theſe ſecondary cryſtals, by ſuppoſing that the decrement took place parallel, not to the edges, but to the diagonals of the faces of the primary cubes.

In order to comprehend this, let us ſuppoſe ABCD (fig. 20.) to be the ſurface of a lamina compoſed of ſmall cubes, the baſes of which are repreſented by the little ſquares in the figure. It is evident, that the cubes *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, are in the direction of the diagonal of the ſquare ABCD; that the row of cubes *q*, *v*, *k*, *u*, *x*, *y*, *z*, is parallel to the diagonal; as alſo the row *n*, *t*, *l*, *m*, *p*, *o*, *r*, *s*; and that the whole figure might be divided into rows of ſquares, each of which would be parallel either to the diagonal AC or DB.

Now we may conceive that the laminæ of ſuperpoſition, inſtead of decreaſing by rows of cubes parallel to the edges AB, AD, decreaſe by rows parallel to the diagonals.

Let it be propoſed to conſtruct around the cube AB GF (fig. 21.), conſidered as a nucleus, a ſecondary ſolid, in which the laminæ of ſuperpoſition ſhall decreaſe on all ſides by ſingle rows of cubes, but in a direction parallel to the diagonals. Let ABCD (fig. 22.), the ſuperior baſe of the nucleus, be divided into 81 ſquares, repreſenting the faces of the ſmall cubes of which it is compoſed. Figure 23. repreſents the ſuperior ſurface of the firſt lamina of ſuperpoſition; which muſt be placed above ABCD (fig. 22.) in ſuch a manner that the points a', b', c', d', (fig. 23.) anſwer to the points *a*, *b*, *c*, *d*, (fig. 22.). By this diſpoſition the ſquares A *a*, B *b*, C *c*, D *d* (fig. 22.), which compoſe the four outermoſt rows of ſquares parallel to the diagonals AC, BD, remain uncovered. It is evident alſo, that the borders QV, ON, IL, GF (fig. 23.), project by one range beyond the borders AB, AD, CD, BC (fig. 22.), which is neceſſary, that the nucleus may be enveloped towards theſe edges: For if this were not the caſe,

caſe, re-entering angles would be formed towards the parts AB, BC, CD, DA, of the cryſtal; which angles appear to be excluded by the laws which determine the formation of ſimple cryſtals, or, which comes to the ſame thing, no ſuch angles are ever obſerved in any cryſtal. The ſolid muſt increaſe, then, in thoſe parts to which the decrement does not extend. But as this decrement is alone ſufficient to determine the form of the ſecondary cryſtal, we may ſet aſide all the other variations which intervene only in a ſubſidiary manner, except when it is wiſhed, as in the preſent caſe, to conſtruct artificially a ſolid repreſentation of a cryſtal, and to exhibit all the details which relate to its ſtructure.

The ſuperior face of the ſecond lamina will be A′ G′L′K′ (fig. 24.). It muſt be placed ſo that the points *a″*, *b″*, *c″*, *d″*, correſpond to the points *a′ b′ c′ d′* (fig. 23.), which will leave uncovered a ſecond row of cubes at each angle parallel to the diagonals AC and BD. The ſolid ſtill increaſes towards the ſides. The large faces of the laminæ of ſuperpoſition, which in fig. 23. were octagons, in fig. 24. arrive at that of a ſquare; and when they paſs that term they decreaſe on all ſides; ſo that the next lamina has for its ſuperior face the ſquare B′M′L′S′ (fig. 25.), leſs by one range in every direction than the preceding lamina (fig. 24.). This ſquare muſt be placed ſo that the points *e′*, *f′*, *g′*, *h′*, (fig. 25.) correſpond to the points *e*, *f*, *g*, *h* (fig. 24.). Figures 26, 27, 28, and 29, repreſent the four laminæ which ought to riſe ſucceſſively above the preceding; the manner of placing them being pointed out by correſponding letters, as was done with reſpect to the three firſt laminæ. The laſt lamina *z′* (fig. 30.) is a ſingle cube, which ought to be placed upon the ſquare *z* (fig. 29.).

The laminæ of ſuperpoſition, thus applied upon the ſide ABCD (fig. 22.), evidently produce four faces, which correſpond to the points A, B, C, D, and form a pyramid. Theſe faces, having been formed by laminæ, which began by increaſing, and afterwards decreaſed, muſt be quadrilaterals of the figure repreſented in fig. 31.; in which the inferior angle C is the ſame point with the angle C of the nucleus (fig. 21. and 22.); and the diagonal LQ repreſents L′G′ of the lamina A′G′L′K′ (fig. 24.). And as the number of laminæ compoſing the triangle L Q C (fig. 31.) is much ſmaller than that of the laminæ forming the triangle ZLQ, it is evident that the latter triangle will have a much greater height than the former.

The ſurface, then, of the ſecondary cryſtal thus produced, muſt evidently conſiſt of 24 quadrilaterals (for pyramids are raiſed on the other 5 ſides of the primary cube exactly in the ſame manner), diſpoſed 3 and 3 around each ſolid angle of the nucleus. But in conſequence of the decrement by one range, the three quadrilaterals which belong to each ſolid angle, as C (fig. 21.) will be in the ſame plane, and will form an equilateral triangle ZIN (fig. 32.). The 24 quadrilaterals, then, will produce 8 equilateral triangles; and conſequently the ſecondary cryſtal will be a regular octagon. This is the ſtructure of the octahedral ſulphuret of lead and of muriat of ſoda.

Decrements which take place in this manner have been called by Mr Hauy *decrements on the angles*.

There are certain cryſtals in which the decrements on the angles do not take place in lines parallel to the diagonals, but parallel to lines ſituated between the diagonals and the edges. This is the caſe when the ſubtractions are made by ranges of double, triple, &c. moleculæ. Fig. 33. exhibits an inſtance of the ſubtractions in queſtion; and it is ſeen that the moleculæ which compoſe the range repreſented by that figure are aſſorted in ſuch a manner as if of two there were formed only one; ſo that we need only to conceive the cryſtal compoſed of parallelopipedons having their baſes equal to the ſmall rectangles *a b c d*, *e d f g*, *h g i l*, &c. to reduce this caſe under that of the common decrements on the angles. To this particular kind of decrement Mr Hauy has given the name of *intermediate*.

In other cryſtals the decrements, either on the edges or on the angles, vary according to laws, the proportion of which cannot be expreſſed but by the fraction $\frac{2}{3}$ or $\frac{3}{4}$. It may happen, for example, that each lamina exceeds the following by two ranges parallel to the edges, and that it may at the ſame time have an altitude triple that of a ſimple molecule. Figure 34. repreſents a vertical geometrical ſection of one of the kinds of pyramids which would reſult from this decrement; the effect of which may be readily conceived, by conſidering that AB is a horizontal line taken on the upper baſe of the nucleus, *b a z r* the ſection of the firſt lamina of ſuperpoſition, *g f e n* that of the ſecond, &c. Theſe decrements Mr Hauy has called *mixed*.

Theſe two laſt ſpecies of decrements occur but rarely; Mr Hauy found them only in certain metallic ſubſtances.

All the metamorphoſes to which cryſtals are ſubjected depend, according to Mr Hauy, on the laws of ſtructure juſt explained, and others of the like kind. Sometimes the decrements take place at the ſame time on all the edges; as in the dodecahedron having rhombuſes for its planes, as before mentioned; or on all the angles, as in the octahedron originating from a cube. Sometimes they take place only on certain edges or certain angles. Sometimes there is an uniformity between them; ſo that it is one ſingle law by one, two, three ranges, &c. which acts on the different edges, or the different angles. Sometimes the law varies from one edge to the other, or from one angle to the other; and this happens above all when the nucleus has not a ſymmetrical form; for example, when it is a parallelopipedon, the faces of which differ by their reſpective inclinations, or by the meaſure of their angles In certain caſes the decrements on the edges concur with the decrements on the angles to produce the ſame cryſtalline form. It happens alſo ſometimes that the ſame edge, or the ſame angle, is ſubjected to ſeveral laws of decrement that ſucceed each other. In ſhort, there are caſes where the ſecondary cryſtal has faces parallel to thoſe of the primitive form, and which combine with the faces produced by the decrements to modify the figure of the cryſtal.

The cryſtals ariſing from a ſingle law of decrement have been called by Mr Hauy *ſimple ſecondary forms*; thoſe which ariſe from ſeveral ſimultaneous laws of decrement he has called *compound ſecondary forms*.

" If amidſt this diverſity of laws (he obſerves), ſometimes inſulated, ſometimes united by combinations more or leſs complex, the number of the ranges ſubtracted were itſelf extremely variable; for example, were theſe decrements by twelve, twenty, thirty, or forty ranges, or more, as might abſolutely be poſſible, the multitude of the forms which might exiſt in each kind of mineral would be immenſe, and exceed what could be imagined. But the power which effects the ſubtractions ſeems to have a very limited action. Theſe ſubtractions, for the moſt part, take place by one or two ranges of molecules. I have found none which exceeded four ranges, except in a variety of calcareous ſpar, forming part of the collection of C. Gillet Laumont, the ſtructure of which depends on a decrement by ſix ranges; ſo that if there exiſt laws which exceed the decrements by four ranges, there is reaſon to believe that they rarely take place in nature. Yet, notwithſtanding theſe narrow limits by which the laws of cryſtallization are circumſcribed, I have found, by confining myſelf to two of the ſimpleſt laws, that is to ſay, thoſe which produce ſubtractions by one or two ranges, that calcareous ſpar is ſuſceptible of two thouſand and forty-four different forms: a number which exceeds more than fifty times that of the forms already known; and if we admit into the combination decrements by three and four ranges, calculation will give 8,388,604 poſſible forms in regard to the ſame ſubſtance. This number may be ſtill very much augmented in conſequence of decrements either mixed or intermediary.

"The ſtriæ remarked on the ſurface of a multitude of cryſtals afford a new proof in favour of theory, as they always have directions parallel to the projecting edges of the laminæ of ſuperpoſition, which mutually go beyond each other, unleſs they ariſe from ſome particular want of regularity. Not that the inequalities reſulting from the decrements muſt be always ſenſible, ſuppoſing the form of the cryſtals had always that degree of finiſhing of which it is ſuſceptible; for, on account of the extreme minuteneſs of the molecules, the ſurface would appear of a beautiful poliſh, and the ſtriæ would elude our ſenſes. There are therefore ſecondary cryſtals where they are not at all obſerved, while they are very viſible in other cryſtals of the ſame nature and form. In the latter caſe, the action of the cauſes which produce cryſtallization not having fully enjoyed all the conditions neceſſary for perfecting that ſo delicate operation of nature, there have been ſtarts and interruptions in their progreſs, ſo that, the law of continuity not having been exactly obſerved, there have remained on the ſurface of the cryſtal vacancies apparent to our eyes. Theſe ſmall deviations are attended with this advantage, that they point out the direction according to which the ſtriæ are arranged in lines on the perfect forms where they eſcape our organs, and thus contribute to unfold to us the real mechaniſm of the ſtructure.

"The ſmall vacuities which the edges of the laminæ of ſuperpoſition leave on the ſurface of even the moſt perfect ſecondary cryſtals, by their re-entering and ſalient angles, thus afford a ſatisfactory ſolution of the difficulty a little before mentioned; which is, that the fragments obtained by diviſion, the external ſides of which form part of the faces of the ſecondary cryſtal, are not like thoſe drawn from the interior part. For this diverſity, which is only apparent, ariſes from the ſides in queſtion being compoſed of a multitude of ſmall planes, really inclined to one another, but which, on account of their ſmallneſs, preſent the appearance of one plane; ſo that if the diviſion could reach its utmoſt bounds, all theſe fragments would be reſolved into molecules ſimilar to each other, and to thoſe ſituated towards the centre.

"The fecundity of the laws on which the variations of cryſtalline forms depend, is not confined to the producing of a multitude of very different forms with the ſame molecules. It often happens alſo, that molecules of different figures arrange themſelves in ſuch a manner as gives riſe to like polyhedra in different kinds of minerals. Thus the dodecahedron with rhombuſes for its planes, which we obtained by combining cubic molecules, exiſts in the granite with a ſtructure compoſed of ſmall tetrahedra, having iſoſceles triangular faces; and I have found it in ſparry fluor *(fluat of lime)*, where there is alſo an aſſemblage of tetrahedra, but regular; that is to ſay, the faces of which are equilateral triangles. Nay more, it is poſſible that ſimilar molecules may produce the ſame cryſtalline form by different laws of decrement. In ſhort, calculation has conducted me to another reſult, which appeared to me ſtill more remarkable, which is, that, in conſequence of a ſimple law of decrement, there may exiſt a cryſtal which externally has a perfect reſemblance to the nucleus, that is to ſay, to a ſolid that does not ariſe from any law of decrement *."

SUCH is a ſhort view of the theory by which Mr Hauy explains the various cryſtalline forms of the ſame ſubſtance. We would with pleaſure have entered more into detail, had not moſt of his examples been deduced from ſubſtances which belong rather to mineralogy than to the elements of chemiſtry. This theory, to ſay no more of it, is, in point of ingenuity, inferior to few; and the mathematical ſkill and induſtry of its author are intitled to the greateſt applauſe.

But what we conſider as the moſt important part of that philoſopher's labours, is the method which they point out of diſcovering the figure of the integrant particles of cryſtals; becauſe it may pave the way for calculating the affinities of bodies, which is certainly by far the moſt important part of chemiſtry. This part of the ſubject, therefore, deſerves to be inveſtigated with the greateſt care.

Mr Hauy has found, that the primitive form of all the cryſtals which he has examined may be reduced to ſix; 1. The parallelopipedon in general, comprehending the cube, the rhomboid, and all ſolids terminated by ſix ſides parallel two and two; 2. The regular tetrahedron; 3. The octahedron with triangular ſides; 4. The hexagonal priſm; 5. The dodecahedron bounded by rhombs; 6. The dodecahedron bounded by iſoſceles triangles. Were we to ſuppoſe that theſe primitive forms are exactly ſimilar to the form of the integrant particles which compoſe them, it would follow, that the integrant particles of all the cryſtals hitherto formed have only ſix different forms. This ſuppoſition, however, is not probable; becauſe the ſame nucleus has been diſcovered in different ſpecies of minerals, and becauſe we can eaſily conceive integrant particles of different forms, combining in ſuch a manner as to compoſe nuclei of the ſame figure, juſt as we have ſeen that different primitive forms are capable of producing the ſame ſecondary form. Still, therefore, in endeavouring to diſcover the integrant particles of bodies, there are difficulties to remove, which hitherto, at leaſt, have been unſurmountable. But the theory of Mr Hauy may be conſidered as a firſt ſtep towards the diſcovery; and a *ſtep* in reſearches of ſo difficult a nature is of very great conſequence.

---

* *Ann. de Chim.* xvii. 225.

Concluſion.

We have now finiſhed the three firſt parts of this article, which comprehend all the elementary part of chemiſtry. We ought now to proceed to the fourth part, which was to conſiſt of a chemical examination of ſubſtances as they exiſt in nature in the mineral, vegetable, and animal kingdoms; but this, for various reaſons, we ſhall defer till we come to the words MINERALOGY, and *Animal and Vegetable* SUBSTANCES.

We ſhall finiſh this article with a few remarks upon the chemical nomenclature, which for ſome time paſt has been an object of ſerious attention.

873
Remarks on the chemical nomenclature.

Chemiſtry was unfortunately firſt cultivated by a ſet of ignorant men, filled with the higheſt notions of their own importance, and buoyed up with the mighty feats which they were to perform by their art. The little which they did know they were anxious to conceal; and their anxiety was no leſs to inſpire the world with high ideas of their knowledge and power. The conſequence of this was, that they loaded chemiſtry with the moſt ridiculous and whimſical names that can well be conceived. *Liver of ſulphur*, *mercury of life*, *horned moon*, *butter of antimony*, *the double ſecret*, *the corraline ſecret*, *the ſecret of vitriol*, *the wonderful ſalt*, *the ſecret ſalt*, *the ſalt with many virtues*, *the ſalt of two ingredients*, *the foliated earth of tartar*, were the names by which they diſtinguiſhed ſome of the moſt familiar preparations; and, were it worth while, a great many more names of the ſame ſtamp might eaſily be added.

As ſoon as chemiſtry had attracted the attention of men of ſcience, the abſurdity of its nomenclature was felt, and ſeveral partial improvements were at different times made in it. Macquer, in particular, diſcarded many of the ancient names, and ſubſtituted others leſs exceptionable in their place.

But ſoon after the publication of the firſt edition of his Dictionary, an evil began to be felt ſeverely, which never could have occurred to the earlier chemiſts. Hitherto the number of objects which had engaged the attention of thoſe who cultivated the ſcience had been very limited; the acids amounted only to five, the earths to four, the metals to 12 or 14, and the neutral ſalts ſcarcely exceeded 20 or 30. To remember names for ſo ſmall a number of bodies, however ridiculous they happened to be, was no very difficult matter. But about that time, in conſequence chiefly of the diſcovery of fixed air by Dr Black, which laid the foundation of pneumatic chemiſtry, the ſcience began to extend itſelf, and to enlarge its boundaries with inconceivable rapidity. The number of bodies connected with it, and which it had to deſcribe, ſoon became immenſe; and if every one of them received names not dependant upon one another, the moſt retentive memory could not have remembered the thouſandth part of them.

The difficulty of ſtudying chemiſtry from that time till the year 1782 muſt have been very great: it was even perceived and complained of by the maſters of the ſcience. In 1782 Mr de Morveau, who had undertaken the chemical part of the *Encyclopedie Methodique*, publiſhed in the *Journal de Phyſique* a new chemical nomenclature, and at the ſame time invited all thoſe perſons who were fond of chemiſtry, and intereſted in its progreſs, to propoſe objections and improvements.

This new nomenclature was formed agreeable to the five following rules:.

1. Every ſubſtance ought to have a name, and not to be denoted by a phraſe.

2. Names ought to be as much as poſſible conformable to the nature of the things ſignified by them.

3. When the character of a ſubſtance is not well enough known to determine the denomination, a name which has no meaning is preferable to one which conveys a falſe idea.

4. In the choice of new words thoſe ought to be preferred which have their roots in the dead languages moſt generally known, that the word may be eaſily ſuggeſted by the ſenſe, and the ſenſe by the word.

5. The new words ought to be as ſuitable as poſſible to the genius of the languages for which they are formed.

This nomenclature was approved of by Macquer, and by Bergman, who had himſelf propoſed one upon a plan not very different (D). He wrote to Morveau, and exhorted him to proſecute his undertaking with courage. "Do not ſpare (ſays he) a ſingle improper denomination; thoſe that are already learned will be always ſo, and thoſe that are not will learn the ſooner*."

This nomenclature was adopted by ſeveral chemiſts, and it was uſed in the greateſt part of the firſt volume of the chemical part of the *Encyclopedie Methodique*; but the new diſcoveries in chemiſtry had produced a more accurate method of reaſoning, and had enabled Lavoiſier to explain the phenomena of the ſcience without the aſſiſtance of the hypothetical principle of phlogiſton, which had hitherto been neceſſary. As the language, even in its improved ſtate, was accommodated to this principle, and preſuppoſed its exiſtence, new changes became evidently neceſſary, in order that, according to Morveau's rule, the words might denote the moſt eſſential properties of the things intended to be ſignified. Accordingly, when Morveau was in Paris in 1787, Lavoiſier, Berthollet, and Fourcroy, agreed to labour in concert with him to bring the chemical nomenclature ſtill nearer to perfection. Theſe philoſophers, aſſiſted by the mathematicians of the Royal Academy and by ſeveral chemiſts, formed a new nomenclature, which they made public in 1787.

* *Encycl. Method. Chim.* Preface.

For ſome time little attention was paid to this nomenclature by foreign chemiſts, and it ſeemed generally to be diſapproved. The adherents of the phlogiſtic ſyſtem in France, who were exceedingly numerous, viewed it as an engine artfully formed to undermine and deſtroy their favourite theory. They reſolved, therefore, unanimouſly, to cruſh, if poſſible, this new inſtrument, which they conſidered as

> ——— *in noſtros fabricata machina muros,*
> *Inſpectura domos, venturaque deſuper urbi.*

And for this purpoſe they exerted themſelves with a vigour, which was only equalled by the zeal and indefatigable exertions of their antagoniſts. A kind of civil war was thus kindled in the republic of letters, which was carried on with great animoſity: And poſterity will ſee, with regret, men of undoubted genius at times diveſting themſelves of the armour of truth and of candour, and endeavouring to ſerve their party, and ſtab their adverſaries with darts ſteeped in the poiſon of calumny and falſehood *. This conteſt, however, which was not confined to France, was productive of good effects, which infinitely ſurpaſſed all the bad ones. It occa-

† See the *Journ. de Phyſ.* for 1788, 89, 90, 91, *paſſim.*

(D) See his thoughts on a natural hiſtory of foſſils in the 4th vol. of his *Opuſc.*

occaſioned an accumulation of facts, produced a rigid examination of theories and opinions, introduced an accuracy into chemical experiments which has been of the moſt eſſential ſervice, and gave that tone and vigour to the cultivators of chemiſtry which have brought to light the moſt ſublime and unlooked-for truths. It deſerves attention, and the fact is no inconſiderable evidence in favour of the antiphlogiſtic theory, that almoſt all the illuſtrious chemiſts who at preſent adhere to it declared originally againſt it. Berthollet, Morveau, Black, Kirwan, and many other chemiſts who are now its ableſt defenders, were at firſt its moſt powerful opponents. "This ſyſtem had hardly been publiſhed in France (ſays Dr Prieſtley, who ſtill continues to adhere to the doctrine of phlogiſton) before the principal philoſophers and chemiſts of England, notwithſtanding the rivalſhip which has long ſubſiſted between the two countries, eagerly adopted it. Dr Black in Edinburgh, and as far as I hear all the Scots, have declared themſelves converts, and, what is more, the ſame has been done by Mr Kirwan, who wrote a pretty large treatiſe in oppoſition to it. The Engliſh reviewers of books, I perceive, univerſally favour the new doctrine. In America, alſo, I hear of nothing elſe. It is taught, I believe, in all the ſchools on this continent, and the old ſyſtem is entirely exploded. And now that Dr Crawford is dead, I hardly know of any perſon except my friends of the Lunar Society at Birmingham, who adhere to the doctrine of phlogiſton; and what may now be the caſe with *them* in this age of revolutions, philoſophical as well as civil, I will not at this diſtance anſwer for.

"It is no doubt *time*, and of courſe opportunity of examination and diſcuſſion, that gives ſtability to any principles. But this new theory has not only kept its ground, but has been conſtantly and uniformly advancing in reputation more then *ten years*, which, as the attention of ſo many perſons, the beſt judges of every thing relating to the ſubject, has been unremittingly given to it, is no inconſiderable period. Every year of the laſt twenty or thirty has been of more importance to ſcience, and eſpecially to chemiſtry, than any ten in the preceding century *."

We have endeavoured in the preceding article to ſtate the different theories which have ſucceſſively made their appearance in *chemiſtry* with as much fairneſs as poſſible. If we have ſucceeded, the reader will be enabled to judge for himſelf which of theſe theories is the moſt conſiſtent with truth; or rather, if we have ſucceeded, he will join with us in thinking that the theory of Lavoiſier is in moſt points an accurate account of what takes place in nature.

This we conſider as a ſufficient reaſon for having adopted the new nomenclature; for, as Morveau long ago obſerved, moſt of the objections that were made to it were rather levelled at the doctrine of thoſe who formed it, than at the nomenclature itſelf. Its ſuperiority to every other nomenclature cannot be diſputed for an inſtant; and the vaſt facility which it has added to the acquiſition of chemiſtry, muſt be acknowledged by every one who knows any thing about the ſcience. The Table of the new nomenclature will not be expected here, as it has been already given in the Appendix to the article CHEMISTRY in the *Encyclopedia*. At any rate, it would have been unneceſſary, as we have uſed the new names all along; and therefore our readers muſt by this time be well acquainted with them.

Upon the almoſt infinite number of criticiſms which have been made on the new nomenclature, and the many new terms which ſince its publication have been ſucceſſively propoſed, we do not mean to enter. Few of theſe terms can bear a compariſon with the French nomenclature, and ſtill fewer have any claim to be preferred to it; and the philoſophers who perſiſt in theſe uſeleſs innovations, are more probably actuated by the deſire of appearing to have a ſhare in the great revolution which chemiſtry has undergone, than by any hopes of being able to improve the accuracy or the elegance of its language. How few have diſplayed the magnanimity of an illuſtrious philoſopher of our own country, who, though he had invented a new nomenclature himſelf, exhorted his pupils not to uſe it, but to adopt that of the French chemiſts, which was likely ſoon to come into univerſal uſe.

Even the etymological remarks which have been made on the new nomenclature, we conſider as either of little conſequence or as ill-founded. The philoſophers who formed it have diſplayed a ſagacity and a moderation which could not be excelled, and have, upon the whole, formed a language much more ſyſtematic, and much more perfect, than could have been expected; and whoever compares it with the nomenclature propoſed in 1782 by Morveau, will ſee how great a ſhare of it is due to that illuſtrious philoſopher.

Notwithſtanding what we have here ſaid, we would not be underſtood to conſider the new nomenclature as already arrived at a ſtate of ſuch abſolute perfection, that no alteration whatever can be made in it except for the worſe. Such perfection belongs not to the works of man; nor if it did, could it be expected in this caſe, if we conſider for a moment the preſent ſtate of chemiſtry. New diſcoveries muſt occaſion additions and alterations in the nomenclature; but the authors of the new nomenclature have given us the rules by which changes and additions are to be made; and if they are adhered to, we may expect with confidence that the language of chemiſtry will in its advancement to perfection keep pace with the ſcience. We have in the preceding article ventured in an inſtance or two to adopt little improvements that have been ſuggeſted by later writers. We have taken the liberty, too, of chooſing, from the variety which the Britiſh chemiſts have propoſed, that mode of ſpelling each of the terms which appeared to us moſt agreeable to the Engliſh idiom, and moſt conformable to analogy: Whether or not we have made a proper choice muſt be left for others to determine.

INDEX.

Cherubim.

CHERUBIM were emblematical figures; of which an account, a very vague one indeed, has been given in the *Encyclopædia Britannica*. We are far from thinking ourſelves qualified to improve that account, or to explain emblems in the Jewiſh worſhip, which even Joſephus did not underſtand; and we certainly ſhould not have reſumed the ſubject but to gratify a numerous claſs of our readers, and to comply with the requeſt of ſome highly reſpected friends.

The followers of Mr Hutchinſon, who are firmly perſuaded that their maſter brought to light from the writings of the Old Teſtament many important doctrines which had lain concealed from all the piety, all the induſtry, and all the learning of 1700 years, believe that, among other things, he and they have been able to aſcertain the form and the import of the Hebrew Cherubim. Their diſcoveries on this ſubject, as we have been told by better judges than we pretend to be, are more clearly ſtated by Mr Parkhurſt in his Hebrew Lexicon, than by any other writer of that ſchool. We ſhall therefore lay before our readers his doctrine reſpecting the form of the artificial cherubs, as well as of their emblematical meaning; and ſubjoin a few remarks, which the nature of his reaſoning has forced from us.

" *Firſt*, then, as to the *form* of the artificial cherubs in the tabernacle and temple, Moſes (ſays our author) was commanded (Exod. xxv. 18, 19.) ' Thou ſhalt make two cherubs: of beaten gold ſhalt thou make them at the two ends of the mercy-ſeat. And thou ſhalt make one cherub at the one end, and the other cherub at the other end: מן הבפרת, out of the mercy-ſeat (Margin Eng. Traſlat. of the matter of the mercy-ſeat) ſhall ye make the cherubs at the two ends thereof.' All which was accordingly performed (Exod. xxxvii, 7, 8.), and theſe cherubs were with the ark placed in the holy of holies of the tabernacle (Exod. xxvi. 33, 34. xl. 20.); as thoſe made by Solomon were afterwards in the holy of holies of the temple (1 Kings vii. 23, 27.)

We may obſerve that in Exodus Jehovah ſpeaks to Moſes of the cherubs as of figures well known; and no wonder ſince they had always been among believers in the holy tabernacle from the beginning. (See Gen. iii. 24. Wiſd. ix. 8. And though mention is made of their faces (Exod. xxv. 20. 2 Chron. iii. 13.), and of their wings, (Exod. xxv. 20. 1 Kings viii. 7. 2 Chron. iii. 11, 12.); yet neither in Exodus, Kings, nor Chronicles, have we any particular deſcription of their form. This is however very exactly, and, as it were, anxiouſly ſupplied by the prophet Ezekiel, ch. i. 5. ' Out of the midſt thereof (*i. e.* of the fire infolding itſelf, ver. 4.) דמות the likeneſs of four livings creatures or animals; דמות ארם להנה the likeneſs of a man (being) with them.' This laſt Hebrew expreſſion cannot mean that they, *i. e.* the four animals, had the likeneſs of a man, which interpretation would indeed make the prophet contradict himſelf (comp. ver. 10.); but it imports that the likeneſs of a man in glory, called (verſe 26.) דמות במראה ארם the likeneſs as the appearance of a man, and

and particularly deſcribed in that and the following verſes, was with them. Ver. 6. ‘ And there were four faces to one (דמות or ſimilitude), and four wings to one, לחם to them. So there were at leaſt two compound figures. Ver. 10. ‘ And the likeneſs of their faces; the face of a man, and the face of a lion, on the right ſide, to them four; and the face of an ox to them four; and the face of an eagle to them four.’ Ezekiel knew (ch. x. 1.—20.) that theſe were cherubs. Ver. 21. ‘ Four faces לאחר to one (cherub) and four wings to one.’ This text alſo proves that the prophet ſaw more cherubs than one, and that each had four faces and four wings. And we may be certain that the cherubs placed in the holy of holies were of the form here deſcribed by the prieſt and prophet of Ezekiel, becauſe we have already ſeen from Exodus, 1 Kings, and 2 Chronicles, that they likewiſe had faces and wings, and becauſe Ezekiel knew what he ſaw to be cherubs, and becauſe there were no four-faced cherubs any where elſe but in the holy of holies; for it is plain from a compariſon of Exod. xxvi. 1, 31. 1 Kings vi. 29, 32. and 2 Chron. iii. 14. with Ezekiel xli. 18, 19, 20. that the artificial cherubs on the curtains and vail of the tabernacle, and on the walls, doors, and vail of the temple, had only two faces; namely, thoſe of a lion and of a man.

“ For it muſt be obſerved further, that, as the word כרוב is uſed for one compound figure with four faces, and כרובים in the plural for ſeveral ſuch compounds (ſee Exod. xxv. 18, 19. xxxvii. 8. 1 Kings vi. 23—26), ſo is כרוב applied to one of the cherubic animals, as to the ox, Ezek. x. 14.; (compare ch. i. 10.) to the coupled cherub, or lion-man, Ezek. xli. 18.; and כרובים to ſeveral of the cherubic animals, as to ſeveral oxen, 1 Kings vii. 36. (compare ver. 29.) to ſeveral coupled cherubs, Exod. xxvi. 1. 1 Kings vi. 32, 35. & al. I proceed to ſhew.

“ *Secondly*, of what the cherubs were emblems, and with what propriety.

“ That the cherubic figures were emblems or repreſentatives of ſomething beyond themſelves is, I think, agreed by all, both Jews and Chriſtians. But the queſtion is, Of what they were emblematical? To which I anſwer in a word, Thoſe in the holy of holies were emblematical of the ever-bleſſed Trinity in covenant to redeem man, by uniting the human nature to the Second Perſon; which union was ſignified by the union of the faces of the lion and of the man in the cherubic exhibition, Ezek. i. 10. compare Ezek. xli. 18, 19. The cherubs in the holy of holies were certainly intended to repreſent ſome beings in heaven, becauſe St Paul has expreſsly and infallibly determined that the holy of holies was a figure or type of heaven, even of that heaven where is the peculiar reſidence of God (Heb. ix. 24.). And therefore theſe cherubs repreſented either the ever bleſſed Trinity with the man taken into the eſſence, or created ſpiritual angels. The following reaſons will, I hope, clearly prove them to be emblematical of the former, not of the latter:

“ 1*ſt*, Not of angels; becauſe (not now to inſiſt on other circumſtances in the cherubic form) no tolerable reaſon can be aſſigned why angels ſhould be exhibited with four faces apiece.

“ 2*dly*, Becauſe the cherubs in the holy of holies of the tabernacle were, by Jehovah’s order, ‘ made out of the matter of the mercy-ſeat, or beaten out of the ſame piece of gold as that was’ (Exod. xxv. 18, 19. xxxvii. 9.). Now the mercy-ſeat, made of gold and crowned, was an emblem of the Divinity of Chriſt (See Rom. iii. 25. The cherubs therefore repreſented not the angelic, but the Divine nature.

“ 3*dly*, The typical blood of Chriſt was ſprinkled before them on the great day of atonement (compare Exod. xxxvii. 9. Lev. xvi. 14. Heb. ix. 7, 12.): And this cannot in any ſenſe be referred to created angels, but muſt be referred to Jehovah only; becauſe,

“ 4*thly*, The high prieſt’s entering into the holy of holies on that day, repreſented Chriſt’s entering with his own blood into heaven ‘ to appear in the preſence of God for us’ (Heb. ix. 7, 24.) And,

5*thly*, When God ‘ raiſed Chriſt (the humanity) from the dead, he ſet him at his own right hand in the heavenly places, far above, ʽΥΠΕΡΑΝΩ, all principality and power, and might and dominion, and every name that is named, not only in this world, but alſo in that which is to come (Eph. i. 21.). Angels and authorities and powers being made ſubject unto him’ (1 Peter iii. 22.)

“ 6*thly*, The prophet Ezekiel ſaith (ch. x. 20.), ‘ This is the living creature, החיה (which muſt mean one compound figure, comp. ver. 14.) that I ſaw’ תחת inſtead of, a ſubſtitute of ‘ the Aleim of Iſrael. תחת, it is granted, may refer either to ſituation or ſubſtitution, (ſee Gen. xxx. 2. l. 19.) as the ſenſe requires. Here, notwithſtanding what is ſaid ver. 19. the latter ſenſe is preferable; becauſe it was the glory of the God of Iſrael, *i. e.* the God-man in glory, (compare ch. i. 26.) not the Aleim (the Trinity) of Iſrael that were over the cherubim; and the text ſays not, *theſe* were the living *creatures*, but, *this* was the living *creature*, which I ſaw תחת אלהי ישראל.’ Now the glory was over both the cherubims, ver. 19. but one compound cherub only was a ſubſtitute of the Aleim.

“ If it ſhould be here aſked, Why then were there two compound cherubs in the holy of holies? I anſwer, Had there not in this place been two compound cherubs, it would have been naturally impoſſible for them to repreſent what was there deſigned; for otherwiſe, all the faces could not have looked inwards toward each other, and down upon the mercy-ſeat, and on the interceding high prieſt ſprinkling the typical blood of Chriſt, (ſee Exod. xxxvii. 9.) and at the ſame time have looked outward toward the temple, לבית (Vulg. ad domum exteriorum, to the outer-houſe,) 2 Chron. iii. 13. Or, in other words, the Divine Perſons could not have been repreſented as witneſſing to each other’s voluntary engagements for man’s redemption, as beholding the ſacrifice of Chriſt’s death, typified in the Jewiſh church, and at the ſame time as extending their gracious regards to the whole world. (See Iſa. liv. 5. and Spearman’s Inquiry, p. 382. edit. Edinburgh.

“ The coupled cherub, or lion-man, on the vail and curtains of the outer tabernacle, and on the vail, doors, and walls of the temple, accompanied with the emblematic palm-tree, is ſuch a ſtriking emblem of the lion of the tribe of Judah (Rev. v. 5.) united to the man Chriſt Jeſus, as is eaſy to be perceived, but hard to be evaded. Theſe coupled cherubs appropriate the tabernacle or temple, and their vails, as emblems of Chriſt, and expreſs in viſible ſymbols what he and his apoſtles do in words. See John ii. 19, 21. Heb. viii. 2. ix. 11. x. 20.

x. 20. comp. Matt. xxvii. 51. And as the texts juſt cited from the New Teſtament afford us divine authority for aſſerting that the outer tabernacle or temple was a type of the body of Chriſt, ſo they furniſh us with an irrefragable argument to prove that the cherubs on their curtains or walls could not repreſent angels. For did angels dwell in Chriſt's body? No, ſurely: But 'in him dwelt all the fulneſs of the Godhead bodily.' (Col. ii. 9.)

" I go on to conſider the propriety of the animals in the cherubic exhibition repreſenting the Three Perſons in the ever-bleſſed Trinity. And here to obviate any undue prejudice which may have been conceived againſt the Divine Perſons being ſymbolically repreſented under any animal forms whatever, let it be remarked that Jehovah appeared as three men to Abraham (Gen. xviii.); that the ſerpent of braſs ſet up by God's command in the wilderneſs was a type or emblem of Chriſt, God-man, lifted up on the croſs (comp. Num. xxxi. 1—9. with John iii. 14, 15.); that at Jeſus's baptiſm the Holy Spirit deſcended in a bodily ſhape, like a dove, upon him (Luke iii. 21, 22.); that Chriſt, as above intimated, is expreſsly called the lion of the tribe of Judah (Rev. v. 5.); and continually in that ſymbolical book ſet before us under the ſimilitude of a lamb. All theſe are plain ſcriptural repreſentations, each of them admirably ſuited, as the attentive reader will eaſily obſerve, to the particular circumſtances or ſpecific deſign of the exhibition. Why then ſhould it appear a thing incredible, yea why not highly probable, that Jehovah Aleim ſhould, under the typical ſtate, order his own Perſons and the union of the manhood with the eſſence to be repreſented by animal forms in the cherubim of glory? Eſpecially if it be conſidered that the three animal forms, excluſive of the man (who ſtood for the very human nature itſelf) are the chief of their reſpective genera: the ox or bull of the tame or graminivorous; the lion, of the wild or carnivorous; and the eagle, of the winged kind.—But this is by no means all: For as the great agents in nature, which carry on all its operations, certainly are the fluid of the heavens, or, in other words, the fire at the orb of the ſun, the light iſſuing from it, and the ſpirit or groſs air conſtantly ſupporting, and concurring to the actions and effects of the other two; ſo we are told (Pſal. xix. 1.) that השמים מספרים כבוד אל the heavens (are) the means of declaring, recounting, or particularly exhibiting the glory of God, even his eternal power and godhead, as St Paul ſpeaks, Rom. i. 20. And accordingly Jehovah himſelf is ſometimes, though rarely (I preſume for fear of miſtakes) called by the very name שמים or שמיא heavens in the Old Teſtament, ſee 2 Chron. xxxii. 20. (comp. 2 Kings xix. 14. Iſa. xxxvii. 15.) Dan. iv. 23. or 26.; as he is more frequently expreſſed by ουρανος heaven in the New. (See Mat. xxi. 25. Mark xi. 30. 31. Luke xv. 18, 21. xx. 4, 5. John iii. 27.) Yea not only ſo, but we find in the Scriptures both of the Old and New Teſtament, that the Perſons of the eternal Three and their economical operations in the ſpiritual, are repreſented by the three conditions of the celeſtial fluid and their operations in the material world. Thus the peculiar emblem of the Word or Second Perſon is the שמש or light, and he is and does that to the ſouls or ſpirits of men which the material or natural light is and does to their bodies. (See inter al. 2 Sam. xxiii. 4. Iſa. xlix. 6. lx. 1. Mal. iv. 2. or iii. 20. Luk i. 78. ii. 32. John i. 4—9. viii. 12. xii. 35, 36, 46.) The Third Perſon has no other diſtinctive name in ſcripture but רוח in Hebrew, and Πνευμα in Greek (both which words in their primary ſenſe denote the material ſpirit or air in motion), to which appellation the epithet קדש, αγιος holy, or one of the names of God, is uſually added: and the actions of the Holy Spirit in the ſpiritual ſyſtem are deſcribed by thoſe of the air in the natural (See John iii. 8. xx. 22. Acts ii. 2.) Thus, then, the ſecond and Third Perſons of the ever-bleſſed Trinity are plainly repreſented in ſcripture by the material light and air. But it is further written, Jehovah thy Aleim is a conſuming fire. Deut. iv. 24. (Comp. Deut. ix. 23. Heb. xii. 29. Pſal. xxi. 10. lxxviii. 21. Nah. i. 2.) And by fire, derived either immediately or mediately from heaven, were the typical ſacrifices conſumed under the old diſpenſation. Since, then, Jehovah is in ſcripture repreſented by the material heavens, and even called by their name, and eſpecially by that of fire, and ſince the Second and Third Perſons are exhibited reſpectively by the two conditions of light and ſpirit, and ſince fire is really a condition of the heavenly fluid as much diſtinct from the other two as they are from each other, it remains that the peculiar emblem of the Firſt Perſon (as we uſually ſpeak) of the eternal Trinity, conſidered with reſpect to the other two, be the fire.

" Bearing then in mind that the perſonality in Jehovah is in ſcripture repreſented by the material Trinity of nature; which alſo, like their divine antitype, are of one ſubſtance, that the primary ſcriptural type of the Father is fire; of the Word, light; and of the Holy Ghoſt, ſpirit, or air in motion; we ſhall eaſily perceive the propriety of the cherubic emblems. For the ox or bull, on account of his horns, the curling hair on his forehead, and his unrelenting fury when provoked (ſee Pſal. xxii. 13) is a very proper animal emblem of fire; as the lion from his uſual tawny gold-like colour, his flowing mane, his ſhining eyes, his great vigilancy and prodigious ſtrength, is of light; and thus likewiſe the eagle is of the ſpirit or air in action, from his being chief among fowls, from his impetuous motion (ſee 2 Sam. i. 23. Job ix. 26. Jer. iv. 13. Lam. iv. 19.), and from his towering and ſurpriſing flights in the air (ſee Job xxxix. 27. Prov. xxiii. 5. xxx. 19. Iſa. xl. 31. and Bochart, vol. iii. p. 173.) And the heathen uſed theſe emblematic animals, or the like, ſometimes ſeparate, ſometimes joined, in various manners, as repreſentatives of the material Trinity of nature, which they adored. Theſe particulars Mr Hutchinſon has proved with a variety of uſeful learning, vol. vii. p. 381, et ſeq. and any perſon who is tolerably acquainted with the heathen mythology will be able to increaſe his valuable collection with many inſtances of the ſame kind from modern as well as ancient accounts of the pagan religions.

" Thus, then, the faces of the ox, the lion, and the eagle, repreſenting at ſecond hand the Three Perſons of Jehovah, the Father, the Word, and the Holy Spirit; and the union of the divine light with man being plainly pointed out by the union of the faces of the lion and the man (ſee Ezek. i. 10. xli. 18.), we may ſafely aſſert, that the cherubim of glory (Heb. ix. 5.) in the holy of holies were divinely inſtituted and proper emblems of the Three Eternal Perſons in covenant to redeem man, and of the union of the divine and human natures in the perſon of Chriſt. And we find (Gen. iii. 24) that immediately on Adam's expulſion from paradiſe, and the ceſſation of the firſt or paradiſiacal diſpenſation of religion, Jehovah Aleim himſelf ſet up theſe emblems, together with the burning flame המתהפכת rolling upon itſelf, to keep the way to the tree of life; undoubtedly, conſidering the ſervices performed before them, not to hinder, but to enable, man to paſs through it."

Thus far Mr Parkhurſt; and to his diſſertation where is the man who will deny the merit of erudition, combined with ingenuity? To the latter part of his reaſoning, however, objections obtrude themſelves upon us of ſuch force, that we know not how to anſwer them. The reader obſerves, that, according to this account, the cherubim are only at *ſecond hand* emblematical of the Holy Trinity, and that the *primary* emblem is that fluid which the author conceives to fill the ſolar ſyſtem, and to be one ſubſtance under the different appearances or modifications of *fire*, *light*, and *groſs air*. But unfortunately for this reaſoning, we are as certain as we can be of any matter of fact, that *fire* and *air* are *not* one ſubſtance; that the *groſs air* itſelf is compounded of very *different* ſubſtances; and that even *light* is a different ſubſtance from that which cauſes in us the ſenſation of heat, and to which modern chemiſts have given the name of *caloric* (See CHEMISTRY-*Index* in this Supplement). We admit, that the *primary atoms* of all matter *may be* ſubſtances of the very ſame kind, though we do not *certainly know* that they are: but this makes nothing for our author's hypotheſis; becauſe the ſun and all the planets muſt, in that caſe, be added to his one ſubſtance, which would no longer appear under a triple form. Could it indeed be proved, that all men from Adam downwards, who made uſe of cherubic figures for the very ſame purpoſe with the ancient Jews, *believed* that fire, air, and light, are different modifications of the ſame ſubſtance, their belief, though erroneous, would be a ſufficient foundation for our author's reaſoning; but of this no proof is attempted, and certainly none that is ſatisfactory could be brought.

Our learned author, indeed, takes much for granted without proof. He has not proved that anywhere the bull was the emblem or hieroglyphic of *fire*, the lion of *light*, or the eagle of *air*. We do not, it muſt be owned, know that ſuch hieroglyphics were *not* uſed in Egypt and other countries before the introduction of alphabetical characters; but unleſs they were ſo uſed by Adam, all that is here ſaid of the *propriety* of theſe emblems muſt go for nothing: Indeed we ſee not their peculiar propriety. The tawny colour, flowing mane, and fierceneſs of the lion, might, for any thing that we can perceive to the contrary, repreſent *fire* as fitly as the horns, curling hair, and fury of the bull; and if it be true, as is generally ſaid, that the eagle can look ſteadily on the ſun, he ſeems, of all the three, to be the fitteſt emblem of light.

But there are other objections to this interpretation of the word cherubim. The four animals in the Revelation, which were undoubtedly cherubim, as well as the four and twenty elders, fell down before the Lamb, and worſhipped God*. Now, ſays Dr Gregory Sharp, "it is ſcarce to be conceived, if theſe four beaſts were repreſentatives of the divine perſons, that they could with any propriety, or without the greateſt ſoleciſm, be ſaid and deſcribed to fall down before and worſhip other emblematical repreſentations of the ſame divine nature and perfections: And therefore, whatever theſe beaſts were emblems of, they could not be cherubim in Mr Hutchinſon's ſenſe of that word; it being as contrary to the rational explanation of a viſion to ſay that one emblem of the divinity ſhould worſhip another emblem of it, as it is contrary to the reaſon of mankind, and to all our notions either of the Godhead or of worſhip, to ſay that the Trinity worſhipped the Trinity, or any one Perſon in the Trinity."

This objection is admitted by our learned author to be a very plauſible one. To us it appears unanſwerable. He anſwers it, however, in the following words:

"Let it be carefully obſerved, that theſe repreſentations in Rev ch. v. and xix. are not only viſional but hieroglyphical, and therefore muſt be explained according to the analogy of ſuch emblematical exhibitions; and as at ver. 6. 'the lamb, as it had been ſlain, having ſeven horns and ſeven eyes, ſtanding in the midſt of the throne, and of the four animals, and of the four-and-twenty elders,' is evidently ſymbolical of the Lamb of God now raiſed from the dead, and inveſted with all knowledge and power both in heaven and in earth; ſo 'the four animals falling down before him' (ver. 8.), and, as it is expreſſed (ch. xix. 4.), 'worſhipping God who ſat upon the throne,' muſt, in all reaſon, be explained ſymbolically likewiſe, not from any abſtract or metaphyſical notions we may have framed to ourſelves of worſhip in general, but from the ſpecific and peculiar circumſtances of the caſe before us. Thus, likewiſe, when in 1 Chron. xxix. 20. 'All the congregation worſhipped Jehovah and the king, namely David, the worſhip to both is expreſſed by the ſame ſtrong phraſe—ישתחוו ל proſtrated themſelves to, LXX. προσεκυνησαν; yet ſurely no one will ſay that the people meant to worſhip David as God, but only to acknowledge him as king. So Adonijah, who had conteſted the crown with Solomon, came, וישתחו and worſhipped King Solomon (1 Kings i. 53.), not as God doubtleſs, but as king, thereby ſurrendering his own claim to the throne. However 'contrary therefore it may be to the reaſon of mankind, and to all our notions either of the Godhead or of worſhip, to ſay that the Trinity worſhipped the Trinity, or any one Perſon of the Trinity,' *i. e.* with divine worſhip as a creature worſhips his Creator; yet it is by no means contrary to the rational and ſcriptural explanation of an emblematic viſion, to ſay that the hieroglyphical emblems of the whole ever-bleſſed Trinity fell down and worſhipped the hieroglyphical emblem of the God-man, or God who ſat upon the throne. Since ſuch falling down, proſtration, or worſhipping, was the uſual ſymbolical act, as it ſtill is in the eaſt, not only of divine worſhip, but of acknowledging the regal power to be in the perſon ſo worſhipped; and theſe acts of the cherubic animals in Rev. v. 6. xix. 4. meant nothing more than either a ceſſion of the adminiſtration of all divine power to Chriſt God-man, or a declaration of the divine Perſons, by their hieroglyphical repreſentatives, that He muſt reign till all his enemies were made his footſtool. Comp. Mat. xxviii. 18. 1 Cor. xv. 25."

With every inclination to honour the memory of Mr Parkhurſt, who was certainly a ſcholar, and, which is of

---

* Ch. v. 8. xix. 4.

of more value, a pious and a good man, we cannot help conſidering this anſwer as mere trifling. In the 18th Pſalm, the Lord is ſaid to "ride upon a cherub;" and in Ezekiel, chap. i. there is ſaid to have "been over the heads of the cherubim *a throne*, and upon that throne the likeneſs or appearance of *a man*," whom we take to be the Son of God incarnate. But is there any country in which the regal power of the ſovereign is acknowledged by his riding, not upon his ſubjects, but upon other co-equal ſovereigns? or, in which it is the cuſtom for the ſovereign to place his viceroy (for ſuch our Saviour in his *human* nature certainly is) in his throne above himſelf?

We muſt therefore confeſs, that we know not of what the cherubic figures were emblematical, and that he who labours to eſtabliſh the doctrine of the ever bleſſed Trinity by ſuch criticiſms and reaſonings as thoſe which we have examined, is either a ſecret enemy to that doctrine, or a very injudicious friend.

CHESS, the celebrated game, of which a copious account has been given in the Encyclopædia, is affirmed by Sir William Jones to have been invented by the Hindoos. "If evidence were required to prove this fact (ſays he *), we may be ſatisfied with the teſtimony of the Perſians, who, though as much inclined as other nations to appropriate the ingenious inventions of a foreign people, unanimouſly agree that the game was imported from the weſt of *India* in the ſixth century of our era. It ſeems to have been immemorially known in *Hindoſtan* by the name of *Cheturanga*, i. e. the four *angá's*, or members of an army; which are theſe, *elephants*, *horſes*, *chariots*, and *foot ſoldiers*; and in this ſenſe the word is frequently uſed by epic poets in their deſcriptions of real armies. By a natural corruption of the pure Sanſcrit word, it was changed by the old Perſians into *Chetrang*; but the Arabs, who ſoon after took poſſeſſion of their country, had neither the initial nor final letter of that word in their alphabet, and conſequently altered it further into *Shetranj*, which found its way preſently into the modern *Perſian*, and at length into the dialects of India, where the true derivation of the name is known only to the learned. Thus has a very ſignificant word in the ſacred language of the Brahmins been transformed by ſucceſſive changes into *axedrez*, *ſcacchi*, *échecs*, *cheſs*, and, by a whimſical concurrence of circumſtances, has given birth to the Engliſh word *check*, and even a name to the *exchequer* of Great Britain."

It is confidently aſſerted that Sanſcrit books on *cheſs* exiſt in Bengal; but Sir William had ſeen none of them when he wrote the memoir which we have quoted. He exhibits, however, a deſcription of a very ancient *Indian* game of the ſame kind, but more complex, and in his opinion more modern, than the ſimple cheſs of the *Perſians*. This game is alſo called *Chaturanga*, but more frequently *Chaturaji*, or the *four kings*, ſince it is played by four perſons repreſenting as many princes, two allied armies combating on each ſide. The deſcription is taken from a book called *Bhawiſhya Purán*; in which the form and principal rules of this factitious warefare are thus laid down: "Eight ſquares being marked on all ſides, the *red* army is to be placed to the eaſt, the *green* to the ſouth, the *yellow* to the weſt, and the *black* to the north. Let the *elephant* (ſays the author of the *Purán*) ſtand on the left of the *king*; next to him the *horſe*; then the *boat*; and before them all, four *foot-ſoldiers*; but the *boat* muſt be placed in the angle of the board."

"From this paſſage (ſays the preſident) it clearly appears, that an army with its four *angás* muſt be placed on each ſide of the board, ſince an *elephant* could not ſtand, in any other poſition, on the left hand of each *king*; and RADHACANT (a Pandit) informed me, that the board conſiſted, like our's, of 64 ſquares, half of them occupied by the forces, and half vacant. He added, that this game is mentioned in the oldeſt law-books, and that it was invented by the wife of a king, to amuſe him with an image of war, while his metropolis was beſieged, in the ſecond age of the world. A *ſhip* or *boat* is abſurdly ſubſtituted, we ſee, in this complex game for the *rat'h*, or armed *chariot*, which the *Bengaleſe* pronounce *rot'h*, and which the Perſians changed into *rokh*; whence came the *rook* of ſome European nations; as the *vierge* and *fal* of the French are ſuppoſed to be corruptions of *ferz* and *fil*, the *prime miniſter* and *elephant* of the Perſians and Arabs."

As fortune is ſuppoſed to have a great ſhare in deciding the fate of a battle, the uſe of dice is introduced into this game to regulate its moves; for (ſays the Purán) "if *cinque* be thrown, the *king* or a *pawn* muſt be moved; if *quatre*, the *elephant*; if *trois*, the *horſe*; and if *deux*, the *boat*. The *king* paſſes freely on all ſides, but over *one* ſquare only; and with the ſame limitation the *pawn* moves, but he advances ſtraight forward, and kills his enemy through an angle. The *elephant* marches in all directions as far as his driver pleaſes; the *horſe* runs obliquely, traverſing the ſquares; and the *ſhip* goes over two ſquares diagonally." The *elephant*, we find, has the powers of our *queen*, as we are pleaſed to call the *general* or *miniſter* of the Perſians; and the *ſhip* has the motion of the piece to which we give the unaccountable appellation of *biſhop*, but with a reſtriction which muſt greatly leſſen its value.

In the *Purán* are next exhibited a few general rules and ſuperficial directions for the conduct of the game. Thus, "the *pawns* and the *ſhip* both kill and may be voluntarily killed; while the *king*, the *elephant*, and the *horſe*, may ſlay the foe, but muſt not expoſe themſelves to be ſlain. Let each player preſerve his own forces with extreme care, ſecuring his *king* above all, and not ſacrificing a ſuperior to keep an inferior piece." Here (ſays the preſident) the commentator on the *Purán* obſerves, that the *horſe*, who has the choice of *eight* moves from any central poſition, muſt be preferred to the *ſhip*, which has only the choice of *four*. But the argument would not hold in the common game, where the *biſhop* and *tower* command a whole line, and where a knight is always of leſs value than a tower in action, or the biſhop of that ſide on which the attack is begun. "It is by the overbearing power of the *elephant* (continues the *Purán*) that the king fights boldly; let the whole army, therefore, be abandoned in order to ſecure the *elephant*. The king muſt never place one *elephant* before another, unleſs he be compelled by want of room, for he would thus commit a dangerous fault; and if he can ſlay one of two hoſtile elephants, he muſt deſtroy that on his left hand."

All that remains of the paſſage which was copied for Sir William Jones relates to the ſeveral modes in which a partial ſucceſs or complete victory may be obtained: by

---

* *Aſiatic Reſearches*, vol. ii. Mem. 9.

by any one of the four players ; for, as in a diſpute between two allies, one of the kings may ſometimes aſſume the command of all the forces, and aim at a ſeparate conqueſt. Firſt, " When any one king has placed himſelf on the ſquare of another king (which advantage is called *ſinhaſana* or the *throne*) he wins a ſtake, which is doubled if he kill the adverſe monarch when he ſeizes his place ; and if he can ſeat himſelf on the throne of his ally, he takes the command of the whole army." Secondly, " If he can occupy ſucceſſively the thrones of all the three princes, he obtains the victory, which is named *cheturaji* ; and the ſtake is doubled if he kill the laſt of the three, juſt before he takes poſſeſſion of his throne ; but if he kill him on his throne, the ſtake is quadrupled. Both in giving the *ſinhaſana* and the *cheturaji* the king muſt be ſupported by the *elephants*, or by all the forces united." Thirdly, " When one player has his own king on the board, but the king of his partner has been taken, he may replace his captive ally, if he can ſeize both the adverſe kings ; or if he cannot effect their capture, he may exchange his king for one of them, againſt the general rule, and thus redeem the allied prince, who will ſupply his place." This advantage has the name of *nripacriſhta* or *recovered by the king*. Fourthly, " If a *pawn* can march to any ſquare on the oppoſite extremity of the board, except that of the king, or that of the ſhip, he aſſumes whatever power belonged to that ſquare." Here we find the rule, with a ſlight exception, concerning the advancement of *pawns*, which often occaſions a moſt intereſting ſtruggle at our common cheſs ; but it appears that, in the opinion of one ancient writer on the Indian game, this privilege is not allowable when a player has three pawns on the board ; but when only one pawn and one ſhip remains, the pawn may advance even to the ſquare of a king or a ſhip, and aſſume the power of either. Fifthly, According to the people of *Lancè*, where the game was invented, "there could be neither victory nor defeat if a king were left on the plain without force ; a ſituation which they named *cacacaſht'ha*." Sixthly, " If three ſhips happen to meet, and the fourth ſhip can be brought up to them in the remaining angle, this has the name of *vrihannauca* ; and the player of the fourth ſeizes all the others."

The account of this game in the original Sanſcrit is in verſe, and there are two or three couplets ſtill remaining, ſo very dark, either from an error in the manuſcript, or from the antiquity of the language, that Sir William Jones could not underſtand the *Pandit's* explanation of them, and ſuſpects that even to him they gave very indiſtinct ideas. It would be eaſy, however, he thinks, if it be judged worth while, to play at the game by the preceding rules ; and a little practice would perhaps make the whole intelligible.

CHEVRETTE, in artillery, is an engine employed to raiſe guns or mortars into their carriage. It is formed of two pieces of wood about four feet long, ſtanding upon a third, which is ſquare. The uprights are about a foot aſunder, and pierced with holes exactly oppoſite to one another, to receive a bolt of iron, which is put in, either higher or lower at pleaſure, to ſerve as a ſupport to a handſpike, by which the gun is raiſed up. By the author of the Military Guide, this is ſaid to be the moſt uſeful of all the inventions for raiſing guns into their carriages ; and it ſeems theſe inventions have been many.

CHICHA, the name given by the natives to the iſland of Jeſſo, which lies to the ſouth of Oku-Jeſſo, or Segalian iſland. See SEGALIAN in this Supplement.

CHIMERE, the upper robe worn by biſhops in church and in the Houſe of Peers, to which the lawn ſleeves are generally ſewed. Before the Reformation, and even after it till the reign of Queen Elizabeth, the chimere was always of *ſcarlet ſilk* ; but biſhop Hooper, ſcrupling firſt at the robe itſelf, and then at the colour of it, as too light and gay for the epiſcopal gravity, the chimere was afterwards made of *black ſatin*. The archiepiſcopal chimere has a long train.

CHIMNEY, a particular part of a houſe well known, which Profeſſor Beckmann has, in our opinion, proved to be an invention comparatively modern. It would be very unfair dealing in us to give even a large abſtract of one of the moſt curious diſſertations of a curious book, which has been but lately publiſhed, and thereby injure the intereſt of him to whom the native of Britain is indebted for the pleaſure of peruſing it in his own tongue. No man, however, can blame us for here ſtating, in ſupport of our own opinion, the profeſſor's anſwer to the paſſage of Ferrari, which we have quoted under the word CHIMNEY in the Encyclopædia.

" When the triumviri, ſays Appian *, cauſed thoſe who had been proſcribed by them to be ſought for by the military, ſome of them, to avoid the bloody hands of their perſecutors, hid themſelves in wells, and others, as Ferrarius tranſlates the words, *in fumaria ſub tecto, qua ſcilicet fumus e tecto evolvitur* (A). The true tranſlation, however (ſays Mr Beckmann), is *fumoſa cœnacula*. The principal perſons of Rome endeavoured to conceal themſelves in the ſmoky apartments of the upper ſtory under the roof, which, in general, were inhabited only by poor people ; and this ſeems to be confirmed by what Juvenal † expreſsly ſays, *Rarus venit in cœnacula miles*.

* *De bellis civil.* lib. iv. p. 962. edit. Tollii.

† *Sat.* x. ver. 17.

" Thoſe paſſages of the ancients which ſpeak of ſmoke riſing up from houſes, have with equal impropriety been ſuppoſed to allude to chimneys, as if the ſmoke could not make its way through doors and windows. Seneca ‡ writes, 'Laſt evening I had ſome friends with me, and on that account a ſtronger ſmoke was raiſed ; not ſuch a ſmoke, however, as burſts forth from the kitchens of the great, and which alarms the watchmen, but ſuch a one as ſignifies that gueſts are arrived.' Thoſe whoſe judgments are not already warped by prejudice, will undoubtedly find the true ſenſe of theſe words to be, that the ſmoke forced its way through the kitchen windows. Had the houſes been built with chimney-funnels, one cannot conceive why the watchmen ſhould have been alarmed when they obſerved a ſtronger ſmoke than uſual ariſing from them ; but as the kitchens had no conveniences of that nature, an apprehenſion of fire, when extraordinary entertainments were to be provided in the houſes of the rich for large companies, ſeems to have been well founded ; and on ſuch occaſions people appointed for that purpoſe were ſtationed

‡ *Epiſt.* 64.

(A) Ες καπνωδεις υπωροφια, η των τεγων ταις κεραμισι βυομεναις.

ſtationed in the neighbourhood to be conſtantly on the watch, and to be ready to extinguiſh the flames in caſe a fire ſhould happen. There are many other paſſages to be found in Roman authors of the like kind, which it is hardly neceſſary to mention; ſuch as that of Virgil *,

'Et jam ſumma procul villarum culmina fumant,'

and the following words of Plautus†, deſcriptive of a miſer:

'Quin divum atque hominum clamat continuo fidem,
'Suam rem periiſſe, ſeque eradicarier,
'De ſuo tigillo fumus ſi qua exit foras.'

In the *Veſpæ* of Ariſtophanes, referred to in the Encyclopædia, old Philocleon wiſhes to eſcape through the kitchen. Some one aſks, "What is that which makes a noiſe in the chimney?" "I am the ſmoke (replies the old man), and am endeavouring to get out at the chimney." "This paſſage, however (ſays the Profeſſor), which, according to the uſual tranſlation, ſeems to allude to a common chimney, can, in my opinion, eſpecially when we conſider the illuſtration of the ſcholiaſts, be explained alſo by a ſimple hole in the roof, as Reiſke has determined; and indeed this appears to be more probable, as we find mention made of a top or covering‡ with which the hole was cloſed."

In the Encyclopædia we have ſaid, that the inſtances of chimneys remaining among the ruins of ancient buildings are few, and that the rules given by Vitruvius for building them are obſcure; but we are now ſatiſfied that there are *no* remains of ancient chimneys, and that Vitruvius gives *no* rules, either obſcure or perſpicuous, for building what, in the modern acceptation of the word, deſerves the name of a chimney.

"The ancient maſon-work ſtill to be found in Italy does not determine the queſtion. Of the walls of towns, temples, amphitheatres, baths, aqueducts, and bridges, there are ſome though very imperfect remains, in which chimneys cannot be expected; but of common dwelling-houſes none are to be ſeen except at Herculaneum, and there no traces of chimneys have been diſcovered. The paintings and pieces of ſculpture which are preſerved afford us as little information; for nothing can be perceived in them that bears the ſmalleſt reſemblance to a modern chimney.

"If there were no funnels in the houſes of the ancients to carry off the ſmoke, the directions given by Columella, to make kitchens ſo high that the roof ſhould not catch fire, was of the utmoſt importance. An accident of the kind, which that author ſeems to have apprehended, had almoſt happened at Beneventum, when the landlord who entertained Mæcenas and his company was making a ſtrong fire in order to get ſome birds ſooner roaſted.

'————— ubi ſedulus hoſpes
'Pæne arſit, macros dum turdos verſat in igne;
'Nam vaga per veterem dilapſo flamma culinam
'Vulcano ſummum properabat lambere tectum§.'

Had there been chimneys in the Roman houſes, Vitruvius certainly would not have failed to deſcribe their conſtruction, which is ſometimes attended with conſiderable difficulties, and which is intimately connected with the regulation of the plan of the whole edifice. He does not, however, ſay a word on this ſubject; neither does Julius Pollux, who has collected with great care the Greek names of every part of a dwelling-houſe; and Grapaldus, who in later times made a collection of the Latin terms, has not given a Latin word expreſſive of a modern chimney *."

Our author admits the derivation of the word *chimney* to be as we have given it in the Encyclopædia; but (ſay he) "*Caminus* ſignified, as far as I have been able to learn, firſt a chemical or metallurgic furnace, in which a crucible was placed for melting and refining metals; ſecondly, a ſmith's forge; and, thirdly, a hearth on which portable ſtoves or fire-pans were placed for warming the apartment. In all theſe, however, there appears no trace of a chimney." Herodotus relates (lib. viii. c. 137.), that a king of Libya, when one of his ſervants aſked for his wages, offered him in jeſt the ſun, which at that time ſhone into the houſe through an opening in the roof, under which the fire was perhaps made in the middle of the edifice. If ſuch a hole muſt be called a chimney, our author admits that chimneys were in uſe among the ancients, eſpecially in their kitchens; but it is obvious that ſuch chimneys bore no reſemblance to our's, through which the ſun could not dart his rays upon the floor of any apartment.

"However imperfect may be the information which can be collected from the Greek and Roman authors reſpecting the manner in which the ancients warmed their apartments, it nevertheleſs ſhews that they commonly uſed for that purpoſe a large fire-pan or portable ſtove, in which they kindled wood, and, when the wood was well lighted, carried it into the room, or which they filled with burning coals. When Alexander the Great was entertained by a friend in winter, as the weather was cold and raw, a ſmall fire baſon was brought into the apartment to warm it. The prince, obſerving the ſize of the veſſel, and that it contained only a few coals, deſired his hoſt, in a jeering manner, to bring more wood or frankincenſe; giving him thus to underſtand that the fire was fitter for burning perfumes than to produce heat. Anacharſis, the Scythian philoſopher, though diſpleaſed with many of the Grecian cuſtoms, praiſed the Greeks, however, becauſe they ſhut out the ſmoke and brought only fire into their houſes †. We are informed by Lampridius, that the extravagant Heliogabulus cauſed to be burned in theſe ſtoves, inſtead of wood, Indian ſpiceries and coſtly perfumes ‡. It is alſo worthy of notice, that coals were found in ſome of the apartments of Herculaneum, as we are told by Winklemann, but neither ſtoves nor chimneys."

It is well known to every ſcholar, that the uſeful arts of life were invented in the eaſt, and that the cuſtoms, manners, and furniture of eaſtern nations, have remained from time immemorial almoſt unchanged. In Perſia, which the late Sir William Jones ſeems to have conſidered as the original country of mankind, the methods employed by the inhabitants for warming themſelves have a great reſemblance to thoſe employed by the ancient Greeks and Romans for the ſame purpoſe. According to De la Valle, the Perſians make fires in their apartments, not in chimneys as we do, but in ſtoves in the earth, which they call *tennor*. "Theſe ſtoves conſiſt of a ſquare or round hole, two ſpans or a little more in depth, and in ſhape not unlike an Italian caſk. That this hole may throw out heat ſooner, and with more ſtrength, there is placed in it an iron veſſel of the

† *Plutarch. Sympoſ.* lib. vi. 7. p. 692.

‡ *Æl. Lamprid. Vita Heliogab.* cap. 31.

ſame ſize, which is either filled with burning coals, or a fire of wood and other inflammable ſubſtances is made in it. When this is done, they place over the hole or ſtove a wooden top, like a ſmall low table, and ſpread above it a large coverlet quilted with cotton, which hangs down on all ſides to the floor. This covering condenſes the heat, and cauſes it to warm the whole apartment. The people who eat or converſe there, and ſome who ſleep in it, lie down on the floor above the carpet, and lean, with their ſhoulders againſt the wall, on ſquare cuſhions, upon which they ſometimes alſo ſit; for the *tennor* is conſtructed in a place equally diſtant from the walls on both ſides. Thoſe who are not very cold only put their feet under the table or covering; but thoſe who require more heat can put their hands under it, or creep under it altogether. By theſe means the ſtove diffuſes over the whole body, without cauſing uneaſineſs to the head, ſo penetrating and agreeable a warmth, that I never in winter experienced any thing more pleaſant. Thoſe, however, who require leſs heat let the coverlet hang down on their ſide to the floor, and enjoy without any inconvenience from the ſtove the moderately heated air of the apartment. They have a method alſo of ſtirring up or blowing the fire when neceſſary, by means of a ſmall pipe united with the tennor or ſtove under the earth, and made to project above the floor as high as one chooſes; ſo that the wind, when a perſon blows into it, becauſe it has no other vent, acts immediately upon the fire like a pair of bellows. When there is no longer occaſion to uſe this ſtove, both holes are cloſed up, that is to ſay, the mouth of the ſtove and that of the pipe which conveys the air to it, by a flat ſtone made for that purpoſe. Scarcely any appearance of them is then to be perceived, nor do they occaſion inconvenience, eſpecially in a country where it is always cuſtomary to cover the floor with a carpet, and where the walls are plaſtered. In many parts theſe ovens are uſed to cook victuals, by placing kettles over them. They are employed alſo to bake bread; and for this purpoſe they are covered with a large broad metal plate, on which the cake is laid; but if the bread is thick and requires more heat, it is put into the ſtove itſelf."

Our learned author having proved, to our entire ſatisfaction, that chimneys, ſuch as we have now in every comfortable room, were unknown to the moſt poliſhed nations of antiquity, ſets himſelf to inquire into the era of their invention; and the oldeſt account of them which he finds is an inſcription at Venice, which relates, that in the year 1347 a great many chimneys were thrown down by an earthquake. It would appear, however, that in ſome places they had been in uſe for a conſiderable time before that period; for *De Gataris*, in his Hiſtory of Padua, relates, that *Franceſco de Carraro*, lord of Padua, came to Rome in 1368, and finding no chimneys in the inn where he lodged, becauſe at that time fire was kindled in a hall in the middle of the floor, he cauſed two chimneys like thoſe which had *long* been uſed at Padua to be conſtructed by maſons and carpenters, whom he had brought along with him. Over theſe chimneys, the firſt ever ſeen at Rome, he affixed his arms, which were ſtill remaining in the time of De Gataris, who died of the plague in 1405.

Though chimneys have been thus long in uſe, they are yet far enough from being brought to perfection. There is hardly a modern houſe, eſpecially if highly finiſhed, in which there is not one room at leaſt liable to be filled with ſmoke when it is attempted to be heated by an open fire; and there are many houſes ſo infeſted with this plague as to be almoſt uninhabitable during the winter months; not to mention other great defects in common chimneys, which not being ſo obvious have attracted leſs attention. Many ingenious methods have been propoſed to cure ſmokey chimneys in every ſituation (ſee Smoke, *Encycl.*); but Count Rumford's Eſſay on this ſubject contains the moſt valuable directions that we have ſeen, not only for removing the inconveniency of ſmoke, but likewiſe for increaſing the heat of the room by a diminiſhed conſumption of fuel.

To thoſe who are at all acquainted with the nature and properties of elaſtic fluids, it muſt be obvious, that the whole myſtery of curing ſmokey chimneys conſiſts in finding out and removing the accidental cauſes which prevent the heated ſmoke from being forced up the chimney by the preſſure of the cool and therefore heavier air of the room. Though theſe cauſes are various, yet, ſays our author, that which will moſt commonly be found to operate, is the bad conſtruction of the chimney *in the neighbourhood of the fire-place.* "The great fault of all the open fire-places or chimneys for burning wood or coals in an open fire now in common uſe is, that they are much too large; or rather it is *the throat of the chimney*, or the lower part of its open canal, in the neighbourhood of the mantle, and immediately over the fire, which is too large."

To this fault, therefore, the attention ſhould be firſt turned in every attempt which is made to improve the conſtruction of chimneys; for however perfect a fire-place may be in other reſpects, if the opening left for the paſſage of the ſmoke is larger than is neceſſary for that purpoſe, nothing can prevent the warm air of the room from eſcaping through it; and whenever this happens, there is not only an unneceſſary loſs of heat, but the warm air which leaves the room to go up the chimney being replaced by cold air from without, draughts of cold air cannot fail to be produced in the room, to the great annoyance of thoſe who inhabit it. But although both theſe evils may be effectually remedied by reducing the throat of the chimney to a proper ſize, yet in doing this ſeveral precautions will be neceſſary. And firſt of all, the throat of the chimney ſhould be in its proper place; that is to ſay, in that place in which it ought to be, in order that the aſcent of the ſmoke may be moſt facilitated: now as the ſmoke and hot vapour which riſe from a fire naturally tend *upwards*, the proper place for the throat of the chimney is evidently perpendicularly *over the fire.*

But there is another circumſtance to be attended to in determining the proper place for the throat of a chimney, and that is, to aſcertain its diſtance from the fire, or *how far* above the burning fuel it ought to be placed. In determining this point there are many things to be conſidered, and ſeveral advantages and diſadvantages to be weighed and balanced.

As the ſmoke and vapour which aſcend from burning fuel riſe in conſequence of their being rarefied by heat, and made lighter than the air of the ſurrounding atmoſphere; and as the degree of their rarefaction, and conſequently their tendency to riſe, is in proportion to the intenſity of their heat; and further, as they are hotter near the fire than at a greater diſtance from it—it is clear that the nearer the throat of a chimney is to the fire, the ſtronger will be what is commonly called its *draught*, and the leſs danger there will be of its ſmoking. But, on the other hand, when the draught of a chimney is very ſtrong, and particularly when this ſtrong draught is occaſioned by the throat of the chimney being very near the fire, it may ſo happen that the draught of air into the fire may become ſo ſtrong as to cauſe the fuel to be conſumed too rapidly. There are likewiſe ſeveral other inconveniences which would attend the placing of the throat of a chimney *very near* the burning fuel.

The poſition of the throat of a chimney being once determined, the next points to be aſcertained are its ſize and form, and the manner in which it ought to be connected with the fire-place below, and with the open canal of the chimney above. But as theſe inveſtigations are intimately connected with thoſe which relate to the form proper to be given to the fire-place itſelf, we muſt conſider them all together.

Now the deſign of a chimney fire being ſimply to warm a room, it is neceſſary, firſt of all, to contrive matters ſo that the room ſhally be actually warmed; ſecondly, that it be warmed with the ſmalleſt expence of fuel poſſible; and, thirdly, that in warming it, the air of the room be preſerved perfectly pure, and fit for reſpiration, and free from ſmoke and all diſagreeable ſmells.

To determine in what manner a room is heated by an open chimney fire, it will be neceſſary firſt of all to find out *under what form* the heat generated in the combuſtion of the fuel exiſts, and then to ſee how it is communicated to thoſe bodies which are heated by it.

In regard to the firſt of theſe ſubjects of inquiry, it is quite certain that the heat which is generated in the combuſtion of the fuel exiſts under *two* perfectly diſtinct and very different forms. One part of it is *combined* with the ſmoke, vapour, and heated air which riſe from the burning fuel, and goes off with them into the upper regions of the atmoſphere; while the other part, which appears to be *uncombined*, or, as ſome ingenious philoſophers have ſuppoſed, combined only with light, and therefore called *radiant heat*, is ſent off from the fire in rays in all poſſible directions.

With reſpect to the ſecond ſubject of inquiry, namely, how this heat, exiſting under theſe two different forms, is communicated to other bodies, it is highly probable that the combined heat can only be communicated to other bodies by *actual contact* with the body with which it is combined; and with regard to the rays which are ſent off by burning fuel, it is certain that *they* communicate or generate heat only *when* and *where* they are ſtopped or abſorbed. In paſſing through air, which is tranſparent, they certainly do not communicate any heat to it; and it ſeems highly probable that they do not communicate heat to ſolid bodies by which they are reflected.

As it is the radiant heat alone which can be employed in warming a room, when fuel is burnt for this purpoſe in an open fire-place, it becomes an object of much importance to determine how the greateſt quantity of it may be generated in the combuſtion of the fuel, and how the greateſt proportion poſſible of that generated may be brought into the room.

Now the quantity of radiant heat generated in the combuſtion of a given quantity of any kind of fuel depends very much upon the management of the fire, or upon the manner in which the fuel is conſumed. When the fire burns bright, much radiant heat will be ſent off from it; but when it is *ſmothered up*, very little will be generated, and indeed very little combined heat that can be employed to any uſeful purpoſe: moſt of the heat produced will be immediately *expended* in giving elaſticity to a thick denſe vapour or ſmoke, which will be ſeen riſing from the fire; and the combuſtion being very incomplete, a great part of the inflammable matter of the fuel being merely rarefied and driven up the chimney without being inflamed, the fuel will be waſted to little purpoſe. And hence it appears of how much importance it is, whether it be conſidered with a view to economy, or to cleanlineſs, comfort, and elegance, to pay due attention to the management of a chimney fire.

Nothing can be more perfectly void of common ſenſe, and waſteful and ſlovenly at the ſame time, than the manner in which chimney fires, and particularly where coals are burned, are commonly managed by ſervants. They throw on a load of coals at once, through which the flame is hours in making its way; and frequently it is not without much trouble that the fire is prevented from going quite out. During this time no heat is communicated to the room; and what is ſtill worſe, the throat of the chimney being occupied merely by a heavy denſe vapour, not poſſeſſed of any conſiderable degree of heat, and conſequently not having much elaſticity, the warm air of the room finds leſs difficulty in forcing its way up the chimney and eſcaping than when the fire burns bright. And it happens not unfrequently, eſpecially in chimneys and fire-places ill-conſtructed, that this current of warm air from the room which preſſes into the chimney, croſſing upon the current of heavy ſmoke which riſes ſlowly from the fire, obſtructs it in its aſcent, and beats it back into the room: hence it is that chimneys ſo often ſmoke when too large a quantity of freſh coals is put upon the fire. So many coals ſhould never be put on the fire at once as to prevent the free paſſage of the flame between them. In ſhort, a fire ſhould never be ſmothered; and when proper attention is paid to the quantity of coals put on, there will be very little uſe for the pocker; and this circumſtance will contribute very much to cleanlineſs, and to the preſervation of furniture.

As we have ſeen what is neceſſary to the *generation* of the greateſt quantity of radiant heat, it remains to be determined how the greateſt proportion of that which is generated and ſent off from the fire in all directions may be made to *enter the room*, and aſſiſt in warming it.

This muſt be done, firſt, by cauſing as many as poſſible of the rays, as they are ſent off from the fire in ſtraight lines, to come *directly* into the room; which can only be effected by bringing the fire as far forward as poſſible, and leaving the opening of the fire-place as wide and as high as can be done without inconvenience: and, ſecondly, by making the ſides and back of the fire-place of ſuch a form, and conſtructing them of ſuch materials, as to cauſe the direct rays from the fire, which ſtrike againſt them, to be ſent into the room by reflection in the greateſt abundance.

Now it will be found upon examination, that the beſt form for the vertical ſides of a fire-place, or the *covings* (as they are called), is that of an upright plane, making an angle with the plane of the back of the fire-place of about 135 degrees.—According to the preſent conſtruction of chimneys, this angle is ſometimes only 90, and very ſeldom above 100 or 110 degrees; but it is obvious, that in all theſe caſes the two ſides or coverings of the fire-place are very ill-contrived for throwing into the room by reflection the rays from the fire which fall upon them.

With regard to the materials which ſhould be employed in the conſtruction of fire-places, particularly the backs and covings, it is obvious that thoſe are to be preferred which *abſorb* the *leaſt*, and of courſe *reflect* the greateſt quantity of radiant heat. Iron, therefore, and, in general, metals of all kinds, are the very worſt materials which can poſſibly be employed for the backs and covings of chimneys; whilſt fire-ſtone white-waſhed, or common bricks and mortar, covered with a thin coating of plaſter, and white-waſhed, anſwer the purpoſe extremely well. A white colour ſhould, indeed, be always given to the inſide of a chimney of whatever materials it be conſtructed; and black, which is at preſent ſo common, ſhould be carefully avoided, becauſe white reflects the moſt, and black the leaſt, radiant heat. The grate, however, cannot well be made of any thing elſe than iron; but there is no neceſſity whatever for that immenſe quantity of iron which ſurrounds grates as they are commonly fitted up, and which not only renders them very expenſive, but eſſentially injures the fire-place.

To have only pointed out the faults of the chimneys in uſe, without ſhewing how theſe faults may be corrected, would have been a work of very little value; but the Count's Treatiſe is complete, and contains the plaineſt directions for the conſtruction of fire-places. Theſe directions are introduced by an explanation of ſome technical words and expreſſions. Thus, by the *throat* of a chimney, already mentioned, he means the lower extremity of its canal, where it unites with the upper part of its open fire-place. This throat is commonly found about a foot above the level of the lower part of the mantle, and it is ſometimes contracted to a ſmaller ſize than the reſt of the canal of the chimney, and ſometimes not.

Plate XX. Fig. 1. ſhews the ſection of a chimney on the common conſtruction, in which *de* is the throat.

Fig. 2. ſhews the ſection of the ſame chimney altered and improved, in which *di* is the reduced throat.

The *breaſt* of a chimney is that part of it which is immediately behind the mantle. It is the wall which forms the entrance from below into the throat of the chimney in front, or towards the room. It is oppoſite to the upper extremity of the back of the open fire-place, and parallel to it: in ſhort, it may be ſaid to be the back part of the mantle itſelf.—In the figures 1. and 2. it is marked by the letter *d*. The width of the throat of the chimney (*de* fig. 1. and *di* fig. 2.) is taken from the breaſt of the chimney to the back, and its length is taken at right angles to its width, or in a line parallel to the mantle (*a* fig. 1. and 2.).

The bringing-forward of the fire into the room, or rather bringing it nearer to the front of the opening of the fire-place, and the diminiſhing of the throat of the chimney, being two objects principally had in view in the alterations in fire-places propoſed by the Count, it is evident that both theſe may be attained merely by bringing forward the back of the chimney. The only queſtion therefore is, How far it ſhould be brought forward? The anſwer is ſhort, and eaſy to be underſtood; bring it forward as far as poſſible, without diminiſhing too much the paſſage which muſt be left for the ſmoke. Now as this paſſage, which in its narroweſt part he calls *the throat of the chimney*, ought, for reaſons which have been already explained, to be immediately, or perpendicularly over the fire, it is evident that the back of the chimney muſt always be built perfectly upright. To determine, therefore, the place for the new back, or how far preciſely it ought to be brought forward, nothing more is neceſſary than to aſcertain how wide the throat of the chimney ought to be left, or what ſpace muſt be left between the top of the breaſt of the chimney where the upright canal of the chimney begins, and the new back of the fire-place carried up perpendicularly to that height.

Numerous experiments have convinced the Count, that, all circumſtances being well conſidered, and the advantages and diſadvantages compared and balanced, *four inches* is the beſt width that can be given to the throat of a chimney, whether the fire-place be deſtined to burn wood, coals, turf, or any other fuel. In very large halls where great fires are kept up, it may ſometimes, though very rarely, be proper to increaſe this width to four inches and a half, or even to five inches.

The next thing to be conſidered is the width which it will be proper to give to the back of the chimney; and, in moſt caſes, this ſhould be *one-third* of the width of the opening of the fire place in front. It is not indeed abſolutely neceſſary to conform with rigour to this deciſion, nor is it always poſſible; but it ſhould invariably be conformed to as far as circumſtances will permit. Where a chimney, ſays the Count, is deſigned for warming a room of a middling ſize, and where the thickneſs of the wall of the chimney in front, meaſured from the front of the mantle to the breaſt of the chimney, is nine inches, I ſhould ſet off four inches more for the width of the throat of the chimney, which, ſuppoſing the back of the chimney to be built upright, as it always ought to be, will give thirteen inches for the depth of the fire-place, meaſured upon the hearth, from the opening of the fire-place in front to the back. In this caſe, thirteen inches would be a good ſize for the width of the back; and three times thirteen inches, or 39 inches, for the width of the opening of the fire-place in front; and the angle made by the back of the fire-place and the ſides of it, or covings, would be juſt 135 degrees, which is the beſt poſition they can have for throwing heat into the room. This poſition, indeed, it may ſometimes be impoſſible to attain in altering chimneys already built; but a deviation from it of two or three degrees will be of no great conſequence; for the points of by much the greateſt importance in altering fire-places upon the principles here recommended, are the bringing forward the back to its proper place, and making it of the proper width.

Proviſion, however, muſt be made for the paſſage of the chimney-ſweeper up the chimney; and this may eaſily be done in the following manner: In building up the new back of the fire-place; when this wall (which need never be more than the width of a ſingle brick in thickneſs) is brought up ſo high that there remains no more than about ten or eleven inches between what is then the top of it and the inſide of the mantle, or lower extremity of the breaſt of the chimney, an opening or door way, eleven or twelve inches wide, muſt be begun in the middle of the back, and continued quite to the top of it, which, according to the height to which it will commonly be neceſſary to carry up the back, will make the opening abundantly ſufficient to let the chimney-ſweeper paſs. When the fire-place is finiſhed, this door-way is to be cloſed by a tile or fit piece of ſtone placed in it without mortar, and by means of a rabbit made in the brick-work, confined in its place in ſuch a manner as that it may be eaſily removed when the chimney is to be ſwept, and reſtored to its place when that work is over. Of this contrivance the reader will be able to form a clear conception from fig. 2. which repreſents the ſection of a chimney after it has been properly altered from what is exhibited in fig. 1. In this improved chimney *k l* is the new back of the fire-place; *l i* the tile or ſtone which cloſes the door-way for the chimney-ſweeper; *d i* the throat of the chimney narrowed to four inches; *a* the mantle, and *b* the ſtone placed under the mantle, ſuppoſed to have been too high, in order to diminiſh the height of the opening of the fire-place in front.

It has been obſerved above, that the new back, which it will always be found neceſſary to build in order to bring the fire ſufficiently forward, in altering a chimney conſtructed on the common principles, need never be thicker than the width of a common brick. The ſame may be ſaid of the thickneſs neceſſary to be given to the new ſides or covings of the chimney; or if the new back and covings are conſtructed of ſtone, one inch and three quarters, or two inches in thickneſs, will be ſufficient. Care ſhould be taken in building up theſe new walls to unite the back to the covings in a ſolid manner.

Whether the new back and covings are conſtructed of ſtone or built of bricks, the ſpace between them and the old back and covings of the chimney ought to be filled up, to give greater ſolidity to the ſtructure. This may be done with looſe rubbiſh, or pieces of broken bricks or ſtones, provided the work be ſtrengthened by a few layers or courſes of bricks laid in mortar; but it will be indiſpenſably neceſſary to finiſh the work where theſe new walls end, that is to ſay, at the top of the throat of the chimney, where it ends abruptly in the open canal of the chimney, by a horizontal courſe of bricks well ſecured with mortar. This courſe of bricks will be upon a level with the top of the door-way left for the chimney-ſweeper; and the void behind the door-way muſt be covered with a horizontal ſtone or tile, to be removed at the ſame time the door is removed, and for the ſame purpoſe.

From theſe deſcriptions it is clear, that where the throat of the chimney has an end, that is to ſay, where it enters into the lower part of the open canal of the chimney, *there* the three walls which form the two covings and the back of the fire-place all end abruptly. It is of much importance that they ſhould end in this manner; for were they to be ſloped outward, and raiſed in ſuch a manner as to ſwell out the upper extremity of the throat of the chimney in the form of a trumpet, and increaſe it by degrees to the ſize of the canal of the chimney, this manner of uniting the lower extremity of the canal of the chimney with the throat would tend to aſſiſt the winds, which may attempt to blow down the chimney, in forcing their way through the throat, and throwing the ſmoke backward into the room; but when the throat of the chimney ends abruptly, and the ends of the new walls form a flat horizontal ſurface, it will be much more difficult for any wind from above to find and force its way through the narrow paſſage of the throat of the chimney.

As the two walls which form the new covings of the chimney are not parallel to each other, but inclined, preſenting an oblique ſurface towards the front of the chimney, and as they are built perfectly upright, and quite flat, from the hearth to the top of the throat, where they end, it is evident that an horizontal ſection of the throat will not be an oblong ſquare; but its deviation from that form is a matter of no conſequence; and no attempts ſhould ever be made, by twiſting the covings above where they approach the breaſt of the chimney, to bring it to that form. All twiſts, bends, prominences, excavations, and other irregularities of form in the covings of a chimney, never fail to produce eddies in the current of air which is continually paſſing into, and through, an open fire-place in which a fire is burning; and all ſuch eddies diſturb either the fire or the aſcending current of ſmoke, or both; and not unfrequently cauſe the ſmoke to be thrown back into the room. Hence it appears, that the covings of chimneys ſhould never be made circular, or in the form of any other curve, but always quite flat.

For the ſame reaſon, that is to ſay, to prevent eddies, the breaſt of the chimney, which forms that ſide of the throat that is in front or neareſt to the room, ſhould be neatly cleaned off, and its ſurface made quite regular and ſmooth. This may be eaſily done by covering it with a coat of plaſter, which may be made thicker or thinner in different parts, as may be neceſſary in order to bring the breaſt of the chimney to be of the proper form.

With regard to the form of the breaſt of a chimney, this is a matter of very great importance, and which ought always to be particularly attended to. The worſt form it can have is that of a vertical plane or upright flat; and next to this the worſt form is an inclined plane. Both theſe forms cauſe the current of warm air from the room, which will, in ſpite of every precaution, ſometimes find its way into the chimney, to croſs upon the current of ſmoke which riſes from the fire in a manner moſt likely to embarraſs it in its aſcent, and drive it back.

The current of air which, paſſing under the mantle, gets into the chimney, ſhould be made *gradually to bend its courſe upwards*; by which means it will unite *quietly* with the aſcending current of ſmoke, and will be leſs likely to check it, or force it back into the room. Now this may be effected with the greateſt eaſe and certainty, merely by *rounding off* the breaſt of the chimney or back part of the mantle, inſtead of leaving it flat or full of holes and corners; and this of courſe ought always to be done.

Having thus aſcertained the form and poſition of the new covings, the ingenious author next turns his attention to the height to which they ſhould be carried. This will depend not only on the height of the mantle, but alſo, and more eſpecially, on the height of the breaſt of the chimney, or of that part of the chimney where the breaſt ends and the upright canal begins.—The back and covings muſt riſe a few inches, five or ſix for inſtance, higher than this part, otherwiſe the throat of the chimney will not be properly formed; but no advantage would be gained by carrying them higher.

One important circumſtance reſpecting chimney fire-places ſtill remains to be conſidered; and that is the grate. In placing the grate, the thing principally to be attended to is, to make the back of it coincide with the back of the fire-place. But as many of the grates now in common uſe will be found to be too large, when the fire places are altered and improved, it will be neceſſary to diminiſh their capacities by filling them up at the back and ſides with pieces of fire ſtone. When this is done, it is the front of the flat piece of fire-ſtone which is made to form a new back to the grate, which muſt be made to coincide with, and make part of the back of the fire place.—But in diminiſhing the capacities of grates with pieces of fire-ſtone, care muſt be taken not to make them *too narrow*.

The proper width for grates deſtined for rooms of a middling ſize will be from ſix to eight inches, and their length may be diminiſhed more or leſs according as the room is heated with more or leſs difficulty, or as the weather is more or leſs ſevere.—But where the width of a grate is not more than five inches it will be very difficult to prevent the fire from going out.

It frequently happens that the iron backs of grates are not vertical, or upright, but inclined backwards.—When theſe grates are ſo much too wide as to render it neceſſary to fill them up behind with fire-ſtone, the inclination of the back will be of little conſequence; for by making the piece of ſtone with which the width of the grate is to be diminiſhed in the form of a wedge, or thicker above than below, the front of this ſtone, which in effect will become the back of the grate, may be made perfectly vertical; and the iron back of the grate being hid in the ſolid work of the back of the fire-place, will produce no effect whatever; but if the grate be already ſo narrow as not to admit of any diminution of its width, in that caſe it will be beſt to take away the iron back of the grate entirely, and fixing the grate firmly in the brick-work, cauſe the back of the fire-place to ſerve as a back to the grate.

Where grates, which are deſigned for rooms of a middling ſize, are longer than 14 or 15 inches, it will always be beſt, not merely to diminiſh their lengths, by filling them up at their two ends with fire-ſtone, but, forming the back of the chimney of a proper width, without paying any regard to the length of the grate, to carry the covings through the two ends of the grate in ſuch a manner as to conceal them, or at leaſt to conceal the back corners of them in the walls of the covings.

Had theſe directions been duly attended to by the maſons who in Scotland pretend to alter chimneys on the principles of Count Rumford, we ſhould not have obſerved ſo many of the grates placed by them jutting out beyond the mantle of the chimney; nor of courſe heard ſo many complaints of rooms being rendered more ſmokey, and the conſumption of fuel increaſed by theſe pretended improvements. But when the grate is not ſet in its proper place, when its ſloping iron back is retained, when no pains have been taken to make its ends coincide with the covings of the fire-place, when the mantle, inſtead of having its back rounded off, is a vertical plane of iron cutting the column of ſmoke which riſes beneath it, and, above all, when the throat of the chimney, inſtead of four, is made, as we often ſee, fourteen inches wide; let it be remembered, that not one of Count Rumford's directions has been followed, and that his principles have as little to do with the conſtruction of ſuch a chimney as with the building of the wall of China or the pyramids of Egypt.

To contribute our aid to prevent theſe blunders for the future, we ſhall here ſubjoin the Count's directions for laying out the work; not to inſtruct maſons and bricklayers, to whom we earneſtly recommend the ſtudy of the eſſay itſelf (B), which contains much valuable information that we have omitted; but merely to give the country gentleman an opportunity of diſcovering whether the workmen whom he employs deviates far and needleſsly from the principles which he pretends to follow.

When a chimney is to be altered, after taking away the grate and removing the rubbiſh, firſt draw a ſtraight line with chalk, or with a lead pencil, upon the hearth, from one jamb to the other,—even with the front of the jambs. The dotted line A B, fig. 3. may repreſent this line.

From the middle *c* of this line, (A B) another line *c d* is to be drawn perpendicular to it, acroſs the hearth, to the middle *d*, of the back of the chimney.

A perſon muſt now ſtand upright in the chimney, with his back to the back of the chimney, and hold a plumb-line to the middle of the upper part of the breaſt of the chimney (*d*, fig. 1.), or where the canal of the chimney begins to riſe perpendicularly;—taking care to place the line above in ſuch a manner that the plumb may fall on the line *c d* (fig. 3.) drawn on the hearth from the middle of the opening of the chimney in front to the middle of the back, and an aſſiſtant muſt mark the preciſe place *e*, on that line where the plumb falls.

This being done, and the perſon in the chimney having quitted his ſtation, four inches are to be ſet off on the line *c d*, from *e*, towards *d*; and the point *f*, where theſe four inches end, (which muſt be marked with chalk, or with a pencil), will ſhow how far the new back is to be brought forward.

Through *f*, draw the line *g h* parallel to the line A B, and this line *g h* will ſhow the direction of the new back, or the ground line upon which it is to be built. The line *c f* will ſhow the depth of the new fire-place; and if it ſhould happen that *c f* is equal to about *one-third* of the line A B, and if the grate can be accommodated to the fire-place, inſtead of its being neceſſary to accommodate the fire place to the grate; in that caſe, half the length of the line *c f* is to be ſet off from *f* on the line *g f h*, on one ſide to *k*, and on the other to *i*, and the line *i k* will ſhow the ground line of the fore part of the back of the chimney.

In all caſes where the width of the opening of the fire-place in front (A B) happens to be not greater, or not

---

(B) It coſts but two ſhillings; and he muſt be a poor bricklayer indeed who cannot afford to pay that ſum for inſtruction in the moſt important, as well as moſt difficult, part of his buſineſs.

not more than two or three inches greater than *three times* the width of the new back of the chimney (*i k*), this opening may be left; and lines drawn from *i* to A, and from *k* to B, will ſhow the width and poſition of the front of the new covings;—but when the opening of the fire-place in front is ſtill wider, it muſt be reduced; which is to be done in the following manner:

From *c*, the middle of the line A B, *c a* and *c b* muſt be ſet off equal to the width of the back (*i k*), added to half its width (*f i*); and lines drawn from *i* to *a*, and from *k* to *b*, will ſhow the ground plan of the fronts of the new covings.

When this is done, nothing more will be neceſſary than to build up the back and covings; and if the fire-place is deſigned for burning coals, to fix the grate in its proper place, according to the directions already given.—When the width of the fire-place is reduced, the edges of the covings *a* A and *b* B are to make a finiſh with the front of the jambs.—And in general it will be beſt, not only for the ſake of the appearance of the chimney, but for other reaſons alſo, to lower the height of the opening of the fire-place whenever its width in front is diminiſhed.

A front view of the chimney, after it has been thus altered, is exhibited in fig. 4. where the under part of the door-way is repreſented, as cloſed by the white dotted lines.

When the wall of the chimney in front, meaſured from the upper part of the breaſt of the chimney to the front of the mantle, is very thin, it may happen, and eſpecially in chimneys deſigned for burning wood upon the hearth, or upon dogs, that the depth of the chimney, determining according to the directions here given, may be too ſmall.

Thus, for example, ſuppoſing the wall of the chimney, in front, from the upper part of the breaſt of the chimney to the front of the mantle, to be only four inches, (which is ſometimes the caſe, particularly in rooms ſituated near the top of a houſe), in this caſe, if we take four inches for the width of the throat, this will give eight inches only for the depth of the fire-place, which would be too little, even were coals to be burnt inſtead of wood.—In this caſe (ſays the Count) I ſhould increaſe the depth of the fire-place at the hearth to 12 or 13 inches, and ſhould build the back perpendicular to the height of the top of the burning fuel (whether it be wood burnt upon the hearth or coals in a grate); and then, ſloping the back by a gentle inclination forward, bring it to its proper place, that is to ſay, *perpendicularly under the back part of the throat of the chimney*. This ſlope, (which will bring the back forward four or five inches, or juſt as much as the depth of the fire-place is increaſed), though it ought not to be too abrupt, yet it ought to be quite finiſhed at the height of eight or ten inches above the fire, otherwiſe it may perhaps cauſe the chimney to ſmoke; but when it is very near the fire, the heat of the fire will enable the current of riſing ſmoke to overcome the obſtacle which this ſlope will oppoſe to its aſcent, which it could not do ſo eaſily were the ſlope ſituated at a greater diſtance from the burning fuel.

Fig. 5, 6, and 7, ſhow a plan, elevation, and ſection of a fire-place conſtructed or altered upon this principle.—The wall of the chimney in front at *a*, fig. 7. being only four inches thick, four inches more added to it for the width of the throat would have left the depth of the fire-place meaſured upon the hearth *b c* only eight inches, which would have been too little;—a niche *c* and *e* was therefore made in the new back of the fire-place for receiving the grate, which niche was ſix inches deep in the centre of it, below 13 inches wide, (or equal in width to the grate,) and 23 inches high; finiſhing above with a ſemicircular arch, which, in its higheſt part, roſe ſeven inches above the upper part of the grate.—The door-way for the chimney-ſweeper, which begins juſt above the top of the niche, may be ſeen diſtinctly in both the figures 6 and 7.—The ſpace marked *g*, fig. 7. behind this door-way, may either be filled with looſe bricks, or may be left void.—The manner in which the piece of ſtone *f*, fig. 7. which is put under the mantle of the chimney to reduce the height of the opening of the fire-place, is rounded off on the inſide in order to give a fair run to the column of ſmoke in its aſcent through the throat of the chimney, is clearly expreſſed in this figure. The plan fig. 5. and elevation fig. 6. ſhow how much the width of the opening of the fire-place in front is diminiſhed, and how the covings in the new fire-place are formed.

A perfect idea of the form and dimenſion of the fire-place in its original ſtate, as alſo after its alteration, may be had by a careful inſpection of theſe figures.

In chimneys, like that repreſented in figure 8, where the jambs A and B project far into the room, and where the front edge of the marble ſlab *o*, which forms the coving, does not come ſo far forward as the front of the jambs, the workmen in conſtructing the new covings are very apt to place them,—not in the line *c A*, which they ought to do,—but in the line *c o*, which is a great fault.—The covings of a chimney ſhould never range *behind* the front of the jambs, however thoſe jambs may project into the room;—but it is not abſolutely neceſſary that the covings ſhould *make a finiſh* with the internal front corners of the jambs, or that they ſhould be continued from the back *c*, quite to the front of the jambs at *A*.—They may finiſh in front at *a* and *b*; and ſmall corners *A*, *o*, *a*, may be left for placing the ſhovels, tongs, &c.

Were the new coving to range with the front edge of the old coving *o*, the obliquity of the new coving would commonly be too great;—or the angle *d c o* would exceed 135 degrees, *which it never ſhould do*,—or at leaſt never be more than a very few degrees. No inconvenience of any importance will ariſe from making the obliquity of the covings *leſs* than what is here recommended; but many cannot fail to be produced by making it much greater.

Theſe extracts, which we have made ſo liberally from Count Rumford's eſſay on chimney fire-places, will be ſufficient, we hope, to bring fully within the comprehenſion of thoſe who are acquainted with pneumatics and pneumatic chemiſtry the principles on which chimneys and fire-places ſhould be conſtructed; but ſuch as are in a great meaſure ſtrangers to theſe ſciences will do well to conſult the eſſay itſelf. With a benevolence which does him honour, the ingenious author has expreſſed a wiſh that his doctrines on this important ſubject may be widely propagated; and to encourage artiſts to ſtudy them, he has declared to the public in general, "that as he does not intend to take out himſelf, or to ſuffer others to take out, any patent for any invention of his which may be of public utility, all perſons are at full liberty to imitate them, and vend them, for their own emolument, when and where, and in any way they may think proper."

Chimney-Sweepers are a claſs of men who earn their ſubſiſtence by clearing chimneys of ſoot, which occaſions them to ſmoke. While chimneys continued to be built in ſo ſimple a manner, and of ſuch a width as they are ſtill obſerved to be in old houſes, they were ſo eaſily cleaned that this ſervice could be performed by a ſervant with a wiſp of ſtraw, or a little bruſhwood faſtened to a rope; but after the flues, in order to ſave room, were made narrower, or when ſeveral flues were united together, the cleaning of them became ſo difficult, that they required boys, or people of ſmall ſize, accuſtomed to that employment. The firſt chimney-ſweepers in Germany came from Savoy, Piedmont, and the neighbouring territories. Theſe for a long time were the only countries where the cleaning of chimneys was followed as a trade; and hence Profeſſor Beckmann concludes with great probability, that chimneys were invented in Italy. The Lotharingians, however, undertook the buſineſs of chimney-ſweeping alſo; on which account the duke of Lotharingia was ſtyled the *imperial fire-maſter*. The firſt Germans who condeſcended to clean chimneys were miners; and the chimney-ſweepers in that empire ſtill procure their boys from the foreſt of Hartz, where the greateſt mines are wrought. Very lately, and perhaps at preſent, the greater part of the chimney-ſweepers in Paris were Savoyards, many of them not above eight years of age, who, for the paltry ſum of five ſous, which they were obliged to ſhare with their avaricious maſter, would ſcramble, at the hazard of their lives, through a narrow funnel fifty feet in length, and with their beſoms clean it from ſoot and dirt. At what preciſe period chimney-ſweeping became a trade in England and Scotland, we have not been able to learn; but among us, as well as elſewhere, young boys are employed in this buſineſs, who are ſaid to be very harſhly treated by fellows who ſtole them from the doors of cottages in the country. That children have been ſometimes kidnapped by chimney-ſweepers, we can have no doubt; but that the practice is frequent, we do not believe. We think however that the buſineſs might be wholly aboliſhed; for a narrow funnel might certainly, if not very crooked, be ſwept by a bundle of ſtraw or bruſhwood faſtened to a rope, as well as one that is wider: and the bricks which ſeparate the contiguous flues we know to be leſs injured by this method of ſweeping, when cautiouſly gone about, than by ſending boys up the chimneys.

On the 4th July 1796, letters patent were granted to Daniel Davis, of the pariſh of St Giles, Middleſex, for his invention of a machine, by which he propoſes to ſweep and cleanſe chimneys, and extinguiſh chimneys on fire, without any perſon going up the ſame, as is now the practice. The machine conſiſts of an apparatus of rack-work, of various lengths, which, by means of a hand-turn, is made to aſcend the chimney. The lengths of the rack-work are joined together by means of mortices and tenons, with a ſpring which holds them faſt. In each length is a joint, by which the rack-work will accommodate itſelf to angles or turns in the flues. To the firſt or uppermoſt length is fixed a bruſh of hair, or wire, or ſpunge, or other elaſtic ſubſtance as the occaſion may require.

This invention is doubtleſs well calculated to anſwer the purpoſe intended, and may perhaps be the means of diminiſhing the number of thoſe objects of miſery, the unfortunate chimney-ſweepers.

CHINA is an empire of ſuch antiquity and extent, the laws and cuſtoms of the people are ſo ſingular, and the populouſneſs of the country ſo very great—that it has attracted much of the attention of Europeans ever ſince it was viſited in the 13th century by Marco Paulo the Venetian traveller. Of ſuch a country it would be unpardonable not to give ſome account in a work of this nature; but we have not, in truth, much to add to what has been ſaid of China and the Chineſe in the Encyclopædia Britannica. Since the article China in that work was publiſhed, the court of Pekin has indeed been viſited by an embaſſy from Great Britain, and the origin of the people, as well as the antiquity of their empire, has been inveſtigated by Sir William Jones with his uſual diligence; but from his memoir, publiſhed in the ſecond volume of the Aſiatic Reſearches, and from Sir George Staunton's account of the embaſſy, there is not much to be extracted which would be either amuſing or inſtructive to our readers.

We have already obſerved from Groſier and others, that the Chineſe not only lay claim to the higheſt antiquity, but even contend that their firſt emperor was the firſt man. Both theſe poſitions are controverted by Sir William Jones, who, though he allows the Chineſe empire to be very ancient when compared with the oldeſt European ſtate, is yet decidedly of opinion that it was not founded at an earlier period than the 12th century before the Chriſtian era; and that the people, ſo far from being aborigines, are a mixed race of Tartars and Hindoos. He begins his inveſtigation with aſking, "Whence came the ſingular people who long had governed China, before they were conquered by the Tartars? On this problem (ſays he[*]) four opinions have been advanced, and all rather peremptorily aſſerted, than ſupported by argument and evidence. By a few writers it has been urged, that the *Chineſe* are an original race, who have dwelled for ages, if not from eternity, in the land which they now poſſeſs. By others, and chiefly by the miſſionaries, it is inſiſted that they ſprung from the ſame ſtock with the *Hebrews* and the *Arabs*. A third aſſertion is that of the Arabs themſelves, and of M. Pauw, who hold it indubitable, that they were originally *Tartars*, deſcending in wild clans from the ſteeps of Imaus: And a fourth, at leaſt as dogmatically pronounced as any of the preceding, is that of the *Brahmans*, who decide, without allowing any appeal from their deciſion, that the *Chinas* (for ſo they are named in *Sanſcrit*) were Hindoos of the military caſt, who, abandoning the privileges of their tribe, rambled in different bodies to the north-eaſt of *Bengal*; and forgetting by degrees the rites and the religion of their anceſtors, eſtabliſhed ſeparate principalities, which were afterwards united in the plains and valleys which are now poſſeſſed by them.

Of theſe opinions, Sir William having very completely demoliſhed the firſt three, proceeds to eſtabliſh the fourth, which he conſiders as intereſting as well as new in Europe. In the Sanſcrit inſtitutes of civil and religious duties, revealed, as the Hindoos believe, by Menu the

[*] *Aſiatic Reſearches*, vol. ii. mem. 25.

the ſon of Brahma, we find (ſays he) the following curious paſſage: 'Many families of the military claſs, having gradually abandoned the ordinances of the *Veda*, and the company of *Brahmans*, lived in a ſtate of degradation; as the people of *Pundraca* and *Odra*, thoſe of *Dravira* and *Camboja*, the *Yavanas* and *Sacas*, the *Paradas* and *Pahlavas*, the Chinas, and ſome other nations.' A full comment on this text (continues the preſident) would be ſuperfluous; but ſince the teſtimony of the Indian author, who, though not a divine perſonage, was certainly a very ancient lawyer, moraliſt, and hiſtorian, is direct and poſitive, diſintereſted and unſuſpected, it would decide the queſtion before us if we could be ſure that the word *China* ſignifies a *Chineſe*." Of this fact Sir William Jones took the very beſt methods to be ſatisfied. He conſulted a number of Pandits ſeparately, who all aſſured him that the word *China* has no other ſignification in *Sanſcrit*; that the *Chinas* of Menu ſettled in a fine country to the north-eaſt of *Gaur*, and to the eaſt of *Camarup* and *Napal*; that they had long been, and ſtill are, famed as ingenious artificers; and that they (the Pandits) had themſelves ſeen old Chineſe idols, which bore a manifeſt relation to the primitive religion of India. He then laid before one of the beſt informed *Pandits* a map of Aſia; and when his own country was pointed out to him, the *Pandit* immediately placed his finger on the north-weſtern provinces of China, as the place where he ſaid the *Chinas* of Menu firſt eſtabliſhed themſelves.

In the opinion of Sir William Jones, this is complete evidence that the Chineſe are deſcended from an Indian race; but he does not believe that the Chineſe empire, as we now call it, was formed when the laws of Menu were collected; and for his calling this fact in queſtion, he offers reaſons, which to us are perfectly ſatisfactory. By a diligent and accurate compariſon of ancient Sanſcrit writings, he has been able to fix the period of the compilation of thoſe laws at between 1000 and 1500 years before Chriſt; but by the evidence of Confucius himſelf, he proves, that if the Chineſe empire was formed, it could be only in its cradle in the 12th century before our era. In the ſecond part of the work, intitled *Lún Yú*, Confucius declares, that "although he, like other men, could relate, as mere leſſons of morality, the hiſtories of the firſt and ſecond imperial houſes, yet, *for want of evidence*, he could give no certain account of them." Now, ſays Sir William, if the Chineſe themſelves do not pretend that any hiſtorical monument exiſted in the age of Confucius preceding the riſe of their third dynaſty, about 1100 years before the Chriſtian epoch, we may juſtly conclude that their empire was then in its infancy, and did not grow to maturity till ſome ages afterwards. Nay, he is inclined to bring its origin ſtill lower down. "It was not, ſays he, till the eighth century before the birth of our Saviour, that a ſmall kingdom was erected in the province of *Shen ſi*, the capital of which ſtood nearly in the 35th degree of northern latitude, and about five degrees to the weſt of *Si-gan*. That country and its metropolis were both called *Chin*; and the dominion of its princes was gradually extended to the eaſt and weſt. The territory of *Chin*, ſo called by the old Hindoos, by the Perſians, and by the Chineſe, gave its name to a race of emperors, whoſe tyranny made their memory ſo unpopular, that the modern inhabitants of China hold the word in abhorrence, and ſpeak of themſelves as the people of a milder and more virtuous dynaſty: but it is highly probable that the whole nation deſcended from the *Chinas* of Menu, and mixing with the *Tartars*, by whom the plains of *Honan* and the more ſouthern provinces were thinly inhabited, formed by degrees the race of men whom we now ſee in poſſeſſion of the nobleſt empire in Aſia."

In ſupport of this opinion, which the accompliſhed author offers as the reſult of long and anxious inquiries, he obſerves, that the Chineſe have no ancient monuments from which their origin can be traced, even by plauſible conjecture; that their ſciences are wholly *exotic*; that their mechanic arts have nothing in them which any ſet of men, in a country ſo highly favoured by nature, might not have diſcovered and improved; that their philoſophy ſeems yet in ſo rude a ſtate as hardly to deſerve the appellation; and that their popular religion was imported from *India* in an age comparatively modern. He then inſtitutes a compariſon between the mythology of the Chineſe and that of the Hindoos; of which the reſult is, that the former people had an *ancient* ſyſtem of ceremonies and ſuperſtitions which has an apparent affinity with ſome parts of the oldeſt Indian worſhip. "They believed in the agency of genii or tutelary ſpirits, preſiding over the ſtars and the clouds; over lakes and rivers, mountains, valleys, and woods; over certain regions and towns; over all the elements, of which, like the Hindoos, they reckoned five; and particularly over *fire*, the moſt brilliant of them. To thoſe deities they offered victims on high places. And the following paſſage from one of their ſacred books, ſays Sir William, is very much in the ſtyle of the Brahmans: 'Even they who perform a ſacrifice with due reverence, cannot perfectly aſſure themſelves that the divine ſpirits accept their oblations; and far leſs can they, who adore the gods with languor and oſcitancy, clearly perceive their ſacred illapſes.' Theſe (continues the Preſident) are imperfect traces indeed, but they *are* traces of an affinity between the religion of Menu and that of the *Chinas*, whom he names among the apoſtates from it; and beſides them, we diſcover many other very ſingular marks of relation between the Chineſe and the old Hindoos.

"This relation (he thinks) appears in the remarkable period of 432,000, and the cycle of 60 years; in the predilection for the myſtical number *nine*; in many ſimilar faſts and great feſtivals, eſpecially at the ſolſtices and equinoxes; in the obſequies, conſiſting of rice and fruits offered to the manes of their anceſtors; in the dread of dying childleſs, leſt ſuch offerings ſhould be intermitted; and perhaps in their common abhorrence of *red* objects, which the Indians carried ſo far, that Menu himſelf, where he allows a *Brahman* to trade, if he cannot otherwiſe ſupport life, abſolutely forbids his trading in any ſort of *red* cloths, whether linen, or woollen, or made of woven bark. In a word, ſays Sir William Jones, all the circumſtances which have been mentioned ſeem to prove (as far as ſuch a queſtion admits proof), that the Chineſe and Hindoos were originally the ſame people; but having been ſeparated near 4000 years, they have retained few ſtrong features of their ancient conſanguinity, eſpecially as the Hindoos have preſerved their old language and ritual, while the Chineſe very ſoon loſt both; and the Hindoos have conſtantly intermarried among themſelves, while the Chineſe, by a mixture of Tartarian blood from the time of their firſt eſtabliſhment, have at length formed a race diſtinct in appearance both from Indians and Tartars."

Sir George Staunton, who accompanied the Earl of Macartney on his embaſſy to the Emperor of China, does not indeed directly controvert this reaſoning; but overlooking it altogether, gives to the Chineſe a much higher antiquity than Sir William Jones is inclined to allow them. Taking it for granted that their *cycle* is their own, and that it is not the offspring of aſtronomical ſcience, but of repeated obſervations, he ſeems to give implicit credit to thoſe annals of the empire which almoſt every other writer has conſidered as fabulous.

"Next to the ſtudies which teach the economy of life, the Chineſe (ſays he) value moſt the hiſtory of the events of their own country, which is, to them, the globe; and of the celeſtial movements which they had an opportunity of obſerving at the ſame time." In regard to the former, he tells us, that "from about *three* centuries before the Chriſtian era the tranſactions of the Chineſe empire have been regularly, and without any intervening chaſm, recorded both in official documents and by private contemporary writers. Nowhere had hiſtory become ſo much an object of public attention, and nowhere more the occupation of learned individuals. Every conſiderable town throughout the empire was a kind of univerſity, in which degrees were conferred on the proficient in the hiſtory and government of the ſtate. Hiſtorical works were multiplied throughout. The accounts of *recent* events were expoſed to the correction of the witneſſes of the facts, and compilations of former tranſactions to the criticiſms of rival writers." In regard to the latter, the movements of the heavenly bodies, he thinks that in no country are there ſtronger inducements or better opportunities to watch them than in China; and hence he infers, that the cycle of ſixty years is of Chineſe formation. "In a climate (ſays he) favourable to aſtronomy, the balance of hours beyond the number of days during which the ſun appeared to return oppoſite to, and to obſcure, or to mix among the ſame fixed ſtars, might be aſcertained in a ſhort time; and occaſioned the addition of a day to every fourth year, in order to maintain regularity in the computation of time, in regard to the return of the ſeaſons; but many ages muſt have paſt before a period could have been diſcovered, in which the unequal returns of the ſun and moon were ſo accurately adjuſted, that at its termination the new and full moons ſhould return, not only to the ſame day, but within an hour and a half of the time they had happened, when the period commenced. The knowledge of ſuch a period or cycle could be obtained only by a multiplicity of careful and accurate obſervations. Many revolutions of thoſe great luminaries muſt have been completed, and numberleſs conjunctions have paſt over, before their returns could be aſcertained to happen in the ſame day, at the end of nineteen years. The ſmall difference of time between the returning periods of this cycle, was partly leſſened by the intervention of another of 60 years, or of 720 revolutions of the moon, which, with the ſettled intercalation of 22 lunations, were at firſt ſuppoſed to bring a perfect coincidence of the relative poſitions of the ſun and moon: but even according to this period, every new year was made conſtantly to recede, in a very ſmall degree, which the Chineſe corrected afterwards from time to time. This cycle anſwered a double purpoſe, one as an era for chronological reckoning, and the other as a regulating period for a luni-ſolar year. Each year of the cycle is diſtinguiſhed by the union of two characters, taken from ſuch an arrangement of an unequal number of words placed in oppoſite columns, that the ſame two characters cannot be found again together for ſixty years. The firſt column contains a ſeries of ten words, the other twelve; which laſt are, in fact, the ſame that denote the twelve hours or diviſions of the day, each being double the European hour. The firſt word or character of the firſt ſeries or column of ten words, joined to the firſt word of the ſecond ſeries or column of twelve, marks the firſt year of the cycle; and ſo on until the firſt ſeries is exhauſted, when the eleventh word of the ſecond ſeries, combined with the firſt of the firſt ſeries, marks the eleventh year of the cycle; and the twelfth or laſt of the ſecond ſeries, joined with the ſecond of the firſt ſeries, ſerves for denoting the twelfth year. The third of the firſt ſeries becomes united in regular progreſſion with the firſt of the ſecond ſeries, to mark the thirteenth year; and proceeding by this rule, the firſt character in the firſt and in the ſecond ſeries cannot come again together for ſixty years, or until the firſt year of the ſecond cycle. The Chriſtian year 1797 anſwers to the 54th year of the 60th Chineſe cycle, which aſcertains its commencement to have been 2277 years before the birth of Chriſt; unleſs it be ſuppoſed that the official records and public annals of the empire, which bear teſtimony to it, ſhould all be falſified, and that the cycle when firſt eſtabliſhed ſhould have been antidated; which is indeed as little probable as that the period, for example, of the Olympiads ſhould be aſſerted to have commenced many ages prior to the firſt Olympic games."

This is a very poſitive deciſion againſt the opinion of a man whoſe talents and knowledge of oriental learning were ſuch as to give to his opinions on ſuch ſubjects the greateſt weight. If the ſtatements and reaſonings of Sir George Staunton be accurate, the Chineſe empire muſt have ſubſiſted at leaſt 3000 years before the Chriſtian era; for he ſays expreſsly, that *many ages* muſt have elapſed before the commencement of that cycle, which, according to him, commenced 2277 years before the birth of Chriſt. But ſurely Confucius was as well acquainted with the ancient annals of his own country, and the credibility which is due to them, as any man of the preſent age, whether Chineſe or European; and we have ſeen, that he conſidered none of them as authentic which relate events previous to the 11th century before our era. Even this is by much too early a period at which to rely upon them with implicit confidence, if it be true, as Sir George informs us, that the tranſactions of the empire have been regularly recorded only from about *three* centuries before the birth of Chriſt. With reſpect to the cycle, there is every probability that it was derived from India, where we know that aſtronomy has been cultivated as a ſcience from time immemorial, and where, we have ſhewn in another place, that the commencement of the cycle was actually antedated (ſee PHILOSOPHY, n° 9. *Encycl.*) We have therefore no heſitation in preferring Sir William Jones's opinion of the origin of the Chineſe empire to Sir George Staunton's; not merely becauſe we believe the

the

the former of theſe gentlemen to have been more converſant than the latter with Chineſe literature, but becauſe we think his reaſoning more conſiſtent with itſelf, and his concluſion more conſonant to that outline of chronology, which, as he obſerves, has been ſo correctly traced for the laſt 2000 years, that we muſt be hardy ſceptics to call it in queſtion.

There is another point very nearly related indeed to this, about which theſe two learned men likewiſe differ. Sir George Staunton informs us, that "no accounts of a general deluge are mentioned in Chineſe hiſtory." Sir William Jones, on the other hand, in the diſcourſe already quoted, ſays, "I may aſſure you, after full inquiry and conſideration, that the Chineſe, like the Hindoos, believe this earth to have been wholly covered with water, which, in works of undiſputed authenticity, they deſcribe as *flowing abundantly, then ſubſiding, and ſeparating the higher from the lower age of mankind.*" To which of theſe authors ſhall we give credit? The high antiquity which Sir George Staunton aſſigns to the Chineſe empire, rendered it neceſſary for the perſons from whom he drew his information to get quit by any means of an univerſal deluge. The ſyſtem of Sir William Jones left him at liberty to admit or reject that event according to evidence; and in addition to the authentic records to which he appeals, he quotes a mythological fable of the Chineſe, and another of the Hindoos, which, though he lays not upon them any great ſtreſs, appear to us, when compared together, not only to corroborate his opinion reſpecting the deſcent of the Chineſe, but likewiſe to ſhew that both they and the Hindoos have preſerved a traditionary account of the deluge very ſimilar to that which is given by Moſes. The Chineſe fable is this: "The mother of FO-HI was the *daughter of Heaven*, ſurnamed *Flower-loving*; and as the nymph was walking alone on the brink of a river with a ſimilar name, ſhe found herſelf on a ſudden encircled with a *rainbow*; ſoon after which ſhe became pregnant, and at the end of twelve years was delivered of a ſon, radiant as herſelf, who, among other titles, had that of *Sui*, or *the Star of the Year*." In the mythological ſyſtem of the Hindoos, "the nymph ROHINI, who preſides over the fourth lunar manſion, was the favourite miſtreſs of SOMA or the Moon, among whoſe numerous epithets we find *Cumudanáyaca*, or delighting in a ſpecies of *water-flower* that bloſſoms at night. The offspring of ROHINI and SOMA was BUDHA, regent of a planet; and he married ILA, whoſe father was preſerved in a MIRACULOUS ARK from an univerſal deluge." The learned preſident ſhews, that, according to the Brahams, the Chineſe deſcended from BUDA; and he mentions a divine perſonage connected with the Chineſe account of the birth of FO-HI, whoſe name was NIU-VA. But if all theſe circumſtances be laid together, it will appear, we think, pretty evident, that the two ancient nations have preſerved the ſame tradition of an univerſal deluge, and that the Chineſe RAINBOW and NIU-VA, with the Indian ARK, point to the flood of NOAH.

To Sir William Jones's derivation of the Chineſe from the Hindoos, the ſtate of their written language may occur as an objection; for ſince it is certain that alphabetical characters were in uſe among the Hindoos before the period at which he places the emigration of the *Chinas*, how, it may be aſked, came theſe people to drop the mode of writing practiſed by their anceſtors, and to adopt another ſo very inconvenient as that which the Chineſe have uſed from the foundation of their empire? The force of this objection, however, will vaniſh, when it is remembered that the *Chinas* were of the military caſt; that they had gradually abandoned the ordinances of the Veda, and were in conſequence degraded; and that they rambled from their native country in ſmall bodies. We do not know that the military caſt among the Hindoos was ever much devoted to letters; there is the greateſt reaſon to believe that a degraded caſt would neglect them; and it is certain that ſmall bodies of men, wandering in deſerts, would have their time and their attention completely occupied in providing for the day that was paſſing over them. That the *Chinas* ſhould have forgotten the alphabetical characters of the Hindoos, is therefore ſo far from being an objection to Sir William Jones's account of their deſcent from that people, that it is the natural conſequence of the manner in which he ſays they rambled from Hindoſtan to the northern provinces of what now conſtitutes the Chineſe empire.

Of the origin of the characters which are uſed by this ſingular people, the illuſtrious preſident of the Aſiatic Society gives the following account from a Chineſe writer named LI YANG PING. "The earlieſt of them were nothing more than the outlines of viſible objects, earthly and celeſtial; but as things merely intellectual could not be expreſſed by thoſe figures, the grammarians of *China* contrived to repreſent the various operations of the mind by metaphors drawn from the productions of nature. Thus the idea of roughneſs and of rotundity, of motion and reſt, were conveyed to the eye by ſigns repreſenting a mountain, the ſky, a river, and the earth. The figures of the ſun, the moon, and the ſtars, differently combined, ſtood for ſmoothneſs and ſplendour, for any thing artfully wrought, or woven with delicate workmanſhip. Extenſion, growth, increaſe, and many other qualities, were painted in characters taken from the clouds, from the firmament, and from the vegetable part of the creation. The different ways of moving, agility and ſlowneſs, idleneſs and diligence, were expreſſed by various inſects, birds, fiſhes, and quadrupeds. In this manner paſſions and ſentiments were traced by the pencil, and ideas not ſubject to any ſenſe were exhibited to the ſight; until by degrees new combinations were invented, new expreſſions added, the characters deviated imperceptibly from their primitive ſhape, and the Chineſe language became not only clear and forcible, but rich and elegant in the higheſt degree *."

Of this language, both as it is ſpoken and written, Sir George Staunton has given an account ſo clear and ſcientific, that it will undoubtedly place him high among the moſt eminent philologiſts of the 18th century. As there is nothing relating to the Chineſe more wonderful than their language, which is very little underſtood in Europe, we ſhall lay before our readers a pretty copious abſtract of what he ſays on the ſubject, referring them for further information to his account of Lord Macartney's Embaſſy to China.

"In the Chineſe tongue (ſays Sir George) the ſounds of ſeveral letters in moſt alphabets are utterly unknown, and the organs of a native advanced in life cannot pronounce them. In endeavouring to utter the

---

* *Aſiatic Reſearches*, vol ii. Memoir 13.

ſounds of B, D, R, and X, for inſtance, he ſubſtitutes ſome other ſounds to which the ſame organ has been accuſtomed; L for R, and, as we have reaſon to think from ſome expreſſions of Sir William Jones's, F for B. The nice diſtinctions between the tones and accents of words nearly reſembling each other in ſound, but varying much in ſenſe, require a nicety of ear to diſtinguiſh, and of vocal powers to render them exactly. Synonymous words are therefore frequently introduced in Chineſe dialogue to prevent any doubt about the intended ſenſe; and if in an intricate diſcuſſion any uncertainty ſhould ſtill remain as to the meaning of a particular expreſſion, recourſe is had to the ultimate criterion of tracing with the finger in the air, or otherwiſe, the form of the character, and thus aſcertaining at once which was meant to be expreſſed. In a Chineſe ſentence there is no marked diſtinction of ſubſtantives, adjectives, or verbs; nor any accordance of gender, number, and caſe. A very few particles denote the paſt, the preſent, and the future; nor are thoſe auxiliaries employed when the intended time may be otherwiſe inferred with certainty. A Chineſe who means to declare his intention of departing to-morrow, never ſays that he *will* depart to-morrow; becauſe the expreſſion of the morrow is ſufficient to aſcertain that his departure muſt be future. The plural number is marked by the addition of a word, without which the ſingular always is implied. Neither the memory nor the organs of ſpeech are burthened with the pronunciation of more ſounds to expreſs ideas than are abſolutely neceſſary to mark their difference. The language is entirely monoſyllabic. A ſingle ſyllable always expreſſes a complete idea. Each ſyllable may be ſounded by an European conſonant preceding a vowel, ſometimes followed by a liquid. Such an order of words prevents the harſhneſs of ſucceeding conſonants ſounding ill together; and renders the language as ſoft and harmonious as the Italian is felt to be, from the rarity of conſonants, and the frequency of its vowel terminations.

"The names or ſounds, by which men may be firſt ſuppoſed to have diſtinguiſhed other animals, when occaſion offered to deſignate them in their abſence, were attempts at an imitation of the ſounds peculiar to thoſe beings; and ſtill, in Chineſe, the name, for example, of a cat, is a pretty near reſemblance of its uſual cry. It occurred as naturally to endeavour, in ſpeaking, to imitate the voice, if practicable, as it was in writing to ſketch a rude figure of the object of deſcription. It is obſervable, that the radical words of moſt languages, ſeparated from the ſervile letters which mark their inflections, according to their conjugations or declenſions, are monoſyllabic. A part of each radical word is retained in compoſition to denote the meaning and etymology of the compound, which thus becomes polyſyllabic; but the Chineſe grammarians, aware of the inconvenience reſulting from the length and complication of ſounds, confined all their words, however ſignificant of combined ideas, to ſingle ſounds; and retained only in writing, ſome part at leaſt of the form of each character denoting a ſimple idea, in the compound characters conveying complex ideas."

This is a very plauſible, and perhaps the true, account of the monoſyllabic form of the Chineſe language; but it is proper to ſtate the different account which is given of this peculiarity by Sir William Jones. "It has ariſen, according to him, from the ſingular habits of the people; for though their common tongue be ſo *muſically* accented as to form a kind of recitative, yet it wants thoſe *grammatical* accents without which all human tongues would appear monoſyllabic. Thus *Amita*, with an accent on the firſt ſyllable, means, in the *Sanſcrit* language, *immeaſurable*, and the natives of Bengal pronounce it *Omito;* but when the religion of BUDDHA, the ſon of Máyá, was carried into *China*, the people of that country, unable to pronounce the name of their new god, called him FOE, the ſon of MO-YE.; and divided his epithet *Amita* into three ſyllables O-MI-TO, annexing to them certain ideas of their own, and expreſſing them in writing by three diſtinct ſymbols. Hence it is that they have clipped their language into monoſyllables, even when the ideas expreſſed by them, and the written ſymbols for thoſe ideas, are very complex."

"In the Chineſe language Sir George Staunton informs us, that there is a certain order, or ſettled ſyntax, in the ſucceſſion of words in the ſame ſentence; a ſucceſſion fixed by cuſtom, differently in different languages, but founded on no rule or natural order of ideas, as has been ſometimes ſuppoſed; for though a ſentence conſiſts of ſeveral ideas, to be rendered by ſeveral words, theſe ideas all exiſt and are connected together in the ſame inſtant; forming a picture or image, every part of which is conceived at once. The formation of Chineſe ſentences is often the ſimpleſt and moſt artleſs poſſible, and ſuch as may naturally have occurred at the origin of ſociety. To interrogate, for example, is often at leaſt to require the ſolution of a queſtion, whether the ſubject of doubt be in a particular way or the contrary; and accordingly a Chineſe inquiring about his friends health, will ſometimes ſay, *hou, poo hou?* The literal meaning of which words is, "well, not well?" A ſimple character repeated ſtands ſometimes for more than one of the objects which ſingly it denotes, and ſometimes for a collective quantity of the ſame thing. The character of *moo* ſingly is a tree, repeated is a thicket, and tripled is a foreſt.

"In Chineſe there are ſcarcely fifteen hundred diſtinct ſounds. In the written language there are at leaſt eighty thouſand characters or different forms of letters, which number divided by the firſt gives nearly fifty ſenſes or characters upon an average to every ſound expreſſed; a diſproportion, however, that gives more the appearance than the reality of equivocation and uncertainty to the oral language of the Chineſe.

"The characters of the Chineſe language were originally traced, in moſt inſtances, with a view to expreſs either real images, or the allegorical ſigns of ideas: a circle, for example, for the ſun, and a creſcent for the moon. A man was repreſented by an erect figure, with lines to mark the extremities. It was evident that the difficulty and tediouſneſs of imitation will have occaſioned ſoon a change to traits more ſimple and more quickly traced. Of the entire figure of a man, little more than the lower extremities only continue to be drawn, by two lines forming an angle with each other. A faint reſemblance, in ſome few inſtances, ſtill remains of the original forms in the preſent hieroglyphic characters; and the gradation of their changes is traced in ſeveral Chineſe books. Not above half a dozen of the preſent characters conſiſt each of a ſingle line; but moſt of of them conſiſt of many, and a few of ſo many as ſeventy different ſtrokes. The form of thoſe characters has not been ſo flux as the ſound of words, as appears in the inſtance of almoſt all the countries bordering on the Chineſe Sea or Eaſtern Aſia, where the Chineſe written, but not the oral language, is underſtood; in like manner, as one form of Arabic figures to denote numbers, and one ſet of notes for muſic, are uniform and intelligible throughout Europe, notwithſtanding the variety of its languages.

“ A certain order or connection is to be perceived in the arrangement of the written characters of the Chineſe; as if it had been formed originally upon a ſyſtem to take place at once, and not grown up, as other languages, by ſlow and diſtant intervals. Upwards of two hundred characters, generally conſiſting each of a few lines or ſtrokes, are made to mark the principal objects of nature, ſomewhat in the manner of Biſhop Wilkin's diviſions, in his ingenious book on the ſubject of univerſal language, or real character. Theſe may be conſidered as the genera or roots of language, in which every other word or ſpecies, in a ſyſtematic ſenſe, is referred to its proper genus. The heart is a genus, of which the repreſentation of a curve line approaches ſomewhat to the form of the object; and the ſpecies referable to it include all the ſentiments, paſſions, and affections, that agitate the human breaſt. Each ſpecies is accompanied by ſome mark denoting the genus or heart. Under the genus *hand* are arranged moſt trades and manual exerciſes. Under the genus *word* every ſort of ſpeech, ſtudy, writing, underſtanding, and debate. A horizontal line marks a unit; croſſed by another line it ſtands for ten, as it does in every nation which repeats the units after that number. The five elements, of which the Chineſe ſuppoſe all bodies in nature to be compounded, form ſo many genera, each of which comprehends a great number of ſpecies under it. As in every compound character or ſpecies, the abridged mark of the genus is diſcernible by a ſtudent of that language, in a little time he is enabled to conſult the Chineſe dictionary, in which the compound characters or ſpecies are arranged under their proper genera. The characters of theſe genera are placed at the beginning of the dictionary, in an order which, like that of the alphabet, is invariable, and ſoon becomes familiar to the learner. The ſpecies under each genus follow each other, according to the number of ſtrokes of which each conſiſts, independently of the one or few which ſerve to point out the genus. The ſpecies wanted is thus ſoon found out. Its meaning and pronunciation are given through other words in common uſe; the firſt of which denotes its ſignification and the other its ſound. When no one common word is found to render exactly the ſame ſound, it is communicated by two words with marks, to inform the inquirer that the conſonant of the firſt word and the vowel of the ſecond joined together form the preciſe ſound wanted.

“ The compoſition of many of the Chineſe characters often diſplays conſiderable ingenuity, and ſerves alſo to give an inſight into the opinions and manners of the people. The character expreſſive of happineſs includes abridged marks of land, the ſource of their phyſical, and of children that of their moral, enjoyments. This character, embelliſhed in a variety of ways, is hung up almoſt in every houſe. Sometimes written by the hand of the emperor, it is ſent by him as a compliment, which is very highly prized, and ſuch as he was pleaſed to ſend to the embaſſador.

“ Upon the formation, changes, and alluſions of compound characters, the Chineſe have publiſhed many thouſand volumes of philological learning. Nowhere does criticiſm more abound, or is more ſtrict. The introduction or alteration of a character is a ſerious undertaking, and ſeldom fails to meet with oppoſition. The moſt ancient writings of the Chineſe are ſtill claſſical amongſt them. The language ſeems in no inſtance to have been derived from or mixed with any other. The written ſeems to have followed the oral language ſoon after the men who ſpoke it were formed into a regular ſociety. Though it is likely that all hieroglyphical languages were originally founded on the principles of imitation, yet in the gradual progreſs towards arbitrary forms and ſounds, it is probable that every ſociety deviated from the originals in a different manner from the others; and thus for every independent ſociety there aroſe a ſeparate hieroglyphic language. As ſoon as a communication took place between any two of them, each would hear names and ſounds not common to both; each reciprocally would mark down ſuch names in the ſounds of its own characters, bearing, as hieroglyphics, a different ſenſe. In that inſtance, conſequently, thoſe characters ceaſe to be hieroglyphics, and were merely marks of ſound. If the foreign ſounds could not be expreſſed but by the uſe of a part of two hieroglyphics, in the manner mentioned to be uſed ſometimes in Chineſe dictionaries, the two marks joined together become in fact a ſyllable. If a frequent intercourſe ſhould take place between communities ſpeaking different languages, the neceſſity of uſing hieroglyphics merely as marks of ſound would frequently recur. The practice would lead imperceptibly to the diſcovery that, with a few hieroglyphics, every ſound of the foreign language might be expreſſed; and the hieroglyphics which anſwered beſt this purpoſe, either as to exactneſs of ſound or ſimplicity of form, would be ſelected for this particular uſe; and ſerving as ſo many letters, would form in fact together what is called an alphabet. Thus, the paſſage from hieroglyphic to alphabetic writing may naturally be traced, without the neceſſity of having ‘ recourſe to divine inſtruction, as ſome learned men have conjectured, on the ground that the art of writing by an alphabet is too refined and artificial for untutored reaſon.’

“ The Chineſe printed character is the ſame as is uſed in moſt manuſcripts, and is chiefly formed of ſtraight lines in angular poſitions, as moſt letters are in Eaſtern tongues, eſpecially the Sanſcrit; the characters of which, in ſome inſtances, admit of additions to their original form, producing a modification of the ſenſe. A running hand is uſed by the Chineſe only on trivial occaſions, or for private notes, or for the eaſe and expedition of the writer; and differs from the other as much as an European manuſcript does from print. There are books with alternate columns of both kinds of writing for their mutual explanation to a learner.

“ The principal difficulty in the ſtudy of Chineſe writings ariſes from the general excluſion of the auxiliary particles of colloquial language, that fix the relation between indeclinable words, ſuch as are all thoſe of the Chineſe language. The judgment muſt be conſtantly exerciſed.

exerciſed by the ſtudent, to ſupply the abſence of ſuch aſſiſtance. That judgment muſt be guided by attention to the manners, cuſtoms, laws, and opinions of the Chineſe, and to the events and local circumſtances of the country, to which the alluſions of language perpetually refer. If it in general be true, that a language is difficult to be underſtood in proportion to the diſtance of the country where it is ſpoken, and that of him who endeavours to acquire it, becauſe in that proportion the alluſions to which language has continually recourſe are leſs known to the learner, ſome idea may be conceived of the obſtacles which an European may expect to meet in reading Chineſe, not only from the remoteneſs of ſituation, but from the difference between him and the native of China in all other reſpects. The Chineſe characters are in fact ſketches or abridged figures, and a ſentence is often a ſtring of metaphors. The different relations of life are not marked by arbitrary ſounds, ſimply conveying the idea of ſuch connection; but the qualities naturally expected to ariſe out of ſuch relations become frequently the name by which they are reſpectively known. Kindred, for example, of every degree is thus diſtinguiſhed with a minuteneſs unknown in other languages. That of China has diſtinct characters for every modification known by them of objects in the phyſical and intellectual world. Abſtract terms are no otherwiſe expreſſed by the Chineſe than by applying to each the name of the moſt prominent objects to which it might be applied, which is likewiſe indeed generally the caſe of other languages. Among the Latins the abſtract idea of virtue, for example, was expreſſed under the name of valour or ſtrength (*virtus*), being the quality moſt eſteemed among them, as filial piety is conſidered to be in China. The words of an alphabetic language being formed of different combinations of letters or elemental parts, each with a diſtinct ſound and name, whoever knows and combines theſe together, may read the words without the leaſt knowledge of their meaning; not ſo hieroglyphic language, in which each character has indeed a ſound annexed to it, but which bears no certain relation to the unnamed lines or ſtrokes of which it is compoſed. Such character is ſtudied and beſt learned by becoming acquainted with the idea attached to it; and a dictionary of hieroglyphics is leſs a vocabulary of the terms of one language with the correſpondent terms in another, than an encyclopædia containing explanations of the ideas themſelves repreſented by ſuch hieroglyphics. In ſuch ſenſe only can the acquiſition of Chineſe words be juſtly ſaid to engroſs moſt of the time of men of learning among them. The knowledge of the ſciences of the Chineſe, however imperfect, and of their moſt extenſive literature, is certainly ſufficient to occupy the life of man. Enough, however, of the language is imperceptibly acquired by every native, and may, with diligence, be acquired by foreigners for the ordinary concerns of life; and further improvements muſt depend on capacity and opportunity."

Next to the ſingular ſtructure of the oral and written language of the Chineſe, there is perhaps nothing in their hiſtory more ſurpriſing to a native of Europe than the number of the people, and the means by which they contrive to procure ſubſiſtence, without foreign trade, in a country ſo crouded, and at the ſame time not everywhere of a fertile ſoil. In the Encyclopædia, the population of this vaſt empire is ſtated, from M. Groſier, at 200 millions: but great as this is, when compared with the population of every other extenſive country, it appears to be far ſhort of the truth. Sir George Staunton has publiſhed a ſtatement, taken from one of the public offices in the capital, and given by a great and reſpectable manderin to Lord Macartney, in which it is ſhewn that China Proper contains not fewer than 333 millions of inhabitants. As the extent of the country is 1,297,999 ſquare miles, there are of courſe very near 260 inhabitants to every ſquare mile; and of theſe miles a very conſiderable proportion conſiſts of nothing but barren rocks. That this account is accurate there can be little doubt; for the extent of the provinces was aſcertained by aſtronomical obſervations, as well as by admeaſurement; and the number of individuals is regularly taken in each diviſion of a diſtrict by a tythingman, or every tenth maſter of a family. Theſe returns are collected by officers reſident ſo near as to be capable of correcting any groſs miſtake, and are all lodged in the great regiſter of Pekin.

For this exceſſive population our author ſatisfactorily accounts. Celibacy, ſays he, is rare in China, even in the military profeſſion; the marriages are prolific as well as early, and the influence of the patriarchal ſyſtem, to be explained afterwards, is ſuch, that a man's children adds to his wealth. It is reckoned a diſcredit to be without offspring; and they who have none adopt others, who become theirs excluſively. In caſe of marriage, ſhould a wife prove barren, a ſecond may be eſpouſed in the lifetime of the firſt. The opulent, as in moſt parts of the Eaſt, are allowed, without reproach, to keep concubines, of whom the children are conſidered as being thoſe of the legitimate wife, and partake in all the rights of legitimacy. "Accidents ſometimes of extraordinary drought, and ſometimes of exceſſive inundations, occaſionally produce famine in particular provinces, and famine diſeaſe; but there are few drains from moral cauſes either of emigration or foreign navigation. The number of manufactures, whoſe occupations are not always favourable to health, whoſe conſtant confinement to particular ſpots, and ſometimes in a cloſe or tainted atmoſphere, muſt be injurious, and whoſe reſidence in towns expoſes them to irregularities, bears but a very ſmall proportion to that of huſbandmen in China. In general there ſeems to be no other bounds to Chineſe populouſneſs than thoſe which the neceſſity of ſubſiſtence may put to it. Theſe boundaries are certainly more enlarged than in other countries. The whole ſurface of the empire is, with trifling exceptions, dedicated to the production of food for man alone. There is no meadow, and very little paſture; nor are fields cultivated in oats, beans, or turnips, for the ſupport of cattle of any kind. Few parks or pleaſure grounds are ſeen, excepting thoſe belonging to the emperor. Little land is taken up for roads, which are few and narrow, the chief communication being by water. There are no commons, or lands ſuffered to lie waſte by the neglect, or the caprice, or for the ſport of great proprietors. No arable land lies fallow. The ſoil, under a hot and fertilizing ſun, yields annually, in moſt inſtances, double crops, in conſequence of adapting the culture to the ſoil, and of ſupplying its defects by mixture with other earths, by manure, by irrigation, by careful and judicious induſtry of every kind. The labour of man is little diverted from that induſtry to to miniſter to the luxuries of the opulent and powerful, or in employments of no real uſe. Even the ſoldiers of the Chineſe army, except during the ſhort intervals of the guards which they are called to mount, or the exerciſes, or other occaſional ſervices which they perform, are moſtly employed in agriculture. The quantity of ſubſiſtence is increaſed alſo, by converting more ſpecies of animals and vegetables to that purpoſe than is uſual in other countries. And even in the preparation of their food the Chineſe have economy and management."

The government of China is deſpotic; and it is a curious ſpectacle to behold ſo large a proportion of the whole human race, connected together in one great ſyſtem of polity, ſubmitting quietly, and through ſo conſiderable an extent of country, to one great ſovereign; and uniform in their laws, their manners, and their language, but differing eſſentially in each of theſe reſpects from every other portion of mankind: and neither deſirous of communicating with nor forming any deſigns againſt the reſt of the world. To produce ſuch a phenomenon, many cauſes muſt be combined; but perhaps the principal are to be found in the patriarchal ſyſtem already mentioned, in the laws and cuſtoms of the empire, and in the belief that the emperor is the vicegerent of heaven, and guided in all his actions by divine inſpiration.

The patriarchal ſyſtem is founded upon that filial piety which the philoſophers of China have uniformly repreſented as the greateſt of human virtues. Theſe ſages, while they ſucceſsfully inculcated this duty, have left parental affection to its own natural influence; and hence in China parents are leſs frequently neglected than infants are expoſed. The laws of the empire, to corroborate the diſpoſition to filial obedience, furniſh an opportunity for puniſhing any breach of it, by leaving a man's offspring entirely within his own power: and hence it is, that with the poor, marriage, as we have ſaid, is a meaſure of prudence; becauſe the children, particularly the ſons, are bound to maintain their parents.

A Chineſe dwelling is generally ſurrounded by a wall ſix or ſeven feet high. Within this incloſure a whole family, of three generations, with all their reſpective wives and children, will frequently be found. One ſmall room is made to ſerve for the individuals of each branch of the family, ſleeping in different beds, divided only by mats hanging from the ceiling. One common room is uſed for eating.

The prevalence of this cuſtom, of retaining the ſeveral branches of a family under the ſame roof, is attended with important effects. It renders the younger temperate and orderly in their conduct under the authority and example of the older; and it enables the whole to ſubſiſt, like ſoldiers in a meſs, with more economy and advantage. As the venerable patriarch of each habitation preſides over his deſcendants with the authority of a magiſtrate; ſo the different orders of magiſtrates are, in their different diſtricts and provinces, looked up to with the veneration due from children to their parents, while the emperor is revered as the grand patriarch of the whole empire.

Another thing which contributes much to the permanency of the government and the internal quiet of the empire is, that in China there is leſs inequality in the fortunes than in the conditions of men. The ancient annals of the empire teſtify, that for a long period of time, the earth, like the other elements of nature, was enjoyed by its inhabitants almoſt in common. Their country was divided into ſmall equal diſtricts; every diſtrict was cultivated conjointly by eight labouring families, which compoſed each hamlet; and they enjoyed all the profit of their labours, except a certain ſhare of the produce reſerved for public expences. It is true, indeed, that after a revolution, deplored in all the Chineſe hiſtories, which happened prior to the Chriſtian era, the uſurper granted all the lands away to the partners of his victories, leaving to the cultivators of the ſoil a ſmall pittance only out of the revenue which it yielded. Property in land alſo became hereditary: but in proceſs of time, the moſt conſiderable domains were ſubdivided into very moderate parcels by the ſucceſſive diſtribution of the poſſeſſions of every father equally among all his ſons; the daughters being always married without dower. It very rarely happened that there was but an only ſon to enjoy the whole property of his deceaſed parents; and it could ſcarcely be increaſed by collateral ſucceſſion.

From the operations of all thoſe cauſes, there was a conſtant tendency to level wealth; and few could ſucceed to ſuch an accumulation of it as to render them independent of any efforts of their own for its increaſe. Beſides, wealth alone confers in China but little importance, and no power; nor is property, without office, always perfectly ſecure. There is no hereditary dignity, which might accompany, and give it pre-eminence and weight. The delegated authority of government often leans more heavily on the unprotected rich than on the poor, who are leſs objects of temptation. And it is a common remark among the Chineſe, that fortunes, either by being parcelled out to many heirs, or by being loſt in commercial ſpeculations, gaming, or extravagance, or extorted by oppreſſive mandarines, ſeldom continue to be conſiderable in the individuals of the ſame family beyond the third generation. To aſcend again the ladder of ambition, it is neceſſary, by long and laborious ſtudy, to excel in the learning of the country, which alone qualifies for public employments.

There are properly but three claſſes of men in China: men of letters, from whom the mandarines are taken; cultivators of the ground; and mechanics, including merchants. In Pekin alone is conferred the higheſt degree of literature upon thoſe who, in public examinations, are found moſt able in the ſciences of morality and government as taught in the ancient Chineſe writers; with which ſtudies the hiſtory of their country is intimately blended. Among ſuch graduates all the civil offices in the ſtate are diſtributed by the emperor; and they compoſe all the great tribunals of the empire. The candidates for thoſe degrees are ſuch as have ſucceeded in ſimilar examinations in the principal city of each province. Thoſe who have been choſen in the cities of the ſecond order, or chief town of every diſtrict in the province, are the candidates in the provincial capital. They who fail in the firſt and ſecond claſſes have ſtill a claim on ſubordinate offices, proportioned to the claſs in which they had ſucceeded. Thoſe examinations are carried on with great ſolemnity, and apparent fairneſs. Military rank is likewiſe given to thoſe who are found upon competition to excel in the military art, and in warlike exerciſes. This diſtribution of offices contributes greatly to the peace of the empire; for the people cheerfully ſubmit to the authority of thoſe whom they believe to be placed over them by merit alone, and love that conſtitution which brings within the reach of the meaneſt ſubject, who has talents and induſtry, the higheſt ſtation next to the ſupreme.

“The great tribunals are ſituated, for the ſake of convenience, near the ſouthern gate of the imperial palace at Pekin. To them accounts of all the tranſactions of the empire are regularly tranſmitted. They are councils of reference from the emperor, to whom they report every buſineſs of moment, with the motives for the advice which they offer on the occaſion. There is a body of doctrine compoſed from the writings of the earlieſt ages of the empire, confirmed by ſubſequent lawgivers and ſovereigns, and tranſmitted from age to age with increaſing veneration, which ſerves as rules to guide the judgment of thoſe tribunals. This doctrine ſeems, indeed, founded on the broadeſt baſis of univerſal juſtice, and on the pureſt principles of humanity.

“His imperial majeſty generally conforms to the ſuggeſtions of thoſe tribunals. One tribunal is directed to conſider the qualifications of the different mandarines for different offices, and to propoſe their removal when found incapable or unjuſt. One has for object the preſervation of the manners or morals of the empire, called by Europeans *the tribunal of ceremonies*, which it regulates on the maxim; that exterior forms contribute not a little to prevent the breach of moral rules. The moſt arduous and critical is the tribunal of cenſors; taking into its conſideration the effect of ſubſiſting laws, the conduct of the other tribunals, of the princes and great officers of ſtate, and even of the emperor himſelf. There are ſeveral ſubordinate tribunals; ſuch as thoſe of mathematics, of medicine, of public works, of literature and hiſtory. The whole is a regular and conſiſtent ſyſtem, eſtabliſhed at a very early period, continued with little alterations through every dynaſty, and revived after any interruption from the caprice or paſſions of particular princes. Whatever deviation has been made by the preſent family on the throne, ariſes from the admiſſion of as many Tartars as Chineſe into every tribunal.” The opinions of the former are ſuppoſed always to preponderate; and many of them are indeed men of conſiderable talents and ſtrength of mind, as well as poliſhed manners. They are, however, in general, fitter for military than civil offices. The hardy education, the rough manners, the active ſpirit, the wandering diſpoſition, the looſe principles, and the irregular conduct, of the Tartar, fit him better for the profeſſion, practice, and purſuits of war, than the calm, regulated, and domeſtic habits of the Chineſe. Warriors ſeem naturally the offspring of Tartary, as literati are of China; and accordingly, the principal military commands are conferred on natives of the former country, as, with many exceptions indeed, the chief civil offices are on thoſe of the latter.

A military mandarin, who was much with Lord Macartney, and was himſelf a diſtinguiſhed officer, aſſerted that, “including Tartars, the total of the army in the pay of China amounted to 1,000,000 infantry and 800,000 cavalry. From the obſervations made by the embaſſy in the courſe of their travels through the empire, of the garriſons in the cities of the ſeveral orders, and of the military poſts at ſmall diſtances from each other, there appeared nothing unlikely in the calculation of the infantry; but they met few cavalry. If the number mentioned really do exiſt, a great proportion of them muſt have been in Tartary, or on ſome ſervice diſtant from the route of the embaſſy.

“Of the troops, eſpecially cavalry, a vaſt number are Tartars, who have a higher pay than their Chineſe fellow-ſoldiers. The principal officers of confidence in the army are Tartars alſo. None of either nation are received into the ſervice but ſuch as are healthy, ſtrong, and ſightly. The pay and allowances of a Chineſe horſeman are three Chineſe ounces, heavier than European ounces, and three-tenths of an ounce, of ſilver, and fifteen meaſures or rations (the weight not mentioned) of rice every lunar month. A Tartar horſeman, ſeven ſimilar ounces of ſilver, and 20 meaſures of rice for the ſame period. A Chineſe foot ſoldier has one ounce and ſix-tenths of an ounce of ſilver, and ten meaſures of rice; and a Tartar of the ſame deſcription has two ounces of ſilver and ten meaſures of rice every lunar month. The Emperor furniſhes the arms, accoutrements, and the upper garment, to all the ſoldiers. Beſide their ordinary pay and allowances, they alſo receive donations from the Emperor on particular occaſions; as when they marry, and when they have male children born. On the death of their parents they obtain ‘a gift of conſolation;’ as do their families when the ſoldiers themſelves die.

“The public revenues of China Proper are ſaid to be little leſs than 200,000,000 of ounces of ſilver, which may be equal to about 66,000,000 of pounds ſterling; or about three times thoſe of France before the late ſubverſion. From the produce of the taxes all the civil and military expences, and the incidental and extraordinary charges, are firſt paid upon the ſpot out of the treaſuries of the reſpective provinces where ſuch expences are incurred; and the remainder is remitted to the Imperial treaſury at Pekin. This ſurplus amounted in the year 1792 to the ſum of 36,614,328 ounces of ſilver, or 12,204,776 pounds ſterling, according to an account taken in round numbers. In caſe of inſurrections, or other occurrences requiring extraordinary expences, they are generally levied by additional taxes on the provinces adjacent to the ſcene of action, or connected with the occaſion of the expence.

“In the adminiſtration of the vaſt revenue of the ſtate, the opportunities of committing abuſes are not often neglected; as may be inferred from the frequent confiſcation to the Emperor in conſequence of ſuch tranſgreſſions. It is indeed affirmed, that much corruption and oppreſſion prevail in moſt of the public departments, by which conſiderable fortunes are acquired, notwithſtanding the modicity of the public ſalaries.”

With ſuch a ſtanding army and ſo vaſt a revenue, it will no longer appear wonderful that one man ſhould govern with deſpotic ſway even the immenſe multitude of people who inhabit the empire of China, eſpecially trained up as thoſe people are in habits of filial ſubmiſſion to their ſuperiors. But there are ſome circumſtances in the ſyſtem of Chineſe policy, not yet mentioned, which contribute perhaps more than even theſe habits and that power to preſerve the ſtability of the government. The Emperor reſerves to himſelf alone the right of relieving the wants of the poor, produced by famine or any other unforeſeen calamity. On ſuch occaſions he always comes forward. He orders the public granaries to be opened; remits the taxes to thoſe who are viſited with misfortune; affords aſſiſtance to enable them to retrieve their affairs; and appears to his ſubjects as ſtanding almoſt in the place of Providence in their favour. He is perfectly aware by how much a ſtronger chain he thus maintains his abſolute dominion, than the mere dread of puniſhment would afford. The emperor, to whom the Britiſh embaſſy was ſent, ſhewed himſelf ſo jealous of retaining the excluſive privilege of benevolence to his ſubjects, that he not only rejected, but was offended at, a propoſal once made to him by ſome conſiderable merchants, to contribute towards the relief of a ſuffering province; whilſt he ſcrupled not, at the ſame time, to accept the donation of a rich widow towards the expences of a war in which he was engaged.

This veneration, excited towards the emperor by his apparent benevolence, is increaſed by an opinion zealouſly inſtilled into the people, that he has the faculty of predicting future events of the greateſt importance. The Chineſe, given up to the dotages of judicial aſtrology, are firmly perſuaded that eclipſes of the ſun and moon have a powerful influence on the operations of nature and the tranſactions of mankind; and the periods of their occurrence become, of courſe, objects of attention and ſolicitude. The government of the country, ever anxious to eſtabliſh its authority in the general opinion of its ſuperior wiſdom and conſtant care for the welfare of the people, employs the European miſſionaries at Pekin (for it is doubtful if any one of the natives has ſo much ſcience) to calculate eclipſes, and then announces them to the people with that ſolemnity which is fitted to enſure veneration for the ſuperintending power whence ſuch knowledge is immediately derived to them. Eclipſes of the ſun, in particular, are conſidered as omenous of ſome general calamity; and as great pains are taken to inſpire them with a belief that their proſperity is owing to the wiſdom and virtues of their ſovereign, ſo they are tempted to attribute to ſome deficiency on his part whatever they think portentous. To this prejudice the emperor finds it prudent to accommodate his conduct. He never ventures on any undertaking of importance at the approach of a ſolar eclipſe, but affects to withdraw himſelf from the preſence of his courtiers, to examine ſtrictly into his late adminiſtration of the empire, in order to correct any error, for the commiſſion of which the eclipſe may have been an admonition. On theſe occaſions he invites his ſubjects to give him freely their advice: but it is plain that advice muſt be offered with great deference to a being for whoſe admonition the motions of the ſun and moon are believed to be regulated; and while ſuch notions are implicitly admitted, the perſon of the Chineſe emperor, as well as his authority, muſt be looked upon by his ſubjects as ſomething more than human. This is in fact the caſe. He is not only approached in perſon with teſtimonies of the utmoſt reſpect, but is adored when abſent with all the rites and ceremonies which are uſed by the Chineſe in the worſhip of their divinities. On his birth-day, at the new and full moon, and probably on other feſtivals, all the mandarines reſident in the neighbourhood of any of his numerous palaces aſſemble about noon, and repairing to the palace, ſolemnly proſtrate themſelves nine times before the throne, their foreheads ſtriking the floor each time; whilſt incenſe is burning on tripods on each ſide of it, and offerings are made, on an alter before it, of tea and fruits to the ſpirit of the abſent emperor. Over the throne are ſeen the Chineſe characters of glory and perfection; and the name of the Deity is given to the emperor, who is conſidered by his votaries as poſſeſſing in ſome ſenſe the attribute of ubiquity. Mr Barrow, one of the gentlemen of the embaſſy, was preſent at *Yuen-min-yuen*, one of the imperial palaces, when theſe idolatrous rites of adoration were performed; and he was aſſured that they took place on that day in all parts of the empire, the proſtraters being everywhere attentive to turn their faces towards the capital.

That he who claims adoration in his abſence does not appear on his birth-day to receive the compliments of his ſubjects, will not ſurpriſe the reader. The manner in which that feſtival is celebrated at the palace, where the emperor happens to be reſident, is thus deſcribed by Sir George Staunton, who witneſſed this more than auguſt ceremony at the palace of *Zhe-hal* in Tartary. "The princes, tributaries, ambaſſadors, great officers of ſtate, and principal mandarines, were aſſembled in a vaſt hall; and upon particular notice, were introduced into an inner building, bearing, at leaſt, the ſemblance of a temple. It was chiefly furniſhed with great inſtruments of muſic, among which were ſets of cylindrical bells, ſuſpended in a line from ornamented frames of wood, and gradually diminiſhing in ſize from one extremity to the other, and alſo triangular pieces of metal arranged in the ſame order as the bells. To the ſound of theſe inſtruments a ſlow and ſolemn hymn was ſung by eunuchs, who had ſuch a command of their voices as to reſemble the effect of the muſical glaſſes at a diſtance. The performers were directed, in gliding from one tone to another, by the ſtriking of a ſhrill and ſonorous cymbal; and the judges of muſic among the gentlemen of the embaſſy were much pleaſed with their execution. The whole had indeed a grand effect. During the performance, and at particular ſignals, nine times repeated, all the perſons proſtrated themſelves nine times, except the ambaſſador and his ſuit, who made a profound obeiſance (A). But he whom it was meant to honour, continued, as if it were in imitation of the Deity, inviſible the whole time."

That the awful impreſſion meant to be made upon

(A) The Chineſe court, which conſiders all other ſovereigns as ſubordinate to their own, exacts from foreign miniſters, as well as from natives of the empire, nine proſtrations upon their firſt introduction to the emperor. This demand was made, in the laſt century, of the Dutch, who inſtantly complied with it in hopes of obtaining in return ſome lucrative advantages; and the conſequence was, that their ambaſſador was treated with neglect, and diſmiſſed without promiſe of the ſmalleſt favour. It was likewiſe made of a Ruſſian ambaſſador in the preſent century; but he would not comply with it, until a regular agreement was made for its return, on a like occaſion, to his own ſovereign. Lord Macartney, who was repeatedly urged to go through the ſame abject ceremony, diſplayed ſuch firmneſs and addreſs, that after much evaſion it was at laſt announced to him, that his imperial majeſty would be ſatisfied with the ſame form of reſpectful obedience that the Engliſh are in the habit of paying to their own ſovereign; and upon theſe terms his lordſhip was introduced and graciouſly received.

the minds of men by this apparent worſhip of a fellow-mortal might not be too quickly effaced, all ſcenes of ſport and gaiety were poſtponed to the next day, when a variety of entertainments was exhibited in the preſence of the emperor, ſurrounded by his court and tributary princes.

Notwithſtanding the general veneration of the Chineſe for the perſon and government of their emperor, the mandarines aſſerted that a ſect had for ages ſubſiſted in the country, whoſe chief principles were founded on an antipathy to monarchy, and who nouriſhed hopes of at laſt ſubverting it. Their meetings were held in the utmoſt ſecrecy, and no man avowed any knowledge of them; but a ſort of inquiſition was ſaid to be eſtabliſhed in order to find them out, and they who were ſuſpected of ſuch ſentiments were cut off, or hunted out of ſociety. Should the French declaration of the rights of man, which, through the zeal of its authors, has been tranſlated into one of the languages of India, find its way into China (of which the court is ſaid to be much afraid), it would indeed be a powerful engine in the hands of this ſecret ſect to ſap the foundations of the ancient government. The minds of many of the Chineſe are far from ſatisfied with their condition, which lays both their perſons and their fortunes at the mercy of the mandarines. No private man in China is exempted from corporal puniſhment, which may be inſtantly inflicted on him at the nod of a magiſtrate; and when he has occaſion to ſpeak to a great mandarine, he is obliged, by the police of the country, to throw himſelf on his knees, and in that poſture to communicate his buſineſs. The mandarine himſelf, on the other hand, lies under the hardſhip of being frequently reſponſible for events which he could not controul. Upon the general principle that it is his duty to watch over the morals of the people, he is in many caſes conſidered as a criminal for not preventing crimes which he had not been able to prevent. The mandarines are thus aware of not being guaranteed by good conduct againſt diſgrace; and feeling the chagrin of inſecurity, many of them muſt doubtleſs be ripe for a revolt. Fear may keep them quiet during the reign of a ſovereign poſſeſſed of abilities and vigilance; but the maxims which regulate the imperial ſucceſſion are ſuch, that a firm confederacy could hardly fail at the death of an emperor to introduce great changes into the conſtitution. The throne of China is neither hereditary nor elective. The choice of a ſucceſſor is left entirely to the reigning prince, who may exclude, as has been inſtanced, even his own offspring and family. To prevent commotions and fraud, it is no uncommon practice for the emperor, during his lifetime, to declare his ſucceſſor; for when his ſucceſſion is ſettled by a written teſtament, the throne is not always filled by him for whom it was deſtined. The father of the emperor to whom the Britiſh embaſſy was ſent, is ſaid to have obtained poſſeſſion of the throne by ſuddenly entering the palace in the laſt moments of his predeceſſor, and ſubſtituting his own name in a teſtament intended for the exaltation of another.

To what has been ſaid in the Encyclopædia of the religion of the Chineſe, we have here very little to add. Various deities are worſhipped in the empire by very different rites and ceremonies; but there is in China no ſtate religion. None is paid, preferred, or encouraged by it. The emperor is of one faith; many of the mandarines of another; and the majority of the common people of a third, which is that of Fo. The men of letters venerate rather than adore Confucius; and meet to honour and celebrate his memory in halls of a ſimple but neat conſtruction. The numerous and lower claſſes of the people are leſs able than inclined to contribute much towards the erection of large and coſtly edifices for public worſhip: their attention is almoſt wholly engaged by their houſhold gods; for every houſe has its altar and its deities.

“ No people are, in fact, more ſuperſtitious than the common Chineſe. Beſide the habitual offices of devotion on the part of the prieſts and females, the temples are particularly frequented by the diſciples of Fo previouſly to any undertaken of importance; whether to marry, or go a journey, or conclude a bargain, or change ſituation, or for any other material event in life, it is neceſſary firſt to conſult the ſuperintendant deity. This is performed by various methods. Some place a parcel of conſecrated ſticks, differently marked and numbered, which the conſultant, kneeling before the altar, ſhakes in a hollow bamboo, until one of them falls on the ground; its mark is examined, and referred to a correſpondent mark in a book which the prieſt holds open, and ſometimes even it is written upon a ſheet of paper paſted upon the inſide of the temple. Polygonal pieces of wood are by others thrown into the air. Each ſide has its particular mark; the ſide that is uppermoſt when fallen on the floor is in like manner referred to its correſpondent mark in the book or ſheet of fate. If the firſt throw be favourable, the perſon who made it proſtrates himſelf in gratitude, and undertakes afterwards with confidence the buſineſs in agitation. But if the throw ſhould be adverſe, he tries a ſecond time, and the third throw determines, at any rate, the queſtion. In other reſpects, the people of the preſent day ſeem to pay little attention to their prieſts. The temples are, however, always open for ſuch as chooſe to conſult the decrees of heaven. They return thanks when the oracle proves propitious to their wiſhes. Yet they oftener caſt lots to know the iſſue of a projected enterpriſe than ſupplicate for its being favourable; and their worſhip conſiſts more in thankſgiving than in prayer.

“ The Chineſe are ſeldom ſaid to carry the objects to be obtained by their devotion beyond the benefits of this life. Yet the religion of Fo profeſſes the doctrine of the tranſmigration of ſouls, and promiſes happineſs to the people on conditions, which were no doubt originally intended to conſiſt in the performance of moral duties; but in lieu of which are too frequently ſubſtituted thoſe of contributions towards the erection or repair of temples, the maintenance of prieſts, and a ſtrict attention to particular obſervances. The neglect of theſe is announced as puniſhable by the ſouls of the defaulters paſſing into the bodies of the meaneſt animals, in whom the ſufferings are to be proportioned to the tranſgreſſions committed in the human form.”

Though the Chineſe artiſts are very ingenious as mere workmen, there is hardly any thing which deſerves the name of ſcience in the whole empire. So little is the ſtudy of mathematics cultivated, that there are few ſhopkeepers in China who can perform the ordinary operations of arithmetic; but caſt up their accounts by means of an inſtrument called *ſwanpan* (See

Swanpan, *Encycl.*). Though the compoſition of gunpowder was certainly known in China much earlier than in Europe, and though the Chineſe had employed it from the beginning in blaſting rocks, and in making a vaſt variety of fire-works; yet Sir George Staunton ſeems convinced, that they never thought of the invention of guns till they were taught by the Europeans to introduce them into their armies.

The ſtate of phyſic in this vaſt country is extremely low, being nowhere taught in public ſchools or colleges. "A young man who wiſhes to become a phyſician, has no other way of acquiring medical knowledge than by engaging himſelf to ſome practitioner as an apprentice. He has thus the opportunity of ſeeing his maſter's practice, of viſiting his patients with him, and of learning ſuch parts of his knowledge and ſecrets as the other chooſes to communicate to him. The emoluments of the profeſſion ſeldom exceed the ſkill of the practitioner. As many copper coin as ſcarcely are equal to ſixpence ſterling is ſaid to be the uſual fee among the people; and perhaps quadruple among the mandarines. Medicine is not divided in China into diſtinct branches as in moſt parts of Europe. The ſame perſon acts as phyſician, ſurgeon, and apothecary. The ſurgical part of the profeſſion is ſtill more backward than the others. Amputation, in caſes of compound fracture and gangrene, is utterly unknown; and death is the ſpeedy conſequence of ſuch accidents. The Chineſe method of inoculation, which was introduced into the empire about the beginning of the tenth century of our era, is as follows: When the diſeaſe breaks out in any diſtrict, the phyſicians of the place carefully collect a quantity of ripe matter from puſtules of the proper ſort; which being dried and pulveriſed, is cloſely ſhut up in a porcelain jar, ſo as to exclude from it the atmoſpheric air; and in this manner it will retain its properties for many years. When the patient has been duly prepared by medicines, generally of an aperient kind, and ſtrictly dieted for a ſhort time, a lucky day is choſen to ſprinkle a little of the variolus powder upon a ſmall piece of fine cotton wool, and to inſert it into the noſtrils of the patient.

"No male phyſician is allowed to attend a pregnant woman, and ſtill leſs to practiſe midwifery; in the indelicacy of which both ſexes ſeem to agree in China. There are books written on that art for the uſe of female practitioners, with drawings of the ſtate and poſition of the infant at different periods of geſtation; together with a variety of directions and preſcriptions for every ſuppoſed caſe that may take place: the whole mixed with a number of ſuperſtitious obſervances.

Many practitioners of phyſic take the advantage, as elſewhere, of the obſcurity in which that art is involved, and of the ignorance and credulity of the people, to gain money by the ſale of noſtrums and ſecrets of their own. They diſtribute hand bills, ſetting forth the efficacy of their medicines, with atteſted cures annexed to them. And there is one ſect which boldly arrogates to itſelf the poſſeſſion of a medical ſecret *not to die!* To thoſe who had all the enjoyments of this life, there remained unaccompliſhed no other wiſh than that of remaining for ever in it. And accordingly ſeveral ſovereigns of China have been known to cheriſh the idea of the poſſibility of ſuch a medicine. They had put themſelves, in full health, under the care of thoſe religious empirics, and took large draughts of the boaſted beverage of immortality. The compoſition did not conſiſt of merely harmleſs ingredients; but probably of ſuch extracts and proportions of the poppy, and of other ſubſtances and liquors, as occaſioning a temporary exaltation of the imagination, paſſed for an indication of its vivifying effects. Thus encouraged, they had recourſe to frequent repetitions of the doſe, which brought on quickly languor and debility of ſpirits: and the deluded patients often became victims to deceit and folly in the flower of their age.

"There are in China no profeſſors of the ſciences connected with medicine. The human body is never, unleſs privately, diſſected there. Books, indeed, with drawings of its internal ſtructure are ſometimes publiſhed; but theſe are extremely imperfect, and conſulted, perpaps, oftener to find out the name of the ſpirit under whoſe protection each particular part is placed, than for obſerving its form and ſituation.

"It is a matter of doubt, whether natural hiſtory, natural philoſophy, or chemiſtry, be, as ſciences, much more improved than anatomy in China. There are ſeveral treatiſes, indeed, on particular ſubjects in each. The Chineſe likewiſe poſſeſs a very voluminous Encyclopædia, containing many facts and obſervations relative to them; but from the few reſearches which the gentlemen of the embaſſy had leiſure or opportunity to make during their ſhort viſit to the country, they perceived no traces of any general ſyſtem or doctrine by which ſeparate facts or obſervations were connected and compared, or the common properties of bodies aſcertained by experiment; or where kindred arts were conducted on ſimilar views, or rules framed, or deductions drawn from analogy, or principles laid down to conſtitute a ſcience."

Of all people the Chineſe are perhaps the moſt eager in their curioſity about foreigners coming among them, and the moſt indifferent about the countries of ſuch foreigners. They have been always in the habit of confining their ideas to their own country, emphatically ſtyled *the middle kingdom*. No Chineſe ever thinks of quitting it, except a few of deſperate fortunes reſiding near the ſea-coaſt, or ſea-faring men, who form a claſs, in a great meaſure, apart from ſociety. Even foreign commodities conſumed in China remind them only of Canton, whence they received them, as if produced in it; and theſe commodities they conſider, perhaps properly, as of no real benefit to the empire. Regions out of Aſia are ſcarcely mentioned in their books, or noticed in their diſtorted maps; and the great body of the people would be little gratified with accounts of ſuch regions, which did not contain tales of wonders not performed at home, or of powers exerted beyond the ordinary boundaries of nature.

CHINESE pump. See Pump in this Supplement.

Chinese Weights are ſo very different in many reſpects from thoſe in uſe elſewhere, that it will at leaſt gratify the curioſity of our readers to take ſome notice of them in this Work. Of theſe weights Charles Coquebert has preſented a ſpecimen to the Philomathematical Society in Paris. They are made of copper, and bear a great reſemblance in form to the body of a violin. Like that inſtrument, they are rounded off at the extremities, and indented on the ſides to admit the fingers. The faces are flat and parallel, and have Chineſe characters

racters engraven on the upper ſurface. They advance in a regular decimal progreſſion, of which Coquebert has diſcovered four diſtinct ſeries, the units of which are in the proportion of 1, 10, 100, 1000. Inſtead of employing a combination of one, two, four, and eight units, or after the new ſyſtem of one, two, and five units, the Chineſe have a diſtinct weight for every intermediate number between one and ten. Thus they have weights of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, &c. Of courſe, thoſe weights which ſtand related to each other in the proportion of 6 to 7, 7 to 8, 8 to 9, 9 to 10, differ ſo little in ſize, that it would be impoſſible to diſtinguiſh them without the help of the characters which are engraven upon the face. This is confeſſedly a defect in the ſyſtem. Of the four different ſeries exhibited to the ſociety, the higheſt bears in China the name of *kin*, and is nearly of equal value with a pound avoirdupois. The kin contains ten times the number of units of the next inferior weight, which the Chineſe denominate *leang* or *loam*, and which the Europeans call *tael*, *taille*, or Chineſe *ounce*. This ounce is divided into ten *tſien*, which anſwers nearly to our drachm. The tſien is again ſubdivided into ten *fen*. The Chineſe extend the decimal ſubdiviſion of their weights conſiderably farther. They have diſtinct names, which are all monoſyllabic, for nine ſeries below the fen. Suppoſing the kin to ſtand for unity, they have,

1,	0	0	0	0	0	0	0	0	0	0	0	0
kin,	leang	tſien	fen	li	hav	ſen	tchin	yai	miao	mo	tſun	ſun

The Chineſe weights, compared with the greateſt preciſion, and with the help of the beſt inſtruments, bear the following proportion to our weights: The kin is equal to 1 pound 12 ounces 2 drachms 24 grains; the leang 1 ounce 1 drachm 60 grains; the tſien 70 grains $\frac{8}{10}$; the fen 7 grains $\frac{8}{100}$. Conſequently the laſt of this ſeries, the ſun, amounts to no more than 0 grains 00000000708.

Chinese Wheel is an engine employed in the province of *Kiang-ſee*, and probably through the whole empire, for raiſing water from rivers to irrigate plantations of ſugar canes, on a ſandy ſoil, conſiderably elevated above the level of the river. By Sir George Staunton, who ſays that it is ingenious in its contrivance, cheap in its materials, eaſy in its operation, and effectual to its purpoſe, it is thus deſcribed:

"Two hard wood-poſts or uprights are firmly fixed in the bed of the river, in a line perpendicular to its bank. Theſe poſts ſupport the axis, about ten feet in length, of a large and durable wheel, conſiſting of two unequal rims, the diameter of one of which, cloſeſt to the bank, being about fifteen inches ſhorter than that of the outer rim; but both dipping in the ſtream, while the oppoſite ſegment of the wheel riſes above the elevated bank. This double wheel is connected with the axis, and is ſupported by 16 or 18 ſpokes obliquely inſerted near each extremity of the axis, and croſſing each other at about two-thirds of their length. They are there ſtrengthened by a concentric circle, and faſtened afterwards to the rims: the ſpokes inſerted in the interior extremity of the axis reaching the outer rim, and thoſe proceeding from the exterior extremity of the ſame axis, reaching the inner and ſmaller rim. Between the rims and the croſſing of the ſpokes is woven a kind of cloſe baſket-work, ſerving as laddle-boards or floats, which meeting ſucceſſively the current of the ſtream, obey its impulſe, and turn round the wheel. To both its rims are attached ſmall tubes or ſpouts of wood, with an inclination of about 25 degrees to the horizon, or to the axis of the wheel. The tubes are cloſed at their outer extremity, and open at the oppoſite end. By this poſition the tubes, which happen in the motion of the wheel to be in the ſtream with their mouths or open ends uppermoſt, fill with water. As that ſegment of the wheel riſes, the mouths of the tubes attach to it, alter their relative inclination, but not ſo much as to let their contents flow out till ſuch ſegment of the wheel becomes the top. The mouths of thoſe tubes are then relatively depreſſed, and pour the water into a wide trough placed on poſts, from whence it is conveyed as may be wanted among the canes.

"The only materials employed in the conſtruction of this water-wheel, except the nave or axis, and the poſts on which it reſts, are afforded by the bamboo. The rims, the ſpokes, the laddle-boards or floats, and the tubes or ſpouts, and even the cords, are made of entire lengths, or ſingle joints, or large pieces, or thin ſlices, of the bamboo. Neither nails, nor pins, nor ſcrews, nor any kind of metal, enters into its conſtruction. The parts are bound together firmly by cordage, alſo of ſlit bamboo. Thus, at a very trifling expence, is conſtructed a machine which, without labour or attendance, will furniſh, from a conſiderable depth, a reſervoir with a conſtant ſupply of water adequate to every agricultural purpoſe.

"Theſe wheels are from 20 to 40 feet in diameter, according to the height of the bank and conſequent elevation to which the water is to be raiſed. Such a wheel is capable of ſuſtaining with eaſe 20 tubes or ſpouts, of the length of four feet, and diameter two inches in the clear. The contents of ſuch a tube would be equal to ſix-tenths of a gallon, and a periphery of 20 tubes, twelve gallons. A ſtream of a moderate velocity would be ſufficient to turn the wheel at the rate of four revolutions in one minute, by which would be lifted 48 gallons of water in that ſhort period; in one hour, 2880 gallons; and 69120 gallons, or upwards of 300 tons of water, in a day."

Sir George, who ſaw this wheel in motion, thinks it preferable in many reſpects to any machine yet in uſe for ſimilar purpoſes. He obſerves, that, while it approaches near to the Perſian wheel, of which a deſcription and figure is given in the article Hydrostatics, *Encycl.* it is more ſimple than that wheel in its contrivance, and much leſs expenſive. This is indeed true; but the ſimpleſt engine of the kind, and therefore the beſt that has yet been invented, is perhaps that which is employed to throw water into the moſs of Blair Drummond in Perthſhire. See Moss, *Encycl.*

CHOPINE, Choppine, or *Chopeene*, a high ſhoe, or rather clog, worn 200 years ago by the Italians.

Tom Coryat, in his Crudities 1611. p. 262, calls them *chapineys*, and gives the following account of them: "There is one thing uſed of the Venetian women, and ſome others dwelling in the cities and towns ſubject to the ſigniory of Venice, that is not to be obſerved, I thinke, amongſt any other women in Chriſtendome, which is ſo common in Venice, that no women whatſoever goeth without it, either in her houſe or abroad, *a thing made of wood and covered with leather of ſundry colors, ſome with white, ſome redde, ſome yellow. It is called a* chapiney, *which they wear under their ſhoes.* Many of them are curiouſly painted; ſome alſo of them I have ſeen fairly gilt; ſo uncomely a thing, in my opinion, that it is pitty this fooliſh cuſtom is not cleane baniſhed and exterminated out of the citie. *There are many of theſe chapineys of a great height, even half a yard high*, which maketh many of their women that are very ſhort ſeeme much taller than the talleſt women we have in England. Alſo I have heard it obſerved among them, that by how much the nobler a woman is, by ſo much the higher are her *chapineys*. All their gentlewomen, and moſt of their wives and widowes that are of any wealth, are aſſiſted eyther by men or women when they walke abroad, to the end they may not fall. They are borne up moſt commonly by the left arme, otherwiſe they might quickly take a fall."

CHOWDRY, in Bengal, the poſſeſſor of ſeveral *Talooks*. It is alſo uſed as ſynonymous with *Talookdar*, anciently a collector. See TALOOK in this Supplement.

CHRISOM was not, as is ſaid in the Encyclopædia, a face-cloth or piece of linen laid over the child's head when it was baptized; but it was a white veſture or garment, which, immediately after it was baptiſed, the prieſt put upon it, ſaying, "Take this white veſture as a token of the innocency, which, by God's grace in this holy ſacrament of baptiſm, is given unto thee, and for a ſign whereby thou art admoniſhed, ſo long as thou liveſt, to give thyſelf to innocence of living, that after this tranſitory life thou mayeſt be partaker of life everlaſting. Amen."

As ſoon as the prieſt had pronounced theſe words, he anointed the infant upon the head, ſaying, "Almighty God, the Father of our Lord Jeſus Chriſt, who hath regenerated thee by water and the Holy Ghoſt, and hath given unto thee the remiſſion of all thy ſins; he vouchſafe to anoint thee with the unction of his Holy Spirit, and bring thee to the inheritance of everlaſting life. Amen."

It was from this anointing or *chriſm* that the white garment got the name of *chriſom*, which, after being worn a few days, was offered to the prieſt to be kept in the church or veſtry, in order to be produced as evidence againſt the perſon whoſe chriſom it was, ſhould he afterwards deny the faith in which he had been baptized. Theſe ceremonies were retained, for ſome time after the reformation, in the church of England, which ordered the mother of the child (if the child was then alive) to offer, when ſhe was churched, the *chriſom* and other accuſtomed offerings. If the child died before its mother was churched, the *chriſom* was not given to the prieſt, but employed as a ſhroud, in which the body was buried; and hence it is that chriſoms are now enumerated, moſt abſurdly indeed, in the weekly bills of mortality. We ſay abſurdly; becauſe children who die unbaptized are called *chriſoms*, though the chriſom, when it was uſed, was never put on till baptiſm. See *Whitby on the Book of Common Prayer, &c.*

CHRONOLOGICAL CHARACTERS are characters by which times are diſtinguiſhed. Of theſe ſome are natural or aſtronomical; others, artificial or hiſtorical. The natural characters are ſuch as depend on the motions of the ſtars or luminaries, as *eclipſes, ſolſtices, equinoxes*, the *different aſpects of the planets*, &c. The artificial characters are thoſe that have been invented and eſtabliſhed by men; as the *ſolar cycle*, the *lunar cycle*, &c. Hiſtorical chronological characters are thoſe ſupported by the teſtimony of hiſtorians, when they fix the *dates* of certain *events* to certain *periods*. *Hutton's Mathematical Dictionary.*

CHRONOSCOPE, a word ſometimes uſed to denote a pendulum or machine to meaſure time.

CHUCKIAH, in Bengal, the juriſdiction of a *Fogedar*. See FOGEDÂR in this Supplement.

CHURCH is a word which has many different ſignifications, all ſufficiently explained in the Encyclopædia Britannica, where there is likewiſe given a conciſe *hiſtory* of the Chriſtian church (ſee HISTORY, Sect. ii.), defective, indeed, but perhaps not more ſo than was to be expected from the limits of the work and the extent of the ſubject.

Of the conſtitution of the primitive and apoſtolical church, no man can have a correct notion who has not taken the trouble to conſult the primitive and apoſtolical writers; for, as we have elſewhere obſerved, all modern compilers of eccleſiaſtical hiſtory are more or leſs prejudiced in behalf of the particular church to which they belong, and wreſt the language of the original writers ſo as to make them bear witneſs to the antiquity of *modes of faith* and *eccleſiaſtical polity*, which are not perhaps a hundred years old.

On this account we ſhall not here attempt to correct what we really think the miſtakes of him who compiled the ſection of eccleſiaſtical hiſtory in the Encyclopædia. Moſheim and Sir Peter King, whom he ſeems to have implicitly followed, were indeed great men; and it would be folly to deny that the *Hiſtory* of the former, and the *Inquiry* of the latter *into the Conſtitution of the Primitive Church*, are works of learning and ingenuity; but it is not perhaps too much to ſay, that both authors wrote under the influence of prejudice. Our readers will diſcover how cloſely either the one or the other has adhered to truth, by ſtudying the eccleſiaſtical writers of the firſt four centuries. Such a ſtudy will make them acquainted with the doctrines, diſcipline, and worſhip of the church before it was incorporated with the ſtate; and we know not that kind of knowledge which is of more importance to the divine, however much it may be deſpiſed in this age of affected ſcience and real ignorance.

Of the principal churches at preſent exiſting, a pretty full account is given in the Encyclopædia, either under their different denominations, or under the titles of thoſe tenets by which they are chiefly diſtinguiſhed; ſo that from that Work alone a reader may form a tolerably accurate notion of the faith, worſhip, conſtitution, and diſcipline of the church of Rome, the churches of England and Scotland, the Lutheran and Calviniſtical churches on the continent of Europe, as well as of the various ſects which have ariſen in theſe kingdoms during the courſe of the laſt and preſent centuries. There is, however, one church which boaſts of a very high antiquity, and is certainly ſpread over a larger extent of country than all the other churches that we have mentioned, of which the account given in the Encyclopædia is exceedingly defective. Our readers will perceive that the church to which we allude is

1
The Greek church.

The Greek CHURCH, which comprehends in its boſom (A) a conſiderable part of Greece, the Grecian iſles, Wallachia, Moldavia, Egypt, Abyſſinia, Nubia, Lybia, Arabia, Meſopotamia, Syria, Cilicia, and Paleſtine. which are all under the juriſdiction of the patriarchs of Conſtantinople, Alexandria, Antioch, and Jeruſalem. If to theſe we add the whole of the Ruſſian empire in Europe, great part of Siberia in Aſia, Aſtracan, Caſan, and Georgia—it will be evident that the Greek church has a wider extent of territory than the Latin, with all the branches which have ſprung from it; and that it is with great impropriety that the church of Rome is called by her members the *catholic* or univerſal church. That in theſe widely diſtant countries the profeſſors of Chriſtianity are agreed in every minute article of belief, it would be raſh to aſſert; but there is certainly ſuch an agreement among them with reſpect both to faith and to diſcipline, that they mutually hold communion with each other, and are in fact but one church.

2
The faith of that church.

As the Greek church has no public or eſtabliſhed articles, like thoſe of the churches of England and Scotland, we can collect what is its doctrine only from its creeds, from the councils whoſe decrees it receives (B), from the different offices in its liturgies, and from the catechiſms which it authoriſes to be taught. "The doctrine of the Trinity, and the articles of the Nicene and Athanaſian creeds, are received by the Greeks in common with other Chriſtians. In one particular, indeed, they differ from the other churches of Europe, whether Romiſh or reformed. They believe that the Holy Spirit proceeds from the father only, and not from the Father and the Son; and in defence of this opinion they appeal to eccleſiaſtical hiſtory, the acts of councils, the writings of the fathers, ancient manuſcripts, and eſpecially to a copy of the creed of Conſtantinople, engraven on two tables of ſilver, and hung up in the church of St Peter at Rome by order of Leo III. Of the Nicene or Conſtantinopolitan creed, therefore, as it is received by them, the eighth article runs in theſe words, 'I believe in the Holy Ghoſt, the Lord and Giver of life, who proceedeth from the FATHER, and with the Father and the Son together is worſhipped and glorified:' And the correſponding article of the Athanaſian creed is of courſe, "The Holy Ghoſt is of the FATHER, neither made, nor created, nor begotten, but proceeding †."

3
It admits of pictures, but not of graven images.

Though the biſhops and clergy of the Greek church abhor the uſe of images, which they pretend to be one cauſe of their ſeparation from the ſee of Rome, they admit into their churches the pictures of ſaints to inſtruct, they ſay, the ignorant, and to animate the devotion of others. This practice they conſider as by no means contrary to the ſecond commandment of the decalogue, which, according to them, prohibits only the worſhipping of ſuch idols as the Gentiles believed to be gods; whereas their pictures, being uſed merely as remembrancers of Chriſt and the ſaints, have written on each of them the name of the perſon whom it is meant to repreſent. Dr King aſſures us that the more learned of the Ruſſian clergy would willingly allow no repreſentation whatever of God the Father; and that, during the reign of Peter the Great, the ſynod not only cenſured the uſe of ſuch pictures in churches, but petitioned the emperor that they might be everywhere taken down. Peter, however, though he fully concurred in opinion with the ſynod, thought this a meaſure for which the minds of his ſubjects were not ripe, and dreaded, that if carried into execution it would occaſion a general inſurrection. Such pictures, therefore, though not more impious than abſurd, are ſtill in uſe; and in many churches, as well ancient as modern, the figure of Daniel's *Ancient of Days*, together with that of *Chriſt* and a *dove*, are painted in one group to ſignify the Holy Trinity. Nay, when our author was in St Peterſburg, not thirty years ago, there was in the church of St Nicholas the picture of an old man holding a globe, and ſurrounded with angels, on which GOD THE FATHER was inſcribed; and we have not heard that the picture has been ſince taken down.

4
Invocation of ſaints.

In the Greek as well as in the Roman church, the invocation of ſaints is practiſed, but they are not invoked in either as deities, but merely as interceſſors with the Supreme God, "it being more modeſt (ſay the Greeks), as well as more available, to apply to them to intercede with God, than to addreſs ourſelves immediately to the Almighty." Plauſible as this reaſoning may at firſt ſight appear, it aſcribes to the ſaints the divine attribute of ubiquity, and is likewiſe in direct contradiction to the doctrine of St Paul, who hath taught us, that as "there is one God, ſo there is but one mediator between God and man, the man Chriſt Jeſus."

5
Prayers for the dead.

The Greek church, at the celebration of the Lord's Supper, commemorates the faithful departed, and even prays for the remiſſion of their ſins; but ſhe allows not of purgatory, nor pretends to determine dogmatically concerning the ſtate or condition of departed ſouls. She muſt, however, believe that no final judgment is paſſed upon the great body of mankind (C) till the conſummation of all things, otherwiſe ſuch prayers could not be offered without abſurdity; and in this part of her doctrine ſhe is certainly countenanced by all the writers of the primitive church, if not by ſome paſſages of the ſacred ſcriptures *. The practice of praying for the dead is loudly condemned in every Proteſtant country, and yet there is no Chriſtian who does not in effect pray

† Dallaway's *Conſtantinople, Ancient and Modern*, and King's *Rites and Ceremonies*, &c.

* *Math.* xxv. 19, 20, —31—34. 2 *Tim.* i. 18, iv. 8.

(A) King's *Rites and Ceremonies of the Greek Church*—Bruce's *Travels to the Source of the Nile*—and Lobo's *Voyage to Abyſſinia.*

(B) In the Greek church ſeven general councils are received, and nine provincial ones. The ſeven general councils are, 1. The council of Nice, held in the year 325, under Conſtantine. 2. The firſt council of Conſtantinople, held A. D. 381, under Theodoſius the Great. 3. The council of Epheſus, A. D. 431, in the reign of Theodoſius Minor. 4. The council of Calcedon, A. D. 451, in the reign of Marcian. 5. The ſecond council of Conſtantinople, A. D. 553, in the reign of Juſtinian. 6. The third council of Conſtantinople in Trull, A. D. 680, in the reign of Conſtantine Pagonatus. 7. The ſecond council of Nice, A. D. 787.

(C) We ſay the great body of mankind, becauſe ſhe doubtleſs believes that Enoch, Elias, and thoſe ſaints who roſe with our Saviour, have been already judged, and now enjoy their reward in heaven.

pray for his departed friends. This may appear a paradox, but it is an obvious and a certain truth; for where is the man who believes in a general judgment, and does not *wiſh* that his deceaſed wife, or parent, or child, or friend, "may find mercy of the Lord in that day?" Such a wiſh is the eſſence of a prayer; which conſiſts not of the ſounds in which our ſentiments are cloathed, but in the aſpirations of a devout heart.

6
Grants no indulgencies.

Supererogation, with its conſequent indulgencies and diſpenſations, which were once ſo profitable, and afterwards ſo fatal to the intereſts of the court of Rome, are utterly diſallowed in the Greek church, which likewiſe lays no claim to the character of infallibility. She is indeed, like ſome other churches, very inconſiſtent on this laſt topic; for whilſt ſhe pretends not to an abſolute exemption from error, her clergy ſeem to conſider their own particular mode of worſhip as that which alone is acceptable to God.

7
Predeſtination.

Predeſtination is a dogma of the Greek church, and a very prevailing opinion amongſt the people of Ruſſia; "and I muſt do the juſtice (ſays Dr King) to thoſe who have written upon it, eſpecially the lateſt authors of that country, to ſay that they have treated it, as depending on the attribute of preſcience in the divine nature, with a much better kind of logic than that with which ſuch points are generally diſcuſſed." As our author has not given us the reaſoning of the Ruſſian doctors on this difficult ſubject, we cannot hazard any opinion of our own on the ſoundneſs of their logic; but from the ſtate of ſcience in that vaſt empire, as it was repreſented to us by an abler judge than he, we doubt of its being entitled to the praiſe which he beſtows on it. (See RUSSIA, n° 104. *Encycl.*)

8
Seven ſacraments.

In the Greek church there are ſeven *ſacraments*; or, as they are there termed, *myſteries*, viz. *baptiſm*: the *chriſm*, or baptiſmal unction; the *euchariſt*; *confeſſion*; *ordination*; *marriage*; and the myſtery of *the holy oil*, or *euchelaion*. By the Greeks a myſtery is defined to be "a ceremony or act appointed by God, in which God giveth or ſignifieth his grace; and of the ſeventh which they celebrate, four are to be received by all Chriſtians, viz. *baptiſm*, the *baptiſmal unction*, the *euchariſt*, and *confeſſion*. Of theſe, *baptiſm* and the *euchariſt* are deemed the chief; and of the other three, none, not even the *euchelaion*, is conſidered as obligatory upon all.

With reſpect to baptiſm, we know not that they hold any peculiar opinions. They conſider it indeed as ſo abſolutely neceſſary to ſalvation, that in caſes of extremity, when a prieſt or deacon cannot be had, it may be adminiſtered by a midwife or any other perſon, and is not to be repeated on any occaſion whatever. In this opinion, as well as in the practice founded on it, they are in perfect harmony with the church of Rome, which, as every perſon knows, has for many ages allowed the validity of lay-baptiſm in caſes of neceſſity. The Portugueſe Jeſuits, who in the laſt century viſited Abyſſinia in the capacity of miſſionaries, have maintained that, once every year, all grown people are in that country baptiſed: but Mr Bruce has ſhewn, by the moſt incontrovertible evidence, that this was a mere fiction, invented to throw odium upon what the church of Rome calls the eaſtern chiſm, and abhors perhaps more than paganiſm itſelf.

9
Daily ſervice of the church,

The daily ſervice of the Greek church is ſo long and ſo complicated, that it is impoſſible for us to give an adequate account of it without ſwelling this article far beyond its due proportion. Of this the reader will be convinced, when he is informed that the ſeveral books containing the church ſervice for all the days in the year, amount to more than twenty volumes in folio, beſides one large volume called *the regulation*, which contains the directions how the reſt are to be uſed.

10
Intricate and tedious.

The four goſpels make one volume by themſelves; and whenever the goſpel is read in any ſervice, the deacon exclaims; "Wiſdom, ſtand up. Let us hear the holy goſpel." The prieſt then ſaith, "The leſſon from the goſpel according to St Matthew, St Mark, &c." The deacon ſays again, "Let us ſtand." The choir, at the beginning and end of the goſpel, always ſays, "Glory be to thee, O Lord, glory be to thee." From the old teſtament and the epiſtles extracts only are uſed in the ſervice; and when they are to be read, the deacon calls out, "Attend."

The ſervice of this church as it now ſtands, and was at firſt drawn up in writing, is calculated for the uſe of monaſteries; and when it was afterwards applied to parochial churches, many of the offices or forms, which were compoſed for different hours of the day and night, were uſed as one ſervice, without the ſlighteſt alteration being made to avoid repetitions. Something of this kind has taken place in the church of England, where the matins, the litany, and the communion, which were formerly three diſtinct ſervices, read at different times of the day, are now run into one ſervice; which by thoſe not accuſtomed to it is therefore deemed long, as well as deformed by needleſs repetitions.

11
Begins in the evening.

The ſervice of every day, whether it has a vigil or not, begins in the evening of what we would call the preceding day, as among the Jews; and for the ſame reaſon, becauſe it is ſaid in the Moſaic account of the creation, that "the evening and the morning were the firſt day." The ſeveral ſervices, according to the original or monkiſh inſtitution, are, 1. *The veſpers*, which uſed to be celebrated a little before ſun-ſet; 2. *The after-veſpers*, anſwering to the *completorium* of the Latin church, which uſed to be celebrated after the monks had ſupped, and before they went to bed; 3. *The meſonyecticon*, or midnight ſervice; 4. *The matins* at break of day, anſwering to the *laudes* of the Romiſh church; 5. The *firſt hour* of prayer, or *prima*, at ſun-riſe; 6. The *third hour*, or *tertia*, at the third hour of the day; 7. The *ſixth hour*, or *ſexta*, at noon; 8. The *ninth hour*, or *nona*, in the afternoon at the ninth hour of the day. Theſe are called the canonical hours; but it is to be obſerved, that the *after-veſpers* were not added till a late period, before which the reaſon aſſigned for the number of ſervices being ſeven, was, that David ſaith, "Seven times a-day will I praiſe thee." When all the pſalms and hymns were ſung, theſe daily ſervices could not poſſibly have been performed in leſs than twelve or fourteen hours. In the church of Ruſſia, and probably in other branches of the Greek church, there are at preſent but three ſervices in the day: the *ninth hour*, the *veſpers*, and the *after-veſpers* making one; the *meſonyecticon*, the *matins*, and *prima*, another; and the *third* and *ſixth hour*, with the *communion*, the laſt. In all the ſervices, except the communion, prayers and praiſes are offered to ſome ſaint; and to the Virgin Mary, almoſt as often as to God; and in ſome of the ſervices, after every ſhort prayer uttered by the deacon or the prieſt, the choir chaunts "Lord have mercy upon us," thirty, forty, or fifty times, ſucceſſively.

Though the number of ſervices is the ſame every day, the ſervices themſelves are conſtantly varying in ſome particular or other, as there is not a day which, in the Greek church, is not either a faſt or a feſtival. Beſides the ſaints, whoſe feſtivals are marked in the calendar, and who are ſo very numerous that there are more than one for every day in the year, there are other ſaints and feſtivals, to which ſome portion of the ſervice for every day of the week is appropriated. Thus, Sunday is dedicated to the reſurrection: Monday, to the angels; Tueſday, to St John Baptiſt; Wedneſday, to the Virgin and the croſs; Thurſday, to the apoſtles; Friday, to the paſſion of Chriſt; and Saturday, to the ſaints and martyrs. For theſe days there are particular hymns and ſervices, in two volumes folio, to which there is a ſupplement containing ſervices for the ſaints and feſtivals, as they occur in the calendar throughout the year. Theſe different ſervices are mixed together, and adjuſted by the directions contained in the book of *regulation*; and it is the difficulty of this adjuſtment which makes the public worſhip of the Greek church ſo very intricate, that, as was ſaid of the ſervice of the Engliſh church before the Reformation, "there is more buſineſs to find out what ſhould be read, than to read it when found out."

12
Mode of adminiſtering baptiſm.

We have obſerved, that the Greeks have no peculiar opinions reſpecting the nature of baptiſm; but the rites and ceremonies with which that ordinance is adminiſtered will appear to our unlearned readers very extraordinary. On the day that a woman is delivered, the prieſt goes to the houſe, and uſes a form of prayer for her and for the child. On the eighth day the child ſhould be regularly carried to the church, where the prieſt having ſigned it with the ſign of the croſs on the forehead, on the mouth, and on the breaſt, offers up for it a prayer, in which he firſt gives it a name, commonly the name of the ſaint for that day in the calendar; he then takes it from the midwife, and ſtanding before the picture of the bleſſed Virgin, he makes the ſign of the croſs with the infant, uttering a kind of hymn in honour of the Virgin and of Simeon, who held in his boſom the Saviour of our ſouls. He then diſmiſſes the company with an exhortation not to delay the baptiſing of the infant, ſhould it appear in danger of death before the regular time for its baptiſm.

On the fortieth day after her delivery, the mother ſhould attend the church to be purified, and carry the child again to be preſented, the perſon who is to be ſponſor being preſent. Upon their arrival at the church door, the prieſt utters ſome pious exclamations; and then, the mother holding the child in her arms and bowing down her head, he makes the ſign of the croſs upon her and the child, and laying his hand upon its head, he prays that the woman may be cleanſed from every ſin and from every defilement, and that the child may be ſanctified and endued with underſtanding, with wiſdom, and with gentleneſs of manners. He then ſigns it again, and again prays for it, for its parents, and for its ſponſor; after which, if it has been privately baptiſed, he takes it in his arms, and makes with it the ſign of the croſs before the door of the church, ſaying, "N. N. the ſervant of God, enters into the church, in the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen." He then carries the child into the church, ſaying, "he ſhall go into thine houſe, and ſhall worſhip toward thy holy temple;" and advancing into the middle of the church, he ſays, "In the midſt of thy church ſhall he praiſe thee." Then, if the child be a boy, he carries him within the rails of the altar; but if a girl, only to the door, and ſays "*Nunc dimittis* (D);" after which he delivers it to the ſponſor, who makes three reverences, and retires.

This is called the preſentation of the child in the temple, and can only be performed after it has been baptized. In the detail we have given, we have ſuppoſed that it was baptized privately before the purification of the mother, which is now indeed commonly the caſe. Such baptiſm, however, is not regular, being allowed only in caſes of neceſſity; and when it has not taken place, the mother and child are diſmiſſed as ſoon as ſhe is purified, and return at ſome other time, not fixed, in order that the child may be publicly baptized.

Previous to baptiſm, the child, though not two months old, muſt be ſolemnly initiated into the church as a catechumen (See CATECHUMEN, *Encycl.*) By thoſe whoſe religion is a reaſonable ſervice, ſuch initiation of an infant will be conſidered as a very idle ceremony; and the rites with which it is performed are not well calculated to give it even a fictitious importance. At the door of the church the prieſt unties the girdle of the infant; takes off all his clothes but one looſe garment; turns him towards the eaſt, with his head uncovered, his feet naked, and his hands held down; blows thrice in his face; ſigns him thrice with the ſign of the croſs on the forehead and on the breaſt, and lays his hand upon his head, praying that his "*ancient* error may be put away from him; that his heart may be filled with faith, hope, and charity; and that he may walk in the ways of God's commandments." The prieſt then four times exorciſes the infant, commanding Satan, in the firſt exorciſm, to "tremble, depart, and flee from Chriſt's creature, nor dare to return again, nor dare to lurk concealed within him, or to meet him, or to meditate againſt him, either in the evening or the morning, at midnight or at noon-day." In the laſt exorciſm he blows thrice upon the child's mouth, upon his forehead, and upon his breaſt; ſaying, each time, "Drive away from him every evil and unclean ſpirit that lurks in him, and hath made itſelf a neſt in his heart." The child is now become a catechumen, and, being turned to the weſt, uncovered, without ſhoes, and his hands lifted up, the prieſt repeatedly aſks him if he *renounces* and *has* renounced the Devil and all his works? and receiving from the ſponſor the proper anſwer, he ſays, "Blow and ſpit upon him;" and having blown and ſpit upon the catechumen, he turns him to the eaſt, and holding down his hands, aſks him repeatedly if he be joined to Chriſt, and if he believes in him? The catechumen or his ſponſor replies to each queſtion, that he is, and has been, joined to Chriſt; and as a proof of his

---

(D) We quote the words of Dr King. Is it poſſible that in the Greek church Latin hymns are uſed, or that Greek hymns have Latin deſignations?

his faith he repeats, from beginning to end, the Nicene creed. After a repetition of the formerly repeated queſtions and anſwers, the prieſt prays that the catechumen may be called to God's holy ſanctification, and receive the grace of God's holy baptiſm.

Baptiſm may be celebrated immediately after the candidate has been made a catechumen, or on any ſubſequent day at no great diſtance. In the firſt part of the form there is not much that is ſingular, or with which every ſcholar is not acquainted. After praying that the water may be ſanctified, in terms differing little from thoſe which are uſed in the moſt reſpectable Proteſtant churches, the prieſt dips his fingers in it, ſigns it thrice with the ſign of the croſs; and then blowing upon it, ſays three times, “Let every adverſe power be confounded under the ſign of the croſs.” He then ſolemnly exorciſes it of the dæmon of darkneſs and all evil ſpirits; and prays, that “the perſon to be baptiſed therein may put off the old man, which is corrupt after the luſt of fraud, and may put on the new man after the image of Him that made him. After this, he blows thrice into a veſſel of oil of olives held by the deacon, ſigns it thrice with the ſign of the croſs; and prays fervently, that it may “become to thoſe who are anointed with faith, and are partakers thereof, the unction of incorruption, the armour of righteouſneſs, the renewing of ſoul and body, for turning aſide all machinations of the devil, and for deliverance from all evil.” He then ſings allelujah thrice with the people, and pours the oil on the top of the water; and making three croſſes with it, ſays aloud, “Bleſſed be God, who enlighteneth and ſanctifieth every man that cometh into the world, now and forever, even unto ages of ages.” The perſon to be baptized is then preſented; and the prieſt, taking ſome of the oil with two fingers, and making the ſign of the croſs on his forehead, on his breaſt, and betwixt his ſhoulders, ſays, “N the ſervant of God is anointed with the oil of gladneſs, in the name of the Father, and of the Son, and of the Holy Ghoſt, now and forever, even unto ages of ages. Amen.” He then ſigns him on the breaſt and the middle of the back, ſaying, “For the healing of his ſoul and body;” then on the ears, ſaying, “For hearing the faith;” then on the palms of the hands, ſaying, “Thy hands have made me and faſhioned me;” then on the feet, “That he may walk in the way of thy commandments.” After the whole body is thus anointed, the prieſt baptizes him, uſing the trine immerſion; which is unqueſtionably the moſt primitive manner. He takes the child in his arms, and holding him upright with his face towards the eaſt, he ſays, “N the ſervant of God is baptized (*dipping him the firſt time*), in the name of the Father, Amen; in the name of the Son (*dipping him again*), Amen; and of the Holy Ghoſt (*dipping him the third time*), Amen, now and for ever, even unto ages of ages. Amen.” After the baptiſm, the prieſt wipes his hands, and with the people ſings thrice, from beginning to end, the 32d Pſalm; he then puts upon the baptized perſon a white garment; ſaying, “N the ſervant of God is clothed with the garment of righteouſneſs, in the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages (E).” He then prays that he may be delivered from the evil one, and all his inſidious ſnares; that he may be confirmed in the true faith; and that he may preſerve his ſoul in purity and righteouſneſs: and proceeds immediately to anoint him with the *Holy Chriſm*.

13 The baptiſmal chriſm.

This chriſm is a very different thing from the oil with which he was anointed previous to baptiſm, and which was uſed in the conſecration of the baptiſmal water. It can be prepared only by a biſhop, and only on one day in the year, *viz.* Thurſday in Paſſion-week; and as the anointing with it is ſubſtituted in place of the apoſtolical rite of laying on hands, called *confirmation* in the weſtern churches, great quantities of it are of courſe prepared at once, and diſtributed through the different churches of each dioceſe. The chriſm conſiſts of the following ingredients, which in different proportions are all boiled together, and afterwards ſolemnly conſecrated by the biſhop: Fine oil (we ſuppoſe of olives), white wine, ſtyrax calamita (F), palm-dew, roſe-flowers, black palm-gum, Baſil-gum, marjoram, thick and thin oil of nutmegs in very different quantities, oil of cinnamon, oil of cloves, lignum Rhodii, oil of oranges, oil of marjoram, oil of lavendar, oil of roſemary, eſſence of roſemary, cedar, black balſam of Peru, ſandarac, whiteſt maſtic, and Venice turpentine. With this holy mixture the baptized perſon is anointed, the prieſt making with it the ſign of the croſs on his forehead, on his eyes, his noſtrils, his mouth, both ears, his breaſt, his hands, and his feet; ſaying at each part, “The ſeal of the gift of the Holy Ghoſt. Amen.” Then with the ſponſor and the child he goes thrice round the font, turning from the right to the left; the choir, in the mean time, ſinging, “As many of you as are baptized unto Chriſt have put on Chriſt, allelujah.”

Seven days after this ceremony is performed, the child is again brought to the church; when the prieſt, after praying for him, unties his girdle and linen clothes, waſhes him with clean water, and, ſprinkling him, ſays, “Thou haſt been juſtified, enlightened, ſanctified in the name of our Lord Jeſus Chriſt, and with the Spirit of our God.” Then taking a new ſponge moiſtened with water, he waſhes his face, breaſt, &c.; ſaying, “Thou haſt been baptized, enlightened, anointed, ſanctified, waſhed, in the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen.”

14 The tonſure.

The laſt ceremony appended to baptiſm is that of the tonſure, or ſhaving the head of the child in the form of the croſs. At what time this rite crept into the church it would not be eaſy to diſcover. Some think it received its origin from the religious ceremonies of the Heathen, who certainly rounded the corners

---

(E) The reader will perceive, that many of theſe rites and ceremonies are common to the Greek church and the church of Rome in the celebration of the ſacrament of baptiſm.

(F) We quote the words of Dr King, taking it for granted that our readers will pardon our not giving ourſelves much trouble to diſcover, on the preſent occaſion, what particular ſpecies or variety of the ſtorax he means by this deſignation. See Styrax, *Encycl.*

of their heads, and marred their beards, at a very early period, in honour of their idols (See Theology, n° 155. *Encycl*,) ; and ſome pious, but fooliſh Chriſtians, eſteemed it highly commendable to transfer to the true God that worſhip, in a different form, which had been rendered by their anceſtors to falſe deities. Others will have the tonſure to typify the dedication of the perſon to the ſervice of God ; the cutting off of the hair being always conſidered as a mark of ſervitude. Be theſe conjectures as they may, the prieſt, after the child is baptized, offers up for him ſeveral prayers, all alluding to the rite to be performed; and then cuts his hair croſswiſe, ſaying, " N the ſervant of God is ſhorn, in the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen."

15 The Greeks have three communion-offices.

We have given a full account of the manner in which the ſacrament of baptiſm is celebrated among the Greeks, that the reader may have ſome notion of the childiſh ſuperſtition of that church, with which certain zealous Proteſtants in England were very deſirous, at the beginning of this century, to form a union. There is no occaſion for dwelling ſo long upon their other offices. For the celebration of the Lord's Supper they have three liturgies that are occaſionally uſed, *viz.* that of St Chryſoſtom, which is in ordinary daily uſe ; that of St Baſil, uſed on particular days ; and that of the *preſanctified*, as it is called, which is uſed on the Wedneſdays and Fridays during the great faſt before Eaſter. Between the liturgies of St Chryſoſtom and St Baſil there is no eſſential difference; and the office of the preſanctified is merely a form of diſpenſing the communion with elements which had been conſecrated on the preceding Sunday. We would gladly inſert the liturgy of St Chryſoſtom, or at leaſt ſuch an abſtract of it as we have given of the form of adminiſtering baptiſm ; but as our limits will not permit us to do ſo, we muſt refer ſuch of our readers as have any curioſity reſpecting ſubjects of this nature to *Dr King's Rites and Ceremonies of the Greek Church*.

16 Strange ceremony at the offertory.

17 The conſecration of the elements.

It is proper, however, to obſerve here, that many ſuperſtitious ceremonies have been added to the ſervice ſince the age of St Chryſoſtom, and that no man can compare his genuine works with the liturgy which now goes under his name, and entertain the ſmalleſt doubt but that the latter has been greatly, though gradually, corrupted. In the offertory there is a ſtrange ceremony, called *the ſlaying of the Holy Lamb*, when the prieſt, taking into his left hand one of the five loaves which are to be conſecrated, thruſts a ſpear into the right ſide of it ; ſaying, " He was led as a lamb to the ſlaughter ;" then into the left ſide, adding, " And as a blameleſs lamb before his ſhearers is dumb, ſo he openeth not his mouth :" then into the upper part of the loaf ; ſaying, " In his humiliation his judgment was taken away :" and into the lower part ; adding, " And who ſhall declare his generation ?" He then thruſts the ſpear obliquely into the loaf, lifting it up, and ſaying, " For his life was taken away from the earth." After this he lays down the loaf, and cutting it croſswiſe, ſays, " The Lamb of God, which taketh away the ſins of the world, is ſlain for the life and ſalvation of the world." All this, and more to the ſame purpoſe, is unqueſtionably modern; but we have no doubt but that the prieſt uſes the words of Chryſoſtom himſelf, when, in the conſecration of the elements, he ſays, " We offer unto thee this reaſonable, this unbloody ſacrifice ; and we implore, we pray thee, we humbly beſeech thee, to ſend down the Holy Spirit upon us, and thoſe oblations preſented unto thee ; and make this bread the precious body of thy Chriſt ; and that which is in this cup the precious blood of thy Chriſt, changing them by thy Holy Spirit."

18 Tranſubſtantiation.

Dr King obſerves, that this invocation of the Holy Spirit upon the elements, which in the eaſtern church is always uſed after the words of Chriſt, " This is my body, this is my blood, &c." is inconſiſtent with the Popiſh doctrine of tranſubſtantiation : and he is undoubtedly right ; for the church of Rome teaches, that the change is made about the middle of the maſs, when the prieſt, taking into his hand firſt the bread and then the wine, pronounces over each ſeparately the ſacred words of conſecration; *i. e.* the words of Chriſt. " It is the office of the prieſt, in this and in all other ſacraments (ſays a dignitary of that church), only to perform the outward ſenſible part ; but the inward inviſible effect is the work of the great God, who accordingly changes the ſubſtance of the bread and wine into the body and blood of Chriſt the very inſtant that the ſacred words of conſecration are pronounced by the prieſt over them." But if this be ſo, it would be impious, and we believe that by the church of Rome it is deemed impious, to pray afterwards, that God would ſend down his Holy Spirit to change into the body and blood of Chriſt elements which he had already changed into that body and blood, in conſequence of the prieſt's pronouncing over them the all-powerful words of Chriſt. Yet is it certain, that in the preſent Greek church tranſubſtantiation is as much an article of faith as in the church of Rome ; for now every biſhop at his conſecration declares, in the moſt ſolemn manner, that he believes and " underſtands that the tranſubſtantiation of the body and blood of Chriſt, in the holy ſupper, is effected by the influence and operation of the Holy Ghoſt, when the biſhop or prieſt invokes God the Father in theſe words, *and make this bread the precious body of thy Chriſt*, &c." This is indeed a different account from that of the Latin church of the time at which this portentous change is wrought; but ſuch difference is a matter of very little importance (G). If the change itſelf be admitted, the conſequence muſt be the ſame, whether it be ſuppoſed to take place when the

---

(G) Mr Bruce ſeems to doubt whether tranſubſtantiation be the doctrine of the Abyſſinian church, and relates a converſation which he had on the ſubject with a prieſt ; who ſolemnly affirmed, that he never believed in the converſion of the ſubſtance of the bread and wine into the ſubſtance of our Saviour's body and blood. It muſt be remembered, however, that the prieſt had at the time a powerful reaſon for wiſhing that doctrine not to be true. The Jeſuits uniformly atteſt, that the Abyſſinians believe in the real preſence ; though it muſt not be forgotten that Ludolf was of a different opinion, and that no man had ſtudied the language of Abyſſinia more ſucceſsfully than he.

the prieſt pronounces the words of inſtitution, or after he has invoked the deſcent of the Holy Ghoſt; in either caſe it leads to idolatry. It may be proper to mention, that in the Greek church it is deemed eſſential to the validity of this holy ſacrament, that a little warm water be mixed with the wine; that the napkin, which is ſpread over the holy table, and anſwers to the *corporale* of the church of Rome, be conſecrated by a biſhop, and that it have ſome ſmall particles of the reliques of a martyr mixed in the web, otherwiſe the euchariſt cannot be adminiſtered. In this church children may receive the communion immediately after baptiſm; and the lay communicants, of whatever age, receive both the elements together, the bread being ſopped in the cup: The clergy receive them ſeparately.

19 The laity communicate in both kinds.

20 Confeſſion in the Greek church.

We have obſerved, that one of the ſeven *myſteries* or ſacraments of the Greek church is *confeſſion;* but among the Greeks it is a much more rational and edifying ſervice than in the church of Rome. In the Greek church the end of confeſſion is the amendment of the penitent; in the church of Rome it is to magnify the glory of the prieſt. In the former church, the confeſſors pretend only to abate or remit the penance, declaring the pardon from God alone; in the latter, they take upon them to forgive the ſin itſelf. The Greek church preſcribes confeſſion four times in the year to all her members; but the laity, for the moſt part, confeſs only once a year previous to receiving the holy communion; and to this they are in Ruſſia obliged by the laws of the empire.

21 Matrimony.

The ceremonies with which matrimony is performed in the Greek church conſiſt of three diſtinct offices, formerly celebrated at different times, after certain intervals, which now make but one ſervice. Firſt, there was a ſolemn ſervice, when the parties betrothed themſelves to each other, by giving and receiving rings or other preſents, as pledges of their mutual fidelity and attachment. The ancient uſage was for the man to receive a gold ring and the woman a ſilver one, which is ſtill alluded to in the rubric, though, in the preſent practice, the rings are generally both of gold. At this time the dowry was paid, and certain obligations were entered into to forfeit ſums in proportion to it, if either of the parties ſhould refuſe to ratify the engagement. At this ceremony, called the μνηστρον, or *recording of the pledges before witneſſes,* the prieſt gives lighted tapers to the parties to be contracted, making the ſign of the croſs on the forehead of each with the end of the taper before he deliver it.

The ſecond ceremony, which is properly the marriage, is called the office of *matrimonial coronation,* from a ſingular circumſtance in it, that of *crowning* the parties. This is done in token of the triumph of continence; and therefore it has, in ſome places, been omitted at ſecond marriages. Formerly theſe crowns were garlands made of flowers or ſhrubs; but now there are kept, in moſt churches, crowns of ſilver or ſome other metal for the celebration of matrimony. At the putting of them on, the prieſt ſays, "N, the ſervant of God, is crowned for the handmaid of God; and "N, handmaid of God, is crowned for the ſervant of God, in the name of the Father, and of the Son, and of the Holy Ghoſt;" adding thrice, "O Lord our God, crown them with glory and honour."

The third ceremony is that of diſſolving the crowns on the eighth day; after which the bride is conducted to the bridegroom's houſe, immediately to enter on the cares of his family.

22 Regular and ſecular clergy.

With reſpect to diſcipline and government, the Greek church bears a ſtriking reſemblance to that of Rome. In both there is the ſame diviſion of the clergy into regular and ſecular; the ſame ſpiritual juriſdiction of biſhops and their officials, and the ſame diſtinction of ranks and offices. In ſome points the diſcipline of the Greeks differs from that of the Romans. All orders of ſecular clergy in the Greek church inferior to biſhops are permitted to marry; but celibacy, and the aſſumption of the monaſtic habits, are indiſpenſably requiſite in thoſe who are candidates for the mitre. The regular clergy, ſays Mr Dallaway, are generally men of a certain education; whereas the ſeculars are of the meaner ſort, and illiterate in the extreme.

23 Five orders of clergy.

In the Greek church there are five orders of clergy promoted by the impoſition of hands; but it does not appear that the ordination of the reader, or of the ſubdeacon, is conſidered as a ſacrament. The forms uſed in the ordination of deacons, preſbyters, and biſhops, are ſerious and ſignificant (H), bearing in themſelves evidence of great antiquity. The candidate for the deaconate or prieſthood kneels before the holy table, and the biſhop, laying his right hand on his head, ſaith, "The divine grace, which healeth our infirmities, and ſupplieth our defects, promoteth N, the moſt pious *ſubdeacon,* to the order of *deacon;*" or, in the caſe of the prieſthood, "The moſt pious *deacon* to the order of a *preſbyter;* let us pray for him, that the Grace of the Holy Spirit may come upon him." It does not appear, from Dr King's account of theſe offices, that in the Greek church the attending preſbyters lay on their hands together with the biſhop at the ordination of a preſbyter,

24 Form of ordination.

(H) We muſt except thoſe uſed in the church of Abyſſinia, which, according to Mr Bruce, are ſhamefully indecent. "A number of men and children preſent themſelves at a diſtance, and there ſtand, from humility, not daring to approach the *abuna* or biſhop. He then aſks who theſe are? and they tell him that they want to be deacons. On this, with a ſmall iron croſs in his hand, after making two or three ſigns, he blows with his mouth twice or thrice upon them; ſaying, *Let them be deacons.* I ſaw once (ſays our author) all the army of Begemder made deacons, juſt returned from ſhedding the blood of 10,000 men. With thoſe were mingled about 1000 women, who conſequently having part of the ſame blaſt and brandiſhment of the croſs, were as good deacons as the reſt. In the ordination of prieſts a little more ceremony is uſed; for they muſt be able to read a chapter of St Mark, which they do in a language of which the abuna underſtands not one word. They then give him a brick of ſalt, to the value perhaps of ſixpence, for their ordination; which, on account of this preſent, the Jeſuits maintained to be Simoniacal." There is but one biſhop or abuna in Abyſſinian, and he is always a foreigner, ſubordinate in his juriſdiction to the patriarch of Alexandria.

preſbyter, as is practiſed in the church of England; but ſeveral biſhops lay on their hands together with the archbiſhop at the conſecration of a biſhop.

25 Solemn conſecration of biſhops.

This is indeed a very ſolemn ceremony. The candidate for the epiſcopate, who is always an *archimandrite* or *hieromonachus*, i. e. an abbot or chief monk in ſome monaſtery, being named to the vacant ſee, and the election being confirmed, repairs, at the time appointed, to the church where the conſecration is to be performed. Being arrived, he is introduced by the proto-pope (I) and proto-deacon to the archbiſhop and biſhops, who are arranged in proper order on a temporary theatre or platform erected in the church for the occaſion. He there gives an account of his faith; declares ſolemnly that he has neither given nor promiſed money, or any bribe-worthy ſervice, for his dignity; and promiſes to adhere ſteadily to the traditions and canons of the eaſtern church, to viſit his dioceſe regularly, and to oppoſe ſtrenuouſly all innovations and hereſies, particularly the errors of the Latin church. This being done, the archbiſhop ſays, "The grace of the Holy Spirit, through my humility, exalts thee N. archimandrite or hieromonachus, beloved of God, to be biſhop of the cities N. N. which God preſerve." With much ceremony the biſhop elect is then conducted from the theatre, within the rails of the holy altar, where he kneels down with the other biſhops, who hold open over his head the holy goſpel with the letters inverted, the archbiſhop ſaying aloud, "The divine grace, which always healeth our infirmities, and ſupplieth our defects, by my hand conducteth thee N. archimandrite or hieromonachus, beloved of God, biſhop elect of the cities of N. N. which God preſerve!—Let us pray therefore for him, that the Grace of the moſt Holy Spirit may come upon him." Then the prieſts ſay thrice, "Lord have mercy upon us;" and while the biſhops continue to hold the goſpel, the archbiſhop ſigns the newly conſecrated biſhop thrice with the ſign of the croſs, ſaying, "In the name of the Father, and of the Son, and of the Holy Ghoſt, now and for ever, even unto ages of ages. Amen." Then all the biſhops putting their right hands on his head, the archbiſhop prays that he may be confirmed in the office of which they have judged him worthy, that his prieſthood may be rendered irreproachable, and that he himſelf may be made holy and worthy to be heard of God. After this, one of the aſſiſting biſhops reads a ſhort litany in a low voice, to be heard only by thoſe within the altar, and the other biſhops make the reſponſes. At the end of the litany the archbiſhop, laying his hand again upon the head of the newly conſecrated biſhop, prays in very decent and devout terms, that Chriſt will render him an imitator of himſelf, the true Shepherd; that he will make him a leader of the blind, a light to thoſe who walk in darkneſs, and a teacher of infants; that he may ſhine in the world, and receive at laſt the great reward prepared for thoſe who contend boldly for the preaching of the goſpel. After this the paſtoral-ſtaff is delivered to the new biſhop, with a very proper and ſolemn exhortation from the archbiſhop, to feed the flock of Chriſt committed to his care.

The laſt ſacrament of the Greek church is that of the holy oil or euchelaion, which is not confined to perſons *periculoſe ægrotantibus, et mortis periculo imminente*, like the extreme unction of the Romiſh church; but is adminiſtered, if required, to devout perſons upon the ſlighteſt malady. Though this ordinance is derived from St James, chap. v. ver. 14, 15. it is by no means deemed neceſſary to ſalvation, or obligatory upon all Chriſtians; and it is well that it is not, for ſeven prieſts are required to adminiſter it regularly, and it cannot be adminiſtered at all by leſs than three. The oil is conſecrated with much ſolemnity; after which each prieſt, in his turn, takes a twig, and dipping it in the oil now made holy, anoints the ſick perſon croſs-wiſe, on the forehead, on the noſtrils, on the paps, the mouth, the breaſt, and both ſides of the hands, praying that he may be delivered from the bodily infirmity under which he labours, and raiſed up by the grace of Jeſus Chriſt.

26 The lavipedium.

In the Greek, as well as in the Latin church, there is a ſervice, called the divine *lavipedium*, obſerved on the Thurſday of paſſion-week, in imitation of our Saviour's humility. At Conſtantinople Jeſus Chriſt is, on this occaſion, perſonified by the Patriarch, and everywhere elſe by the biſhop of the dioceſe, and the twelve apoſtles by twelve regular prieſts, when a ludicrous conteſt ariſes who ſhall repreſent Judas; for the name attaches for life. This office is performed at the weſt end of the church, where an arm-chair is ſet at the bottom, facing the eaſt, for the biſhop; and on each ſide are placed twelve chairs for the twelve prieſts, who are to repreſent the twelve apoſtles. The prayers and hymns uſed on this occaſion are exceedingly beautiful and appropriate; and when the firſt goſpel, relating our Saviour's waſhing of his diſciples feet, begins to be read, the biſhop or patriarch riſes up, and takes off his pontifical veſtments by himſelf without aſſiſtance. He then girds himſelf with a towel, and taking a baſon of water in his hand, kneels down and waſhes one foot of each prieſt, beginning with the youngeſt; and after having waſhed it he kiſſes it. All this is done as the ſeveral circumſtances are read; and when he comes to the laſt prieſt, who is ſuppoſed to repreſent Peter, that prieſt riſeth up and ſaith, "Lord, doſt thou waſh my feet?" &c. The biſhop anſwers in the words of our Saviour; and having finiſhed the whole, puts on his garments again, and ſits down; and as the ſecond goſpel is read (K), repeats the words of our Saviour, "Know ye what I have done unto you?" &c. The office is certainly ancient, and, if decently performed, muſt be affecting.

27 The privileges of the patriarch of Conſtantinople.

Under the word Patriarchs, *Encycl.* we have given a ſufficient account of the riſe of the patriarchates, as well as of the various degrees of rank and authority claimed by the biſhops of ſeveral other ſees in the Greek chuch. It may be proper to add here, that after the taking of Conſtantinople by Mohammed II. he continued to the patriarch of that city the ſame preſent which the Greek emperors had been accuſtomed to make—a paſtoral ſtaff, a white horſe, and four hundred ducats in gold. To the Greek church and the maintenance of its clergy he left indeed ample revenues, which they have gradually ſacrificed to their inconſtancy,

---

(I) In the Greek church all pariſh prieſts are called *papas* or popes; and the proto-pope is an archpreſbyter.

(K) The firſt goſpel is John xiii. 3—12. The ſecond goſpel is John xiii. 12—18.

cy, their ambition, and their private jealouſy. Still, however, the patriarch of Conſtantinople fills a very lucrative and high office. "Beſides the power of nominating the other three patriarchs, and all epiſcopal dignitaries (ſays Mr Dallaway), he enjoys a moſt extenſive juriſdiction, compriſing the churches of Anatolia, Greece, Wallachia, Moldavia, and the iſlands of the Archipelago. Since the cloſe of the ſixteenth century, the Ruſſian church has claimed a juriſdiction independent of the ſee of Conſtantinople; though appeals have been made to that ſee in caſes of extraordinary importance. The influence of the patriarch with the Porte is very extenſive, as far as his own nation is concerned. His memorials are never denied; and he can, in fact, command the death, the exile, impriſonment for life, depoſition from offices, or pecuniary fine, of any Greek whom he may be inclined to puniſh with rigour, or who has treated his authority with contempt. On the death of the patriarch the moſt eager competition is exerted to fill the vacant throne; which, as it is obtained by bribery and intrigue, is of courſe a very unſtable ſeat to the ſucceſsful candidate, ſhould another offer to accept the appointment at a lower ſalary." For a fuller account of the doctrines, diſcipline, and worſhip of the Greek church at preſent, we refer the reader to *King's Rites and Ceremonies of the Greek Church in Ruſſia*, and to *Dallaway's Conſtantinople ancient and modern* (publiſhed in 1797); from which two works this abſtract has been moſtly taken.

CHUSAN-Islands, a cluſter of ſmall iſlands on the eaſt coſt of China, which were viſited by Lord Macartney in his courſe to Pekin. Moſt of theſe iſlands ſeem to be hills riſing regularly out of the ſea, and rounded at top, as if any points or angles exiſting in their original formation had been gradually worn off into a globular and uniform ſhape. Many of them, though cloſe to each other, are divided by channels of great depth. They reſt upon a foundation of grey or red granite, ſome part reſembling porphyry, except in hardneſs. They were, certainly, not formed by the ſucceſſive alluvian from the earth brought into the ſea by the great river at whoſe mouth they are ſituated, like the numerous low and muddy iſlands at the mouth of the Po, and many others; but ſhould rather be conſidered as the remains of part of the continent thus ſcooped and furrowed, as it were, into iſlands, by the force of violent torrents carrying off, further into the ſea, whatever was leſs reſiſtable than the rocks juſt mentioned. Some of them wore a very inviting aſpect; one in particular, called Poo-too, is deſcribed as a perfect paradiſe. This ſpot was choſen, no doubt, for its natural beauties, and afterwards embelliſhed, by a ſet of religious men, who, to the number of three thouſand, poſſeſs the whole of it, living there in a ſtate of celibacy. It contains four hundred temples, to each of which are annexed dwelling-houſes and gardens for the accommodation of thoſe monks. This large monaſtery, as it may be called, is richly endowed, and its fame is ſpread throughout the empire.

The Engliſh Eaſt India Company had once a factory at Chuſan, the principal of theſe iſlands, from which they were many years ago interdicted. This, according to the account of a Chineſe merchant who remembered the factory, was not occaſioned by any offence given by the Engliſh, but by the avarice of the officers governing at Canton, who draw large ſums from the accumulation of foreign trade in that port. Perhaps, too, the exceſſive jealouſy of the Chineſe government might fancy danger in the unreſtrained communication between foreigners and the ſubjects of that empire in ſeveral of its ports at the ſame time.

Ting-hai, the chief town of Chuſan, reſembles Venice, but on a ſmaller ſcale. It is ſurrounded, as well as interſected, by canals, over which are thrown ſteep bridges, aſcended by ſteps like the Rialto. The ſtreets are narrow, and paved with ſquare flat ſtones; but the houſes, unlike the Venetian buildings, are low and moſtly of one ſtory. The ornaments of theſe buildings are confined chiefly to the roofs, on the ridges of which are uncouth figures of animals in clay, ſtone, or iron. The town is full of ſhops, containing chiefly articles of clothing, food, and furniture, diſplayed to full advantage. Even coffins are painted in a variety of lively and contraſting colours. The ſmaller quadrupeds, including dogs, intended for food, are expoſed alive for ſale, as well as poultry, and fiſh in tubs of water, with eels in ſand. When the gentlemen belonging to the embaſſy were at Ting-hai, they were ſtruck with the number of places where tin-leaf and ſticks of odoriferous wood were ſold for burning in the temples, which indicated no ſlight degree of ſuperſtition in the people. Superſtition, however, made them not idle; for throughout the whole place there was a quick and active induſtry. Men paſſed buſily through the ſtreets, while not an individual was ſeen aſking alms; and the women were employed in the ſhops. At Chuſan, the number of valuable harbours, or places of perfect ſecurity for ſhips of any burden, is almoſt equal to the number of iſlands. This advantage, together with that of their central ſituation, in reſpect to the eaſtern coſt of China, and the vicinity of Corea, Japan, Leoo-keoo, and Formoſa, attract conſiderable commerce, eſpecially to Ning-poo, a city of great trade in the adjoining province of Che-chiang, to which all the Chuſan iſlands are annexed. From one port in that province twelve veſſels ſail annually for copper to Japan.

According to Brookes, Chuſan is in N. Lat. 30. 0. and E. Long. 124. 0.

CINARA, or Cynara, which we tranſlate *artichoke*, is, according to Profeſſor Beckmann, the name which was given by the ancients to a plant very different from the artichoke of our kitchen gardens, though he admits that they belong to the ſame genus. The proofs which he adduces for the truth of his opinion are too tedious to be introduced into this Work, eſpecially as they appear not to us to be abſolutely concluſive. We muſt therefore refer the reader to his Hiſtory of Inventions. The *cinara*, *carduus*, and *ſcolymus* (ſee Scolymus in this Supplement), were in his opinion ſpecies of the *thiſtle*, of which the *roots* and young *ſhoots*, as well as the bottom of the *calyx* of the laſt, were eaten. He has proved indeed, he thinks, that the Greeks and Romans uſed the pulpy bottom of the calyx, and the tendereſt ſtalks and young ſhoots of many plants belonging to the thiſtle kind, in the ſame manner as we uſe artichokes and cardoons, but that theſe latter were unknown to them.

"It appears probable (ſays he) that the uſe of theſe thiſtles, at leaſt in Italy and Europe in general, was in the courſe of time laid aſide and forgotten, and that the artichoke, when it was firſt brought to Italy from the Levant, was conſidered as a new ſpecies of food. It is undoubtedly certain that our artichoke was firſt known in that country in the 15th century. Hermolaus Barbarus, who died in 1494, relates that this plant was firſt ſeen at Venice in a garden in 1473, at which time it was very ſcarce. About the year 1466, one of the family of Strozza brought the firſt artichokes to Florence from Naples. Politian, in a letter in which he deſcribes the diſhes he found at a grand entertainment in Italy in 1488, among theſe mentions artichokes. They were introduced into France in the beginning of the 16th century, and into England in the reign of Henry VIII."

The original country of the artichoke is unknown. Linnæus ſays that it grew wild in Narbonne, Italy, and Sicily, as the cardoon did in Crete; but our author has proved very ſufficiently, that with reſpect to both theſe facts the great botaniſt was miſinformed. The artichoke is certainly known in Perſia; but Tavernier ſays expreſsly, that it was carried thither, like aſparagus and other European vegetables of the kitchen garden, by the Carmelite and other monks; and that it was only in latter times that it became common.

CINNABAR. See CHEMISTRY in this Supplement, n° 91.

CIRCLE OF CURVATURE, or circle of equicurvature, is that circle which has the ſame curvature with a given curve at a certain point; or that circle whoſe radius is equal to the radius of curvature of the given curve at that point.

CIRCLES of Declination are great circles interſecting each other in the poles of the world.

CIRCLE of Diſſipation, in optics. See OPTICS, *Encycl.* n° 253.

CIRCLE Equant, in the Ptolemaic aſtronomy, is a circle deſcribed on the centre of the equant. Its chief uſe is to find the variation of the firſt inequality.

CIRCLES of Excurſion are little circles parallel to the ecliptic, and at ſuch a diſtance from it, as that the excurſions of the planets towards the poles of the ecliptic may be included within them; being uſually fixed at about 10 degrees.

CIRCLES of Poſition, are circles paſſing through the common interſections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any ſtar, or other point in the heavens; and are uſed for finding out the ſituation or poſition of any ſtar. Theſe are uſually ſix in number, cutting the equinoctial into 12 equal parts, which the aſtrologers call the *celeſtial houſes*, and hence they are ſometimes called *circles of the celeſtial houſes*.

CIRCULAR LINES, a name given by ſome authors to ſuch ſtraight lines as are divided by means of the diviſions made in the arch of a circle; ſuch as the ſines, tangents, ſecants, &c.

CIRCULAR Parts, called, from the uſe which he firſt made of them, *Napier's* circular parts, are the five parts of a right-angled or a quadrantal ſpherical triangle; they are the two legs, the complement of the hypothenuſe, and the complements of the two oblique angles.

Concerning theſe circular parts, Napier gave a general rule in his *Logarithmorum Canonis Deſcriptio*, which is this; "The rectangle under the radius and the ſine of the middle part is equal to the rectangle under the tangents of the adjacent parts, and to the rectangle under the coſines of the oppoſite parts. The right angle or quadrantal ſide being neglected, the two ſides and the complements of the other three natural parts are called the *circular parts*, as they follow each other as it were in a circular order. Of theſe, any one being fixed upon as the middle part, thoſe next it are the adjacent, and thoſe fartheſt from it the oppoſite parts."

This rule contains within itſelf all the particular rules for the ſolution of right-angled ſpherical triangles, and they were thus brought into one general comprehenſive theorem, for the ſake of the memory; as thus, by charging the memory with this one rule alone: All the caſes of right-angled ſpherical triangles may be reſolved, and thoſe of oblique ones alſo, by letting fall a perpendicular, excepting the two caſes in which there are given either the three ſides, or the three angles. And for theſe a ſimilar expedient has been deviſed by Lord Buchan and Dr Minto, which may be thus expreſſed: "Of the circular parts of an oblique ſpherical triangle, the rectangle under the tangents of half the ſum and half the difference of the ſegments at the middle part (formed by a perpendicular drawn from an angle to the oppoſite ſide), is equal to the rectangle under the tangents of half the ſum and half the difference of the oppoſite parts." By the circular parts of an oblique ſpherical triangle are meant its three ſides and the ſupplements of its three angles. Any of theſe ſix being aſſumed as a middle part, the oppoſite parts are thoſe two of the ſame denomination with it, that is, if the middle part is one of the ſides, the oppoſite parts are the other two, and, if the middle part is the ſupplement of one of the angles, the oppoſite parts are the ſupplements of the other two. Since every plane triangle may be conſidered as deſcribed on the ſurface of a ſphere of an infinite radius, theſe two rules may be applied to plane triangles, provided the middle part be reſtricted to a ſide.

Thus it appears that two ſimple rules ſuffice for the ſolution of all the poſſible caſes of plane and ſpherical triangles. Theſe rules, from their neatneſs, and the manner in which they are expreſſed, cannot fail of engraving themſelves deeply on the memory of every one who is a little verſed in trigonometry. It is a circumſtance worthy of notice, that a perſon of a very weak memory may carry the whole art of trigonometry in his head.

CIRCULATING DECIMALS. See DECIMALS in this Supplement.

CLOCK, a machine for meaſuring time, of which a deſcription is given in the Encyclopædia. For the ſcientific principles of *clock* and *watch-making*, as well as for a ſhort account of the moſt valuable conſtructions, ſee WATCH-*Making* in this Supplement.

COACH, as we have obſerved in the Encyclopædia, is a very modern invention, if by that word be meant a covered carriage ſuſpended on ſprings. We learn, indeed, from the laborious reſearches of Profeſſor Beckmann, that coaches of ſome kind were known in the beginning of the 16th century; but they were uſed only by women of the firſt rank, for the men thought it diſgraceful to ride in them. At that period, when the electors and princes did not chooſe to be preſent at the meetings of the ſtates, they excuſed themſelves by informing the emperor that their health did not permit them

them to ride on horſeback; and it was conſidered as a point eſtabliſhed, that it was unbecoming for them to ride like women. It is certain, however, that, about the end of the 15th century, the emperor, kings, and princes, began to employ covered carriages on journeys, and afterwards on public ſolemnities.

The wedding carriage of the firſt wife of the Emperor Leopold, who was a Spaniſh princeſs, coſt, together with the harneſs, 38,000 florins. The coaches uſed by that Emperor are thus deſcribed by Kink: “In the imperial coaches no great magnificence was to be ſeen; they were covered over with red cloth and black nails. The harneſs was black, and in the whole work there was no gold. The pannels were of glaſs, and on this account they were called the *imperial glaſs coaches*. On feſtivals the harneſs was ornamented with red ſilk fringes. The imperial coaches were diſtinguiſhed only by their having leather traces; but the ladies in the imperial ſuite were obliged to be contented with carriages, the traces of which were made of ropes.” At the magnificent court of Duke Erneſt Auguſtus of Hanover, there were in the year 1681 fifty gilt coaches with ſix horſes each. So early did Hanover begin to ſurpaſs other cities in the number of its carriages. The firſt time that ambaſſadors appeared in coaches on a public ſolemnity was at the imperial commiſſion held at Erfurth in 1613 reſpecting the affair of Juliers.

In the hiſtory of France we find many proofs that at Paris, in the 14th, 15th, and even 16th centuries, the French monarchs rode commonly on horſes, the ſervants of the court on mules, and the princeſſes, together with the principal ladies, ſometimes on aſſes. Perſons of the firſt rank often ſat behind their equerry, and the horſe was often led by ſervants. Carriages, however, of ſome kind appear to have been uſed very early in France. An ordinance of Philip the Fair, iſſued in 1294 for ſuppreſſing luxury, and in which the citizens wives are forbid to uſe carriages (*cars*), is ſtill preſerved. Under Francis I. or rather about 1550, ſomewhat later, there were in Paris for the firſt time only three coaches.

The oldeſt carriages uſed by the ladies in England were known under the now forgotten name of *whirlicotes*. When Richard II. towards the end of the 14th century, was obliged to fly before his rebellious ſubjects, he and all his followers were on horſeback; his mother only, who was indiſpoſed, rode in a carriage. This, however, became afterwards ſomewhat unfaſhionable, when that monarch's queen, Ann, the daughter of the Emperor Charles IV. ſhewed the Engliſh ladies how gracefully and conveniently ſhe could ride on a ſide-ſaddle. Whirlicotes were laid aſide, therefore, except at coronations and other public ſolemnities. Coaches were firſt known in England about the year 1580, and, as Stow ſays, were introduced from Germany by Fitzallen, earl of Arundel. In the year 1598, when the Engliſh ambaſſador came to Scotland, he had a coach with him. Anderſon places the period when coaches began to be in common uſe about the year 1605. The celebrated duke of Buckingham, the unworthy favourite of two kings, was the firſt perſon who rode with a coach and ſix horſes, in 1619. To ridicule this new pomp, the earl of Northumberland put eight horſes to his carriage.

Reſpecting the progreſs of luxury with regard to coaches, the reader will find much curious information in the firſt volume of Profeſſor Beckmann's *Hiſtory of Inventions*. It is perhaps one of the moſt entertaining articles in that very learned work. The author, however, with all his labour, has not been able to aſcertain the country in which coaches hung on ſprings were firſt uſed; but he ſeems inclined to give the credit of the invention to Hungary.

COBALT (ſee Chemistry-*Index*, in this Supplement), is a valuable article to potters and dyers. To fit it for their uſe, it is firſt roaſted and freed from the foreign mineral bodies with which it is united: it is then well calcined, and ſold either mixed or unmixed with fine ſand under the name of zaffer (*zaffera*); or it is melted with ſiliceous earth and potaſhes to a kind of blue glaſs called *ſmalt*, which when ground very fine is known in commerce by the name of *powder blue*. All theſe articles, becauſe they are moſt durable pigments, and thoſe which beſt withſtand fire, and becauſe one can produce with them every ſhade of blue, are employed above all for tinging cryſtal and for enamelling; for counterfeiting opaque and tranſparent precious ſtones, and for painting and varniſhing real porcelain and earthen and potters ware. This colour is indiſpenſably neceſſary to the painter when he is deſirous of imitating the fine azure colour of many butterflies and other natural objects; and the cheaper kind is employed to give a blueiſh tinge to new-waſhed linen, which ſo readily changes to a diſagreeable yellow, though not without injury to the health as well as to the linen.

Profeſſor Beckmann, in his *Hiſtory of Inventions*, gives the following account of the paint prepared from cobalt. “About the end of the 15th century cobalt appears to have been dug up in great quantity in the mines on the borders of Saxony and Bohemia, diſcovered not long before that period. As it was not known at firſt to what uſe it could be applied, it was thrown aſide as a uſeleſs mineral. The miners had an averſion to it, not only becauſe it gave them much fruitleſs labour, but becauſe it often proved prejudicial to their health by the arſenical particles with which it was combined; and it appears even that the mineralogical name *cobalt* then firſt took its riſe. At any rate, I have never met with it before the beginning of the 16th century; and Matheſius and Agricola ſeem to have firſt uſed it in their writings. Friſch derives it from the Bohemian word *kow*, which ſignifies *metal*; but the conjecture that it was formed from *cobalus*, which was the name of a ſpirit that, according to the ſuperſtitious notions of the times, haunted mines, deſtroyed the labours of the miners, and often gave them a great deal of unneceſſary trouble, is more probable; and there is reaſon to think that the latter is borrowed from the Greek. The miners, perhaps, gave this name to the mineral out of joke, becauſe it thwarted them as much as the ſuppoſed ſpirit, by exciting falſe hopes, and rendering their labour often fruitleſs. It was once cuſtomary, therefore, to introduce into the church ſervice a prayer that God would preſerve miners and their works from *kobolts* and ſpirits.

“Reſpecting the invention of making an uſeful kind of blue glaſs from cobalt, we have no better information than that which Klotzſch has publiſhed from the papers of Chriſtian Lehmann. The former, author of an hiſtorical work reſpecting the upper diſtrict of the mines in Miſnia, and a clergyman at Scheibenberg, collected with great diligence every information that reſpected the hiſtory of the neighbouring country, and died at a great age in 1688. According to his account, the colour mills at the time when he wrote were about 100 years old; and as he began firſt to write towards the end of the thirty years war, the invention ſeems to fall about 1540 or 1560. He relates the circumſtance as follows: 'Chriſtopher Schurer, a glaſs-maker at Platten, a place which belongs ſtill to Bohemia, retired to Neudeck, where he eſtabliſhed his buſineſs. Being once at Schneeberg, he collected ſome of the beautiful coloured pieces of cobalt which were found there, tried them in his furnace; and finding that they melted, he mixed ſome cobalt with glaſs metal, and obtained fine blue glaſs. At firſt he prepared it only for the uſe of the potters; but in the courſe of time it was carried as an article of merchandiſe to Nuremberg, and thence to Holland. As painting on glaſs was then much cultivated in Holland, the artiſts there knew better how to appreciate this invention. Some Dutchmen therefore repaired to Neudeck, in order that they might learn the proceſs uſed in preparing this new paint. By great promiſes they perſuaded the inventor to remove to Magdeburg, where he alſo made glaſs from the cobalt of Schneeberg; but he again returned to his former reſidence, where he conſtructed a handmill to grind his glaſs, and afterwards erected one driven by water. At that period the colour was worth 7¼ dollars per cwt. and in Holland from 50 to 60 florins. Eight colour mills of the ſame kind, for which roaſted cobalt was procured in caſks from Schneeberg, were ſoon conſtructed in Holland; and it appears that the Dutch muſt have been much better acquainted with the art of preparing, and particularly with that of grinding it, than the Saxons; for the Elector John George ſent for two colour-makers from Holland, and gave a thouſand florins towards the enabling them to improve the art. He was induced to make this advance chiefly by a remark of the people of Schneeberg, that the part of the cobalt which dropped down while it was roaſting contained more colour than the roaſted cobalt itſelf. In a little time more colour-mills were erected around Schneeberg. Hans Burghard, a merchant and chamberlain of Schneeberg, built one, by which the eleven mills at Platten were much injured. Paul Nordhoff, a Frieſlander, a man of great ingenuity, who lived at the Zwittermill, made a great many experiments in order to improve the colour; by which he was reduced to ſo much poverty that he was at length forced to abandon that place, where he had been employed for ten years in the colour-manufactory. He retired to Annaberg, eſtabliſhed there in 1649, by the aſſiſtance of a merchant at Leipſic, a colour-manufactory, of which he was appointed the director; and by theſe means rendered the Annaberg cobalt of utility. The conſumption of this article, however, muſt have decreaſed in the courſe of time; for in the year 1659, when there were mills of the ſame kind at more of the towns in the neighbourhood of mines, he had on hand above 8000 quintals.' Thus far Lehmann."

Koſsler ſays, that the Bohemian cobalt is not ſo good as that of Miſnia, and that its colour is more like that of aſhes. We truſt, however, that the qualities of foreign cobalt ſhall ſoon be a matter of little importance to the Britiſh artiſt, as a rich mine of this mineral has lately been diſcovered near Penzance in Cornwal.

COFFEA, the *Coffee-Tree*, is a plant which has been botanically deſcribed in the Encyclopædia Britannica, where ſome account is likewiſe given of the modes of cultivating it, as well as of the qualities of its fruit. Since that account, however, was publiſhed, two works have fallen into our hands, from which we deem it our duty to make ſuch extracts as may not only correct ſome miſtakes which we had committed, but alſo communicate uſeful information to the public.

In our former article we adopted the common opinion, that the coffee produced in Arabia is ſo greatly ſuperior to that which is raiſed everywhere elſe, that it is vain to think of cultivating the plant to any extent in the Weſt India iſlands. We are happy to find that this is a vulgar error. In the year 1783, when the cultivation of coffee was not ſo well underſtood in Jamaica as at preſent, ſome ſamples from that iſland were produced in London, and pronounced by the dealers to be equal to the very beſt brought from the Eaſt. "Two of the ſamples were equal to the beſt Mocha coffee, and two more of them ſuperior to any coffee to be had at the grocers ſhops in London, unleſs you will pay the price of *picked* coffee for it, which is two ſhillings per pound more than for that which they call the *beſt* coffee. All the reſt of the ſamples were far from bad coffee, and very little inferior, if at all, to what the grocers call *beſt* coffee *."

If this be ſo, it ſurely becomes the legiſlature of Great Britain to encourage the cultivation of coffee in the Weſt Indies, eſpecially as it thrives beſt in ſoil which is not fit for the ſugar-cane, and may be raiſed in conſiderable quantities by thoſe who are not able to ſtock a ſugar plantation. The encouraging every article which increaſes the intercourſe with our colonies is increaſing our commerce. The payment for all the ſtaples of the Weſt Indies is made in our manufactures; the ſale of which muſt increaſe in proportion to the numbers that are employed in the cultivation of what is bartered for them. Our Weſt India iſlands, without draining us of ſpecie or bullion, can ſupply us with many of thoſe very articles for which we are drained in other parts of the world, and particularly with coffee.

To give a detailed account of the introduction of the coffee-tree into the Weſt Indies, would ſwell this article to very little purpoſe. According to Boerhaave, a Dutch governor was the firſt perſon who procured freſh berries from Mocha, and planted them in Batavia; and in the year 1690 ſent a plant from thence to Amſterdam, which came to maturity, and produced thoſe berries which have ſince furniſhed all that is now cultivated in the Weſt Indies.

In 1714 a plant from the garden of Amſterdam was ſent by Mr Pancras, a burgomaſter and director of the botanic garden, as a preſent to Louis XIV. which was placed in the garden at Marly. In 1718, the Dutch began to cultivate coffee in Surinam; in 1721, the French began to cultivate it at Cayenne; in 1727, at Martinico; and in 1728, the Engliſh began to cultivate it in Jamaica.

As it has been more cultivated in the French Weſt India iſlands than in the Britiſh, it may be of importance to our coloniſts to be made acquainted with the practice of the French planters. Accordingly Dr Laborie, a royaliſt of St Domingo, has lately publiſhed a volume for their inſtruction on this ſubject; in which are

---

* *Moſeley's Treatiſe on Coffee.*

are many judicious obſervations, the reſult of long experience, reſpecting the ſoil fit for a coffee plantation; the various eſtabliſhments neceſſary; the cultivation of the coffee-tree through the ſeveral ſtages of its growth and duration; and the management and uſe of the negroes and cattle.

With reſpect to ſoil, it is a fact, ſays he, beyond contradiction, that low lands, and even the mountains near the champaign country, are leſs proper for the production of coffee, than lands which are high and at a diſtance from the ſea. The coffee-tree delights in a comparatively cool climate, and in an open and permeable virgin ſoil; and is hurt by the parching deſtructive air of the ſea. The ſoil on the mountains of St Domingo conſiſts generally of a bed of mould more or leſs deep; but which, for the production of coffee-trees, ought not to be leſs than four or five feet. If the declivity be gentle, the ſofteſt and moſt friable earth is preferable to all others; but in ſteep grounds a firm though not clayey ſoil, mixed with a proportion of gravel or ſmall ſtones, through which the water may find an eaſy way, is the moſt deſirable. The colour of the ground is of little conſequence, though ſuch as is ſomewhat reddiſh is generally to be preferred. With regard to expoſure, the north and weſt are the moſt eligible in low and hot ſituations, becauſe theſe expoſures are the cooleſt; and on the higheſt mountains the ſouth and eaſt are to be choſen, becauſe they are the hotteſt. On the whole, neither the higheſt nor the loweſt ſituations are the beſt, but thoſe which are conſiderably above the middle of the mountains.

Whatever be the planter's circumſtances in point of fortune, and our author thinks that he ought not to undertake a ſettlement without the command of 3000 or 4000 pounds ſterling, he ought not to ſet out with a great number of negroes. If he cannot command a plentiful ſupply of victuals from ſome contiguous plantation, ſix, or at the moſt twelve, male negroes, with one or two women, will be found ſufficient to make the firſt eſſay. After building two huts, one for the maſter or overſeer and the other for the ſlaves, they are to commence their operations by cutting away the underwood and creeping plants with the bill, and felling the trees. The trees are to be cut as low as poſſible, but the roots are to be left in the ground, becauſe they preſerve the ſoil during the firſt period of culture; and in burning this maſs of wood and ſhrubs, the only way ſometimes of clearing the ground, care muſt be taken that the fire be nowhere ſo violent as to convert the ſoil into the conſiſtence of brick, which it is very apt to do if the ſoil be clayey. Amid the coffee-trees, after they are planted, may be ſown beans, maize, and all kinds of eſculent plants, pot herbs, and roots; but particular care muſt be taken to remove from theſe plantations all creeping plants, ſuch as melons, yams, potatoes, gourds, and more eſpecially tobacco, which multiplies to a vaſt extent, and exhauſts the ground.

In St Domingo the moſt approved method of planting the coffee-tree is in ſtraight rows croſſing each other at right angles, and the diſtance between the plants is regulated by the quality and expoſure of the ground. The richer the ſoil, the expoſures being the ſame, and the cooler the expoſure, the quality of the ſoil being the ſame, the farther muſt the trees be planted aſunder. If on the north and weſt the ground be good, plant ſtill farther; but, on the contrary, if to the eaſt or ſouth it be light (which it generally is), plant ſtill nearer. Thus if it be proper on a ſouth or eaſt expoſure to plant at the diſtance of ſix feet, it will be neceſſary to plant at the diſtance of ſeven on a weſt or north expoſure, if the ground be of the ſame quality as in the other ſituations.

Though coffee, like all other vegetables, grows from the ſeed, Dr Laborie adviſes, in the forming of large plantations, to make uſe of ſaplings reared in nurſeries; and the ſituation fitteſt for a nurſery is a plain, or at leaſt a ground of gentle aſcent, where the mould is crumbly. In forming a nurſery, ſome plant the whole cherry; but our author recommends the taking off the ſkin, and waſhing the ſeparated ſeeds; in which we ſuſpect that he is miſtaken, as his practice is certainly a deviation from nature. The nurſery muſt be kept very clear of weeds, and neither corn nor any thing elſe ſown in it.

The beſt ſeaſon for tranſplanting the ſaplings is during the genial rains of April and May, when great attention is required, as the treaſures of future harveſts are at ſtake. Thoſe plants are the fitteſt for being removed which, in the language of our author, are *crowned*, or have each four little boughs; and, if the ſeeds were freſh and ſown in furrows about an inch from each other, this perfection is generally attained in the courſe of a year. The ſaplings muſt not be pulled up by force, but carefully raiſed by means of a flat, ſharp, iron ſhovel, thruſt deep under their roots; and the ſooner they are planted, after being taken up, the better.

In planting, the firſt thing to be done is to thruſt into the ground a dibble, or ſharp pointed ſtick, round which a hole is dug from nine to twelve inches in diameter, and from fifteen to eighteen in depth. Then a quantity of the mould taken out of the hole is thrown back into it, till its depth be diminiſhed about four or ſix inches; and the plant being ſupported with the left hand, in the middle of the hole, while the end of its ſtraight root, which our author calls its pivot, touches lightly the new bed, the ſurrounding mould is with the right hand thrown in, to the height of ſix inches. This being lightly preſſed down with both hands, more earth is thrown in and preſſed in the ſame manner, care being taken not to hurt, or bend, or diſplace the ſapling, which muſt be ſet ſo deep that its two inferior branches be rather below the level of the ground. On this account three or four inches of the hole are left open, which, by the time that theſe branches riſe above its margin, are filled up by the ſurrounding earth. The buſineſs is finiſhed by ſinking the ſharp-pointed ſtick at the upper margin of the hole, where it ſerves as a ſmall fence to the infant tree. In hot ſituations plantain trees are intermingled with the coffee trees for the purpoſe of ſhade and coolneſs. They are uſually placed in every fourth or ſixth row, as the trees are more or leſs diſtant, and the expoſure more or leſs hot.

To the buſineſs of planting very ſoon ſucceeds that of weeding; for there is hardly any plant to which weeds are ſo pernicious as the coffee-tree: they cauſe it to grow yellow, fade, wither, and periſh. Where the ground ſlopes much, eſpecially if the ſoil be ſoft and friable, the weeds muſt be taken up by the hand; for if they be rooted out by the hoe, the ſoil will be ſo looſened that the rains will ſweep it away. Some weeds, however, from the depth of their roots muſt be dug up; and when that is the caſe the earth muſt be carefully returned and preſſed down. If, in weeding, any ſaplings be found withered, others of the ſame ſize muſt be brought from the nurſery and planted in their ſtead, with what our author calls their clod, *i. e.* with the earth of the nurſery adhering to their roots. If any ſapling be found broken or twiſted, it muſt be cut cloſe by the ground in a ſloping direction, the cut ſurface facing the north, and it will ſoon put forth ſuckers, of which the beſt only need be preſerved. In plantations of eighteen or twenty months old trees are often found with yellow, withered leaves, of which the cauſe is ſometimes a premature load of fruit, which muſt therefore be inſtantly removed or the tree will periſh. If, after this, it begin not in a few days to recover, it is probably eaten at the roots by a large white worm reſembling a ſlug. In that caſe the tree muſt be removed, the worm taken out, and before another tree be planted in its ſtead, a large hole muſt be made in the ground, expoſed to the influence of the ſun at leaſt for a fortnight.

The natural height of the coffee tree is from 15 to 18 feet; and if left to itſelf it would have the form of moſt other trees, *i. e.* a naked trunk and a branchy head. This is prevented by what the planters call *ſtopping*; which is performed by cutting off the top of the tree when it has arrived at the proper height, which varies according to circumſtances. In the beſt ſoil and moſt genial expoſure, it is ſuffered to grow to the height of five feet, and in the worſt ſtopped at two; but under the ſame aſpect, and on ground of the ſame quality, all the trees ought to be ſtopped at the ſame height. This operation of ſtopping is very apt to make the trees put forth ſuperfluous branches, which renders them inacceſſible to the genial warmth of the ſun, and, of courſe, deficient in the powers of fructification. Theſe muſt be *plucked* away while yet tender; for if they be ſuffered to grow till it become neceſſary to cut them, a number of ſprouts ſucceed; whereas, when they are plucked, the wound ſoon cicatrizes, and nothing follows.

The ſaw and the knife, however, muſt ſometimes be uſed; for when trees grow old their heads are apt to ſpoil; ſuperfluous branches may have been left upon them through neglect; a bough may have been broken by accident; or branches may be ſpent by too great a load of fruit. In all theſe caſes recourſe muſt be had to pruning, which ſhould be performed immediately after crop, and in ſuch a manner as that the tree, when it puts forth its new branches, may ſtill have as much as poſſible its natural or former appearance. This will be accompliſhed by cutting the withered bough immediately above a knot, whence a good ſecondary branch is put forth, which may be eaſily trained into the proper ſhape. Our author directs the cut to be always made ſo as that the ſloping ſurface ſhall face the north; by which expoſure it will eſcape the injury which it would otherwiſe receive from the exceſſive heat of the ſun. This is a good advice; but it would ſtill be an improvement on it to treat the wound with Forſyth's or Hit's plaſter, which we have deſcribed elſewhere (See *Encycl.* Vol. XVIII. page 562). When the tree is completely pruned, the moſs and other excreſcences muſt be ſcraped from the trunk with a wooden knife, great care being taken not to injure the bark.

After pruning follows what is called *nipping*. This is nothing more than the removal of thoſe ſuperfluous ſmall twigs which are ſent forth from every cut ſurface in ſuch numbers as would ſoon exhauſt the tree; and it is called nipping, becauſe they are plucked away by the hand, and not cut by the knife. It is needleſs to add, that when the ground begins to be impoveriſhed, it muſt be enriched by proper manure. This is known to every huſbandman both in Europe and in the Weſt Indies; but it is not perhaps ſo generally known that the weedings, and chiefly the red ſkins of coffee, when gathered into pits, are, in proceſs of time, converted into a black mould, which our author ſays makes the very beſt manure.

"The fruit of the coffee, when perfectly ripe, appears like a ſmall oval cherry. Under a red and ſhining ſkin a whitiſh clammy luſcious pulp preſents itſelf, which generally incloſes two ſeeds. Theſe ſeeds have one ſide flat, the other hemiſpherical. The firſt is marked with a longitudinal fiſſure, and the flat ſides are applied to each other. When the ſeeds are opened, they are found covered with a white, ligneous, brittle membrane, denominated *parchment*; on the inſide of which is another ſilver-coloured membrane, exceedingly thin, and ſeeming to originate from the fiſſure of the ſeeds. Sometimes the cherry has but one ſeed or grain, which then is in the form of a ſmall egg. This is peculiar to old decayed trees, or to the extremities of ſome ſmall branches."

The buſineſs of preparation conſiſts in taking the ſeed from its covering, in drying, and in cleaning it ſo as to have every advantage at market. Our author thinks that the beſt method of preparing the coffee is to ſtrip the ſeed of its outer ſkin immediately on its being pulled, and to dry it in its parchment. The proceſs has been already deſcribed in the Encyclopædia; but we believe it to be an injudicious one. We have the authority of a very eminent botaniſt *, well acquainted with all the vegetable productions of the Weſt Indies, to ſay, that the improvement which we have there mentioned, as propoſed by Mr Miller, is greatly preferable to Dr Laborie's practice. Indeed he himſelf admits, that coffee dried in the cherry is more heavy than when dried in parchment, and that it generally has a higher flavour. Nay, he ſays expreſsly, that "if a planter wants to have coffee of the firſt quality, either for himſelf or for his friends, he muſt ſet a part a number of his oldeſt trees, and not gather the fruit till it is ripened into *dryneſs*. It is in that manner, he believes, that the Arabians in Yemen make their little harveſts; and he declares, that coffee thus nouriſhed on the tree to the laſt moment, muſt have every perfection of which it is capable." His only plauſible objection is, that the trees are ſoon exhauſted when the fruit is left ſo long upon them; but doubtleſs this exhauſtion might be retarded by proper manure.

The chemical analyſis of coffee evinces that it poſſeſſes a great portion of mildly bitter and lightly aſtringent gummous and reſinous extract; a conſiderable quantity of oil; a fixed ſalt; and a volatile ſalt.—Theſe are its medicinal conſtituent principles. The intention of torrefaction is not only to make it deliver thoſe principles, and make them ſoluble in water, but to give it a property it does not poſſeſs in the natural ſtate of the berry. By the action of fire, its leguminous taſte and

---

* *Dr Wright.*

the aqueous part of its mucilage are deſtroyed ; its ſaline properties are created and diſengaged, and its oil is rendered empyreumatic.—From thence ariſes the pungent ſmell, and exhilarating flavour, not found in its natural ſtate.

The roaſting of the berry to a proper degree requires great nicety : Du Four juſtly remarks, that the virtue and agreeableneſs of the drink depend on it, and that both are often injured in the ordinary method. Bernier ſays, when he was at Cairo, where it is ſo much uſed, he was aſſured by the beſt judges, that there were only two people in that great city, in the public way, who underſtood the preparing it in perfection. If it be under-done, its virtues will not be imparted, and in uſe it will load and oppreſs the ſtomach :—If it be overdone, it will yield a flat, burnt, and bitter taſte, its virtues will be deſtroyed, and in uſe it will heat the body, and act as an aſtringent.

Fourteen pounds weight of raw coffee is generally reduced, at the public roaſting houſes in London, to eleven pounds by the roaſting ; for which the dealer pays ſeven pence half-penny, at the rate of five ſhillings for every hundred weight. In Paris, the ſame quantity is reduced to ten pounds and an half. But the roaſting ought to be regulated by the age and quality of the coffee, and by nicer rules than the appearance of the fumes, and ſuch as are uſually practiſed : therefore the reduction muſt conſequently vary, and no exact ſtandard can be aſcertained. Beſides, by mixing different ſorts of coffee together, that require different degrees of heat and roaſting, coffee has ſeldom all the advantages it is capable of receiving to make it delicate, grateful, and pleaſant. This indeed can be effected no way ſo well as by people who have it roaſted in their own houſes, to their own taſte, and freſh as they want it for uſe. The cloſer it is confined at the time of roaſting, and till uſed, the better will its volatile pungency, flavour, and virtues, be preſerved.

The mode of preparing this beverage for common uſe differs in different countries, principally as to the additions made to it.—But though that is generally underſtood, and that taſte, conſtitution, the quality of the coffee, and the quantity intended to be drunk, muſt be conſulted, in regard to the proportion of coffee to the water in making it—yet there is one material point, the importance of which is not well underſtood, and which admits of no deviation.

The preſervation of the virtues of coffee, particularly when it is of a fine quality, and exempt from rankneſs, as has been ſaid, depends on carefully confining it after it has been roaſted ; and not powdering it until the time of uſing it, that the volatile and ethereal principles, generated by the fire, may not eſcape. But all this will ſignify nothing, and the beſt materials will be uſeleſs, unleſs the following important admonition is ſtrictly attended to ; which is, that after the liquor is made, it ſhould be bright and clear, and entirely exempt from the leaſt cloudineſs or foul appearance, from a ſuſpenſion of any of the particles of the ſubſtance of the coffee.

There is ſcarcely any vegetable infuſion or decoction whoſe effects differ from its groſs origin more than that of which we are ſpeaking. Coffee taken in ſubſtance cauſes oppreſſion at the ſtomach, heat, nauſea, and indigeſtion : conſequently a continued uſe of a preparation of it, in which any quantity of its ſubſtance is contained, beſides being diſguſting to the palate, muſt tend to produce the ſame indiſpoſitions. The reſiduum of the roaſted berry, after its virtues are extracted from it, is little more than an earthy calx, and muſt therefore be injurious.

The want of attention to this circumſtance has been the cauſe of many of the complaints againſt coffee, and of the averſion which ſome people have to it ; and it is from this conſideration that coffee ſhould not be prepared with milk inſtead of water, nor ſhould the milk be added to it on the fire, as is ſometimes the caſe, for economical dietetic purpoſes, where only a ſmall quantity of coffee is uſed, as the tenacity of the milk impedes the precipitation of the grounds, which is neceſſary for the purity of the liquor, and therefore neither the milk nor the ſugar ſhould be added until after it is made with water in the uſual way, and the clarification of it is completed (A).—The milk ſhould be hot when added to the liquor of the coffee, which ſhould alſo be hot, or both ſhould be heated together, in this mode of uſing coffee as an article of ſuſtenance.

If a knowledge of the principles of coffee, founded on examination and various experiments, added to obſervations made on the extenſive and indiſcriminate uſe of it, cannot authoriſe us to attribute to it any particular quality unfriendly to the human frame ; if the unerring teſt of experience has confirmed its utility, in many countries, not excluſively productive of thoſe inconveniences, habits, and diſeaſes, for which its peculiar properties ſeem moſt applicable—let thoſe properties be duly conſidered ; and let us reflect on the ſtate of our atmoſphere, the food and modes of life of the inhabitants, and the chronical infirmities which derive their origin from theſe ſources, and it will be evident what ſalutary effects might be expected from the general dietetic uſe of coffee in Great Britain.

COFFER-DAMS, or *Batardeaux*, in bridge-building, are encloſures formed for laying the foundation of piers, and for other works in water, to exclude the ſurrounding water, and ſo prevent it from interrupting the workmen.

COLCHESTER, the chief town in Eſſex, is deſcribed in the Encyclopædia Britannica ; but the deſcription is in many reſpects erroneous. The following account of it was ſent to us by an obliging correſpondent, who is deſirous that the place of his nativity may be accurately deſcribed in this Supplement.

Colcheſter is pleaſantly ſituated upon an eminence, gradually riſing on the ſouth ſide of the river Colne. It is the ancient *Colonia Camulodunum*, from which word Colonia, both the town and the river Colne received their names. The Saxons called it *Colneceaſter*. That it flouriſhed under the Romans, ſeveral buildings full of their bricks, and innumerable quantities of coin

---

(A) It is not to coffee alone that this reflection is confined ; every article we uſe as a diluter demands the ſame attention. Malt liquors, particularly ſmall beer, which in this reſpect is much neglected, ought always to be carefully fined. The fæculent matter entangled by the mucilage of the malt is hurtful to digeſtion, and detrimental to health.

dug up in and about it, fully evince. In the year 1763, a curious teſſellated or moſaic pavement was found in the garden of the late Mr Barnard, ſurgeon in the High Street, now the property of Mr John Wallis, about three feet under the ſurface of the earth. The emperor Conſtantine the Great was born here, his mother Helen being daughter of Cool, governor or king of this diſtrict under the Romans. She is ſaid to have found out the croſs of Chriſt at Jeruſalem; and on that account the arms of this town are a croſs regulee between three ducal coronets, two in chief and one in baſe, the coronet in baſe paſſing through the croſs.

The walls wherewith the town was encompaſſed are ſtill tolerably entire on the ſouth, eaſt, and weſt ſides, but much decayed on the north ſide: they are generally about nine feet thick. By a ſtatute of King Henry VIII. this town was made the ſee of a ſuffragan biſhop.

This town is the moſt noted in England for making of baize; it is alſo of ſpecial note for candying the eringo roots, and for oyſters.

In the concluſion of the civil war 1648, this town ſuffered a ſevere ſiege of ten weeks; and the beſieged making a very reſolute defence, the ſiege was turned into a blockade, wherein the garriſon and inhabitants ſuffered the utmoſt extremity of hunger, being reduced to eat horſe-fleſh, dogs, and cats, and were at laſt obliged to ſurrender at diſcretion, when their two valiant chief officers, Sir Charles Lucas and Sir George Liſle, were ſhot under the caſtle walls in cold blood. Colcheſter is a borough by preſcription, and under that right ſends two members to parliament, all their charters being ſilent upon that head. The charter was renewed in 1763. The town is now governed by a mayor, recorder, 12 aldermen, 18 aſſiſtants, and 18 common-council men. Quarter-ſeſſions are held here four times in the year.

The famous abbey gate of St John is ſtill ſtanding, and allowed to be a ſurpriſing, curious, and beautiful piece of Gothic architecture, great numbers of perſons coming from remote parts to ſee it. It was built, together with the abbey, in 1097, and Gudo, ſteward to King William Rufus, laid the firſt ſtone.

St Ann's chapel, ſtanding at the eaſt end of the town, is valuable in the eſteem of antiquarians as a building of great note in the early days of Chriſtianity, and made no ſmall figure in hiſtory many centuries paſt. It is now pretty entire.

St Botoph's priory was founded by Ernulphus in the reign of Henry I. in the year 1110. It was demoliſhed in the wars of Charles I. by the parliament army under Sir Thomas Fairfax. The ruins ſtill exhibit a beautiful ſketch of ancient maſonry, much admired by the lovers of antiquities. The caſtle is ſtill pretty entire, and is a magnificent ſtructure, in which great improvements have of late been made. Here is an excellent and valuable library.

The markets, which are on Wedneſday and Saturday, are very well ſupplied with all kinds of proviſions. There are no leſs than ſix diſſenting meeting-houſes in this town. Colcheſter is 51 miles from London. It had 16 pariſh churches, in and out of the walls, but now only 12 are uſed, the reſt being damaged at the ſiege in 1648.

COLOURS. See Pigments in this Supplement.

Accidental Colours, a name given to a very curious optical phenomenon, which was firſt, we believe, attended to by Buffon. That philoſopher wrote a ſhort paper on it, which was publiſhed in the Memoirs of the Academy of Sciences for the year 1743.

If a perſon look ſtedfaſtly and for a conſiderable time at a ſmall *red* ſquare painted upon *white* paper, he will at laſt obſerve a kind of green-coloured border ſurround the red ſquare. If he now turn his eyes to ſome other part of the paper, he will ſee an imaginary ſquare of a delicate green bordering on blue, and correſponding exactly in point of ſize with the red ſquare. This imaginary ſquare continues viſible for ſome time, and indeed does not diſappear till the eye has viewed ſucceſſively a number of new objects. It is to this imaginary ſquare that the improper name of *accidental colour* has been given. If the ſmall ſquare be *yellow*, the imaginary ſquare or accidental colour is blue: the accidental colour of green is red; of blue, yellow; of white, black; and on the contrary, that of black is white.

The firſt perſon, as far as we know, who gave a ſatisfactory explanation of theſe phenomena was Profeſſor Scherffer of Vienna, whoſe diſſertation, tranſlated by Mr Bernoulli, has been publiſhed in the 26th volume of the Journal de Phyſique.

In order to underſtand theſe phenomena, let us recollect, in the firſt place, that light conſiſts of ſeven rays, namely, red, orange, yellow, green, blue, indigo, violet; that whiteneſs conſiſts in a mixture of all theſe rays: and that thoſe bodies which reflect but very little light are black. Thoſe bodies that are of any particular colour, reflect a much greater quantity of the rays which conſtitute that particular colour than of any other rays. Thus red bodies reflect moſt red rays; green bodies, moſt green rays, and ſo on.

Let us recollect, in the ſecond place, that when two impreſſions are made at the ſame time upon any of our organs of ſenſation, one of which is ſtrong and the other weak, we only perceive the former. Thus if we examine by the priſm the rays reflected by a red roſe, we ſhall find that they are of four kinds; namely red, yellow, green, and blue. In this caſe, the impreſſion made by the red rays makes that made by the others quite inſenſible. For the ſame reaſon, when a perſon goes from broad day light into an ill-lighted room, it appears to him at firſt perfectly dark, the preceding ſtrong impreſſion rendering him for ſome time incapable of feeling the weaker impreſſion.

With the aſſiſtance of theſe two remarks, it will not be difficult to explain the phenomena of accidental colours. When a perſon conſiders attentively for ſome time a white ſquare lying on any black ſubſtance (paper for inſtance), it is evident that the part of the retina on which the white ſquare is painted, receives a ſtronger impreſſion than any other part; at leaſt the greateſt number of rays ſtrike upon it. A weaker impreſſion, therefore, will act on it with much leſs force than upon the reſt of the retina. Conſequently, when the eye is turned from the white ſquare to ſome other part of the black paper, a ſquare is perceived of the ſame ſize with the white ſquare, and much blacker than any other part of the paper: this is evidently in conſequence of the weaker impreſſion made by the rays reflected by the black paper upon that part of the eye previouſly fatigued by the copious reflection from the white ſquare. For the very ſame reaſon, if, after looking for a ſufficient

cient time at a white ſquare lying on a black ground, we turn our eyes upon a ſheet of white paper, we perceive a very well defined black ſquare. In this caſe, the part of the retina already fatigued is not ſo ſenſible to the rays reflected by the white paper as the other parts of it which have not been fatigued. The reaſon then that *black* is the accidental colour of white is ſufficiently evident.

On the contrary, when we look a ſufficient time at a black ſquare lying upon a white ground, if we turn our eyes to any other part of the white paper, or even upon black paper, we ſhall perceive a ſmall ſquare anſwering to the black ſquare, and much brighter than any other part of the paper: evidently becauſe that part of the retina on which the black ſquare was painted being leſs fatigued is more ſuſceptible of impreſſions than any other part of the eye. Thus we ſee why the accidental colour of black is white, and why that of white on the contrary is black. Theſe facts, indeed, have been long known, and they have been generally explained in this manner.

When a perſon has looked for a ſufficient time at a red ſquare placed on a ſheet of white paper, and then turns his eyes to another part of the paper, that part of the retina on which the red was painted being fatigued, the red rays reflected from the white paper ceaſe to make any ſenſible impreſſion on it, and conſequently there will be ſeen upon the white paper a ſquare ſimilar to the red ſquare, and the colour of which is that which would reſult from the mixture of all the rays of light except the red. In general, therefore, the *accidental colour* is the colour which reſults from the mixture of all the rays of light, thoſe rays excepted which are the ſame with the primitive colour.

Now, in order to diſcover the accidental colours, let us recollect the manner which Newton employed to determine the colour which reſults from the mixture of ſeveral others, the ſpecies and quantity of which are known. He did it by dividing the circumference of a circle, ſo that the arches are to one another in the proportion of a ſtring ſhortened by degrees, in order to ſound one after another the notes of an octave; which is nearly the proportion that the different rays occupy when light is decompoſed by means of the priſm. Or ſuppoſe the circumference of the circle, as uſual, divided into 360 degrees, the different rays, according to Benvenut, ſhould occupy the following arches:

Red, - - - - -	45°
Orange, - - - -	27
Yellow, - - - - - -	48
Green, - - - - -	60
Blue, - - - - -	60
Indigo, - - - - -	40
Violet, - - - - -	80

Let us now compare the action of colours on one another with that of different weights; and for that purpoſe let us ſuppoſe each colour concentrated in the centre of gravity of its arch. In order to find the colour reſulting from any mixture, we have only to find the common centre of gravity of the arches which repreſent the different colours: The colour reſulting from the mixture will be that of the arch to which the common centre of gravity approaches neareſt. And if that common centre of gravity is not in the ſtraight line which joins the centre of the circle, and the centre of gravity of the arch to which it is moſt contiguous, the reſulting colour will approach more or leſs to the colour of the contiguous arch towards which the line, paſſing through the centre of the circle, and the common centre of gravity of the arches, falls. And farther, the reſulting colour will be more or leſs deep according to the diſtance of the common centre of gravity from the centre of the circle.

In the caſe under conſideration at preſent, namely, to determine the different accidental colours, the application of this method is remarkably eaſy; becauſe only one of the ſeven primitive colours is excluded, and conſequently the ſix colours from the mixture of which we wiſh to know the reſulting colour are all contiguous. For it is evident, that the ſum of the ſix arches, repreſenting theſe ſix colours, will be divided into two equal parts by the line which paſſes through the centre of the circle and their common centre of gravity; and that if the ſame line be produced till it reaches the circumference of the circle on the other ſide, it will alſo divide the arch repreſenting the ſeventh or omitted colour into two equal parts. Let us ſuppoſe, for inſtance, that the violet is omitted, and that we wanted to know the colour reſulting from the mixture of the other ſix colours, we have only to biſect the arch repreſenting the violet, and from the point of ſection to draw a diameter to the circle, the arch of the circle oppoſite to the violet through which the diameter paſſes will indicate the colour of the mixture. The arch repreſenting the violet being 80°, let us take the half of it, which is 40°, and let us add to it 45° for the red, 27° for the orange, and 48° for the yellow, we ſhall have 160°, which wants 20° of half the circumference of the circle. If now we add the 60° for the green, the ſum total will be 220°, conſiderably more than half the circumference; conſequently the common centre of gravity is neareſt the green arch; but it falls 10° nearer the yellow than the ſtraight line which joins the centre of the circle and the centre of gravity of the green arch. Hence we ſee that the reſulting colour will be green, but that it will have a ſhade of yellow.

It is evident, then, that the accidental colour of violet muſt be green with a ſhade of yellow; and this is actually the caſe, as any one may convince himſelf by making the experiment.

Suppoſe, now, we wanted to know the accidental colour of *green*, or, which is the ſame thing, the colour reſulting from the mixture of all the primitive rays except the green. The green arch is 60°, the half of which is 30°; if to this we add 60° for the blue arch, and 40° for the indigo arch, we ſhall have 130°, or 50° degrees leſs than a ſemicircle. If to this we add the violet arch, which is 80°, we ſhall have 30° more than the ſemicircle; conſequently the common centre of gravity falls neareſt the violet, and it is 10° nearer the red arch than is the centre of gravity of the violet arch. Hence we know that the accidental colour of green will be violet or purple, with a ſhade of red: And experiment confirms this.

Buffon obſerved that the accidental colour of blue was reddiſh and pale. Let us ſee whether we ſhall obtain the ſame reſult from our method. Let us ſuppoſe that Buffon employed a light blue. In that caſe, if to 30, the half of the blue arch, we add 60 for the green, 48 for the yellow, and 27 for the orange, we ſhall have 165°, or 15° leſs than half the circumference of the circle:

circle: Conſequently the common centre will fall neareſt the red arch, but within 15° of the orange. The accidental colour muſt therefore be red, with a ſhade of orange; or, which is the ſame thing, it muſt be a pale red.

In the ſame manner we may diſcover, that the accidental colour of indigo is yellow, inclining a good deal to orange; and that the accidental colour of indigo and blue together is orange, with a ſtrong ſhade of red. Both of which correſpond accurately with experiment.

It would be eaſy to indicate, in the ſame manner, the accidental colour of any primitive colour, if what has been ſaid were not ſufficient to explain the cauſe of accidental colours, and to ſhow that their phenomena correſpond exactly, both with the Newtonian theory of optics, and with what we know to be laws of our ſenſations in other particulars.

From the theory above given, which is that of Profeſſor Scherffer, the following conſequences may be deduced: 1. The accidental colour of a red ſquare, lying upon a white or a black ground, ought to be blackiſh, if we caſt our eyes upon a red coloured ſurface. 2. If the ſurface upon which we look at a red ſquare be itſelf coloured, if it be yellow, for inſtance, the white paper upon which we afterwards caſt our eyes will appear blue, with a green ſquare in it correſponding to the original red ſquare. And, in general, we ought to perceive the accidental colour of the ground on which the ſquare is placed, as well as the ſquare itſelf. 3. If while we are looking at the little ſquare we change the ſituation of the eye, ſo that its image ſhall occupy a different place on the retina, when we turn our eyes to the white paper we ſhall ſee two ſquares, or at leaſt one unlike the figure of the original one. 4. If the white paper on which we look be farther diſtant than the little ſquare was, the imaginary ſquare will appear conſiderably larger than the true one. 5. If while we are looking at the little ſquare, we gradually make the eye approach to it, without altering its ſituation, the imaginary ſquare will appear with a pale border. Theſe, and many other conſequences that might eaſily be deduced, will be found to take place conſtantly and accurately, if any one chooſes to put them to the teſt of experiment; and therefore may be conſidered as a complete confirmation of the theory given above of the cauſe of accidental colours.

There is another circumſtance reſpecting accidental colours which deſerves attention. If we continue looking ſtedfaſtly at the little ſquare longer than is neceſſary, in order to perceive its accidental colour, we ſhall at laſt ſee its border tinged with the accidental colour of the ground on which the ſquare is lying. For inſtance, if a white ſquare be placed upon blue paper, its border becomes yellow; if upon red paper, it becomes green; and it becomes reddiſh upon green. In like manner, the border of a yellow ſquare becomes greeniſh upon a red ground, and that of a red ſquare on a green ground becomes purple.

The cauſe of this phenomenon ſeems to depend upon the contraction and extenſion of the image of the ſquare painted on the retina. We know for certain, that the diameter of the pupil changes during our inſpecting the ſquare; at firſt it becomes leſs, and afterwards increaſes. And though we cannot ſee what paſſes in the bottom of the eye, we can ſcarcely doubt that ſimilar movements are going on there, if we attend to the changes that are continually taking place in the border of our little ſquare; ſometimes it is large, ſometimes ſmall; at one time it diſappears altogether, and the next moment makes its appearance again.

There is another phenomenon connected with accidental colours, which it is not ſo eaſy to explain; namely, that if we look at theſe little ſquares for a very long time, till the eye is very much fatigued, their accidental colours will appear even after we ſhut our eyes. The very ſame thing takes place if we attempt to look at a very luminous object; as the ſun, for inſtance. Profeſſor Scherffer thinks that this may be partly owing to the light which ſtill paſſes through the eye-lids. That ſome light paſſes through the eye-lids is evident, becauſe when we look towards a ſtrong light with our eye-lids ſhut, we ſee diſtinctly their colour, derived from the blood-veſſels with which they are filled; and if we paſs our finger before our eyes, we ſee the ſhadow of the finger though our eye-lids be ſhut, provided our eyes be turned towards the window. But that this light is not ſufficient to explain the phenomenon in queſtion is evident from this circumſtance, that the ſame accidental colours make their appearance though we go immediately into the darkeſt place. Perhaps we have accounted for the phenomenon elſewhere (See Metaphysics, *Encycl.* n° 54.) We paſs over the other conjectures of Profeſſor Scherffer, which are exceedingly ingenious, but not ſufficiently ſupported by facts to be admitted.

COLUMBA Noachi, *Noah's Dove*, a ſmall conſtellation in the ſouthern hemiſphere, conſiſting of 10 ſtars.

COMAR, or Khomar, a Zemindar's demeſne of land.

COMBUSTION is an operation of nature, which, though of the higheſt importance, ſeems not to have attracted much of the attention of philoſophers previous to the ſeventeenth century. Since that period indeed, the labours of Bacon and Boyle, and Hooke and Mayow, together with thoſe of Stahl and Lavoiſier, have thrown much light on the ſubject; as the reader will find by conſulting the articles Chemistry both in this Supplement and in the Encyclopædia. The theory of Lavoiſier is by far the moſt rational that has yet been offered to the public, and places its author in the firſt ranks of philoſophy. He corrects the errors of his predeceſſors, and has advanced before them one very important ſtep; but, as we have elſewhere obſerved, many new ſteps are ſtill wanting to render his theory of combuſtion complete. It explains indeed, in a ſatisfactory manner, why, during the proceſs of combuſtion, the burning body gradually waſtes away; but it gives no explanation of the conſtant emiſſion of heat and light, though a circumſtance as worthy of attention as the waſting of the body.

The emiſſion of light and heat the French chemiſts ſeem indeed to have conſidered as of no importance; for rather than acknowledge that the theory of their juſtly admired and ill-fated aſſociate is incomplete, they have choſen to give a new meaning to the word *combuſtion;* and to make it ſignify the *combination of a body with oxygen*, whether during that proceſs light and heat be evolved or not. Surely ſuch conduct is unphiloſophical; and yet our own chemiſts, with a ſervility which ill becomes the countrymen of Bacon and Newton,

ton, have, for the moſt part, acquieſced in this abſurd definition of combuſtion.

From the claſs of idolaters of the ſcience of the *great nation* muſt be excepted Dr Thomſon, the author of the article CHEMISTRY in this Supplement. Senſible that *combuſtion*, in the ſenſe uſually affixed to that word, denotes a phenomenon very different from many of thoſe which are included under the term in its new acceptation, he acknowledges the theory of Lavoiſier to be defective; but influenced by that diffidence which is the inſeparable attendant on the ſpirit of true philoſophy, he has not ventured to complete it in the article to which we have referred. He has indeed formed a theory of his own, and ſubmitted it to public diſcuſſion; but, with great propriety, gives it no place in his Syſtem of the Science, till it ſhall have undergone the examination of other chemiſts.

The conductor of this work, however, perſuaded that, while gratifying his readers in general, he ſhall not injure his friend's fame, embraces with pleaſure the opportunity afforded him, by a new edition, of laying before them a conciſe view of this very ingenious theory.

Dr Thomſon, then, admitting the truth and accuracy of the Lavoiſerian theory as far as it proceeds, divides the bodies which occupy the attention of chemiſts into, 1. *Combuſtibles*; 2. *Supporters of combuſtion*; and, 3. *Incombuſtiblts*.

The COMBUSTIBLES, or thoſe bodies which, in common language, are ſaid to *burn*, may be divided into, 1. *Simple* combuſtibles; 2. *Compound* combuſtibles; and, 3. Combuſtible *oxides*. *Simple* combuſtibles are, *ſulphur*, *phoſphorus*, *carbon*, *hydrogen*, and all the *metals*, except perhaps *gold*, *ſilver*, and *mercury*. *Compound* combuſtibles conſiſt of compounds formed by the ſimple combuſtibles uniting together two and two; and combuſtible *oxides* are compoſed of one or more ſimple combuſtibles combined with a doſe of *oxygen*. Theſe oxides may be arranged under two heads: viz. thoſe which containing only a *ſingle baſe* combined with oxygen, may therefore be termed *ſimple* combuſtible *oxides*; and thoſe which containing *more than one baſe*, may therefore be termed *compound* combuſtible oxides. The ſimple combuſtible oxides are only four in number; namely, *oxide of ſulphur*, *oxide of phoſphorus*, *charcoal*, and *carbonic oxide gas*. All the ſimple combuſtible oxides are by combuſtion converted into *acids*. The compound combuſtible oxides include by far the greater number of combuſtible bodies; for almoſt all the animal and vegetable ſubſtances belong to them, and the double baſe is uſually *carbon* and *hydrogen*.

The SUPPORTERS *of combuſtion* are a ſet of bodies which are not of themſelves, ſtrictly ſpeaking, capable of undergoing combuſtion, but which are abſolutely neceſſary for the proceſs. All the ſupporters known at preſent are ſix; viz. 1. *Oxygen gas*; 2. *Air*; 3. *Gaſeous oxide of azot*; 4. *Nitrous gas*; 5. *Nitric acid*; and, 6. *Oxy-muriatic acid*. There are other ſubſtances, to be mentioned afterwards, to which the author gives the name of *partial ſupporters*; but *all* ſupporters contain one common principle, namely *oxygen*.

The INCOMBUSTIBLE BODIES are neither capable of undergoing combuſtion themſelves, nor of ſupporting the combuſtion of bodies that are. Of courſe, they are not immediately connected with combuſtion; but they are noticed here, becauſe ſome of the alkalies and earths, which belong to this claſs, poſſeſs certain properties in common with combuſtibles, and are capable of exhibiting phenomena ſomewhat analogous to combuſtion; phenomena which the author deſcribes under the title of *ſemi-combuſtion*.

From the preceding obſervations it is obvious, that, in every caſe of combuſtion, there muſt be preſent a *combuſtible* and a *ſupporter*; and Lavoiſier aſcertained beyond a doubt, that, during the proceſs, the combuſtible always unites with the oxygen of the ſupporter. This new compound our author calls *a product of combuſtion*; and maintains that every ſuch product is either *water*, or an *acid*, or a *metallic oxide*. He admits, indeed, that other bodies ſometimes make their appearance during combuſtion; but affirms that theſe, upon examination, will be found neither to be products, nor to have undergone combuſtion.

But though the combination of the combuſtible with oxygen be a conſtant part of combuſtion, yet the facility with which combuſtibles burn is not in proportion to their apparent affinity for that gas. Phoſphorus, for inſtance, burns more readily than charcoal; yet charcoal is capable of abſtracting oxygen from phoſphorus. The combuſtible oxides take fire more readily than ſome of the ſimple combuſtibles. Thus, charcoal burns more eaſily than carbon or diamond; and alcohol, ether, and oils, which are all compound combuſtible oxides, are exceedingly combuſtible; whereas the metals, which are ſimple combuſtibles, do not burn, when air is the ſupporter, but at a very high temperature. This facility of burning combuſtible oxides is probably owing to the weak affinity by which their particles are united; and to the ſame cauſe, viz. the inferiority of the coheſion of heterogeneous particles, is to be attributed the fact, that ſome of the *compound ſupporters* occaſion combuſtion in circumſtances when the combuſtibles would not be acted on by *ſimple ſupporters*.

None of the *products* of combuſtion are themſelves combuſtible, in the uſual and proper acceptation of that word. This, however, is not owing to their being ſaturated with oxygen, for ſeveral of them are capable of combining with an additional doſe of it; but during this new combination no caloric nor light is ever emitted, and the compound formed differs eſſentially from a mere *product* of combuſtion, being by the additional doſe of oxygen converted into a *ſupporter*.

When the *ſupporters*, thus formed by the combination of oxygen with *products*, are made to ſupport combuſtion, they do not loſe *all* their oxygen, but only the *additional doſe* which conſtituted them ſupporters. Of courſe they are again reduced to their original ſtate of products of combuſtion; and as they owe their properties as ſupporters, not to the whole of the oxygen which they contain, but to the additional doſe, the author calls them *partial ſupporters*.

All the partial ſupporters with which we are acquainted contain a metallic baſis; for metallic oxides are the only products at preſent known capable of combining with an additional doſe of oxygen. The following oxides, which are products of combuſtion, combined each with an additional doſe of oxygen, are *partial ſupporters*: 1. Red oxide of iron; 2. Yellow oxide of gold; 3. White oxide of ſilver; 4. Red oxide of mercury; 5. Arſenic acid; 6. Red and brown oxides of lead; 7. Black oxide of manganeſe; 8. Acidulous oxide of antimony? 9. White oxide of tin.

Thus it appears that ſeveral of the products of combuſtion are capable of combining with oxygen; and hence it follows that the incombuſtibility of products is not owing to their want of affinity for oxygen, but to ſome other cauſe.

Though no *mere product* of combuſtion is capable of *ſupporting* combuſtion, this is not occaſioned by any want of affinity for combuſtible bodies; for ſeveral of theſe products are capable of combining with an additional doſe of their baſes. By this combination, however, they loſe their properties as products, and are converted into *combuſtibles;* whence it follows that the proceſs muſt differ eſſentially from that of combuſtion. Thus ſulphuric acid, a *product* of combuſtion, by combining with an additional doſe of ſulphur or its oxide, is converted into *ſulphurous acid;* a ſubſtance which, from many of its properties, Dr Thomſon concludes to be *combuſtible.* Thus alſo phoſphoric acid, a product of combuſtion, is capable of combining with phoſphorated hydrogen, and forming *phoſphorous acid*, a combuſtible body. When this laſt acid is heated in contact with a ſupporter, it undergoes combuſtion; but it is only the additional doſe of the combuſtible which burns, and the whole is converted into phoſphoric acid. Hence we ſee that it is not the whole baſis of theſe compounds that is combuſtible, but merely the additional doſe; and therefore the compounds themſelves may be termed *partial combuſtibles*, to indicate, that *part* only of the baſe is capable of undergoing combuſtion. Now, ſince the products of combuſtion are capable of combining with oxygen, but never exhibit the phenomena of combuſtion, except when they are in the ſtate of partial combuſtibles, combuſtible bodies muſt contain ſome principle, which they loſe during combuſtion, and to which they owe their combuſtibility; for after they have loſt it, they unite to oxygen without exhibiting the phenomena of combuſtion.

Though the *products* of combuſtion are not capable of *ſupporting* combuſtion, they not unfrequently part with their oxygen juſt as ſupporters do, give it out to combuſtibles, and convert them into products; but during this proceſs no heat nor light is ever evolved. Water, for inſtance, gives out its oxygen to iron, and converts it into *black oxide*, a product; and ſulphuric acid gives out its oxygen to phoſphorus, and converts it into phoſphoric acid. Thus we ſee that the oxygen of products is capable of converting combuſtibles into products, juſt as the oxygen of ſupporters; but during the combination of the laſt only are heat and light emitted. The oxygen of ſupporters, then, contains ſomething which the oxygen of products wants.

Whenever the whole of the oxygen is abſtracted from products, the combuſtibility of their baſe is reſtored as completely as before combuſtion; but no ſubſtance is capable of abſtracting the whole of oxygen, except a *combuſtible* or a *partial combuſtible*; and when this is done, the combuſtible or partial combuſtible loſes its own combuſtibility by the proceſs, and is converted into a product.

From theſe facts, which have been all eſtabliſhed by Stahl, Lavoiſier, and our author, it follows that the products of combuſtion may be formed without actual combuſtion: but in theſe caſes a *new combuſtible* is always evolved. The proceſs is merely an interchange of combuſtibility; for the combuſtible is converted into a product only by means of a product. Both the oxygen and the baſe of the product having undergone combuſtion, have loſt ſomething which is eſſential to combuſtion. The proceſs is merely a double decompoſition. The product yields its oxygen to the combuſtible, while, at the ſame time, the combuſtible gives out ſomething to the baſe of the product. The combuſtibility of that baſe, then, is reſtored by the loſs of its oxygen, and by the reſtoration of ſomething which it receives from the other combuſtible thus converted into a product.

No *ſupporter* can be produced by combuſtion, or by any equivalent proceſs. Now as all the ſupporters, except oxygen gas, conſiſt of oxygen combined with a baſe, it follows as a conſequence, that oxygen may combine with a baſe, without loſing that ingredient, whatever it is, which gives occaſion to combuſtion. The mere act of combination of oxygen with a baſe, therefore, is by no means the ſame with combuſtion.

Several of the ſupporters and partial ſupporters are capable of combining with combuſtibles, without undergoing decompoſition, or exhibiting the phenomena of combuſtion. In this manner the yellow oxide of gold, and the white oxide of ſilver, combine with ammonia; the red oxide of mercury with oxalic acid; and oxy-muriatic acid with ammonia. Thus alſo nitre and oxy-muriat of potaſh may be combined, or at leaſt intimately mixed with ſeveral combuſtible bodies, as in gunpowder, &c. In all theſe compounds the oxygen of the ſupporter retains each the ingredients proper to itſelf, which render them ſuſceptible of combuſtion; and hence the compound is ſtill combuſtible. They burn indeed with amazing facility, not only when heated, but when triturated or ſtruck ſmartly with a hammer; and have received, in conſequence, the name of *detonating* or *fulminating* bodies.

Such are the properties of the combuſtibles, the ſupporters, and the products; and ſuch the phenomena which they exhibit when made to act upon each other. If we compare together the *ſupporters* and the *products*, we ſhall find that they reſemble each other in ſeveral reſpects. Both of them contain oxygen as an eſſential part; both are capable of converting combuſtibles into products; and of both ſeveral combine with combuſtibles and with additional doſes of oxygen. But they differ widely from each other in the phenomena which accompany their action on combuſtibles. The ſupporters convert theſe bodies into products; and at the ſame time combuſtion, or the emiſſion of light and heat, takes place; whereas the products convert combuſtibles into products without any ſuch emiſſion. Now as the ultimate change produced upon combuſtibles by both theſe ſets of bodies is the ſame, and as the ſubſtance which combines with the combuſtibles is in both caſes the ſame, namely oxygen, we muſt conclude that this oxygen in the ſupporters contains ſomething which the oxygen of the products wants; ſomething which ſeperates during the paſſage of the oxygen from the ſupporter to the combuſtible, and occaſions the combuſtion, or emiſſion of fire, which accompanies this paſſage. The oxygen of ſupporters, then, contains ſome ingredient

dient which the oxygen of products wants. Many circumſtances concur to render it probable that this ingredient is CALORIC.

The *combuſtibles* and the *products* alſo reſemble each other in ſeveral reſpects. Both of them contain the ſame or a ſimilar baſe; both frequently combine with combuſtibles, and likewiſe with oxygen: but they differ eſſentially in the phenomena which accompany their combination with oxygen. In the one caſe, *fire* is emitted; in the other, not. If we recollect that no ſubſtance but a combuſtible is capable of reſtoring combuſtibility to the baſe of a product, and that at its doing ſo, it always loſes its own combuſtibility; and if we recollect farther, that the baſe of the product does not exhibit the phenomenon of combuſtion even when it combines with oxygen—we cannot avoid concluding, that all combuſtibles contain an ingredient which they loſe when converted into products, and that this loſs contributes to the fire which makes its appearance during the converſion. Many circumſtances concur to render it probable that this ingredient is LIGHT.

If we ſuppoſe that the oxygen of *ſupporters* contains *caloric* as an eſſential ingredient, and that *light* is a component part of all *combuſtibles*, the phenomena of combuſtion, numerous and intricate as they are, admit of an eaſy and obvious explanation. The component parts of the oxygen of ſupporters are two; namely, 1. A *baſe*; and, 2. *Caloric*. The component parts of combuſtibles are likewiſe two; namely, 1. A *baſe*; and, 2. *Light*. During combuſtion the baſe of the oxygen combines with the baſe of the combuſtible, and forms the product; while at the ſame time the caloric of the oxygen combines with the light of the combuſtible, and the compound flies off in the form of fire. Thus combuſtion is a double decompoſition; the oxygen and combuſtible divide themſelves each into two portions, which combine in pairs; the one compound is the *product*, and the other the *fire*, which eſcapes. Hence the reaſon that the oxygen of products is unfit for combuſtion: It wants its *caloric*. Hence the reaſon that combuſtion does not take place when oxygen combines with products, or with the baſe of ſupporters: Theſe bodies contain no *light*. The caloric of the oxygen of courſe is not ſeparated, and no *fire* appears. Hence alſo the reaſon why a combuſtible alone can reſtore combuſtibility to the baſe of a product. In all ſuch caſes a double decompoſition takes place. The oxygen of the product combines with the baſe of the combuſtible, while the light of the combuſtible combines with the baſe of the product."

Such is the theory of Dr Thomſon, propoſed to the public* under the humble title of *Remarks on Combuſtion*. As the author completely eſtabliſhes the facts on which his reaſoning reſts, we can conceive to it but one plauſible objection. Why is not the caloric of the oxygen ſeparated when that gas combines with bodies deſtitute of light? That there is caloric emitted on many occaſions, when no light *appears* with it, is incontrovertible; but perhaps the matter of light is chemically combined with all bodies which emit heat, though it never flies off but when the heat is great. If this be a fact, and it is not improbable, the theory before us ſeems to be eſtabliſhed; for it not only completes the theory of Lavoiſier, but affords an eaſy ſolution to ſome phenomena which have been thought inconſiſtent with that theory.

In the year 1793, the aſſociated Dutch chemiſts drew the attention of philoſophers to a curious phenomenon which accompanies the formation of ſome of the ſulphurets. When eight parts of copper, iron, lead, tin, or zinc filings, and three parts of flowers of ſulphur, are mixed together in a glaſs receiver, and the veſſel placed upon burning coals, the mixture melts, a kind of exploſion takes place, it becomes ſuddenly red hot, and a glow, like that of a piece of red hot charcoal fanned with bellows, rapidly pervades the whole. When this diſappears, the mixture is found in the ſtate of ſolid ſulphuret of copper, or iron, &c. The experiment ſucceeds whether the veſſel be filled with air, or with azotic or hydrogen gas, or even with water or mercury. What is ſingular in this experiment is the glowing *red heat*, or the emiſſion of fire, which accompanies the combination of the ſulphur and metal. This emiſſion being the ſame which takes place during combuſtion, the proceſs has been conſidered as a combuſtion, and ſtated as ſuch, by the German chemiſts, as an objection to Lavoiſier's theory. But our author ſhews that no objection can be urged from this experiment againſt the truth of that theory as far as it goes; and that all the phenomena are fully explained by the additions which he has made to it. Thus, we have only to recollect, 1. That the ſulphur is in a melted ſtate, and therefore contains caloric as an ingredient; 2. That the metals which produce the phenomenon contain light as an eſſential ingredient; and, 3. That the ſulphuret produced is always in a ſolid ſtate—and the explanation is ſimple and obvious. The *ſulphur* combines with the *baſe* of the metal, while the *caloric*, to which the ſulphur owed its fluidity, combines with the *light* of the metal, and the compound flies off under the form of *fire*.

Thus the proceſs is exactly the ſame with combuſtion, excepting what regards the product. The melted ſulphur acts the part of the *ſupporter*, while the metal occupies the place of the *combuſtible*. The firſt furniſhes caloric, the ſecond light, while the baſes of both combine together. Hence we ſee that the baſe of ſulphurets (and the ſame thing holds of ſome phoſphurets) reſembles the baſe of products in being deſtitute of light, the formation of theſe bodies exhibiting the ſeparation of fire like *combuſtion*; but the product, differing from a product of combuſtion in being deſtitute of oxygen, our author propoſes to diſtinguiſh the proceſs by the title of *ſemi-combuſtion*, to indicate that it poſſeſſes one half of the characteriſtic marks of combuſtion, but is deſtitute of the other half.

COMPASS, or MARINER'S STEERING COMPASS, is an inſtrument of ſo great value, that every improvement of it, propoſed by men of ſcience or of experience, is entitled to notice. We ſhall therefore lay before our readers ſome obſervations on the defects of the compaſs in common uſe, which have fallen into our hands ſince the article in the Encyclopædia was publiſhed. The firſt is by Captain O'Brien Drury of the royal navy, and relates entirely to the needle.

" Experience (ſays this officer) ſhews us, that the needle of a compaſs, as well as all other magnets, whether artificial or real, perpetually loſes ſomething of its

---

* *Nicholſon's Journal*, vol. ii. ſecond ſeries.

magnetic powers, which often produces a difference exceeding a point; and I am well convinced that the great errors in ſhip-reckonings proceed more frequently from the incorrectneſs of the compaſs than from any other cauſe.

"Steel cannot be too highly tempered for the needle of a ſea-compaſs, as the more it is hardened the more permanent is the magnetiſm it receives; but, to preſerve the magnetiſm, and conſequently the polarity of the needle, I recommend to have the needle caſed with thin, well-poliſhed, ſoft iron; or elſe to have it armed at the poles with a bit of ſoft iron. I have found, from many experiments, that the caſed needle preſerved its magnetiſm in a much more perfect degree than the needle not caſed; and I have ſometimes thought that the magnetic power of the caſed needle had inreaſed, while the magnetic power of the uncaſed and unarmed needle always loſes of its polarity."

This is not an opinion taken up at random, but is the reſult of what appears to have been a fair and judicious experiment; for our author placed a caſed needle, an armed needle, and one without either caſe or armour, in a room for three months; each having at that time preciſely the ſame direction, and nearly the ſame degree of force. At the expiration of the three months, he found that the caſed needle and the armed needle had not in the leaſt changed their direction; but the other had changed two degrees, and had loſt very conſiderable of its magnetic power. If there was any change in either of the other needles, it was too inconſiderable to be perceived.

Theſe obſervations ſeem to be new, and may tend to the improvement of the compaſs. But it is not with reſpect to the needle only that this inſtrument is defective. Mr Bernard Romans of Penſacola well obſerves, that, on another account, the heavieſt braſs compaſſes now in uſe are by no means to be relied on in a hollow or high ſea. This is owing to the box hanging in two braſs rings, confining it to only two motions, both vertical and at right angles with each other; by which confinement of the box, upon any ſuccuſſion, more eſpecially ſudden ones, the card is always put into too much agitation, and, before it can well recover itſelf, another jerk prevents its pointing to the pole; nor is it an extraordinary thing to ſee the card unſhipped by the violence of the ſhip's pitching.

All theſe inconveniences are remedied to the full by giving the box a vertical motion at every degree and minute of the circle, and compounding theſe motions with a horizontal one of the box as well as of the card. By this unconfined diſpoſition of the box, the effects of the jerks on the card are avoided, and it will always very ſteadily point to the pole. "Experience (ſays our author) has taught me, that the card not only is not in the ſmalleſt degree affected by the hollow ſea, but that, in all the violent ſhocks and whirlings the box can receive, the card lies as ſtill as if in a room unaffected by the leaſt motion.

"Lately a compaſs was invented and made in Holland, which has all theſe motions. It is of the ſize of the common braſs compaſſes; the bottom of the braſs box, inſtead of being like a bowl, muſt be raiſed into a hollow cone, like the bottom of a common glaſs bottle; the vertex of the cone muſt be raiſed ſo high as to leave but one inch between the card and the glaſs; the box muſt be of the ordinary depth, and a quantity of lead muſt be poured in the bottom of the box, round the baſe of the cone; this ſecures it on the ſtile whereon it traverſes.

"This ſtile is firmly fixed in the centre of a ſquare wooden box, like the common compaſs, except that it requires a thicker bottom. The ſtile muſt be of braſs, about ſix inches long, round, and of the thickneſs of one-third of an inch; its head blunt, like the head of a ſewing-thimble, but of a good poliſh: the ſtile muſt ſtand perpendicular. The inner vertex of the cone muſt alſo be well poliſhed; the vertical part of the cone ought to be thick enough to allow of a well-poliſhed cavity, ſufficient to admit a ſhort ſtile, proceeding from the centre of the card whereon it traverſes. The compaſs I ſaw was ſo conſtructed; but I ſee no reaſon why the ſtile might not proceed from the centre of the vertex of the cone, and ſo be received by the card the common way. The needle muſt be a magnetic bar, blunt at each end; the glaſs and cover are put on in the common way."

A compaſs of this kind was ſubmitted to our author's examination by the captain of a ſloop of war, who aſſured him, that in a hard gale, which laſted ſome days, there was no other compaſs of the ſmalleſt ſervice. Mr Romans was ſatiſfied that the officer did not praiſe the apparatus more than it deſerved; and we feel ourſelves ſtrongly inclined to be of the ſame opinion.

It muſt not be concealed, however, that the ingenious Mr Nicholſon ſeems to think very differently of all ſuch contrivances. In a paper publiſhed in the ninth number of his valuable Journal, he labours to prove, that the compaſs is very little diſturbed by tilting the box on one ſide, but very much by ſudden horizontal changes of place; that a ſcientific proviſion againſt the latter is therefore the chief requiſite in a well made inſtrument of this kind; and that no other proviſion is requiſite or can eaſily be obtained, than good workmanſhip according to the common conſtruction, and a proper adjuſtment of the weight with regard to the centres or axes of ſuſpenſion. The ſame author is of opinion, that it would greatly improve the compaſs to make the needle flat and thin, and to ſuſpend it, not, as is moſt commonly done, with its flat ſide, but with its edge uppermoſt; for it being a well-known fact, that ſoft ſteel loſes its magnetiſm ſooner than hard, it is obvious, that unleſs both ſides of a needle be equally hard (which is almoſt impoſſible if they be diſtant from each other), the magnetic power will, in proceſs of time, deviate towards the harder ſide.

The Chineſe COMPASS has ſome advantages over the European compaſs, from which it differs with reſpect to the length of the needle, and the manner in which it is ſuſpended. In the compaſs of China, the magnetic needle is ſeldom above an inch in length, and is leſs than a line in thickneſs. It is poiſed with great nicety, and is remarkably ſenſible, or, in other words, points ſteadily towards the ſame portion of the heavens. This ſteadineſs is accompliſhed by the following contrivance: "A piece of thin copper is ſtrapped round the centre of the needle. This copper is rivetted by its edges to the upper part of a ſmall hemiſpherical cup, of the ſame metal, turned downwards. The cup ſo inverted ſerves as a ſocket to receive a ſteel pivot riſing from a cavity made into a round piece of light wood or cork, which thus forms the compaſs-box. The ſurfaces of the ſocket and pivot, intended to meet each other, are perfectly poliſhed, to avoid, as much as poſſible, all friction. The cup has a proportionably broad margin, which, beſide adding to its weight, tends, from its horizontal poſition, to keep the centre of gravity, in all ſituations of the compaſs, nearly in coincidence with the centre of ſuſpenſion. The cavity, in which the needle is thus ſuſpended, is in form circular, and is little more than ſufficient to remove the needle, cup, and pivot. Over this cavity is placed a thin piece of tranſparent talc, which prevents the needle from being affected by any motion of the external air; but permits the apparent motion of the former to be eaſily obſerved. The ſmall and ſhort needle of the chineſe has a material advantage over thoſe of the uſual ſize in Europe, with regard to the inclination or dip towards the horizon; which, in the latter, requires that one extremity of the needle ſhould be made ſo much heavier than the other as will counteract the magnetic attraction. This being different in different parts of the world, the needle can only be accurately true at the place for which it had been conſtructed. But in ſhort and light needles, ſuſpended after the Chineſe manner, the weight below the point of ſuſpenſion is more than ſufficient to overcome the magnetic power of the dip or inclination in all ſituations of the globe; and therefore ſuch needles will never deviate from their horizontal poſition."

COMPLEMENT, in general, is what is wanting, or neceſſary, to complete ſome certain quantity or thing.

Arithmetical COMPLEMENT, is what a number or logarithm wants of unity or 1 with ſome number of cyphers. It is beſt found by beginning at the left hand ſide, and ſubtracting every figure from 9, except the laſt, or right hand figure, which muſt be ſubtracted from 10. So, the arithmetical comp. of the log. 9·5329714,
by ſubtracting from 9's, &c. is 0·4670286.

The arithmetical complements are much uſed in operations by logarithms, to change ſubtractions into additions, which are more conveniently performed, eſpecially when there are more than one of them in the operation.

COMPLEMENT, in aſtronomy, is uſed for the diſtance of a ſtar from the zenith; or the arc contained between the zenith and the place of a ſtar which is above the horizon. It is the ſame as the complement of the altitude, or co-altitude, or the zenith diſtance.

COMPLEMENT *of the Courſe*, in navigation, is the quantity which the courſe wants of 90°, or 8 points, viz. a quarter of the compaſs.

COMPLEMENT *of the Curtain*, in fortification, is that part of the anterior ſide of the curtain which makes the demigorge.

COMPLEMENT *of the Line of Defence*, is the remainder of that line, after the angle of the flank is taken away.

COMPLEMENTS *of a Parallelogram*, or *in a Parallelogram*, are the two leſſer parallelograms, made by drawing two right lines parallel to each ſide of the given parallelogram, through the ſame point in the diagonal.

COMPLEMENT *of Life*, a term much uſed, in the doctrine of life annuities, by De Moivre; and, according to him, it denotes the number of years which a given life wants of 86, this being the age which he conſidered as the utmoſt probable extent of life. So 56 is the complement of 30, and 30 is the complement of 56.

COMPOSITION OF PROPORTION, according to the 15th definition of the 5th book of Euclid's Elements, is when, of four proportionals, the ſum of the firſt and ſecond is to the ſecond, as the ſum of the third and fourth is to the fourth.

COMPOSITION *of Ratios*, is the adding of ratios together: which is performed by multiplying together their correſponding terms, viz. the antecedents together, and the conſequents together, for the antecedent and conſequent of the compound ratio; like as the addition of logarithms is the ſame thing as the multiplication of their correſponding numbers. Or, if the terms of the ratios be placed fraction-wiſe, then the addition or compoſition of the ratios is performed by multiplying the fractions together.

COMPOUND INTEREST. See ALGEBRA, *Encycl.* and *Compound* INTEREST in this *Supplement*.

CONCEPTION, a city of Chili in South America, was viſited in 1786 by the celebrated, though unfortunate, navigator La Perouſe, who gives an account of ſome particulars relating to it very different from what we have given of it under the article CONCEPTION, *Encycl.* So far are the Spaniards from living in ſecurity with reſpect to the Indians, that, according to him, they are under continual alarms of being attacked by thoſe bold and enterpriſing ſavages. "The Indians of Chili (ſays he) are no longer thoſe Americans who were inſpired with terror by European arms. The increaſe of horſes, which are diſperſed through the interior of the immenſe deſerts of America, and that of oxen and ſheep, which has alſo been very great, have converted theſe people into a nation of Arabs, in every thing reſembling thoſe who inhabit the deſerts of Arabia. Conſtantly on horſeback, they conſider an excurſion of two hundred leagues as a very ſhort journey. They march accompanied by their flocks; feed upon their fleſh and milk, and ſometimes upon their blood; and cover themſelves with their ſkins, of which they make helmets, cuiraſſes, and bucklers. All their old cuſtoms are laid aſide. They no longer feed upon the ſame fruits, nor wear the ſame dreſs; but have a more ſtriking reſemblance to the Tartars, or to the inhabitants of the banks of the Red Sea, than to their anceſtors, who lived two centuries ago. So deciſive an influence has the introduction of two domeſtic animals had upon the manners of that once timid people. It is eaſy to conceive what formidable enemies they muſt now be to the Spaniards; for ſuppoſing them defeated in battle, how is it poſſible to follow them in ſuch long excurſions? How is it poſſible to prevent aſſemblages, which bring together in a ſingle point nations ſcattered over 400 leagues of country, and thus form armies of 30,000 men?"

Of theſe people M. Rollin, ſurgeon-major of the frigate *la Buſſale*, gives the following phyſiological particulars: "They are, in general (ſays he), of lower ſtature, and leſs robuſt, than Frenchmen, though they endure with great courage the fatigues of war and all its attendant privations. There is a great ſameneſs in the phyſiognomy of moſt individuals. The face is larger and rounder than that of Europeans. The features are more ſtrongly marked. The eyes are ſmall, dull, black, and deeply ſeated. The forehead is low; the eyebrows black and ſhaggy; the noſe ſhort and flattened; the cheek-bones high; the lips thick; the mouth wide;

and the chin diminutive. The women are ſhort, ill-made, and with diſguſting countenances. Both men and women bore their noſe and ears, which they adorn with glaſs or mother-of-pearl trinkets. The colour of their ſkin is a reddiſh brown: That of their nails is ſimilar, but not ſo deep. The hair of both is black, coarſe, and very thick. The men have little beard; but their arm-pits and parts of ſex are well furniſhed with hair, which parts, in moſt of the women, have none."

The military governor of Conception, who was an Iriſhman, returned, while M. de la Perouſe was there, from the frontiers of the Spaniſh ſettlements, where he had juſt concluded a glorious peace with the Indians. This peace was highly neceſſary to the people of his government, whoſe diſtant habitations were expoſed to the inroads of ſavage cavalry, whoſe practice it is to maſſacre the men and children, and to make the women priſoners. This amiable man, whoſe name was *Higguins* (probably *Higgins*), had ſucceeded in gaining the good-will of theſe ſavages, and thereby rendered the moſt ſignal ſervice to the nation that had adopted him. For while the Indians and Spaniards are at variance, an alliance with the former by any of the maritime powers of Europe would become ſo formidable to the latter, as to induce them, for fear of their lives, to abandon their ſettlements in Chili, and retire to Peru. This was clearly ſeen by *Monneron* the engineer on the expedition, who, with the true ſpirit of a Frenchman, pointed out to his government the method of wreſting from its moſt faithful ally one of the moſt valuable provinces of the Spaniſh empire.

La Perouſe deſcribes the common people of Conception as much addicted to thieving, and the women as exceedingly eaſy of acceſs. "They are a degenerated and mongrel race (ſays he); but the inhabitants of the firſt claſs, the true bred Spaniards, are polite and obliging in the extreme. The biſhop was a man of great ſenſe, of agreeable manners, and of a charity of which the Spaniſh prelates afford frequent examples." He was a Creole, and had never been in Europe. Of the monks our author gives a very different character. "The misfortune (ſays he) of having nothing to do, the want of family ties, the profeſſion of celibacy, without being ſeparated from the world, and their living in the convenient retirement of their cells, has rendered, and could not fail to render, them the greateſt profligates in America. Their effrontery is inconceivable. I have ſeen ſome of them ſtay till midnight at a ball; aloof, indeed, from the good company, and ſeated among the ſervants. Theſe ſame monks gave our young men more exact information than they could get elſewhere, concerning places with which prieſts ought to have been acquainted only in order to interdict the entrance."

M. de la Perouſe repreſents that part of Chili, which is called *the Biſhopric of Conception*, as one of the moſt fertile countries in the univerſe. Corn yields ſixty to one; the vineyards are equally productive; and the plains are covered with innumerable flocks, which, tho' left to themſelves, multiply beyond all imagination. Yet this colony is far from making the progreſs that might be expected from a ſituation ſo favourable to an increaſe of population. The influence of the government inceſſantly counteracts the climate and the ſoil. Prohibitory regulations exiſt from one end of Chili to the other; and this kingdom, of which the productions, if carried to their higheſt pitch, would feed the half of Europe; of which the wool would ſuffice for the manufactures of Great Britain and France, even when manufactures flouriſhed in the latter country; and of which the cattle, if ſalted down, would produce an immenſe revenue—is entirely deſtitute of commerce, and its inhabitants ſunk in ſloth and indolence. Unleſs, therefore, Spain change its ſyſtem entirely, Chili will never reach that pitch of proſperity which might be expected from its ſituation and fertility. For the latitude and longitude of Conception, ſee *Encycl.*

CONDORCET (Jean-Antoine Nicolas Caritat de), was born at Ribemont in Picardy, the 17th of September 1743, of a noble and very ancient family. At the age of 15 he was ſent to ſtudy philoſophy at the college of Navarre, and had the good fortune to fall into the hands of an able profeſſor, who has ſince diſtinguiſhed himſelf by his geometrical works. The young Condorcet had no reliſh for the buſineſs of the firſt courſe, for the quibbles of ontology and pneumatology, and all the wretched appendages of ſchool metaphyſics: But in the following year, his ſtudies, being directed to the mathematical and phyſical ſciences, were entirely congenial to his taſte; and though there were upwards of 120 ſcholars, he diſtinguiſhed himſelf above them all. At Eaſter he held a public theſis, at which Clairaut, D'Alembert, and Fontaine, aſſiſted. He now returned home, but continued to cultivate geometry. To enjoy more opportunities of improvement, he removed in 1762 to Paris; where he attended the chemical courſe of Macquer and Beaumé, and frequented the literary ſocieties which D'Alembert had formed at the houſe of Mademoiſelle de Leſpinaſſe.

In 1765, when only 22 years old, he publiſhed a work on the Integral Calculus, which diſcovered vaſt extent and originality of views. Condorcet was already numbered with the foremoſt mathematicians in Europe. "There was not (ſays La Lande) above ten of that claſs; one at Peterſburgh, one at Berlin, one at Baſle, one at Milan, and five or ſix at Paris; England, which had ſet ſuch an illuſtrious example, no longer produced a ſingle geometer that could rank with the former." It is mortifying to us to confeſs that this remark is but too much founded in truth. We doubt not but there are in Great Britain at preſent mathematicians equal in profundity and addreſs to any who have exiſted ſince the illuſtrious Newton; but theſe men are not known to the learned of Europe, becauſe they keep their ſcience to themſelves. They have no encouragement, from the taſte of the nation, to publiſh any thing in thoſe higher departments of geometry which have ſo long occupied the attention of the mathematicians on the continent.

In 1767 Condorcet publiſhed his ſolution of the problem of three bodies; and in the following year, the firſt part of his Analytical Eſſays; in which he entered very profoundly into thoſe arduous queſtions. He was received into the academy on the 8th of March 1769; and from that time till 1773 he enriched their annual volumes with memoirs on infinite ſeries, on partial and finite differences on equations of condition, and on other objects of importance in the higher calculus. It muſt be regretted, that he indulged ſpeculation perhaps to exceſs; the methods that he propoſes for integration

gration are ſometimes of a nature ſo extremely general, as to refuſe to be accommodated to practice. Proſecuting thoſe reſearches for ſeveral years longer, he compoſed an ample Treatiſe on the Integral Calculus, in five parts, compriſing the doctrines and their application. It was afterwards copied out for the preſs in 1785 by Keralio, formerly governor to the Infant of Parma. Only 128 pages were printed; but the manuſcript ſtill exiſts; as does that of an elementary Treatiſe on Arithmetic. It is to be hoped that both of theſe will yet be given to the public.

His attention was not, however, entirely abſorbed in thoſe recondite ſtudies. He publiſhed about this time an anonymous pamphlet, intitled *A Letter to a Theologian;* in which he replied with keen ſatire to the attacks made by the author of the *Three Centuries of Literature* againſt the philoſophical ſect. "But (ſubjoins the prudent La Lande) he puſhed the matter ſomewhat too far; for, admitting the juſtneſs of his ſyſtem, it was more prudent to confine within the circle of the initiated thoſe truths which are dangerous for the multitude, who cannot replace by ſound principles what they would loſe of fear, of conſolation, and of hope." Condorcet was now leagued with the atheiſts; and *La Lande*, who wiſhes well to the ſame ſect, cenſures not his principles, but only regrets his raſhneſs. He was indeed, as Mr Burke obſerved, a fanatic atheiſt and furious democratic republican.

On the 10th of June 1773 he was made ſecretary of the academy of ſciences; and that important truſt he diſcharged through the reſt of his life with great ability and uncommon reputation. The duties of his office required him to write the lives of the deceaſed academicians, which he performed with diligence, judgment, and univerſal applauſe: And what ſpecies of compoſition is capable of being rendered ſo extenſively uſeful as biography? In the moſt inſinuating form it conveys inſtruction; and, beſtowing vitality and action on the rules of conduct and on the leſſons of virtue, it fires the breaſt with the nobleſt emulation. The life of a philoſopher muſt alſo include a portion of the hiſtory of ſcience. We there trace the ſucceſſive ſteps which led to diſcoveries, and learn to eſtimate the value of thoſe acquiſitions by the efforts that were made, and the obſtacles that were ſurmounted. The literati of France have long excelled in the compoſition of *Eloges:* but thoſe of Condorcet are of a very ſuperior caſt. Replete with information and genuine ſcience, they maintain a dignified impartiality, and diſplay vigour of imagination, with boldneſs and energy of ſtyle. The intrepidity (ſay his Panegyriſts) with which he uttered the ſentiments of truth and of freedom, could not have been expected from the mouth of an academician under an abſolute monarchy. It could not, indeed, till the preſent eventful age, have been expected under any government whatever; for what he called the ſentiments of truth were the dogmas of debaſing irreligion, which would not have been permitted in the far-famed republics of Greece and Rome; and what he dignified with the appellation of the principles of freedom, experience has ſhown to have been the immediate ſource of anarchy, out of which has ſprung a deſpotiſm, the heavieſt under which any people have groaned ſince the creation of the world.

Beſides the eloges, which properly belonged to his province, Condorcet publiſhed in a ſeparate volume the lives of thoſe *ſavants*, who, having died before the renewal of the academy in 1699, did not fall in with the plan of Fontenelle. The ſuppreſſion of the hiſtory of the academy, or the regular abſtracts of the printed memoirs, which he effected in 1783, afforded him more leiſure. In 1787 appeared, yet without a name, his account of Turgot; an ineſtimable piece, which, in developing the beneficial views of a virtuous and enlightened miniſter, exhibits the neateſt abſtract of the principles of political economy that is extant in any language. Nearly about the ſame time he compoſed that elegant life which is prefixed to the ſplended edition of the works of Voltaire. Condorcet had been elected member of the *Academie Françaiſe* in 1782; and his reputation as a fine writer was ſo well eſtabliſhed, that bookſellers were ſolicitous to cover their undertakings with the ſanction of his name. He promiſed an additional volume to the tranſlation of Euler's Letters to a German Princeſs; but it was never finiſhed. The part which was printed, amounting to only 112 pages, contains the elements of the calculation of probabilities, and a curious plan of a dictionary, in which objects ſhould be arranged by their qualities merely. A new tranſlation of Smith's celebrated *Wealth of Nations* was likewiſe announced with the notes of Condorcet, tho' he was never heartily engaged about it. On equally ſlight grounds, his name was lent to the *Bibliotheque de l'Homme Public;* and the facility of his temper laid him but too open, at this period, to ſuch diſingenuous arts. Indeed diſingenuous arts ſeem to be the natural offspring of the preſent philoſophy of France; for the tricks played by Voltaire to his bookſellers, which are well known, would in this country have ſunk into diſgrace the greateſt genius that ever lived; and the attempt of Diderot to cheat the late empreſs of Ruſſia, by ſelling to her, at an immenſe price, a library, which he pretended to be one of the moſt valuable in Europe, when he poſſeſſed not perhaps one hundred volumes, was diſingenuity ingrafted on impudence. But to return from this ſhort digreſſion.

Theſe literary purſuits did not entirely ſeduce Condorcet from more profound ſtudies. At the inſtigation of Turgot, he ſought to apply analyſis to queſtions of politics and morality. His firſt Memoir on Probabilities was read to the academy in 1781. He afterwards extended his reſearches to the conſideration of elections, ſales, and ſucceſſions; and digeſting thoſe remarks and calculations into a ſyſtematic ſhape, he publiſhed in 1785 a quarto volume, containing the elements of a new and important ſcience.

It is eaſy to conceive the intereſt that Condorcet would take in the ſucceſs of the revolution. Aware of the prodigious influence of newſpapers, he contributed largely to the *Journal de Paris*, and the *Chronique*, which acquired great celebrity from the elegance of his pen; and not very long before his death, he began, in concert with the famous Sieyes, a Journal of Social Inſtruction. In 1791 he wrote a pamphlet in favour of republican government, which procured him a ſeat in the Legiſlative Aſſembly, and the academy permitted him ſtill to retain the office of ſecretary. He drew up a manifeſto on the ſubject of the war menaced by the crowned heads; and a very ample report on public inſtruction, which has in part been lately adopted by the councils of France. He was an early member of the

Jacobin club, that active inſtrument of the revolution: but perceiving the progreſſive ferocity of its meaſures, he forſook it in March 1792.

On the 13th of Auguſt, when the king was conducted to the temple, Condorcet was named by the Aſſembly to draw up a juſtificatory memorial addreſſed to all Europe. At the diſſolution of that Aſſembly, he was choſen deputy to the National Convention, and for ſome time acted a diſtinguiſhed part in its deliberations. He was at the head of the committee appointed to prepare the plan of a republican conſtitution. But, in the meanwhile, the faction of the Mountain, with a peculiar energy of character, was rapidly acquiring ſtrength. The report of the committee was coldly received—was even treated with contempt; and, on the 31ſt of May 1793, Robeſpierre completely triumphed.

During the conteſt between the Mountain and the Briſſotines, Condorcet maintained a cautious ſilence. For eight months he hardly ſpoke in the Convention; and ſeems to have been ſingularly wary in not riſking an opinion on any party queſtion. At length he was ſo far rouſed by the indignities which the legiſlative body daily endured, that he propoſed the diſſolution of the Convention, and the calling of a new one. This probably exaſperated the Mountain to ſuch an exceſs, that in a ſubſequent inſurrection his printing-office was deſtroyed. He was not, however, included in the liſt of proſcribed deputies; nor was he one of the members who ſigned the famous proteſt againſt the proceedings on the 31ſt of May. See REVOLUTION (*Encycl.*), n° 159.

But though he could conquer every ſentiment of friendſhip, and ſtifle every indignant ſenſation at the deſtruction of his party, his vanity as an author propelled him to a fatal exertion. When the conſtitution of 1793 was accepted, he publiſhed *An Addreſs to all French Citizens;* reprobating the extreme rapidity and want of conſideration with which it had been framed and accepted, and detailing the numerous acts of violence by which the prevailing party in the Convention had eſtabliſhed their influence. This raſh act placed him in the power of the Mountain: Chabot denounced the publication, and moved for a decree of accuſation againſt Condorcet; which was immediately granted.

He eſcaped from the arreſt, and concealed himſelf nine months in the houſe of a woman in Paris, who, though ſhe knew him only by name, had the generoſity to riſk her life, and ſuſtain all the inconveniences ariſing from her harbouring ſuch a gueſt. At length a domiciliary viſit was threatened, and he was obliged to quit his aſylum. He had the good fortune, though unprovided with a paſſport or civic card, to eſcape through the barrier; when he went to the country-houſe of a friend on the plain of Mont-Rouge. Unfortunately his friend was at Paris, and not expected to return in leſs than three days; during which the fugitive was obliged to wander about, expoſed to hunger, cold, ſuſpenſe, and the pain ariſing from a wound in his foot. At length his friend returned into the country, and found him; but conſidering it dangerous to take him to his houſe in the day-time, requeſted him to wait till night, when he would receive and conceal him. Condorcet, on that day which his friend had fixed as the end of his miſeries, forgot the dictates of prudence, and went to an inn at Chemars, where he ordered an amelette. His ſqualid appearance, dirty cap, torn clothes, leanneſs, and voracity, fixed the attention of a municipal officer, who aſked him whence he came, whither he was going, and if he had a paſſport? His confuſion at theſe interrogatories betrayed him, and he was inſtantly apprehended. He was confined that night in a dungeon, and in the morning was found dead. He always carried about him a doſe of poiſon, with which he terminated his life, to avoid a trial before the revolutionary tribunal, and ſhun the *gradual approach* of inevitable deſtruction.

Thus miſerably periſhed a philoſopher, whoſe "genius (ſays Madame Roland) was equal to the comprehenſion of the vaſteſt ſubjects; but he had no other characteriſtic beſides fear. It may be ſaid of his underſtanding, combined with his perſon, that it was a fine eſſence abſorbed in cotton. No one could ſay of him, that in a feeble body he diſplayed great courage; for his heart and his conſtitution were equally weak. After having deduced a principle, or demonſtrated a fact, in the Aſſembly, he would give a vote decidedly oppoſite; overawed by the thunder of the tribunes, armed with inſults, and prodigal of threats."

It was during the period of his concealment at Paris, uncertain of a day's exiſtence, that he wrote his Sketch of the Progreſs of the Human Mind; a production which undoubtedly diſplays genius, though it contains ſome of the moſt extravagant paradoxes that ever fell from the pen of a philoſopher. Among other wonderful things, the author inculcates the poſſibility, if not the probability, that the nature of man may be improved to abſolute perfection in body and mind, and his exiſtence in this world protracted to immortality. So firmly does he ſeem to have been perſuaded of the truth of this unphiloſophical opinion, that he ſet himſelf ſeriouſly to conſider how men ſhould conduct themſelves when the population ſhould become too great for the quantity of food which the earth can produce; and the only way which he could find for counteracting this evil was, to check population by promiſcuous concubinage and other practices, with an account of which we will not ſully our pages. Yet we are told by La Lande, that this ſketch is "only the outline of a great work, which, had the author lived to complete it, would have been conſidered as a monument erected to the *honour* of human nature!!!" La Lande, indeed, ſpeaks of the author in terms of high reſpect; and his abilities are certainly unqueſtionable: but what ſhall we think of the morals of that man, who firſt purſued with malicious reports, and afterwards hired ruffians to aſſaſſinate *, the old Duke of Rochefoucalt, in whoſe houſe he had been brought up; by whom he had been treated as a ſon; and at whoſe ſolicitation Turgot created for him a lucrative office; and by the power of the court raiſed him to all his eminence? There is a living Engliſh writer, who has laboured hard to prove that gratitude is a crime. Condorcet muſt ſurely have held the ſame opinion; and therefore could not blame thoſe low-born tyrants who paſſed againſt him what we muſt think an unjuſt decree of accuſation; for it was in ſome degree to his writings that thoſe tyrants were indebted for their power.

About the end of the year 1786, Condorcet married Marie-Louiſe Sophie de Grouchy, whoſe youth, wit, and beauty, were leſs attractive in the eyes of a philo-

ſopher

---

* *Jour. de Phyſ.* Nov. 1792.

ſopher than the tender and courageous anxiety with which ſhe watched the couch, and aſſuaged the ſufferings, of the ſon of the preſident du Paty, who had been bitten by a mad dog. This union, however, we are told, was fatal to his repoſe ; it tempted him into the dangerous road of ambition ; and the idea of providing for a wife and daughter induced him to ſeek for offices which once he would have deſpiſed.

CONFERVA JUGALIS (ſee CONFERVA, *Encycl.*) is introduced here merely on account of a curious circumſtance reſpecting it, which was communicated, not long ago, to the Philomatic Society at Paris. Citizens Charles and Romain Coquebert having collected ſome of this *Conferva* in the neighbourhood of Paris, aſcertained, by means of an excellent microſcope, conſtructed by Nairne and Blunt, that, in this ſpecies, there are male and female filaments, which unite by an actual copulation ; that certain globules contained in the male filaments paſs into the interior part of the female filaments ; and that by this union there are formed in the latter ſeeds, or, if we may uſe the expreſſion, ſmall *ova*, which reproduce the ſpecies. This is the firſt inſtance, in the vegetable kingdom, of a reproduction abſolutely analogous to that which we find among animals.—*Philoſophical Magazine*, N° 3.

May this fact be depended on ? We queſtion not, in the ſlighteſt degree, the veracity of the editor of the very reſpectable miſcellany from which we have copied it ; but we confeſs ourſelves inclined to admit the phyſiological diſcoveries of citizen philoſphers with great heſitation. The fact, if real, is certainly curious, and may lead to important concluſions; and we therefore recommend an inveſtigation of its truth to our botanical readers.

CONGELATION. See CHEMISTRY in this Supplement, n° 280—283.

CONTAGION (ſee *Encycl.*) is a ſubject on which much has been written to very little purpoſe. Of all the attempts which have been made to account for it, there is not one that can be thought ſatisfactory. This, however, is not perhaps a matter of great importance, if a method could only be diſcovered to ſtop the progreſs of contagion where it is known to have place. Among the many benefits which may be reaped from the late diſcoveries in chemiſtry, even this deſideratum promiſes to be one ; and we ſurely need not add one of the greateſt. Dr James Carmichael Smyth, phyſician extraordinary to his Majeſty, ſuggeſted, in the year 1795 or 1796, a proceſs for determining the effect of the nitric acid in deſtroying contagion ; and experiments, according to his directions, were made on board the *Union* and other ſhips at Sheerneſs.

The Union was an hoſpital ſhip, and the experiment on board her was conducted by Mr Menzies, late ſurgeon to his Majeſty's ſloop Diſcovery, and by Mr Baſſan, ſurgeon of the Union; and when it is conſidered that freſh contagion was daily pouring into the hoſpital from the Ruſſian veſſels, which were at that time lying in the Downs, and which had brought with them a ſpecies of fever that might in every ſenſe of the word be termed an epidemy, it will be allowed, that the ſucceſs which attended it was ſuch that it cannot be too generally known.

The wards were extremely crowded, and the ſick of every deſcription lay in cradles, promiſcuouſly arranged, to the number of nearly two hundred ; of which about one hundred and fifty were in different ſtages of the above malignant fever, which was extremely contagious, as appeared evident from its rapid progreſs and fatal effects among the attendants on the ſick and the ſhip's company.

The utenſils and materials provided for the proceſs were the following: A quantity of fine ſand, about two dozen quart earthen pipkins, as many common teacups, ſome long ſlips of glaſs to be uſed as ſpatulas, a quantity of concentrated vitriolic (ſulphuric) acid, and a quantity of pure nitre (nitrat of potaſh).

The proceſs was conducted in the following manner: *1ſt*, All the ports and ſcuttles were ſhut up ; the ſand, which had been previouſly heated in iron pots, was then ſcooped out into the pipkins by means of an iron ladle; and in this heated ſand, in each pipkin, a ſmall tea-cup was immerſed, containing about half an ounce of the ſulphuric acid, to which, after it had acquired a proper degree of heat, an equal quantity of nitrat of potaſh in powder was gradually added, and the mixture ſtirred with a glaſs ſpatula till the vapour aroſe from it in conſiderable quantity (A). The pipkins were then carried through the wards by the nurſes and convaleſcents, who kept walking about with them in their hands, occaſionally putting them under the cradles of the ſick, and in every corner where any foul air was ſupected to lodge. In this manner they continued fumigating, until the whole ſpace between decks was fore and aft filled with the vapour, which appeared like a thick haze.

The vapour at firſt excited a good deal of coughing among the patients, which gradually ceaſed as it became more generally diffuſed through the wards ; part of this effect, however, was to be attributed to the inattention of thoſe who carried the pipkins, in putting them too near the faces of the ſick; which cauſed them to inhale the ſtrong vapour as it immediately iſſued from the cups.

The body-clothes and bed-clothes of the ſick were as much as poſſible expoſed to the nitrous vapour during the fumigation ; and all the foul linen removed from them was immediately immerſed in a tub of cold water, afterwards carried on deck, rinſed out, and hung up till nearly dry, and then fumigated before it was taken to the waſh-houſe : a precaution extremely neceſſary in every caſe of infectious diſorder. Due attention was alſo paid to cleanlineſs and ventilation.

It took about three hours to fumigate the ſhip. In about an hour after, the vapour having entirely ſubſided, the ports and ſcuttles were thrown open for the admiſſion of freſh air. It could plainly be perceived that

---

(A) That the fumes of the mineral acids poſſeſſed the property of ſtopping contagion was proved by Morveau as far back as the year 1773, who, by means of the fumes of muriatic acid extricated from the muriat of ſoda (ſea ſalt) by the ſulphuric acid, purified the air of the cathedral of Dijon, which had been ſo much infected by exhumations that they were obliged to abandon the building. See CHEMISTRY, n 426. in this *Suppl.*

that the air of the hoſpital was greatly ſweetened even by this firſt fumigation. The proceſs was repeated again next morning; and the people employed, being now better acquainted with it, were more expert, and finiſhed the whole in about an hour's time. In an hour afterwards, the vapour having entirely ſubſided, the freſh air was freely admitted into the hoſpital as before. Fewer pipkins were employed for the evening fumigations than for thoſe of the mornings, as the freſh air could not be admitted ſo freely after the former as the latter.

The pleaſing and immediate effect of the fumigation in deſtroying the offenſive and diſagreeable ſmell, ariſing from ſo many ſick crowded together, was now very perceptible, even to the nurſes and attendants; the conſequence of which was, that they began to place ſome degree of confidence in its efficacy, and approached the cradles of the infected with leſs dread of being attacked with the diſorder: ſo that the ſick were better attended, and the duty of the hoſpital was more regularly and more cheerfully performed. In ſhort, a pleaſing gleam of hope ſeemed now to caſt its cheering influence over that general deſpondency, which was before evidently pictured in every countenance, from the dread and horror each individual naturally entertained of being, perhaps, the next victim to the malignant powers of a virulent contagion.

It is a remarkable fact, that from the 26th of November 1795, when the fumigation was firſt reſorted to, till the 25th of December, not a perſon on board was attacked with the fever, though, in the three months preceding, more than one-third of all the people in the ſhip had been ſeized with the diſtemper, and of theſe more than one in four were carried off by it; and the probability is, that the ſickneſs and mortality would have gone on, increaſing in proportion to the diffuſion of the contagion, and to the increaſing deſpondency of the people, who conſidered themſelves as ſo many devoted victims.

The advantage of the fumigation was not felt by the ſhip's company and attendants alone, whom it preſerved from the baneful effects of the fever: the ſick and convaleſcents derived almoſt an equal benefit from it. The ſymptoms of the diſeaſe were meliorated, and loſt much of their malignant appearance; and the advantage of a pure air, and free from ſtench, to convaleſcents, may be readily conceived.

Great confidence is always dangerous. It proved ſo on the preſent occaſion. On the 17th of December they imagined themſelves ſo ſecure, that they diſcontinued the cuſtom of fumigating morning and evening, thinking that once a day was ſufficient. On the 25th, one of the nurſes ſuffered a ſlight attack; and on the 26th, a marine, who, for a week before, had been in a ſtate of intoxication, was ſeized with the fever, of which he died. Theſe two accidents gave immediate alarm: they returned again to the practice of fumigating twice a-day; and from that time to the extermination of the diſorder, there was not an inſtance of a perſon ſuffering from contagion on board the ſhip.

The ſucceſs of the experiment was not confined to the Union: the power of the nitrous vapour to deſtroy contagion was equally diſplayed on board the Ruſſian ſhips in which it was employed. The ſafety, too, with which it may be employed, in any ſituation, without inconvenience or riſk of fire, is another great recommendation in its favour.

From the deſcription that has been given of the proceſs, no perſon can be at any loſs in reſorting to the ſame kind of fumigation. It is only neceſſary to obſerve, for the ſake of thoſe who may not be verſant in chemical purſuits, that the ingredients ought to be pure, and that metal veſſels or rods muſt not be employed. Any kind of metal getting among the ingredients would cauſe the vapour to be very noxious inſtead of ſalutary. The fumes that riſe ſhould be white; if they are of a red colour, there is reaſon to ſuſpect the purity of the ingredients.

The importance of this diſcovery need not be inſiſted on: it is equally applicable to every ſpecies of putrid contagion, even to the plague itſelf. It ſhould therefore be uſed in all hoſpitals and pariſh workhouſes; and ſhould be conſtantly reſorted to by the proprietors of all large works, on the firſt appearance of infectious diſeaſe among the people employed in them:—Indeed, it ſhould be employed even as a preventive in all ſituations where a number of people, from the nature of their buſineſs, are obliged to be crowded together, or where, from local circumſtances, there are reaſons for ſuſpecting that the purity of the air is injured by noxious exhalations or other cauſes. If there be any circumſtances in which its utility may be called in queſtion, it can only be in caſes of inflammatory diſeaſes; for in ſuch ſuperoxygenation has been found hurtful.

CONTRA-HARMONICAL *Proportion*, that relation of three terms, in which the difference of the firſt and ſecond is to the difference of the ſecond and third, as the third is to the firſt. Thus, for inſtance, 3, 5, and 6, are numbers contra-harmonically proportional; for 2 : 1 : : 6 : 3.

CONTRA-Mure, in fortification, is a little wall built before another partition wall, to ſtrengthen it, ſo that it may receive no damage from the adjacent buildings.

COOPER, an artificer who makes coops, caſks, tubs, or barrels, *i. e.* all kinds of wooden veſſels bound together by hoops. See *Encycl.*

The art of the cooper appears to be of great antiquity, and to have very ſoon attained to all the perfection which it poſſeſſes at preſent. This being the caſe, it is obvious that we can communicate no inſtruction to the cooper himſelf, and, on the ſubject of his art, very little that could be intereſting to our other readers. In the *Encyclopedie Methodique* there is a long and verboſe account of the tools or inſtruments employed by the cooper; of the kinds of timber proper for the different kinds of caſks; of the methods of preparing the wood for his various purpoſes; of the manner in which he ought to *hold the plane* when dreſſing the ſtaves; and of the time when it is proper to put the ſtaves together, or, in other words, to mount the caſk. From this detail we ſhall extract ſuch particulars as appear to us to be leaſt generally known, though perhaps of no great importance in themſelves.

Notwithſtanding the antiquity of the art of *caſk-building*, there are ſome countries in which even now it is wholly unknown; and others where, though it is ſufficiently known, yet, from the ſcarcity of wood or ſome other cauſe, earthen veſſels, and ſkins lined with pitch, are preferred to wooden barrels for the holding and tranſporting of liquors. The Latin word *dolium*, which we tranſlate "a caſk," was employed by the Romans to denote earthen veſſels uſed for this purpoſe; though the word *dolare*, from which it is derived, applies very well to our caſks, which are compoſed of ſeveral pieces of wood hewn from the ſame tree, and fitted by planes before they be joined together. We are indeed certain that caſks of the ſame kind with our own were in uſe among the Romans before the Chriſtian era; for both Varro and Columella, in treating of the rural economy of their days, ſpeak of veſſels formed of ſeveral ſtaves of wood bound together by circles or hoops. The merit of having invented ſuch veſſels is given by Pliny to certain people who lived at the foot of the Alps, and who in his days lined their caſks with pitch.

At what period the fabrication of caſks was introduced into Britain is unknown to us, though it is probable that we derived the art from the French, who might have it from the Romans.

We need hardly inform any of our readers, that a caſk has the appearance of two truncated cones joined at their baſes, or that the part where the junction appears to be made being the moſt capacious, or that of which the diameter is the largeſt, is vulgarly called the belly of the caſk. Theſe cones, however, were they completed, would not be regular, but rather *conoids*, being formed of pieces of timber, or ſtaves, which are not ſtraight lines as in the cone, but are curved from the vertex to the baſe.

In chooſing his wood, if he can have a choice, the cooper prefers old and thick and ſtraight trees, from which he hews thin planks to be formed into ſtaves; and in France, where this art is practiſed on a large ſcale, the winter months are allotted for the preparation of the ſtaves and bottoms, and the ſummer for putting them together or mounting the caſk. The author of the article in the *Encyclopedie Methodique* directs the cooper, when dreſſing the ſtaves with the plane, to cut the wood always acroſs; a practice which we doubt not is proper, though we think it would not be eaſy to aſſign the reaſon of it. Plaining is the moſt laborious and difficult part of the work; and there are but few coopers who plane quickly, and at the ſame time well. In ſhops where the work is diſtributed into parts, plaining is reckoned a great object; and in France, before the revolution, a good plainer gained from three ſhillings and threepence ſterling to four ſhillings and three farthings a-day.

In forming the ſtaves, it muſt never be forgotten that each is to conſtitute part of a double conoid; that it muſt therefore be broadeſt at the middle, becoming gradually, though not in ſtraight lines, narrower towards the extremities; that the outſide acroſs the wood muſt be wrought into the ſegment of a circle; and that the ſtave muſt be thickeſt near the middle, growing thinner, by very gentle degrees, towards the ends. To adjuſt accurately theſe different curves (for even the *narrowing* of the ſtaves muſt be in a curve) to the ſize and intended ſhape of the caſk, would require either great experience, or a larger portion of mathematical ſcience than we have reaſon to think that many coopers poſſeſs. With reſpect to the inſide of the ſtave, it is of little conſequence whether it be rounded into the ſegment of a circle or not, and therefore the cooper very ſeldom takes that trouble.

The ſtaves being all dreſſed and ready to be arranged in a circular form, it might be thought neceſſary, in order to make the ſeams tight, to trim the thin edges, which are to be joined together, in ſuch a manner as that a ray paſſing from the outſide of the caſk through a ſeam to the centre, ſhould touch the contiguous ſtaves from the exterior to the interior ſide; in other words, that the thin edges ſhould be ſloped as the archſtones of a bridge are ſloped, ſo that the contiguous ſtaves may be brought into firm contact throughout the whole joint. This, however, is not the practice of the cooper. With great propriety he brings the contiguous ſtaves into contact at their inner ſurfaces only; ſo that by driving the hoops hard, he can make the joints much cloſer than he could poſſibly have done had the edges of the ſtaves been ſo ſloped as to permit them to touch each other throughout before being drove together by the compreſſion of the hoops. This, together with giving to the ſtaves the proper curvature, ſeems to be the only part of the cooper's work which deſerves the name of art; for the driving of the hoops and the forming of the bottoms could certainly be accompliſhed by any carpenter, we had almoſt ſaid by any man, though he had never ſeen a hoop driven or a bottom formed.

In many parts of Scotland, inſtead of ale or beer mugs, they uſe ſmall hooped wooden veſſels, of which the ſtaves are feather-edged or dove-tailed into one another. This, as the ſtaves are of different colours, increaſes the beauty of the veſſel, and to a ſuperficial obſerver appears to be an ingenious contrivance; but it adds nothing to the ſtrength or tightneſs of the ſeam, and cannot be attended with the ſmalleſt difficulty. We think, indeed, that in a large caſk or tub it would prove injurious to the ſeam; for either theſe dove-tails muſt be very thin ſlips raiſed from the interior edges of the ſtaves, which in many caſes could not be done if the wood were thoroughly ſeaſoned; or if they be cut out like inverted wedges, the contiguous ſtaves muſt be brought into contact from the interior to the exterior ſide previous to the driving of the hoops; and in that caſe, as we have ſeen, the ſeams could not be made completely tight.

COPERNICUS (Nicolaus), the reſtorer, if not the inventor, of the true ſyſtem of the ſun, holds ſo conſpicuous a place in the republic of ſcience, that every man of a liberal education muſt be intereſted both in the events of his life and in the hiſtory of his diſcoveries. Accordingly, in the Encyclopædia, we have given a ſhort ſketch of his hiſtory, as well as an account of what led him to ſuppoſe the ſun placed in the centre of our ſyſtem (ſee COPERNICUS, and ASTRONOMY, n° 22. *Encycl.*) Since theſe articles were publiſhed, Dr Adam Smith's *Eſſays on Philoſophical Subjects* have been given to the world; and in that which is intitled *The Hiſtory of Aſtronomy*, we have an account of Copernicus's diſcoveries, ſo much more perſpicuous and ſatisfactory than any thing which we have elſewhere ſeen on the ſubject, that we are perſuaded our readers will be pleaſed to meet with it here.

"The confuſion (ſays Dr Smith) in which the old hypotheſis repreſented the heavenly bodies, was, as Copernicus himſelf tells us, what firſt ſuggeſted to him the deſign of forming a new ſyſtem, that theſe, the nobleſt works of Nature, might no longer appear devoid of that harmony and proportion which diſcover themſelves in her meaneſt productions. What moſt of all diſſatisfied him was, the notion of the equalizing circle, which, by repreſenting the revolutions of the celeſtial ſpheres as equable only, when ſurveyed from a point that was different from their centres, introduced a real inequality into their motions; contrary to that moſt natural, and indeed fundamental idea, with which all the authors of aſtronomical ſyſtems, Plato, Eudoxus, Ariſtotle, even Hipparchus and Ptolemy themſelves, had hitherto ſet out, that the real motions of ſuch beautiful and divine objects muſt neceſſarily be perfectly regular, and go on in a manner as agreeable to the imagination as the objects themſelves are to the ſenſes. He began to conſider, therefore, whether, by ſuppoſing the heavenly bodies to be arranged in a different order from that in which Ariſtotle and Hipparchus had placed them, this ſo much ſought for uniformity might not be beſtowed upon their motions. To diſcover this arrangement, he examined all the obſcure traditions delivered down to us, concerning every other hypotheſis which the ancients had invented for the ſame purpoſe. He found, in Plutarch, that ſome old Pythagoreans had repreſented the earth as revolving in the centre of the univerſe, like a wheel round its own axis; and that others, of the ſame ſect, had removed it from the centre, and repreſented it as revolving in the ecliptic like a ſtar round the central fire. By this central fire he ſuppoſed they meant the ſun; and though in this he was very widely miſtaken, it was, it ſeems, upon this interpretation that he began to conſider how ſuch an hypotheſis might be made to correſpond to the appearances. The ſuppoſed authority of thoſe old philoſophers, if it did not originally ſuggeſt to him his ſyſtem, it ſeems at leaſt to have confirmed him in an opinion which, it is not improbable, he had before-hand other reaſons for embracing, notwithſtanding what he himſelf would affirm to the contrary.

“ It then occurred to him, that if the earth was ſuppoſed to revolve every day round its axis, from weſt to eaſt, all the heavenly bodies would appear to revolve, in a contrary direction, from eaſt to weſt. The diurnal revolution of the heavens, upon this hypotheſis, might be only apparent; the firmament, which has no other ſenſible motion, might be perfectly at reſt; while the ſun, the moon, and the five planets, might have no other movement beſide that eaſtward revolution which is peculiar to themſelves. That, by ſuppoſing the earth to revolve with the planets round the ſun, in an orbit, which comprehended within it the orbits of Venus and Mercury, but was comprehended within thoſe of Mars, Jupiter, and Saturn, he could, without the embarraſſment of epicycles, connect together the apparent annual revolutions of the ſun, and the direct, retrograde, and ſtationary appearances of the planets; that while the earth really revolved round the ſun on one ſide of the heavens, the ſun would appear to revolve round the earth on the other; that while ſhe really advanced in her annual courſe, he would appear to advance eaſtward in that movement which is peculiar to himſelf. That, by ſuppoſing the axis of the earth to be always parallel to itſelf, not to be quite perpendicular, but ſomewhat inclined to the plane of her orbit, and conſequently to preſent to the ſun, the one pole when on the one ſide of him, and the other when on the other, he would account for the obliquity of the ecliptic; the ſun's ſeemingly alternate progreſſion from north to ſouth, and from ſouth to north, the conſequent change of the ſeaſons, and different lengths of days and nights in the different ſeaſons.

“ If this new hypotheſis thus connected together all theſe appearances as happily as that of Ptolemy, there were others which it connected together much better. The three ſuperior planets, when nearly in conjunction with the ſun, appear always at the greateſt diſtance from the earth, are ſmalleſt, and leaſt ſenſible to the eye, and ſeem to revolve forward in their direct motion with the greateſt rapidity. On the contrary, when in oppoſition to the ſun, that is, when in their meridian about midnight, they appear neareſt the earth, are largeſt, and moſt ſenſible to the eye, and ſeem to revolve backwards in their retrograde motion. To explain theſe appearances, the ſyſtem of Ptolemy ſuppoſed each of theſe planets to be at the upper part of their ſeveral epicycles in the one caſe, and at the lower in the other. But it afforded no ſatisfactory principle of connection, which could lead the mind eaſily to conceive how the epicycles of thoſe planets, whoſe ſpheres were ſo diſtant from the ſphere of the ſun, ſhould thus, if one may ſay ſo, keep time to his motion. The ſyſtem of Copernicus afforded this eaſily, and like a more ſimple machine, without the aſſiſtance of epicycles, connected together, by fewer movements, the complex appearances of the heavens. When the ſuperior planets appear nearly in conjunction with the ſun, they are then in the ſide of their orbits, which is almoſt oppoſite to, and moſt diſtant from, the earth, and therefore appears ſmalleſt and leaſt ſenſible to the eye. But as they then revolve in a direction which is almoſt contrary to that of the earth, they appear to advance forward with double velocity; as a ſhip that ſails in a contrary direction to another, appears from that other to ſail both with its own velocity and the velocity of that from which it is ſeen. On the contrary, when thoſe planets are in oppoſition to the ſun, they are on the ſame ſide of the ſun with the earth, are neareſt it, moſt ſenſible to the eye, and revolve in the ſame direction with it; but as their revolutions round the ſun are ſlower than that of the earth, they are neceſſarily left behind by it, and therefore ſeem to revolve backwards; as a ſhip which ſails ſlower than another, though it ſails in the ſame direction, appears from that other to ſail backwards. After the ſame manner, by the ſame annual revolution of the earth, he connected together the direct and retrograde motions of the two inferior planets, as well as the ſtationary appearances of all the five.

“ Thus far did this new account of things render the appearances of the heavens more completely coherent than had been done by any of the former ſyſtems. It did this, too, by a more ſimple and intelligible, as well as more beautiful machinery. It repreſented the ſun, the great enlightener of the univerſe, whoſe body was alone larger than all the planets taken together, as eſtabliſhed immoveable in the centre, ſhedding light and heat on all the worlds that circulated around him in one uniform direction, but in longer or ſhorter periods, according to their different diſtances. It took away the diurnal revolution of the firmament, whoſe rapidity,

upon

upon the old hypotheſis, was beyond what even thought could conceive. It not only delivered the imagination from the embarraſſment of epicycles, but from the difficulty of conceiving theſe two oppoſite motions going on at the ſame time, which the ſyſtem of Ptolemy and Ariſtotle beſtowed upon all the planets ; I mean, their diurnal weſtward, and periodical eaſtward revolutions. The earth's revolution round its own axis took away the neceſſity for ſuppoſing the firſt, and the ſecond was eaſily conceived when by itſelf. The five planets, which ſeem, upon all other ſyſtems, to be objects of a ſpecies by themſelves, unlike to every thing to which the imagination has been accuſtomed, when ſuppoſed to revolve along with the earth round the ſun, were naturally apprehended to be objects of the ſame kind with the earth, habitable, opaque, and enlightened only by the rays of the ſun. And thus this hypotheſis, by claſſing them in the ſame ſpecies of things, with an object that is of all others the moſt familiar to us, took off that wonder and uncertainty which the ſtrangeneſs and ſingularity of their appearance had excited ; and thus far, too, better anſwered the great end of philoſophy.

“ Neither did the beauty and ſimplicity of this ſyſtem alone recommend it to the imagination ; the novelty and unexpectedneſs of that view of nature which it opened to the fancy, excited more wonder and ſurpriſe than the ſtrangeſt of thoſe appearances, which it had been invented to render natural and familiar, and theſe ſentiments ſtill more endeared it. For though it is the end of philoſophy to allay that wonder which either the unuſual or ſeemingly disjointed appearances of Nature excite, yet ſhe never triumphs ſo much as when, in order to connect together a few, in themſelves perhaps inconſiderable objects, ſhe has, if I may ſay ſo, created another conſtitution of things, more natural indeed, and ſuch as the imagination can more eaſily attend to, but more new, more contrary to common opinion and expectation, than any of thoſe appearances themſelves. As in the inſtance before us, in order to connect together ſome ſeeming irregularities in the motions of the planets, the moſt inconſiderable objects in the heavens, and of which the greater part of mankind have no occaſion to take any notice during the whole courſe of their lives, ſhe has, to talk in the hyperbolical language of Tycho Brahé, moved the earth from its foundations, ſtopt the revolution of the firmament, made the ſun ſtand ſtill, and ſubverted the whole order of the univerſe.

“ Such were the advantages of this new hypotheſis, as they appeared to its author when he firſt invented it. But though that love of paradox, ſo natural to the learned, and that pleaſure which they are ſo apt to take in exciting, by the novelty of their ſuppoſed diſcoveries, the amazement of mankind, may, notwithſtanding what one of his diſciples tells us to the contrary, have had its weight in prompting Copernicus to adopt this ſyſtem ; yet when he had completed his Treatiſe of Revolutions, and began coolly to conſider what a ſtrange doctrine he was about to offer to the world, he ſo much dreaded the prejudice of mankind againſt it, that, by a ſpecies of continence of all others the moſt difficult to a philoſopher, he detained it in his cloſet for thirty years together. At laſt, in the extremity of old age, he allowed it to be extorted from him, but died as ſoon as it was printed, and before it was publiſhed.”

This noble theory, however, being repugnant to the prejudices of habit and education, was at firſt coldly received, or utterly rejected, by every claſs of men. The aſtronomers alone favoured it with their notice, though rather as a convenient hypotheſis than an important truth. By the vulgar it was conſidered as a chimera, belied by the cleareſt evidence of our ſenſes ; while the learned beheld it with diſdain, becauſe it militated againſt the fanciful diſtinctions and the vague erroneous tenets of the Peripatetic philoſophy, which no one had ventured to call in queſtion ; and it is amuſing to obſerve with what dexterity the Copernicans, ſtill uſing the ſame weapons, endeavoured to parry the blows of their antagoniſts. Its real merits and blemiſhes appear to have been overlooked by both parties. Brahé framed a ſort of intermediate ſyſtem ; but this Daniſh aſtronomer was more remarkable for his patience and ſkill in obſerving the heavens, than for his talents of philoſophical inveſtigation. Towards the commencement of the 16th century, a new order of things emerged. The ſyſtem of Copernicus became generally known and daily made converts. Its reception alarmed the ever-watchful authority of the church, rouſed her jealouſy, and at length provoked her vindictive artillery. The *ultima ratio theologorum* was pointed at the head of the illuſtrious Galileo, whoſe elegant genius diſcovered the laws of motion, extended the ſcience of mechanics, and added luſtre and ſolidity to the true ſyſtem of the univerſe. From the ſtorms of perſecution Copernicus himſelf had been exempted only by a timely death.

COPPER, one of the metals ; for the properties of which, ſee CHEMISTRY *Index* in this Supplement.—The Chineſe have a metal which they call *pe-tung*, but which Sir George Staunton denominates

White Copper. This metal has a beautiful ſilver-like appearance, and a very cloſe grain. It takes a fine poliſh, and many articles of neat workmanſhip, in imitation of ſilver, are made of it. An accurate analyſis has determined it to conſiſt of copper, zinc, a little ſilver ; and in ſome ſpecimens a few particles of iron and of nickel have been found. From this account it would appear that white copper is not an artificial mixture of metals, but is found native in the mine. Yet in the very ſame page and paragraph, Sir George proceeds to ſay that Dr Gallan was informed at Canton, that the artiſts, in making their pe-tung, reduce the copper into as thin ſheets or laminæ as poſſible, which they make red-hot, and increaſe the fire to ſuch a pitch as to ſoften in ſome degree the laminæ, and to render them ready almoſt to flow. In this ſtate they are ſuſpended over the vapour of their pureſt tu-te-nag or zinc, placed in a ſubliming veſſel over a briſk fire. The vapour thus penetrates the heated laminæ of the copper, ſo as to remain fixed with it, and not to be eaſily diſſipated or calcined by the ſucceeding fuſion it has to undergo. The whole is ſuffered to cool gradually, and is then found to be of a brighter colour, and of a cloſer grain, than when prepared in the European way. Surely this is not the white copper, which conſiſts of copper, zinc, ſilver, iron, and nickel.

CORK is the exterior bark of a tree which has been deſcribed in the Encyclopædia. When the tree is about 15 years old it is fit to be barked, and this can be done ſucceſſively for eight years. The bark always grows up again, and its quality improves as the age of the tree increaſes. It is commonly ſinged a little over a ſtrong fire or glowing coals, or laid to ſoak a certain time in water; after which it is placed under ſtones in order to be preſſed ſtraight. We were wont to procure the greater part of our cork from the Dutch, who brought it principally from France; but they imported ſome alſo from Portugal and Spain.

This tree, as well as the uſes to which its bark is put, was known to the Greeks and the Romans; by the former of whom it was called φελλος. and by the latter *ſuber*. By the Romans, as we learn from Pliny, it was even employed to ſtop veſſels of every kind; but its application to this uſe ſeems not to have been very common till the invention of glaſs bottles, of which Profeſſor Beckmann finds no mention before the 15th century.

In later times, ſome other vegetable productions have been found which can be employed inſtead of cork for the laſt-mentioned purpoſe. Among theſe is the wood of a tree common in South America, particularly in moiſt places, which is called there *monbin* or *monbain*, and by botaniſts *ſpondias lutea*. This wood is brought to England in great abundance for that uſe. The ſpongy root of a North American tree, known by the name of *nyſſa*, is alſo uſed for the ſame end, as are the roots of liquorice, which, on that account, is much cultivated in Sclavonia, and exported to other countries.

CORNUA Ammonis, in natural hiſtory, are foſſil ſhells, of which a pretty full account is given in the Encyclopædia. See Cornu *Ammonis* and Snake-*Stones*. It was obſerved in the laſt of theſe articles, that few, if any, of theſe ſhells are known in their recent ſtate, or as occupied by the living animal; but ſome authors have aſſerted, on the authority of Linnæus, that *ammonites*, with ſhells ſimilar to all the varieties of the foſſil ones, are yet found alive in the depth of the ſea. We are much inclined to embrace this opinion; but it has been controverted by *M. de Lamanon*, who accompanied *La Perouſe* on his voyage of diſcovery, by ſuch arguments as we know not how to anſwer. This unfortunate naturaliſt (ſee Lamanon in this Supplement) allows that there are ſtill in the ſea living *cornua ammonis*; but he thinks that they are in very ſmall numbers, and materially different from the greater part of the foſſil ones. According to him, theſe laſt ought to be conſidered as a race, formerly the moſt numerous of all, of which, either there are no deſcendants, or thoſe deſcendants are reduced to a few degenerate individuals. That there are no living animals with ſhells of the very ſame kind with ſome of the foſſil *cornua ammonis*, the following obſervations he conſiders as a ſufficient proof.

" The foſſil ſhells are very light and thin, whereas the ſhells of thoſe animals that live in very deep water are always thick and ponderous; beſides, the form of the foſſil cornua ammonis points out to us, in ſome meaſure, the organization of the animal which inhabited it. The celebrated Juſſieu proved, in 1721, that there exiſted a very cloſe analogy between the ammonite and nautilus (a). It is well known that the nautilus, by filling or emptying a part of its ſhell, has the power of remaining ſtationary in any depth it pleaſes: the ſame was doubtleſs the caſe with the ammonite; and if this ſpecies ſtill abounds in the ſea, it would ſurely be occaſionally diſcovered by ſailors.

" The waves alſo would throw fragments of it on the ſhore; fiſhermen might ſometimes entangle it in their nets; or, at leaſt, there would be fragments ſticking to the lead of the ſounding line when aſcertaining great depths. It may alſo be added, that if the ammonites never quitted the abyſs of the ſea, thoſe which are found petrified would not be conſtantly met with on the ſame level, and in the ſame bed, as thoſe ſhell-fiſh that only inhabit the ſhallows. There are, however, found in Normandy, Provence, Touraine, and a multitude of other places, ammonites mixed with turbines, buccina (whelks), and other littoral ſhells. They are found, beſides, at every degree of elevation from below the level of the ſea to the ſummits of the higheſt mountains. Analogy alſo leads us to ſuppoſe, that Nature, who has given eyes to the nautilus, has not refuſed them to the ammonite: now what uſe could theſe be of if they remained confined to thoſe depths which the light is unable to penetrate?

" The extinction of the ancient race of ammonites is therefore an eſtabliſhed fact, which no rational ſuppoſition can deſtroy; and this fact is undoubtedly the moſt ſurpriſing of any that is preſented to us in the hiſtory of aquatic animals. The diſcovery of a few living ſpecies of cornua ammonis does not deſtroy the truth of this, for theſe ammonites are very different from thoſe which are found petrified. They are extremely rare, and cannot be looked up to as the repreſentatives of the old ammonites, ſo varied in their ſpecies, and the number of which in the ancient ocean was probably far more conſiderable than that of all the other ſhells beſides."

To every univolve ſhell, rolled in a ſpiral, ſo as that a horizontal plane will divide it into two equal parts, formed of united ſpirals, and bearing a certain proportion to each other, our author gives the name of an *ammonite*. " I thought it abſolutely neceſſary (ſays he) to aſcertain the preciſe meaning of the term *ammonite*, previous to deſcribing that which I found during our voyage round the world. The form of this is almoſt orbicular, the long diameter being to the ſhort one as three lines to two lines and three quarters. The firſt ſpire is by far the largeſt, occupying nearly half of the longitudinal diameter. The ſummit is placed at the diſtance of about two-thirds of this diameter; it is terminated on the right ſide by a very ſmall knob viſible only through a magnifier, thus differing from the ammonite of Rimini, which beſides is microſcopical and celled, the inſide of this which we are now ſpeaking of being entirely plain. The number of ſpiral circumvolutions is four and a half; they are equally convex on both ſides, and are fixed on a plane, dividing the ſhell into

---

(a) There are, however, ſome ſtriking internal differences: firſt, the partitions in the ſhell of the nautilus are more curved than thoſe of the ammonite: ſecondly, the ammonite wants the ſmall hole which communicates from one cell to the other.

into two equal parts: there is on each ſide a kind of boſs formed by the increaſe of the perpendicular diameter of the ſpires, in proportion as they recede from the centre. The ſurface is ſmooth; the back is armed with a flat, even, brittle creſt, as thin as paper, ſurrounding it on every ſide like a ruff: it is about half a line broad, extends over the ſummit of the ſpires, and ſerves to join them together. The mouth of the ſhell is nearly triangular; its edges project in the form of lips, and are rounded at the border. I have often found this ammonite encloſed in the ſtomach of the bonetta (ſcomber pelamis, Linn.), caught in the South Sea, between the tropics, where no bottom was found with a line of more than two hundred fathoms. Theſe ſhells were covered with a black clayey mud. Their ſize varies from one to four lines acroſs; they are conſequently the largeſt living ammonites that have yet been diſcovered."

It is well known for what purpoſe the modern philoſophers of France have been ſo indefatigable in the ſtudy of natural hiſtory; and there can be little doubt but that it is to ſerve the ſame purpoſe that Lamanon thus reaſons for the deſtruction of the ancient race of ammonites in ſome univerſal convulſion of the world. But ſuppoſing his arguments concluſive, they affect not the truth of the Jewiſh and Chriſtian ſcriptures. It is nowhere ſaid in the Bible, that the *matter* of this globe was brought into being at the moment when Moſes repreſents the Creator as beginning to reduce the chaos into order; and it is more than inſinuated that there will be a *new earth* after the preſent ſyſtem of things ſhall be diſſolved. That *new* earth will certainly be ſtored with ſome kind of inhabitants; and could it be demonſtrated that there was an *old* earth, previous to the era of the Moſaic coſmogany, inhabited by creatures rational and irrational, and that the foſſil *cornua ammonis* make part of the wreck of that ſyſtem, the cauſe of revelation would remain uninjured. "Moſes, as a real philoſopher * has well obſerved, writes the hiſtory, not of this globe through all its revolutions, but of the race of Adam."

This ſecret attack, therefore, made by Lamanon againſt that religion of which he once profeſſed to diſcharge the duties of a prieſt, is nothing more than *telum imbelle ſine ictu*. Yet it may be worth ſome naturaliſt's while to enquire, whether, though feeble, it has been fairly made. We confeſs that our own ſuſpicions of unfair dealing are ſtrong; for when a man of ſcience contradicts himſelf in the courſe of two pages, the blunder muſt be attributed to ſome other ſource than mere inadvertency. M. de Lamanon wiſhes to prove, among other things, that the ancient ammonites did not inhabit great depths of the ſea; and that Linnæus was miſtaken when he ſuppoſed that in great depths they may ſtill be found. Yet he himſelf tells us, that he frequently caught ammonites in the South Sea, where no bottom was to be found with a line of *more than* 200 *fathoms;* and to put it beyond a doubt that the animals had been at that bottom, he informs us, that their ſhells were covered with a *black clayey mud*. It is true theſe ammonites were but ſmall; while of 300 varieties of foſſil ammonites which he mentions, ſome, he ſays, have been found ten feet in circumference. But is it certain that theſe large ſhells were real *cornua ammonis?* If they agree not exactly with our author's deſcription of the ſhell of the ammonite (a fact into which we have had no opportunity of inquiring), his arguments for the extinction of the ancient race are groſs ſophiſms, unworthy of a man either of ſcience or of candour.

CORRECTION-HOUSE is a priſon where idle vagrants are compelled to work, and where perſons guilty of certain crimes ſuffer puniſhment and make reparation to the public. Of the former kind of *correction houſes*, perhaps enough has been ſaid in the Encyclopædia under the title WORK-*Houſe*; but of the latter very little will be found in that work under the titles BRIDEWELL and IDLENESS.

Perhaps houſes of correction, as means of puniſhment, are not, in this country, employed ſo frequently as juſtice and expediency ſeem to require. In the opinion of Dr Paley, whoſe opinions are always worthy of attention, it is one of the greateſt defects of the laws of England (and we may ſay the ſame thing of the laws of Scotland), that "they are not provided with any other puniſhment than that of death, ſufficiently terrible to keep offenders in awe. Tranſportation, which is the puniſhment ſecond in the order of ſeverity, anſwers the purpoſe of example very imperfectly; not only becauſe exile is in reality a ſlight puniſhment to thoſe who have neither property, nor friends, nor regular means of ſubſiſtence at home, but becauſe the puniſhment, whatever it be, is unobſerved and unknown. A tranſported convict *may* ſuffer under his ſentence, but his ſufferings are removed from the view of his countrymen; his miſery is unſeen; his condition ſtrikes no terror into the minds of thoſe for whoſe warning and admonition it was intended. This chaſm in the ſcale of puniſhment produces alſo two farther imperfections in the adminiſtration of penal juſtice; of which the firſt is, that the ſame puniſhment is extended to crimes of very different characters and malignancy; and the ſecond, that puniſhments, ſeparated by a great interval, are aſſigned to crimes hardly diſtinguiſhable in their guilt and miſchief."

Perhaps this chaſm might be properly filled up by houſes of correction under judicious management, which might likewiſe promote another important purpoſe, better than the puniſhments in common uſe.

The end of puniſhment is twofold, *amendment* and *example*. In the firſt of theſe, the *reformation* of criminals, little has ever been effected, and little indeed ſeems practicable by the puniſhments known to the laws of Britain. From every ſpecies of puniſhment inflicted among us, from impriſonment and exile, from pain and infamy, malefactors return more hardened in their crimes, and more inſtructed. The caſe we think would often be different when they returned to the world from a well-regulated houſe of correction. As experience is the only ſafe guide in matters of legiſlation and police, we ſhall lay before our readers *M. Thouin*'s account of the houſe of correction at Amſterdam, which ſeems to corroborate our opinion.

The Amſterdam correction houſe, from the employment of the priſoners confined in it, is called the *raſping-houſe*, and is deſtined to the reception of thoſe malefactors whoſe crimes do not amount to a capital offence. Their puniſhment cannot ſo properly be denominated ſolitary confinement as a ſequeſtration from ſociety during a limited term of years. The building is ſituated in a part of the ſuburbs to the north-eaſt of the city.

---

* *Profeſſor Robiſon of Edinburgh.*

The exterior has nothing remarkable, either with reſpect to form or extent. It is detached from the ſtreet by a ſpacious court, which contains the keeper's lodge, together with apartments for the different ſervants belonging to the eſtabliſhment. Over the gate, which opens from this court into the priſon, are placed two ſtatues, as large as life, repreſenting two men in the act of ſawing a piece of logwood.

The inner court is in the form of a ſquare, round which are arranged the apartments of the priſoners, together with the neceſſary warehouſes. One part of the ground ſtory is divided into different chambers; the other ſerves as a depot for the logwood, and the implements employed in its preparation.

The keeper, whoſe countenance, contrary to the general cuſtom of perſons of his profeſſion, was ſtrongly indicative of urbanity and gentleneſs, introduced M. Thouin into an apartment where two priſoners were at work in ſawing a large log of Campeachy wood. The ſaw is compoſed of four blades joined together, with very ſtrong, large, and ſharp teeth, which make a ſciſſure in the wood of nearly two inches in breadth. The operation is repeated, till the pieces become too ſmall to undergo the ſaw, when they are ground in mills peculiarly conſtructed for this purpoſe.

This employment requires an extraordinary exertion of ſtrength, and is at firſt a ſevere penance even to robuſt perſons; but habit, addreſs, and practice, ſoon render it eaſy; and the priſoners in a ſhort time become competent to furniſh, without painful exertion, their weekly contingent of 200 lb. weight of ſawed pieces. After completing this taſk, they even find time to fabricate a variety of little articles in wood and ſtraw, which they ſell to thoſe who viſit the priſon, or diſpoſe of, by means of agents, in the town.

M. Thouin next inſpected three apartments of different dimenſions, which opened into the inner court. The one was inhabited by four, the ſecond by ſix, and the third by ten priſoners. The furniture of the rooms conſiſted in hammocks, with a matraſs, a blanket, and a coverlid to each, tables, chairs, and ſtools, glaſs, &c. earthen veſſels, and various other articles of convenience. Every thing in theſe apartments was diſtinguiſhed by neatneſs and propriety; and notwithſtanding the number of inhabitants allotted to each, was fully adequate to the dimenſions of the rooms; the ſenſes were not offended with any diſagreeable ſcent, and the air was in every reſpect as pure and wholeſome as the ſurrounding atmoſphere.

In an obſcure part of the building are a number of cells, in which formerly thoſe priſoners who revolted againſt the proper ſubordination of the place, or ill-treated their comrades, were confined for a few days. But the keeper aſſured M. Thouin that theſe cells had not been made uſe of for upwards of 10 years. They are dark gloomy dungeons, with only a ſmall aperture for the admiſſion of light and air. The ſuppreſſion of this barbarous and coercive puniſhment does honour to the humanity of government.

The ſtore rooms are filled with various kinds of wood for the purpoſes of dyeing; as the haemotoxylum campechianum, the morus tinctoria, the caeſalpinia ſappan, &c. They are all exotics, with the exception of the Evonymus Europæus. The warehouſes were not of ſufficient extent to contain the quantity of wood, which was depoſited in piles in different parts of the court.

The priſoners, amounting to 76 in number, were uniformly habited in coarſe woollens; wear very good ſtockings, large leather ſhoes, white ſhirts, and caps or hats. They are, by the rules of the houſe, obliged to frequent ablutions, which greatly contribute to the preſervation of their health. There was only one ſick perſon amongſt them; and, what is not a little remarkable, almoſt all the priſoners had formerly lived in large commercial towns; very few villagers were amongſt them. They had all been ſentenced to impriſonment for theft; but it depends upon themſelves, by reformation and good behaviour, to ſhorten the term of their confinement, which many of them frequently do.

The keeper, whoſe humanity to the unfortunate perſons committed to his care entitles him rather to the title of their protector than their gaoler (and M. Thouin informs us, that the priſoners generally called him by no other name than *father*), aſſiſts them with his counſels and friendly admonitions. He regiſters every week, in a book appropriated to this purpoſe, both the inſtances of good and bad behaviour, which is annually ſubmitted to the examination of the magiſtracy, who, from this report, abridge or prolong the term of confinement, according to the degree of indulgence which each priſoner appears to merit. Caſes frequently happen where a malefactor, condemned to an impriſonment of eight years, by his good behaviour procures his enlargement at the expiration of four; and ſo in proportion for a ſhorter term. But great attention is paid to diſcriminate between actual reform and hypocritical artifice.

The reward of good behaviour is not, however, confined to, or withheld till, the period of actual liberation. Their reſtoration to ſociety is preceded by a progreſſive amelioration of their lot. Their work is gradually rendered leſs laborious, they are accommodated with ſeparate apartments, and employed in the ſervices of domeſtic economy. The keeper even entruſts them with commiſſions beyond the precincts of the priſon; and ſcarce a ſingle inſtance has occurred of their abuſing this indulgence. By this prudent management, a conſiderable ſaving is effected in the expence of the eſtabliſhment, at the ſame time that it tends to wear away prejudice, and to initiate the priſoners by gradual advances into the reciprocal duties of ſocial life.

M. Thouin made particular inquiries whether it was cuſtomary for perſons after their diſcharge to be confined a ſecond and third time, as is but too often the caſe in many countries, for a repetition of their offence. He was informed, that ſuch inſtances very rarely occur; but the caſe is not without precedent, as he obſerved in the perſon of a young Jew, who was then in the raſping-houſe for the third time. The caſe of this man is ſomewhat extraordinary. During the period of his detention, he always conforms, with the moſt ſcrupulous obſervance, to the rules of the place, and gives general ſatisfaction by his exemplary conduct. But ſuch, as he himſelf avowed to our traveller, is his conſtitutional propenſity to thieving, that no ſooner is the term of his impriſonment elapſed, than he returns with redoubled ardour to his lawleſs courſes. It is not ſo much for the ſake of plunder, as to gratify his irreſiſtible impulſe, that he follows this vicious life; and M. Thouin adds, that he recounted his different exploits with as much exultation and triumph as a veteran diſplays when rehearſing his warlike atchievements.

Another ſalutary regulation in this inſtitution, from which the beſt conſequences reſult, is the indulgence granted to the priſoners of receiving the viſits of their wives and miſtreſſes twice every week. Proper care, however, is taken to guard againſt the introduction of diſeaſe; and the ladies, in one ſenſe, purchaſe their admiſſion by giving a trifling ſum of money at the gate, which becomes the perquiſite of the aged priſoners, whoſe wants are of a different nature from their youthful comrades. Thus the pleaſures of one claſs contribute to the comforts of the other; and the entrance money, trifling as it is, keeps away a croud of idle vagabonds, who have no acquaintance with the priſoners. The ladies at their viſits are permitted to eat and drink with their lovers; and when the converſation becomes too animated for a third perſon to be preſent, the reſt of the company obligingly take the hint, and leave them to enjoy a *tete-a-tete.*—By this prudent regulation, many hurtful conſequences attendant on a total ſecluſion from female ſociety are guarded againſt.

M. Thouin concludes his account with obſerving, that the raſping-houſe at Amſterdam bears a greater reſemblance to a well-ordered manufactory than to a priſon. It were to be wiſhed that all ſimilar inſtitutions were conducted upon a ſimilar plan (A).

So ſays our author: But though we have admitted experience to be the only ſafe guide in regulating inſtitutions of this kind, we cannot help thinking that the plan is ſuſceptible of improvement. We do not ſee the propriety of locking up four, ſix, or ten thieves in the ſame apartment. The uncommon attention to cleanlineſs, which diſtinguiſhes all ranks among the Dutch, may indeed prevent the room from having an offenſive ſcent; but what can prevent ſuch a number of unprincipled perſons from corrupting each other in Holland, as we know that they do in Great Britain? The introduction of females of looſe character to felons ſuffering puniſhment for their offences in a priſon, is a practice which we truſt will be approved only by philoſophers of the French ſchool. The Britiſh philoſopher, whom we have already quoted with approbation, is of opinion, and we heartily agree with him, that "of reforming puniſhments, none promiſes ſo much ſucceſs as that of ſolitary impriſonment, or the confinement of criminals in ſeparate apartments. This improvement of the Amſterdam houſe of correction would augment the terror of the puniſhment, would ſeclude the criminal from the ſociety of his fellow-priſoners, in which ſociety the worſe are ſure to corrupt the better; would wean him from the knowledge of his companions, and from the love of that turbulent pernicious life in which his vices had engaged him; would raiſe up in him reflections on the folly of his choice, and diſpoſe his mind to ſuch bitter and continued penitence, as might produce a laſting alteration in the principles of his conduct."

In ſome houſes of correction, the priſoners are ſubjected to the diſcipline of flagellation at ſtated intervals. We will not take it upon us to ſay that this puniſhment is never proper; but we are fully convinced that it is not often ſo; and that flagellation, if it can at all produce any good effect, muſt be adminiſtered in private. It is obſerved by Fielding, who well underſtood human nature, that faſting is the proper puniſhment of profligacy, not any puniſhment that, like flagellation, is attended with ſhame. Puniſhment (ſays he) that deprives a man of all ſenſe of honour, never will contribute to make him virtuous; and we believe it is generally admitted by the gentlemen of the army, that a ſoldier who has ſuffered the puniſhment of whipping ſeldom proves good for any thing.

COWRY-SHELLS, the loweſt money in ſome parts of the Eaſt. See MONEY (*Encycl.*), where they are called *laris.*

CRANE, in mechanics, a machine uſed for raiſing or lowering great weights. For the principles on which theſe machines act, ſee DYNAMICS in this *Supplement*, and likewiſe MECHANICS, *Encycl.* where deſcriptions are given of ſeveral very powerful cranes.

The crane in common uſe is employed with ſome danger to thoſe who work it; and therefore a machine of this kind, acting upon a ſimple and certain principle, by which the men walking in the wheel can lower goods with ſafety as well as expedition, has long been conſidered as a great deſideratum in mechanics. Repeated premiums have been offered by the *Society for the Encouragement of Arts* to induce ingenious men to attempt the invention of ſuch a machine; and various have been the contrivances for accompliſhing ſo deſirable a purpoſe. A clergyman, who ſubſcribes E. C. we ſuppoſe as the initials of his name, propoſes, through the medium of the Repertory of Arts, to accompliſh it merely by introducing the action of a worm or ſcrew into the crane.

Whenever a worm of two threads is introduced into a machine, all retrograde motion is ſtopped, unleſs that worm receive its reaction from the firſt moving force; for, powerfully as a worm acts upon a wheel, a wheel has no power upon a worm, whatever force may be applied to it. Suppoſe, then, the firſt motion in a crane were given by a worm upon the axis of the wheel in which the man walks, the man would have perfect command of the machine, to raiſe or lower the goods at pleaſure, with the remoteſt poſſibility of being overpowered by the deſcending weight.

"Were I to conſtruct (ſays the author) a crane upon this principle, I would have the axis of the wheel in which the man walks, and the axis of the worm, in ſeparate parts, and occaſionally united by a coupling-box. When goods were to be raiſed, the two axes ſhould be connected; when lowered, they might be diſunited, and the worm turned by a winch, which would be done much more expeditiouſly that way than by the wheel. For the reaſons before ſuggeſted, the deſcent of the weight could be accelerated or ſtopped at pleaſure, at the diſcretion of the perſon turning the winch.

"This contrivance might be not inconveniently applied

(A) We do not know that M. Thouin's journal of his travels has been yet publiſhed. Extracts from it have been inſerted into the *Decade*, a periodical publication at Paris, whence this account of the *Amſterdam houſe of correction* was firſt copied into the Monthly Magazine for June 1798.

plied to a crane already erected upon the common principle: Let there be a wheel put upon any convenient axis in the machine as it now ſtands; upon this let there lie a worm, that can be thrown in or out of gear at pleaſure; and let the lever by which it is done lie within reach of the man's hand in the wheel. The goods being faſtened to the crane, and raiſed off the floor of the warehouſe ready for letting down, the man puts the worm into gear, leaves the wheel, and lets the goods down by the winch. Provided it can be conveniently done, it would be adviſable to throw the wheel in which the man walks out of gear when the winch is made uſe of; this, however, I ſhould apprehend, would not be a matter of abſolute neceſſity."

Our author is aware of two objections which may be urged againſt the introduction of a worm into a crane in the manner which he propoſes. The firſt ariſes from the ſlowneſs of the motion produced by the turning of a ſcrew, which he conſiders as unworthy of regard; becauſe the neceſſary ſpeed is to be gained by the firſt pair of wheels and the diameter of the barrel of the windlaſs.

To the ſecond, ariſing from the ſuppoſed greater friction between a worm and wheel, he replies, that as the friction between the teeth of two wheels (if not formed on the true epicycloidal principle) muſt, while it laſts, be greater than between a worm and wheel for the ſame ſpace of time, it ſeems no unreaſonable ſuppoſition that the aggregate of friction will, in the two caſes, nearly balance each other; eſpecially if it be taken into the account, that to obtain the power of one worm and wheel, there will be, in moſt caſes, required two pair of wheels, and two additional axes—all which will add to the friction. But, granting the balance of friction to be againſt the action of the worm, the power to overcome it is greater in proportion than to overcome the friction of two wheels.

Mr James Whyte of Chevening, in the county of Kent, whoſe improvement in the conſtruction of pullies has, with due reſpect, been noticed elſewhere *, gives, in *the Tranſactions of the Society for the Encouragement of Arts*, &c. the following deſcription of a new crane for wharfs:

Plate XX.

A (fig. 1.), a circular inclined plane, moving on a pivot underneath it, and carrying round with it the axis E. A perſon walking on this plane, and preſſing againſt the lever B, throws off the gripe D, by means of an iron rod C; and thus admits the plane and its axis to move freely, and raiſe the weight G by the coiling of the rope F round the axis E.

To ſhew more clearly the conſtruction and action of the lever and gripe, a plan of the circular inclined plane, with the lever and gripe, is added (ſee fig. 2.), where B repreſents the lever, D the ſpring or gripe. In this plan, when the lever B is in the ſituation in which it now appears, the ſpring or gripe D preſſes againſt the periphery of the plane, as ſhewn by the double line, and the machine cannot move; but when the lever B is preſſed out to the dotted line H, the gripe is alſo thrown off to the dotted line I, and the whole machine left at liberty to move. One end of a rope or cord, of a proper length, is fixed near the end of the lever B, and the other end made faſt to one of the uprights, ſerving to prevent the lever moving too far when preſſed by the man.

The properties of this crane, for which the premium of 40 guineas was adjudged by the ſociety to the inventor, are as follows:

1. It is ſimple, conſiſting merely of a wheel and axle. 2. It has comparatively little friction, as is obvious from the bare inſpection of the figure. 3. It is durable, as is evident from the two properties above mentioned. 4. It is ſafe; for it cannot move but during the pleaſure of the man, and while he is actually preſſing on the gripe-lever. 5. This crane admits of an almoſt infinite variety of different powers; and this variation is obtained without the leaſt alteration of any part of the machine. If, in unloading a veſſel, there ſhould be found goods of every weight, from a few hundreds to a ton and upwards, the man that does the work will be able ſo to adapt his ſtrength to each as to raiſe it in a ſpace of time proportionate to its weight; he walking always with the ſame velocity as nature and his greateſt eaſe may teach him.

It is a great diſadvantage in ſome cranes, that they take as long time to raiſe the ſmalleſt as the largeſt weight, unleſs the man who works them turn or walk with ſuch velocity as muſt ſoon tire him. In other cranes, perhaps, two or three different powers may be procured; to obtain which, ſome pinion muſt be ſhifted, or freſh handle applied or reſorted to. In this crane, on the contrary, if the labourer find his load ſo heavy as to permit him to aſcend the wheel without its turning, let him only move a ſtep or two toward the circumference, and he will be fully equal to the taſk. Again, if the load be ſo light as ſcarcely to reſiſt the action of his feet, and thus to oblige him to run through ſo much ſpace as to tire him beyond neceſſity, let him move laterally towards the centre, and he will ſoon feel the place where his ſtrength will ſuffer the leaſt fatigue by raiſing the load in queſtion. One man's weight applied to the extremity of the wheel would raiſe upwards of a ton; and it need not be added, that a ſingle-ſheaved block would double that power. Suffice it to ſay, that the ſize may be varied in any required *ratio*; and that this wheel will give as great advantage at any point of its plane as a common walking-wheel of equal diameter, as the inclination can be varied at pleaſure, as far as expediency may require. It may be neceſſary to obſerve, that what in the figure is the frame, and ſeems to form a part of the crane, muſt be conſidered as a part of the houſe in which it is placed; ſince it would be moſtly unneceſſary ſhould ſuch cranes be erected in houſes already built. With reſpect to the horizontal part, by walking on which the man who attends the gib occaſionally aſſiſts in raiſing the load, it is not an eſſential part of this invention, where the crane is not immediately contiguous to the gib, although, where it is, it would be certainly very convenient and economical.

Crane is alſo a popular name for a ſyphon, employed in drawing off liquors.

CROSS, *in ſurveying*, is an inſtrument conſiſting of a braſs circle, divided into four equal parts by two lines croſſing each other in the centre. At each extremity of theſe lines is fixed a perpendicular ſight, with ſmall holes below each ſlit, for the better diſcovering of diſtant objects. The croſs is mounted on a ſtaff or ſtand, to fix it in the ground, and is very uſeful for meaſuring ſmall pieces of land, and taking offſets, &c.

Cross-ſtaff, or ***Fore-ſtaff***, is a mathematical inſtrument

of box or pear-tree, conſiſting of a ſquare ſtaff of about three feet long, having each of its faces divided like a line of tangents, and having four croſs pieces of unequal lengths to fit on the ſtaff, the halves of theſe being as the radii to the tangent lines on the faces of the ſtaff.—The inſtrument was uſed in taking the altitudes of the celeſtial bodies at ſea.

CROWN, in aſtronomy, a name given to two conſtellations, the ſouthern and the northern.

Crown, in geometry, a plane ring included between two parallel or concentric peripheries of unequal circles.

Crown-Poſt, is a poſt in ſome buildings ſtanding upright in the middle between two principal rafters; and from which proceed ſtruts or braces to the middle of each rafter. It is otherwiſe called a *king-poſt*, or *king's-piece*, or *joggle-piece*.

La CRUZ, an excellent harbour on the north-weſt coaſt of America, diſcovered by the Spaniards in 1779. They were introduced into it by a paſſage which they called *Bucarelli's Entrance*, and which they placed in 55° 18′ N. Lat. and 139° 15′ W. Long. from the meridian of Paris. There is no good reaſon to queſtion the exactneſs of the latitude of this paſſage as laid down by the Spaniards; but the editor of Perouſe's voyage juſtly concludes, from the ſurvey made by our celebrated navigator Captain Cook on the coaſts adjacent to the entrance of Bucarelli, that this entrance is about 135° 20′ to the weſt of Paris, or very nearly 133° weſt of Greenwich.

The Spaniards were not long in the harbour of *La Cruz* before they received a viſit from the inhabitants in its neighbourhood. Bartering took place. The Indians gave their peltry, and various trifles, for glaſs beads, bits of old iron, &c. By this traffic the Spaniards were enabled to gain a ſufficiently exact knowledge of their genius, of their offenſive and defenſive arms; of their manufactures, &c.

Their colour is a clear olive; many among them have, however, a perfectly white ſkin: their countenance is well proportioned in all its parts. They are robuſt, courageous, arrogant, and warlike.

They clothe themſelves in one or two undreſſed ſkins (with the fur apparently); theſe are the ſkins of otters, of ſea-wolves, of benades (a ſpecies of deer), of bears, or other animals, which they take in hunting. Theſe dreſſes cover them from the neck to the middle of the leg; there are, however, many among them who wear boots of ſmooth ſkin, reſembling Engliſh boots, only that thoſe of the Indians open before, and are laced tight with a ſtring. They wear hats woven from the fine bark of trees, the form of which reſembles that of a funnel or a cone. At the wriſts they have bracelets of copper or iron, or for want of theſe metals the fins of whales; and round the neck, necklaces of ſmall fragments of bones of fiſhes and other animals, and even copper collars of the bigneſs of two fingers. They wear in their ears pendants of mother-of-pearl, or flat pieces of copper, on which is emboſſed a reſin of a topaz colour, and which are accompanied with jet beads. Their hair is long and thick, and they make uſe of a comb to hold it together in a ſmall queue from the middle to the extremity; a narrow ribbon of coarſe linen, woven for this purpoſe, ſerves as a ligament. They wear alſo as a covering a kind of ſcarf, woven in a particular manner, ſomething more than a yard and a half long, and about half a yard broad, round which hangs a fringe ſomething more than half a quarter of a yard deep, of which the thread is regularly twiſted.

The women give proofs of their modeſty and decency by their dreſs. Their phyſiognomy is agreeable, their colour freſh, their cheeks vermilioned, and their hair long; they plait it together in one long treſs. They wear a long robe of a ſmooth ſkin tied round the loins, like that of a nun; it covers them from the neck as low as the feet; the ſleeves reach down to the wriſts. Upon this robe they put divers ſkins of otters or other animals to defend themſelves from the inclemency of the weather. Better dreſſed, many of them might diſpute charms with the moſt handſome Spaniſh women; but diſſatisfied with their natural charms, they have recourſe to art, not to embelliſh, but to disfigure themſelves. All the married women have a large opening in the under lip, and this opening or orifice is filled up by a piece of wood cut in an oval ſhape, of which the ſmalleſt diameter is almoſt an inch; the more a woman is advanced in years, the more this curious ornament is extended: it renders them frightful, the old women eſpecially, whoſe lip, deprived of its wonted ſpring, and dragged by the weight of this extraordinary jewel, neceſſarily hangs in a very diſagreeable manner. The girls wear only a copper needle, which croſſes the lip in the place where the ornament is intended hereafter to be placed.

Theſe Indians in war make uſe of cuiraſſes and ſhoulder pieces of a manufacture like that of the whalebone ſtays among the Europeans. Narrow boards or ſcantlings form, in ſome ſort, the woof of the texture, and threads are the warp: in this manner the whole is very flexible, and leaves a free uſe to the arms for the handling of weapons. They wear round the neck a coarſe and large gorget which covers them as high as below the eyes, and their head is defended by a morion, or ſkull-piece, uſually made of the head of ſome ferocious animal. From the waiſt downwards, they wear a kind of apron, of the ſame contexture as their cuiraſs. Laſtly, a fine ſkin hangs from their ſhoulders down to the knee. With this armour they are invulnerable to the arrows of their enemies; but thus armed, they cannot change poſition with ſo much agility as if they were leſs burdened.

Their offenſive arms are arrows; bows, of which the ſtrings are woven like the large cords of our beſt muſical inſtruments; lances, four yards in length, tongued with iron; knives, of the ſame metal, longer than European bayonets, a weapon, however, not very common among them; little axes of flint, or of a green ſtone, ſo hard that they cleave the moſt compact wood without injury to their edge.

The pronunciation of their language is extremely difficult; they ſpeak from the throat, with a movement of the tongue againſt the palate. The little uſe the women make of the inferior lip greatly injures the diſtinctiveneſs of their language. The Spaniards could neither pronounce nor write the words which they heard.

From the vivacity of ſpirit in theſe Indians, and from their attention amply to furniſh the market eſtabliſhed in the harbour, it may be concluded that they are pretty laborious. They continually brought ſtuffs well woven and ſhaded by various colours, the ſkins of land and ſea wolves, of otters, bears, and other ſmaller animals;

mals; of theſe ſome were raw, and others dreſſed. There were to be found at this market alſo coverlets of coarſe cloth, ſhaded with white and brown colours, very well woven, but in ſmall quantities: large ribbons of the ſame linen which might match with that of the Spaniſh officers mattreſſes; ſkeins of thread ſuch as this cloth was made of; wooden plates or bowls neatly worked; ſmall boats, or canoes, painted in various colours, the figures of which repreſented heads with all their parts; frogs in wood, nicely imitated, which opened like tobacco boxes, and which they employed to keep their trinkets in: boxes made of ſmall planks, of a cubical form, being three quarters of a yard on each ſide, with figures well drawn, or carved on the outſide, repreſenting various animals; the covers fabricated like Flanders etwees, with rabbeted edges, formed ſo as to ſhut into the body of the box; animals in wood, as well thoſe of the earth as of the air; figures of men of the ſame material, with ſkull-caps repreſenting the heads of various fierce animals; ſnares and nets for fiſhing; copper collars for the neck, and bracelets of iron for the wriſt, but which they would not part with except at a very high price; beak-like inſtruments, from which they drew ſounds as from a German flute. The principal officers took ſuch of theſe merchandizes as were moſt agreeable to them, and left the remainder to the ſhips crews.

As the Indians diſcovered that the Spaniards were very dainty in their fiſh, they did not let them want for choice: the greateſt abundance was in ſalmon, and a ſpecies of ſole or turbot three yards and a quarter long, broad and thick in proportion; cod and pilchards were alſo brought to market, and fiſhes reſembling trout. From all this it may be inferred, that this gulf is full of fiſh; the banks too are covered with ſhells.

The quantity of mother-of-pearl that theſe Indians cut to pieces for making ear-rings awakened the curioſity of the Spaniards: they tried to diſcover whether theſe people had not in their poſſeſſion, or whether their country did not produce pearls, or ſome precious ſtones: their reſearches were fruitleſs; they only found ſome ſtones which they judged to be metallic, and which they carried on board, not having the neceſſary means for extracting the metal they might contain.

Theſe Indians feed upon fiſh, freſh or dry, boiled or roaſted; herbs and roots which their mountains yielded them, and particularly that which in Spain is called ſea parſley; and, laſtly, upon the fleſh of animals which they take in hunting: the productions of the chaſe are undoubtedly abundant, ſeeing the number of dogs they keep for this purpoſe.

Theſe Indians appeared to the Spaniards to worſhip the ſun, the earlieſt and moſt natural of all idolatrous worſhip; and they paid a decent reſpect to the remains of their dead. Don Maurelle, one of the Spaniſh officers, in an expedition round the gulf, found in two iſlands three dead bodies laid in boxes of a ſimilar form to thoſe which have been deſcribed above, though conſiderably larger, and decked in their furs. Theſe biers were placed in a little hut upon a platform, or raiſed floor, made of the branches of trees.

The country is very hilly, the mountains are lofty, and their ſlope extends almoſt every where to the ſea. The ſoil, limeſtone; it is nevertheleſs covered with an impenetrable foreſt of tall fir trees, very large and very ſtrait. As theſe trees cannot ſtrike very deep into the earth, the violence of the wind often tears them up by the roots: they rot and become a light mould, upon which grows a buſhy thicket; and in this are found nettles, camomile, wild celery, aniſe, a ſpecies of cabbage, celandine, elder, wormwood, ſorrel; and without doubt there are other plants along the rivers.

The Spaniards ſaw ducks, gulls, divers, kites, ravens, geeſe, ſtorks, gold-finches, and other little birds unknown to them.

The commerce between the Spaniards and the Indians was quite undiſturbed; and ſo deſirous were the latter to obtain iron, cloth, and other ſtuffs, that they ſold their children for broken iron hoops and other wares. The Spaniards in this manner bought three young lads, one from five to ſix years old, another of four, and the third from nine to ten, not to make ſlaves, but Chriſtians of them; they hoped beſides to derive uſeful information from them as to the nature of the country and its inhabitants. Theſe youths were ſo contented in being with the Spaniards, that they hid themſelves when their parents came on board, from the apprehenſion of being again reſtored to them. Two young girls were alſo purchaſed with the ſame view; one very ugly, ſeven years of age; the other younger, better made, but ſickly, and almoſt at the gates of death.

At the full and change of the moon, the ſea riſes in the harbour of La Cruz ſeventeen feet three inches Engliſh; it is then high water at a quarter after 12 at noon: the loweſt tides are fourteen feet three inches; the night tides exceed by one foot nine inches thoſe of the day.

CRYSTALLIZATION,
and
Rock-Crystal.
} See Crystal and Crystallization, *Encycl.* and Chemistry-*Index* in this Supplement.

CUBIC Hyperbola, is a figure expreſſed by the equation $xy^2 = a$, having two aſymptotes, and conſiſting of two hyperbolas, lying in the adjoining angles of the aſymptotes, and not in the oppoſite angles, like the Apollonian hyperbola; being otherwiſe called by Newton, in his *Enumeratio Linearum Tertii Ordinis*, an hyperboliſmus of a parabola; and is the 65th ſpecies of thoſe lines according to him.

Cubic Parabola, a curve of the ſecond order, having two infinite legs tending contrary ways. The curve of this parabola cannot be rectified even by means of the conic ſections.

CULLEN (Dr William) was a man to whom phyſical ſcience is ſo deeply indebted, that it has often ſtruck us with wonder that no account of him has yet been given to the public, which deſerves to be claſſed with Britiſh biography. We know, indeed, that a life of him has been written by an eminent phyſician well qualified and ſtrongly inclined to do juſtice to the merits of his revered preceptor; but that life has been withheld from us by him who has certainly the beſt right to conſider himſelf as the guardian of the Doctor's fame, and who, we have been told, is to enlarge and publiſh it himſelf. In this ſtate of things our readers muſt pardon us for laying before them a very imperfect account of this eminent man, to whom we were ourſelves almoſt ſtrangers. There is a character of him in the periodical publication called *The Bee*, which we ſhall

ſhall appropriate to our own uſe, we are perſuaded, with the entire approbation of its author, though ſometimes we may expreſs our ſuſpicions that his praiſe is exaggerated.

Dr William Cullen was born in Lanarkſhire, in the weſt of Scotland, 11th December 1712. His father was for ſome time chief magiſtrate of the town of Hamilton; but though a very reſpectable man, his circumſtances were not ſuch as to permit him to lay out much money on the education of his ſon. William therefore, after ſerving an apprenticeſhip to a ſurgeon apothecary in Glaſgow, went ſeveral voyages to the Weſt Indies as a ſurgeon in a trading veſſel from London: but of this employment he tired, and ſettled himſelf, at an early period of life, as a country ſurgeon in the pariſh of Shotts, where he ſtaid a ſhort time practiſing among the farmers and country people, and then went to Hamilton with a view to practiſe as a phyſician, having never been fond of operating as a ſurgeon.

While he reſided near Shotts, it chanced that Archibald Duke of Argyle, who at that time bore the chief political ſway in Scotland, made a viſit to a gentleman of rank in that neighbourhood. The Duke was fond of literary purſuits, and was then particularly engaged in ſome chemical reſearches, which required to be elucidated by experiment. Eager in theſe purſuits, his Grace, while on this viſit, found himſelf much at a loſs for the want of ſome ſmall chemical apparatus, which his landlord could not furniſh: but happily recollecting young Cullen in the neighbourhood, he mentioned him to the Duke as a perſon who could probably furniſh it. He was accordingly invited to dine; was introduced to his Grace,—who was ſo much pleaſed with his knowledge, his politeneſs, and addreſs, that he formed an acquaintance which laid the foundation of all Dr Cullen's future advancement.

The name of Cullen by this time became familiar at every table in that neighbourhood; and thus he came to be known, by character, to the Duke of Hamilton, who then reſided, for a ſhort time, in that part of the country: and that nobleman having been ſuddenly taken ill, the aſſiſtance of young Cullen was called in; which proved a fortunate circumſtance in ſerving to promote his advancement to a ſtation in life more ſuited to his talents than that in which he had hitherto moved.

The character of the Douglaſſes, of which name the family of Hamilton now forms a principal branch, has always been ſomewhat of the ſame ſtamp with that of the riſing Cullen. Genius, benevolence, frankneſs, and conviviality of diſpoſition, have been, with them in general, very prominent features; and if to that be added a ſpirit of frolic and diſſipation, theſe will be accounted as only natural conſequences of thoſe youthful indulgences that ſpring from an exceſs of wealth at an early period of life, and the licence allowed to people of elevated rank. The Duke was therefore highly delighted with the ſprightly character and ingenious converſation of his new acquaintance. Receiving inſtruction from him in a much more pleaſing, and an infinitely eaſier way than he had ever before obtained, the converſation of Cullen proved highly intereſting to his Grace.—No wonder then that he ſoon found means to get his favourite Doctor, who was already the eſteemed acquaintance of the man through whoſe hands all preferments in Scotland were obliged to paſs, appointed to a place in the univerſity of Glaſgow, where his ſingular talents for diſcharging the duties of the ſtation he now occupied ſoon became very conſpicuous (A).

During his reſidence in the country, however, ſeveral important incidents occurred, that ought not to be paſſed over in ſilence. It was during this time that was formed a connection in buſineſs in a very humble line between two men, who became afterwards eminently conſpicuous in much more exalted ſtations. William, afterwards Doctor, Hunter, the famous lecturer on anatomy in London, was a native of the ſame part of the country; and not being in affluent circumſtances more than Cullen, theſe two young men, ſtimulated by the impulſe of genius to proſecute their medical ſtudies with ardour, but thwarted by the narrowneſs of their fortune, entered into a copartnery buſineſs as ſurgeons and apothecaries in the country. The chief end of their contract being to furniſh the parties with the means of proſecuting their medical ſtudies, which they could not ſeparately ſo well enjoy, it was ſtipulated, that one of them alternately ſhould be allowed to ſtudy in what college he inclined, during the winter, while the other ſhould carry on the buſineſs in the country for their common advantage. In conſequence of this agreement, Cullen was firſt allowed to ſtudy in the univerſity of Edinburgh for one winter; but when it came to Hunter's turn next winter, he, preferring London to Edinburgh, went thither. There his ſingular neatneſs in diſſecting, and uncommon dexterity in making anatomical preparations, his aſſiduity in ſtudy, his mildneſs of manner, and pliability of temper, ſoon recommended him to the notice of Dr Douglaſs, who then read lectures upon anatomy and midwifery there; who engaged Hunter as an aſſiſtant, and whoſe chair he afterwards filled with ſo much honour to himſelf and ſatisfaction to the public.

Thus was diſſolved, in a premature manner, a copartnery perhaps of as ſingular a kind as is to be found in the annals of literature: nor was Cullen a man of that diſpoſition to let any engagement with him prove a bar to his partner's advancement in life. The articles were freely departed from by him; and Cullen and Hunter ever after kept up a very cordial and friendly correſpondence; though, it is believed, they never from that time had a perſonal interview.

During the time that Cullen practiſed as a country ſurgeon and apothecary, he formed another connection of a more permanent kind, which, happily for him, was not diſſolved till a very late period of his life. With

---

(A) It was not, however, ſolely to the favour of theſe two great men that Cullen owed his literary fame. He was recommended to the notice of men of ſcience in a way ſtill more honourable to himſelf. The diſeaſe of the Duke of Hamilton having reſiſted the effect of the firſt applications, Dr Clarke was ſent for from Edinburgh; and he was ſo much pleaſed with every thing that Cullen had done, that he became his eulogiſt upon every occaſion. Cullen never forgot this; and when Clarke died, gave a public oration in his praiſe in the Univerſity of Edinburgh; which, it is believed, was the firſt of the kind in this country.

the ardour of diſpoſition he poſſeſſed, it cannot be ſuppoſed he beheld the fair ſex with indifference. Very early in life he took a ſtrong attachment to an amiable woman, a Miſs Johnſton, daughter to a clergyman in that neighbourhood, nearly of his own age, who was prevailed on to join with him in the ſacred bonds of wedlock, at a time when he had nothing elſe to recommend him to her except his perſon and diſpoſitions; for as to riches and poſſeſſions he had little of theſe to boaſt of. She was beautiful, had great good ſenſe, equanimity of temper, an amiable diſpoſition, and elegance of manners, and brought with her a little money, which, though it would be accounted nothing now, was ſomething in thoſe days to one in his ſituation in life. After giving to him a numerous family, and participating with him the changes of fortune which he experienced, ſhe peacefully departed this life in ſummer 1786.

In the year 1746, Cullen, who had now taken the degree of doctor in phyſic, was appointed a lecturer in chemiſtry in the univerſity of Glaſgow: and in the month of October began his lectures in that ſcience. His ſingular talents for arrangement, his diſtinctneſs of enunciation, his vivacity of manner, and his knowledge of the ſcience he taught, rendered his lectures intereſting to the ſtudents to a degree that had been till then unknown at that univerſity. He became, therefore, in ſome meaſure, adored by the ſtudents. The former profeſſors were eclipſed by the brilliancy of his reputation; and he had to experience all thoſe little rubs that envy and diſappointed ambition naturally threw in his way. Regardleſs, however, of theſe ſecret ſhagreens, he preſſed forward with ardour in his literary career; and, ſupported by the favour of the public, he conſoled himſelf for the contumely he met with from a few individuals. His practice as a phyſician increaſed from day to day; and a vacancy having occurred in the year 1751, he was then appointed by the king profeſſor of medicine in that univerſity. This new appointment ſerved only to call forth his powers, and to bring to light talents that it was not formerly known he poſſeſſed; ſo that his fame continued to increaſe.

As, at that period, the patrons of the univerſity of Edinburgh were conſtantly on the watch for the moſt eminent medical men to ſupport the riſing fame of the college, their attention was ſoon directed towards Cullen; who, on the death of Dr Plumber, profeſſor of chemiſtry, was, in 1756, unanimouſly invited to accept the vacant chair. This invitation he accepted: and having reſigned all his employments in Glaſgow, he began his academical career in Edinburgh in the month of October of that year; and there he reſided till his death.

If the admiſſion of Cullen into the univerſity of Glaſgow gave great ſpirit to the exertions of the ſtudents, this was ſtill, if poſſible, more ſtrongly felt in Edinburgh. Chemiſtry, which had been till that time of ſmall account in that univerſity, and was attended to by very few of the ſtudents, inſtantly became a favourite ſtudy; and the lectures upon that ſcience were more frequented than any others in the univerſity, anatomy alone excepted. The ſtudents, in general, ſpoke of Cullen with the rapturous ardour that is natural to youth when they are highly pleaſed. Theſe eulogiums appeared extravagant to moderate men, and could not fail to prove diſguſting to his colleagues. A party was formed among the ſtudents for oppoſing this new favourite of the public; and theſe ſtudents, by miſrepreſenting the doctrines of Cullen to others who could not have an opportunity of hearing theſe doctrines themſelves, made even ſome of the moſt intelligent men in the univerſity think it their duty publicly to oppoſe theſe imaginary tenets. The ferment was thus augmented; and it was ſome time before the profeſſors diſcovered the arts by which they had been impoſed upon, and univerſal harmony reſtored.

During this time of public ferment, Cullen went ſteadily forward, without taking any part himſelf in theſe diſputes. He never gave ear to any tales reſpecting his colleagues, nor took any notice of the doctrines they taught: That ſome of their unguarded ſtrictures might at times come to his knowledge, is not impoſſible; but if they did, they ſeemed to make no impreſſion on his mind.

Theſe attempts of a party of ſtudents to lower the character of Cullen on his firſt outſet in the univerſity of Edinburgh having proved fruitleſs, his fame as a profeſſor, and his reputation as a phyſician, became more and more reſpected every day. Nor could it well be otherwiſe: Cullen's profeſſional knowledge was always great, and his manner of lecturing ſingularly clear and intelligible, lively and entertaining; and to his patients, his conduct in general as a phyſician was ſo pleaſing, his addreſs ſo affable and engaging, and his manner ſo open, ſo kind, and ſo little regulated by pecuniary conſiderations, that it was impoſſible for thoſe who had occaſion to call once for his medical aſſiſtance, ever to be ſatisfied on any future occaſion without it. He became the friend and companion of every family he viſited; and his future acquaintance could not be diſpenſed with.

But if Dr Cullen in his public capacity deſerved to be *admired*, in his private capacity by his ſtudents he deſerved to be *adored*. His conduct to them was ſo attentive, and the intereſt he took in the private concerns of all thoſe ſtudents who applied to him for advice, was ſo cordial and ſo warm, that it was impoſſible for any one who had a heart ſuſceptible of generous emotions, not to be enraptured with a conduct ſo uncommon and ſo kind. Among ingenuous youth, gratitude eaſily degenerates into rapture—into reſpect nearly allied to adoration. Thoſe who advert to this natural conſtruction of the human mind, will be at no loſs to account for that popularity that Cullen enjoyed—a popularity, that thoſe who attempt to weigh every occurrence by the cool ſtandard of *reaſon* alone, will be inclined to think exceſſive. It is fortunate, however, that the bulk of mankind will ever be influenced in their judgment not leſs by feelings and affections than by the cold and phlegmatic dictates of *reaſon*. The adoration which generous conduct excites, is the reward which nature hath appropriated excluſively to diſintereſted beneficence. This was the ſecret charm that Cullen ever carried about with him, which faſcinated ſuch numbers of thoſe who had intimate acceſs to him. This was the power which his envious opponents never could have an opportunity of feeling.

The general conduct of Cullen to his ſtudents was thus. With all ſuch as he obſerved to be attentive and diligent, he formed an early acquaintance, by inviting them by twos, by threes, or by fours at a time, to ſup with him, converſing with them on theſe occaſions with the moſt engaging eaſe, and freely entering with them on the ſubject of their ſtudies, their amuſements, their difficulties, their hopes, and future proſpects. In this way he uſually invited the whole of his numerous claſs, till he made himſelf acquainted with their abilities, their private character, and their objects of purſuit. Thoſe among them whom he found moſt aſſiduous, beſt diſpoſed, or the moſt friendleſs, he invited the moſt frequently, till an intimacy was gradually formed, which proved highly beneficial to them. Their doubts, with regard to their objects of ſtudy, he liſtened to with attention, and ſolved with the moſt obliging condeſcenſion. His library, which conſiſted of an excellent aſſortment of the beſt books, eſpecially on medical ſubjects, was at all times open for their accommodation; and his advice, in every caſe of difficulty to them, they always had it in their power moſt readily to obtain. They ſeemed to be his family; and few perſons of diſtinguiſhed merit have left the univerſity of Edinburgh in his time, with whom he did not keep up a correſpondence till they were fairly eſtabliſhed in buſineſs. By theſe means he came to have a moſt accurate knowledge of the ſtate of every country, with reſpect to practitioners in the medical line; the only uſe he made of which knowledge was, to direct ſtudents in their choice of places, where they might have an opportunity of engaging in buſineſs with a reaſonable proſpect of ſucceſs. Many, very many, able men has he thus put into a good line of buſineſs where they never could have thought of it themſelves; and they are now reaping the fruits of this beneficent foreſight on his part.

Nor was it in this way only that he befriended the ſtudents at the univerſity of Edinburgh. Poſſeſſing a benevolence of mind that made him ever think firſt of the wants of others, and recollecting the difficulties that he himſelf had had to ſtruggle with in his younger days, he was at all times ſingularly attentive to their pecuniary concerns. From his general acquaintance among the ſtudents, and the friendly habits he was on with many of them, he found no difficulty in diſcovering thoſe among them who were rather in hampered circumſtances, without being obliged to hurt their delicacy in any degree. To ſuch perſons, when their habits of ſtudy admitted of it, he was peculiarly attentive. They were more frequently invited to his houſe than others; they were treated with more than uſual kindneſs and familiarity; they were conducted to his library, and encouraged by the moſt delicate addreſs to borrow from it freely whatever books he thought they had occaſion for: and as perſons in theſe circumſtances were uſually more ſhy in this reſpect than others, books were ſometimes preſſed upon them as a ſort of conſtraint, by the Doctor inſiſting to have their opinion of ſuch or ſuch paſſages they had not read, and deſiring them to carry the book home for that purpoſe. He, in ſhort, behaved to them rather as if he courted their company, and ſtood in need of their acquaintance than they of his. He thus raiſed them in the opinion of their acquaintance to a much higher degree of eſtimation than they could otherwiſe have obtained; which, to people whoſe minds were depreſſed by penury, and whoſe ſenſe of honour was ſharpened by the conſciouſneſs of an inferiority of a certain kind, was ſingularly engaging. Thus they were inſpired with a ſecret ſenſe of dignity, which elevated their minds, and excited an uncommon ardour of purſuit, inſtead of that melancholy inactivity which is ſo natural in ſuch circumſtances, and which too often leads to deſpair. Nor was he leſs delicate in the manner of ſupplying their wants, than attentive to diſcover them. He often found out ſome polite excuſe for refuſing to take payment for a firſt courſe, and never was at a loſs for one to an after courſe. Before they could have an opportunity of applying for a ticket, he would ſometimes lead the converſation to ſome ſubject that occurred in the courſe of his lectures; and as his lectures were never put in writing by himſelf, he would ſometimes beg the favour to ſee their notes, if he knew they had been taken with attention, under a pretext of aſſiſting his memory. Sometimes he would expreſs a wiſh to have their opinion of a particular part of his courſe, and preſented them with a ticket for that purpoſe; and ſometimes he refuſed to take payment, under the pretext that they had not received his full courſe the preceding year, ſome part of it having been neceſſarily omitted for want of time, which he meant to include in this courſe. By ſuch delicate addreſs, in which he greatly excelled, he took care to forerun their wants. Thus he not only gave them the benefit of his own lectures, but by refuſing to take their money, he alſo enabled them to attend thoſe of others that were neceſſary to complete their courſe of ſtudies. Theſe were particular devices he adopted to individuals to whom economy was neceſſary; but it was a general rule with him, never to take money from any ſtudent for more than two courſes of the ſame ſet of lectures, permitting him to attend theſe lectures as many years longer as he pleaſed *gratis*.

He introduced another general rule into the univerſity, that was dictated by the ſame principle of diſintereſted beneficence, that ought not to be here paſſed over in ſilence. Before he came to Edinburgh, it was the cuſtom of medical profeſſors to accept of fees for their medical aſſiſtance, when wanted, even from medical ſtudents themſelves, who were perhaps attending the profeſſor's own lectures at the time. But Cullen never would take fees as a phyſician from any ſtudent at the univerſity, though he attended them, when called in as a phyſician, with the ſame aſſiduity and care as if they had been perſons of the firſt rank, who paid him moſt liberally. This gradually induced others to adopt a ſimilar practice; ſo that it is now become a general rule for medical profeſſors to decline taking any fees when their aſſiſtance is neceſſary to a ſtudent. For this uſeful reform, with many others, the ſtudents of the univerſity of Edinburgh are ſolely indebted to the liberality of Dr Cullen.

The firſt lectures which Cullen delivered in Edinburgh were on chemiſtry; and for many years he alſo gave clinical lectures on the caſes which occurred in the Royal Infirmary. In the month of February 1763, Dr Alſton died, after having begun his uſual courſe of lectures on the materia medica; and the magiſtrates of Edinburgh, as patrons of that profeſſorſhip in the univerſity, appointed Dr Cullen to that chair, requeſting that he would finiſh the courſe of lectures that had been begun for that ſeaſon. This he agreed to do; and though he was under a neceſſity of going on with the courſe in a few days after he was nominated, he did not once think of reading the lectures of his predeceſſor, but reſolved to deliver a new courſe entirely his own.

The

The popularity of Cullen at this time may be gueſſed at by the increaſe of new ſtudents who came to attend his courſe in addition to the eight or ten who had entered to Dr Alſton. The new ſtudents exceeded 100. An imperfect copy of theſe lectures, thus fabricated in haſte, having been publiſhed, the Doctor thought it neceſſary to give a more correct edition of them in the latter part of his life. But his faculties being then much impaired, his friends looked in vain for thoſe ſtriking beauties that characteriſed his literary exertions in the prime of life.

Some years afterwards, on the death of Dr White, the magiſtrates once more appointed Dr Cullen to give lectures on the theory of phyſic in his ſtead. And it was on that occaſion Dr Cullen thought it expedient to reſign the chemical chair in favour of Dr Black, his former pupil, whoſe talents in that department of ſcience were then well known, and who filled the chair till his death with great ſatisfaction to the public*. Soon after, on the death of Dr Rutherford, who for many years had given lectures with applauſe on the practice of phyſic, Dr John Gregory (whoſe name can never be mentioned by any one who had the pleaſure of his acquaintance without the warmeſt tribute of a grateful reſpect) having become a candidate for this place along with Dr Cullen, a ſort of compromiſe took place between them; by which they agreed each to give lectures alternately on the theory and on the practice of phyſic during their joint lives, the longeſt ſurvivor being allowed to hold either of the claſſes he ſhould incline. In conſequence of this agreement, Dr Cullen delivered the *firſt* courſe of lectures on the practice of phyſic in winter 1766, and Dr Gregory ſucceeded him in that branch the following year. Never perhaps did a literary arrangement take place that could have proved more beneficial to the ſtudents than this. Both theſe men poſſeſſed great talents, though of a kind extremely diſſimilar. Both of them had certain failings or defects, which the other was aware of, and counteracted. Each of them knew and reſpected the talents of the other. They co-operated, therefore, in the happieſt manner, to enlarge the underſtanding, and to forward the purſuits of their pupils. Unfortunately this arrangement was ſoon deſtroyed by the unexpected death of Dr Gregory, who was cut off in the flower of life by a ſudden and unforeſeen event. After this time, Cullen continued to give lectures on the practice of phyſic till a few months before his death, which happened on the 5th of February 1790, in the 77th year of his age.

In drawing the character of Dr Cullen, Dr Anderſon, to whom we are indebted for this ſketch, obſerves, that in ſcientific purſuits men may be arranged into two grand claſſes, which, though greatly different from each other in their extremes, yet approximate at times ſo near as to be blended indiſcriminately together; thoſe who poſſeſs a talent for detail, and thoſe who are endowed with the faculty of arrangement. The firſt may be ſaid to view objects individually as through a microſcope. The field of viſion is confined; but the objects included within that field, which muſt uſually be conſidered ſingly and apart from all others, are ſeen with a wondrous degree of accuracy and diſtinctneſs. The other takes a ſweeping view of the univerſe at large, conſiders every object he perceives not individually, but as a part of one harmonious whole: His mind is therefore not ſo much employed in examining the ſeparate parts of this individual object, as in tracing its relations, connections, and dependencies, on thoſe around it.—Such was the turn of Cullen's mind. The talent for arrangement was that which peculiarly diſtinguiſhed him from the ordinary claſs of mortals; and this talent he poſſeſſed perhaps in a more diſtinguiſhed degree than any other perſon of the age in which he lived. Many perſons exceeded him in the minute knowledge of particular departments, who, knowing this, naturally looked upon him as their inferior; but poſſeſſing not at the ſame time that glorious faculty, which, "with an eye wide roaming, glances from the earth to heaven," or the charms which this talent can infuſe into congenial minds, felt diſguſt at the pre-eminence he obtained, and aſtoniſhment at the means by which he obtained it. An Ariſtotle and a Bacon have had their talents in like manner appretiated; and many are the perſons who can neither be exalted to ſublime ideas with Homer, nor raviſhed with the natural touches of a Shakeſpeare. Such things are wiſely ordered, that every department in the univerſe may be properly filled by thoſe who have talents exactly ſuited to the taſk aſſigned them by heaven.

Had Cullen, however, poſſeſſed the talents for arrangement alone, ſmall would have been his title to that high degree of applauſe he has attained. Without a knowledge of *facts*, a talent for arrangement produces nothing but chimeras; without materials to work upon, the ſtructures which an over-heated imagination may rear up are merely "the baſeleſs fabric of a viſion." No man was more ſenſible of the juſtneſs of this remark than Dr Cullen, and few were at greater pains to avoid it. His whole life, indeed, was employed, almoſt without interruption, in collecting facts. Whether he was reading, or walking, or converſing, theſe were continually falling into his way. With the keen perception of an eagle, he marked them at the firſt glance; and without ſtopping at the time to examine them, they were ſtored up in his memory, to be drawn forth as occaſion required, to be confronted with other facts that had been obtained after the ſame manner, and to have their truth aſcertained, or their falſity proved, by the evidence which ſhould appear when carefully examined at the impartial bar of juſtice. Without a memory retentive in a ſingular degree, this could not have been done; but ſo very extraordinary was Dr Cullen's memory, that till towards the very decline of life, there was ſcarcely a fact that had ever occurred to him which he could not readily recollect, with all its concomitant circumſtances, whenever he had occaſion to refer to it. It was this faculty which ſo much abridged his labour in ſtudy, and enabled him ſo happily to avail himſelf of the labour of others in all his literary ſpeculations. He often reaped more by the converſation of an hour than another man would have done in whole weeks of laborious ſtudy.

In his prelections, Dr Cullen never attempted to read. His lectures were delivered *viva voce*, without having been previouſly put into writing, or thrown into any particular arrangement. The vigour of his mind was ſuch, that nothing more was neceſſary than a few ſhort notes before him, merely to prevent him from varying from the general order he had been accuſtomed to obſerve. This gave to his diſcourſes an eaſe, a vivacity,

---

* See *Black*, Suppl.

vacity, a variety, and a force, that are rarely to be met with in academical diſcourſes. His lectures, by conſequence, upon the ſame ſubject were never exactly the ſame. Their general tenor indeed was not much varied; but the particular illuſtrations were always new, well ſuited to the circumſtances that attracted the general attention of the day, and were delivered in the particular way that accorded with the caſt of mind the prelector found himſelf in at the time. To theſe circumſtances muſt be aſcribed that energetic artleſs elocution, which rendered his lectures ſo generally captivating to his hearers. Even thoſe who could not follow him in thoſe extenſive views his penetrating mind glanced at, or who were not able to underſtand thoſe apt alluſions to collateral objects which he could only rapidly point at as he went along, could not help being warmed in ſome meaſure by the vivacity of his manner. But to thoſe who could follow him in his rapid career, the ideas he ſuggeſted were ſo numerous, the views he laid open were ſo extenſive, and the objects to be attained were ſo important—that every active faculty of the mind was rouſed; and ſuch an ardour of enthuſiaſm was excited in the proſecution of ſtudy, as appeared to be perfectly inexplicable to thoſe who were merely unconcerned ſpectators. In conſequence of this unſhackled freedom in the compoſition and delivery of his lectures, every circumſtance was in the niceſt uniſon with the tone of voice and expreſſion of countenance, which the particular caſt of mind he was in at the time inſpired. Was he joyous, all the figures introduced for illuſtration were fitted to excite hilarity and good humour: was he grave, the objects brought under view were of a nature more ſolemn and grand: and was he peeviſh, there was a peculiarity of manner in thought, in word, and in action, which produced a moſt ſtriking and intereſting effect. The languor of a nerveleſs uniformity was never experienced, nor did an abortive attempt to excite emotions that the ſpeaker himſelf could not at the time feel, ever produce thoſe diſcordant ideas which prove diſguſting and unpleaſing.

It would ſeem as if Dr Cullen had conſidered the proper buſineſs of a preceptor to be that of putting his pupils into a proper train of ſtudy, ſo as to enable them to proſecute thoſe ſtudies at a future period, and to carry them on much farther than the ſhort time allowed for academical prelections would admit. He did not, therefore, ſo much ſtrive to make thoſe who attended his lectures deeply verſed in the particular details of objects, as to give them a general view of the whole ſubject; to ſhew what had been already attained reſpecting it; to point out what remained yet to be diſcovered; and to put them into a train of ſtudy that ſhould enable them at a future period, to remove thoſe difficulties that had hitherto obſtructed our progreſs; and thus to advance of themſelves to farther and farther degrees of perfection. If theſe were his views, nothing could be more happily adapted to them than the mode he invariably purſued. He firſt drew, with the ſtriking touches of a maſter, a rapid and general outline of the ſubject, by which the whole figure was ſeen at once to ſtart boldly from the canvas, diſtinct in all its parts, and unmixed with any other object. He then began anew to retrace the picture, to touch up the leſſer parts, and to finiſh the whole in as perfect a manner as the ſtate of our knowledge at the time would permit. Where materials were wanting, the picture there continued to remain imperfect. The wants were thus rendered obvious; and the means of ſupplying theſe were pointed out with the moſt careful diſcrimination. The ſtudent, whenever he looked back to the ſubject, perceived the defects; and his hopes being awakened, he felt an irreſiſtible impulſe to explore that hitherto untrodden path which had been pointed out to him, and fill up the chaſm which ſtill remained. Thus were the active faculties of the mind moſt powerfully excited; and inſtead of labouring himſelf to ſupply deficiencies that far exceeded the power of any one man to accompliſh, he ſet thouſands at work to fulfil the taſk, and put them into a train of going on with it, when he himſelf ſhould be gone to that country "from whoſe dread bourne no traveller returns."

It was to theſe talents, and to this mode of applying them, that Dr Cullen owed his celebrity as a profeſſor; and it was in this manner that he has perhaps done more towards the advancement of ſcience than any other man of his time, though many individuals might perhaps be found who were more deeply verſed in the particular departments he taught than he himſelf was. Chemiſtry, which was before his time a moſt diſguſting purſuit, was by him rendered a ſtudy ſo pleaſing, ſo eaſy, and ſo attractive, that it is now proſecuted by numbers as an agreeable recreation, who but for the lights that were thrown upon it by Cullen and his pupils, would never have thought of engaging in it at all; though perhaps they never heard of Cullen's name, nor have at this time the moſt diſtant idea that they owe any obligations to him; and the ſame may be ſaid of the other branches of ſcience which he taught.

According to a man who knew him well, there are three things which eminently diſtinguiſhed Cullen as a profeſſor. "The energy of his mind, by which he viewed every ſubject with ardour, and combined it immediately with the whole of his knowledge.

"The ſcientific arrangement which he gave to his ſubject, by which there was a *lucidus ordo* to the dulleſt ſcholar. He was the firſt perſon in this country who made chemiſtry ceaſe to be a chaos.

"A wonderful art of intereſting the ſtudents in every thing which he taught, and of raiſing an emulative enthuſiaſm among them."

We are well aware that this character will by many be deemed an extravagant panegyric; but having no opportunity of judging for ourſelves, we would rather adopt from others an extravagant panegyric than an unmerited cenſure. Dr Anderſon himſelf admits that Cullen's character was far from perfect; and, in the opinion of moſt other men with whom we have converſed on the ſubject, and who were at the ſame time qualified to form an eſtimate of his mental powers, his imagination was not balanced by his judgment. Hence the common remark in the univerſity of Edinburgh, that Dr Cullen was more ſucceſsful in demoliſhing the theories of others than in giving ſtability to thoſe which were reared by himſelf.

Dr Cullen's external appearance, though ſtriking and not unpleaſing, was not elegant. His countenance was expreſſive, and his eye in particular remarkably lively, and at times wonderfully penetrating. In his perſon he was tall and thin, ſtooping very much about the ſhoulders. When he walked, he had a contemplative look, and

and did not ſeem much to regard the objects around him.

CURFEU Bell (ſee Curfew, *Encycl*), called in the law Latin of the middle ages *ignitegium* or *pyritegium*, and in French, *cuvre-feu*—was a ſignal for all perſons to extinguiſh their fires at a certain hour. In thoſe ages people made fires in their houſes in a hole or pit in the centre of the floor, under an opening formed in the roof; and when the fire was burnt out, or the family went to bed, the hole was ſhut by a cover of wood or of earth. This practice ſtill prevails among the cottagers in ſome parts of Scotland, and we doubt not of other countries. In the dark ages, when all ranks of people were turbulent, a law was almoſt everywhere eſtabliſhed, that the fire ſhould be extinguiſhed at a certain time in the evening; that the cover ſhould be put over the fire-place; and that all the family ſhould retire to reſt, or at leaſt keep within doors The time when this ought to be done was ſignified by the ringing of a bell, called therefore the *curfeu-bell* or *ignitegium*. The law of William the Conqueror, which introduced this practice into England, as has been mentioned in the Encyclopædia, was aboliſhed by Henry I. in 1100.

The ringing of the curfeu-bell gave riſe to the prayer-bell, as it is called, which is ſtill retained in ſome Proteſtant countries. Pope John XXIII. with a view to avert certain apprehended misfortunes, which rendered his life uncomfortable, gave orders, that every perſon, on hearing the *ignitegium*, ſhould repeat the *Ave Maria* three times. When the appearance of a comet, and a dread of the Turks, afterwards alarmed all Chriſtendom, Pope Calixtus III. increaſed theſe periodical times of prayer, by ordering the prayer-bell to be rung alſo at noon. *Beckmann's Hiſtory of Inventions.*

CURVE of Equable Approach. It was firſt propoſed by Leibnitz, namely, to find a curve, down which a body deſcending by the force of gravity ſhall make equal approaches to the horizon in equal portions of time. It has been found by Bernoulli and others, that the curve is the ſecond cubical parabola, placed with its vertex uppermoſt, and which the deſcending body muſt enter with a certain determinate velocity. Varignon rendered the queſtion general for any law of gravity, by which a body may approach towards a given point by equal ſpaces in equal times. And Maupertuis alſo reſolved the problem in the caſe of a body deſcending in a medium which reſiſts as the ſquare of the velocity.

CUSSO, or Banksia Abyssinica, is a beautiful and uſeful tree, indigenous to the high country of Abyſſinia. At leaſt Mr Bruce, who has given of it the only deſcription which we have ſeen, ſays that he never ſaw it in any other part of Aſia or Africa. It ſeldom grows above 20 feet high, very rarely ſtraight, generally crooked or inclined. Its leaf, which is of a deep unvarniſhed green, having the fore part covered with ſoft hair or down, is about 2¼ inches long, divided by a ſtrong rib into two unequal diviſions, of which the upper is broader and larger than the lower. It is more indented than even the nettle leaf, which it in ſome meaſure reſembles, only the leaf of the *Cuſſo* is narrower and longer.

Thoſe leaves grow two and two upon a branch, having between each two the rudiments of *two pair* of leaves, which probably are *deciduous;* but the branch is terminated with a ſingle leaf or *ſtipula* at the point. The end of this ſtalk is broad and ſtrong, like that of a palm branch. It is not ſolid like the gerid of the date tree, but opens in the part that is without leaves about an inch and a half from the bottom, and out of this aperture proceeds the flower. There is a round ſtalk, bare for about an inch and a quarter, from which proceed crooked branches with ſingle flowers attached to their ends; the ſtalk that carries theſe proceeds out of every crook or geniculation. The whole cluſter of flowers has very much the ſhape of a cluſter of grapes; the ſtalks which ſupport it reſemble the ſtalks of the grape; and a very few ſmall leaves are ſcattered through the cluſter of flowers.

"The calyx or flower cup is of a *greeniſh* colour, tinged with purple; when fully blown it is altogether of a deep *red* or purple; the corolla is *white*, and conſiſts of five petals; in the midſt is a ſhort piſtil with a round head, ſurrounded by eight ſtamina, of the ſame form, loaded with yellow farina. The cup conſiſts of five petals, which much reſemble another flower; they are rounded at the top, and nearly of an equal breadth every way. The ſeed is very ſmall, ſmaller than even the ſemen ſantonicum; and being likewiſe very bitter it is uſed in Abyſſinia as a vermifuge. From its ſmallneſs, however, and its being very eaſily ſhed, no great quantity of it is ever gathered, and therefore the flower is often ſubſtituted in its ſtead. The Abyſſinians, ſays our author, of both ſexes, and at all ages, are troubled with the ſort of worm called aſcarides, of which every individual evacuates a large quantity once a-month. The method of promoting theſe evacuations is by infuſing a handful of dry cuſſo flowers in about two Engliſh quarts of bouza, or the beer they make of teff (ſee Teff, *Encycl.*), and after it has been ſteeped all night, the next morning it is fit for uſe.

"The bark of the tree is ſmooth, of a yellowiſh white, interſperſed with brown ſtreaks, which paſs through the whole body of the tree. It is not firm or hard, but rather ſtringy and reedy. On the upper part, before the firſt branch of leaves ſet out, are rings round the trunk, of ſmall filaments of the conſiſtence of horſe hair: theſe are generally fourteen or ſixteen in number, and are a very remarkable characteriſtic belonging to the tree."

From this deſcription, which, it muſt be confeſſed, is not remarkable for perſpicuity, and from an inſpection of the figure which Mr Bruce has given of the cuſſo, we are inclined to rank it with the palms, as a new genus, neareſt to the *caryota*.

CUVETTE, or Cunette, in fortification, is a kind of ditch within a ditch, being a pretty deep trench, about four fathoms broad, ſunk and running along the middle of the great dry ditch, to hold water; ſerving both to keep off the enemy and prevent him from mining.

CYCLE of Indiction, is a ſeries of 15 years, returning conſtantly around like the other cycles, and commenced from the third year before Chriſt; whence it happens that if 3 be added to any given year of Chriſt, and the ſum be divided by 15, what remains is the year of the indiction.

CYCLOID (ſee *Encycl.*) is a curve, which is thus generated: Suppoſe a wheel or circle to roll along a ſtraight line till it has completed juſt one revolution; a nail or point in that part of the circumference of the circle, which at the beginning of the motion touches the ſtraight line, will, at the end of the revolution, have deſcribed on a vertical plane a cycloid.

DAGELET,

D.

Dagelet, Dairy.

DAGELET, the name given by *La Perouſe*, the celebrated though unfortunate navigator, to an iſland on the coaſt of Corea (ſee Corea, *Encycl.*), which he diſcovered in the year 1787. It is little more than three leagues in circumference; and our author almoſt made its circuit at the diſtance of a mile without finding bottom. This ſmall ſpot is very ſteep, but covered with the fineſt trees from the ſea-ſhore to the ſummit. A rampart of bare rock, like a wall, encircles the whole outline of it, with the exception of ſeven little ſandy creeks, where it is poſſible to land. In theſe creeks the Frenchmen ſaw upon the ſtocks ſome boats of a conſtruction altogether Chineſe; but the ſight of their ſhips frightened the workmen, who fled from their dock-yard into the wood, which was not more than fifty paces diſtant. As a few huts were ſeen, but neither villages nor cultivation, La Perouſe concluded that the iſland is without inhabitants, and that the men whom he ſaw at work were Corean carpenters, who during the ſummer months go with proviſion to Dagelet for the purpoſe of building boats, which they ſell upon the continent. He places the north-eaſt point of this iſland in Lat. 37°. 25′. and E. Long. 129°. 2′. from Paris.

DAIRY is a word which ſignifies ſometimes the art of making various kinds of food from milk; ſometimes the place where milk is manufactured; and ſometimes the management of a milk-farm. On the *dairy*, in the firſt and ſecond of theſe ſenſes, enough has been ſaid in the *Encyclopædia* under the titles Butter, Cheese, and Dairy; on the management of a milk farm that work contains nothing.

When a dairy is eſtabliſhed, the undertaker may ſometimes think it his intereſt to obtain the greateſt poſſible quantity of produce; ſometimes it may be more beneficial for him to have it of the fineſt quality; and at other times it may be neceſſary to have both theſe objects in view, the one or the other in a greater or leſs proportion: it is therefore of importance that he ſhould know how he may accompliſh the one or the other of theſe purpoſes in the eaſieſt and moſt direct manner.

To be able to convert his milk to the higheſt poſſible profit in every caſe, he ought to be fully acquainted with every circumſtance reſpecting the manufacture both of butter and of cheeſe; as it may in ſome caſes happen, that a certain portion of that milk may be more advantageouſly converted into butter than into cheeſe, while another portion of it would return more profit if made into cheeſe.

The firſt thing to be adverted to, in an undertaking of this nature, is to chooſe cows of a proper ſort. Among this claſs of animals, it is found, by experience, that ſome kinds give milk of a much thicker conſiſtence and richer quality than others; nor is this richneſs of quality neceſſarily connected with the ſmallneſs of the quantity yielded by cows of nearly an equal ſize; it therefore behoves the owner of a dairy to be peculiarly attentive to this circumſtance. In judging of the value of a cow, it ought rather to be the quantity and the quality of the cream produced from the milk of the cow, in a given time, than the quantity of the milk itſelf: this is a circumſtance that will be ſhewn hereafter to be of more importance than is generally imagined. The ſmall cows of the Alderney breed afford the richeſt milk hitherto known; but individual cows in every country may be found, by a careful ſelection, that afford much thicker milk than others; theſe therefore ought to be ſearched for with care, and their breed reared with attention, as being peculiarly valuable.

Few perſons who have had any experience at all in the dairy, can be ignorant, however, that in comparing the milk of two cows, to judge of their reſpective qualities, particular attention muſt be paid to the time that has elapſed ſince their calving; for the milk of the ſame cow is always thinner ſoon after calving than it is afterwards; as it gradually becomes thicker, though generally leſs in quantity, in proportion to the time ſince the cow has calved. The colour of the milk, ſoon after calving, is richer than it is afterwards; but this, eſpecially for the firſt two weeks, is a faulty colour that ought not to be coveted.

To make the cows give abundance of milk, and of a good quality, they muſt at all times have plenty of food. Graſs is the beſt food yet known for this purpoſe, and that kind of graſs which ſprings up ſpontaneouſly on rich dry ſoils is the beſt of all. If the temperature of the climate be ſuch as to permit the cows to graze at eaſe throughout the day, they ſhould be ſuffered to range on ſuch paſtures at freedom; but if the cows are ſo much incommoded by the heat as to be prevented from eating through the day, they ought in that caſe to be taken into cool ſhades for protection; where, after allowing them a proper time to ruminate, they ſhould be ſupplied with abundance of green food, freſh-cut for the purpoſe, and given to them by hand frequently, in ſmall quantities, freſh and freſh, ſo as to induce them to eat it with pleaſure. When the heat of the day is over, and they can remain abroad with eaſe, they may be again turned into the paſture, where they ſhould be allowed to range with freedom all night, during the mild weather of ſummer.

Cows, if abundantly fed, ſhould be milked three times a-day, during the whole of the ſummer ſeaſon (a); in

---

(a) If cows be milked only twice in the day (24 hours), while they have abundance of ſucculent food, they will yield a much ſmaller quantity of milk, in the ſame time, than if they be milked three times. Some attentive obſervers think a cow, in theſe circumſtances, will give nearly as much milk at each time, if milked three times, as if ſhe were milked only twice. This fact, however, has not, that we know of, been aſcertained by experiment. There can be no doubt but they give more, how much more is not aſcertained; nor, whether it would be advantageous, in any caſe, to milk them four times, or oftener; nor, what effect frequent milking produces on the quality of the milk.

the morning early, at noon, and in the evening, juſt before night-fall. In the choice of perſons for milking the cows, great caution ſhould be employed; for if that operation be not carefully and properly performed, not only the quantity of the produce of the dairy will be greatly diminiſhed, but its quality alſo will be very much debaſed; for if all the milk be not thoroughly drawn from a cow when ſhe is milked, that portion of milk which is left in the udder ſeems to be gradually abſorbed into the ſyſtem, and Nature generates no more than to ſupply the waſte of what has been taken away. If this leſſened quantity be not again thoroughly drawn off, it occaſions a yet farther diminution of the quantity of milk generated; and thus it may be made to proceed, in perpetual progreſſion from little to leſs, till none at all is produced. In ſhort, this is the practice in all caſes followed, when it is meant to allow a cow's milk to dry up entirely, without doing her hurt. In this manner, therefore, the profits of a dairy might be wonderfully diminiſhed; ſo that it much behoves the owner of it to be extremely attentive to this circumſtance, if he wiſhes to avoid ruin. It ought to be a rule without an exception, never to allow this important department to be entruſted, without controul, to the management of hired ſervants (B). Its importance will be ſtill more manifeſt from what follows.

It is to Dr James Anderſon that we are indebted for theſe judicious obſervations, as well as for the following aphoriſms which, though they may be in part known to attentive houſewifes, he has reaſon to believe are not commonly adverted to as their importance deſerves.

Aphoriſm 1.

“ Of the milk that is drawn from any cow at one time, that which comes off at the firſt is always thinner, and of a much worſe quality, than that which comes afterwards; and the richneſs goes on continually increaſing to the very laſt drop that can be drawn from the udder at that time.”

Few perſons are ignorant that the milk which is laſt of all taken from the cow at milking (in this country called *ſtroakings*) is richer than the reſt of the milk; but fewer ſtill are aware of the greatneſs of the diſproportion between the quality of the firſt and the laſt drawn milk, from the ſame cow, at one milking. The following facts (ſays our author) reſpecting this circumſtance were aſcertained by me many years ago, and have been confirmed by many ſubſequent experiments and obſervations.

Having taken ſeveral large tea-cups, exactly of the ſame ſize and ſhape, one of theſe tea-cups was filled at the beginning of the milking, and the others at regular intervals, till the laſt, which was filled with the dregs of the ſtroakings. Theſe cups were then weighed, the weight of each having been ſettled, ſo as to aſcertain that the quantity of milk in each was preciſely the ſame; and from a great number of experiments, frequently repeated with many different cows, the reſult was in all caſes as follows:

The quantity of cream obtained from the firſt-drawn cup was, in every caſe, much ſmaller than from that which was laſt drawn; and thoſe between afforded leſs or more as they were nearer the beginning or the end. It is unneceſſary here to ſpecify theſe intermediate proportions; but it is proper the reader ſhould be informed, that the quantity of cream obtained from the laſt-drawn cup, from ſome cows, exceeded that from the firſt in the proportion of ſixteen to one. In other cows, however, and in particular circumſtances, the diſproportion was not quite ſo great; but in no caſe did it fall ſhort of the rate of eight to one. Probably, upon an average of a great many cows, it might be found to run as ten or twelve to one.

Secondly, The difference in the quality of the cream, however, obtained from theſe two cups, was much greater than the difference in the quantity. In the firſt cup, the cream was a thin tough film, thinner, and perhaps whiter, than writing paper; in the laſt, the cream was of a thick *butyrous* conſiſtence, and of a glowing richneſs of colour that no other kind of cream is ever found to poſſeſs.

Thirdly, The difference in the quality of the milk that remained, after the cream was ſeparated, was perhaps ſtill greater than either in reſpect to the quantity or the quality of the cream. The milk in the firſt cup was a thin bluiſh liquid, as if a very large proportion of water had been mixed with ordinary milk; that in the laſt cup was of a thick conſiſtence, and yellow colour, more reſembling cream than milk both in taſte and appearance.

From this important experiment, it appears that the perſon who, by bad milking of his cows, loſes but half a pint of his milk, loſes in fact about as much cream as would be afforded by ſix or eight pints at the beginning, and loſes, beſides, that part of the cream which alone can give richneſs and high flavour to his butter.

Aphoriſm 2.

“ If milk be put into a diſh, and allowed to ſtand till it throws up cream, that portion of cream which riſes firſt to the ſurface is richer in quality, and greater in quantity, than what riſes in a ſecond equal ſpace of time; and the cream that riſes in the ſecond interval of time is greater in quantity, and richer in quality, than that which riſes in a third equal ſpace of time; that of the third than the fourth, and ſo on: the cream that riſes decreaſing in quantity, and declining in quality, continually, as long as any riſes to the ſurface.”

Our ingenious author confeſſes, that his experiments not having been made with ſo much accuracy in this caſe as in the former, he was not enabled to aſcertain the difference in the proportion that takes place in equal portions of time; but they have been ſo often repeated as not to leave any room to doubt the fact, and it will be allowed to be a fact of no ſmall importance in the management of the dairy. It is not certain, however, but that a greater quantity of cream may, upon the whole, be obtained from the milk by taking it away

---

(B) Cows ſhould always be treated with great gentleneſs, and ſoothed by mild uſage, eſpecially when young and ticklish, or when the paps are tender; in which laſt caſe, the udder ought to be fomented with warm water before milking, and touched with the greateſt gentleneſs, otherwiſe the cow will be in danger of contracting bad habits, becoming ſtubborn and unruly, and retaining her milk ever after. A cow never lets down her milk pleaſantly to the perſon ſhe dreads or diſlikes. The udder and paps ſhould always be waſhed with clean water before milking; but care ſhould be taken that none of that water be admitted into the milking-pail.

away at different times; but the proceſs is ſo troubleſome as not to be counterbalanced by the increaſed quantity obtained, if indeed an increaſed quantity be thus obtained, which is not as yet quite certain.

Aphoriſm 3. "Thick milk always throws up a ſmaller proportion of the cream it actually contains to the ſurface, than milk that is thinner; but that cream is of a richer quality. If water be added to that thick milk, it will afford a conſiderably greater quantity of cream than it would have done if allowed to remain pure, but its quality is, at the ſame time, greatly debaſed."

This is a fact that every perſon attentive to a dairy muſt have remarked; but I have never (ſays our author) heard of any experiment that could aſcertain, either the preciſe amount of the increaſed quantity of cream that might thus be obtained, or of the ratio in the decreaſe of its quality. The effects of mixing water with the milk in a dairy are at leaſt aſcertained; and the knowledge of this fact will enable attentive perſons to follow that practice which they think will beſt promote their own intereſt.

Aphoriſm 4. "Milk which is put into a bucket or other proper veſſel, and carried in it to any conſiderable diſtance, ſo as to be much agitated, and in part cooled, before it be put into the milk-pans to ſettle for cream, never throws up ſo much, nor ſo rich cream, as if the ſame milk had been put into the milk-pans directly after it was milked."

In this caſe, it is believed the loſs of cream will be nearly in proportion to the time that has elapſed, and the agitation the milk has ſuſtained, after being drawn from the cow. But Dr Anderſon ſays that he is not yet in poſſeſſion of any experiments which ſufficiently aſcertain how much is to be aſcribed to the time, and the agitation, taken ſeparately. On every branch of agriculture we find experiments wanting, at each ſtep we advance in our inquiries; and it is the duty of every enquirer to point out, as he goes along, where they are wanted, ſince the labours of no one man can poſſibly complete the whole.

From the above facts, the following corollaries ſeem to be clearly deducible:

Firſt. It is of importance that the cows ſhould be always milked as near the dairy as poſſible, to prevent the neceſſity of carrying and cooling the milk before it is put into the diſhes; and as cows are much hurt by far driving, it muſt be a great advantage in a dairy-farm to have the principal graſs fields as near the dairy or homeſtead as poſſible.

Secondly. The practice of putting the milk of all the cows of a large dairy into one veſſel, as it is milked, there to remain till the whole milking is finiſhed, before any part of it is put into the milk-pans—ſeems to be highly injudicious; not only on account of the loſs that is ſuſtained by agitation and cooling, but alſo, more eſpecially, becauſe it prevents the owner of the dairy from diſtinguiſhing the good from the bad cow's milk, ſo as to ſeparate theſe from each other, where it is neceſſary. He may thus have the whole of his dairy product greatly debaſed by the milk of one bad cow, for years together, without being able to diſcover it. A better practice, therefore, would be, to have the milk drawn from each cow put ſeparately into the creaming-pans as ſoon as it is milked, without being ever mixed with any other. Thus would the careful manager of the dairy be able on all occaſions to obſerve the particular quality of each individual cow's milk, as well as its quantity, and to know with preciſion which of his cows it was his intereſt to diſpoſe of, and which of them he ought to keep and breed from.

Thirdly. If it be intended to make butter of a very fine quality, it will be adviſable in all caſes to keep the milk that is firſt drawn ſeparate from that which comes laſt; as it is obvious, that if this be not done, the quality of the butter will be greatly debaſed, without much augmenting its quantity. It is alſo obvious, that if this is done, the quality of the butter will be improved in proportion to the ſmallneſs of the quantity of the laſt-drawn milk that is retained; ſo that thoſe who wiſh to be ſingularly nice in this reſpect, will do well to retain only a very ſmall portion of the laſt-drawn milk.

To thoſe owners of dairies who have profit only in view, it muſt ever be a matter of trial and calculation, how far it is expedient for them to carry the improving of the quality of their butter at the expence of diminiſhing its quantity. In different ſituations prudence will point out different kinds of practice as moſt eligible; and all perſons muſt be left, after making accurate trials, to determine for themſelves. It is likewiſe a conſideration of no ſmall importance, to determine in what way the inferior milk, that is thus to be ſet apart where fine butter is wanted, can be employed with the greateſt profit. In the Highlands of Scotland they have adopted, without thinking of the improvement of their butter, a very ſimple and economical practice in this reſpect. As the rearing of calves is there a principal object with the farmer, every cow is allowed to ſuckle her own calf with a part of her milk, the remainder only being employed in the dairy. To give the calf its portion regularly, it is ſeparated from the cow, and kept in an incloſure, with all the other calves belonging to the ſame farm. At regular times, the cows are driven to the door of the incloſure, where the young calves fail not to meet them. Each calf is then ſeparately let out, and runs directly to its mother, where it ſucks till the dairy-maid judges it has had enough; ſhe then orders it to be driven away, having previouſly ſhackled the hinder legs of the mother, by a very ſimple contrivance, to oblige her to ſtand ſtill. Boys drive away the calf with ſwitches, and return it to the incloſure, while the dairy-maid milks off what was left by the calf: thus they proceed till the whole of the cows are milked. They obtain only a ſmall quantity of milk, it is true, but that milk is of an exceeding rich quality; which in the hands of ſuch of the inhabitants as know how to manage it, is manufactured into the richeſt marrowy butter that can be anywhere met with. This richneſs of the Highland butter is univerſally aſcribed to the old graſs the cows feed upon in their remote glens; but it is in fact chiefly to be attributed to the practice here deſcribed, which has long prevailed in thoſe regions. Whether a ſimilar practice could be economically adopted elſewhere, our author takes not upon him to ſay; but doubtleſs other ſecondary uſes might be found for the milk of inferior quality. On ſome occaſions, it might be converted into butter of an inferior quality; on other occaſions, it might be ſold ſweet, where the ſituation of the farm was within reach of a market-town; and on others, it might be converted into cheeſes, which, by being made of ſweet milk, would be of a very fine quality if carefully made (c). Still other uſes might be deviſed for its application; of which the following is worthy of notice. Take common ſkimmed milk, when it has begun to turn ſour, put it into an upright ſtand churn, or a barrel with one of its ends out, or any other convenient veſſel. Heat ſome water, and pour it into a tub that is large enough to contain with eaſe the veſſel in which the milk was put. Set the veſſel containing the milk into the hot water, and let it remain there for the ſpace of one night. In the morning it will be found that the milk has ſeparated into two parts; a thick cream-like ſubſtance, which occupies the upper part of the veſſel, and a thin watery part that remains at the bottom. Draw off the thin part (called in Scotland *wigg*), by opening a ſtop-cock, placed for that purpoſe cloſe above the bottom, and reſerve the cream for uſe. Not much leſs than half of the milk is thus converted into a ſort of cream, which, when well made, ſeems to be as rich and fat as real cream itſelf, and is only diſtinguiſhable from it by its ſourneſs. It is eaten with ſugar, and eſteemed a great delicacy, and uſually ſells at double the price of freſh unſkimmed milk. It requires practice, however, to be able to make this nicely; the degree of the heat of the water, and many other circumſtances, greatly affecting the operation.

Fourthly. If the quality of the butter be the chief object attended to, it will be neceſſary, not only to ſeparate the firſt from the laſt drawn milk, but alſo to take nothing but the cream that is firſt ſeparated from the beſt milk, as it is this firſt riſing cream alone that is of the prime quality. The remainder of the milk, which will be ſtill ſweet, may be either employed for the purpoſe of making ſweet milk cheeſes, or may be allowed to ſtand, to throw up cream for making butter of an inferior quality, as circumſtances may direct.

Fifthly. From the above facts, we are enabled to perceive, that butter of the very beſt poſſible quality can only be obtained from a dairy of conſiderable extent, judiciouſly managed; for when only a ſmall portion of each cow's milk can be ſet apart for throwing up cream, and when only a ſmall proportion of that cream can be reſerved, of the prime quality, it follows (the quantity of milk being upon the whole very inconſiderable), that the quantity of prime cream produced would be ſo ſmall as to be ſcarcely worth manufacturing ſeparately.

Sixthly. From theſe premiſes we are alſo led to draw another concluſion, extremely different from the opinion that is commonly entertained on this ſubject, viz. That it ſeems probable, that the very beſt butter could be made with economy in thoſe dairies only where the manufacture of cheeſe is the principal object. The reaſons are obvious: If only a ſmall portion of milk ſhould be ſet apart for butter, all the reſt may be made into cheeſe, while it is yet warm from the cow, and perfectly ſweet; and if only that portion of cream which riſes during the firſt three or four hours after milking is to be reſerved for butter, the rich milk which is left after that cream is ſeparated, being ſtill perfectly ſweet, may be converted into cheeſe with as great advantage nearly as the newly-milked milk itſelf.

But as it is not probable that many perſons could be found who would be willing to purchaſe the very fineſt butter, made in the manner above pointed out, at a price that would be ſufficient to indemnify the farmer for his trouble in making it, theſe hints are thrown out merely to ſhew the curious in what way butter poſſeſſing this ſuperior degree of excellence may be obtained, if they chooſe to be at the expence; but for an ordinary market, Dr Anderſon is ſatisfied, from experience and attentive obſervation, that if in general about the firſt drawn half of the milk be ſeparated at each milking, and the remainder only ſet up for producing cream, and if that milk be allowed to ſtand to throw up the whole of its cream (even till it begins ſenſibly to taſte ſouriſh), and that cream be afterwards carefully managed, the butter thus obtained will be of a quality greatly ſuperior to what can uſually be procured at market, and its quantity not conſiderably leſs than if the whole of

---

(c) The making of cheeſe has never yet been reduced to ſcientific principles, and conſequently the reaſoning relating to it is very inconcluſive. It is in general ſuppoſed, that the goodneſs of cheeſe depends almoſt entirely upon its richneſs, by which is meant the proportion of oily matter, whether natural or extraneous, it contains; nothing, however, is more certain, than that this opinion is erroneous. Sometimes a very lean cheeſe is much better taſted than one that is much fatter; and, which will appear to moſt perſons ſtill more extraordinary, it frequently happens that a cheeſe that taſtes ſoft and fat is much leaner than one that is hard, dry, and ſticky. The mode of manufacturing it occaſions this, and not the quantity of cream it contains. It is very poſſible by art to make poor ſkim milk cheeſe aſſume the ſoft buttery taſte and appearance even of cream cheeſe. This ſubject, therefore, deſerves to be more particularly elucidated than it has hitherto been.

Connected as they are with the object diſcuſſed in the text, we beg leave with our author to ſuggeſt the following particulars, as proper objects of examination and experiment, viz. Is the quantity of caſeous matter afforded by milk neceſſarily connected with the proportion of cream that milk contains, or does it depend upon ſome other principle not hitherto inveſtigated? Without pretending to decide this queſtion, Dr Anderſon feels himſelf ſtrongly inclined to believe it does not depend upon the quantity of cream. It is well known that cow's milk, which always throws up more cream, and that of a much richer quality, than ewe-milk, does in no caſe afford above one-half the proportion of cheeſe that ewe-milk does. Nor can this ſingular tendency of ewe-milk, to yield a great proportion of curd, be attributed to its ſuperior thickneſs; for cow-milk can be often had that is thicker and richer than ewe-milk, but it always affords a much ſmaller proportion of curd. From theſe conſiderations, it is not impoſſible but it might be found, upon a careful inveſtigation, that the refuſe milk, which ought to be ſeparated from the other in making the beſt butter, might be equally proper, or very nearly ſo, for making cheeſe, as if no ſuch ſeparation had been made. We therefore recommend this as a proper object of experimental enquiry.

of the milk had been treated alike. This, therefore, is the practice that our author thinks moſt likely to ſuit the frugal farmer, as his butter, though of a ſuperior quality, could be afforded at a price that would always enſure it a rapid ſale.

Dr Anderſon throws out many other ingenious and uſeful obſervations on this important branch of rural economy. In particular, he points out, in the plaineſt manner, the requiſites of a good milk-houſe, which, as he truly obſerves, ſhould be cool in ſummer and warm in winter, ſo as to preſerve a temperature nearly the ſame throughout the year. But we have treated of this part of the ſubject elſewhere, and muſt therefore refer ſuch as are deſirous to know the Doctor's ſentiments on it, to *The Letters and Papers of the Bath and Weſt-of-England Society* for the encouragement of agriculture, &c. or to the eighth volume of *The Repertory of Arts and Manufactures*.

DAHALAC, the largeſt iſland in the Red Sea, is thus deſcribed by Mr Bruce. It is low and even, the ſoil fixed gravel and white ſand, mixed with ſhells and other marine productions. It is deſtitute of all ſorts of herbage, at leaſt in ſummer, unleſs a ſmall quantity of bent graſs, juſt ſufficient to feed the few antelopes and goats that are on the iſland. There is a very beautiful ſpecies of this laſt animal found here, ſmall, ſhort-haired, with thin black ſharp horns, having rings upon them, and they are very ſwift of foot.

This iſland is, in many places, covered with large plantations of acacia trees, which grow to no height, ſeldom above eight feet, but ſpread wide, and turn flat at top, probably by the influence of the wind from the ſea. Though in the neighbourhood of Abyſſinia, Dahalac does not partake of its ſeaſons; no rain falls here from the end of March to the beginning of October; but in the intermediate months, eſpecially December, January, and February, there are violent ſhowers for 12 hours at a time, which deluge the iſland, and fill the ciſterns ſo as to ſerve all next ſummer; for there are no hills nor mountains in Dahalac, and conſequently no ſprings. Theſe ciſterns alone preſerve the water, and of them there yet remain 370, all hewn out of the ſolid rock. They ſay theſe were the works of the Perſians; it is more probable they were thoſe of the firſt Ptolemies. But whoever were the conſtructors of theſe magnificent reſervoirs, they were a very different people from thoſe that now poſſeſs them, who have not induſtry enough to keep one of the 370 clear for the uſe of man. All of them are open to every ſort of animal, and half full of the filth they leave there, after drinking and waſhing in them; yet one of theſe ciſterns, cleaned and ſhut up with a door, might afford them wholeſome ſweet water all the year over.

After the rains fall, a prodigious quantity of graſs immediately ſprings up; and the goats give the inhabitants milk, which in winter is the principal part of their ſubſiſtence, for they neither plow nor ſow; all their employment is to work the veſſels which trade to the different parts of the coaſt. One half of the inhabitants is conſtantly on the Arabian ſide, and by their labour is enabled to furniſh with *dora* (millet or Indian corn) and other proviſions the other half who ſtay at home; and when their time is expired, they are relieved by the other half, and ſupplied with neceſſaries in their turn. But the ſuſtenance of the poorer ſort is entirely ſhell and other fiſh. Their wives and daughters are very bold and expert fiſherwomen. Several of them, entirely naked, ſwam off to the veſſel before it came to an anchor, begging handfuls of wheat, rice, or dora. They are very importunate and ſturdy beggars, and not eaſily put off with denials. These miſerable people, who live in the villages not frequented by barks from Arabia, are ſometimes a whole year without taſting bread. Yet ſuch is the attachment to their place of nativity, they prefer living in this bare, barren, parched ſpot, almoſt in want of neceſſaries of every kind, eſpecially of theſe eſſential ones, bread and water, to thoſe pleaſant and plentiful countries on both ſides of them.

There are in Dahalac twelve villages or towns, of which each has a plantation of doomtrees round it, which furniſh the only manufacture in the iſland. The leaves of this tree, when dried, are of a gloſſy white, which might very eaſily be miſtaken for ſattin: of theſe they make baſkets of ſurpriſing beauty and neatneſs, ſtaining part of the leaves with red or black, and working them into figures very artificially. Our author knew ſome of theſe, reſembling ſtraw-baſkets, continue full of water for 24 hours, without one drop coming through. They ſell theſe at Loheia and Jidda, the largeſt of them for four commeſh, or ſixpence. This is the employment, or rather amuſement, of the men who ſtay at home; for they work but very moderately at it, and all of them indeed take ſpecial care not to prejudice their health by any kind of fatigue from induſtry.

People of the better ſort, ſuch as the Shekh and his relations, men privileged to be idle, and never expoſed to the ſun, are of a brown complexion. But the common ſort employed in fiſhing, and thoſe who go conſtantly to ſea, are not indeed black but red, and little darker than the colour of new mahogany.

The inhabitants of Dahalac ſeemed to be a ſimple, fearful, and inoffenſive people. It is the only part of Africa or Arabia (call it which you pleaſe) where you ſee no one carry arms of any kind: neither gun, knife, nor ſword, is to be ſeen in the hands of any one. Whereas at Loheia, and on all the coaſt of Arabia, and more particularly at Yamboo, every perſon goes armed; even the porters, naked and groaning under the weight of their burden and heat of the day, have yet a leather belt, in which they carry a crooked knife, ſo monſtrouſly long, that it needs a particular motion and addreſs in walking not to lame the bearer. This was not always the caſe at Dahalac; ſeveral of the Portugueſe, on their firſt arrival here, were murdered, and the iſland often treated ill, in revenge, by the armaments of that nation. The men ſeemed healthy. They told our author they had no diſeaſes among them, unleſs ſometimes in ſpring, when the boats of Yemen and Jidda bring the ſmall-pox among them, and very few eſcape with life that are infected. He did not obſerve among them a man that ſeemed to be ſixty years old; from which he inferred that they are not long livers, though the air ſhould be healthy, as being near the channel, and as they have the north wind all ſummer, which moderates the heat.

Dahalac, like all the other iſlands in the Red Sea, depends upon Maſuah. The revenue of its governor conſiſts in a goat brought to him monthly by each of the twelve villages. Every veſſel that puts in there for Maſuah pays him alſo a pound of coffee, and every one from

from Arabia a dollar or pataka. No ſort of ſmall money is current at Dahalac, excepting Venetian glaſs-beads, old and new, of all ſizes and colours, broken and whole.

Although this is the miſerable ſtate of Dahalac at preſent, matters were widely different in former times. The pearl fiſhery flouriſhed greatly here under the Ptolemies; and even long after, in the time of the caliphs, it produced a great revenue, and till the ſovereigns of Cairo, of the preſent miſerable race of ſlaves, began to withdraw themſelves from their dependency on the port, Dahalac was the principal iſland that furniſhed the pearl fiſhers or divers. It was, indeed, the chief port for the fiſhery on the ſouthern part of the Red Sea, as Suakem was on the north; and the baſha of Maſuah paſſed part of every ſummer here, to avoid the heat at his place of reſidence on the continent.

The fiſhery extended from Dahalac and its iſlands nearly to lat. 20°. The inhabited iſlands furniſhed each a bark and ſo many divers, and they were paid in wheat, flour, &c. ſuch a portion to each bark for their uſe, and ſo much to leave with their family for their ſubſiſtence; ſo that a few months employment furniſhed them with every thing neceſſary for the reſt of the year. The fiſhery was rented in later times to the baſha of Suakem; but there was a place between Suakem and the ſuppoſed river Frat, in lat. 21° 28′ north, called *Gungunnah*, which was reſerved to the grand ſignior in particular, and a ſpecial officer was appointed to receive the pearls on the ſpot and ſend them to Conſtantinople. The pearls found there were of the largeſt ſize, and inferior to none in water or roundneſs. Tradition ſays, that this was excluſively the property of the Pharaohs; by which is meant, in Arabian manuſcripts, the old kings of Egypt before Mahomet.

In the ſame extent between Dahalac and Suakem was another very valuable fiſhery, that of tortoiſes, from which the fineſt ſhells of that kind were produced, and a great trade was carried on with the Eaſt Indies (China eſpecially) at little expence, and with very conſiderable profits. But the immenſe treaſures in the bottom of the Red Sea have now been abondoned for near 200 years, though they never were richer in all probability than at preſent. No nation can now turn them to any profit but the Engliſh Eaſt India Company, more intent on multiplying the number of their enemies, and weakening themſelves by ſpreading their inconſiderable force over new conqueſts, than creating additional profit by engaging in new articles of commerce. A ſettlement upon the river Frat, which never yet has belonged to any one but wandering Arabs, would open them a market both for coarſe and fine goods from the ſouthern frontiers of Morocco, to Congo and Angola, and ſet the commerce of pearls and tortoiſe ſhell on foot again. All this ſection of the gulf from Suez, as we are told, is in their charter, and twenty ſhips might be employed on the Red Sea without any violation of territorial claims. The myhrrh, the frankincenſe, ſome cinnamon, and variety of drugs, are all in the poſſeſſion of the weak king of Adel; an uſurper, tyrant, and Pagan, without protection, and willing to trade with any ſuperior power that only would ſecure him a miſerable livelihood.

There are neither horſes, dogs, ſheep, cows, nor any ſort of quadruped but goats, aſſes, a few half-ſtarved camels, and antelopes at Dahalac, which laſt are very numerous. The inhabitants have no knowledge of fire-arms, and there are no dogs nor beaſts of prey in the iſland to kill them; they catch indeed ſome few of them in traps.

The language at Dahalac is that of the ſhepherds, though Arabic, too, is ſpoken by moſt of them. Our author ſtates the latitude of Dahalac to lie between 15° 27′ 30″, and 15° 54′ 30′ north.

DALRYMPLE (Sir David), was born in Edinburgh on the 28th of October (N. S.) 1726. His father was Sir James Dalrymple of Hailes, Bart. and his mother Lady Chriſtian Hamilton, a daughter of the Earl of Hadinton. His grandfather Sir David Dalrymple was the youngeſt ſon of the firſt Lord Stair, and is ſaid to have been the ableſt of that family, ſo much diſtinguiſhed for ability. He was Lord Advocate for Scotland in the reign of George I. and his ſon Sir James had the auditorſhip of the exchequer for life.

The ſubject of this memoir was educated at Eton ſchool, where he was diſtinguiſhed as a ſcholar, and long remembered as a virtuous and orderly youth. In that juſtly celebrated ſeminary he acquired a claſſical taſte, which, though it was once prevalent in Scotland, has in that country been long on the decline; and formed, beſides, friendſhips to perſons and attachments to things, which accompanied him through life. Hence probably ſprung his partiality to Engliſh manners and cuſtoms, which marked both his public conduct and private converſation, and was the ſource of much of his dignity, and ſome of his littleneſſes.

From Eton he returned to Edinburgh, whence, after the uſual courſe of a gentleman's ſtudies in that univerſity, he went to Utrecht to ſtudy the civil law; and remained there till after the rebellion in 1746. Upon his return to his native country, ſo promiſing were his parts, and ſuch his induſtry and ſoberneſs of mind, that very ſanguine expectations were entertained of his future eminence; and in ſome reſpects theſe expectations were not fruſtrated. To his intimate friends it was well known, that if left to follow the bent of his own inclinations, he would have devoted his time and his talents to the ſtudy of antiquities and the belles lettres; in both which departments of literature he was eminently qualified to excel. On the death of his father, however, he found his affairs ſo very much encumbered, that in order to retrieve them, and to provide for his brothers and ſiſters, he reſolved to follow the law as a profeſſion, in which ſome of his anceſtors had made a diſtinguiſhed figure.

He was called to the Scotch bar in 1748, where, notwithſtanding the elegant propriety of the caſes which he drew, it muſt be confeſſed that his ſucceſs did not anſwer the expectations which had been formed of him. This was not owing either to want of ſcience or to want of induſtry, but to certain peculiarities, which, if not inherent in his nature, were the reſult of early and deep-rooted habits. He poſſeſſed on all occaſions a ſovereign contempt, not only for verbal antitheſis, but for well rounded periods, and every thing which had the ſemblance of declamation; and indeed he was wholly unfitted by an ill-toned voice and ungraceful elocution, for ſhining as an orator. No wonder, then, that his pleadings, which were never addreſſed to the paſſions, did not rival thoſe of ſome of his opponents, who, poſſeſſed of great rhetorical powers, did not, like him, employ ſtrokes of irony too fine to be perceived by the bulk of any audience, but expreſſed themſelves in full, clear, and harmonious periods. Even his memorials, though claſſically written, and often replete with valuable matter, did not on every occaſion pleaſe the court; for they were always brief, and ſometimes, as it was ſaid, indicated more attention to the minutiæ of forms than to the merits of the cauſe. Yet on points which touched his own feelings, or the intereſts of truth and virtue, his language was animated, his arguments forcible, and his ſcrupulous regard to form thrown aſide.

He was ſometimes employed as a depute advocate, which gave him opportunities at the circuits of diſplaying that candour and tenderneſs of diſpoſition which ſo well becomes the public proſecutor in a criminal court. Of this the following inſtance may be worth relating. On the firſt day of the court at Stirling, he was once accoſted by another advocate in theſe words: “Sir David, why is there not a trial this forenoon? I would be getting on.” “There are (replied he) ſome unhappy culprits to be tried for their *lives;* and therefore it is proper that they have time to confer with their men of law.” “That is of little conſequence (ſaid the other). Laſt year I came to viſit Lord Kames when he was here on the circuit, and he appointed me counſel for a man accuſed of a rape. Though I had very little time to prepare, yet I made a decent ſpeech.” “Pray, Sir, (ſaid Sir David), was your client acquitted or condemned?” “O (replied the other), moſt unjuſtly condemned.” “That, Sir, (ſaid the depute advocate) is no good argument for hurrying on trials.”

To return from this digreſſion, if it be conſidered as ſuch, it is ſurely to the honour of Sir David Dalrymple, that whatever men thought of his ſingularities, his detractors concurred with his admirers in believing him incapable of miſleading the judge by a falſe ſtatement of facts; or his clients, by holding out to them fallacious grounds of hope.

His high ſenſe of honour, and his inflexible integrity, were indeed univerſally admitted; and it was with the warmeſt approbation of the public, that in 1766 he was appointed one of the judges of the court of ſeſſion, the higheſt civil tribunal in Scotland. He took his ſeat on the bench, according to the uſage of that court, by the title of Lord Hailes, the deſignation by which he is generally known among the learned of Europe; and the expectations entertained of him were again ſanguine. His unwearied aſſiduity in ſifting dark and intricate matters to the bottom was well known; his elegant and conciſe manner of expreſſing his ſentiments was admirably ſuited to the character of a judge; and his legal opinions had been generally ſound. Yet it muſt be confeſſed, that as a judge he was neither ſo uſeful nor ſo highly revered as he ought to have been from the extent of his knowledge, and his unqueſtioned integrity. The ſame minute attention to forms, which had in ſome degree obſtructed his riſe at the bar, accompanied him to the bench, and brought upon him the ridicule of the wits about the court (A): and we all know, that the character even of Socrates himſelf was not able to reſiſt the torrent of ridicule. In extenuation of this foible, it may be obſerved, that by ſome of the judges of the court of ſeſſion perhaps too little regard has been paid to form; and that forms, even apparently trifling, cannot in legal proceedings be wholly diſregarded without involving in danger truth and juſtice. Be this as it may, ſuch was the opinion which the other judges entertained of Lord Hailes's accuracy, diligence, and dignified manners, that, in the abſence of the preſident, they generally voted him into the vacant chair.

In May 1776 he was appointed one of the lords commiſſioners of juſticiary; and in that ſtation he commanded the reſpect of all mankind. Fully impreſſed with a deep ſenſe of the importance of his office, he ſeemed, in the criminal court, to lay aſide his ſingularities. So far from throwing his whole weight into the ſcale of the crown, a charge which has been ſometimes brought, we believe unjuſtly, againſt the Scotch judges, Lord Hailes, like the judges of England, was always counſel for the priſoner when the king's counſel appeared too ſtrong for their opponents, or when there was any particular intricacy in the caſe. In adminiſtering the oath to the witneſſes, he had none of that indecorum which we have elſewhere cenſured in ſome of his brethren (ſee Oath, *Encycl.*); but riſing ſolemnly from his ſeat, he repeated the words in ſo ſerious a manner, as left no doubt in the moſt profligate mind but that he was himſelf impreſſed with a ſenſe of the immediate preſence of the Supreme Being, and with the firm belief of a future judgment. When the witneſs appeared to be young or ignorant, we have beheld, with the utmoſt love and veneration, the pious pains which his Lordſhip took to diſcover whether he was duly acquainted with the nature and obligation of an oath, before he admitted him to ſwear; and though it is perhaps impoſſible for human vigilance and ſagacity to prevent perjury altogether in courts of juſtice, he muſt ſurely have been a villain uncommonly hardened and artful who could perjure himſelf in the preſence of Lord Hailes. In doubtful caſes his Lordſhip inclined always to the ſide of mercy; but when it became his duty to paſs ſentence of death upon convicted criminals, he addreſſed them in a ſtrain of ſuch piety and commiſeration, as to draw tears from the eyes of every beholder, and was calculated to make a deep and proper impreſſion on the unhappy perſon himſelf. In the diſcharge of this painful duty, we never ſaw him ſurpaſſed, and have ſeldom ſeen him equalled.

Had Lord Hailes been conſpicuous only as a ſound lawyer and an able and upright judge, we ſhould not have thought his life intitled to a place in this Work; but he was no leſs eminent as a man of general erudition, and as a voluminous author. His ſkill in claſſical learning, the belles lettres, and hiſtorical antiquities, eſpecially thoſe of his own country, is univerſally admitted;

(A) In a ſatirical ballad on the court of ſeſſion, Mr Boſwell, alluding to Lord Hailes's fondneſs for verbal criticiſm, makes him addreſs the preſident in the following words:

To judge of this matter I cannot pretend,
For juſtice, my Lord, wants an *e* at the end.

ted; but it cannot be denied, that the ſame faſtidiouſneſs, and the ſame microſcopic attention to minutiæ, which characteriſed him as a barriſter, prevented him from riſing to that rank in the republic of letters to which his learning and genius would otherwiſe have infallibly carried him. But if he was not one of the moſt celebrated writers of the age, he was unqueſtionably one of the moſt virtuous; if his publications were not always edifying, they were at leaſt innocent and ingenious; and ſome of them are in the higheſt degree valuable. In proof of this aſſertion, we need inſtance only his *Annals of Scotland*, and his *Inquiry into the Secondary Cauſes which Mr Gibbon has aſſigned for the Rapid Progreſs of Chriſtianity.* Of the former of theſe works, though little calculated to pleaſe the common herd of readers, it may with truth be ſaid, that in reſearch and ingenuity it ſtands unrivalled among the writings of Scotch antiquaries; and of the latter, it is ſurely not too much to ſay, that it diſplays uncommon acumen, cloſeneſs of reaſoning, and zeal for the cauſe of truth, without the uſual rancour of theological controverſy.

His taſte for retirement, which the ſtate of his affairs rendered for a while neceſſary, grew upon him as he advanced in years. His conſtitution, of which he was very careful, as well as his principles and habits, rendered him averſe from diſſipation of every kind. After he was made a judge, he conſidered abſtraction from the gay and faſhionable world as connected with the duty of one whoſe time was no longer his own; and when he choſe to unbend his mind, it was in the ſociety of a few eaſy friends, whom he ſelected as much for their worth and good humour as for their genius or their learning. He had indeed occaſionally much converſation with that conſtellation of wits and men of ſcience who flouriſhed in Edinburgh at the ſame period with himſelf; but it was impoſſible for friendſhip or intimacy to ſubſiſt between men who thought ſo differently as he and they thought on the moſt important of all ſubjects. Though an old-faſhioned whig, zealouſly attached to the conſtitution, he ſcorned to take any ſhare in the civil or eccleſiaſtical broils in which ſome of his brother judges were warmly engaged for the firſt 20 years of the preſent reign; for he looked on theſe as either frivolous or miſchievous.

Although his Lordſhip's conſtitution had been long in an enfeebled ſtate, he proſecuted his ſtudies, and attended his duty on the bench, till within three days of his death, which happened on the 29th of November 1792, in the 66th year of his age.

His Lordſhip was twice married; by his firſt wife Anne Brown, only daughter of Lord Coalſton, one of the judges of the court of ſeſſion, he left iſſue one daughter, who inherits the family eſtate. His ſecond marriage (of which alſo their is iſſue one daughter) was to Helen Ferguſſon, youngeſt daughter of Lord Kilkerran, who has the affliction to ſurvive him. Leaving no male iſſue, the title of Baronet deſcends to his nephew.

Though the church of Scotland does not much encourage funeral diſcourſes, a very laudable endeavour was made to render the talents and virtues of Lord Hailes a theme of inſtruction to mankind, in a ſermon preached ſoon after his death in the church of Invereſk, by his learned friend and venerable paſtor Dr Carlyle; from which we ſhall tranſcribe a ſummary view of his character as a judge, a ſcholar, a Chriſtian, and a citizen.

“ His knowledge of the laws was accurate and profound, and he applied it in judgment with the moſt ſcrupulous integrity. In his proceedings in the criminal court, the ſatisfaction he gave to the public could not be ſurpaſſed. His abhorrence of crimes, his tenderneſs for the criminals, his reſpect for the laws, and his reverential awe of the Omniſcient Judge, inſpired him on ſome occaſions with a commanding ſublimity of thought, and a feeling ſolemnity of expreſſion, that made condemnation ſeem juſt as the doom of Providence to the criminals themſelves, and raiſed a ſalutary horror of crimes in the breaſt of the audience.

“ Conſcious of the dignity and importance of the high office he held, he never departed from the decorum that becomes that reverend character; which indeed it coſt him no effort to ſupport, becauſe he acted from principle and ſentiment, both public and private. Affectionate to his family and relations, ſimple and mild in his manners, pure and conſcientious in his morals, enlightened and entertaining in his converſation; he left ſociety only to regret, that, devoted as he was to more important employments, he had ſo little time to ſpare for intercourſe with them.

“ He was well known to be of high rank in the republic of letters, and his loſs will be deeply felt through many of her departments. His labours, in illuſtration of the hiſtory of his country, and many other works of profound erudition, remain as monuments of his accurate and faithful reſearch for materials, and his ſound judgement in the ſelection of them. Of his unfeigned piety and devotion, you have very often been witneſſes where we now are. I muſt add, however, that his attendance on religious ordinances was not merely out of reſpect to the laws and for the ſake of example (motives which ſhould never fail to have influence on perſons of ſuperior rank, for the moſt obvious reaſons), but from principle and conviction, and the moſt conſcientious regard to his duty; for he not only practiſed all the virtues and charities in proof of his faith, but he demonſtrated the ſincerity of his zeal by the uncommon pains he took to illuſtrate primitive Chriſtianity, and by his elaborate and able defences of it againſt its enemies.

“ His profound reſearches into hiſtory, and his thorough knowledge of the laws, made him perfectly acquainted with the progreſs of the conſtitution of Britain, from the firſt dawn of liberty in the common law of the land, and the trial by jury which precede all written records, and afterwards in the origin and eſtabliſhment of parliaments, through all its viciſſitudes and dangers, till at laſt, by the bleſſing of divine Providence, which brought many wonderful events to concur to the ſame end, it was renewed, ſtrengthened, and finally confirmed by the Revolution.

“ It was this goodly and venerable fabric of the Britiſh conſtitution which the deceaſed moſt reſpectable character contemplated with admiration and delight (of late, indeed, with a mixture of anxiety and fear), as the temple of piety, as the genuine ſource of greater happineſs and freedom, to a larger portion of mankind than ever flowed from any government upon earth.

“ Ill indeed can the times bear the loſs of ſuch an

affectionate

affectionate patriot and able guardian of the laws of his country. But we muſt not murmur at the will of Providence, which in its mercy ‘ may have withdrawn the good man from the evil to come.’ In mercy, I ſay, to him, whoſe righteous ſpirit was ſo deeply grieved when ‘ he ſaw the wicked rage, and the people imagine a vain thing.”

Such is the memorial which, in the hour of recent ſorrow, followed this excellent man to the grave; and we believe it will yet be allowed to be juſt by all who had the happineſs of his Lordſhip's acquaintance, and are what he was, friends to the beſt intereſts of mankind.

This ſketch of the life of Lord Hailes would be more imperfect than even it is, if we could not ſubjoin to it a catalogue of his publications, of which the greater part are exceedingly curious. We call them *publications*, becauſe he employed almoſt as much of his time in republiſhing old and uſeful books as in preparing for the preſs his own valuable works.

Beſides his eſſays in the papers called *The World* and *The Mirror*, which are well known and univerſally admired, his Lordſhip publiſhed the following works:

Sacred Poems, or a Collection of Tranſlations and Paraphraſes from the Holy Scriptures; by various authors, Edinburgh, 1751, 12mo. Dedicated to Charles Lord Hope, with a preface of ten pages.

The Wiſdom of Solomon, Wiſdom of Jeſus the Son of Sirach, or Eccleſiaſticus, 12mo, Edin. 1755.

Select Diſcourſes (in number nine), by John Smith, late Fellow of Queen's College, Cambridge, 12mo, 291 pages. Edin. 1756; with a preface of five pages, “ many quotations from the learned languages tranſlated,—and notes added, containing alluſions to ancient mythology, and to the erroneous philoſophy which prevailed in the days of the author,—various inaccuracies of ſtyle have been corrected, and harſh expreſſions ſoftened.”

A diſcourſe of the unnatural and vile Conſpiracy attempted by John Earl of Gowry and his brother, againſt his Majeſty's perſon, at St Johnſtoun, upon the 5th of Aug. 1600. No date of the republication, but the edition and notes ſuppoſed by Lord Hailes, 12mo, 1757.

A Sermon, which might have been preached in Eaſt Lothian upon the 25th day of October 1761, on Acts xxviii. 1, 2. “ The barbarous people ſhewed us no little kindneſs.” Edin. 1761, pp. 25, 12mo. “ Occaſioned by the country people pillaging the wreck of two veſſels, viz. the Betſy, Cunningham, and the Leith Packet, Pitcairn, from London to Leith, caſt away on the ſhore between Dunbar and North Berwick. All the paſſengers on board the former, in number 17, periſhed; five on board the latter, October 16. 1761.”—A moſt affecting diſcourſe, admirably calculated to convince the offenders!

Memorials and Letters relating to the Hiſtory of Britain, in the reign of James I. publiſhed from the originals, Glaſgow, 1762.—Addreſſed to Philip Yorke, Viſcount Royſton, pp. 151. “ From a collection in the advocate's library, by Balfour of Dennyln.” The preface of four pages, ſigned Dav. Dalrymple.

The works of the ever memorable Mr John Hales of Eaton, now firſt collected together in 3 vols, Glaſgow, 1765; preface of three pages. Dedicated to William (Warburton), Biſhop of Glouceſter. “ The edition ſaid to be undertaken with his approbation; obſolete words altered, with corrections in ſpelling and punctuation.”

A ſpecimen of a book entitled “ Ane Compendious Booke of Godly and Spiritual Sangs, collectit out of ſundrie parts of the Scripture, with ſundrie of other Ballates changed out of prophaine Sanges, for avoyding of Sin and Harlotrie, with augmentation of ſundry Gude and Godly Ballates, not contained in the firſt edition. Edinburgh, printed by Andro Hart.” 12mo. Edin. 1765, pp. 42; with a Gloſſary of four pages.

Memorials and Letters relating to the Hiſtory of Britain in the reign of Charles I. publiſhed from the originals, Glaſgow, 1766, pp. 189. Preface of ſix pages, ſigned Dav. Dalrymple, chiefly collected by Mr Wodrow, author of the Hiſtory of the Church of Scotland. Inſcribed to Robert Dundas of Arniſton, Lord Preſident of the Court of Seſſion.

An account of the preſervation of Charles II. after the Battle of Worceſter, drawn up by himſelf; to which are added, his Letters to ſeveral perſons. Glaſgow, 1766, pp. 190, from the MSS. of Mr Pepys, dictated to him by the king himſelf, and communicated by Dr Sandby, maſter of Magdalen College. The letters are collected from various books; ſome of them now firſt publiſhed, communicated by the tutors of the Duke of Hamilton, by the Earl of Dundonald, &c. The preface of four pages, ſigned Dav. Dalrymple, dedicated to Thomas Holles, Duke of Newcaſtle, chancellor of the univerſity of Cambridge.

The Secret Correſpondence between Sir Robert Cecil and James VI. 12mo, 1766.

A catalogue of the Lords of Seſſion, from the Inſtitution of the College of Juſtice in the year 1532, with Hiſtorical Notes. *Suum cuique rependet poſteritas.* Edin. 1767, 4to, pp. 26.

The Private Correſpondence of Dr Francis Atterbury, Biſhop of Rocheſter, and his friends, in 1725, never before publiſhed. Printed in 1768, 4to. Advertiſement, pp. 2. Letters, pp. 10. A fac ſimile of the firſt from Biſhop Atterbury to John Cameron of Lochiel, to prove their authenticity.

An examination of ſome of the Arguments for the High Antiquity of *Regiam Majeſtatem*; and an Inquiry into the authenticity of the *Leges Malcolmi*; by Sir David Dalrymple, 4to, pp. 52. Edin. 1769.

Hiſtorical Memoirs concerning the Provincial Councils of the Scottiſh Clergy, from the earlieſt Accounts to the Æra of the Reformation; by Sir David Dalrymple. Edinburgh, 1769, 4to, pp. 41.—*Nota*, Having no high opinion of the popularity of his writings, he prefixes to this work the following motto: “ Si delectamur quum ſcribimus quis eſt tam invidus qui ab eo nos abducat? ſin laboramus quis eſt qui alienæ modum ſtatuat induſtriæ.”—*Cicero*.

Canons of the church of Scotland, drawn up in the Provincial Councils held at Perth, A. D. 1242, and 1269. Edinburgh, 1769, 4to, pp. 48.

Ancient Scottiſh Poems, publiſhed from the MS. of George Bannatyne, 1568. Edin. 1770, 12mo. Preface ſix pages; Poems pp. 221; very curious notes pp. 92; gloſſary and liſts of paſſages and words not underſtood, pp. 14.

The additional caſe of Elizabeth, claiming the title and dignity of Counteſs of Sutherland; by her Guardians. Wherein the facts and arguments in ſupport of her claim are more fully ſtated, and the errors in the additional caſes for the other claimants are detected, 4to.—This ſingularly learned and able caſe was ſubſcribed by Alexander Wedderburn (preſent Lord Chancellor), and Sir Adam Ferguſſon, but is the well-known work of Lord Hailes. It ought not to be regarded merely as a law-paper of great ability, but as a treatiſe of profound reſearch into the hiſtory and antiquity of many important and general points of ſucceſſion and family hiſtory. Introduction, pp. 21 ; the firſt four chapters pp. 70 ; the fifth and ſixth chapters pp. 177.

Remarks on the Hiſtory of Scotland, by Sir David Dalrymple.—" Utinam tam facile vera invenire poſſem quam falſa convincere." *Cicero.*—Edin. 1773, inſcribed to George Lord Lyttleton, in nine chapters, pp. 284. 12mo.

Huberti Langueti Epiſtolæ ad Philippum Sydneium Equitem Anglum, accurante D. Dalrymple de Hailes, Eq. Edinburgh, 1776, 8vo. Inſcribed to Lord Chief Baron Smythe.—Virorum Eruditorum Teſtimonia de Langueto, pp. 7. Epiſtolæ, pp. 289. Index Nominum, pp. 41.

Annals of Scotland, from the Acceſſion of Malcolm III. ſurnamed Canmore, to the Acceſſion of Robert I. by Sir David Dalrymple. Edin. 1776, pp. 311. Appendix, pp. 51.

Tables of the Succeſſion of the Kings of Scotland, from Malcolm III. to Robert I. their marriages, children, and time of their death ; and alſo of the Kings of England and France, and of the Popes who were their contemporaries.

Chronological Abridgement of the Volume, pp. 30. The Appendix contains eight diſſertations : 1. Of the law of Evenus and Mercheta Mulierum, pp. 17. 2. A commentary on the 22d ſtatute of William the Lion, pp. 8. 3. Of the 18th ſtatute of Alexander III. pp. 5. 4. Bull of Pope Innocent IV. pp. 6. 5. Of Walter Stewart Earl of Menteeth, 1296, pp. 7. 6. Of M'Duff, ſlain at Falkirk in 1298, pp. 3. 7. Of the death of John Comyn, 10th February, 1305, pp. 4. 8. Of the origin of the houſe of Stuart, pp. 6.

Annals of Scotland, from the Acceſſion of Robert I. ſurnamed Bruce, to the Acceſſion of the Houſe of Stuart ; by Sir David Dalrymple, Edin. 1779, 4to, pp. 277. Appendix, pp. 54, containing, 1. Of the manner of the death of Marjory, daughter of Robert I. pp. 7. 2. Journal of the campaign of Edward III. 1327, pp. 9. 3. Of the genealogy of the family of Seton in the 14th century. 4. Liſt of the Scottiſh commanders at the battle of Hallidon, 19th July 1383, pp. 11. 5. Whether Edward III. put to death the ſon of Sir Alexander Seton, pp. 8. 6. Liſt of the Scottiſh commanders killed or made priſoners at the battle of Durham, pp. 8. 7. Table of kings, p. 1. 8. Corrections and additions to volume i. pp. 16. Chronological abridgement of the volume, pp. 39.

Account of the Martyrs of Smyrna and Lyons, in the 2d century, 12mo, with explanatory notes, Edin. 1776. Dedicated to Biſhop Hurd, pp. 68. Notes and illuſtrations, pp. 142. This is a new and correct verſion of two moſt ancient epiſtles, the one from the church at Smyrna to the church at Philadelphia ; the other from the Chriſtians at Vienna and Lyons to thoſe in Aſia and Phrygia—their antiquity and authenticity are undoubted. Great part of both is extracted from Euſebius's Eccleſiaſtical Hiſtory. The former was firſt completely edited by Archbiſhop Uſher. The author of the notes ſays of them, with his uſual and ſingular modeſty, " That they will afford little new or intereſting to men of erudition, though they may prove of ſome benefit to the unlearned reader." But the erudition he poſſeſſed in theſe branches is ſo rare, that this notice is unneceſſary. They diſplay much uſeful learning and ingenious criticiſm, and breathe the moſt ardent zeal, connected with an exemplary knowledge of Chriſtianity. N. B. This is the firſt volume of the remains of Chriſtian Antiquity.

Remains of Chriſtian Antiquity, with explanatory notes, vol. ii. Edin. 1778, 12mo. Dedicated to Dr Newton biſhop of Briſtol. Preface, pp. 7. This volume contains the trial of Juſtin Martyr and his companions, pp. 8. Epiſtle of Dionyſius biſhop of Alexandria, to Fabius biſhop of Antioch, pp. 16. The trial and execution of Cyprian biſhop of Carthage, pp. 8. The trial and execution of Fructuoſus biſhop of Tarracona in Spain, and of his two deacons, Augurius and Eulogius, pp. 8. The maiden of Antioch, pp. 2. Theſe are all newly tranſlated by Lord Hailes from Ruinart, Euſebius, Ambroſe, &c. The notes and illuſtrations of this volume extend from p. 47 to 165, and diſplay a moſt intimate acquaintance with antiquity, great critical acumen, both in elucidating the ſenſe and detecting interpolations ; and above all, a fervent and enlightened zeal, in vindicating ſuch ſentiments and conduct as are conformable to the word of God, againſt the malicious ſarcaſms of Mr Gibbon. To this volume is added an Appendix of pp. 22, correcting and vindicating certain parts of vol. i.

Remains of Chriſtian Antiquity, vol. iii. Edin. 1780. Dedicated to Thomas Balguy, D. D. Preface, pp. 2. It contains the Hiſtory of the martyrs of Paleſtine in the third century, tranſlated from Euſebius, pp. 94. Notes and illuſtrations, pp. 135 ; in which Mr Gibbon again comes, and more frequently, under review.—The partiality and miſrepreſentations of this popular writer are here expoſed in the calmeſt and moſt ſatisfactory manner.

Pity it is that Lord Hailes ſhould have printed and publiſhed theſe valuable volumes, and indeed moſt of his other works, at his own expence ; and diſperſed them ſo liberally to his friends, that they have been little circulated among any other.

Octavius, a Dialogue, by Marcus Minucius Felix. Edin. 1781, pp. 16. Preface.—The ſpeakers are, Cæcilius a Heathen, Octavius a Chriſtian ; whoſe arguments prevail with his friend to renounce Paganiſm and become a Chriſtian proſelyte. Notes and illuſtrations, pp. 120.

Of the Manner in which the Perſecutors died ; a Treatiſe, by L. C. F. Lactantius, Edin. 1782. Inſcribed to Dr Porteous biſhop of Cheſter (preſent biſhop of London). Preface, pp. 37, in which it is proved that Lactantius is the author. Text, pp. 125. Notes and illuſtrations, pp. 109.

L. C. F. Lactantii Divinarum Inſtitutionum Liber Quintus ſeu de Juſtitia, 1777.

Diſquiſitions concerning the Antiquity of the Chriſtian Church. Glaſgow, 1783. Inſcribed to Dr Halifax biſhop of Glouceſter, pp. 194.—This ſmall original and moſt excellent work conſiſts of ſix chapters. Chap 1. A commentary on the conduct and character of Gallio. Acts xviii. 5, 12, 17.—Chap. 2. Of the time at which the Chriſtian religion became publicly known at Rome.—Chap. 3. Cauſe of the perſecution of the Chriſtians under Nero. In this the hypotheſis of Mr Gibbon, vol. i. 4to, p. 641, is examined.—Chap. 4. Of the eminent Heathen writers who are ſaid (by Gibbon) to have diſregarded or contemned Chriſtianity, viz. Seneca, Pliny ſen. Tacitus, Pliny jun. Galen, Epictetus, Plutarch, Marcus Antoninus. To the admirers of Heathen philoſophers, and to thoſe eſpecially who ſtate between them and the Chriſtian doctrine any conſanguinity, this chapter is earneſtly recommended.—Chap. 5. Illuſtration of a conjecture by Gibbon, reſpecting the ſilence of Dio Caſſius concerning the Chriſtians. In this chapter, with extreme impartiality, he amplifies and ſupports an idea of Mr Gibbon on this head. Chap. 6. Of the circumſtances reſpecting Chriſtianity that are to be found in the Auguſtan hiſtory.

It ſeems very probable that the cloſe attention which Lord Hailes appears to have given to ſuch ſubjects, was in ſome meaſure the effect of the miſtakes and partiality of Gibbon. In no one work from 1776, the date of Mr Gibbon's firſt publication, has he omitted to trace this unfair and inſinuating author; but in 1786 he came forth of ſet purpoſe with the moſt able and formidable reply which he has received, intitled, "An Inquiry into the Secondary Cauſes which Mr Gibbon has aſſigned for the rapid growth of Chriſtianity; by Sir David Dalrymple." Edin. 1786; gratefully and affectionately inſcribed to Richard (Hurd) Biſhop of Worceſter, 4to, pp. 213. In five chapters.

Sketch of the Life of John Barclay, 4to, 1786.

Sketch of the Life of John Hamilton, a Secular Prieſt, 4to (one of the moſt ſavage and bigotted adherents of Popery, who lived about A. D. 1600.)

Sketch of the Life of Sir James Ramſay, a general officer in the armies of Guſtavus Adolphus king of Sweden, with a head.

Life of George Leſlie (an eminent capuchin friar in the early part of the 17th century, 4to, pp. 24.

Sketch of the Life of Mark Alex. Boyd, 4to.

Theſe lives were written and publiſhed as a ſpecimen of the manner in which a *Biographia Scotica* might be executed; and it is likely that Lord Hailes ſelected purpoſely the leaſt intereſting.

The Opinions of Sarah Dutcheſs Dowager of Marlborough, publiſhed from her original MSS. 1788, 12mo, pp. 120. (with a few foot notes by Lord Hailes, in which he corrects the ſplenetic partiality of her Grace).

The Addreſs of Q. Sept. Tertullian to Scapula Tertullus, Proconſul of Africa, tranſlated by Sir David Dalrymple, 12mo. Edin. 1790, inſcribed to Dr John Butler, biſhop of Hereford; preface, pp. 4; tranſlation, pp. 18; original, pp. 13; notes and illuſtrations, pp. 135.

This addreſs contains many particulars relating to the church after the third century. The tranſlator has rejected all words and phraſes of French origin, and written entirely in the Anglo Saxon dialect. In the courſe of the notes many obſcurities of the original, not adverted to by other commentators, are explained. Some ſtrange inaccuracies of Mr Gibbon are alſo detected, not included in the miſrepreſentations of his two famous chapters.

This was the laſt work of this truly learned, reſpectable, and uſeful man. Whether he left behind him any thing elſe finiſhed for the preſs, is known only to his friends. We have repeatedly heard that he was engaged in examining the authenticity of the books of the New Teſtament, and that, with the exception of two or three, he found every verſe contained in it in the writings of the firſt three centuries. This ſeems indeed to have been an object in all his works; for, at the end of each of his tranſlations and editions of the primitive Chriſtian writers, a table is given of paſſages quoted or mentioned by them. If his Lordſhip completed any work of this kind, it ſhould not be withheld from the public. We may indeed be told that its utility is in a great meaſure ſuperſeded by the laborious collections of Lardner (B), and the more elegant work of Paley (C); but not to mention the prejudices generally entertained againſt Lardner on account of his evident bias to Unitarianiſm, it would ſurely be proper, in the preſent age of wild opinions, to ſhew the multitude, who are guided by authority, how important a ſubject the Chriſtian religion was deemed by this learned and accompliſhed layman.

DARCY (Count), an ingenious philoſopher and mathematician, was born in Ireland in the year 1725; but his friends being, like many other great and good families at that period, attached to the houſe of Stuart, he was at 14 years of age ſent to France, where he ſpent the reſt of his life. Giving early indications of a genius for ſcience, he was put under the care of the celebrated Clairaut (ſee CLAIRAUT, *Encycl*), under whoſe tuition he improved ſo rapidly in the mathematics, that at 17 years of age he gave a new ſolution of the problem concerning the curve of equal preſſure in a reſiſting medium. This was followed the year after by a determination of the curve deſcribed by a heavy body, ſliding by its own weight along a moveable plane, at the ſame time that the preſſure of the body cauſes a horizontal motion in the plane.

Though Darcy ſerved in the war of 1744, he found leiſure, during the buſtle of a military life, to ſend two memoirs to the academy: the firſt of theſe contained a general principle in mechanics, that of the preſervation of the rotatory motion; a principle which he again brought forward in 1750, by the name of the principle of the preſervation of action. He was taken priſoner in this war by the Engliſh; and ſuch was either the reſpect paid to ſcience, or the mercy of the cabinet of St James's, that he was treated, not as an Iriſh rebel, but as a French ſubject fighting for his king and his country.

In 1760, Darcy publiſhed An Eſſay on Artillery, containing ſome curious experiments on the charges of gunpowder, &c. &c. and improvements on thoſe of the

---

(C) See his *Evidences of the Chriſtian Religion*, in 2 vols 8vo.

ingenious Robins; a kind of experiments which our author carried on occaſionally to the end of his life. In 1765, he gave to the public the moſt ingenious of all his works, his Memoir on the Duration of the Senſation of Sight; in which he endeavours to prove, and indeed completely proves, that a body may ſometimes paſs by our eyes without producing a ſenſation attended with conſciouſneſs or marking its preſence, otherwiſe than by weakening the brightneſs of the object which it may chance to cover in its paſſage. If in this work he ſhall be thought to have taken hints from Dr Hartley, it is not perhaps too much to ſay, that ſome of our moſt celebrated writers on viſion have ſince been beholden to Darcy. No man indeed has cauſe to be aſhamed of being indebted to him; for all his works diſplay in an eminent degree the union of genius and philoſophy; but as he meaſured every thing upon the largeſt ſcale, and required extreme accuracy in experiment, neither his time, fortune, nor avocations, allowed him to execute more than a very ſmall part of what he projected.

In his diſpoſition, Darcy was amiable, ſpirited, lively, and a lover of independence; a paſſion to which he nobly ſacrificed, even in the midſt of literary ſociety.—He died of a cholera morbus in 1779, at 54 years of age. He was admitted of the French academy in 1749, and was made penſioner-geometrician in 1770. His eſſays, printed in the Memoirs of the Academy of Sciences, are various and very ingenious, and are contained in the volumes for the years 1742, 1747, 1749, 1750, 1751, 1752, 1753, 1754, 1758, 1759, 1760, 1765, and in tom. 1. of the Savans Etrangers.

DATA OF EUCLID, the firſt in order of the books that have been written by the ancient geometricians, to facilitate and promote the method of reſolution or analyſis. In general, a thing is ſaid to be given which is either actually exhibited or can be found out, that is, which is either known by hypotheſis, or that can be demonſtrated to be known: and the propoſitions in the book of Euclid's data ſhew what things can be found out or known, from thoſe that by hypotheſis are already known: ſo that in the analyſis or inveſtigation of a problem, from the things that are laid down as given or known, by the help of theſe propoſitions, it is demonſtrated that other things are given, and from theſe laſt that others again are given, and ſo on, till it is demonſtrated that that which was propoſed to be found out in the problem is given; and when this is done, the problem is ſolved, and its compoſition is made and derived from the compoſitions of the data which were employed in the analyſis. And thus the data of Euclid are of the moſt general and neceſſary uſe in the ſolution of problems of every kind.

Marinus, at the end of his preface to the data, is miſtaken in aſſerting that Euclid has not uſed the ſynthetical, but the analytical method in delivering them: for though in the analyſis of a theorem, the thing to be demonſtrated is aſſumed in the analyſis; yet in the demonſtrations of the data, the thing to be demonſtrated, which is, that ſomething is given, is never once aſſumed in the demonſtration; from which it is manifeſt, that every one of them is demonſtrated ſynthetically: though indeed if a propoſition of the data be turned into a problem, the demonſtration of the propoſition becomes the analyſis of the problem. *Simpſon's Preface to his Edition of the Data.*

CIRCULATING DECIMALS, called alſo *recurring* or *repeating decimals*, are thoſe in which a figure or ſeveral figures are continually repeated. They are diſtinguiſhed into *ſingle* and *multiple*, and theſe again into *pure* and *mixed*.

A *pure ſingle* circulate is that in which one figure only is repeated; as $\cdot 222$, &c. and is marked thus $\cdot\dot{2}$.

A *pure multiple* circulate is that in which ſeveral figures are continually repeated; as $\cdot 232323$, &c. marked $\cdot\dot{2}\dot{3}$; and $\cdot 524524$, &c. marked $\cdot\dot{5}2\dot{4}$.

A *mixed ſingle* circulate is that which conſiſts of a terminate part, and a ſingle repeating figure; as $4\cdot 222$, &c. or $4\cdot\dot{2}$. And

A *mixed multiple* circulate is that which contains a terminate part with ſeveral repeating figures; as $45\cdot\dot{5}2\dot{4}$.

That part of the circulate which repeats is called the *repetend;* and the whole repetend, ſuppoſed infinitely continued, is equal to a vulgar fraction, whoſe numerator is the repeating number or figures, and its denominator the ſame number of nines: ſo $.\dot{2}$ is $= \frac{2}{9}$; and $\cdot\dot{2}\dot{3}$ is $= \frac{23}{99}$; and $\cdot\dot{5}2\dot{4}$ is $= \frac{524}{999}$.

It ſeems it was Dr Wallis who firſt diſtinctly conſidered or treated of infinite circulating decimals, as he himſelf informs us in his Treatiſe of infinites. Since his time many other authors have treated on this part of arithmetic; the principal of theſe, however, to whom the art is moſtly indebted, are Meſſrs Brown, Cunn, Martin, Emerſon, Malcolm, Donn, and Henry Clarke; in whoſe writings the nature and practice of this art may be fully ſeen, eſpecially in the laſt mentioned ingenious author.

DEFERENS, or DEFERENT, in the ancient aſtronomy, an imaginary circle, which, as it were, carries about the body of a planet, and is the ſame with the eccentric; being invented to account for the eccentricity, perigee, and apogee of the planets.

DEFLECTION, the turning any thing aſide from its former courſe by ſome adventitious or external cauſe. The word is often applied to the tendency of a ſhip from her true courſe by reaſon of currents, &c. which turn her out of her right way. It is likewiſe applied by aſtronomers to the tendency of the planets from the line of their projection, or the tangent of their orbit. See ASTRONOMY in this Supplement.

DEJECTION, in aſtrology, is applied to the planets when in their detriment, as aſtrologers ſpeak, i. e. when they have loſt their force or influence, as is pretended, by reaſon of their being in oppoſition to ſome others which check and counteract them. Or it is uſed when a planet is in a ſign oppoſite to that in which it has its greateſt effect or influence, which is called its *exaltation*. Thus, the ſign Aries being the exaltation of the ſun, the oppoſite ſign Libra is its dejection.

DELIACAL PROBLEM, a celebrated problem among the ancients, concerning the duplication of the cube.

DEMI-BASTION, in fortification, a baſtion that has only one face and one flank.

DENDROMETER, in its uſual acceptation, is the name of an inſtrument for meaſuring trees, of which the reader will find a deſcription in the Encyclopædia Britannica. The ſame name has been lately given, by

William Pitt, Eſq; of Pendeford near Wolverhampton, to an inſtrument propoſed by him for meaſuring diſtances by one obſervation.

The idea of ſuch an inſtrument is not new. It has been frequently diſcuſſed, both in converſation and upon paper; but has been generally treated by ſound mathematicians with contempt, on the ſuppoſition of its being founded on falſe principles. Of all this our author is fully aware; but he, notwithſtanding, ſtrongly recommends it to the attention of the ingenious mathematical inſtrument maker.

To determine diſtances by one obſervation, two methods may be propoſed, founded on different principles; the one on the ſuppoſition of the obſerver being in the centre, and the object in the circumference, of a circle; the other, on the contrary ſuppoſition, of the obſerver being in the circumference, and the object in the centre.

To determine the diſtance of any object on the firſt ſuppoſition, the bulk or dimenſions of ſuch object muſt be known, either by meaſure or eſtimation, and the angle formed by lines drawn to its extremities being taken by an accurate inſtrument, the diſtance is eaſily calculated; and ſuch calculations may be facilitated by tables or theorems adapted to that purpoſe. For this method our preſent inſtruments, with a nonius, and the whole very accurately divided, are ſufficient; the only improvement wanting ſeems to be the application of a micrometer to ſuch inſtruments, to enable the obſerver to read his angle with more minute accuracy, by aſcertaining, not only the degrees and parts of a degree, but alſo the minutes and parts of a minute.

As in this method the bulk of inacceſſible objects can only be eſtimated, the error in diſtance will be exactly in the proportion of the error in ſuch eſtimation; little dependence can therefore be placed on diſtances thus aſcertained. For the purpoſes of ſurveying, indeed, a ſtaff of known length may be held by an aſſiſtant; and the angle from the eye of the obſerver to its two ends being meaſured by an accurate inſtrument, with a micrometer fitted to aſcertain minutes and parts of a minute, diſtances may be thus determined with great accuracy; the application of a micrometer to the theodelite, if it could be depended upon, for thus determining the minute parts of a degree, in ſmall angles, is very much a deſideratum with the practical ſurveyor.

This method of meaſuring diſtances, though plain and ſimple enough, our author illuſtrates by an example: Suppoſe A, fig. 1. (ſee Plate XXI.) the place of the inſtrument; BC the aſſiſtant's ſtaff, with a perpendicular pin at D, to enable the aſſiſtant to hold it in its right poſition; now, if the angle BAC could, by the help of a micrometer, be aſcertained to parts of a minute, the diſtance from A to B, or to C, might be eaſily calculated by the rules of plane TRIGONOMETRY; for which ſee that article in the Encyclopædia.

But this method of aſcertaining diſtances cannot be applied to inacceſſible objects, and it is moreover ſubject to the inconvenience of an aſſiſtant being obliged to go to the object whoſe diſtance is required (an inconvenience almoſt equal to the trouble of actual admeaſurement); therefore the perfection of the ſecond method propoſed, if attainable, is principally to be deſired; namely, that of conceiving the obſervation made on the circumference of a circle, whoſe centre is in the object whoſe diſtance is to be aſcertained; and, none of our inſtruments now in uſe being adapted to this mode of obſervation, a new conſtruction of a mathematical inſtrument is therefore propoſed, the name intended for which is the *dendrometer*.

Our author admits, that this name is not now uſed for the firſt time, though he thinks that the principle has never been applied in practice, for the familiar purpoſe of aſcertaining terreſtrial diſtances, in ſurveying, or otherwiſe, though the ſame principle has been ſo generally and ſucceſsfully applied in determining the diſtance of the heavenly bodies by means of their parallax.

The following principles of conſtruction are propoſed, which may perhaps be otherwiſe varied and improved. O, fig. 2. the object of whoſe diſtance is required; ABCDE the inſtrument *in plano*; BC a teleſcope, placed exactly parallel to the ſide AE; CE an arch of a circle, whoſe centre is at A, accurately divided from E in degrees, &c.; AD an index, moveable on the centre A, with a nonius ſcale at the end D, graduated to apply to the diviſions of the arch; alſo with a teleſcope, to enable the obſerver to diſcriminate the object, or any particular part or ſide thereof, the more accurately. The whole ſhould be mounted on three legs, in the manner of a plain table or theodolite, and furniſhed with ſpirit-tubes to adjuſt it to an horizontal poſition. The inſtrument being placed in ſuch poſition, the teleſcope BC muſt be brought upon the object O, or rather upon ſome particular point or ſide thereof; when, being there faſtened, the index AD muſt be moved till its teleſcope exactly ſtrikes the ſame point of the object; then the diviſions on the arch ED mark out the angle DAE, which will be exactly equal to the angle BOA, as is demonſtrated in the XV. and XXIX. propoſitions of Euclid, Book I.; and the ſide BA, as well as the angles ABO, and BAO, being already known, the diſtance BO or AO may be eaſily determined.

As the perfection of this inſtrument depends altogether upon its accuracy in taking ſmall angles, ſo that accuracy muſt depend, not only upon the inſtrument's being properly fitted with a micrometer, but alſo in ſome meaſure upon the length of the line BA in the figure. That line, therefore, might be extended, by the inſtrument being conſtructed to fold or ſlide out to a greater length when in uſe; upon which principle, connected with the application of a micrometer, an accurate and uſeful inſtrument might certainly be conſtructed. To adjuſt ſuch inſtrument for uſe, let a ſtaff be held up at a diſtance, in the manner of fig. 1. exactly equal in length to the diſtance of the two teleſcopes, and the index AD being brought exactly upon the ſide AE, if the two teleſcopes accurately ſtrike either end of the ſtaff, the inſtrument is properly adjuſted.

The conſtruction of a ſimilar inſtrument, on the principles of Hadley's quadrant, for naval obſervations, would alſo doubtleſs be an acceptable object in navigation, by enabling the mariner to aſcertain the diſtances of ſhips, capes, and other objects, at a ſingle obſervation; and that, perhaps, with greater accuracy than can be done by any method now in uſe.

For this purpoſe, the following conſtruction is propoſed: ABCDE, fig. 3. the inſtrument *in plano*; O the object whoſe diſtance is required; at A, at C, at E, and at 3, are to be fixed ſpeculums, properly framed.

med and fitted, that at 3 having only its lower part quickſilvered, the upper part being left tranſparent to view the object; the ſpeculum at A being fixed obliquely, ſo that a line A 1, drawn perpendicular to its ſurface, may biſect the angle BAC in equal parts; that at C being perpendicular to the line C 2; thoſe at E and 3 being perpendicular to the index E 3, and that at E being furniſhed with a ſight; the arch DC to be divided from D in the manner of Hadley's quadrant; the movement of the index to be meaſured as before by a micrometer; and as the length of the line AE would tend to the perfection of the inſtrument, it may be conſtructed to fold up in the middle, on the line C 2, into leſs compaſs when not in uſe. The inſtrument may be adjuſted for uſe by holding up a ſtaff at a diſtance, as before propoſed, whoſe length is exactly equal to the line AE.

To make an obſervation by this inſtrument, it being previouſly properly adjuſted, the eye is to be applied at the ſight in the ſpeculum E, and the face turned towards the object; when the object being received on the ſpeculum A, is reflected into that at C, and again into that at E, and that at 3 on the index; the index being then moved till the reflected object in the ſpeculum at 3 exactly coincides with the real object in the tranſparent part of the glaſs, the diviſions on the arch D 3, ſubdivided by the micrometer, will determine the angle DE 3 = the angle AOE; from which the diſtance O may be determined as before.

DENOMINATOR of a Ratio is the quotient ariſing from the diviſion of the antecedent by the conſequent. Thus, 6 is the denominator of the ratio 30 to 5, becauſe 30 divided by 5 gives 6. It is otherwiſe called the *exponent* of the ratio.

DEPRESSION of a Star, or *of the Sun*, is its diſtance below the horizon; and is meaſured by an arc of a vertical circle, intercepted between the horizon and the place of the ſtar.

Depression of the Viſible Horizon, or *Dip of the Horizon*, denotes its ſinking or dipping below the true horizontal plane, by the obſerver's eye being raiſed above the ſurface of the ſea; in conſequence of which, the obſerved altitude of an object is by ſo much too great.

DEROOBUST, in Bengal, Entire; as an entire diſtrict, oppoſed to Kismut, which ſee.

DESAULT (Peter Joſeph), ſurgeon in chief to the Hoſpital of Humanity, formerly the *Hotel-Dieu* at Paris, was born on the 6th of February 1744 at Magny Vernois, a village in the neighbourhood of Lure, in the department of Haute Saone (formerly the province of *Franche Comté)*. His father and mother were in that ſituation of life which is removed from want, and yet does not diſpenſe with labour; he himſelf was the youngeſt child of a numerous family.

At Lure, under the direction of a private inſtructor, he was taught the firſt rudiments of the Latin tongue; his parents afterwards confided him to the care of the Jeſuits, then almoſt excluſively entruſted with the education of youth in the public ſchools. This celebrated ſociety, prompt in diſcovering, as expert at developing, and adroit in appropriating talents, ſoon diſtinguiſhed the young ſtudent from the crowd; and he, in his turn, was not diſpleaſed with the life he led in one of their ſeminaries.

On the completion of his ſtudies, his father, who had deſtined him for the church, intimated a wiſh that he ſhould apply himſelf to theology; but his genius had taken a different direction, and he was averſe to the profeſſion of an eccleſiaſtic: in ſhort, young Deſault declared that he was determined to betake himſelf to the ſtudy of the healing art; and, after a long and ineffectual reſiſtance on the part of his family, he was ſent to Béfort, in order to ſerve an *apprenticeſhip*, as it was then termed, in the military hoſpital of that place. He accordingly ſpent three years there; during which he acquired ſome knowledge of anatomy, attended to the dreſſing of the patients, and endeavoured to ſupply, by his own obſervations, what was wanting in his inſtruction.

In the midſt of theſe profeſſional labours, his mind frequently rambled towards another ſcience but little connected with ſurgery: this was mathematics, the elements of which he had acquired among the Jeſuits. His progreſs in this favourite ſtudy was rapid; but he fell into one of the many errors ſo common among the phyſicians of that day; this conſiſted in a falſe application of the rules of geometry to the laws of the animal economy.

He not only peruſed with avidity the treatiſe of Borelli *De Motu Animalium*, but actually tranſlated the whole of it, and even added a commentary, ſtill more abundant in calculation than that of the celebrated profeſſor of Naples.

His ſucceſs in a branch of phyſiology ſo much cultivated at that time, attracted the attention of one of his ſuperiors, a zealous partizan of the doctrine of the mechanicians, who wiſhed to attach him to his perſon; but his deſire of fame required a more extenſive theatre, and his love of ſtudy made him ſolicitous of better means of inſtruction. Paris preſented both theſe advantages; and he accordingly repaired thither in 1764, at the age of nineteen, in ſearch of them.

Surgery at that period flouriſhed in the capital under the auſpices of a Lafaye, a Morand, an Andouillet, and a Louis. The ſight of ſuch great maſters excited the genius of thoſe who aſpired to emulate them: young Deſault deemed himſelf worthy of equalling men whom other ſtudents were content with only admiring. Animated by this ſentiment, he entirely reſigned himſelf to his ardour; anatomy became the ſpecial object of his labours, and his diſſections were not confined to the human body, for he inveſtigated, by means of his knife, a prodigious number of animals of all kinds: at firſt, from a difficulty of procuring human ſubjects, and afterwards on account of the advantages which he experienced from this general method. In order to become intimately acquainted with our own organization, it is neceſſary to compare it with whatever has a reſemblance to it in other bodies.

He accordingly ſpent the greater part of the day in the amphitheatres. The hours ſtolen from his favourite labours were employed in attending the hoſpitals; he was the firſt at the bed of the patient where an operation was to be performed, and was ſure to be preſent at the dreſſings, on purpoſe to examine the reſult. The infirmities of mankind, ſterile in reſpect to the vulgar, ſerved him as the beſt treatiſe for curing them; and the great ſurgeons of all nations have formed their mode of practice by contemplating the ſame book.

But he reckoned too much on a robuſt and vigorous temperament; for, after two years cloſe and aſſiduous application, he fell into a cachectical habit of body, which had nearly proved mortal, and which confined him for almoſt twelve months to his bed; but at length, owing partly to the vigour of his youth, and partly to the attention of his young friend Chopart, his inſeparable companion in his operations, who attended him alſo during his laſt illneſs, and only ſurvived him a few days, he was ſo fortunate as to recover.

Reſtored to life, he forgot that an exceſs of attention had conducted him to the very gates of death; a new career opened to his view, and required new efforts on his part. In the winter of 1766 he commenced a courſe of anatomy, and ſoon reckoned 300 pupils, moſt of them older than himſelf, who were attracted by the clearneſs of his demonſtrations, the methodical arrangement of his deſcriptions, and, above all, by his indefatigable zeal in the ſcience of inſtruction.

His ſucceſs inſpired the privileged profeſſors, whoſe ſchools became deſerted, with jealouſy and revenge; they employed the authority of the corporation againſt him, and would have nipped his efforts in the bud, had it not been for the protection of Louis and Lamartiniere, who were zealous of protecting a youth of talents, whoſe ſole reproach was, that he had not wealth enough to purchaſe certain franchiſes. After all, had it not been for the permiſſion he obtained of borrowing the name of a celebrated phyſician, he muſt have actually deſiſted from his lectures.

Default's reputation now began to be buzzed about, and a multitude of patients claimed his aſſiſtance; but he conſtantly refuſed to practiſe until he ſhould be placed at the head of ſome great eſtabliſhment.

At length, at the repeated ſolicitations of his friends, he preſented himſelf as a candidate to the corporation of ſurgeons; and they, much to their honour, admitted him in 1776, on condition of paying the uſual fees when convenient. The following is the title of his theſis: "*De calculo veſicæ urinariæ, eoque extrahendo, præviâ ſectione, ope inſtrumenti Haukenſiani emendati.*"

His public lectures were accompanied with as much celebrity as his private ones. Brilliant diſcoveries were not the object of his anatomical labours, which were always connected with the art of healing: he was, however, the firſt man in France who taught ſurgical anatomy.

After becoming firſt a ſimple member, and then a counſellor, of the perpetual committee of the academy of ſurgery, he was appointed chief ſurgeon to the hoſpital of the college, and conſulting ſurgeon to that of St Sulpice: neither of theſe added any thing to his fortune, but they gave him a clear inſight into practice, and enabled him to judge of caſes by the inductions ariſing from his own experience.

In 1779 he invented the bandage now in uſe for fractures; by means of which, the fragments being kept in a ſtate of perpetual contact, become conſolidated, without the leaſt appearance of deformity, an almoſt inevitable conſequence of the former mode.

On his appointment to the place of ſurgeon major to the hoſpital *de la Charité*, in 1782, he introduced a new method of treatment in oblique fractures of the thigh-bone; and he alſo healed, by means of a methodical compreſſion, thoſe various ulcers whoſe cure had hitherto been attended with great difficulty. In addition to this, he ſubſtituted new bandages in fractures of the humerus and clavicle, and adopted a new mode of treating the hare-lip, ſuperior to that uſed by Louis. He never recurred to amputation but in extreme caſes, when there was a certainty that diſſolution would have followed a neglect of the operation.

When a premature death carried off Ferrand, chief ſurgeon of the *Hotel Dieu* in Paris, Default was conſidered as the moſt proper perſon to ſucceed him; and, on the demiſe of Moreau, the whole charge of the hoſpital devolved on him. After three years of ſolicitations and diſputes, he at length in 1788 proceeded in his long projected ſcheme of eſtabliſhing a clinical ſchool; and a ſpacious amphitheatre was accordingly erected for that purpoſe. Scarcely had his firſt (A) courſe commenced, when the number of pupils who flocked around him was really aſtoniſhing. Foreigners repaired from all parts, and ſeveral of the neighbouring ſtates ſent ſtudents to Paris, expreſsly for the purpoſe of aſſiſting at his demonſtrations. More than 600 auditors conſtantly attended, in order to learn a new ſyſtem, conſiſting of a ſimple mode of treatment, diſengaged from ancient prejudices, and a complex incoherent practice.

A few of his improvements are here ſpecified.

1. The method of ligature employed by the ancients in the cure of umbilical hernias of children, having been generally omitted in the practice of the moderns, he again introduced and perfected this mode, and demonſtrated, by his ſucceſs, its ſuperiority over compreſſive bandages.

2. He was one of the firſt men in France to extract the looſe cartilages *(cartilâges flottans)* in joints.

3. He employed a new treatment, that of a methodical compreſſion, in reſpect to ſchirroſities of the rectum; in order to which he introduced a candle or bougie, the ſize of whice he gradually augmented.

4. He ſimplified, and rendered more commodious, the reduction of luxations of the humerus.

5. Fatal experience having pointed out the danger of employing the trepan in wounds of the head, he ſubſtituted another method of treatment *(l'uſage de l'émétique)* now adopted by many practitioners.

6. He made ſeveral very uſeful improvements on chirurgical inſtruments; ſuch as thoſe employed in the

---

(A) The buſineſs of the day was conducted in the following routine: 1. A public conſultation concerning the indigent out-patients. 2. The young practitioners belonging to the hoſpital read a detailed account of all the intereſting caſes of ſuch patients as were to be diſcharged that day. 3. The operations: each of theſe was preceded by a diſſertation on the ſtate of the patient, who was then carried to the amphitheatre, where Default, attended by his aſſiſtants, performed the operation in preſence of all the pupils. 4. Argumentative details, by the profeſſor, either on the dangerous maladies exiſting in the hoſpital, or on the ſituation of the patients on whom operations had been performed during the preceding day. 5. The diſſection of ſubjects. And, 6. A lecture on ſome particular branch of pathology.

caſes of polypus in the womb and noſtrils (*la pince à gaîne et des porte-nœuds pour la ligature des polypes*, &c.;) for cutting through obſtructions in the different cavities (*le kiotome*); and for the *fiſtula in ano*. In caſes of inciſion he introduced the uſe of the inſtrument (*le gorgeret*) invented by Marchetti, well known among foreigners, but almoſt totally neglected in France before this period.

He at the ſame time retrenched the uſe of a great number of ſuperfluous ones, and baniſhed all practices attended with greater pain than utility. Avoiding every thing that was complex, he proved that the art of healing, in imitation of nature, ought to be ſimple in its means, and fruitful in its reſources.

In 1791 he publiſhed his *Journal de Chirurgerie*, which was edited by his pupils, and deſtined to deſcribe the moſt intereſting occurrences in his ſchool, and alſo extracts from his lectures, which were then dedicated to the inveſtigation of the maladies incident to the urinary paſſages. The treatment of theſe diſeaſes, hitherto the reproach of practitioners, had been much improved by the aſſiſtance of the artiſt Bernard. The elaſtic probes (*les ſandes élaſtiques*), on their firſt appearance, fixed the attention of all profeſſional men; but none knew better than Default how to appretiate their advantages. By means of them, he introduced a novel mode of cure in contractions of the urethra, which ſaved a great number of lives every year in the *Hotel-Dieu*. But he did not confine their uſe to the diſeaſes of the urethra alone, for he employed them to remove the divers obſtacles that impede deglutition or reſpiration.

In the midſt of ſuch a multiplicity of labours, and although he was obliged to attend 400 ſick twice a-day, Default nevertheleſs employed more than four hours of his time in viſiting private patients.

Few ſurgeons ever enjoyed ſuch an excluſive ſhare of public confidence; few ever poſſeſſed ſimilar means of enriching themſelves; and yet he neglected for a long time to take advantage of this. Had he been leſs ardent for glory, he would have been more favoured by fortune; but he ſacrificed all intereſted views to the noble ambition of advancing his art. His clinical and anatomical courſes were gratuitouſly opened by him to the world after the year 1790; and while the public ſchools languiſhed in the midſt of troubles, inſeparable perhaps from a mighty revolution, he was forming the greater part of thoſe ſurgeons employed at this preſent moment in the numerous armies of the republic. Conſidered under this point of view alone, the ſervices which he rendered to humanity are incalculable: too happy if perſecution had not been his ſole reward!

While out of mere attachment to the public weal, he added to his various functions that of a member of the council of health, conferred on him in 1792 by the miniſter Servan, he was denounced in the popular ſocieties as an *egotiſt*, an *indifferent*, &c. and became one of the firſt victims of that proſcription which, under Robeſpierre, extended to nearly every man of talents.

Chaumette accuſed him to the ſections as having neglected the brave men wounded on the 10th of Auguſt, while they themſelves were laviſhing their bleſſings at the *Hotel-Dieu* on their ſaviour. Twice was he brought to the bar of a commune; deſirous of diſcovering a pretext for perſecution, the clamours of the people were unremittingly excited againſt him. He was at length carried away from his amphitheatre, while in the very act of haranguing his pupils; and, in conſequence of a *mandat d'arr't* from the revolutionary committee, conducted by a body of armed men to the Luxembourg. From this horrid priſon few ever departed but to meet their fate; luckily, however, his name was not yet entered on that bloody liſt, in which thoſe of Maleſherbes and Lavoiſier were inſerted. On the contrary, at the end of three days he was liberated, and inſtantly reſumed all his functions.

On the eſtabliſhment of *L'Ecolede Santé*, Default was appointed clinical profeſſor; and for external maladies he ſoon after obtained from the government the converſion of the *Eveché* into an hoſpital for ſurgical operations.

In the midſt of theſe plans, the troubles that occurred in the month of May unfortunately affected his mind, and made him dread leſt the days of proſcription ſhould return. It was in vain that his friends attempted to ſoothe his ſufferings; for on the night of the 29th of May, a malignant fever made its appearance, and a nearly continual delirium enſued until his death, which occurred on the 1ſt of June 1795. on which day he breathed his laſt, in the arms of his pupils, at the age of 51.

The populace were perſuaded that he was poiſoned. This ridiculous opinion originated in conſequence of the epoch of his death, which preceded but a ſhort time that of the ſon of Louis XVI. whom he had viſited during his illneſs in the priſon of the Temple. It is pretended that he fell a victim to his conſtant refuſal to yield to the criminal views entertained againſt the life of that child.

Default was of a middling ſtature. He was well proportioned, and poſſeſſed an open countenance. His temperament, naturally robuſt, had been fortified by his early education, and was never ſapped by an exceſs of pleaſures, for to them his heart was always indifferent. His ruling paſſion was the love of glory; his favourite purſuit, the practice and advancement of his art. He was warm, nay ſometimes violent; and his ſcholars were not always inclined to praiſe the ſweetneſs of his temper. On the other hand, his mind was noble, elevated, and great, even to exceſs.

The French republic, eager to pay homage to his memory, has preſented his widow with a penſion of 2000 livres *per annum*. A ſon, Alexis Mathias Default, was the ſole fruit of his marriage; and he has left but one work behind him, in which the name of his friend Chopart is joined with his own. It is entitled *Traité des Maladies Chirurgicales et des Operations qui leur conviennent*, 2 vols 8vo.

DETERMINATE PROBLEM, is that which has but one ſolution, or a certain limited number of ſolutions; in contradiſtinction to an indeterminate problem, which admits of infinite ſolutions.

DETERMINATE Section, the name of a tract or general problem, written by the ancient geometrician Apollonius. None of this work has come down to us, excepting ſome extracts and an account of it by Pappus, in the Preface to the 7th book of his Mathematical Collections. He there ſays that the general problem was. "To cut an infinite right line in one point ſo, that, of the ſegments contained between the point of ſection ſought, and given points in the ſaid line, either the ſquare on one of them, or the rectangle contained by two of them, may have a given ratio, either to the rectangle contained by one of them and a given line, or to the rectangle contained by two of them."

DETONATION (ſee that word *Encycl.*). The aſtoniſhing violence with which the oxy-muriat of potaſs, when mixed with various ſubſtances, detonates, has been already noticed in this Supplement under the article CHEMISTRY, n° 722, where the theory of theſe exploſions is likewiſe given. But as ſeveral chemiſts ſeem to think that this ſalt, which decrepitates by friction, and ſpontaneouſly takes fire when mixed with ſulphur, contains in itſelf the elements and phenomena of thunder, it will not probably be unacceptable to our readers to find, in this place, a diſtinct account of the various mixtures which produce its detonations. The following are the principal which have been diſcovered by Fourcroy and Vauquelin.

1. Three parts of the oxy-muriat of potaſs, and one part of powdered ſulphur, rubbed together in a metal mortar, produce numerous ſucceſſive exploſions, reſembling the ſmacking of a whip, or even as loud as the report of a piſtol or a muſket, according to the rapidity of the motion, and the force of the preſſure made uſe of. A few grains of the ſame mixture, by being ſtruck ſmartly upon an anvil with a hammer, occaſion a report equal to that of a muſket; and torrents of purpliſh light are ſeen about the anvil. If this mixture be thrown into concentrated ſulphuric acid, it inſtantly takes fire, and burns, without noiſe, with a flame of a dazzling whiteneſs.

2. A mixture of three parts of this ſalt, half a part of ſulphur, and half a part of charcoal, cauſes ſtronger exploſions than the preceding when rubbed in a mortar, and a louder noiſe when ſtruck upon an anvil. Its flame alſo, when the mixture is made to explode, or when it is thrown into ſulphuric acid, is more rapid, more lively, and of a redder colour, than that of the preceding.

3. A mixture of equal parts of oxy-muriat of potaſs and antimony in powder explodes with noiſe by percuſſion; but produces only reddiſh ſparks when thrown into ſulphuric acid. If zinc be ſubſtituted in the place of antimony, a ſimilar exploſion takes place, accompanied with a white flame. Sulphuric acid has no effect upon this laſt mixture.

4. With regulus of arſenic, this ſalt explodes very violently by the ſtroke of a hammer; it inflames, with ſingular rapidity and brilliancy, by the contact of ſulphuric acid. In this laſt experiment there ariſes a ſmoke, which in the air takes the form of a crown, in the ſame manner as phoſphorated hydrogenous gas does when it inflames ſpontaneouſly in a ſtill atmoſphere.

5. Sulphuret of iron or martial pyrites inflames rapidly, but without noiſe, when rubbed in a metal mortar with oxy-muriat of potaſs. This mixture, when ſtruck upon an anvil, explodes violently, and with a red flame.

6. The red ſulphuret of mercury or cinnabar, and the ſulphurated calces of antimony, explode with the oxy-muriat of potaſs by percuſſion, but they do not inflame by ſulphuric acid. The ſame thing happens when charcoal alone is mixed with this ſalt.

Any of the following ſubſtances, namely, ſugar, gums, oils (both fixed and volatile), alcohol, ether, when mixed with oxy-muriat of potaſs, have the property of exploding very violently by the ſtroke of a hammer, and all of them ſend forth a briſk flame at the time of their exploſion. The liquid combuſtible ſubſtances above mentioned are to be mixed with the ſalt in ſuch a manner as to form a kind of paſte. None of theſe mixtures explode or inflame by being rubbed in a mortar; but ſome of them inflame by being mixed with concentrated ſulphuric acid, their combuſtion being ſlow and progreſſive.

8. All the ſubſtances above mentioned, which, being mixed with the oxy-muriat of potaſs, take fire and burn inſtantly, and with conſiderable noiſe, by the quick preſſure of the ſtrokes of a hammer, produce a much ſtronger exploſion when they are ſo cloſely wrapped up in paper, two or three times doubled, as to be thereby compreſſed before they are ſtruck.

9. An electric ſhock from a battery of large ſurface, charged by a ſtrong electric machine, cauſes all the forementioned mixtures to explode in the ſame manner as percuſſion, and their exploſion is alſo accompanied by a bright light.

To the above mentioned facts, the authors add, that it was already well known that gunpowder would explode by a violent blow, or very ſtrong preſſure; but they obſerve, that the ſtroke which is neceſſary for that purpoſe muſt be much ſtronger than that which ſuffices to produce an exploſion in the above-mentioned mixtures of combuſtible ſubſtances with the oxy-muriat of potaſs; and that its exploſion is by no means ſo remarkable as that which is produced by the help of this new ſalt.

DEWAN, under the Mogul government, the receiver general and civic governor of a province: in private life a ſteward.

DEWANNY, the revenue department of a province.

DIABETES MELLITUS (ſee MEDICINE, n° 318, &c. *Encycl.*), is ſo formidable a diſeaſe, though not very frequent, that it would be unpardonable in us not to mention every method of treating it ſucceſsfully which has come to our knowledge. Since our article MEDICINE was publiſhed, Dr Rollo, ſurgeon general to the royal artillery, has ſuggeſted a method of treating this diſeaſe, which in various inſtances has been crowned with ſucceſs.

The Doctor ſuppoſes, that in this complaint the vegetable matter taken into the ſtomach has not, from ſome defect in this organ, undergone a ſufficient change to form proper chyle; that in conſequence of this, much ſaccharine matter is evolved, which, when carried into the circulation, proves a general ſtimulus, producing head-aches and quickneſs of pulſe, but that it acts more remarkably on the kidneys, occaſioning a conſtant and copious ſecretion of ſweet urine. From this hypotheſis, he was naturally led to adopt a plan of cure, which has proved completely ſucceſsful. The indications he lays down are: 1. To prevent the formation of ſaccharine matter in the ſtomach; and, 2. To remove the morbidly increaſed action of this organ, and reſtore it to a healthful condition. Theſe indications are to be anſwered by a complete diet of animal food, and by the uſe of ſuch medicines as ſhall diminiſh the action of the ſtomach, and at the ſame time counteract the formation of ſaccharine matter. The remedies employed for this purpoſe have been emetics, kali ſulphuratum, lime-water, hepatized ammonia, and vegetable narcotics. But the principal dependence is to be placed on a total abſtinence from all vegetable matter, which alone can ſupply the ſaccharine principle. By a regular perſeverance in this plan, the firſt of two patients was completely cured in four weeks, although the diſeaſe had been of ſeven months continuance. The urine, which at the commencement of the treatment was ſweet, and amounted to 24 pints daily, was at laſt reduced to 1½ pint, being at the ſame time free from any ſaccharine impregnation. The ſecond patient, from his age and other circumſtances, although relieved from the diabetic affection, did not regain his wonted ſtate of health; but even in this caſe, the effects produced by the treatment, when properly attended to, were moſt decidedly in confirmation of this plan of cure.

The Doctor has received ſeveral communications in conſequence of the diſperſion of the printed notes on the firſt caſe. The moſt important are the reſult of two caſes treated in this way by Dr Cleghorn of Glaſgow, and one by Drs Currie and Gerard at Liverpool; all of which afford the ſtrongeſt corroboration of the efficacy of this mode of treatment.

DIAMOND, the moſt precious of all the gems; for the nature of which ſee CHEMISTRY, nº 33, &c. in this *Supplement*.

DIDEROT (Dionyſius) of the academy of Berlin, the ſon of a cutler, was born at Langres in 1713. The Jeſuits, with whom he went through a courſe of ſtudy, were deſirous of having him in their order; and one of his uncles, deſigning him for a canonry which he had in his gift, prevailed upon him to take the tonſure.

His father ſeems to have known him better; for perceiving that he was not inclined to be a Jeſuit, nor fit to be a canon, he ſent him to Paris to proſecute the ſtudy of the law. To the law, however, he paid very little attention, but devoted his time to ſcience and general literature; which ſo offended his father, that he ſtopped the remittance of his pecuniary allowance, and ſeemed for ſome time to have abandoned him.

The talents of young Diderot ſupplied him with a maintenance, and drew him from obſcurity. According to his friends, his capacious mind embraced phyſics, geometry, metaphyſics, ethics, and the belles lettres, from the time that he began to read with reflection; and it is certain that he aſpired at being a maſter in all theſe departments of literature. His bold and elevated imagination ſeemed to give him likewiſe a turn for poetry; but he neglected it for the ſciences. He ſettled at an early period at Paris, where the natural eloquence which animated his converſation procured him friends and patrons. What firſt drew the attention of the public to him as an author, and gave him a high reputation among a certain claſs of readers, was a ſmall volume written againſt the Chriſtian religion, and intitled *Penſées Philoſophiques*; which was reprinted afterwards under the title of *Etrennes aux Eſprits-forts*.

This book appeared in 1746, 12mo. The adepts of the new philoſophy compared it, for perſpicuity, elegance, and force of diction, to the *Penſées de Paſcal.* But the aim of the two authors was widely different; Paſcal employed his talents and his erudition, which was profound and various, to ſupport and illuſtrate the great truths of our holy religion, which Diderot attacked by all the diſingenuous arts of an unprincipled ſophiſt. The *Penſées Philoſophiques*, however, became popular. It contributed to promote the object of that conſpiracy which had been for ſome time formed againſt every thing which ennobles human nature (See JACOBINS in this *Supplement*). It was therefore applauded by Voltaire and D'Alembert, and read, of courſe, by every man and woman of taſte in Paris.

Our author was more uſefully employed in 1746, when, together with Meſſrs *Eidous* and *Touiſſant*, he publiſhed a general Dictionary of Medicine, in ſix volumes folio. This work, it muſt be confeſſed, has conſiderable merit; for though there are in it ſeveral articles ſuperficial and erroneous, there are many others of ſuch deep and accurate diſquiſition, as deſervedly recommended it to men of ſcience.

It was about this time that an intimacy was formed between Diderot and D'Alembert, and that, under the direction of Voltaire, they formed the idea of a *Dictionaire Encyclopedique*. The great objects which they had in view when they entered upon this work are now univerſally known. D'Alembert was a profound mathematician, Diderot had conſiderable knowledge in the phyſical ſciences, more eſpecially mechanical philoſophy, and Voltaire was a maſter of the belles lettres.

It is not to be ſuppoſed that ſuch men would publiſh any thing very defective in theſe departments of ſcience; but an *Encyclopædia* muſt treat of *religion*; and to every kind of religion they were all ſworn enemies. They engaged, however, a very worthy, though not very acute, clergyman, to furniſh the theological articles; and for other branches of knowledge, they were promiſed the aſſiſtance of ſeveral men of letters, and of a variety of artiſts.

Diderot took upon himſelf the deſcription of arts and trades; one of the moſt important departments of the work, and the moſt acceptable to the public. To the particulars of the ſeveral proceſſes of the workmen he ſometimes added reflections, ſpeculations, and principles, adapted to the elucidation. But beſides his own department, he furniſhed articles on almoſt every other ſubject.

By thoſe who knew not the great aim of the undertakers of this work, it has been regretted that Diderot was not leſs verboſe, leſs of the diſſertator, and leſs inclined to digreſſions. He has alſo been cenſured for employing needleſsly a ſcientific language, and for having recourſe to metaphyſical doctrines, frequently unintelligible, which occaſioned him to be called *the Lycophron of philoſophy*; for having introduced a number of definitions incapable of enlightening the ignorant, and which the philoſopher ſeems to have invented for no other purpoſe than to have it thought that he had great conceptions; while, in fact, he had not the art of expreſſing perſpicuouſly and ſimply the ideas of others. But theſe complaints ariſe from miſtaking entirely the purpoſe for which he wrote.

It has been completely proved, that one great object for which the philoſophers, as they called themſelves, undertook the compilation of the *Encyclopedie* was to ſap the foundation of all religion. This was to be attempted, not directly and avowedly; for bare-faced atheiſm would not then have been ſuffered in France.

A cloak, therefore, was to be worn, and the poiſoned dagger to be concealed under it. Whilſt the well-meaning divine was ſupporting, by the beſt arguments which he could deviſe, the religion of his country, Diderot and D'Alembert were overturning thoſe arguments under titles which properly allowed of no ſuch diſquiſitions. This neceſſarily produced digreſſions; for the greateſt genius on earth could not, when writing on the laws of motion, attack the myſteries of Chriſtianity without wandering from his ſubject; but that the object of theſe digreſſions might not paſs unnoticed by *any* claſs of readers, care was taken to refer to them from the articles where the queſtion was diſcuſſed by the divine. That when employed in this way, Diderot ſeems to write obſcurely, is indeed true; but the obſcurity is not his. His atheiſm was ſo plain, that for the moſt part D'Alembert, or ſome other leader of the gang, had to retouch his articles, and throw a miſt over them, to render their intention the leſs obvious.

Even with all this care and ſtudied obſcurity, the deſign of the *Encyclopedie* was too palpable not to be ſeen, and too wicked not to give offence. Certain wild poſitions on government and on religion occaſioned the impreſſion to be ſuſpended in 1752. At that time there were no more than two volumes of the dictionary publiſhed; and the prohibition of the ſucceeding ones was only taken off at the end of 1753. Five new volumes then ſucceſſively appeared. But in 1757 a new ſtorm aroſe, and the book was ſuppreſſed. The remainder did not appear till about ten years after; and was then for a while only privately diſtributed; ſome copies having been ſeized by government, and the printers ſhut up in the Baſtile. The merit, however, of ſome of the articles is confeſſedly great; and the firſt edition was quickly ſold off.

Thus was this great work in the preſs from 1751 to 1767; during which period, Diderot and D'Alembert were accuſtomed to frequent the coffee-houſes of Paris, and to enter with keenneſs into religious diſputes: the former attacking Chriſtianity; and the latter, under the maſk of piety, defending it; but always yielding to the arguments of his opponent. This practice was put a ſtop to by the police; and Diderot, when reproached by the lieutenant with preaching atheiſm, replied, "Cela eſt vrai, je ſuis athée, & m'en fais gloire."

Finding his impious converſations interrupted, and the publication of the *Encyclopedie* rendered tedious by the vigilance of government, he thought of propagating his notions by other vehicles. Alternately ſerious and ſportive, ſolid and frivolous, he publiſhed, at the very time he was working on the Dictionary of Sciences, ſeveral productions, which could ſcarcely have been expected from a man ſo completely employed. His *Bijoux Indiſcrets*, 2 vols 12mo, are of this number—a diſguſting work, even to thoſe young people who are unhappily too eager for following after licentious romances. Even here a certain philoſophical pedantry appears in the very paſſages where it is moſt miſplaced, and never is the author more aukward than where he intends to diſplay a graceful eaſe.

The *Fils Naturel*, and the *Pere de Famille*, two comedies in proſe, which appeared in 1757 and 1758, are not of the ſame kind with the *Bijoux Indiſcrets*. They are moral and affecting dramas, where we ſee at once a nervous ſtyle and pathetic ſentiments. The former piece is a picture of the trials of virtue, a conflict between intereſts and paſſions, wherein love and friendſhip play important parts. It has been ſaid that Diderot borrowed it from Goldoni: but if that be the caſe, the copy does honour to the original; and, with the exception of a ſmall number of ſcenes, where the author mixes his philoſophical jargon with the ſentiments of the heart, and ſome ſentences out of place, the ſtyle is affecting and natural enough. In the ſecond comedy, a tender, virtuous, and humane father appears, whoſe tranquillity is diſturbed by the parental ſolicitudes, inſpired by the lively and impetuous paſſions of his children. This philoſophical, moral, and almoſt tragical comedy, has produced conſiderable effects on ſeveral theatres of Europe. The dedication, to the princeſs of Naſſau Saarbuck, is a little moral tract of a ſingular turn, without deviating from nature. This piece, written with a true dignity of ſtyle, proves that the author poſſeſſed a great fund of moral ſentiments and philoſophical ideas. At the end of theſe two pieces, publiſhed together under the title of *Theatre de M. Diderot*, are dialogues, containing profound reflections and novel views of the dramatic art. In his plays he has endeavoured to unite the characters of Ariſtophanes and Plato; and in his reflections he ſometimes diſplays the genius of Ariſtotle.

This ſpirit of criticiſm is exhibited, but with too much licence, in two other works, which made a great noiſe. The former appeared in 1749, 12mo, intitled *Letters on the Blind for the Uſe of thoſe who See.* The free notions of the author in this work coſt him his liberty. He underwent a ſix months impriſonment at Viorcennes. Having naturally ſtrong paſſions and a haughty ſpirit, and finding himſelf on a ſudden deprived of liberty and of all intercourſe with human beings, he was threatened with the loſs of his reaſon. The danger was great; and to prevent it, they were obliged to allow him to leave his room, to take frequent walks, and to receive the viſits of a few literary men; among whom J. J. Rouſſeau, at that time his friend, went and adminiſtered conſolation to him, which he ought not to have forgotten.

The letter on the Blind was followed by another *On the Deaf and Dumb, for the Uſe of thoſe who can Hear and Speak*; 1751; 2 vols, 12mo. Under this title the author delivered reflections on metaphyſics, on poetry, on eloquence, on muſic, &c. In this eſſay there are ſome good things, among others abſurd and imperfect. Though he ſtrives to be perſpicuous, yet he is not always underſtood; and this is more his fault than that of his readers. Of what he has compoſed on abſtract ſubjects, it has been ſaid that it is a chaos on which the light ſhines only at intervals The other productions of Diderot betray the ſame defect of clearneſs and preciſion, and the ſame uncouth emphaſis, for which he has always been blamed.

The principal of them are, 1. Principles of Moral Philoſophy, 1745, 12mo; of which the Abbé de Fontaine ſpeaks well, though it met with no great ſucceſs. It was our philoſopher's fate to write a great deal, and not to leave a good book, or at leaſt a book well compoſed. 2. Hiſtory of Greece, tranſlated from the Engliſh of Stanyan. 3 vols, 12mo; an indifferent tranſlation of an indifferent book 3. Pieces on ſeveral Mathematical Subjects, 1748. 8vo. 4. Reflections on the Inter-

Interpretation of Nature, 1754, 12mo. This interpreter is very obſcure. 5. The Code of Nature, 1755, 12mo; which is certainly not the code of Chriſtianity. 6. The Sixth Senſe, 1752, 12mo. 7. Of Public Education; one of that ſwarm of publications produced by the appearance of Emelius, and the abolition of the Jeſuits. Though all the ideas of this author could not be adopted, yet ſome of them are very judicious, and would be highly uſeful in the execution. 8. Panegyric on Richardſon. Full of nerve and animation. 9. Life of Seneca. This is the laſt work which he acknowledged; and it is one of thoſe by Diderot that is peruſed with moſt pleaſure, even in rectifying the judgments he paſſes on Seneca and other celebrated men. The Abbé Barruel ſays, that he was the author of *Syſteme de la Nature*, which is uſually given to Robinet; and it is certain, that if he was not the author, he furniſhed hints, and reviſed the whole. Yet the junto of atheiſts were themſelves aſhamed of the firſt edition of that work; and after all Diderot's care to improve it, the ſubſequent editions are, notwithſtanding his boaſted knowledge of the laws of nature, contemptible in the eyes of a real mechanical philoſopher.

When a new edition of the *Encyclopedie* was reſolved on, Diderot, the editor of the former edition, thus addreſſes the bookſellers who had undertaken to republiſh it. "The imperfections (ſays he) of this work originated in a great variety of cauſes. We had not time to be very ſcrupulous in the choice of our coadjutors. Among ſome excellent perſons, there were others weak, indifferent, and altogether bad. Hence that motley appearance of the work, where we ſee the rude attempt of the ſchool-boy by the ſide of a piece from the hand of a maſter; a piece of nonſenſe next neighbour to a ſublime performance. Some working for no pay, ſoon loſt their firſt fervour; others, badly recompenſed, ſerved us accordingly. The *Encyclopedie* was a gulf into which all kinds of ſcribblers promiſcuouſly threw their contributions; their pieces ill conceived, and worſe digeſted, good, bad, contemptible, true, falſe, uncertain, and always incoherent and unequal; the reference that belonged to the very parts aſſigned to a perſon, never filled up by him. A refutation is often found where we ſhould naturally expect a proof. There was no exact correſpondence between the text and the plates. To remedy this defect, recourſe was had to long explications. But how many unintelligible machines, for want of letters to denote the plates!" To this confeſſion Diderot added particular details on various parts; ſuch as proved that there were in the *Encyclopedie* ſubjects to be not only retouched, but to be compoſed afreſh: and this was what a new company of literati and artiſts ſet themſelves to work upon in the *Encyclopedie Methodique*.

This immenſe work is not yet completed; and therefore we cannot ſpeak of it as a whole; but it is ſurely not leſs verboſe than the former edition, nor do the aims of its editors appear to be purer. That it contains much valuable information in chemiſtry, and indeed in every department of phyſical ſcience, no candid man will controvert: but its articles on abſtract philoſophy are prolix and obſcure; and it betrays the ſame impiety, the ſame eager deſire to corrupt the principles of the riſing generation, and the ſame contempt for every thing which can make mankind happy here or hereafter, with the former edition.

Notwithſtanding his numerous publications, Diderot was never rich. Soon after the publication of the laſt volumes of the *Encyclopedie*, upon which he had been employed for upwards of twenty years, his circumſtances were ſo ſtraitened, that an expedient was to be deviſed for their improvement. He had long correſponded with the late Empreſs of Ruſſia, whom he perſuaded to conſider him as the greateſt, or *one* of the greateſt economiſts of France. In the courſe of the correſpondence he had mentioned his own library as one of the moſt valuable in Europe; and when Catharine wanted to purchaſe it and make him librarian, he ſaid that his conſtitution could not ſupport the cold climate of St Peterſburgh. She offered to let him keep it during his lifetime in Paris; and the library was ſold for an immenſe price. When her ambaſſador wanted to ſee it, after a year or two's payments, and the viſitation could be no longer put off, Diderot was obliged to run in a hurry through all the bookſellers ſhops in Germany to fill his empty ſhelves with old volumes. He had the good fortune to ſave appearances; but the trick took air, becauſe he had been niggardly in his attention to the ambaſſador's ſecretary. This, however, did not hinder him from viſiting his imperial pupil, to whom he told a poor ſtory, in hopes of getting his daughter married with parade, and patroniſed by her majeſty; but it was ſeen through, and he was diſappointed.

In the year 1784 Diderot's health began viſibly to decline; and one of his domeſtics, perceiving that his death was at no great diſtance, acquainted him with his apprehenſions, and addreſſed him on the importance of preparing for another world. He heard the man with attention, thanked him kindly, acknowledged that his ſituation required ſeriouſneſs, and promiſed to weigh well what he had ſaid. Some time after this converſation he deſired that a prieſt might be brought; and the ſame domeſtic introduced to him M. de Farſac, Curé de St Sulpice. Diderot ſaw this eccleſiaſtic ſeveral times, and was preparing to make a public recantation of his errors. Condorcet and the other adepts now crowded about him, perſuaded him that he was cheated, that his caſe was not ſo dangerous as it was ſaid to be, and that he only wanted the country air to reſtore him to health. For ſome time he reſiſted their attempts to bring him back to atheiſm, but was at laſt prevailed upon to try the effect of the country air. His departure was kept ſecret, and he was concealed in the country till the 2d of July, when he died. His dead body was ſecretly brought back to Paris, and a report was ſpread and believed that he died ſuddenly on riſing from the table, without remorſe, and with his atheiſm unſhaken.

To draw a formal character of this wretch is ſurely ſuperfluous. His friends extol his frankneſs, his diſintereſtedneſs, and his integrity; but except his groſs avowal of atheiſm, which may in France be called frankneſs, this character is belied by every tranſaction of his life. He married, and had a daughter, as has been already mentioned. M. Bauzé, referred to by Abbé Barruel, coming one day into Diderot's houſe, found him explaining to this daughter a chapter of the goſpel. When he expreſſed ſome ſurpriſe at this conduct, Diderot ſaid: "J'entends ce que vous voulez dire;

mais

mais au fond, quelles meilleures leçons pourrois-je lui donner, ou trouverái-je mieux?" It was a common aſſertion of Diderot's, that between him and his dog "il n'y avoit de difference que habit." In uttering this ſentiment, he reſembled not Pope's Indian with untutored mind,

> "Who thinks, admitted to that equal ſky,
> "His faithful dog ſhall bear him company."

The Indian hopes to carry his dog with him to heaven; but Diderot hoped to die like a dog, and to be as if he had never been.

DIFFERENTIAL METHOD, is the art of working with the differences of quantities. By this method any term of a ſeries may be found from the ſeveral orders of differences being given; or *vice verſa*, any difference may be found from having the terms of the ſeries given: it likewiſe ſhews how to find the ſum of ſuch a ſeries. And it gives rules to find by interpolation any intermediate term, which is not expreſſed in the ſeries, by having its place or poſition given.

When any ſeries of quantities is propoſed, take the firſt term from the ſecond, the ſecond from the third, the third from the fourth, &c. then all theſe remainders make a new ſeries, called the *firſt order of differences*. In this new ſeries take the firſt term from the ſecond, the ſecond from the third, the third from the fourth, &c. as before; and theſe remainders make another ſeries, called the *ſecond order of differences*. In like manner, in this ſeries, take the firſt term from the ſecond, the ſecond from the third, &c.; and theſe will make a ſeries called the *third order of differences;* and after this manner you may proceed as far as you will. Thus in the following propoſition A, b, c, d, e, &c. is the ſeries; B, B^2, B^3, B^4, &c. the firſt order of differences; C, C^2, C^3, &c. the ſecond order of differences; D, D^2, &c. the third order; E, &c. the fourth order, and ſo on. But the firſt terms of theſe ſeveral orders of differences, as B, C, D, E, &c. are thoſe that are principally made uſe of in calculations by this method.

PROP. I. If there be any ſeries, A, b, c, d, e, &c. and if there be taken the firſt differences B, B^2, B^3, &c. the ſecond differences C, C^2, C^3, &c. the third differences D, D^2, D^3, &c. and ſo on.

Then if T ſtand for the firſt term of the nth differences,

$$\pm T = A - nb + n \times \frac{n-1}{2} c - n \times \frac{n-1}{2} \times \frac{n-2}{3} d + n \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4} e - \text{\&c.}$$

that is, + T, when n is even, and — T when n is odd.

The ſeveral orders of differences being taken as before directed, will ſtand thus. Then,

$$\begin{array}{ccccc} A & & & & \\ & B & & & \\ b & & C & & \\ & B^2 & & D & \\ & & C^2 & & E \\ c & & & D^2 & \\ & B^3 & C^3 & & \\ d & & & & \\ & B^4 & \text{\&c.} & & \\ e & & & & \end{array}$$

ſeries	A , b , c , d , e, &c.
1ſt diff.	$b-A$, $c-b$, $d-c$, $e-d$, &c.
2d diff.	$c-2b+A$, $d-2c+b$, $e-2d+c$, &c.
3d diff.	$d-3c+3b-A$, $e-3d+3c-b$, &c.
4th diff.	$e-4d+6c-4b+A$, &c.

That is, $B = b - A$, $C = c - 2b + A$, $D = d - 3c + 3b - A$, $E = e - 4d + 6c - 4b + A$, &c. or $-B = A - b$, $+C = A - 2b + c$, $-D = A - 3b + 3c - d$, $+E = A - 4b + 6c - 4d + e$, &c. where, putting T ſucceſſively equal to B, C, D, E, &c. and $n = 1, 2, 3, 4$, &c. the prop. will be evident.

Cor. Hence

$A = A$, the firſt term.
$B = -A + b$, the firſt difference.
$C = A - 2b + c$, the 2d difference.
$D = -A + 3b - 3c + d$, the 3d difference.
$E = A - 4b + 6c - 4d + e$, the 4th difference.
$F = -A + 5b - 10c + 10d - 5e + f$, the 5th difference,
&c.

PROP. II. If A, b, c, d, e, &c. be any ſeries, and there be taken B, C, D, E, &c. the firſt of the ſeveral orders of differences;

Then, the nth term of the ſeries will be

$$= A + \frac{n-1}{1} B + \frac{n-1}{1} \times \frac{n-2}{2} C + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n--3}{3} D + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} \times \frac{n-4}{4} E +, \text{\&c.}$$

For from the equations in the laſt Prop. viz $B = b - A$, $C = c - 2b + A$, &c. we have, by tranſpoſing, $b = A + B$, $= -A + 2b + C = -A + 2A + 2B + C$ (expunging b); that is, $c = A + 2B + C$, $d = A - 3b + 3c + D = A - 3A - 3B + 3A + 6B + 3C + D$ (expunging b and c); that is, $d = A + 3B + 3C + D$. Alſo $e = -A + 4b -- 6c + 4d + E =$ (expunging b, c, d) $-A + 4A + 4B - 6A - 12B - 6C + 4A + 12B + 12C + 4D + E$; that is, $e = A + 4B + 6C + 4D + E$, &c.

Then putting A, b, c, d, &c. for the nth term, and n ſucceſſively $= 1, 2, 3, 4$, &c. the ſeries will be evident.

Cor. 1. If d', d'', d''', &c. be the firſt of the firſt, ſecond, third order, &c. of differences; then

The nth term of the ſeries A, b, c, d, &c. will be

$$= A + \frac{n-1}{1} d' + \frac{n-1}{1} \times \frac{n-2}{2} d'' + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} d''' + \frac{n-1}{1} \times \frac{n-2}{2} \times \frac{n-3}{3} \times \frac{n-4}{4} d'''' + \text{\&c.}$$

For $B = d'$, $C = d''$, $D = \underline{d'''}$, &c. And the coefficients are the unciæ of the $n - 1$th power.

Cor. 2. Hence alſo it follows, that any term of a given ſeries may be accurately determined, if the differences of any order happen at laſt to be equal.

Cor. 3. Hence

$A = A$, the firſt term.
$b = A + B$, the 2d term.
$c = A + 2B + C$, the 3d term.
$d = A + 3B + 3C + D$, the 4th term.
$e = A + 4B + 6C + 4D + E$, the 5th term.
$f = A + 5B + 10C + 10D + 5E + F$, the 6th term.
$g = A + 6B + 15C + 20D + 15E + 6F + G$, the 7th term,
&c.

PROP. III. If a, b, c, d, e, &c. be any ſeries, and d' d'', d''', &c. the firſt of the ſeveral orders of differences; then

The ſum of n terms of the ſeries is

$$= na + n \times \frac{n-1}{2} d' + n \times \frac{n-1}{2} \times \frac{n-2}{3} d'' + n \times \frac{n-1}{2} \times \frac{n-2}{3} \times$$

$\times \frac{n-3}{4} d'' + n \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4} \times \frac{n-4}{5} d''' +$, &c.

For in the ſeries of quantities,

$o, a, a+b, a+b+c, a+b+c+d$, &c.
1ſt diff. are a, b, c, d, &c.
2d diff. $d', d'2, d3$, &c.
3d diff. $d'', d''2$, &c.
4th diff. d''', &c.

Therefore (by Cor. 1. Prop. II.) the $\overline{n+1}$th term of the ſeries, $o, a, a+b, a+b+c, a+b+c+d$, &c. or the $\overline{n}$th term of the ſeries, $a, a+b, a+b+c, a+b+c+d$, &c. is $= o + na + n \times \frac{n-1}{2} d' + n \times \frac{n-1}{2} \times \frac{n--2}{3} d'' +$ &c. But the nth term of the ſeries $a, a+b, a+b+c$, &c. is the ſum of n terms of the ſeries, a, b, c, d, &c. and therefore equal to $na + n \times \frac{n-1}{2} d + n \times \frac{n-1}{2} \times \frac{n-2}{3} d' +$ &c.

For a fuller account of this method, and its application to curves, we refer the reader to Emerſon's works, from which theſe three propoſitions are taken.

DIFFRACTION, a term firſt uſed by Grimaldi, to denote that property of the rays of light which others have called inflection; the diſcovery of which is attributed by ſome to Grimaldi, and by others to Dr Hook.

DIMINUTION, in muſic, is the abating ſomething of the full value or quantity of any note.

DIOPHANTUS, a celebrated mathematician of Alexandria, has been reputed to be the inventor of algebra; at leaſt his is the earlieſt work extant on that ſcience. It is not certain when Diophantus lived. Some have placed him before Chriſt, and ſome after, in the reigns of Nero and the Antonines; but all with equal uncertainty. It ſeems he is the ſame Diophantus who wrote the Canon Aſtronomicus, which Suidas ſays was commented on by the celebrated Hypatia, daughter of Theon of Alexandria. His reputation muſt have been very high among the ancients, ſince they ranked him with Pythagoras and Euclid in mathematical learning. Bachet, in his notes upon the 5th book De Arithmeticis, has collected, from Diophantus's epitaph in the Anthologia, the following circumſtances of his life; namely, that he was married when he was 33 years old, and had a ſon born five years after; that this ſon died when he was 42 years of age, and that his father did not ſurvive him above four years; from which it appears that Diophantus was 84 years old when he died.

DIOPTER, or DIOPTRA, the ſame with the index or alhidade of an aſtrolabe, or other ſuch inſtrument.

DIOPTRA was an inſtrument invented by Hipparchus, which ſerved for ſeveral uſes; as, to level water courſes; to take the height of towers, or places at a diſtance; to determine the places, magnitudes, and diſtances of the planets, &c.

DIRECT, in arithmetic, is when the proportion of any terms. or quantities, is in the natural or direct order in which they ſtand; being the oppoſite to inverſe, which conſiders the proportion in the inverted order of the terms. So, 3 : 4 : : 6 : 8 directly; or 3 : 4 : : 8 : 6 inverſely.

DIRECTION, in aſtronomy, the motion and other phenomena of a planet when direct.

DIRECTION, in aſtrology, is a kind of calculus, by which they pretend to find the time in which any notable accident ſhall befal the perſon whoſe horoſcope is drawn.

DISCRETE QUANTITY, is ſuch as is not continued and joined together. Such, for inſtance, is any number.

DITTON (Humphry), an eminent mathematician, was born at Saliſbury, May 29. 1675. Being an only ſon, and his father obſerving in him an extraordinary good capacity, determined to cultivate it with a good education. For this purpoſe he placed him in a reputable private academy; upon quitting of which he, at the deſire of his father, though againſt his own inclination, engaged in the profeſſion of divinity, and began to exerciſe his function at Tunbridge in the county of Kent, where he continued to preach ſome years; during which time he married a lady of that place.

But a weak conſtitution, and the death of his father, induced Mr Ditton to quit that profeſſion. And at the perſuaſion of Dr Harris and Mr Whiſton, both eminent mathematicians, he engaged in the ſtudy of mathematics; a ſcience to which he had always a ſtrong inclination. In the proſecution of this ſcience he was much encouraged by the ſucceſs and applauſe he received: being greatly eſteemed by the chief profeſſors of it, and particularly by Sir Iſaac Newton, by whoſe intereſt and recommendation he was elected maſter of the new mathematical ſchool in Chriſt's Hoſpital; where he continued till his death, which happened in 1715, in the 40th year of his age, much regretted by the philoſophical world, who expected many uſeful and ingenious diſcoveries from his aſſiduity, learning, and penetrating genius.

Mr Ditton publiſhed ſeveral mathematical and other tracts, as below. — 1. Of the Tangents of Curves, &c. Philoſ. Tranſ. vol. 23.

2. A Treatiſe on Spherical Catoptrics, publiſhed in the Philoſ. Tranſ. for 1705; from whence it was copied and reprinted in the Acta Eruditorem 1707, and alſo in the Memoirs of the Academy of Sciences at Paris.

3. General Laws of Nature and Motion, 8vo, 1705. Wolfius mentions this work, and ſays that it illuſtrates and renders eaſy the writings of Galileo, Huygens, and the Principia of Newton. It is alſo noticed by La Roche, in the Memoires de Literature, vol. viii. p. 46.

4. An Inſtitution of Fluxions, containing the firſt Principles, Operations, and Applications, of that admirable Method, as invented by Sir Iſaac Newton, 8vo, 1706. This work, with additions and alterations, was again publiſhed by Mr John Clarke, in the year 1728.

5. In 1709 he publiſhed the Synopſi Algebraica of John Alexander, with many additions and corrections.

6. His Treatiſe on Perſpective was publiſhed in 1712. In this work he explained the principles of that art mathematically; and beſides teaching the methods then generally practiſed, gave the firſt hints of the new method afterwards enlarged upon and improved by Dr Brook Taylor; and which was publiſhed in the year 1715.

7. In 1714, Mr Ditton publiſhed ſeveral pieces both theological and mathematical; particularly his Diſcourſe on the Reſurrection of Jeſus Chriſt; and The New Law of Fluids, or a Diſcourſe concerning the Aſcent of Liquids, in exact Geometrical Figures, between two nearly contiguous Surfaces. To this was annexed a tract, to demonſtrate the impoſſibility of thinking or perception being the reſult of any combination of the parts of matter and motion: a ſubject much agitated about that time. To this work alſo was added an advertiſement from him and Mr Whiſton, concerning a method for diſcovering the longitude, which it ſeems they had publiſhed about half a year before. This attempt probably coſt our author his life; for although it was approved and countenanced by Sir Iſaac Newton, before it was preſented to the Board of Longitude, and the method has been ſucceſsfully put in practice, in finding the longitude between Paris and Vienna; yet that board then determined againſt it: ſo that the diſappointment, together with ſome public ridicule (particularly in a poem written by Dean Swift), affected his health ſo that he died the enſuing year, 1715.

In an account of Mr Ditton, prefixed to the German tranſlation of his Diſcourſe on the Reſurrection, it is ſaid that he had publiſhed, in his own name only, another method for finding the longitude; but which Mr Whiſton denied. However, Raphael Levi, a learned Jew, who had ſtudied under Leibnitz, informed the German editor, that he well knew that Ditton and Leibnitz had correſponded upon the ſubject; and that Ditton had ſent to Leibnitz a delineation of a machine he had invented for that purpoſe; which was a piece of mechaniſm conſtructed with many wheels like a clock, and which Leibnitz highly approved of for land uſe; but doubted whether it would anſwer on ſhip-board, on account of the motion of the ſhip.

DIVING-BELL has been already deſcribed in the *Encyclopædia*; but in that work was given no account of its antiquity or its invention. In the works of Ariſtotle we read of a kind of kettle uſed by divers to enable them to remain for ſome time under water; but the manner in which thoſe kettles were employed is not clearly deſcribed. "The oldeſt information (ſays Profeſſor Beckmann) which we have of the uſe of the diving bell in Europe, is that of John Taiſnier, who was born at Hainault in 1509, had a place at court under Charles V. whom he attended on his voyage to Africa. He relates in what manner he ſaw at Toledo, in the preſence of the emperor and ſeveral thouſand ſpectators, two Greeks let themſelves down under water, in a large inverted kettle, with a burning light, and riſe up again without being wet. It appears that this art was then new to the emperor and the Spaniards, and that the Greeks were cauſed to make the experiment in order to prove the poſſibility of it."

When the Engliſh, in 1588, diſperſed the Spaniſh fleet, called the Invincible Armada, part of the ſhips went to the bottom, near the Iſle of Mull, on the weſtern coaſt of Scotland; and ſome of theſe, according to the account of the Spaniſh priſoners, contained great riches. This information excited, from time to time, the avarice of ſpeculators, and gave riſe to ſeveral attempts to procure part of the loſt treaſure. In the year 1665, a perſon was ſo fortunate as to bring up ſome cannon, which, however, were not ſufficient to defray the expences. Of theſe attempts, and the kind of diving bell uſed in them, the reader will find an account in a work printed at Rotterdam in 1669, and entitled *G. Sinclari Ars nova et magna gravitatis et levitatis*. In the year 1680, William Phipps, a native of America, formed a project for ſearching and unloading a rich Spaniſh ſhip ſunk on the coaſt of Hiſpaniola; and repreſented his plan in ſuch a plauſible manner, that King Charles II. gave him a ſhip, and furniſhed him with every thing neceſſary for the undertaking. He ſet ſail in the year 1683; but being unſucceſsful, returned again in great poverty, though with a firm conviction of the poſſibility of his ſcheme. By a ſubſcription promoted chiefly by the Duke of Albemarle, the ſon of the celebrated Monk, Phipps was enabled, in 1687, to try his fortune once more, having previouſly engaged to divide the profit according to the twenty ſhares of which the ſubſcription conſiſted. At firſt all his labour proved fruitleſs; but at laſt, when his patience was almoſt entirely exhauſted, he was ſo lucky as to bring up, from the depth of ſix or ſeven fathoms, ſo much treaſure that he returned to England with the value of two hundred thouſand pounds ſterling. Of this ſum he himſelf got about ſixteen, others ſay twenty thouſand, and the duke ninety thouſand pounds. After he came back, ſome perſons endeavoured to perſuade the king to ſeize both the ſhip and the cargo, under a pretence that Phipps, when he ſolicited for his majeſty's permiſſion, had not given accurate information reſpecting the buſineſs. But the king anſwered, with much greatneſs of mind, that he knew Phipps to be an honeſt man, and that he and his friends ſhould ſhare the whole among them had he returned with double the value. His majeſty even conferred upon him the honour of knighthood, to ſhew how much he was ſatisfied with his conduct. We know not the conſtruction of Phipps's apparatus: but of the old figures of a diving-machine, that which approaches neareſt to the diving-bell is in a book on fortification by Lorini; who deſcribes a ſquare box bound round with iron, which is funiſhed with windows, and has a ſtool affixed to it for the diver. This ingenious contrivance appears, however, to be older than that Italian; at leaſt he does not pretend to be the inventor of it.

In the year 1617, Francis Keſsler gave a deſcription of his water-armour, intended alſo for diving, but which cannot really be uſed for that purpoſe. In the year 1671, Witſen taught, in a better manner than any of his predeceſſors, the conſtruction and uſe of the diving-bell; but he is much miſtaken when he ſays that it was invented at Amſterdam. In 1679 appeared, for the firſt time, Borelli's well known work *de motu animalium*; in which he not only deſcribed the diving-bell, but alſo propoſed another, the impracticability of which was ſhewn by James Bernoulli. When Sturm publiſhed his *Collegium curioſum* in 1678, he propoſed ſome hints for the improvement of this machine, on which remarks were made in the *Journal des ſçavans*. To him ſucceeded Dr Halley, whoſe bell is well known.

DODECATEMORY, the 12 houſes or parts of the zodiac of the primum mobile. Alſo the 12 ſigns of the zodiac are ſometimes ſo called, becauſe they contain each the 12th part of the zodiac.

DOME. See ARCH in this Supplement.

DON Martin de Mayorga, the name given by the Spaniards to a cluſter of iſlands in the South Sea, diſcovered on the 27th of February 1781 by Don F. A. Maurelle, a celebrated pilot of that nation.

Thoſe iſlands are deſcribed by him as abounding with tropical fruits and roots, as highly cultivated, and as inhabited by a people conſiderably poliſhed. The fertility of the land, ſays he, is ſuch, that its cultivation cannot fail to promiſe a favourable harveſt. Every where are ſeen an endleſs number of cocoa-nut trees, beautiful banana trees ranged in lines with the greateſt order, and numerous plantations of potatoes, of which he deſcribes ſome as fifteen feet in length, and of the thickneſs of a man's thigh. He admired the order with which every thing was diſpoſed. No weeds were ſuffered to grow between the plants; and their roads were kept in repair with a diligence deſerving imitation by the moſt civilized nations.

Their government appears from his account to be deſpotic. The ſovereign, who is called the *Tubou*, is held in the higheſt veneration by his ſubjects, whoſe lives and properties are at his diſpoſal. Under him there is an order of nobles called *Equis*, who, though they ſhrink into inſignificance in the preſence of the *Tubou*, have great authority over the people. Theſe people are ſaid by Maurelle to be of great muſcular ſtrength and large ſtature, the ordinary height of the men being ſix feet or ſix feet four inches, while many of them are much taller. It would appear, too, that they delight in gymnaſtic exerciſes; for when the *Tubou*, by whom he had been treated with great hoſpitality, wiſhed to amuſe him and his ſhip's company, he exhibited to them ſeats of wreſtling and boxing, and that as well by the women as by the men.

Though theſe people put the greateſt confidence in the Spaniards, and frequently ſtaid whole nights on board the frigate, they had yet the common inclination of ſavages to ſteal. "Every time they came on board (ſays our author), clothes, iron-work, whatever fell in their way, they conſidered as lawful prize. They drew out through the port-holes, or the windows, whatever was within their reach. They thieved even to the very chain of the rudder. I made my complaints to the king; he gave me permiſſion to kill whomſoever I ſhould detect in the act; and I was aſſured he had himſelf diſcovered and puniſhed with death the authors of the complained of theft. Our vigilance was neceſſarily called into action; we ſurpriſed the iſlanders ſtriving to tear away the new rudder chains; we fired a piſtol at them, one of them fell dead on the occaſion, and this was an awful leſſon for thoſe who were either on board or alongſide of the frigate; they ſaid to themſelves, or to one another, *chito* (robber) *fama* (death)."

They make of the bark of trees a kind of cloth not unlike that which has been brought from other iſlands in the South Sea; and our author deſcribes the women as being peculiarly neat both in their dreſs and in their perſons. They had their mantles or looſe garments adjuſted in neat plaits and folds, and becomingly attached by a knot over the left ſhoulder. They wore garlands or wreaths on the head, and chaplets of large glaſs beads round their necks; the hair was pleaſingly diſpoſed in treſſes, and the whole perſon perfumed with an oil of an agreeable odour; above all, the ſkin was ſo exquiſitely clean, that they would not have ſuffered the ſmalleſt particle of duſt to remain upon it a moment.

In this archipelago Don Maurelle found a ſafe harbour, to which he gave the name of El Refugio; and which he places in South Lat. 18°. 36′. and W. Lon. 177°. 47′. 45″. of Greenwich.

DRACŒNA Draco (ſee Dracoena, *Encycl.*), is a native of Madeira, though it is there becoming ſcarce. The following account of it is by La Martiniere, naturaliſt in the laſt voyage of diſcovery by La Perouſe. "The idea of the dracœna draco (ſays he) given by the ſhabby ſpecimens cultivated in our hot-houſes, is far inferior to that we entertain of it when we have an opportunity of ſeeing it in its native ſoil. I met with three in particular, of which the trunk was ſix or ſeven feet high, and four and a half, or five in diameter. The principal branches, 12 or 15 in number, and as thick as a man's body, ſhoot out a little obliquely, dividing themſelves generally into two, and now and then into three, to the height of 40 or 50 feet, including the ſeven feet of the trunk. The leaves are all at the extremity of the branches, where they are placed in alternate order, and form a cluſter. This tree preſents the moſt perfect regularity to the eye, and tempts the ſpectator to think that the moſt ſkilful gardener makes it the object of his daily care."

DRAINS. Under this word in the Encyclopædia we publiſhed Mr Bayley of Hope's method of draining land; and by a letter from the author, we have ſince learned, that experience, the beſt guide, has fully proved the uſefulneſs and durability of his *drains*. With a candour, however, worthy of a man who writes not for fame, but for the good of the public, he informs us of a miſtake into which he had led us; and requeſts us to correct it in this Supplement.

"I wiſh (ſays he) that, in the Supplement to the Encyclopædia, due notice may be taken of a very great error into which I was led in my ſcheme of making the *main drains*. I conjectured, that where the bottom of the trench was of a hard or ſolid body, as *clay* or *marl*, it might not be neceſſary to lay it with bricks or ſtones; but in this I was quite wrong. By the runs of water, the alternate changes from wet to dry, and the acceſs of air, theſe hard bottoms have been rendered friable; they have crumbled away, and let in all my drains which were not ſupported by a bottom laid with brick or ſtone." For this information we requeſt the author to accept of our thanks, and we are perſuaded we may add the thanks of the public.

As the draining of land is a matter of great importance in agriculture, and as the ſubject has been again brought before us, we imagine that our agricultural readers will be glad to find here the ſubſtance of a paper on this ſubject, for which the author received the ſilver medal of the *Society* inſtituted for the encouragement of Arts, Manufactures, and Commerce. That author is Mr John Wedge of Bickenhill, near Coventry, who is not only a great farmer himſelf, but had likewiſe been employed by the Earl of Alesford in the management of ſeveral eſtates. Encouraged by his lordſhip's liberality, Mr Wedge informs the ſociety, that he had been employed for ſome years in draining large portions of land, of which part was in the Earl's occupation, and part in his own, as tenant to his lordſhip.

The

The principles upon which he proceeded, as well as his mode of procedure, he ſtates in the following terms:

In every country there are large portions of land that, in wet ſeaſons, have always what may be called a *dry ſurface*, and other portions of land that have always a *moiſt* or *wet ſurface*; the former of theſe admitting all the water which falls upon them to ſink freely through their pores to various depths, till falling on clay, or ſome other unctuous earth, whoſe pores will not permit it to paſs through, it is there held up to a height proportioned to the quantity of water which comes upon it, and the facility with which that water is diſcharged. Thus, held up to various heights, it ſerves as a fountain to diſtribute its water (either by veins of ſand, pebbles, or rock), according to the formation of the different under ſtrata on the neighbouring lands, and there forms bogs and other varieties of wet ſurface, on a baſis that will be always found to conſiſt of marl, or clay, or ſome mixture thereof. The effect of water thus diſtributed may be divided into two claſſes. The firſt claſs, where the water is thrown out by a body of marl or clay, &c. upon the ſurface of deſcending ground, and in the valley (there held up by clay alſo) forms bogs or ſwamps. The ſecond claſs, where the water is held up by marl or clay, as before, having above that marl or clay a ſtratum of ſand, or pebbles, through which the water paſſes; and above thoſe ſands or pebbles another ſtratum of marl or clay, through the weakeſt parts of which the water, by a continual preſſure from its fountain, forces a paſſage upwards; and thus, through the weakeſt parts of the marl or clay, furniſhes a continual ſupply of water on the ſurface, for the formation or growth of bogs, &c. in proportion as this water is more or leſs abundantly ſupplied by its fountain or head, namely, the higher lands, into which rain-water freely paſſes, as before deſcribed. There are alſo different ſoils, under different circumſtances, which may form a third claſs of land for draining; ſuch as, ſtrong deep ſoils, or open light ſoils, having near the ſurface a body of marl or clay. In either of theſe caſes, the water which falls on the ſurface muſt, for reaſons which are ſelf-evident, keep ſuch lands, in rainy ſeaſons, conſtantly wet and cold; and it ſhould be obſerved, that a mixture of all the three before-deſcribed claſſes of wet land ſometimes occur in one field, by ſudden alterations of the under ſtrata, and thereby perplex the operator, by requiring all the different modes of draining in the ſame field.

If it be admitted that bogs are thus formed and fed, their cure may be effected with certainty. The firſt claſs, by cutting through the ſtratum (be it ſand, pebbles, or rock,) that conveys the water to the bog, and carrying off that water by a cloſe drain to ſome proper place, where the level admits of its diſcharge. The ſecond claſs, by ſinking a drain to any convenient depth in the upper clay; and then digging or boring with a large auger, at a ſmall diſtance on one ſide of this drain, through the remaining part, be it (the upper clay) ever ſo deep, into the under ſtratum of ſand, pebbles, or rock, through which the water paſſes; which will then ruſh up into the drain ſo made, with a velocity proportioned to the height of the land or fountain whence it is ſupplied. As this drain advances through the land, holes muſt be dug or bored, as before, every ſeven yards, or at ſuch diſtance as the ſtrength of the ſprings may require; and the whole of the water thus brought up by tapping the ſprings, is carried off by the drain made in the upper clay, which muſt be a cloſe one, to its proper level, and there diſcharged.

By both theſe methods of draining, large tracts of land, under favourable circumſtances, may be cured with one drain. The beſt place for fixing theſe drains is where the ſtratum that conveys the water comes neareſt to the ſurface; and the beſt method of aſcertaining that, is to bore or dig in different parts through the different under ſtrata.

The third claſs may be eaſily cured by cloſe drains, at ſuch diſtances and depths as will beſt carry off the ſurface-water. It may not be improper to obſerve, that where the different ſtrata or meaſures crop out, that is, become gradually more and more ſhallow in ſome certain direction (as is often the caſe, till, one after the other, they all preſent themſelves in ſucceſſion on the ſurface of the earth), draining may often be much more eaſily and better effected by croſſing with the drain the different ſtrata or meaſures where the levels and other circumſtances will admit.

Some of the land drained was part of a common, in the pariſh of Church Bickenhill, in the county of Warwick; part of it was covered with moſs and ling, had a peaty ſurface about ſix inches deep, and produced little or no graſs: in all wet ſeaſons it was filled quite to the ſurface, and often overflowed, with water. Some of the land was much more unſound, deeper of peat, and covered with moſs, in moſt parts nine inches long; another part was an abſolute bog in all ſeaſons.

Having dug or bored with a large auger into ſeveral parts of the land, Mr Wedge found peat, gravel, and ſand mixed, and a quick-ſand almoſt uniformly. The quick-ſand in every part, after getting an inch or two into it, ſeemed almoſt as fluid as water. Judging from this, that no materials for a drain could be laid in the quick-ſand, but what it would immediately bury, he dug a trench almoſt to the quick-ſand, leaving gravel, &c. of ſufficient ſtrength to bear up the materials for a hollow drain; theſe materials were two ſides and a coverer of ſtone, with a peat-turf on the top to keep out the ſoil. At every ſeven yards forward, by the ſide of this drain, he dug a hole in the quick-ſand as deep as it would permit. From theſe holes the water roſe freely into the hollow drain, and was by it diſcharged at a proper level. It may be proper to remark, that the ſtone made uſe of for this drain, and all others here mentioned, was a red ſand and rag-ſtone, which eaſily ſplit into proper ſizes for the purpoſe, and is very durable; it coſt about ſixpence per ton getting, excluſive of carriage. The drain thus formed ran on the whole rather freely, and made the land dry for a few yards on each ſide thereof, but was far from having the effect he improperly expected; for it evidently appears that the drain could only take a very ſmall portion of the water from ſo large a quick-ſand, which it did not penetrate more than two inches; and that it could drain only to its own depth, or, at moſt, to that depth in the fountain which ſupplied the quick-ſand. His purpoſe was then defeated; and his motive for mentioning this error cannot, he hopes, be miſtaken.

He now did what he ſays he ought to have done before, that is, examined the different ſtrata to a greater depth, particularly on the bog, and at the upper edges thereof, and found the bog to be what has been deſcribed under the firſt claſs. He therefore determined to attempt the cure in the manner before preſcribed for that claſs, namely, to cut through the whole of the ſtratum (in this inſtance, of quick-ſand), through which he found the water paſs. This he effected as follows: The ſummer being dry, and favourable for the purpoſe, and having previouſly made his main open drain, he began his main cloſe drain the firſt week in June 1791, three feet wide, on the declivity near the edge of the great bog. In the firſt operation he dug through the peat, the hard ſand, and gravel, and one ſpade's graft (about nine inches deep, and ſeven inches wide) into the quick-ſand the whole length of this drain, which was 73 perches, of eight yards to the perch, in length. The drain thus dug ran copiouſly, not leſs than 60 gallons per minute. In this ſtate he left it about nine days: the effect of it was rapid, both above the drain and on the bog below. Upon examination, he now found about three inches on the top of the ſpade's graft, which had been made into the quick-ſand perfectly dry. He then dug out theſe three inches of dry ſand, to nearly the whole width of the drain, three feet; and at the ſame time dug out, as before, another ſpade's graft from the top of the quick-ſand, as near the middle of the drain as poſſible. This was left to run a few days, as before, and had the ſame effect, namely, three or four inches more of the top of the quick-ſand became dry and hard. The ſame operation was repeated again and again with the ſame effect, till the purpoſe of getting through this quick-ſand was completed, ſo far at leaſt as the level of the main open drain would permit. The ſtream of water continued increaſing during the whole operation; the bog below the drain was quite dry, and the land above perfectly ſo. The drain which was firſt made, and continued running for ſome time during the progreſs of the main cloſe drain, became gradually dry; and has not, ſince that drain was finiſhed, diſcharged one ſingle drop of water. Great care was neceſſary, in making the main cloſe drain, to keep the ſtream of water in the middle of it, otherwiſe the current would have undermined the ſides, as it ſometimes had done, and cauſed them to fall in. For this reaſon it was neceſſary, when the dry ſand was taken from the top of the quick-ſand, immediately to take out a ſpade's graft from the middle thereof, in order to divert the current from the ſides.

The main cloſe drain thus made was three feet wide at top, about nine feet deep on the average, and, bevelling a little from the top, it was about one foot ten inches wide at the bottom. The ſtone and other materials were put into this drain in the following manner:

Where the drain went through the quick-ſand into the ſtratum of clay below it, as in moſt places it did, the bottom, and in ſome inſtances the ſides, wanted no particular ſecurity (A); but where it did not go quite through the quick-ſand, which the level of his main open drain in ſome places would not admit, the bottom of the drain was covered half an inch thick with ling; then peat-turfs, one foot wide and three or four inches thick, were cut in convenient lengths, and placed on their edges on each ſide of the bottom of the drain, forming two ſides of a trough of peat; then ſide ſtones about eight inches high, and a ſtone coverer, were put in upon the ling between the peat-turfs; a large peat-turf, near two feet wide and four inches thick, was then cut and firmly placed over the whole: this left in the bottom of the drain an open ſpace, of more than ſix inches ſquare, for the water to paſs. The whole was then completed by filling in the upper part of the drain.

In this way the author drained, for about L. 80, thirty acres of land, which, from being of no value whatever, became worth at leaſt 14 ſhillings per acre of yearly rent. He likewiſe hollow-drained nine acres by the method preſcribed for the third claſs of wet land. Theſe drains were made a few yards below that part of each field where the dry and wet land ſeparate, about 22 inches deep, with ſides and a coverer of ſtone, and ling on the top of it, to keep the earth from running in. The length of theſe drains was 880 yards, and the expence of labour and materials three halfpence per yard. The drains, in wet weather, diſcharge a large quantity of water; and will, he has no doubt, anſwer the intended purpoſe. Thus far relates to land in his own occupation.

Nine acres of the land in the earl of Ayleſford's occupation was almoſt an entire pulp. This bog was of the ſecond claſs, namely, water paſſing through a quick-ſand, and confined by a ſtratum of clay below, and another ſtratum of clay above it. The water thus confined, being preſſed by its fountain, and forced up thro' the weakeſt parts of the clay, had formed a bog of irregular thickneſs on the ſurface, in ſome places ſix feet deep, in others not more than two. As there is a conſiderable fall in this land from eaſt to weſt, he thought it expedient to put two drains into it; and this appears to him to have been neceſſary, from a conſideration that both theſe drains continue to run in the ſame proportions as when firſt opened. The manner in which theſe drains were executed was, by digging through the different upper ſtrata, and as deep into the clay as the main open drain would admit; then digging or boring through the remaining part of that clay into the quick-ſand, at the diſtance of about ſix yards in a progreſſive manner.

The water riſing rapidly through theſe holes into the cloſe drains, has effected a complete cure of this land, every part of which will now bear a horſe to gallop upon it. Theſe drains diſcharge 3660 gallons an hour; which is much leſs than they did at firſt, as muſt be the caſe in all bogs. This land will be worth twenty ſhillings per acre. The draining coſt twenty-five pounds; and the length of the under-ground drains is eight hundred and fourteen yards.

Mr Wedge had juſt finiſhed (January 1792) draining another piece of land, about forty-three acres. As this was intended to anſwer two purpoſes, one, to drain the land, the other, to give an additional ſupply of water to a mill-pool, and as a circumſtance aroſe in the execution of the work which frequently happens in draining land, namely, a ſudden alteration in the poſition

---

(A) He will probably find in time that he was under the ſame miſtake with Mr Bayley, and we hope that with Mr Bayley's candour he will acknowledge it.

ſition of the under ſtrata—a deſcription thereof will not, we hope, be thought tedious. This draining was begun at the level of a mill-pool, and continued, without any great difficulty, to the diſtance of about thirty-two chains, in the manner before deſcribed as a cure for the ſecond claſs of boggy land: but at or near that place the under ſtrata altered their poſition; the quick-ſand which conveyed the water now became of twice its former thickneſs; and the clay, which had hitherto been above that quick ſand, for ſome diſtance diſappeared. From the quick-ſand thus becoming ſo much deeper, he could not, with the level of the mill-pool, cut through it; nor indeed, from the wetneſs of the ſeaſon, would ſuch an operation have been proper. He therefore continued a ſhallow drain to ſome diſtance, making ſide-holes into the quick-ſand, which ran freely; but as this could not cure the whole of the bog below, he branched out another drain (which was made by the method deſcribed for curing the ſecond claſs of wet or boggy land), by ſinking a cloſe drain through the upper ſtrata into the upper clay, and then, at a ſmall diſtance on one ſide of this cloſe drain, boring a hole with an auger through the remaining part of that clay into the quick-ſand; and at every eight yards, as this cloſe drain advanced, ſtill boring other holes, in the manner before deſcribed: through many of theſe holes the water ruſhed with great rapidity. The water diſcharged by theſe drains into the mill-pool is 168 gallons per minute, or 3780 hogſheads in a day; which is after the rate of 1,379,700 hogſheads in a year.

About ſix acres of this land were always ſound; about twelve acres on the north ſide were an abſolute pulp, and the remaining twenty ſix acres very unſound. The whole is now ſound, and will, when cultivated, be worth ſixteen ſhillings per acre. This land would have been drained at a much leſs expence into the main open drain; but then the water, which was much wanted for the mill, would have been loſt. Theſe cloſe drains are in length 1452 yards, and coſt L. 100, of which about L. 30 ought to be charged to the mill.

Important as this ſubject is, we muſt not enlarge this article, or we ſhould make large extracts from Dr Anderſon's *Practical Treatiſe on Draining Bogs and Swampy Grounds*, lately publiſhed. It is proper, however, to inform the public, that the author puts in his claim for being the firſt diſcoverer of that mode of draining for which Mr Elkington has obtained from Parliament a premium of L. 1000; and the reader who ſhall turn to the article DRAINS in the Encyclopædia, will perceive that his claim is well-founded.

DROSSERA ANGLICANA, or the SUNDEW (ſee DROSSERA, *Encycl.*), is a very minute villous plant, uſually growing entangled with moſs on peat bogs; the leaves are curiouſly fringed with numerous ſtrong reddiſh hairs, terminated by ſmall pellucid globules of viſcous liquor, which occaſion, by the reflection of the ſun, that peculiar luſtre from which its name is derived. It is in theſe hairs that theſe eſſential properties of the plant reſide; for if a ſmall inſect ſhould fix itſelf on one of the leaves, theſe hairs immediately begin to cloſe, one by one, till the inſect is wholly environed by them, and then the leaf in which it is impriſoned gradually bends inwards, ſo as to reach the baſe: in this ſtate the inſect is killed by the operation of the acrimonious juice exuding from the ends of the hairs. Rothius (as quoted by Withering, in his Arrangement of Britiſh Plants,) mentions the effects of this ſingular plant, occaſioned by the irritation of an ant, which he placed on the centre of one of the leaves with a pair of pincers. The ant, in endeavouring to eſcape, was held faſt by the viſcous juice of the ſmaller hairs till the large ones, together with the edges of the leaf, cloſed in and impriſoned it. The ant died in fifteen minutes; but he obſerves, that the effects followed ſooner or later, in different experiments, according to the ſtate of the weather. Dr Whithering has publiſhed a ſimilar account of the ſenſitive properties of the ſundew, which was communicated to him by two of his botanical friends, and which he has made very entertaining and intereſting. The ſame thing is confirmed by a writer in the Monthly Magazine for Auguſt 1797; who ſays, that whenever he made experiments on the droſſera with ants and other diminutive inſects, he commonly found them periſh in a ſhorter time than fifteen minutes. His experiments were made on the droſſera rotundifolia. Rothius, however, obſerves, that the longifolia produces the ſame effects, but with greater rapidity. In concluding his account, Dr Withering ſuggeſts this enquiry, "Whether this deſtruction of inſects be not neceſſary to the welfare of the plant?" And it is ſurely worth ſome botaniſt's while to take ſome pains to anſwer the queſtion.

DRUGS (ſee *Encycl.*) are ſo commonly counterfeited, or at leaſt adulterated, that, in London, the royal college of phyſicians, it is well known, has long ago appointed a court of examiners to inveſtigate the goodneſs of drugs and medicines in the different chemiſts and apothecaries ſhops. The counterfeit, however, is made up with ſuch dexterity, that not only the merchant and drug-broker, but even the man of ſkill, is ſometimes deceived; and indeed nothing can detect this impoſition but a practical knowledge of chemiſtry. We therefore recommend it to every father of a family to ſtudy our Supplementary article CHEMISTRY with this view, if with no other; for whatever be the faults of that atricle, we have loſt much labour if it be not ſufficiently perſpicuous to enable every man, not an abſolute ſtranger to phyſical ſcience in all its branches, to detect the common impoſtures of drug-ſellers.

DUFTER, in Bengal, an office or department.

DUFTER Cana, the place where the office is kept.

DWARFING OF VEGETABLES, an art invented by the Chineſe, to which the attention of Sir George Staunton was attracted on the following occaſion:

When the embaſſy was at Chuſan (See CHUSAN in this Supplement), the gentlemen who went on ſhore were introduced to the governor in his hall of audience, where on ſeveral tables were placed, in frames filled with earth, dwarf pines, oaks, and orange trees, bearing fruit. None of them exceeded in height two feet. Some of thoſe dwarfs bore all the marks of decay from age: and upon the ſurface of the ſoil were interſperſed ſmall heaps of ſtones, which, in proportion to the adjoining dwarfs, might be termed rocks. Theſe were honey-combed and moſs-grown, as if untouched for ages, which ſerved to maintain the illuſion, and to give an antique appearance to the whole. This kind of ſtunted vegetation ſeemed to be much reliſhed by the curious in China; and ſpecimens of it were to be found in every conſiderable dwelling. To produce them formed a part of the gardener's ſkill, and was an art invented in that country. Beſide the mere merit of overcoming a difficulty, it had that of introducing vegetables into common apartments, from which their natural ſize muſt otherwiſe have excluded them.

The general method of obtaining vegetable dwarfs is ſaid to be the following: A quantity of clay or mould is applied to the upper part of the trunk of a tree, from which a dwarf is intended to be taken, and cloſe to its diviſion into branches. The mould is to be confined to the ſpot by coarſe hempen or cotton cloth, and to be carefully kept moiſt by water. In conſequence of this application, continued ſometimes above a twelvemonth, ſmall tender fibres ſhoot down like roots from the wood into the mould. The part of the trunk emitting thoſe new fibres, together with the branch riſing immediately above it, is then to be carefully ſeparated from the reſt of the tree, and planted in new earth, in which the fibres become new roots, while the former branch is now the ſtem of the vegetable thus transformed in ſome meaſure. This operation does not deſtroy or alter the productive faculty which thoſe parts enjoyed before their ſeparation from their parent root. That which, while a branch of the original tree, bore flowers and fruit, continues to produce the ſame, though no longer ſupported upon any ſtock. The terminal buds of ſuch branches of trees as are meant to become dwarfs are torn off; which circumſtance prevents the further elongation of thoſe branches, and forces other buds and branchlets from the ſides. Theſe branchlets are bent by wires to whatever form the operator wiſhes: and when the appearance of age and decay is meant to be given to a dwarf tree, it is repeatedly ſmeared with treacle or molaſſes, which attracts multitudes of ants, who, in purſuit of thoſe ſweet juices, attack the bark, and, by a gradual corroſion of it, produce the deſired effect. Theſe different proceſſes are ſometimes attempted to be kept ſecret by the gardeners, and they vary deſignedly in the mode of carrying them on; but the principle on which they are founded is ſufficiently apparent from what is related here; and the contrivance argues ingenuity and perſeverance, rather than the practice does true taſte, which conſiſts in aſſiſting Nature in its moſt favourite works—not in counteracting its operations or diſtorting its productions.

DYEING is an art into which, ſince the article in the Encyclopædia was publiſhed, improvements have been introduced of ſuch importance, that it would be unpardonable not to notice them in this Supplement. They ought to be noticed under the preſent title; but, for reaſons aſſigned at the time, we were under the neceſſity of poſtponing them, in the firſt edition, to the title *Vegetable*, *Animal*, and *Dyeing* SUBSTANCES. We might now reſtore the article DYEING to its proper place; but though we confidently announce this as an improved edition, we doubt whether we can, in juſtice to the purchaſers of the firſt edition, alter its arrangement. We therefore ſtill refer the reader to the article *Dyeing* SUBSTANCES.

DYNAMICS.

1 Definition.

THIS name marks that department of phyſico-mathematical ſcience which contains the abſtract doctrine of MOVING FORCES; that is, whatever neceſſarily reſults from the relations of our ideas of motion, and of the immediate cauſes of its production and changes.

2 Object of dynamics is change of that condition of a thing which we call its *motion*.

All *changes* of motion are conſidered by us as the indications, the characteriſtics, and the meaſures of changing cauſes. This is a phyſical law of human thought, and therefore a principle to which we may refer, and from which we muſt derive all our knowledge of thoſe cauſes. When we appeal to our own thoughts or feelings, we do not find in ourſelves any diſpoſition to refer mere exiſtence to any cauſe, although the beginning of exiſtence certainly produces this reference in an inſtant. Had we always obſerved the univerſe in motion, it does not appear that we ſhould have aſcribed it to a cauſe, till the obſervation of relative reſt, or ſomething leading to it, had enabled us to ſeparate, by abſtraction, the notion of matter from that of motion. We might then perceive, that reſt is not incompatible with matter; and we might even obſerve, by means of relative motions, that abſolute reſt might be produced by the concourſe of equal and oppoſite motions. But all this requires reflection and reaſoning; whereas we are now ſpeaking of the firſt ſuggeſtions of our minds.

3. We cannot have any notion of motion *in abſtracto*, without conſidering it as a ſtate or condition of exiſtence, which would remain, if not changed by ſome cauſe. It is from changes alone, therefore, that we infer any agency in nature; and it is in theſe that we are to find all that we know of their cauſes.

4 Mechanica relation, what.

When we look around us, we cannot but obſerve that the motions of bodies have, in moſt caſes, if not always, ſome relation to the ſituation, the diſtance, and the diſcriminating qualities of other bodies. The motions of the moon have a palpable relation to the earth; the motions of the tides have as evident a relation to the moon; the motions of a piece of iron have a palpable dependence on a magnet. The vicinity of the one ſeems to be the occaſion, at leaſt, of the motions of the other. The cauſes of theſe motions have an evident connection with or dependence on the other body. We are even diſpoſed to imagine, that they are inherent in that body, and that it poſſeſſes certain qualities which are the cauſes of thoſe modifications of motion in other bodies. Theſe ſerve to diſtinguiſh ſome bodies from others, and may therefore be called PROPERTIES; and, ſince the condition of other bodies ſo evidently depends on them, theſe properties expreſs very intereſting relations of bodies, and are chiefly attended to in the enumeration of the circumſtances which aſcertain what we call the *nature* of any thing. We do not mean to ſay that theſe inferences are always juſt; nay, we know that many of them are ill-founded: but they are real, and they ſerve abundantly for informing us what we may expect from any propoſed ſituation of things. It is enough for us to know, that when a piece of iron is ſo and ſo ſituated in relation to a magnet, it will move in a certain manner.

This mutual relation of bodies is differently conſidered, according to the intereſt that we chance to take in the phenomenon. The cauſe of the approach of the iron to a magnet is generally aſcribed to the magnet, which

which is ſaid to attract the iron, becauſe we commonly employ the magnet in order that theſe motions may take place. The ſimilar approach of a ſtone to the earth is aſcribed to the ſtone, and we ſay that it tends to the earth. In all probability, the procedure of nature is the ſame in both; for they are obſerved, in every inſtance, to be mutual between the related bodies. As iron approaches a magnet, ſo the magnet approaches the iron. The ſame thing is obſerved in the motions of electrified bodies ; alſo in the caſe of the ſtone and the earth. Therefore the cauſe of the motions may be conceived as inherent in either, or in both.

Force and *Action* are figurative terms when uſed in mechaniſm;

The qualities thus inherent in bodies, conſtituting their mechanical relations, have been called the MECHANICAL AFFECTIONS OF MATTER. But they are more commonly named POWERS or FORCES ; and the event which indicates their preſence, is conſidered as the effect and mark of their agency. The magnet is ſaid to ACT on the iron, the earth is ſaid to ACT on the ſtone, and the iron and the ſtone are ſaid to ACT on the magnet and on the earth.

All this is figurative or metaphorical language. All languages have begun with ſocial union, and have improved along with it. The firſt collections of words expreſſed the moſt familiar and the moſt intereſting notions. In the proceſs of ſocial improvement, the number of words did not increaſe in the ſame proportion with the notions that became intereſting and familiar in their turn: for it often happened that relations of certain ideas ſo much reſembled the relations of certain other ideas, that the word expreſſing one of them ſerved very well for expreſſing the other; becauſe the diſſimilar circumſtances of the two caſes prevented all chance of miſtake. Thus we are ſaid to *ſurmount* a difficulty without attaching to the word the notion of *getting over* a ſteep hill. Languages are thus filled with figurative expreſſions.

5
But the analogy is not in the force, but in the effect.

Power, Force, and Action, are words which muſt have appeared in the language of the moſt ſimple people ; becauſe the notions of perſonal ability, ſtrength, and exertion, are at once the moſt familiar and the moſt intereſting that can have a place in the human mind. Theſe terms, when uſed in their pure, primitive ſenſe, expreſs the notions of the power, force, and action of a ſentient, active, being. Such a being only is an agent. The exertion of his power or force is (excluſively) action : But the relation of cauſe and effect ſo much reſembles in its reſults the relation between this force and the work performed, that the ſame term may be very intelligibly employed for both. Perhaps the only caſe of pure unfigurative action is that of the mind on the body. But as this is always with the deſign of producing ſome change on external bodies, we think only of them; the inſtrument or tool is overlooked, and we ſay that we act on the external body. Our *real* action therefore is but the firſt movement in a long train of ſucceſſive events, and is but the remote cauſe of the intereſting event. The reſemblance to ſuch actions is very ſtrong indeed in many caſes of mechanical phenomena. A man throws a ball by the motion of his arm. A ſpring impels a ball in the ſame manner by unbending. Theſe two events reſemble each other in every circumſtance but the action of the mind on the corporeal organ—the reſt of it is a train of pure mechaniſm. In general, becauſe the ultimate reſults of the mutual influence of bodies on each other greatly reſemble the ultimate reſults of our actions on bodies, we have not invented appropriated terms, but have contented ourſelves with thoſe already employed for expreſſing our own actions, the exertions of our own powers or forces. The relation of phyſical cauſe and effect is expreſſed metaphorically in the words which belong properly to the relation of agent and action. This has been attended by the uſual conſequences of poverty of language, namely, ambiguity, and ſometimes miſtake, both in our reflections (which are generally carried on by mental diſcourſe), our reaſonings, and our concluſions. It is neceſſary to be on our guard againſt ſuch miſtakes ; for they frequently amount to the confounding of things totally different. Many philoſophers of great reputation, on no better foundation than this metaphorical language, have confounded the relations of activity and of cauſation, and even denied that there is any difference ; and they have affirmed, that there is the ſame invariable relation between the determinations of the will and the inducements that prompt them, as there is between any phyſical power and its effect. Others have maintained, that the firſt mover in the mechanical operations, and indeed through the whole train of any complicated event, is a percipient and intending principle in the ſame manner as in our actions. According to theſe philoſophers, a particle of gravitating matter perceives its relation to every other particle in the univerſe, and determines its own motion according to fixed laws, in exact conformity to its ſituation. But the language, and even the actions of all men, ſhew that they have a notion of the relation of an agent to the action, eaſily diſtinguiſhable (becauſe all diſtinguiſh it) from the relation between the phyſical cauſe and its effect. The proofs of this fact have been adduced in other parts of the Encyclopædia Britannica, as, for example, in the article PHILOSOPHY, n° 42. and in this Supplement in the article ACTION.

Theſe remarks are not made in this place for any philological purpoſe, ſuch as the mere improvement of language ; but becauſe this metaphorical language has affected the doctrines of mechanical philoſophy, and has produced a diſpute about ſome of its firſt principles; and becauſe we find that the only way to decide this diſpute is to avoid, moſt ſcrupulouſly, all metaphorical language, though at the expence of much circumlocution.

6
Directions for the ſafe employment of this analogy.

When we ſpeak of powers or forces as reſiding in a body, and the effect as produced by their exertion, the body, conſidered as poſſeſſing the power, is ſaid to ACT on the other. A magnet is ſaid to act on a piece of iron ; a billiard ball in motion is ſaid to act on one that is hit by it : but if we attempt to fix our attention on this action, as diſtinct both from the agent and the thing acted on, we find no object of contemplation—the exertion or procedure of nature in producing the effect does not come under our view. When we *ſpeak* of the action as diſtinct from the agent, we find that it is not the action, properly ſpeaking, but the act, that we ſpeak of. In like manner, the action of a mechanical power can be conceived only in the effect produced.

7
Action implies change; and mere motion is not action.

A man is not ſaid to act unleſs he produces ſome effect. Thought is the act of the thinking principle ; motion of the limb is the act of the mind on it. In mechanics, alſo, there is action only in ſo far as there is mechanical effect produced. I muſt act violently in order

order to begin motion on a ſlide: I muſt exert force, and this force exerted produces motion. I conceive the production of motion, in all caſes, as the exertion of force; but it requires no exertion to continue the motion along the ſlide; I am conſcious of none, therefore I ought to infer that no force is neceſſary for the continuation of any motion. The continuation of motion is not the production of any new effect, but the permanency of an effect already produced. We indeed conſider motion as the effect of an action; but there would be no effect if the body were not moving. Motion is not the action, but the effect of the action.

8 *Preſſion, impulſion.*

Mechanical actions have been uſually claſſed under two heads: they are either PRESSURES or IMPULSIONS. They are generally conſidered as of different kinds; the exertions of different powers. PRESSURE is ſuppoſed to differ eſſentially from IMPULSE.

Inſtead of attempting to define, or deſcribe, theſe two kinds of forces and actions, we ſhall juſt mention ſome inſtances. This will give us all the knowledge of their diſtinctions that we can acquire.

Examples of preſſion.

When a ball lies on a table, and I preſs it gently on one ſide, it moves toward the other ſide of the table. If I follow it with my finger, continuing my preſſure, it accelerates continually in its motion. In like manner, when I preſs on the handle of a common kitchen jack, the fly *begins* to move. If I continue to urge or preſs round the handle, the fly accelerates continually, and may be brought into a ſtate of very rapid motion. Theſe motions are the effects of genuine preſſure. The ball would be urged along the table in the ſame manner, and with a motion continually accelerated, by the unbending of a ſpring. Alſo, a ſpring coiled up round the axis of the handle of the jack would, by uncoiling itſelf, urge round the fly with a motion accelerating in the ſame way. The more I reflect on the preſſure of my finger on the ball, and compare it with the effect of the ſpring on it, the more clearly do I ſee the perfect ſimilarity; and I call theſe influences, exertions, or actions, by one name, PRESSURE, taken from the moſt familiar inſtance of them.

Again, the very ſame motion may be produced in the ball or fly, by pulling the ball or the machine by means of a thread, to which a weight is ſuſpended. As both are motions accelerated in the ſame manner, I call the influence or action of the thread on the ball or machine by the ſame name PRESSURE, and WEIGHT is conſidered as a preſſing power. Indeed I feel the ſame compreſſion from the real preſſure of a man on my ſhoulders that I would feel from a load laid on them. But the weight in our example is acting by the intervention of the thread. By its preſſure, it is pulling at that part of the thread to which it is faſtened; this part is pulling at the next by means of the force of coheſion; and this pulls at a third, and ſo on, till the moſt remote pulls at the ball or the machine. Thus may elaſticity, weight, coheſion, and other forces, perform the office of a genuine power; and ſince their reſult is always a motion beginning from nothing, and accelerating by perceptible degrees to any velocity, this reſemblance makes us call them by one familiar name.

But farther, I ſee that if the thread be cut, the weight will fall with an accelerated motion, which I will increaſe to any degree, if the fall be great enough. I aſcribe this alſo to a preſſing power acting on the weight. Nay, after a very little refinement, I conſider this power as the cauſe of the body's weight; which word is but a diſtinguiſhing name for this particular inſtance of preſſing power. Gravitation is therefore added to the liſt of preſſures; and, for ſimilar reaſons, the attractions and repulſions of magnets or electric bodies may be added to the liſt; for they produce actual compreſſions of bodies placed between them, and they produce motions gradually accelerated, preciſely as gravitation does. Therefore all theſe powers may be diſtinguiſhed by this deſcriptive name *preſſures*, which, in ſtrict language, belongs to one of them only.

Gravity, attractions, and repulſions, are conſidered as preſſions

Several writers, however, ſubdivide this great claſs into preſſions and ſolicitations. Gravity is a ſolicitation *ab extra*, by which a body is urged downward. In like manner, the forces of magnetiſm and electricity, and a vaſt variety of other attractions and repulſions, are called *ſolicitations*. We ſee little uſe for this diſtinction, and the term is too like an affection of mind.

9 Examples of impulſion.

IMPULSION is exhibited when a ball in motion puts another ball into motion by hitting, or (to ſpeak metaphorically) by ſtriking it. The appearances here are very different. The body that is ſtruck acquires, in the inſtant of impulſe, a ſenſible quantity of motion, and ſometimes a very rapid motion. This motion is neither accelerated nor retarded after the ſtroke, unleſs it be affected by ſome other force. It is alſo remarked, that the rapidity of the motion depends, *inter alia*, on the previous velocity of the ſtriking body. For inſtance, if a clay ball, moving with any velocity, ſtrike another equal ball which is at reſt, the ſtruck ball moves with half the velocity of the other. And it is farther remarkable, that the ſtriking body always loſes as much motion as the ſtruck body gains. This univerſal and remarkable fact ſeems to have given riſe to a confuſed or indiſtinct notion of a ſort of transference of motion from one body to another. The phraſeology in general uſe on this ſubject expreſſes this in the moſt preciſe terms. The one ball is not ſaid to cauſe or produce motion in the other, but to *communicate* motion to it; and the whole phenomenon is called the *communication of motion*. We call this an *indiſtinct* notion; for ſurely no one will ſay that he has any clear conception of it. We can form the moſt diſtinct notion of the communication of heat, or of the cauſe of heat; of the communication of ſaltneſs, ſweetneſs, and a thouſand other *things*; but we cannot conceive how part of that identical motion which was formerly in A, is now infuſed into B, being given up by A. It is in our attempt to form this notion that we find that motion is not a *thing*, not a ſubſtance which can exiſt independently, and is ſuſceptible of actual transference. It appears in this caſe to be a ſtate, or condition, or mode of exiſtence, of which bodies are ſuſceptible, which is producible, or (to ſpeak without metaphor) cauſable, in bodies, and which is the effect and *characteriſtic* of *certain* natural qualities, properties, or powers. We are anxious to have our readers impreſſed with clear and preciſe notions on this ſubject, being confident that ſuch, and only ſuch, will carry them through ſome intricate paths of mechanical and philoſophical reſearch.

Communication of motion, not a good expreſſion.

10 *Inherent force* is the diſtinctive character of impulſion,

The remarkable circumſtance in this phenomenon is, that a rapid motion, which requires for the effecting it the action of a preſſing power, continued for a ſenſible, and frequently a long time, ſeems to be effected in an inſtant by impulſion. This has tended much to ſupport the notion of the actual transference of ſomething formerly

formerly

formerly poſſeſſed excluſively by the ſtriking body, inhering in it, but ſeparable, and now transfuſed, into the body ſtriken. And now room is found for the employment of metaphor, both in thought and language. The *ſtriking* body affects the body which it thus impels: It therefore poſſeſſes the *power* of impulſion, that is, of *communicating* motion. It poſſeſſes it only while it is in motion. This *power*, therefore, is the efficient diſtinguiſhing cauſe of its motion, and its only office muſt be the continuation of this motion. It is therefore called the INHERENT FORCE, the force inherent in a moving body, VIS INSITA *corpori moto*. This force is transfuſed into the body impelled; and *therefore* the transference is inſtantaneous, and the impelled body continues its motion till it is changed by ſome other action. All this is at firſt ſight very plauſible; but a ſcrupulous attention to thoſe feelings which have given riſe to this metaphorical conception, ſhould have produced very different notions. I am conſcious of exertion in order to begin motion on a ſlide; but if the ice be very ſmooth, I am conſcious of no exertion in order to ſlide along. My power is felt only while I am conſcious of exerting it: Therefore I have no primitive feeling or notion of power while I am ſliding along. I am certain that no exertion of power is neceſſary here. Nay, I find that I cannot think of my moving forward without effort otherwiſe than as a certain mode of my exiſtence. Yet we imagine that the partiſans of this opinion did really deduce it in ſome ſhape from their feelings. We muſt continue the *exertion* of walking in order to walk on; our power of walking muſt be continually exerted, otherwiſe we ſhall ſtop. But this is a very imperfect, incomplete, and careleſs obſervation. Walking is much more than mere continuance in progreſſive motion. It is a continually repeated lifting our body up a ſmall height, and allowing it to come down again. This renewed aſcent requires repeated exertion.

11
nd ſaid to
e infinite-
y greater
han preſ-
on.

We have other obſervations of importance yet to make on this force of moving bodies, but this is not the moſt proper occaſion. Mean while we muſt remark, that the inſtantaneous production of rapid motion by impulſe has induced the firſt mechanicians of Europe to maintain, that the power or force of impulſe is unſuſceptible of any compariſon with a preſſing power. They have aſſerted, that impulſe is infinitely great when compared with preſſure; not recollecting that they held them to be things totally diſparate, that have no proportion more than weight and ſweetneſs. But theſe gentlemen are perpetually enticed away from their creed by the ſimilarity of the ultimate reſults of preſſure and impulſe. No perſon can find any difference between the motion of two balls moving equally ſwift, in the ſame direction, one of which is deſcending by gravity and the other has derived its motion from a blow. This ſtruggle of the mind to maintain its faith, and yet accommodate its doctrines to what we ſee, has occaſioned ſome other curious forms of expreſſion. Preſſure is conſidered as an *effort* to produce motion. When a ball lies on a table, its weight, which they call a *power*, continually and repeated *endeavours* (mark the metaphorical word and thought) to move the ball downward. But theſe efforts are ineffectual. They ſay that this ineffectual power is *dead*, and call it a VIS MORTUA; but the force of impulſion is called a VIS VIVA, a living force. But this is very whimſical and very inaccurate. If the impelling ball falls perpendicularly on the other lying on the table, it will produce no motion any more than gravity will; and if the table be annihilated, gravity becomes a *vis viva*.

Arguments indiſtinct and inconcluſive.

We muſt now add, that in order to prove that impulſe is infinitely greater than preſſure, theſe mechanicians turn our attention to many familiar facts which plead ſtrongly in their favour. A carpenter will drive a nail into a board with a very moderate blow of his hammer. This will require a preſſure which ſeems many hundred times greater than the impelling effort of the carpenter. A very moderate blow will ſhiver into pieces a diamond which would carry the weight of a mountain. Seeing this prodigious ſuperiority in the impulſe, how ſhall they account for the production of motion by means of preſſure? for this motion of the hammer might have been acquired by its falling from a height; nay, it is actually acquired by means of the continued preſſure of the carpenter's arm. They conſider it as the aggregate of an infinity of ſucceeding preſſures in *every* inſtant of its continuance; ſo that the inſignificant ſmallneſs of each effort is compenſated by their inconceivable number.

No difference between preſſion and impulſion.

On the whole, we do not think that there is clear evidence that there are two kinds of mechanical force eſſentially different in their nature. It is virtually given up by thoſe who ſay that impulſe is infinitely greater than preſſure. Nor is there any conſiderable advantage to be obtained by arranging the phenomenon under thoſe two heads. We may perhaps find ſome method of explaining ſatisfactorily the remarkable difference that is really obſerved in the two modes of producing motion; namely, the gradual production of motion by acknowledged preſſure, and the inſtantaneous production of it by impulſe. Indeed, we ſhould not have taken up ſo much of our reader's attention with this ſubject, had it not been for ſome inferences that have been made from theſe premiſes, which meet us in our very entry on the conſideration of firſt principles, and that are of extenſive influence on the whole ſcience of mechanical philoſophy, and, indeed, on the whole ſtudy of nature.

12
Is impulſion the ſole cauſe of motion?

Mechanicians are greatly divided in their opinion about the nature of the ſole moving force in Nature. Thoſe whom we are now ſpeaking of, ſeem to think that all motion is produced by preſſure: For when they conſider impulſe as equivalent to the aggregate of an infinity of repeated preſſures, they undoubtedly ſuppoſe any preſſure, however inſignificant, as a moving force. But there is a party, both numerous and reſpectable, who maintain that impulſion is the ſole cauſe of motion. We ſee bodies in motion, ſay they, and we ſee them impel others; and we ſee that this production of motion is regulated by ſuch laws, that there is but one abſolute quantity of motion in the univerſe which remains unalterably the ſame. It muſt therefore be transfuſed in the acts of colliſion. We alſo ſee, with clear evidence, in ſome caſes, that motion can produce preſſure. Euler adduces ſome very whimſical and complicated caſes, in which an action, preciſely ſimilar to preſſure, may be produced by motion. Thus, two balls connected by a thread, may be ſo ſtruck that they ſhall move forward, and at the ſame time wheel round. In this caſe the connecting thread will be ſtretched between them. Now, ſay the philoſophers, ſince we ſee motion, and ſee that preſſure may be produced by motion, it is prepoſterous to imagine that it is any thing elſe than

a

a reſult of certain motions; and it is the buſineſs of a philoſopher to inquire and diſcover what motions produce the preſſures that we obſerve.

They then proceed to account for thoſe preſſing powers, or ſolicitations to motion, which we obſerve in the acceleration of falling bodies, the attractions of magnetiſm and electricity, and many other phenomena of this kind, where bodies are put in motion by the vicinity of other bodies, or (in the popular language) by the action of other bodies at a diſtance. To ſay that a magnet cannot act on a piece of remote iron, is to ſay that it can act *where* it is not; which is as abſurd as to ſay, that it can act *when* it is not. *Nihil movetur*, ſays Euler, *niſi a contiguo et moto*.

How does it produce preſſure?

The bulk of theſe philoſophers are not very anxious about the way in which theſe motions are produced, nor do they fall upon ſuch ingenious methods of producing preſſure as the one already mentioned, which was adduced by Euler. The piece of iron, ſay they, is put in motion when brought into the neighbourhood of a magnet, becauſe there is a ſtream of fluid iſſuing from one pole of the magnet, which circles round the magnet, and enters at the other pole: This ſtream impels the iron, and arranges it in certain determined poſitions, juſt as a ſtream of water would arrange the flote graſs. In the ſame manner, there is a ſtream of fluid continually moving towards the centre of the earth, which impels all bodies in lines perpendicular to the ſurface; and ſo on with regard to other like phenomena. Theſe motions are thus reduced to very ſimple caſes by impulſion.

Incompatible with the rules of philoſophiſing.

It is unneceſſary to refute this doctrine at preſent; it is enough that it is contrary to all the dictates of common ſenſe. To *ſuppoſe* an agent that we do not ſee, and for whoſe exiſtence we have not the ſmalleſt argument; with equal propriety we might ſuppoſe miniſtering ſpirits, or any thing that we pleaſe.

13
Others maintain that preſſure is the ſole moving force.

Other philoſophers are ſo diſſatisfied with this notion of the production of preſſure, that they, on the other hand, affirm that preſſure is the only moving force in nature; not according to the popular notion of preſſure, by the mutual contact of ſolid bodies, but that kind of preſſure which has been called *ſolicitation*; ſuch as the power of gravity. They affirm, that there is no ſuch thing as contact on inſtantaneous communication of motion by real colliſion. They ſay (and they prove it by very convincing facts (ſee Optics, n° 63—68. *Encycl.*), that the particles of ſolid bodies exert very ſtrong repulſions to a ſmall diſtance; and therefore, when they are brought by motion ſufficiently near to another body, they repel it, and are equally repelled by it. Thus is motion produced in the other body, and their own motion is diminiſhed. And they then ſhew, by a ſcrupulous conſideration of the ſtate of the bodies while the one is advancing and the other retiring, in what manner the two bodies attain a common velocity, ſo that the quantity of motion before colliſion remains unchanged, the one body gaining as much as the other loſes. They alſo ſhew caſes of ſuch mutual action between bodies, where it is evident that they have never come into contact; and yet the reſult has been preciſely ſimilar to thoſe caſes where the motion appeared to be changed in an inſtant. Therefore they conclude, that there is no ſuch thing as inſtantaneous *communication*, or transfuſion of motion, by contact in colliſion or impulſe. The reaſon why previous motion of the impelling body is neceſſary, is not that it may have a *vis inſita corpori moto*, a force inherent in it *by its being in motion*, but that it may continue to follow the impelled and retiring body, and exert on it a force inherent in itſelf, whether in motion or at reſt.—According to theſe philoſophers, therefore, all moving forces are of that kind which has been named *ſolicitation*; ſuch as gravity. We ſhall know it afterwards by the more familiar and deſcriptive name of Accelerating or Retarding force.

14
Action, Reſiſtance, Reaction.

The exertions of mechanical forces are differently termed, according to the reference that we make to the reſult. If, in boxing or wreſtling, I ſtrike, or endeavour to throw my antagoniſt, I am ſaid to act; but if I only parry his blows, or prevent him from throwing me, I am ſaid to resist. This diſtinction is applied to the exertions of mechanical powers. When one body A changes the motion of another B, we may conſider the change in the motion of B either as the indication and meaſure of A's power of producing motion, or as the indication and meaſure of A's reſiſtance to the being brought to reſt, or having its motion any how changed. The diſtinction is not in the thing itſelf, but only in the reference that we are diſpoſed, by other conſiderations, to make of its effect. They may be diſtinguiſhed in the following manner: If a change of motion follow when one of the powers ceaſes to be exerted, that power is conceived as having reſiſted. The whole language on this ſubject is metaphorical. Reſiſtance, effort, endeavour, &c. are words which cannot be employed in mechanical diſcuſſions without figure, becauſe they all expreſs notions which relate to ſentient beings; and the unguarded indulgence of this figurative language has ſo much affected the imagination of philoſophers, that many have almoſt animated all matter. Perhaps the word Reaction, introduced (we think) by Newton, is the beſt term for expreſſing that mutual force which is perceived in all the operations of nature that we have inveſtigated with ſucceſs. As the magnet attracts iron, and in ſo doing is ſaid to *act* on it; ſo the iron attracts the magnet, and may be ſaid to *react* on it.

15
We need not ſuppoſe action at a diſtance.
Tendency.

With reſpect to the difficulty that has been objected to the opinion of thoſe who maintain that all the mechanical phenomena are produced by the agency of attracting or repelling forces; namely, that this ſuppoſes the bodies to act on each other at a diſtance, however ſmall thoſe diſtances may be, which is thought to be abſurd, we may obſerve, that we may aſcribe the mutual approaches or receſſes to tendencies to or from each other. What we call *the attraction of the magnet* may be conſidered as a tendency of the iron to the magnet, ſomewhat ſimilar to the gravitation of a ſtone toward the earth. We ſurely (at leaſt the unlearned) can and do conceive the iron to be affected by the magnet, *without thinking* of any intermedium. The thing is not therefore inconceivable; which is all that we know about abſurdity: and we do not know any thing about the nature or eſſence of matter which renders this tendency to the magnet impoſſible. That we do not ſee intuitively any reaſon why the iron ſhould approach the magnet, muſt be granted; but this is not enough to entitle us to ſay, that ſuch a thing is impoſſible or inconſiſtent with the nature of matter. It appears, therefore, to be very haſty and unwarrantable, to ſuppoſe the impulſe of an inviſible fluid, of which we know nothing, and of the exiſtence of which we have no proof. Nay, if it be true that bodies do not come into contact, even when one ball hits another, and drives it before it, this inviſible fluid will not ſolve the difficulty; becauſe the ſame difficulty occurs in the action of any particle of the fluid on the body. We are obliged to ſay, that the production of motion without any *obſerved* contact, is a much more familiar phenomenon than the production of motion by impulſion. More motion has been produced in this way by the gravitation of a ſmall ſtream of water, running ever ſince the creation, than by all the impulſes in the world twice told. We do not mean by this to ſay, that the giving to this obſerved mutual relation between iron and a loadſtone the name tendency makes it leſs abſurd, than when we ſay that the loadſtone attracts the iron; it only makes it more conceivable: It ſuggeſts a very familiar analogy; but both are equally figurative expreſſions; at leaſt as the word tendency is uſed at preſent. In the language of ancient Rome, there was no metaphor when Virgil's hero ſaid, *Tendimus in Latium. Tendere verſus ſolem* means, in plain Latin, to *approach the ſun*. The ſafe way of conceiving the whole is to ſay, that the condition of the iron depends on the vicinity of the magnet.

16 *Attraction, Repulſion,* are figurative terms

When the exertions of a mechanical power are obſerved to be always directed toward a body, that body is ſaid to attract; but when the other body always moves off from it, it is ſaid to repel. Theſe alſo are metaphorical expreſſions. I attract a boat when I pull it toward me by a rope; this is purely ATTRACTION: and it is pure, unfigurative REPULSION, when I puſh any body from me. The ſame words are applied to the mechanical phenomena, merely becauſe they reſemble the reſults of real attraction or repulſion. We muſt be much on our guard to avoid metaphor in our conceptions, and never allow thoſe words to ſuggeſt to our mind any opinion about the *manner* in which the mechanical forces produce their effects. It is plain, that if the opinion of thoſe who maintain the exiſtence and action of the above-mentioned inviſible fluid be juſt, there is nothing like attraction or repulſion in the univerſe. We muſt always recur to the ſimple phenomenon, the motion to or from the attracting or repelling body; for this is all we ſee, and generally all that we know.

17 Forces are conceived as meaſurable quantities.

We conceive one man to have twice the ſtrength of another man, when we ſee that he can withſtand the united effort of two others. Thus animal force is conceived as a quantity, made up of, and meaſured by, its own parts. But we doubt exceedingly whether this be an accurate conception. We have not a diſtinct notion of one ſtrain added to another; though we have of their being joined or combined. We want words to expreſs the difference of theſe two notions in our own minds; but we imagine that others perceive the ſame difference. We conceive clearly the addition of two lines or of two minutes; we can conceive them apart, and perceive their boundaries, common to both, where one ends and the other begins. We cannot conceive thus of two forces combined; yet we cannot ſay, that two equal forces are *not* double of one of them. We meaſure them by the effects which they are known to produce. Yet there are not wanting many caſes where the action of two men, equally ſtrong, does not produce a double motion.

How meaſured.

In like manner, we conceive all mechanical forces as meaſurable by their effects; and thus they are made the ſubjects of mathematical diſcuſſion. We talk of the proportions of gravity, magnetiſm, electricity, &c.; nay, we talk of the proportion of gravity to magnetiſm:—Yet theſe, conſidered in themſelves, are diſparate, and do not admit of any proportion; but they produce effects, ſome of which are meaſurable, and whoſe aſſumed meaſures are ſuſceptible of compariſon, being quantities of the ſame kind. Thus, one of the effects of gravity is the acceleration of motion in a falling body: magnetiſm will alſo accelerate the motion of a piece of iron; theſe two accelerations are comparable. But we cannot compare magnetiſm with heat; becauſe we do not know any meaſurable effects of magnetiſm that are of the ſame kind with any effects of heat.

By their effects.

When we ſay, that the gravitation of the moon is the 3600th part of the gravitation at the ſea-ſhore, we mean that the fall of a ſtone in a ſecond is 3600 times greater than the fall of the moon in the ſame time. But we alſo mean (and this expreſſes the proportion of the *tendency* of gravitation more purely), that if a ſtone, when hung on a ſpring ſteelyard, draw out the rod of the ſteelyard to the mark 3600, the ſame ſtone, taken up to the diſtance of the moon, will draw it out no further than the mark 1. We alſo mean, that if the ſtone at the ſea-ſhore draw out the rod to any mark, it will require 3600 ſuch ſtones to draw it out to that mark, when the trial is made at the diſtance of the moon. It is not, therefore, in conſequence of any immediate perception of the proportion of the gravitation at the moon to that at the ſurface of the earth that we make ſuch an aſſertion; but theſe motions, which we conſider as its effects in theſe ſituations, being magnitudes of the ſame kind, are ſuſceptible of compariſon, and have a proportion which can be aſcertained by obſervation. It is theſe proportions that we contemplate; although we ſpeak of the proportions of the unſeen cauſes, the forces, or endeavours to deſcend. It will be of material ſervice to the reader to peruſe the judicious and acute diſſertation on *quantity* in the 45th volume of the Philoſophical Tranſactions; or he may ſtudy the article QUANTITY in the *Encyclopædia*, where, we truſt, he will ſee clearly how force, velocity, denſity, and many other magnitudes of very frequent occurrence in mechanical philoſophy, may be made the ſubjects of mathematical diſcuſſion, by means of ſome of thoſe proper quantities, meaſurable by their own parts, which are to be aſſumed as their meaſures. Preſſures are meaſurable only by preſſures. When we conſider them as moving powers, we ſhould be able to meaſure them by *any* moving powers, otherwiſe we cannot compare them; therefore it is not as preſſures that we then meaſure them. This obſervation is momentous.

One circumſtance muſt be carefully attended to. That thoſe aſſumed meaſures may be accurate, they muſt be invariably connected with the magnitudes which they are employed to meaſure, and ſo connected, that the degrees of the one muſt change in the ſame manner with the degrees of the other. This is evident, and is granted by all. But we muſt alſo *know* this of the meaſure we employ; we muſt ſee this conſtant and preciſe relation. How can we know this? We do not perceive force as a ſeparate exiſtence, ſo as to ſee its proportions, and to ſee that theſe are the ſame with the proportions of the meaſures, in the ſame manner that Euclid ſees the proportions of triangles and thoſe of their

their baſes, and that theſe proportions are the ſame, when the triangles are of equal altitudes. How do we diſcover that to every magnitude which we call *force* is invariably attached a correſponding magnitude of acceleration or deflection?—Clearly. In fact, the very exiſtence of the force is an inference that we make from the obſerved acceleration; and the degree of the force is, in like manner, an inference from the obſerved magnitude of the acceleration. Our meaſures are therefore neceſſarily connected with the magnitudes which they meaſure, and their proportions are the ſame; becauſe the one is always an inference from the other, both in ſpecies and in degree.

18 Dynamics is a demonſtrative ſcience.

It is now evident, that theſe diſquiſitions are ſuſceptible of mathematical accuracy. Having ſelected our meaſures, and obſerved certain mathematical relations of thoſe meaſures, every inference that we can draw from the mathematical relations of the proportions of thoſe repreſentations is true of the proportions of the motions; and therefore of the proportions of the forces. And thus dynamics becomes a demonſtrative ſcience, one of the *diſciplinæ accuratæ*.

19. But moving forces are conſidered as differing alſo in kind; that is, in direction. We aſſign to the force the direction of the obſerved change of motion; which is not only the indication, but alſo the characteriſtic, of the changing force. We call it an *accelerating*, *retarding*, *deflecting*, *force*, according as we obſerve the motion to be accelerated, retarded, or deflected.

Theſe denominations ſhew us inconteſtably that we have no knowledge of the forces different from our knowledge of the effects. The denominations are all either deſcriptive of the effects, as when we call them accelerating, penetrating, protruſive, attractive, or repulſive forces; or they are names of reference to the ſubſtances in which the accelerating, protruſive, &c. forces, are ſuppoſed to be inherent, as when we call them *magnetiſm*, *electricity*, *corpuſcular*, &c.

20 Forces are diſcovered by their oppoſition to other forces.

When I ſtruggle with another, and feel, that in order to prevent being thrown, I muſt exert force, I learn that my antagoniſt is exerting force. This notion is transferred to matter; and when a moving power which is *known* to operate, produces no motion, we conceive it to be oppoſed by another equal force; the exiſtence, agency, and intenſity of which is detected and meaſured by theſe means. The quieſcent ſtate of the body is conſidered as a change on the ſtate of things that would have been exhibited in conſequence of the known action of one power, had this other power not acted; and this change is conſidered as the indication, characteriſtic, and meaſure of another power, detected in this way. Thus forces are recogniſed not only by the changes of motion which they produce, but alſo by the changes of motion which they prevent. The coheſion of matter in a ſtring is inferred not only by its giving motion to a ball which I pull toward me by its intervention, but alſo by its ſuſpending that ball, and hindering it from falling. I know that gravity is acting on the ball, which, however, does not fall. The ſolidity of a board is equally inferred from its ſtopping the ball which ſtrikes it, and from the motion of the ball which it drives before it. In this way we learn that the particles of tangible matter cohere by means of moving forces, and that they reſiſt compreſſion with force; and in making this inference, we find that this corpuſcular force exerted between the particles is mutual, oppoſite, and equal: for we muſt apply force equally to *a* or to *b*, in order to produce a ſeparation or a compreſſion. We learn their equality, by obſerving that no motion enſues while theſe mutual forces are known to act on the particles; that is, each is oppoſed by another force, which is neither inferior nor ſuperior to it.

First Law of Motion.

Of the Laws of Motion.

Such, then, being our notions of mechanical forces, the cauſes of the ſenſible changes of motion, there will reſult certain conſequences from them, which may be called axioms or laws of motion. Some of theſe may be intuitive, offering themſelves to the mind as ſoon as the notions which they involve are preſented to it. Others may be as neceſſary reſults from the relations of theſe notions, but may not readily offer themſelves without the mediation of axioms of the firſt claſs. We ſhall ſelect thoſe which are intuitive, and may be taken for the firſt principles of all diſcuſſions in mechanical philoſophy.

First Law of Motion.

Every body continues in a ſtate of reſt, or of uniform rectilineal motion, unleſs affected by ſome mechanical force.

21. This is a propoſition, on the truth of which the whole ſcience of mechanical philoſophy ultimately depends. It is therefore to be eſtabliſhed on the firmeſt foundation; and a ſolicitude on this head is the more juſtifiable, becauſe the opinions of philoſophers have been, and ſtill are, extremely different, both with reſpect to the truth of this law, and with reſpect to the foundation on which it is built. Theſe opinions are, in general, very obſcure and unſatisfactory; and, as is natural, they influence the diſcuſſions of thoſe by whom they are held through the whole ſcience. Although of contradictory opinions one only can be juſt, and it may appear ſufficient that this one be eſtabliſhed and uniformly applied; yet a ſhort expoſition, at leaſt, of the reſt is neceſſary, that the greateſt part of the writings of the philoſophers may be intelligible, and that we may avail ourſelves of much valuable information contained in them, by being able to perceive the truth in the midſt of their imperfect or erroneous conceptions of it.

22 Does continued motion indicate continued action?

It is not only the popular opinion that reſt is the natural ſtate of body, and that motion is ſomething foreign to it, but it has been ſeriouſly maintained by the greateſt part of thoſe who are eſteemed philoſophers. They readily grant that matter will continue at reſt, unleſs ſome moving force act upon it. Nothing ſeems neceſſary for matter's remaining where it is, but its continuing to exiſt. But it is far otherwiſe, ſay they, with reſpect to matter in motion. Here the body is continually changing its relations to other things; therefore the continual agency of a changing cauſe is neceſſary (by the fundamental principle of all philoſophical diſcuſſion), for there is here the continual production of an effect. They ſay that this metaphyſical argument receives complete confirmation (if confirmation of an intuitive truth be neceſſary) from the moſt familiar obſervation. We ſee that all motions, however violent, terminate in reſt, and that the continual exertion of ſome force is neceſſary for their continuance.

23 Whimſical notion of elemental minds.

Theſe philoſophers therefore aſſert, that the continual action of the moving cauſe is *eſſentially* neceſſary

for

for the continuance of the motion: but they differ among themſelves in their notions and opinions about this cauſe. Some maintain, that all the motions in the univerſe are produced and continued by the immediate agency of Deity; others affirm, that in every particle of matter there is inherent a ſort of mind, the φυσις and ὑπερψυχη of Ariſtole, which they call an ELEMENTAL MIND, which is the cauſe of *all* its motions and changes. An overweaning reverence for Greek learning has had a great influence in reviving this doctrine of Ariſtotle. The Greek and Roman languages are affirmed to be more accurate expreſſions of human thought than the modern languages are. In thoſe ancient languages, the verbs which expreſs motion are employed both in the active and paſſive voice; whereas we have only the active verb *to move*, for expreſſing both the ſtate of motion and the act of putting in motion. "The ſtone *moves* down the ſlope, and *moves* all the pebbles which lie in its way;" but in the ancient languages the mere ſtate of motion is always expreſſed by the paſſive or middle voice. The accurate conception of the ſpeakers is therefore extolled. The ſtate of motion is expreſſed as it ought to be, as the reſult of a continual action." Κινειται, *movetur*, is equivalent to "it is moved." According to theſe philoſophers, every thing which *moves* is mind, and every thing that *is moved* is body.

The argument is futile, and it is falſe; for the modern languages are, in general, equally accurate in this inſtance: "*ſe mouvoir*," in French; "*ſich bewegen*," in German; "*dvigatſu*," in Sclavonic; are all paſſive or reflected. And the ancients ſaid, that "rain falls, water runs, ſmoke riſes," juſt as we do. The ingenious author of *Ancient Metaphyſics* has taken much pains to gives us, at length, the procedures of thoſe elementary minds in producing the oſtenſible phenomena of local motion; but it ſeems to be merely an abuſe of language, and a very frivolous abuſe. This elemental mind is known and characteriſed only by the effect which we aſcribe to its action; that is, by the motions or changes of motions. Uniform and unexcepted experience ſhews us that theſe are regulated by laws as preciſe as thoſe of mathematical truth. We conſider nothing as more fixed and determined than the common laws of mechaniſm. There is nothing here that indicates any thing like ſpontaneity, intention, purpoſe; none of thoſe marks by which mind was firſt brought into view: but they are very like the effects which we produce by the exertions of our corporeal forces; and we have accordingly given the name *force* to the cauſes of motion. It is ſurely much more appoſite than the name mind, and conveys with much more readineſs and perſpicuity the very notions that we wiſh to convey.

24
Action not eceſſary or the ontinunce of notion.

We now wiſh to know what reaſon we have to think that the continual action of ſome cauſe is neceſſary for continuing matter in motion, or for thinking that reſt is its natural ſtate. If we pretend to draw any argument from the nature of matter, that matter muſt be known, as far as is neceſſary for being the foundation of argument. Its very exiſtence is known only from obſervation; all our knowledge of it muſt therefore be derived from the ſame ſource.

If we take this way to come at the origin of this opinion, we ſhall find that experience gives us no authority for ſaying that reſt is the natural condition of matter. We cannot ſay that we have ever ſeen a body at reſt; this is evident to every perſon who allows the validity of the Newtonian philoſophy, and the truth of the Copernican ſyſtem of the ſun and planets; all the parts of this ſyſtem are in motion. Nay, it appears from many obſervations, that the ſun, with his attending planets, is carried in a certain direction, with a velocity which is very great. We have no unqueſtionable authority for ſaying that any one of the ſtars is abſolutely fixed: but we are *certain* that many of them are in motion. Reſt is therefore ſo rare a condition of body, that we cannot ſay, from any experience, that it is its natural ſtate.

25.

It is eaſy, however, to ſee, that it is from obſervation that this opinion has been derived; but the obſervation has been limited and careleſs. Our experiments in this ſublunary world do indeed always require continued action of ſome moving force to continue the motion; and if this be not employed, we ſee the motions ſlacken every minute, and terminate in reſt after no long period. Our firſt notions of ſublunary bodies are indicated by their operation in caſes where we have ſome intereſt. Perpetually ſeeing our own exertions neceſſary, we are led to conſider matter as ſomething not only naturally quieſcent and inert, but ſluggiſh, averſe from motion, and prone to reſt (we muſt be pardoned this metaphorical language, becauſe we can find no other term). What is expreſſed by it, on this occaſion, is preciſely one of the erroneous or inadequate conceptions that are ſuggeſted to our thoughts by reaſon of the poverty of language. We animate matter in order to give it motion, and then we endow it with a ſort of moral character in order to explain the appearance of thoſe motions.

26.

But more extended obſervation has made men gradually deſert their firſt opinions, and at laſt allow that matter has no peculiar aptitude to reſt. All the retardations that we *obſerve* have been diſcovered, one after another, to have a diſtinct reference to ſome external circumſtances. The diminution of motion is always obſerved to be accompanied by the removal of obſtacles, as when a ball moves through ſand, or water, or air; or it is owing to oppoſite motions which are deſtroyed; or it is owing to roughneſs of the path, or to friction, &c. We find that the more we can keep thoſe things out of the way, the leſs are the motions diminiſhed. A pendulum will vibrate but a ſhort while in water; much longer in air; and in the exhauſted receiver, it will vibrate a whole day. We know that we cannot remove *all* obſtacles; but we are led by ſuch obſervations to conclude that, if they *could be completely removed*, our motions would continue for ever. And this concluſion is almoſt demonſtrated by the motions of the heavenly bodies, to which we know of no obſtacles, and which we really obſerve to retain their motions for many thouſand years without the ſmalleſt ſenſible diminution.

27
Inactivity of matter denied by Leibnitz.

Another ſet of philoſophers maintain an opinion directly oppoſite to that of the inactivity of matter, and aſſert, that it is eſſentially active, and continually changing its ſtate. Faint traces of this are to be found in the writings of Plato, Ariſtotle, and their commentators. Mr Leibnitz is the perſon who has treated this queſtion moſt ſyſtematically and fully. He ſuppoſes every particle of matter to have a principle of individuality, which he therefore calls a MONAD. This mo-

Monads, what.

nad has a ſort of *perception* of its ſituation in the univerſe, and of its relation to every other part of this univerſe. Laſtly, he ſays that the monad acts on the material particle, much in the ſame way that the ſoul of man acts on his body. It modifies the motion of the material atom (in conformity, however, to unalterable laws), producing all thoſe modifications of motion that we obſerve. Matter therefore, or at leaſt particles of matter, are continually active, and continually changing their ſituation.

This opinion ill founded.

It is quite unneceſſary to enter on a formal confutation of Mr Leibnitz's ſyſtem of monads, which differs very little from the ſyſtem of elemental minds, and is equally whimſical and frivolous; becauſe it only makes the unlearned reader ſtare, without giving him any information. Should it even be granted, it would not, any more than the action of animals, invalidate the general propoſition which we are endeavouring to eſtabliſh as the fundamental law of motion. Thoſe powers of the monads, or of the elemental minds, are the cauſes of all the changes of motion; but the mere material particle is ſubject to the law, and requires the exertion of the monad in order to exhibit a change of motion.

28
Some philoſophers deduce this law of motion from the want of a *determining* cauſe.

A third ſect of philoſophers, at the head of which we may place Sir Iſaac Newton, maintain the doctrine enounced in the propoſition. But they differ much in reſpect of the foundation on which it is built.

Some aſſert that its truth flows from the nature of the thing. If a body be at reſt, and you aſſert that it will not remain at reſt, it muſt move in ſome one direction. If it be in motion in any direction, and with any velocity, and do not continue its equable, rectilineal, motion, it muſt either be accelerated or retarded; it muſt turn either to one ſide, or to ſome other ſide. The event, whatever it be, is individual and determinate; but no cauſe which can determine it is ſuppoſed: therefore the determination cannot take place, and no change will happen in the condition of the body with reſpect to motion. It will continue at reſt, or perſevere in its rectilineal and equable motion.

But conſiderable objections may be made to this argument, of *ſufficient reaſon*, as it is called. In the immenſity and perfect uniformity of ſpace and time, there is no determining cauſe why the viſible univerſe ſhould exiſt in the place in which we ſee it rather than in another, or at this time rather than at another. Nay, the argument ſeems to beg the queſtion. A cauſe of determination is required as eſſentially neceſſary—a determination may be without a cauſe, as well as a motion without a cauſe.

29
Others deduce it from experience.

Other philoſophers, who maintain this doctrine, conſider it merely as an experimental truth; and proofs of its univerſality are innumerable.

When a ſtone is thrown from the hand, we preſs it forward while in the hand, and let it go when the hand has acquired the greateſt rapidity of motion that we can give it. The ſtone continues in that ſtate of motion which it acquired gradually along with the hand. We can throw a ſtone much farther by means of a ſling; becauſe, by a very moderate motion of the hand, we can whirl the ſtone round till it acquire a very great velocity, and then we let go one of the ſtrings, and the ſtone eſcapes, *by continuing* its rapid motion. We ſee it ſtill more diſtinctly in ſhooting an arrow from a bow. The ſtring preſſes hard on the notch of the arrow, and it yields to this preſſure and goes forward. The ſtring alone would go faſter forward. It therefore *continues* to preſs the arrow forward, and accelerates its motion. This goes on till the bow is as much unbent as the ſtring will allow. But the ſtring is now a ſtraight line. It came into this poſition with an accelerated motion, and it therefore goes a little beyond this poſition, but with a retarded motion, being checked by the bow. But there is nothing to check the arrow; therefore the arrow quits the ſtring, and flies away.

Theſe are ſimple caſes of perſeverance in a ſtate of motion, where the procedure of nature is ſo eaſily traced that we perceive it almoſt intuitively. It is no leſs clear in other phenomena which are more complicated; but it requires a little reflection to trace the proceſs. We have often ſeen an equeſtrian ſhowman ride a horſe at a gallop, ſtanding on the ſaddle, and ſtepping from it to the back of another horſe that gallops alongſide at the ſame rate; and he does this ſeemingly with as much eaſe as if the horſes were ſtanding ſtill. The man has the ſame velocity with the horſe that gallops under him, and keeps this velocity while he ſteps to the back of the other. If that other were ſtanding ſtill, the man would fly over his head. And if a man ſhould ſtep from the back of a horſe that is ſtanding ſtill to the back of another that gallops paſt him, he would be left behind. In the ſame manner, a ſlack wire-dancer toſſes oranges from hand to hand while the wire is in full ſwing. The orange, ſwinging along with the hand, retains the velocity; and when in the air follows the hand, and falls into it when it is in the oppoſite extremity of its ſwing. A ball, dropped from the maſt-head of a ſhip that is ſailing briſkly forward, falls at the foot of the maſt. It retains the motion which it had while in the hand of the perſon who dropped it, and follows the maſt during the whole of its fall.

We alſo have familiar inſtances of the perſeverance of a body in a ſtate of reſt. When a veſſel filled with water is drawn ſuddenly along the floor, the water daſhes over the poſterior ſide of the veſſel. It is left behind. In the ſame manner, when a coach or boat is dragged forward, the perſons in it find themſelves ſtrike againſt the hinder part of the carriage or boat. Properly ſpeaking, it is the carriage that ſtrikes on them. In like manner, if we lay a card on the tip of the finger, and a piece of money on the card, we may nick away the card, by hitting it neatly on its edge; but the piece of money will be left behind, lying on the tip of the finger. A ball will go through a wall and fly onward; but the wall is left behind. Buildings are thrown down by earthquakes; ſometimes by being toſſed from their foundations, but more generally by the ground on which they ſtand being haſtily drawn ſidewiſe from under them, &c.

30
Common experience inſufficient.

But common experience ſeems inſufficient for eſtabliſhing this fundamental propoſition of mechanical philoſophy. We muſt, on the faith of the Copernican ſyſtem, grant that we never ſaw a body at reſt, or in uniform rectilineal motion; yet this ſeems abſolutely neceſſary before we can ſay that we have eſtabliſhed this propoſition experimentally.

What we imagine, in our experiments, to be putting a body, formerly at reſt, into motion, is, in fact, only changing a moſt rapid motion, not leſs, and probably much greater, than 90,000 feet per ſecond. Suppoſe a cannon pointed eaſt, and the bullet diſcharged at noon

day

day with 60 times greater velocity than we have ever been able to give it. It would appear to ſet out with this unmeaſurable velocity to the eaſtward; to be gradually retarded by the reſiſtance of the air, and at laſt brought to reſt by hitting the ground. But, by reaſon of the earth's motion round the ſun, the fact is quite the reverſe. Immediately before the diſcharge, the ball was moving to the weſtward with the velocity of 90,000 feet per ſecond nearly. By the exploſion of the powder, and its preſſure on the ball, ſome of this motion is deſtroyed, and at the muzzle of the gun, the ball is moving ſlower, and the cannon is hurried away from it to the weſtward. The air, which is alſo moving to the weſtward 90,000 feet in a ſecond, gradually communicates motion to the ball, in the ſame manner as a hurricane would do. At laſt (the ball dropping all the while) ſome part of the ground hits the ball, and carries it along with it.

Other obſervations muſt therefore be reſorted to, in order to obtain an experimental proof of this propoſition. And ſuch are to be found. Although we cannot meaſure the abſolute motions of bodies, we can obſerve and meaſure accurately their relative motions, which are the differences of their abſolute motions. Now, if we can ſhew experimentally, that bodies ſhew equal tendencies to reſiſt the augmentation and the diminution of their relative motions, they, *ipſo facto*, ſhew equal tendencies to reſiſt the augmentation or diminution of their abſolute motions. Therefore let two bodies, A and B, be put into ſuch a ſituation, that they cannot (by reaſon of their impenetrability, or the actions of their mutual powers) perſevere in their relative motions. The change produced on A is the effect and the meaſure of B's tendency to perſevere in its former ſtate; and therefore the proportion of theſe changes will ſhew the proportion of their tendencies to maintain their former ſtates. Therefore let the following experiment be made at noon.

Experiments proper for the purpoſe.

Let A, apparently moving weſtward three feet per ſecond, hit the equal body B apparently at reſt. Suppoſe, *1ſt*, That A impels B forward, without any diminution of its own velocity. This reſult would ſhew that B manifeſts no tendency to maintain its motion unchanged, but that A retains its motion undiminiſhed.

2dly, Suppoſe that A ſtops, and that B remains at reſt. This would ſhew that A does not reſiſt a diminution of motion, but that B retains its motion unaugmented.

3dly, Suppoſe that both move weſtward with the velocity of one foot per ſecond. The change on A is a diminution of velocity, amounting to two feet per ſecond. This is the effect and the meaſure of B's tendency to maintain its velocity unaugmented. The change on B is an augmentation of one foot per ſecond made on its velocity; and this is the meaſure of A's tendency to maintain its velocity undiminiſhed. This tendency is but half of the former; and this reſult would ſhew, that the reſiſtance to a diminution of velocity is but half of the reſiſtance to augmentation. It is perhaps but one quarter; for the change on B has produced a double change on A.

4thly, Suppoſe that both move weſtward at the rate of 1½ feet per ſecond. It is evident that their tendencies to maintain their ſtates unchanged are now equal.

5thly, Suppoſe A = 2 B, and that both move, after the colliſion, two feet per ſecond, B has received an addition of two feet per ſecond to its former velocity. This is the effect and the meaſure of A's whole tendency to retain its motion undiminiſhed. Half of this change on B meaſures the perſevering tendency of the half of A; but A, which formerly moved with the apparent or relative velocity three, now moves (by the ſuppoſition) with the velocity two, having loſt a velocity of one foot per ſecond. Each half of A therefore has loſt this velocity, and the whole loſs of motion is two. Now this is the meaſure of B's tendency to maintain its former ſtate unaugmented; and this is the ſame with the meaſure of A's tendency to maintain its own former ſtate undiminiſhed. The concluſion from ſuch a reſult would therefore be, that bodies have equal tendencies to maintain their former ſtates of motion without augmentation and without diminution.

What is ſuppoſed in the *4th* and *5th* caſes is really the reſult of all the experiments which have been tried; and this law regulates all the changes of motion which are produced by the mutual actions of bodies in impulſions. This aſſertion is true without exception or qualification. Therefore it appears that bodies have no preferable tendency to reſt, and that no fact can be adduced which ſhould make us ſuppoſe that a motion once begun ſhould ſuffer any diminution without the action of a changing cauſe.

But experience is not the proper foundation of an axiom.

But we muſt now obſerve, that this way of eſtabliſhing the firſt law of motion is very imperfect, and altogether unfit for rendering it the fundamental principle of a whole and extenſive ſcience. It is ſubject to all the inaccuracy that is to be found in our beſt experiments; and it cannot be applied to caſes where ſcrupulous accuracy is wanted, and where no experiment can be made.

Let us therefore examine the propoſition by means of the general principles adopted in the article PHILOSOPHY, *Encycl.* which contain the foundation of all our knowledge of active nature. Theſe principles will, we imagine, give a deciſion of this queſtion that is ſpeedy and accurate, ſhewing the propoſition to be an axiom or intuitive conſequence of the relations of thoſe ideas which we have of motion, and of the cauſes of its production and changes.

31
Logical proof.

It has been fully demonſtrated that the powers or forces, of which we ſpeak ſo much, are never the immediate objects of our perception. Their very exiſtence, their kind, and their degree, are inſtinctive inferences from the motions which we obſerve and claſs. It evidently follows from this experimental and univerſal truth, *1ſt*, That where no change of motion is obſerved, no ſuch inference is made; that is, no power is *ſuppoſed* to act. But whenever any change of motion is obſerved, the inference is made; that is, a power or force is ſuppoſed to have acted.

In the ſame form of logical concluſion, we muſt ſay that, *2dly*, When no change of motion is *ſuppoſed* or thought of, no force is *ſuppoſed*; and that whenever we *ſuppoſe* a change of motion, we, in fact, though not in terms, ſuppoſe a changing force. And, on the other hand, whenever we ſuppoſe the action of a changing force, we ſuppoſe the change of motion; for the action of this force, and the change of motion, is one and the ſame thing. We cannot think of the action without thinking of the indication of that action; that is, the change of motioo.—In the ſame manner, when we do not think of a changing force, or ſuppoſe that there is no action of a changing force, we, in fact, though not in terms, ſuppoſe that there is no indication of this changing force; that is, that there is no change.

It is a law of human thought,

Whenever, therefore, we ſuppoſe that no mechanical force is acting on a body, we, in fact, ſuppoſe that the body continues in its former condition with reſpect to motion. If we ſuppoſe that nothing accelerates, or retards, or deflects the motion, we ſuppoſe that it is not accelerated, nor retarded, nor deflected. Hence follows the propoſition in expreſs terms—*We ſuppoſe that the body continues in its former ſtate of reſt or motion, unleſs we ſuppoſe that it is changed by ſome mechanical force.*

Thus it appears, that this propoſition is not a matter of experience or contingency, depending on the properties which it has pleaſed the Author of Nature to beſtow on body: it is, to us, a neceſſary truth. The propoſition does not ſo much expreſs any thing with regard to body, as it does the operations of our mind when contemplating body. It may perhaps be eſſential to body to move in ſome particular direction. It may be eſſential to body to ſtop as ſoon as the moving cauſe has ceaſed to act; or it may be eſſential to body to diminiſh its motion gradually, and finally come to reſt. But this will not invalidate the truth of this propoſition. Theſe circumſtances in the nature of body, which render thoſe modifications of motion eſſentially neceſſary, are the cauſes of thoſe modifications; and, in our ſtudy of nature, they will be conſidered by us as changing forces, and will be known and called by that name. And if we ſhould ever ſee a particle of matter in ſuch a ſituation that it is affected by thoſe eſſential properties alone, we ſhall, from obſervation of its motion, diſcover what thoſe eſſential properties are.

And almoſt an identical propoſition.

This law turns out at laſt to be little more than a tautological propoſition: But mechanical philoſophy, as we have defined it, requires no other ſenſe of it: for, even if we ſhould ſuppoſe that body, of its own nature, is capable of changing its ſtate, this change muſt be performed according to ſome law which characteriſes the nature of body; and the knowledge of the law can be had in no other way than by obſerving the deviations from uniform rectilineal motion. It is therefore indifferent whether thoſe changes are derived from the nature of the thing, or from external cauſes: for in order to conſider the various motions of bodies, we muſt firſt conſider this nature of matter as a mechanical affection of matter, operating in every inſtance; and thus we are brought back to the law enounced in this propoſition. This becomes more certain when we reflect that the external cauſes (ſuch as gravity or magnetiſm), which are acknowledged to operate changes of motion, are equally unknown to us with this eſſential original property of matter, and are, like it, nothing but inferences from the phenomena.

The above very diffuſe diſcuſſions may appear ſuperfluous to many readers, and even cumberſome; but we truſt that the philoſophical reader will excuſe our anxiety on this head, when he reflects on the complicated, indiſtinct, and inaccurate notions commonly had of the ſubject; and more eſpecially when he obſerves, that of thoſe who maintain the truth of this fundamental propoſition, as we have enounced it, many (and they too of the firſt eminence), reject it in fact, by combining it with other opinions which are inconſiſtent with it, nay, which contradict it in expreſs terms. We may even include Sir Iſaac Newton in the number of thoſe who have at leaſt introduced modes of expreſſion which miſlead the minds of incautious perſons, and ſuggeſt inadequate notions, incompatible with the pure doctrine of the propoſition. Although, in words, they diſclaim the doctrine that reſt is the natural ſtate of body, and that force is neceſſary for the continuation of its motion, yet in words they (and moſt of them in thought) likewiſe abet that doctrine: for they ſay, that there reſides in a moving body a *power* or *force*, by which it perſeveres in its motion. They call it the VIS INSITA, the INHERENT FORCE OF A MOVING BODY. This is ſurely giving up the queſtion: for if the motion is ſuppoſed to be continued in conſequence of a force, that force is *ſuppoſed* to be exerted; and it is ſuppoſed, that if it were not exerted, the motion would ceaſe; and therefore the propoſition muſt be falſe. Indeed it is ſometimes expreſſed ſo as ſeemingly to ward off this objection. It is ſaid that the body continues in uniform rectilineal motion, unleſs affected by ſome *external cauſe*. But this way of ſpeaking obliges us, at firſt ſetting out in natural philoſophy, to aſſert that gravity, magnetiſm, electricity, and a thouſand other mechanical powers, are external to the matter which they put in motion. This is quite improper: It is the buſineſs of philoſophy to diſcover whether they be external or not; and if we aſſert that they are, we have no principles of argumentation with thoſe who deny it. It is this one thing that has filled the ſtudy of nature with all the jargon of æthers and other inviſible intangible fluids, which has diſgraced philoſophy, and greatly retarded its progreſs.

32
Vis inſita, inherent force, are improper terms in their uſual acceptation.

We muſt obſerve, that the terms *vis inſita*, inherent *force*, are very improper. There is no diſpute among philoſophers in calling every thing a force that produces a change of motion, and in inferring the action of ſuch a force whenever we obſerve a change of motion. It is ſurely incongruous to give the ſame name to what has not this quality of producing a change, or to infer (or rather to ſuppoſe) the energy of a force when no change of motion is obſerved. This is one among many inſtances of the danger of miſtake when we indulge in analogical diſcuſſions. All our language, at leaſt, on this ſubject is analogous. I feel, that in order to oppoſe animal force, I muſt exert force. But I muſt exert force in order to oppoſe a body in motion: Therefore I imagine that the moving body poſſeſſes force. A bent ſpring will drive a body forward by unbending: Therefore I ſay that the ſpring exerts force. A moving body impels the body which it hits: Therefore I ſay, that the impelling body poſſeſſes and exerts force. I imagine farther, that it poſſeſſes force only by being in motion, or becauſe it is in motion; becauſe I do not find that a quieſcent body will put another into motion by touching it. But we ſhall ſoon find this to be falſe in many, if not in all caſes, and that the communication of motion depends on the mere vicinity, and not on the motion of the impelling body; yet we aſcribe the exertion of the *vis inſita* to the circumſtance of the continued motion. We therefore conceive the force as ariſing from, or as conſiſting in, the impelling body's being in motion; and, with a very obſcure and indiſtinct conception of the whole matter, we call it *the force by which the body preſerves itſelf in motion.* Thus, taking it for granted that a force reſides in the body, and being obliged to give it ſome office, this is the only one that we can think of.

But philoſophers imagine that they perceive the neceſſity of the exertion of a force in order to the continuation of a motion. Motion (ſay they) is a continued action; the body is every inſtant in a new ſituation; there is the continual production of an effect, therefore the continual action of a cauſe.

33
Motion is not the continual production of an effect.

But this is a very inaccurate way of thinking. We have a diſtinct conception of motion; and we conceive that there is ſuch a thing as a moving cauſe, which we diſtinguiſh from all other cauſes by the name *force*. It produces motion. If it does this, it produces the character of motion, which is a continual change of place. Motion is not action, but the effect of an action; and this action is as incomplete in the inſtant immediately ſucceeding the beginning of the motion as it is a minute after. The ſubſequent change of place is the continuation of an effect already produced. The *immediate* effect of the moving force is a DETERMINATION, by which, if not hindered, the body would go on for ever from place to place. It is in this determination only that the ſtate or condition of the body can differ from a ſtate of reſt; for in any inſtant, the body does not deſcribe any ſpace, but has a determination, by which it will deſcribe a certain ſpace uniformly in a certain time. Motion is a condition, a ſtate, or mode of exiſtence, and no more requires the continued agency of the moving cauſe than yellowneſs or roundneſs does. It requires ſome chemical agency to change the yellowneſs to greenneſs; and it requires a mechanical cauſe or a force to change this motion into reſt. When we ſee a moving body ſtop ſhort in an inſtant, or be gradually, but quickly, brought to reſt, we never fail to ſpeculate about a cauſe of this ceſſation or retardation. The caſe is no way different in itſelf although the retardation ſhould be extremely ſlow. We ſhould always attribute it to a cauſe. It requires a cauſe to put a body out of motion as much as to put it into motion. This cauſe, if not external, muſt be found in the body itſelf; and it muſt have a ſelf-determining power, and may as well be able to put itſelf into motion as out of it.

If this reaſoning be not admitted, we do not ſee how any effect can be produced by any cauſe. Every effect ſuppoſes ſomething *done*: and any thing done implies that the thing done may remain till it be *undone* by ſome other cauſe. Without this, it would have no exiſtence. If a moving cauſe did not produce continued motion by its inſtantaneous action, it could not produce it by any continuance of that action; becauſe in no inſtant of that action does it produce continued motion.

We muſt therefore give up the opinion, that there reſides in a moving body a force by *which it is kept in motion*; and we muſt find ſome other way of explaining that remarkable difference between a moving body and a body at reſt, by which the firſt cauſes other bodies to move by hitting them, while the other does not do this by merely touching them. We ſhall ſee, with the cleareſt evidence, that motion is neceſſary in the impelling body, in order that it may permit the forces inherent in one or both bodies to continue this preſſure long enough for producing a ſenſible or conſiderable motion. But theſe moving forces are inherent in bodies, whether they are in motion or at reſt.

34
Communication of motion is an improper phraſe,

The foregoing obſervations ſhew us the impropriety of the phraſe *communication of motion*. By thus reflecting on the notions that are involved in the general conception of one body being made to move by the impulſe of another, we perceive that there is nothing individual transferred from the one body to the other. The determination to motion, indeed, exiſted only in the impelling body before colliſion; whereas, afterwards, both bodies are ſo conditioned or determined. But we can form no notion of the thing transferred. With the ſame metaphyſical impropriety, we ſpeak of the communication of joy, of fever.

35
So is *vis inertiæ*.

Kepler introduced a term INERTIA, VIS INERTIÆ, into mechanical philoſophy; and it is now in conſtant uſe. But writers are very careleſs and vague in the notions which they affix to theſe terms. Kepler and Newton ſeem generally to employ it for expreſſing the fact, the perſeverance of the body in its preſent ſtate of motion or reſt: but they alſo frequently expreſs by it ſomething like an indifference to motion or reſt, *manifeſted by its requiring the ſame quantity of force to make an augmentation of its motion as to make an equal diminution of it.* The popular notion is like that which we have of actual reſiſtance; and it always implies the notion of force *exerted* by the reſiſting body. We ſuppoſe this to be the exertion of the *vis inſita*, or the *inherent force* of a body in motion. But we have the ſame notion of reſiſtance from a body at reſt which we ſet in motion. Now ſurely it is in direct contradiction to the common uſe of the word *force*, when we ſuppoſe reſiſtance from a body at reſt; yet *vis inertiæ* is a very common expreſſion. Nor is it more abſurd (and it is very abſurd) to ſay, that a body maintains its ſtate of reſt by the exertion of a *vis inertiæ*, than to ſay, that it maintains its ſtate of motion by the exertion of an *inherent force*. We ſhould avoid all ſuch metaphorical expreſſions as *reſiſtance*, *indifference*, *ſluggiſhneſs*, or *proneneſs to reſt* (which ſome expreſs by *inertia*); becauſe they ſeldom fail to make us indulge in metaphorical notions, and thus lead us to miſconceive the *modus operandi*, or procedure of nature.

There is *no reſiſtance whatever obſerved* in theſe phenomena; for the force employed always produces its *complete* effect. When I throw down a man, and find that I have employed no more force than was ſufficient to throw down a ſimilar and equal maſs of dead matter, I know by this that he *has not* reſiſted; but I conclude that he *has* reſiſted, if I have been obliged to employ much more force. There is therefore no reſiſtance, properly ſo called, when the exerted force is obſerved to produce its full effect. To ſay that there *is* reſiſtance, is therefore a real miſconception of the way in which mechanical forces have operated in the colliſion of bodies. There is no more reſiſtance in theſe caſes than in any other natural changes of condition. We are guilty, however, of the ſame impropriety of language in other caſes, where the cauſe of it is more evident. We ſay that colours in grain *reſiſt* the action of ſoap and of the ſun, but that Pruſſian blue does not. We all perceive, that in this expreſſion the word reſiſtance is entirely figurative: and we ſhould ſay that Pruſſian blue *reſiſts* ſoap, if we are right in ſaying that a body reſiſts any force employed to change its ſtate of motion; for ſoap muſt be employed to diſcharge or change the colour; and *it does change it*. Force muſt be employed to change a motion; *and it does change it*. The impropriety, both of thought and language, is *plain* in the one caſe, and it is no leſs *real* in the other. Both of the terms, *inherent force* and *inertia*, may be uſed with ſafety for abbreviating language, if we be careful to employ them only for expreſſing, *either the ſimple fact of perſevering in the former ſtate*, or *the neceſſity of employing a certain determinate force, in order to change that ſtate, and if we avoid all thought of reſiſtance.*

36 Deviations from uniform rectilineal motion are the only indications of force.

From the whole of this diſcuſſion, we learn, that the deviations from uniform motions are the indications of the exiſtence and agency of mechanical forces, and that they are the only indications. The indication is very ſimple, mere change of place; it can therefore indicate nothing but what is very ſimple, the ſomething competent to the production of the very motion that we obſerve. And when two changes of motion are preciſely ſimilar, they indicate the ſame thing. Suppoſe a mariner's compaſs on the table, and that by a ſmall tap with my finger I cauſe the needle to turn off from its quieſcent poſition 10 degrees. I can do the ſame thing by bringing a magnet near it; or by bringing an electrified body near it; or by the unbending of a fine ſpring preſſing it aſide; or by a puff of wind; or by ſeveral other methods. In all theſe caſes, the indication is the ſame; therefore the thing indicated is the ſame, namely, a certain intenſity and direction of a moving power. How it operates, or in what manner it exiſts and exerts itſelf in theſe inſtances, outwardly ſo different, is not under conſideration at preſent. Impulſiveneſs, intenſity, and direction, are all the circumſtances of reſemblance by which the affections of matter are to be characteriſed; and it is to the diſcovery and determination of theſe alone that our attention is now to be directed. We are directed in this reſearch by the

SECOND LAW OF MOTION.

Every change of motion is proportional to the force impreſſed, and is made in the direction of that force.

37. This law alſo may almoſt be conſidered as an identical propoſition; for it is equivalent to ſaying, that the changing force is to be meaſured by the change which it produces, and that the direction of this force is the direction of the change. Of this there can be no doubt, when we conſider the force in no other ſenſe than that of the cauſe of motion, paying no attention to the form or manner of its exertion. Thus, when a pellet of tow is ſhot from a pop-gun by the expanſion of the air compreſſed by the rammer, or where it is ſhot from a toy piſtol by the unbending of the coiled wire, or when it is nicked away by the thumb like a marble—if, in all theſe caſes, it moves off in the ſame direction, and with the ſame velocity, we cannot conſider or think of the force, or at leaſt of its exertion, as any how different. Nay, when it is driven forward by the inſtantaneous percuſſion of a ſmart ſtroke, although the manner of producing this effect (if poſſible) is eſſentially different from what is conceived in the other caſes, we muſt ſtill think that the propelling force, conſidered as a propelling force, is one and the ſame. In ſhort, this law of motion, as thus expreſſed by Sir Iſaac Newton, is equivalent to ſaying, "That we take the changes of motion as the meaſures of the changing forces, and the direction of the change for the indication of the direction of the forces:" For no reflecting perſon can pretend to ſay, that it is a deduction from the acknowledged principle, that effects are proportional to their cauſes. We do not affirm this law, from having obſerved the proportion of the forces and the proportion of the changes, and that theſe proportions are the ſame; and from having obſerved that this has obtained through the whole extent of our ſtudy of nature. This would indeed eſtabliſh it as a phyſical law, an univerſal fact; and it is, in fact, ſo eſtabliſhed. But this does not eſtabliſh it as a law of motion, according to our definition of that term; as a law of human thought, the reſult of the relations of our ideas, as an intuitive truth. The injudicious attempts of philoſophers to prove it as a matter of obſervation, have occaſioned the only diſpute that has ariſen in mechanical philoſophy. It is well known that a bullet, moving with double velocity, penetrates four times as far. Many other ſimilar facts corroborate this: and the philoſophers obſerve, that four times the force has been expended to generate this double velocity in the bullet; it requires four times as much powder. In all the examples of this kind, it would ſeem that the ratio of the forces employed has been very accurately aſcertained; yet this is the invariable reſult. Philoſophers, therefore, have concluded, that moving forces are not proportional to the velocities which they produce, but to the ſquares of thoſe velocities. It is a ſtrong confirmation, to ſee that the bodies in motion ſeem to poſſeſs forces in this very proportion, and produce effects in this proportion; penetrating four times as deep when the velocity is only twice as great, &c.

But if this be a juſt eſtimation, we cannot reconcile it to the conceſſion of the ſame philoſophers, who grant that the velocity is proportional to the force impreſſed, in the caſes where we have no previous obſervation of the ratio of the forces, and of its equality to the ratio of the velocities. This is the caſe with gravity, which theſe philoſophers always meaſure by its accelerating power, or of the velocity which it generates in a given time. And this cannot be refuſed by them; for caſes occur, where the force can be meaſured, in the moſt natural manner, by the actual preſſure which it exerts. Gravity is thus meaſured by the preſſure which a ſtone exerts on its ſupports. A weight which at Quito will pull out the rod of a ſpring ſteelyard to the mark 312, will pull it to 313 at Spitzbergen. And it is a fact, that a body will fall 313 inches at Spitzbergen in the ſame time that it falls 312 at Quito. Gravitation is the cauſe both of the preſſure and the fall; and it is a matter of unexcepted obſervation, that they have always the ſame ratio. The philoſophers who have ſo ſtrenuouſly maintained the other meaſure of forces, are among the moſt eminent of thoſe who have examined the motions produced by gravity, magnetiſm, electricity, &c.; and they never think of meaſuring thoſe forces any other way than by the velocity. It is in this way that the whole of the celeſtial phenomena are explained in perfect uniformity with obſervation, and that the Newtonian philoſophy is conſidered as a demonſtrative ſcience.

There muſt, therefore, be ſome defect in the principle on which the other meaſurement of forces is built, or in the method of applying it. Preſſure is undoubtedly the immediate and natural meaſure of force; yet we know that four ſprings, or a bow four times as ſtrong, give only a double velocity to an arrow.

The truth of our law reſts on this only, that we aſſume the changes of motion as the meaſure of the changing forces; or, at leaſt, as the meaſures of their exertions in producing motion. In fact, they are the meaſures only

of

of a certain circumſtance, in which the actions of very different natural powers may reſemble each other; namely, the competency to produce motion. They do not, perhaps, meaſure their competency to produce heat, or even to bend ſprings. We can ſurely conſider this apart from all other circumſtances; and it is worthy of ſeparate conſideration. Let us ſee what can be, and what ought to be, deduced from this way of treating the ſubject.

38
Change of motion is, itſelf, a motion.

The motion of a body may certainly remain unchanged. If the direction and velocity remain the ſame, we perceive no circumſtance in which its condition, with reſpect to motion, differs. Its change of place or ſituation can make no difference; for this is implied in the very circumſtance of the body's being in motion.

But if either the velocity or direction change, then ſurely is its mechanical condition no longer the ſame; a force has acted on it, either intrinſic or from without, either accelerating, or retarding, or deflecting it. Suppoſing the direction to remain the ſame, its difference of condition can conſiſt in nothing but its difference of velocity. This is the only circumſtance in which its condition can differ, as it paſſes through two different points of its rectilineal path. It is this determination by which the body will deſcribe a certain determinate ſpace uniformly in a given time, which defines its condition as a moving body: the changes of this determination are the meaſures of their own cauſes;—and to thoſe cauſes we have given the name *force*. Thoſe cauſes may reſide in other bodies, which may have other properties, characteriſed and meaſured by other effects. Preſſure may be one of thoſe properties, and may have its own meaſures; theſe may, or may not, have the ſame proportion with that property which is the cauſe of a change of velocity: and therefore changes of velocity may not be a meaſure of preſſure. This is a queſtion of fact, and requires obſervation and experience; but, in the mean time, velocity, and the change of velocity, is the meaſure of moving force and of changing force. When therefore the change of velocity is the ſame, whatever the previous velocity may be, the changing force muſt be conſidered as the ſame: therefore, finally, if the previous velocity is nothing, and conſequently the change on that body is the very velocity or motion that it acquires, we muſt ſay, that the force which produces a certain change in the velocity of a moving body, is the ſame with the force which would impart to a body at reſt a velocity equal to this change or difference of velocity produced on the body already in motion.

39. This manner of eſtimating force is in perfect conformity to our moſt familiar notions on theſe ſubjects. We conceive the weight or downward preſſure of a body as the cauſe of its motion downwards; and we conceive it as belonging to the body at all times, and in all places, whether falling, or riſing upwards, or deſcribing a parabola, or lying on a table; and, accordingly, we obſerve, that in every ſtate of motion it receives equal changes of velocity in the ſame, or an equal time, and all in the direction of its preſſure.

40. All that we have now ſaid of a change of velocity might be repeated of a change of direction. It is ſurely poſſible that the ſame change of direction may be made on any two motions. Let one of the motions be conſidered as growing continually ſlower, and terminating in reſt. In every inſtant of this motion it is poſſible to make one and the ſame change on it. The ſame change may therefore be made at the very inſtant that the motion is at an end. In this caſe, the change is the very motion which the body acquires from the changing force. Therefore, in this caſe alſo, we muſt ſay, that a change of motion is itſelf a motion, and that it is the motion which the force would produce in a body that was previouſly at reſt.

41
How aſcertained and meaſured.

The reſult of theſe obſervations is evidently this, that we muſt aſcertain, in every inſtance, what is the change of motion, and mark it by characters that are conſpicuous and diſtinguiſhing; and this mark and meaſure of change muſt be a motion: Then we muſt ſay, that the changing force is that which would produce this motion in a body previouſly at reſt. We muſt ſee how this is manifeſt, as a motion, in the difference between the former motion and the new motion; and, on the other hand, we muſt ſee how the motion produceable in a quieſcent body may be ſo combined with a motion already exiſting, as to exhibit a new motion, in which the agency of the changing force may appear.

Suppoſe a ſhip at anchor in a ſtream; while one man walks forward on the quarter-deck at the rate of two miles per hour, another walks from ſtem to ſtern at the ſame rate, a third walks athwart ſhip, and a fourth ſtands ſtill. Let the ſhip be ſuppoſed to cut or part her cable, and float down the ſtream at the rate of three miles per hour. We cannot conceive any difference in the change made on each man's motion in abſolute ſpace; but their motions are now exceedingly different from what they were: the firſt man, whom we may ſuppoſe to have been walking weſtward, is now moving eaſtward one mile per hour; the ſecond is moving eaſtward four miles per hour; and the third is moving in an oblique direction, about three points north or ſouth of due eaſt. All have ſuffered the ſame change of condition with the man who had been ſtanding ſtill. He has now got a motion eaſtward three miles per hour. In this inſtance, we ſee very well the circumſtance of ſameneſs that obtains in the change of theſe four conditions. It is the motion of the ſhip, which is blended with the other motions. But this circumſtance is equally preſent whenever the ſame previous motions are changed into the ſame new motions. We muſt learn to expiſcate this; which we ſhall do, by conſidering the manner in which the motion of the ſhip is blended with each of the mens motions.

42
Compoſition of motion.

This kind of combination has been called the Compoſition of motion; becauſe, in every point of the motion really purſued, the two motions are to be found.

The fundamental theorem on this ſubject is this:—Two uniform motions in the ſides of a parallelogram compoſe an uniform motion in the diagonal.

Plate XXI.

Suppoſe that a point A (fig. 1.) deſcribes AB uniformly in ſome given time, while the line AB is carried uniformly along AC in the ſame time, keeping always parallel to its firſt poſition AB. The point A, by the combination of theſe motions, will deſcribe AD, the diagonal of the parallelogram ABDC, uniformly in the ſame time.

For it is plain, that the velocities in AB and AC are proportional to AB and AC, becauſe they are uniformly deſcribed in the ſame time. When the point has got to E, the middle of AB, the line AB has got into the ſituation GH, half way between AB and CD, and

and the point E is in the place *e*, the middle of GH. Draw E *e* L parallel to AC. It is plain that the parallelograms ABDC and AE *e* G are ſimilar; becauſe AE and AG are the halves of AB and AC, and the angle at A is common to both. Therefore, by a propoſition in the Elements, they are about the ſame diagonal, and the point *e* is in the diagonal of AD. In like manner, it may be ſhewn, that when A has deſcribed AF, $\frac{3}{4}$ths of AB, the line AB will be in the ſituation IK, ſo that AI is $\frac{3}{4}$ths of AC, and the point *f*, in which A is now found, is in the diagonal AD. It will be the ſame in whatever point of AB the deſcribing point A be ſuppoſed to be found. The line AB will be on a ſimilar point of AC, and the deſcribing point will be in the diagonal AD.

Moreover, the motion in AD is uniform: for A *e* is deſcribed in the time of deſcribing AE; that is, in half the time of deſcribing AB, or in half the time of deſcribing AD. In like manner, A *f* is deſcribed in $\frac{3}{4}$ths of the time of deſcribing AD, &c. &c.

Laſtly, the velocity in the diagonal AD is to the velocity in either of the ſides as AD is to that ſide. This is evident, becauſe they are uniformly deſcribed in the ſame time.

This is juſtly called *a compoſition of the motions* AB *and* AC, as will appear by conſidering it in the following manner: Let the lines AB, AC be conceived as two material lines like wires. Let AB move uniformly from the ſituation AB into the ſituation CD, while AC moves uniformly into the ſituation BD. It is plain that their interſection will always be found on AD. The point *e*, for example, is a point common to both lines. Conſidered as a point of EL, it is then moving in the direction *e* H or AB; and, conſidered as a point of GH, it is moving in the direction *e* L. Both of theſe motions are therefore blended in the motion of the interſection along AD. We can conceive a ſmall ring at *e*, embracing looſely both of the wires. This material ring will move in the diagonal, and *will really partake* of both motions.

Thus we ſee how the motion of the ſhip is actually blended with the motions of the three men; and the circumſtance of ſameneſs which is to be found in the four changes of motion is this motion of the ſhip, or of the man who was ſtanding ſtill. By compoſition with each of the three former motions, it produces each of the three new motions. Now, when each of two primitive motions is the ſame, and each of the new motions is the ſame, the change is ſurely the ſame. If one of the changes has been brought about by the actual compoſition of motions, we know preciſely what that change is; and this informs us what the other is, in whatever way it was produced. Hence we infer, that,

43
Its mark and meaſure.

When a motion is any how changed, the change is that motion which, when compounded with the former motion, will produce the new motion. Now, becauſe we aſſume the change as the meaſure and characteriſtic of the changing force, we muſt do ſo in the preſent inſtance; and we muſt ſay,

44
Changing force.

That *the changing force is that which will produce in a quieſcent body the motion which, by compoſition with the former motion of a body, will produce the new motion.*

And, on the other hand,

Its effect.

When the motion of a body is changed by the action of any force, the new motion is that which is compounded of the former motion, and of the motion which the force would produce in a quieſcent body.

Deflecting force.

When a force changes the direction of a motion, we ſee that its direction is tranſverſe in ſome angle BAC; becauſe a diagonal AD always ſuppoſes two ſides. As we have diſtinguiſhed any change of direction by the term DEFLECTION, we may call the tranſverſe force a DEFLECTING FORCE.

In this way of eſtimating a change of motion, all the characters of both motions are preſerved, and it expreſſes every circumſtance of the change; the mere change of direction, or the angle BAD, is not enough, becauſe the ſame force will make different angles of deflection, according to the velocity of the former motion, or according to its direction: but in this eſtimation, the full effect of the deflecting force is ſeen; it is ſeen *as a motion;* for when half of the time is elapſed, the body is at *e* inſtead of E; when three-fourths are elapſed, it is at *f* inſtead of F; and at the end of the time it is at D inſtead of B. In ſhort, the body has moved uniformly away from the points at which it would have arrived independent of the change; and this motion has been in the ſame direction, and at the ſame rate, as if it had moved from A to C by the changing force alone. Each force has produced its full effect; for when the body is at D, it is as far from AC as if the force AC had not acted on it; and it is as far from AB as it would have been by the action of AC alone.

For all theſe reaſons, therefore, it is evident, that if we are to abide by our meaſure and character of force as a mere producer of motion, we have ſelected the proper characteriſtic and meaſure of a changing force: and our deſcriptions, in conformity to this ſelection, muſt be agreeable to the phenomena of nature, and retain the accuracy of geometrical procedure; becauſe, on the other hand, the reſults which we deduce from the ſuppoſed influence of thoſe forces are formed in the ſame mould. It is not even requiſite that the real exertions of the natural forces, ſuch as preſſure of various kinds, &c. ſhall follow theſe rules; for their deviations will be conſidered as new forces, although they are only indications of the differences of the real forces from our hypotheſis. We have obtained the precious advantage of mathematical inveſtigation, by which we can examine the law of exertion which characteriſes every force in nature.

On theſe principles we eſtabliſh the following fundamental elementary propoſition, of continual and indiſpenſable uſe in all mechanical inquiries.

45
Fundamental theorem.

If a body or material particle be ſubjected at the ſame time to the action of two moving forces, each of which would ſeparately cauſe it to deſcribe the ſide of a parallelogram uniformly in a given time, the body will deſcribe the diagonal uniformly in the ſame time.

For the body, whoſe motion AB was changed into AD, had gotten its motion by the action of ſome force. It was moving along NAB; and, when it reached the point A, the force AC acted on it. The primitive motion is the ſame, or the body is in the ſame condition in every inſtant of the primitive motion. It may have acquired this motion when it was in N, or when at O, or any other point of NA. In all theſe caſes, if AC act on it when it is in A, it will always deſcribe AD; therefore it will deſcribe AD when it acquires the primitive motion alſo in A; that is, if the two forces

ces act on it at one and the ſame inſtant. The demonſtration may be neatly expreſſed thus: The change induced by each force on the motion produced by the other, is the motion which it would produce in the body if previouſly at reſt. Therefore the motion reſulting from joint action is the motion which is compounded of theſe two motions; or it is a motion in the diagonal of the parallelogram, of which theſe motions are the ſides.

Compoſition of forces. This is called the COMPOSITION OF FORCES. The forces which produce the motions along the ſides of the parallelogram are called the SIMPLE FORCES, or the CONSTITUENT FORCES; and the force which would alone produce the motion along the diagonal is called the COMPOUND FORCE, the RESULTING FORCE, the EQUIVALENT FORCE.

46. On the other hand, the force which produces a motion along any line whatever, may be conceived as reſulting from the combined action of two or more forces. We may *know* or *obſerve* it to be ſo; as when we ſee a lighter dragged along a canal by two horſes, one on each ſide. Each pulls the boat directly toward himſelf in the direction of the track-rope; the boat cannot go both ways, and its real motion, whatever it is, reſults from this combined action. This might be produced by a ſingle force; for example, if the lighter be dragged along the canal by a rope from another lighter which precedes it, being dragged by one horſe, aided by the helm of the foremoſt lighter. Here the real force is not the reſulting, or the compound, but the equivalent force.

Reſolution of forces. This view of a motion, mechanically produced, is called the RESOLUTION OF FORCES. The force in the diagonal is ſaid to be *reſolved* into the two forces, having the directions and velocities repreſented by the ſides. This practice is of the moſt extenſive and multifareous uſe in all mechanical diſquiſitions. It may frequently be exceedingly difficult to manage the complication of the many real forces which concur in producing a phenomenon; and by ſubſtituting others, whoſe combined effects are equivalent, our inveſtigation may be much expedited. But more of this afterwards.

We muſt carefully remember, that when the motion AD is once begun, all compoſition is at an end, and the motion is a ſimple motion. The two determinations, by one of which the body would deſcribe AB, and by the other of which it would deſcribe AC, no longer *co-exiſt* in the body. This was the caſe only *in the inſtant*, in the very act of changing the motion AB into the motion BD; yet is the motion AD equivalent to a motion which is produced by the *actual compoſition* of two motions AB and AC; in which caſe the two motions co-exiſt in every point of AD.

47 Uſual demonſtration inconcluſive. Accordingly this is the way in which the compoſition of forces is uſually illuſtrated, and thought to be demonſtrated. A man is ſuppoſed (for inſtance) to walk uniformly from A to C on a ſheet of ice, while the ice is carried uniformly along AB by the ſtream. The man's real motion is undoubtedly along AD; but this is by no means a demonſtration that the inſtantaneous or ſhort-lived action of two forces would produce that motion; the man muſt continue to exert force in order to walk, and the ice is dragged along by the ſtream. Some indeed expreſs this proof in another way, ſaying, let a body deſcribe AB, while the ſpace in which this motion is performed is carried along AC. The ice may be carried along, and may, by friction, or otherwiſe, drag the man along with it; but a ſpace cannot be removed from one place to another, nor, if it could, would it take the man with it. Should a ſhip ſtart ſuddenly forward while a man is walking acroſs the deck, he would be left behind, and fall toward the ſtern. We muſt *ſuppoſe* a tranſverſe force, and we muſt *ſuppoſe* the compoſition of this force without proof. This is no demonſtration.

We apprehend that the demonſtration given above of this fundamental propoſition is unexceptionable, when the terms force and deflection are uſed in the abſtract ſenſe which we have affixed to them; and we hope, by theſe means, to maintain the rigour of mathematical diſcuſſion in all our future diſquiſitions on theſe ſubjects. The only circumſtance in it which can be the ſubject of diſcuſſion is, whether we have ſelected the proper meaſure and characteriſtic of a change of motion—We never met with any objection to it.

48 Objections to the demonſtration of n° 45. It will not apply to preſſures. But ſome have ſtill maintained, that it does not evidently appear, from theſe principles, that the motion which reſults from the joint action of two natural powers, whoſe known and meaſurable intenſities have the ſame proportions with AB and BC, and which alſo exert themſelves in thoſe directions, will produce a motion, having the direction and proportion of AD. They will not, if the velocities produced by theſe forces are not in the proportion of thoſe intenſities, but in the ſubduplicate ratio of them. Nay, they ſay, that it is not ſo. If a body be impelled along AC by one ſpring, and along AB by two ſprings equally ſtrong, it will not deſcribe the diagonal of a parallelogram, of which the ſide AB is double the ſide AC. Nay, they add, that an indefinite number of examples can be given where a body *does not* deſcribe the diagonal of the parallelogram by the joint action of two forces, which, ſeparately, would cauſe it to deſcribe the ſides. And, laſtly, they ſay that, at any rate, it does not appear evident to the mind, that two *incitements* to motion, having the directions and the ſame proportion of intenſity with that of the ſides of a parallelogram, actually generate a third, which is the immediate cauſe of the motion in the diagonal. An equivalent force is not the ſame with a reſulting force.

49. Yet we ſee numberleſs caſes of the compoſition of incitements to motion, and they ſeem as determinate, and as ſuſceptible of being combined by compoſition, as the things called moving forces, which are meaſured by the velocities: we ſee them actually ſo combined in a thouſand inſtances, as in the example already given of a lighter dragged by two horſes pulling in different directions. Nay, experiment ſhews, that this compoſition follows preciſely the ſame rule as the compoſition of the forces which are meaſured by the velocities; for if the point A (fig. 1.) be pulled by a thread, or preſſed by a ſpring, in the direction AB, and by another in the direction AC, and if the preſſures are proportional to AB and AC, then it will be withheld from moving, if it be pulled or preſſed by a third force, acting in the direction A *d*, oppoſite to AD, the preſſure being alſo proportional to AD. This force, acting in the direction A *d*, would certainly withſtand an equal force acting in the direction AD; therefore we muſt conclude, that the two preſſures AB and AC really generate a force AD. This uniform agreement ſhews that

that the compoſition is deducible from fixed principles; but it does not appear that it can be held as demonſtrated by the arguments employed in the caſe of motions. A demonſtration of the compoſition of preſſures is ſtill wanted, in order to render mechanics a demonſtrative ſcience.

This compoſition is of more difficult inveſtigation.

Accordingly, philoſophers of the firſt eminence have turned their attention to this problem. It is by no means eaſy; being ſo nearly allied to firſt principles, that it muſt be difficult to find axioms of greater ſimplicity by which it may be proved.

Mechanicians generally contented themſelves with the ſolution given by Ariſtotle; but this is merely a compoſition of motions: indeed he does not give it for any thing elſe, and calls it "συνθεσις των φυ αν." The firſt writer who appears to have conſidered it as different from the mere compoſition of motions, was the celebrated Dutch engineer Stevinus in his work *on Sluices*; but his ſolution is obſcure. It was ſufficient, however, to convince Daniel Bernoulli of the neceſſity and the difficulty of the problem. He has given the firſt complete demonſtration of it in the firſt volume of the Commentaries of the Imperial Academy of Sciences at St Peterſburgh. It is extremely ingenious; but it is tedious and intricate, requiring a ſeries of 15 propoſitions to demonſtrate that two preſſures, having the directions and magnitudes of the ſides of any parallelogram, compoſe a third, which has the direction and magnitude of its diagonal. His firſt propoſition is, that *two equal preſſures, acting at right angles, compoſe a third, in the direction of the diagonal of a ſquare, and having to either of the other two the proportion of the diagonal of a ſquare to its ſides.*

Mr D'Alembert has greatly ſimplified and improved this demonſtration, by beginning with a caſe that is ſelf-evident; namely, *If three equal forces are inclined to each other in equal angles of* 120 *degrees, any one of them will balance the combined action of the other two.* Surely; for neither of them can prevail. Therefore *two* equal forces, inclined in an angle of 120 degrees, produce a third, which has the direction and proportion of the diagonal of the rhombus; for this is equal and oppoſite to one of the three above mentioned. He then demonſtrates the ſame thing of two equal forces inclined in *any* angle; and by a ſeries of eight propoſitions more, demonſtrates the general theorem. This diſſertation is in the Memoirs of the Academy at Paris for 1769. He improves it ſtill farther in a ſubſequent memoir.

Mr Riccati and Mr Fonſenex, in the Commentaries of the Academy of Turin, have given analytical demonſtrations, which are alſo very ingenious and conciſe, but require acquaintance with the higher mathematics.—There is another very ingenious demonſtration in the *Journal des Sçavans* for June 1764, but too obſcure for an elementary propoſition. It is ſomewhat ſimplified by Belidor in his *Ingenieur François*. Friſius, in his *Coſmographia*, has given one, which is perhaps the beſt of all thoſe that are eaſily comprehended without acquaintance with the higher mathematics: but we imagine that, although no one can doubt of the concluſion, it has not that intuitive evidence for every ſtep of the proceſs that ſeems neceſſary.

50 *Compoſition of preſſures.*

We here offer another, compoſed by blending together the methods of Bernoulli and D'Alembert; and we imagine that no objection can be made to any ſtep of it. We limit it entirely to preſſures, and do not at all conſider nor employ the motions which they may be ſuppoſed to produce.

(A) If two equal and oppoſite preſſures or incitements to motion act at once on a material particle, it ſuffers no change of motion; for if it yields in either direction by their joint action, one of the preſſures prevails, and they are not equal.

Equal and oppoſite preſſures are ſaid TO BALANCE each other; and ſuch as balance muſt be eſteemed equal and oppoſite.

(B) If a and b are two magnitudes of the ſame kind, proportional to the intenſities of two preſſures which act in the ſame direction, then the magnitude $a+b$ will meaſure the intenſity of the preſſure, which is equivalent, and may be called equal, to the combined effort of the other two; for when we try to form a notion of preſſure as a meaſurable magnitude, diſtinct from motion or any other effect of it, we find nothing that we can meaſure it by, but another preſſure. Nor have we any notion of a double or triple preſſure different from a preſſure that is equivalent to the joint effort of two or three equal preſſures. A preſſure a is accounted triple of a preſſure b, if it balances three preſſures, each equal to b, acting together. Therefore, in all proportions which can be expreſſed by numbers, we muſt acknowledge the legitimacy of this meaſurement; and it would ſurely be affectation to omit thoſe which the mathematicians call *incommenſurable*.

In like manner, the magnitude $a-b$ muſt be acknowledged to meaſure that preſſure which ariſes from the joint action of two preſſures a and b acting in oppoſite directions, of which a is the greateſt.

(C) Let ABCD and $AbCd$ (fig. A) be two rhombuſes, which have the common diagonal AC. Let the angles BAb, DAd, be biſected by the ſtraight lines AE and AF.

If there be drawn from the points E and F the lines EG, EH, Fg, Fh, making equal angles on each ſide of EA and FA, and if Gg, Hh be drawn, cutting the diagonal AC in I and L: then AI + AL will be greater or leſs than AQ, the half of AC, according as the angles GEH, gFh, are greater or leſs than GAH, gAh.

Draw GH, gh, cutting AE, AF, in O and o, and draw Oo, cutting AC in K.

Becauſe the angles AEG and EAG are reſpectively equal to AEH and EAH, and AE is common to both triangles, the ſides AG, GE are reſpectively equal to AH, HE, and GH is perpendicular to AE, and is biſected in O; for the ſame reaſons, gh is biſected in o. Therefore the lines Gg, Oo, Hh, are parallel, and IL is biſected in K. Therefore AI + AL is equal to twice AK. Moreover, if the angle GEH be greater than GAH, AO is greater than EO, and AK is greater than KQ. Therefore AI + AL is greater than AQ; and if the angle GEH be leſs than GAH, AI + AL is leſs than AQ.

(D) Two equal preſſures, acting in the directions AB and AC (fig. 2.), at right angles to each other, compoſe a preſſure in the direction AD, which biſects the right angle; and its intenſity is to the intenſity of each of the conſtituent preſſures as the diagonal of a ſquare to one of the ſides. It is evident that the direction of the preſſure, generated by their joint action,

will

will biſect the angle formed by their directions; becauſe no reaſon can be aſſigned for the direction inclining more to one ſide than to the other.

In the next place, ſince a force in the direction AD does, in fact, ariſe from the joint action of the equal preſſures AB and AC, the preſſure AB may be conceived as ariſing from the joint action of two equal forces ſimilarly inclined and proportioned to it. Draw EAF perpendicular to AD. One of theſe forces muſt be directed along AD, and the other along AE. In like manner, the preſſure AC may ariſe from the joint action of a preſſure in the direction AD, and an equal preſſure in the direction AF. It is alſo plain, that the preſſures in the directions AE and AF, and the two preſſures in the direction AD, muſt be all equal. And alſo, any one of them muſt have the ſame proportion to AB or to AC, that AB or AC has to the force in the direction AD, ariſing from their joint action.

Therefore, if it be ſaid that AD does not meaſure the preſſure ariſing from the joint action of AB and AC, let A *d*, greater than AD, be its juſt meaſure, and make A *d* : AB = AB : A *g* = AB : A *e*. Then A *g* and A *e* have the ſame inclination and proportion to AB that AB and AC have to A *d*. We determine, in like manner, two forces A *f* and A *g* as conſtituents of AC.

Now A *d* is equivalent to AB and AC, and AB is equivalent to A *e* and A *g*; and AC is equivalent to A *f* and A *g*. Therefore A *d* is equivalent to A *e*, A *f*, A *g*, and A *g*. But (A) A *e* and A *f* balance each other, or annihilate each other's effect; and there remain only the two forces or preſſures A *g*, A *g*. Therefore (B) their meaſure is a magnitude equal to twice A *g*. But if A *d* be greater than the diagonal AD of the ſquare, whoſe ſides are AB and AC; then A *g* muſt be leſs than AI, the ſide of the ſquare whoſe diagonal is AB. But twice A *g* is leſs than AD, and much leſs than A *d*. Therefore the meaſure of the equivalent of AB and AC cannot be a line A *d* greater than AD. In like manner, it cannot be a line A *δ* that is leſs than AD. Therefore it muſt be equal to AD, and the propoſition is demonſtrated.

(E) *Cor.* Two equal forces AB, AC, acting at right angles, will be balanced by a force AO, equal and oppoſite to AD, the diagonal of the ſquare whoſe ſides are AB and AC; for AO would balance AD, which is the equivalent of AB and AC.

(F) Let AECF (fig. 3.) be a rhombus, the acute angle of which EAF is half of a right angle. Two equal preſſures, which have the directions and meaſures AE, AF, compoſe a preſſure, having the direction and meaſure AC, which is the diagonal of the rhombus.

It is evident, in the firſt place, that the compound force has the direction AC, which biſects the angle EAF. If AC be not its juſt meaſure, let it be AP leſs than AC. Let ABCD be a ſquare deſcribed on the ſame diagonal, and make AP : AQ = AE : AO, = AF : A *o*. Draw KOG, K *o g* perpendicular to AE, AF; draw GI *g*, OH *o*, EG, EK, F *g*, FK, PF, and PE.

The angles CAB and FAE are equal, each being half of a right angle. Alſo the figures AEPF and AGEK are ſimilar, becauſe AP : AQ = AE : AO. Therefore FA : AP = KA : AE, and EA : AP = GA : AE. Therefore, in the ſame manner that the forces AE, AF are affirmed to compoſe AP, the forces AG and AK may compoſe the force AE, and the forces A *g* and AK may compoſe the force AF. Therefore (B) the force AP is equivalent to the four forces AG, AK, A *g*, AK. But (D) AG and A *g* are the ſides of a ſquare, whoſe diagonal is equal to twice AI: and the two forces AK, AK are equal to, or are meaſured by, twice AK. Therefore the four forces AG, AK, A *g*, AK, are equivalent to 2 AI + 2 AK, = 4 AH.

But becauſe AP was ſuppoſed leſs than AC, the angle FPE is greater than FAE, and GEK is greater than GAK, AO is greater than OE, and AH is greater than HQ, and 2 AH is greater than AQ; and therefore 4 AH is greater than AC, and much greater than AP. Therefore AP is not the juſt meaſure of the force compoſed of AE and AF.

In like manner, it is ſhewn, that AE and AF do not compoſe a force whoſe meaſure is greater than AC. It is therefore equal to AC; and the propoſition is demonſtrated.

(G) By the ſame proceſs it may be demonſtrated, that if BAD be half a right angle, and EAF be the fourth of a right angle, two forces AE, AF will compoſe a force meaſured by AC. And the proceſs may be repeated for a rhombus whoſe acute angle is $\frac{1}{8}$th, $\frac{1}{16}$th, &c. of a right angle; that is, any portion of a right angle that is produced by continual biſection. Two forces, forming the ſides of ſuch a rhombus, compoſe a force meaſured by the diagonal.

(H) Let ABCD, A *b c d* (fig. 4.) be two rhombuſes formed by two conſecutive biſections of a right angle. Let AECF be another rhombus, whoſe ſides AE and AF biſect the angles BA *b* and DA *d*.

The two forces AE, AF, compoſe a force AC.

Biſect AE and AF in O and *o*. Draw the perpendiculars GOH, *g o h*, and the lines GI *g*, OK *o*, HL *h*, and the lines EG, EH, F *g*, F *h*.

It is evident, that AGEH and A *g* F *h* are rhombuſes; becauſe AO = OE, and A *o* = *o* F. It is alſo plain, that ſince *b* A *d* is half of BAD, the angle GAH is half of *b* A *d*. It is therefore formed by a continual biſection of a right angle. Therefore (G) the forces AG, AH, compoſe a force AE; and A *g*, A *h*, compoſe the force AF. Therefore the forces AG, AH, A *g*, A *h*, acting together, are equivalent to the forces AE, AF acting together. But AG, A *g* compoſe a force = 2 AI; and the forces AH, A *h* compoſe a force = 2 AL. Therefore the four forces acting together are equivalent to 2 AI + 2 AL. or to 4 AK. But becauſe AO is $\frac{1}{2}$ AE, and the lines G *g*, O *o*, H *h*, are evidently parallel, 4 AK is equal to 2 AQ, or to AC; and the propoſition is demonſtrated.

(I) *Cor.* Let us now ſuppoſe, that by continual biſection of a right angle we have obtained a very ſmall angle *a* of a rhombus; and let us name the rhombus by the multiple of *a* which forms its acute angle.

The propoſition (G) is true of *a*, 2 *a*, 4 *a*, &c. The propoſition (H) is true of 3 *a*. In like manner, becauſe (G) is true of 4 *a* and 8 *a*, propoſition (H) is true of 6 *a*; and becauſe it is true of 4 *a*, 6 *a*, and 8 *a*, it is true of 5 *a* and 7 *a*. And ſo on continually till we have demonſtrated it of every multiple of *a* that is leſs than a right angle.

(K) Let RAS (fig. 5.) be perpendicular to AC, and

and let ABCD be a rhombus, whoſe acute angle BAD is ſome multiple of 2 a that is leſs than a right angle. Let A b c d be another rhombus, whoſe ſides A b, A d biſect the angles RAB, SAD. Then the forces A b, A d compoſe a force AC.

Draw bR, dS parallel to BA, DA. It is evident, that AR b B and AS d D are rhombuſes, whoſe acute angles are multiples of a that are each leſs than a right angle. Therefore (I) the forces AR and AB compoſe the force A b, and AS, AD compoſe A d; but AR and AS annihilate each other's effect, and there remains only the forces AB, AD. Therefore A b and A d are equivalent to AB and AD, which compoſe the force AC; and the propoſition is demonſtrated.

(L) *Cor.* Thus is the corrollary of laſt propoſition extended to every rhombus, whoſe angle at A is ſome multiple of a leſs than two right angles. And ſince a may be taken leſs than any angle that can be named, the propoſition may be conſidered as demonſtrated of every rhombus: and we may ſay,

(M) *Two equal forces, inclined to each other in any angle, compoſe a force which is meaſured by the diagonal of the rhombus, whoſe ſides are the meaſures of the conſtituent forces.*

(N) Two forces AB, AC (fig. 6.), having the direction and proportion of the ſides of a rectangle, compoſe a force AD, having the direction and proportion of the diagonal.

Draw the other diagonal CB, and draw EAF parallel to it; draw BE, CF parallel to DA.

AEBG is a rhombus; and therefore the forces AE and AG compoſe the force AB. AFCG is alſo a rhombus, and the force AC is equivalent to AF and AG. Therefore the forces AB and AC, acting together, are equivalent to the forces AE, AF, AG, and AG acting together, or to AE, AF, and AD acting together: But AE and AF annihilate each other's action, being oppoſite and equal (for each is equal to the half of BC). Therefore AB and AC acting together, are equivalent to AD, or compoſe the force AD.

(O) Two forces, which have the direction and proportions of AB, AC (fig. 7.) the ſides of any parallelogram, compoſe a force, having the direction and proportion of the diagonal AD.

Draw AF perpendicular to BD, and BG and DE perpendicular to AC.

Then AFBG is a rectangle, as is alſo AFDE; and AG is equal to CE. Therefore (N) AB is equivalent to AF and AG. Therefore AB and AC acting together, are equivalent to AF, AG, and AC acting together; that is, to AF and AE acting together; that is (N) to AD; or the forces AB and AC compoſe the force AD.

Hence ariſes the moſt general propoſition,

51
Compoſition of all incitements to motion.

If a material particle be urged at once by two preſſures or incitements to motion, whoſe intenſities are proportional to the ſides of any parallelogram, and which act in the directions of thoſe ſides, it is affected in the ſame manner as if it were acted on by a ſingle force, whoſe intenſity is meaſured by the diagonal of the parallelogram, and which acts in its direction: Or, two preſſures, having the direction and proportion of the ſides of a parallelogram, generate a preſſure, having the direction and proportion of the diagonal.

52
Seeming difference of the compoſitions of motion and of preſſure diſappear when carefully examined.

Thus have we endeavoured to demonſtrate from abſtract principles the perfect ſimilarity of the compoſition of preſſures, and the compoſition of forces meaſured by the motions which they produce. We cannot help being of the opinion, that a ſeparate demonſtration is indiſpenſably neceſſary. What may be fairly deduced from the one caſe, cannot always be applied to the other. No compoſition of preſſures can explain the change produced by a deflecting force on a motion already exiſting; for the changing preſſure is the only one that exiſts, and there is none to be compounded with it. And, on the other hand, our notions and obſervations of the compoſition of motions will not explain the compoſition of preſſures, unleſs we take it for granted that the preſſures are proportional to the velocities; but this is perhaps a gratuitous aſſumption. At any rate, it is not an intuitive propoſition; and we have mentioned ſome facts where it ſeems that they do not follow the ſame proportion. The preſſure of four equal ſprings produces only a double velocity. It would appear, therefore, that there are circumſtances which oblige us to ſay, that the *exertion* of preſſure, as a cauſe of motion, is not (always at leaſt) proportional to the real meaſurable preſſure. We are therefore anxious to diſcover in what the difference conſiſts; and in the mean time muſt allow, that the preſſure exerted on a body at reſt is different from its exertion in producing motion. We cannot indeed ſtate any immediate compariſon between preſſure and motion, nor have we any clear conception of the connection between them. It is only by our ſenſations of touch that we have any notion of preſſure, and it is experience that teaches us that it always accompanies every cauſe of motion. We can, however, obſerve the proportions of preſſures, and compare them with the proportions of motion. We very often obſerve them different; and therefore it was indiſpenſably neceſſary to inveſtigate the laws of combined preſſure as we did the laws of combined motion in conſequence of preſſure. Yet we ſhould err, if we haſtily aſſerted that preſſures are not proportional to the motions which they produce; all that we are intitled to call in doubt is, whether the preſſures in their exertion, while they actually produce motion, or changes of motion, continue to be the ſame as when they do not produce motion, being withſtood or balanced by oppoſite preſſures. Conſidered as cauſes of motion, we ought to think that they do not vary while they produce motion, and that the actual preſſure, while it produces a double motion, is really double, although it may be quadruple when the body exerting it is made to act on a body that it cannot move. We are confirmed in this opinion by obſerving, that other facts ſhew us, that even while producing motion, the preſſure which we call quadruple, becauſe we have meaſured it by four equal preſſures balancing it, is really quadruple, conſidered as the cauſe of motion, and produces a quadruple motion. A bow which requires four times the force to draw it to any given extent, will communicate the ſame velocity to a bundle of four arrows that a bow four times eaſier drawn communicates to one arrow, and will therefore produce a quadruple motion. Yet it will only produce a double velocity in the arrow that acquired a ſimple velocity from a bow having one fourth of the ſtrength.

Theſe diſcrepancies ſhould excite the endeavours of mechanicians to inveſtigate the laws obſerved in the action of preſſures in producing motion. Had this been done with care and with candour, we ſhould not have had

had the great difference of opinion, which ſtill divides philoſophers, about the meaſures of moving forces. But a ſpirit of party, which had ariſen from other cauſes, gave importance to what was at firſt only a difference of expreſſion, and made the partiſans of Mr Leibnitz avail themſelves of the figurative language which has done ſo much harm in all the departments of philoſophy. Notwithſtanding all our caution, it is hardly poſſible to avoid metaphorical conceptions when we employ the language of metaphor. The abettors of the Leibnitzian meaſure of moving forces, or perhaps, to ſpeak more properly, the abettors of the Leibnitzian meaſure of that force which is ſuppoſed to preſerve bodies in their condition of motion—inſiſt, that the force which is exerted in producing any change of motion is greater in proportion as the motion changed is greater: and they give a very ſpecious argument for their aſſertion. They appeal to the exertions which we ourſelves make. Here we are conſcious of the fact. Then they give ſimilar examples of the action of bodies. A clay ball, moving ſix feet per ſecond, will make the addition of one foot to the velocity of an equal clay ball that is already moving four feet per ſecond in the ſame direction. But if this laſt ball be already moving ten feet per ſecond, we muſt follow it with a velocity of twelve feet in order to increaſe its velocity one foot. But, without inſiſting on the numberleſs paralogiſms and inconſiſtencies which this way of conceiving the matter would lead us into, it ſuffices to obſerve, that the phenomena give us abundant aſſurance that there has been the ſame exertion in both theſe caſes. This acceleration is always accompanied by a compreſſion of the balls, and the compreſſion is the ſame in both. This compreſſion is a very good meaſure of the force employed to produce it; and in the preſent caſe, we need not even trouble ourſelves with any rule for its meaſurement: for ſurely when the compreſſion is not different, but the ſame, the force exerted is the ſame. This is farther confirmed by obſerving, that it requires the ſame force to make the ſame pit, or to give the ſame motion, to a piece of clay lying on the table of a ſhip's cabin, whether the ſhip be ſailing two miles or ten miles per hour.

Thus we ſee that there are ſtrong reaſons for believing, that the exertions of preſſure in producing motion, or that the preſſures *actually exerted*, are proportional to the changes of motion obſerved, and that they coincide in this reſpect with our abſtract conceptions of moving forces.

But we have ſtill better arguments. None of the Leibnitzians think of denying the equal exertions of gravity, or of any of thoſe powers which they call *ſolicitations* or *accelerating forces*. They all admit, that gravity, or any conſtant accelerating force, produces equal increments of velocity in equal times, and that a double gravity will produce a double increment in an equal time, and an equal increment in half of the time; and that a quadruple gravity will produce a double velocity in half the time. All theſe things are granted by them, and their writings are full of reaſonings from this principle. Now from the fact, acknowledged by the Leibnitzians, that the quadruple force of a bow gives a double velocity to the arrow, in every inſtant of its action, it indiſputably follows, that it has acted on it only for half the time of the action of the four times weaker bow, which gives the arrow only half the velocity; and thus has the diſcrepancy between the effects of preſſures and of our abſtract moving forces entirely diſappeared. For this circumſtance of the difference in the time of acting will be found, on ſtrict examination, in all the caſes of the change of motion by preſſures which we meaſure by their effects on a body at reſt. When this and the appreciable changes of actual preſſure, during the time of producing the motion, are taken into conſideration, all difference vaniſhes, and the compoſition of preſſures is in perfect harmony with the compoſition of motions, or of abſtract moving forces. DYNAMICS is thus made a demonſtrative ſcience, and affords the opportunity of inveſtigating, by obſervation and experiment, the nature of thoſe mechanical powers which reſide in bodies, and which appear to us under the form of preſſure, inducing us to conſider preſſure as a cauſe of motion.

In this, however, we are rather inaccurate. Preſſure is one of the ſenſible effects of that property which is alſo the cauſe of motion. It is not the preſſure of a piece of lead, but its heavineſs, that is the reaſon that it gives motion to a kitchen jack. Preſſure is merely a generic name, borrowed from a familiar inſtance, and given to moving forces, which have the ſame nature, but different names that ſerve to mark their connection with certain ſubſtances, in which they may be ſuppoſed to reſide. Natural philoſophy is almoſt entirely employed in examining the nature of theſe various preſſures or accelerative forces; and the general doctrines of dynamics, by aſcertaining what is common to them all, enable us to mark with preciſion what is characteriſtic of each.

53
General corollaries.

We have now advanced very far in this inveſtigation; for we have obtained the criterion by which we learn the direction and the magnitude of every changing force: and, on the other hand, we ſee how to ſtate what will be the effect of the exertion of any force that is known or ſuſpected to act. All this we learn by the compoſition of forces; and the greateſt part of mechanical diſquiſition conſiſts in the application of this doctrine. For ſuch reaſons it merits minute conſideration; and therefore we muſt point out ſome general concluſions from the properties of figure, which will greatly facilitate the uſe of the parallelogram of forces.

1. The conſtituent and the reſulting forces, or the ſimple and compound forces, act in the ſame plane; for the ſides and diagonal of a parallelogram are in one plane. 54.

2. The ſimple and the compound forces are proportional to the ſides of any triangle which are parallel to their directions. For if any three lines, *ab*, *bd*, *ad*, be drawn parallel to AB, AC, and AD (fig. 7, n° 2.), they will form a triangle ſimilar to the triangle ABD. For the ſame reaſons they are proportional to the ſides of a triangle *a'b'd*, which are reſpectively perpendicular to their directions. 55.

3. Therefore each is proportional to the ſine of the oppoſite angle of this triangle; for the ſides of any triangle are proportional to the ſines of the oppoſite angles. 56.

4. Each is proportional to the ſine of the angle contained by the directions of the other two; for AD is to AB as the ſine of the angle ABD to the ſine of the angle ADB. Now the ſine of ABD is the ſame with 57.

with the ſine of BAC contained between the directions AB and AC, and the ſine of ADB is the ſame with the ſine of CAD; alſo AB is to AC, or BD, as the ſine of ADB (or CAD) to the ſine of BAD.

58 Some ſpecial uſes of the parallelogram of forces.

We now proceed to the application of this fundamental propoſition. And we obſerve, in the firſt place, that ſince AD may be the diagonal of an indefinite number of parallelograms, the motion or the preſſure AD may reſult from the joint action of many pairs of forces. It may be produced by forces which would ſeparately produce the motions AF and AG. This generally gives us the means of diſcovering the forces which concur in its production. If one of them, AB, is known in direction and intenſity, the direction AC, parallel to BD, and the intenſity, are diſcovered. Sometimes we know the directions of both. Then, by drawing the parallelogram or triangle, we learn their proportions. The force which deflects any motion AB into a motion AD, is had by ſimply drawing a line from the point B (to which the body would have moved from A in the time of really moving from A to D) to the point D. The deflecting force is ſuch as would have cauſed the body move from B to D in the ſame time. And, in the ſame manner, we get the compound motion AD, which ariſes from any two ſimple motions AB and AC, by ſuppoſing both of the motions to be accompliſhed in ſucceſſion. The final place of the body is the ſame, whether it moves along AD or along AB and BD in ſucceſſion.

59 Equivalent of many forces.

This theorem is not limited to the compoſition of two motions or two forces only; for ſince the combined action of two forces puts the body into the ſame ſtate as if their equivalent alone had acted on it, we may ſuppoſe this to have been the caſe, and then the action of a third force will produce a change on this equivalent motion. The reſulting motion will be the ſame as if only this third force and the equivalent of the other two had acted on the body. Thus, in fig. 8. the three forces AB, AC, AE, may act at once on a particle of matter. Complete the parallelogram ABDC; the diagonal AD is the force which is generated by AB and AC. Complete the parallelogram AEFD; the diagonal AF is the force reſulting from the combined action of the forces AB, AC, and AE. In like manner, completing the parallelogram AGHF, the diagonal AH is the force reſulting from the combined action of AB, AC, AE, and AG, and ſo on of any number of forces.

Plate XXII.

This reſulting force and the reſulting motion may be much more expeditiouſly determined, in any degree of compoſition, by drawing lines in the proportion and direction of the forces in ſucceſſion, each from the end of the preceding. Thus, draw AB, BD, DF, FH, and join AH; AH is the reſulting force. The demonſtration is evident.

60.

It is to be noticed here, that in the compoſition of more than two forces, we are not limited to one plane. The force AD is in the ſame plane with AB and AC; but AE may be elevated above this plane, and AG may lead below it. AF is in the plane of AD and AE, and AH is in the plane of AF and AG.

Complete the parallelograms ABLE, ACKE, ELFK. It is evident that ABLFKCD is a parallelopiped, and that AF is one of its diagonals. Hence we derive a more general theorem of great uſe.

Three forces having the proportion and direction of the three ſides of a parallelopiped, compoſe a force having the proportion and direction of the diagonal.

61 One force may balance many acting together.

Any number of forces acting together on one particle of matter are balanced by a force that is equal and oppoſite to their reſulting force; for this force would balance their reſulting force which is equivalent to them in action. When this is duly conſidered, we perceive that each force is then in equilibrio with the equivalent of all the others; for a force can balance only what is equal and oppoſite to it. It appears very readily by the geometrical conſtruction. If, inſtead of the circuit A, B, D, F, H, we take B, D, F, H, A, we have BA for the equivalent of the forces AC, AE, AG; but AB is equal and oppoſite to BA. Therefore the force AB is in equilibrio with the equivalent of all the others.

62.

When any number of forces act on one particle of matter, and are in equilibrio, if they be conſidered as acting in parcels, the equivalents of theſe parcels are in equilibrio; for let the forces AB, AC, AE, AG, A*h*, be in equilibrio, and let them be conſidered in the two parcels AB, AC, and AE, AG, A*h*; then AD is the equivalent of AB, BD (or AC), and DA is the equivalent of DF, FH, HA (or A*h*): now AD and DA balance each other. This corollary enables us to ſimplify many intricate complications of force; it alſo enables us to draw accurate concluſions from very imperfect obſervations. In moſt of our practical diſcuſſions we know, or at leaſt we attend to, a part only of the forces which are acting on a material particle; and in ſuch caſes we reaſon as if we ſaw the whole: yet is our mathematical reaſoning good with reſpect to the equivalent of all the parcels which we are contemplating, and the equivalents of the ſmaller parcels of which it conſiſts; and the neglected force, or parcel of forces, induces no error on our concluſions.

63. Expeditious methods for obtaining the reſulting motion in complicated caſes.

In the ſpontaneous phenomena of nature, the inveſtigation and diſcovery of our ultimate object of ſearch is frequently very difficult, on account of the multiplicity of directions and intenſities of the operating forces or motions. We may generally facilitate the proceſs, by ſubſtituting equivalent forces or motions acting in convenient directions. It is in this way that the navigator computes the ſhip's place with very little trouble, by ſubſtituting equivalent motions in the meridional and equatoreal directions for the real oblique courſes of the ſhip. Inſtead of ſetting down ten miles on a courſe, S. 36. 52. W. he ſuppoſes that the ſhip has ſailed eight miles due ſouth, and ſix miles due weſt, which brings her near to the ſame place. Then, inſtead of fourteen miles ſouth-weſt, he ſets down ten miles ſouth and ten miles weſt; and he proceeds in the ſame way for every other courſe and diſtance. He does this expeditiouſly by means of a traverſe table, in which are ready calculated the meridional and equatoreal ſides of right angled triangles, correſponding to every courſe and diſtance. Having done this for the courſe of a whole day, he adds all the ſouthings into one ſum and all the weſtings into another: he conſiders theſe as forming the ſides of a right angled triangle; he looks for them, paired together, in his traverſe table, and then notices what angle and what diſtance correſponds to this pair. This gives him the poſition and magnitude of the ſtraight line joining the beginning and end of his day's work.

Second Law of Motion.

The miner proceeds in the ſame way when he takes the plan of ſubterraneous workings, meaſuring, as he goes along, and noticing the bearing of each line by the compaſs, and ſetting down, from his traverſe table, the northing or ſouthing, and the eaſting or weſting, for each oblique line: but there is another circumſtance which he muſt attend to, namely, the ſlope of the various drifts, galleries, and other workings. This he does by noting the riſe or the dip of each ſloping line. He adds all theſe into two ſums; and taking the riſings from the dips, he obtains the whole dip. Thus he learns how far the workings proceed to the north, how far to the eaſt, and how far to the dip.

The reflecting reader will perceive that the line joining the two extremities of this progreſſion will form the diagonal of a rectangular parallelopiped; one of whoſe ſides lies north and ſouth, the other lies eaſt and weſt, and the third is right up and down.

The mechanician proceeds in the very ſame way in the inveſtigation of the very complicated phenomena which frequently engage his attention. He conſiders every motion as compounded of three motions in ſome convenient directions, at right angles to each other. He alſo conſiders every force as reſulting from the joint action of three forces, at right angles to each other, and takes the ſum or difference of theſe in the ſame or oppoſite directions. From this proceſs he obtains the three ſides of a parallelopiped, and from theſe computes the poſition and magnitude of the diagonal. This is the motion or force reſulting from the compoſition of all the partial ones.

Forces may be eſtimated by, or reduced to,

This procedure is called the Estimation or Reduction of motions and forces.

64
A given direction,

A motion or force AB (fig. 9.) is ſaid to be *eſtimated* in the direction EF, or to be *reduced* to this direction when it is conceived as compounded of the motions or forces AC, AD, one of which AC is parallel to EF, and the other AD is perpendicular to it. This expreſſion is abundantly ſignificant; for it is plain that the motion AD neither promotes nor hinders the progreſs along EF, and that AC expreſſes the whole progreſs in this direction.

65
Or a given plane.

In like manner, a force AB (fig. 10.) is ſaid to be *eſtimated in*, or *reduced to*, a given plane EFGH, when it is conceived as reſulting from the joint action of two forces AC, AD, one of which is parallel to a line *a b* drawn in that plane, and the other AD is perpendicular to it. The poſition of the line *a b* is determined by letting fall B *b* perpendicular to the plane, and drawing *b* P to the point P, in which BA meets the plane; then A *a* heing drawn parallel to B *b*, will cut off *b a*, which is the reduction of the motion AB to the plane. Drawing C parallel to *a b*, and completing the parallelogram ACBD, it is evident that the motion AB is equivalent to AD and AC, which is parallel to *a b*, and the three forces AB, AC, AD, are, as they ſhould be, in one plane perpendicular to the plane EG.

66
Equilibrium of forces ſo eſtimated or reduced.

If three forces AB, AC, AD (fig. 11.), are in equilibrio, and are reduced to any one direction *d* A *l*, or to one plane EFGH, the reduced forces are alſo in equilibrio.

Firſt, Let them be reduced to one direction *d l* by drawing the perpendiculars B *b*, C *c*, D *d*; make AL equal to AD, and join BL, CL, and draw the perpendiculars L *l*, C *c*; then, becauſe the forces AB, AC, AD, are in equilibrio, ABLC muſt be a parallelogram, and AL is the force equivalent to AB and AC combined; then, becauſe the lines D *d*, B *b*, C *c*, L*l*, are parallel, *d* A is equal to A *l*, and A *b* to C *o*, or to *c l*; therefore A *l* is equal to the ſum of A *b* and A *c*, which are the reductions of AB and AC; therefore *d* A is equal to the ſame ſum, and in equilibrio with them.

Second Law of Motion.

Secondly, Let them be reduced to one plane EFGH, and let $\alpha\beta$, $\alpha\kappa$, $\alpha\delta$, be the reduced forces. The lines D δ, A α, B β, C κ, L λ, are all parallel, being perpendicular to the plane; therefore the planes AB $\beta\alpha$ and CL $\lambda\kappa$ are parallel, and $\alpha\beta$, $\kappa\lambda$, are parallel. For ſimilar reaſons $\beta\lambda$, $\alpha\kappa$, are parallel; therefore $\alpha\beta\lambda\kappa$ is a parallelogram. Alſo, becauſe the lines D δ, A α, L λ, are parallel, and DA is equal to AL; therefore $\delta\alpha$ is equal to $\alpha\lambda$. But becauſe $\alpha\beta\lambda\kappa$ is a parallelogram, the forces $\alpha\beta$, $\alpha\kappa$, are equivalent to $\alpha\lambda$; and $\alpha\delta$ is equal and oppoſite to $\alpha\lambda$, and will balance it; and therefore will balance $\alpha\beta$ and $\alpha\kappa$, which are the reductions of AB and AC to the plane EFGH, while $\alpha\delta$ is the reduction of AD; therefore the propoſition is demonſtrated.

The moſt uſeful mode of reduction to their co-ordinates.

The moſt uſual and the moſt uſeful mode of reduction is to eſtimate all forces in the directions of three lines drawn from one point, at right angles to each other, like the three plane angles of a rectangular cheſt, forming the length, the breadth, and the depth of the cheſt. Theſe are commonly called the three co ordinates. The reſulting force will be the diagonal of this parallelopiped. This proceſs occurs in all diſquiſitions in which the mutual action of ſolids and fluids is conſidered, and when the oſcillation or rotation of detached free bodies is the ſubject of diſcuſſion.

67
Relative motions of bodies not affected by any extraneous equal and parallel force.

The only other general theorem that remains to be deduced from this law of motion is, that if a number of bodies are moving in any manner whatever, and an equal force act on every particle of matter in the ſame or parallel directions, their relative motions will ſuffer no change; for the motion of any body A (fig. 12.), relative to another body B, which is alſo in motion, is compounded of the real motion of A, and the oppoſite to the real motion of B; for let A move uniformly from A to C, while B deſcribes BD uniformly, draw AB, alſo draw AE equal and parallel to BD, join EC, DC, ED. The motion of A, relative to B, conſiſts in its change of poſition and diſtance. Had A deſcribed AE, while B deſcribed BD, there would have been no change of relative place or diſtance; but A is now at C, and DC is its new direction and diſtance. The relative or apparent motion of A therefore is EC. Complete the parallelogram ACFE; it is plain that the motion EC is compounded of EF, which is equal and parallel to AC, the real motion of A, and of EA, the equal and oppoſite to BD, the real motion of B.

Now let the motions of A and B ſuſtain the ſame change; let the equal and parallel motions AG, BH, be compounded with the motions AC and BD; or let forces act at once on A and B, in the parallel directions AG, BH, and with equal intenſities; in either ſuppoſition, the reſulting motions will be A *c*, B *d*, the diagonals of the parallelograms A G *c* C, and B H *d* D. Conſtruct the figure as before, and we ſee that the relative motion is now *e c*, and that it is the ſame with EC both in reſpect of magnitude and poſition.

Here we ſtill ſee the conſtant analogy between the compoſition of motions and the compoſition of forces.

In the firſt caſe, the relative motions of things are not changed, whatever common motion be compounded with them all; or, as it is uſually, but inaccurately, expreſſed, although the ſpace in which they move be carried along with any motion whatever. In the ſecond caſe, the relative motions and actions are not changed by any external force, however great, when equally exerted on every particle in parallel directions.

Thus it is that the evolutions of a fleet in a uniform current are the ſame, and produced by the ſame means, as in ſtill water. Thus it is that we walk about on the ſurface of this globe in the ſame manner as if it neither revolved round the ſun, nor turned round its axis. Thus it is that the ſame ſtrength of a bow will communicate a certain velocity to an arrow, whether it is ſhot eaſt, or weſt, or north, or ſouth. Thus it is that the mutual actions of ſublunary bodies are the ſame, in whatever directions they are exerted, and notwithſtanding the very great changes in their velocities by reaſon of the earth's rotation and orbital revolution. The real velocity of a body on the earth's equator is about 3000 feet per ſecond greater at midnight than at midday. For at midnight the motion of rotation nearly conſpires with the orbital motion, and at midday it nearly oppoſes it. The difference between the velocities at the beginning of January and the beginning of July is vaſtly greater. And at other times of the day, and other ſeaſons of the year, both motions of the earth are tranſverſely compounded with the eaſterly or weſterly motion of an arrow or cannon bullet. Yet we can obſerve no change in the effects of the mutual actions of bodies.

68
This affords a demonſtration of the proportionality of moving forces to the motions produced by them,

This is an important obſervation; becauſe it proves that forces are to be meaſured by no other ſcale than by the motions which they produce. We have had repeated occaſions to mention the very different eſtimation of moving forces by Mr Leibnitz; and have ſhewn how, by a very partial conſideration of the action of thoſe natural powers called *preſſures*, he has attempted to prove that moving forces are proportional to the ſquares of the velocities; and we ſhewed briefly, in what manner a right conſideration of what paſſes when motion is produced by meaſurable preſſures, proves that the forces really exerted are as the velocities produced. But the moſt copious proof is had from the preſent obſervation, that, in fact, the mutual actions of bodies depend on their relative motions alone.

69
And is incompatible with their proportionality to the ſquares of thoſe motions.

The Leibnitzian meaſure of moving force is altogether incompatible with the univerſal fact now mentioned, *viz.* that the relative motions of bodies, reſulting from their mutual actions, are not affected by any common motion, or the action of any equal and parallel force on both bodies: for this univerſal fact imports, that when two bodies are moving with equal velocities in the ſame direction, a force applied to one of them, ſo as to increaſe its velocity, gives it the ſame motion relative to the other, as if both bodies had been at reſt. Here it is plain that the ſpace deſcribed by the body in conſequence of the primitive force, and of the force now added, is the ſum of the ſpaces which each of them would generate in a body at reſt. Therefore the forces are proportional to the velocities or changes of motion which they produce, and not to the ſquares of thoſe velocities. This meaſure of forces, or the poſition that a force makes the ſame change on any velocity whatever, and the dependence of the relative motions on any motion that is the ſame on all the bodies of a ſyſtem, are counterparts of each other. Since this independence is a matter of obſervation in all terreſtrial bodies, we are intitled to ſay, that the powers which the Author of Nature has imparted to natural bodies are no way different from what are competent to matter once called into exiſtence. And it alſo follows from this, that we muſt always remain ignorant of the abſolute motions of bodies. The fact, that it has required the unremitted ſtudy of ages to diſcover even the relative motions of our ſolar ſyſtem, is an argument to prove that the influence of this mechanical principle extends far beyond the limits of this ſublunary world; nor has any phenomenon yet been exhibited which ſhould lead us to imagine that it is not univerſal.

So Bernoulli's defence of this laſt opinion is without force.

When we have made uſe of theſe arguments with ſome zealous partizans of Mr Leibnitz's doctrine, they have anſwered, that if indeed this independence of the relative motions of terreſtrial bodies were obſerved to obtain exactly, it would be a concluſive argument. But the motion with which all is carried along is ſo great in compariſon with the motions which we can produce in our experiments, that the ſmall additions or diminutions that we can make to the velocity of this common motion muſt obſerve very nearly the proportions of the additions or diminutions of their ſquares. The differences of the ſquares of 2, 3, and 4, are very unequal; but the differences of the ſquares of 9, 10, 11, are much nearer to the ratio of equality; and the differences of the ſquares of 1000001, 1000002, 1000003, do not ſenſibly deviate from this ratio. But it is not fact that we cannot produce motions which have a very ſenſible proportion to the common motion. The motion of a cannon ball, diſcharged with one-third of its weight of powder, is nearly equal to that of the rotation of the earth's equator. When, therefore, we diſcharge the ball eaſtward, we double its motion; when to the weſtward, we deſtroy it. Therefore, according to Leibnitz, the action in the firſt caſe is three times the action in the ſecond. In the firſt caſe it changes the ſquare of the velocity (which we may call 1) from 1 to 4; and, in the ſecond, it changes it from 1 to 0. But ſay the Leibnitzians, the velocity of rotation is but $\frac{1}{63}$ of the orbital velocity of the earth, and our obſervations of the velocities of cannon bullets are not ſufficiently exact to enſure us againſt an error of $\frac{1}{31\frac{1}{2}}$. But the later obſervations on the peculiar motions of the fixed ſtars concur in ſhewing, that the ſun, with his attending planets, are carried along with a very great motion, which, in all probability, has a ſenſible ratio to the orbital motion of the earth. This muſt make a prodigious change on the earth's abſolute motion, according as her orbital motion conſpires with, oppoſes, or croſſes, this other motion: the earth may even be at abſolute reſt in ſome points of its orbit. Thus will the compoſition with the motions produced in our experiments be ſo varied, that caſes *muſt* occur when the difference of the reſults of the two meaſures of force will be very ſenſible.

But, farther, they have not attended to the agreement of our experiments, when the diſcharges of cannon are made in a direction tranſverſe to that of the common motion. Here the immenſity of the common motion, and the minuteneſs of our experimental velocities, can have no effect in diminiſhing the difference of the reſults of the two doctrines. This will appear diſtinctly

tinctly to every reader who is much converſant in diſquiſitions of this kind ; and it is in theſe more moderate motions that the complete independence of the relative motions on the common motions moſt accurately appears. Pendulum clocks and watches have been often executed which do not deviate from perfect equability of motion one part in 86400. This could not be obtained in all directions of the oſcillations, if the forces deviated from the ratio of the velocities one part in 86400.

Perfect agreement of the abſtract notion of force with all our accurate obſervations of the exertions of natural powers.

On the whole, we may conſider it as eſtabliſhed on the ſureſt foundation, that the action of thoſe powers of natural bodies which we call *preſſure*, ſuch as the force of ſprings, the exertions of animals, the coheſion of bodies, as well as the action of thoſe other incitements to motion which we call *attractions* and *repulſions*, ſuch as gravitation, magnetiſm, and electricity—is proportional to the change of velocity produced by it. And we muſt obſerve here, that this is not a mere mode of conception, the reſult of the laws of human thought, which cannot conceive a natural power as the cauſe of motion otherwiſe than by its producing motion, and which cannot conceive any degree of *moving* power different from the degree of the motion. This is the abſtract doctrine, and is true whether the preſſures are proportional to the velocities or to the ſquares of the velocities. But we ſee farther, that whatever is the preſſure of a ſpring (for example) on a quieſcent body, yet the preſſure actually exerted in producing a double velocity is only double, and not quadruple, as our firſt imperfect obſervations make us imagine.

70
Newton's third law of motion is founded on experience alone, and is not a neceſſary truth.

Sir Iſaac Newton has added another propoſition to the number of laws of motion ; namely, that *every action is accompanied by an equal and contrary reaction.* But in affirming this to be a law of nature, he only means that it is an univerſal fact : And he makes this affirmation on the authority of what he conceives to be a law of human thought ; namely, that thoſe qualities which we find in all bodies on which we can make experiments and obſervations, are to be conſidered as univerſal qualities of body. But we have limited the term *law of motion* to thoſe conſequences that neceſſarily flow from our notions of motion, of the cauſes of its production and changes. Now this third Newtonian propoſition is not ſuch a reſult. A magnet is ſaid to act on a piece of iron when, and only when, the vicinity of the magnet is obſerved to be accompanied by certain motions of the iron. But it by no means follows from this obſervation, that the preſence of the iron ſhall be accompanied by any motion, or any change of ſtate whatever of the magnet, or any appearance that can ſuggeſt the notion that the iron acts on the magnet. When this was obſerved, it was accounted a diſcovery. Newton *diſcovered* that the ſun acts on the planets, and that the earth acts on the moon ; and Kepler *diſcovered* that the moon reacts on the earth. Newton had obſerved that the iron reacts on the magnet ; that the actions of electrified bodies were mutual ; and that every action of ſublunary bodies was, in fact, accompanied by an equal and contrary reaction. On the authority of his rule of philoſophizing, he affirmed that the planets react on the ſun, and that the ſun is not at reſt, but is continually agitated by a ſmall motion round the general centre of gravitation. He pointed out ſeveral conſequences of this reaction. Aſtronomers examined the celeſtial motions more narrowly, and found that thoſe conſequences do really obtain, and diſturb all the planetary motions. It is now found that this reciprocity of action obtains throughout the ſolar ſyſtem with the utmoſt preciſion, and that the third Newtonian propoſition is really a law of nature, although it is not a law of human thought. It is a diſcovery. The contrary involves no abſurdity or contradiction. It would indeed be contrary to experience ; but things might have been otherwiſe. It is conceivable, and poſſible, that a ball A ſhall ſtrike another equal ball B, and carry it along with it, without any diminution of its velocity. The fact, that the velocity of A is reduced to one-half, is the indication of a force reſiding in B, which force changes the motion of A; and the intenſity of this force is learned from the change which it produces. This *is found* to be equal to the change produced by A on B. And thus the reaction of B is *diſcovered* to be equal to the action of A.

It is highly probable, that this univerſality and equality of reaction to action is the conſequence of ſome general principle, which we may in time diſcover ; meanwhile we are intitled to ſuppoſe it univerſal, and to reaſon from this topic in our diſquiſitions about the actions of bodies on each other.

Maupertuis, Leibnitz, and other philoſophers, have entertained very inadequate opinions concerning the foundation of the laws of motion.

Although the celebrated philoſophers of Europe have at laſt agreed in the reception of the two propoſitions ſo largely diſcuſſed by us as the laws of motion, they have differed exceedingly in their opinion about their origin and validity : Some aſſerted that they are entirely matters of experience ; while others affirmed them to be neceſſary truths. The royal academy of Berlin made this queſtion the ſubject of their prize diſſertation in the year 1744. Mr Maupertuis, preſident of the academy, publiſhed a diſſertation ; in which he endeavoured to prove that they are neceſſary truths, only becauſe *they are ſuch as make the quantity of action the leaſt poſſible* an economy which is worthy of infinite wiſdom ; and therefore certainly directs the choice of the Author of Nature. On this account alone are they neceſſary truths.

But this is not the way to conſider a queſtion of this kind. We know too little about infinite wiſdom to be able to ſay with Meſſrs Leibnitz and Maupertuis, that the Deity ſhould or ſhould not impreſs on bodies laws different from thoſe which are eſſential to matter ; and we are not to inquire whether God could or could not do this. We know from our own experience, that matter, when ſubjected to the action of intelligence, may be moved in a way extremely different from what it would follow if left to itſelf, and that its motions may either be regulated by fixed, but contingent, laws, or may be without any conſtancy whatever, and vary in every inſtance. When we ſuppoſe the exiſtence of matter and motion, a variety of truths are involved in the ſuppoſition, in the ſame manner as all the theorems in the third book of Euclid's Elements are involved in the conception of a circle and a ſtraight line. Our firſt employment ſhould be to evolve thoſe truths. We can do this in no way but by firſt noticing the relations of the ideas that we have of the different objects of contemplation, and then following the laws of human thought in our judgments concerning thoſe relations. This proceſs of the mind is expreſſed in the train of a geometrical demonſtration. The different parts or argumentations of this train are not the cauſes of our concluſions, but the means by which we form our judgement; not the reaſons of the truth of our ultimate concluſion, but the ſteps by which we arrive at the knowledge of it. The young geometer generally thinks otherwiſe: But that this is the matter of fact is plain from this, that more than one demonſtration, and often very different, can be given of the ſame theorem. We muſt proceed in the ſame manner in the preſent queſtion; and the firſt general truths which we find involved in the notions of matter, motion, and force, muſt be received as *neceſſary* truths. The ſteps by which we arrive at the diſcovery are the laws of human thought; and the expreſſion of the diſcovery, involving both the truth itſelf and the manner of conceiving it, is a neceſſary law of motion. There may be other facts, perhaps as general as any of thoſe neceſſary laws, but which do not neceſſarily reſult from the relations of our notions of motion and of force. Theſe are diſcovered by obſervation only; and they ſerve to characteriſe the forces which nature preſents to our view. Theſe facts are *contingent* laws of motion.

We apprehend that this method has been followed in treating this article. The firſt propoſition, termed *a law of motion*, is only a more convenient way of expreſſing our contemplation of motion in body as an effect of the general cauſe which we term *force*. The ſecond propoſition does nothing but expreſs more diſtinctly the relation between this cauſe and its effect; it expreſſes what we mean by the magnitude and the kind of the cauſe. The propoſition, ſtating the compoſition of forces, is but another form of the ſame law, better ſuited to the ordinary procedure in geometrical diſquiſitions.

These propoſitions might have completed the doctrines of dynamics; but it appears that, in order to the production of a material univerſe which ſhould accompliſh the purpoſes of the Creator, it was neceſſary that there be certain characteriſtic differences between the forces inherent in the various collections of matter which compoſe this univerſe. The facts or phyſical laws (for the above-mentioned laws are metaphyſical) of motion may be different from thoſe which would have been obſerved had matter been left entirely to itſelf. This difference may have introduced other laws of motion as neceſſarily reſulting from the nature of the forces. We have occaſionally mentioned ſome inſtances where this appears to obtain, but gave good reaſons for affirming, that a due examination of all circumſtances which may be obſerved in the production or variation of motion by thoſe forces, has demonſtrated that there are no ſuch deviations from the two laws of motion already determined, but that all the mechanical powers of bodies, when conſidered merely as cauſes of motion, act agreeably to the ſame laws. Careful examination was, however, ſaid to be neceſſary.

This examination muſt conſiſt in diſtinctly noticing the circumſtances that occur in the production of motion by any force whatever. It is by no means enough to ſtate ſimply the intenſity of the force and the direction of its exertion. If a force continue to act, it continues to vary the motion already produced. Should the force change its intenſity or direction while it is acting, theſe circumſtances muſt induce ſtill farther changes in the motion; and it is not till all action has ceaſed that the motion is brought to its oſtenſible ſtate, in which it is the object of our attention and our future diſcuſſions. Inſtances of the effects of ſuch continued and ſuch varied actions are to be ſeen in moſt of the phenomena of nature or art. The communication of motion by impulſe is perhaps the only inſtance (very frequent indeed) that can be produced where this is not neceſſary: Nay, we ſhall perhaps find reaſon to conclude, that this inſtance is not an exception, and that even the communication of motion from one billiard ball to another is brought about by an action continued for ſome time, and greatly varied during that time. Much preparation is therefore neceſſary before we can apply the general laws of motion to the ſolution of moſt of the queſtions which come before us in the courſe even of our elementary diſquiſitions. We muſt lay down ſome general propoſitions which determine the reſults of the continued, and perhaps varied, actions of moving forces; and we muſt mark the different effects of the ſimple continuation of action, and alſo thoſe of the variations in this continued action, both in reſpect of intenſity and direction. The effect of a mere continuance of action muſt be an acceleration of the motion; or a retardation of it, if the force continue to act in the oppoſite direction. The effect of the continued action of a tranſverſe force muſt be a continual deflection, that is, a curvelineal motion. Theſe muſt therefore now occupy our attention in their order.

Of Accelerated and Retarded Motions.

71 Circumſtantial expoſition of our conception of the condition of a body in reſpect to motion.

All men can perceive, that a ſtone dropped from the hand, or ſliding down an uniform ſlope, has its motion continually accelerated, and that the motion of an arrow riſing perpendicularly through the air is continually retarded; and they feel no difficulty in conceiving theſe changes of motion as the effects of the continual operation of their weight or heavineſs. The falling ſtone is in a different condition in reſpect of motion in the beginning and the end of its fall. In what reſpect do theſe ſtates of the body differ? Only in reſpect to what we call its *velocity*. This is an affection of motion; it is an expreſſion of the relation between the two notions or ideas which concur to form the idea of motion; namely, the ſpace and the time. Theſe are all the circumſtances that we obſerve in a motion. Time elapſes, and during its currency a ſpace is deſcribed. The term *velocity* expreſſes the magnitude of the ſpace which correſponds to ſome unit of time. Thus, the rate of a ſhip's motion is determined, when we ſay that it is nine miles in an hour, or nine miles per hour. We ſometimes ſay (but aukwardly) "The motion is at the rate, or with the velocity, of a mile in three days." It is moſt conveniently expreſſed by a number of ſome given units of length, which completely make up the line deſcribed during this unit of time. But the mechanicians expreſs it in a way more general by a fraction, of which the numerator is a number of inches, feet, yards, fathoms, or miles, and the denominator is the number of ſeconds, minutes, or hours, employed in moving along this line. This is a very proper expreſſion; for when we ſpeak of any velocity, and continue to reaſon from it, we conceive ourſelves to ſpeak of ſomething that remains the ſame, in the different occaſions of uſing the term. Now if the velocity be conſtant, it is indifferent how

how long the line may be; becauſe the time of its deſcription will be lengthened in the ſame proportion. Thus if 48 feet be deſcribed in 12 seconds, 36 feet will be deſcribed in 9 ſeconds, 16 feet will be deſcribed in 4 ſeconds, &c. Now $\frac{48}{12}$, $\frac{16}{9}$, and $\frac{16}{4}$, are fractions of equal value, being equal to $\frac{4}{1}$, or 4, that is, to the velocity of 4 feet per ſecond. The value of this fraction, or the quotient of the number of the units of length, divided by the number of units of time, is the number of thoſe units of length deſcribed uniformly in one unit of time.

Magnitude of a velocity of which we have no actual meaſure.

But how ſhall we determine the velocity of any inſtant or in any point of a motion that is continually changing? Suppoſe that a body has fallen 144 feet, and that we would aſcertain its velocity in that point of its fall, or the velocity which it has in paſſing through that point? In the next ſecond the body falls 112 feet farther. This cannot be the meaſure of the velocity at the beginning of the fourth or the end of the third ſecond. It is too great. The fall during the preceding ſecond was 80 feet. This is too ſmall. The mean of theſe two, or $\frac{80+112}{2}$, $=\frac{192}{2}$, $=96$, is probably more exact. Due attention to the nature of this motion ſhews us, that 96 is the proper meaſure, or that the motion at that inſtant is at the rate of 96 feet per ſecond. But it is peculiar to this kind of motion that the half ſum of the ſpaces deſcribed in two ſucceeding equal moments is the meaſure of the velocity in the middle inſtant. Therefore this method will not generally give an accurate meaſure. Yet it is indiſpenſably neceſſary to obtain ſome accurate meaſure; for it is in this particular alone that the ſtate of the body differs from its ſimilar ſtate in another inſtant. The difference of place makes no diſtinction; for if a body continue its motion unchanged, its condition in every different inſtant of time, or point of ſpace, is unchanged or the ſame. The change of place is not a change of motion, but is involved in the very conception of the continuation of the motion. The change of condition conſiſts, therefore, in the change of velocity. Therefore the change of velocity is the only indication, and the only meaſure of the action (perhaps accumulated) of the changing force. It is therefore the chief object of our ſearch; and accurate meaſures of velocity are abſolutely neceſſary.

When the velocity changes continually, there can be no *actual* meaſure of it. In what then does the magnitude of a velocity conſiſt, when there is no actual meaſure of it? It is a certain undeſcribable DETERMINATION; by which, if not changed, a certain ſpace *would* be uniformly deſcribed in a given unit of time. Thus we know, that if, when a ſtone has fallen 16 feet, its motion be directed along a horizontal plane, without diminution, it will move on for ever at the rate of 32 feet per ſecond. The ſpace which would be thus deſcribed is not the velocity, but the meaſure of the velocity. But the proportions of thoſe ſpaces, being the proportions of thoſe meaſures, are the proportions of the velocities themſelves. We may diſcover theſe proportions in the following manner:

72
Momentary proportion of velocities that are continually changing.

Fundamental requiſite in all mechanical diſquiſitions.

Let ACG (fig. 13.) be a line deſcribed by a body with a motion anyhow continually, but gradually, varied; and let it be required to determine the proportion of the velocity in any point C to the velocity in any other point F.

AXIOM.—If A be to B in a ratio that is greater than any ratio leſs than that of C to D, but leſs than any ratio greater than that of C to D, then A is to B as C to D.

Take the ſtraight line *a c g* to repreſent the time of the body's motion along ACG, ſo that the points *a*, *c*, *f*, *g*, may repreſent the inſtants of time in which the body paſſes through the points A, C, F, G; and the portions *a c*, *c f*, *f g*, of the line *a g*, may repreſent the times employed in deſcribing the portions AC, CF, FG; and therefore *a c* is to *a f* as the time of deſcribing AC to the time of deſcribing AF.

Moreover, let *b k n o* be a line ſo related to the ſtraight line *a c f g*, by the perpendicular ordinates *a h*, *c k*, *f n*, *g o*, and the areas *a c k h*, *a f n h*, *a g o h*, may be proportional to the portions AC, AF, AG, of the line deſcribed by the moving body; and let this relation be true with reſpect to every point B, D, E, &c. and the correſponding points *b*, *d*, *e*, &c.

Then it is affirmed, that *the velocity in the point* C *is to the velocity in the point* F *as c k is to f n.*

Let the equal lines *b c*, *c d*, *e f*, *f g*, repreſent equal moments of time, and let B, D, E, G, be the points through which the body is paſſing at the inſtants *b*, *d*, *e g*. Then the areas *b i k c*, *c k l d*, *e m n f*, *f n o g*, will repreſent, and be proportional to, the ſpaces BC, CD, EF, FG, which are deſcribed during the moments *b c*, *c d*, *e f*, *f g*.

Draw *t p* parallel to *a g*, ſo as to make the rectangle *b t p c* equal to the trapezium *b i k c*; and draw the lines *q v*, *u r*, *s x*, in the ſame manner, ſo that each rectangle may be equal to its correſponding trapezium.

If the motions had been uniform during the moments *b c* and *f g*, that is, if the ſpaces BC and FG had been uniformly deſcribed, then the velocity in the point C would have been to the velocity in the point F as *c p* to *f s*: For ſince the rectangles *b t p c* and *f s x g* are reſpectively equal to the trapeziums *b i k c* and *f n o g*; and ſince *b i k c* is to *f n o g* as BC is to FG, the rectangle *b t p c* is to the rectangle *f s x g* as BC to FG. But becauſe theſe two rectangles have equal altitudes *b c* and *f g*, they are to each other in the proportion of their baſes *c p* and *g x*, or *c p* and *f s*. Therefore BC is to FG as *c p* to *f s*. But if BC and FG are uniformly deſcribed in equal times, they are proportional to the velocities of thoſe uniform motions. Therefore *c p* is to *f s* as the velocity with which BC is uniformly deſcribed to the velocity with which FG is uniformly deſcribed in an equal time.

But the motion expreſſed by the figure is not uniform, becauſe the line *b l o* recedes from the axis *a g*, and the areas, cut off by the parallel ordinates, increaſe in a greater proportion than the correſponding parts of the axis; that is, the ſpaces increaſe faſter than the times: for the moments *b c*, *c d*, *e f*, *f g*, being all equal, it is evident that the correſponding ſlips of the area continually augment. The motion is ſwifter at the inſtant *c* than at the inſtant *b*, and the velocity at the inſtant *c* is *greater* than that with which the ſpace BC would be uniformly deſcribed in the ſame time. For the ſame reaſon, the velocity at the inſtant *f* is *leſs* than that with which the ſpace FG would be uniformly deſcribed in the ſame time. Therefore the velocity at the inſtant *c* is to the velocity at the inſtant *f* in a greater ratio than that of *c p* to *f s*. In the very ſame manner, it will appear by comparing the motion during the moment

c d

cd with the motion during the moment ef, that the velocity at the inſtant c is to the velocity at the inſtant f in a leſs ratio than that of cq to fr.

Therefore the velocity in the point C is to the velocity in the point F in a greater ratio than that of cp to fs, but in a leſs ratio than that of cq to fr.

But by continually diminiſhing the equal moments. bc, cd, ef. fg, it is evident that cp and cq continually approach to equality with ck; and fr and fs, continually approach to equality with fn, that when cp is leſs than ck, fs is greater than fn, and when cq is greater than ch, fr is leſs than fn.

Therefore the velocity in the point C is to the velocity in the point F in a ratio that is greater than the ratio of *any* line leſs than ck to *any* line greater than fn, but which is leſs than the ratio of any line greater than ck to any line leſs than fn. Therefore the ratio of the velocity in C to the velocity in F is greater than any ratio that is leſs than that of ck to fn; but it is leſs than any ratio that is greater than that of ck to fn. Therefore the velocity in the point C is to the velocity in the point F as ck to fn.

This important theorem may be expreſſed in more general terms as follows:

If the abſciſſa ag *of a line* hko *repreſent the time of any motion, and if the areas bounded by parallel ordinates be proportional to the ſpaces deſcribed, the ordinates are proportional to the velocities.*

Remark. The propriety or aptitude of expreſſing the time by the portions of the axis acg, will, perhaps, appear more clearly in the following manner.

Let acg be any ſtraight line, and let hkv be another line, ſtraight or curved. Let the ſtraight line ahz, perpendicular to ag, be carried uniformly down along this line, keeping always perpendicular to it, and therefore always parallel to its firſt poſition ahz. In its various ſituations ckz, emz, &c. it will cut off areas $ackh$, $aemh$, &c. bounded by the axis by the ordinates ah and ck, or by the ordinates ah and em, &c. and by the line hkg. By this motion the moveable ordinate is ſaid, in the language of modern geometry, to *generate* the areas $ackh$, $aemh$, &c. At the ſame time, let a point A move along the line ACG, ſetting out from A at the inſtant when the line az ſets out from a; and let the motion of the point A be ſo regulated, that the ſpaces AB, AC, AD, &c. generated by this motion, may increaſe at the ſame rate with the areas, ab, ih, $ackh$, $adlh$, &c. or ſuch that we ſhall have AB to AC as $abih$, to $ackh$, &c. It is plain, that the motion along AG is the ſame with that deſcribed in the enunciation of the propoſition: for becauſe the motion of the ordinate az, along the axis ag, is ſuppoſed to be uniform, the ſpaces ab, ac, ad, &c. are proportional to the times in which they are deſcribed, and may therefore be taken to meaſure or to repreſent thoſe times.

73. Cor. 1. *In a motion continually varied, the velocities in the different points of the path are to each other in the limiting or ultimate ratio of the ſpaces deſcribed in equal times*, thoſe times being ſuppoſed to diminiſh continually: for it is evident, that if the equal moments bc, cd, ef, fg, are ſuppoſed to diminiſh continually, till the inſtants b and d coaleſce with c, and the inſtants e and g coaleſce with f; then the ratio of ck to fn is the limit of the continually increaſing ratio of cp to fs, or of the continually diminiſhing ratio of cq to fr. Sir Iſaac Newton calls this the ultimate ratio of cp to fs, or of cq to fr. Now the ratio of cp to fs is, by conſtruction, the ſame with the ratio of the rectangle $btpc$ to the rectangle $fsxg$, and the ratio of cq to fr is the ſame with the ratio of the rectangle $cqvd$ to the rectangle $eurf$. But the ratio of the rectangle $btpc$ to the rectangle $fsxg$ is the ſame with the ratio of the ſpace $bikc$ to the ſpace $fnog$; that is (by hypotheſis), the ſame with the ratio of the ſpace BC to the ſpace FG; and the ratio of the rectangles $cqvd$ and $eurf$ is the ſame with that of the ſpaces CD and EF. Therefore the ratio of the velocity at C to the velocity at F is the ſame with the ultimate ratio of the ſmall increments BC, FG, or CD, EF of the ſpaces generated in very ſmall and equal times.

It is alſo evident, that becauſe the ratio of ck to fn is the limit both of the ratio of cp to fs and of the ratio of cq to fr, theſe ultimate ratios are the ſame, and that we may ſay that the velocity in C is to the velocity in F in the ultimate ratio of BC to EF, or in the ultimate ratio of CD to FG.

We alſo can eaſily perceive, that the ratio of the area $bikc$ to the area $emnf$ approaches more near to the ratio of ck to fn as we take the moments bc and ef ſmaller. Therefore, in many caſes of practice, where it may be eaſy to meaſure the ſpaces deſcribed in the different ſmall moments of the motion, but difficult to aſcertain their ultimate ratio, ſo as to obtain accurate meaſures of the proportions of the velocities, we may reduce the errors of meaſurement to ſomething very inſignificant, by taking theſe moments extremely ſmall; and we ſhall diminiſh the error ſtill more, by taking the proportion of the half ſum of BC and CD to the half ſum of EF and FG for the proportion of the velocities in C and F.

It often happens that we have it not in our power to compare the ſpaces deſcribed in ſmall moments which are preciſely equal. Still we can find the exact proportion of the velocities, if we can aſcertain the ultimate ratio of the increments of the ſpaces, and the ultimate ratio of the moments of time in which theſe increments are deſcribed: for it is plain, by conſidering the gradual approach of the points p and r to the points k and n, that the ratio of ck to fn is ſtill the ultimate ratio of the baſes of rectangles equal to the mixtilineal areas, whether the altitudes (repreſenting the moments) are equal or not. Now the baſes of two rectangles are in the proportion of the rectangles directly, and of their altitudes inverſely. But the ultimate ratio of the altitudes is the ultimate ratio of the moments, and the ultimate ratio of the rectangles is the ultimate ratio of the ſpaces deſcribed in thoſe unequal moments. Therefore, in ſuch caſes, we have,

74. Cor. 2. *The velocities are in the ratio compounded of the direct ultimate ratio of the momentary increments of the ſpaces, and the inverſe ultimate ratio of the increments (or moments) of the times in which theſe increments of the ſpaces are made.*

If s, v, and t, are taken to repreſent the magnitudes of the ſpaces, velocities, and times, and if $\dot{s}$, $\dot{v}$, and $\dot{t}$, are taken always in the limiting or ultimate ratio of their momentary increments, we ſhall have v always in the

the proportion of $\dot s$ directly, and of $\dot t$ inverſely. We expreſs this by the proportional equation $v \doteq \frac{\dot s}{\dot t}$, which is equivalent to the analogy $V : v = \frac{\dot S}{\dot T} : \frac{\dot s}{\dot t}$, or $V : v = \dot S \dot t : \dot s \dot T$.

75. *N. B.* Here obſerve, that this is not the only way of ſtating the relation of ſpace and time—the abſciſſa may be made the time, and the ordinate the ſpace; then the velocity $= \frac{\dot y}{\dot x}$.

The converſe of this propoſition may be thus expreſſed.

76
Converſe
heorem.

If the axis a g *of the line* h k o *repreſent the time of a varied motion along the line* AG, *and if the ordinates* a h, b i, c k, *&c. be as the velocities in the inſtants* a, b, c, *or in the points* A, B, C; *then the areas* a b i h, a c k h, a d l h, *&c. are proportional to the ſpaces* AB, AC, AD, *&c.*

This may be demonſtrated in the ſame way with the former; but the indirect demonſtration is more brief, and equally ſtrict.

If the ſpaces AC, AF, &c. are not proportional to the areas *a c k h*, *a f n h*, &c. they are proportional to ſome other areas *a c k h'*, *a f n' h'*, &c. which are bounded by the ſame ordinates, and by another line *h' k n'*. But becauſe the areas *a c k h'*, *a f n' h'*, &c. are always proportional to the ſpaces AC, AF, &c. deſcribed on the line AG, the velocity in the point C is to the velocity in the point F as the ordinate *c k* is to the ordinate *f n'*. But, by hypotheſis, the velocity in C is to the velocity in F as *c k* to *f n*, and *f n'* is equal to *f n*; which is abſurd. Therefore the ſpaces AC, AF, are not proportional to any other areas, &c.

77. Cor. *The ultimate ratio of the momentary increments of the ſpaces is compounded of the ratio of the velocities, and the ultimate ratio of the increments of the times:* for when the moments *b c*, *e f*, are equal, it is evident that the ultimate ratio of the rectangles *b c p t*, *e f r u* is the ſame with the ultimate ratio of the increments of the ſpaces. But the ultimate ratio of theſe rectangles is the ſame with their baſes *c p* and *f r*; that is, the ratio of *c k* to *f n*, that is, the ratio of the velocities. And when the moments are unequal, the ratio of the rectangles is compounded of the ratio of their baſes and the ratio of their altitudes; that is, compounded of the ratio of the velocities and the ultimate ratio of the moments of time.

We have, therefore, $\dot S : \dot s = V\dot T : v\dot t$, and $\dot s \doteq v\dot t$.

It moſt commonly happens, that we can only obſerve the accumulated reſults of varied motions; and in them we only obſerve a ſpace paſſed over, and a certain portion of time that has elapſed during the motion. But being able to diſtinguiſh the portions of the whole ſpace which are deſcribed in known portions of the whole time, and having made ſuch obſervations in ſeveral parts of the motion, we diſcover the general law that the motion affects, and we affirm this law to hold univerſally, even though we have not obſerved it in *every* point. We do this with a degree of probability and confidence proportioned to the frequency of our obſervation. It is not till we have done this that we can make uſe of the firſt of theſe two propoſitions, which enables us to aſcertain the velocity of the motion in its different moments. Thus if we obſerve, that a ſtone in falling deſcends one foot in the quarter of a ſecond, 16 feet in a ſecond, 64 feet in two ſeconds, and 144 feet in three ſeconds; the general law immediately obſerved is, "that the ſpaces deſcribed are as the ſquares of the times;" for 1 is to 16 as the ſquare of $\frac{1}{4}$th to the ſquare of 1. Again, 16 is to 64 as 1^2 to 2^2; and 16 is to 144 as 1^2 to 3^2. Hence we infer, with great probability, that the ſtone would fall 36 feet in a ſecond and a half; for 16 is to 36 as 1^2 to $1\frac{1}{2}^2$; and we conclude in the ſame way for all other parts of the motion.

78
A good example of the geometrical method.

This immediate obſervation of the analogy between the ſpaces and the ſquares of the times ſuggeſts an eaſy determination of the velocity in this particular kind of motion; and it merits particular notice, being very often referred to. We can take *a g* to repreſent the time; and then, becauſe the areas which are to repreſent the ſpaces deſcribed muſt be proportioned to the ſquares of the portions of *a g*, we perceive that the line which comes in place of *h k o* muſt be a ſtraight line drawn from *a*. For example, the ſtraight line $a\,\delta\,\gamma$. For this is the only boundary which will give areas $a\,b\,\beta$, $a\,c\,\gamma$, $a\,d\,\delta$, &c. proportional to $a\,b^2$, $a\,c^2$, $a\,d^2$, &c. And we perceive that *any* ſtraight line drawn from *a* will have this property.

Having thus got our repreſentations of the times and the ſpaces, we ſay, on the authority of our theorem, that the velocity at the inſtant *b* is to the velocity at the inſtant *d* as $b\,\beta$ to $d\,\delta$, &c. And now we begin to make inferences, purely geometrical, and expreſs our diſcovery of the velocities in a very general and ſimple manner. We remark, that $b\,\beta$ is to $d\,\delta$ as *a b* is to *a d*; and we make the ſame affirmation concerning the magnitudes repreſented by theſe lines. We ſay that the velocity at the inſtant *b* is to the velocity at the inſtant *d* as the time *a b* is to the time *a d*. We ſay, in terms ſtill more general, that the velocities are proportional to the times from the beginning of the motion. We moreover perceive, that the ſpaces are alſo proportional to the ſquares of the acquired velocities; or the velocities are as the ſquare roots of the ſpaces.

We can farther infer, from the properties of the triangle, that the momentary increments of the ſpaces are proportional to the momentary increments of the ſquares of the times, or of the ſquares of the velocities.

We alſo obſerve, that not only the whole acquired velocities are proportional to the whole elapſed times, but that the increments of the velocities are proportional to the times in which they are acquired; for $\pi\,\kappa$ is to $\rho\,\varphi$ as *b c* to *d f*, &c. Equal increments of velocity are therefore acquired in equal times. Therefore ſuch a motion may, in great propriety of language, be denominated a UNIFORMLY ACCELERATED MOTION; that is, *a motion in which we obſerve the ſpaces proportioned to the ſquares of the times, is a motion uniformly accelerated*; and ſpaces in the duplicate ratio of the times form the oſtenſible characteriſtic of an uniformly accelerated motion.

79. Laſtly, if we draw $\varepsilon\,\lambda$ parallel to the axis *a b*, we perceive that the rectangle $a\,e\,\varepsilon\,\lambda$ is double of the triangle $a\,e\,\varepsilon$. Now becauſe *a e* repreſents the time of the motion, and $e\,\varepsilon$ repreſents the acquired velocity, the rectangle $a\,e\,\varepsilon\,\lambda$ will repreſent the ſpace which would be uniformly deſcribed with the velocity $e\,\varepsilon$ during the time

a e. But the triangle *a e i* repreſents the ſpace really deſcribed with the uniformly accelerated motion during the ſame time. Hence we infer, that the ſpace that is deſcribed in any time, with a motion increaſing uniformly from nothing, is one-half of the ſpace which would be uniformly deſcribed during the ſame time with the final velocity.

Theſe are but a part of the inferences which we may draw from the geometrical properties of thoſe repreſentations which we had ſelected of the different meaſureable affections of motion. We may affirm, with reſpect to the motions themſelves, all the inferences which relate to magnitude and proportion, and thus improve our knowledge of the motions.

We took the opportunity of this very ſimple and perſpicuous axample, to give our young readers a juſt conception of the *mathematical method* of proſecuting mechanical knowledge, and to make them ſenſible of the unqueſtionable authority for every theorem deduced in this manner.

One of the moſt important is, to diſcover the accumulated reſult of a motion of which we only obſerve the momentary increments. This is to be done by finding the area, or portions of the area, of the mixtilineal ſpace *a g o h*; and it is evidently analogous to the inverſe method of fluxions, or the integral calculus.

In moſt caſes, we muſt avail ourſelves of the corollary $\dot{s} \doteq v\,\dot{t}$, and we obtain the ſolution of our queſtion only in the caſes where our knowledge of the quantities $\dot{s}$, $\dot{t}$, and v (conſidered as geometrical magnitudes, that is, as lines and ſurfaces), enables us to diſcover s and t.

Of Accelerating and Retarding Forces.

80 Having thus diſcovered the proportions of the velocities in motions varying in any manner whatever, we can obſerve the variations which happen in them. Theſe variations are the effects, and the only marks and meaſures, of the changing forces. They are the characteriſtics of their kinds (conſidered merely as moving forces); that is, the indications of the directions in which they act; for this is the only difference *in kind* of which they are ſuſceptible in this general point of view. If they increaſe the velocity, their direction muſt be conceived as the ſame with that of the previous motion; becauſe the reſult of the action of a force is equivalent to the compoſition of the motion which that force would produce in a quieſcent body with the motion already exiſting: and an increaſe of velocity is equivalent to the compoſition of a motion in the ſame direction.

Having no other mark of the force but the acceleration, we have no other name for it in the abſtract doctrines of dynamics, and we call it an ACCELERATING FORCE. Had it retarded the motion, we ſhould have called it a RETARDING FORCE.

In like manner, we have no meaſure of the *magnitude* or *intenſity* of an accelerating force, but the acceleration which it produces. In order therefore to inveſtigate the powers which produce all the changes of motion, we muſt endeavour to obtain meaſures of the acceleration.

A continual increaſe of velocity is the effect of the continued action of accelerating forces. If equal increments of velocity are produced in every ſucceeding equal moment of time, we cannot conceive that there is any change in the accelerating force. Therefore a uniformly accelerated motion is the mark of the unvaried action of an accelerating force, that is, of the continued action of a conſtant force; of a force whoſe intenſity is always the ſame. When therefore we obſerve a body deſcribe ſpaces proportional to the ſquares of the times, we muſt infer that it is urged forward by a force whoſe intenſity does not change; and, on the other hand, a conſtant force muſt produce a uniformly accelerated motion by its continued action. And if any previous circumſtances aſſure us of this continued action of an invaried force, we may make all the inferences which were mentioned under the article of uniformly accelerated motion.

81
Meaſure of an accelerating force.

That force muſt ſurely be accounted double which produces a double increment of velocity in the ſame time hy its uniform action, we can form no other eſtimation of its magnitude. And, in general, *accelerating forces muſt be accounted proportional to the increments of velocity which they produce, by acting uniformly during the ſame or equal times.*

Another meaſure.

Suppoſing them to act on a body at reſt. Then the velocity produced is itſelf the increment; and we muſt ſay, that accelerating forces are proportional to the velocities which they generate in a body in equal times. And becauſe we found (n 79.), that the ſpace deſcribed with a uniformly accelerated motion is half the ſpace which would be uniformly deſcribed in the ſame time with the final velocity, which ſpace is the direct meaſure of this velocity, and becauſe halves have the ſame proportion with the wholes—we may ſay that *accelerating forces are proportional to the ſpaces through which they impel a body from reſt in equal times by their uniform action.*

This is an important remark; becauſe it gives us an eaſy meaſure of the force, without the trouble of firſt computing the velocities. It alſo gives us the only diſtinct notion that we have of the meaſurement of forces by the motions which they produce. When ſpeaking of the compoſition of forces we diſtinguiſhed or denominated them by the ſides and diagonal of a parallelogram These lines muſt be conceived as proportional to the ſpaces through which the forces urge the body *uniformly* during the ſmall and inſenſible time of their action, which time is ſuppoſed to be the ſame for both forces; for the ſides of the parallelogram are ſuppoſed to be ſeparately deſcribed in equal times, and therefore to be proportional to the velocities generated by the conſtituent forces. If indeed the forces do not act uniformly, nor ſimilarly, nor during equal times, we cannot ſay (without farther inveſtigation) what is the proportion of the intenſity of the forces, nor can we infer the compoſition of their action. We muſt at leaſt ſuppoſe, that in every inſtant of this very ſmall time of their joint action, their direction remains unchanged, and that their intenſities are in the ſame ratio. We ſhall ſee by and bye, that with theſe conditions the ſides of the parallelogram are ſtill proportional to the velocities generated. In the mean time, we may take the ſpaces through which a body is uniformly impelled from reſt (that is, with a uniformly accelerated motion) as the meaſures of the forces; yet theſe ſpaces are but the halves of the meaſures of the velocities. Then, if a body be moving with the velocity of 32 feet per ſecond, and an accelerating force acts on it during a ſecond,

and

Of Accelerating and Retarding Forces.

and if this force be ſuch that it would impel the body (from a ſtate of reſt) 16 feet, it will add to the body a velocity of 32 feet per ſecond. Accordingly, this is the effect of gravity—the weight of a pound of lead may be conſidered as a force which does not vary in its intenſity. We know that it will cauſe the lead to fall 16 feet in a ſecond; but if the body has already fallen 16 feet, we know that it is then moving with the velocity of 32 feet per ſecond. And the fact is, that it will fall 48 feet farther in the next ſecond, and will have acquired the velocity of 64 feet per ſecond. It has therefore received an augmentation of 32 feet of velocity by the action of gravity during the 2d ſecond; and gravity is in fact a conſtant force, cauſing equal increments of velocity in equal times, however great the velocities may be. It does not act like a ſtream of fluid, whoſe impulſe or action diminiſhes as the ſolid body withdraws from it by yielding.

But ſuppoſing that we have not compared the increments of velocity uniformly acquired during equal times, in what manner ſhall we meaſure the accelerating forces? In ſuch a caſe, that force muſt be accounted double which generates the ſame velocity, by acting uniformly during half the time; for when the force is ſuppoſed invariable, the changes of velocity which it produces are proportional to the times of its action; therefore if it produces an equal velocity in half the time, it will produce a double velocity in an equal time, and is therefore a double force. The ſame may be ſaid of every proportion of time in which an equal change of velocity is produced by the uniform action of an accelerating force. The force muſt be accounted greater in the ſame proportion that the time required for the production of a given velocity in a body is leſs. Hence we infer, that *accelerating forces are inverſely proportional to the times in which a given change of velocity is produced by their uniform action.*

By combining theſe two propoſitions we eſtabliſh this general theorem:

82
Meaſure of accelerating force,

Accelerating forces are proportional to the changes of velocity which they produce in a body by their uniform action directly, and to the times in which theſe changes are produced inverſely.

If, therefore, A and a are the forces, V' and v' the changes of velocity, and T' and t' the portions of time in which they are uniformly produced, we have

$$A : a = V't' : v'T', = \frac{V'}{T'} : \frac{v'}{t'}$$

$$\text{And } a \doteq \frac{v'}{t'}.$$

The formula $a \doteq \frac{v'}{t'}$ is not reſtricted to any particular magnitude of v' and t'. It is true, therefore, when the portion of time is diminiſhed without end; for ſince the action is ſuppoſed uniform, the increment of velocity is leſſened in the ſame proportion, and the value of the fraction $\frac{v'}{t'}$ remains the ſame. The characters or ſymbols v' and t' are commonly uſed to expreſs *finite* portions of v and t. The ſymbols $\dot{v}$ and $\dot{t}$ are uſed by Newton to expreſs the ſame things taken in the ultimate or limiting ratio. They are uſually conſidered as *indefinitely ſmall* portions of v and t. We ſhall abide by the formula $a \doteq \frac{\dot{v}}{\dot{t}}$.

Of Accelerating and Retarding Forces.

It muſt always be kept in mind, that v and t are abſtract numbers; and that v refers to ſome unit of ſpace, ſuch as a foot, an inch, a yard; and that t refers to ſome unit of time, ſuch as an hour, a minute, a ſecond; and eſpecially that a is the number of the ſame units of ſpace, which will be uniformly deſcribed in *one* unit of the time with the velocity generated, by the force acting uniformly during *that* unit. It is twice the ſpace actually deſcribed by the body during that unit when impelled from reſt by the accelerating force. It is neceſſary to keep hold of theſe clear ideas of the quantities expreſſed by the ſymbols.

83
Is an abſtract number.

Meaſure of a change of velocity.

On the other hand, when the meaſure of the accelerating force is previouſly known, we employ the theorem $a\,t' = v'$; that is, the addition made to the velocity during the whole, or any part, of the time of the action of the force is obtained by multiplying the acceleration of one unit of time by the number of ſuch units contained in t'.

Theſe meaſures expreſs the greateſt part of our knowledge of mechanical nature.

Theſe are evidently leading theorems in dynamics; becauſe all the mechanical powers of nature come under the predicament of accelerating or retarding forces. It is the collection of theſe in any ſubject, and the manner in which they accompany, or are inherent in it, which determine the mechanical character of that ſubject; and therefore the phenomena by which they are brought into view are the the characteriſtic phenomena. Nay, it may even be queſtioned, whether the phenomena bring any thing more into view. This force, of which we ſpeak ſo familiarly, is no object of diſtinct contemplation; it is merely a ſomething that is proportional to $\frac{\dot{v}}{t}$. And when we obſerve, that the $\frac{\dot{V}}{T}$, found in the motions that reſult from the vicinity of a body A, is double of the $\frac{\dot{v}}{t}$, which reſults from the vicinity of another body B; we ſay that a force reſides in A, and that it is double of the force reſiding in B. The accelerations are the things immediately and truly expreſſed by theſe ſymbols. And the whole ſcience of dynamics may be completely taught without once employing the word *force*, or the conception which we imagine that we form of it. It is of no uſe till we come to ſtudy the mechanical hiſtory of bodies. Then, indeed, we muſt have ſome way of expreſſing the fact, that an acceleration $= \frac{32 \text{ feet}}{1''}$ is obſerved in every thing on the ſurface of this globe; and that an acceleration $= \frac{418 \text{ feet}}{1''}$ is obſerved over all the ſurface of the ſun. Theſe facts are characteriſtic of this earth and of the ſun; and we expreſs them ſhortly by ſaying, that ſuch and ſuch forces reſide in the earth and in the ſun. It will preſerve us from many miſtakes and puzzling doubts, if we reſolutely adhere to this meaning of the term *force*; and this will carry mathematical evidence through the whole of our inveſtigations.

84
Another meaſure of accelerating force.

As velocity is not an immediate object of contemplation, and all that we obſerve of motion is a ſpace and a time, it may be proper to give an expreſſion of this meaſure of accelerating force which involves no other idea. Suppoſing the body to have been previouſly at reſt, we have $a \doteq \frac{v}{t}$. Multiply both parts of the fraction by t, which does not change its value, and we have $a \doteqdot \frac{v\,t}{t^2}$. But $v\,t = s$; and therefore $a \doteqdot \frac{s}{t^2}$.

The formula $a = \frac{s}{t^2}$ is equivalent to the proportion $t^2 : 1 = s : a$; and a would then be the ſpace through which the accelerating force would impel the body in one unit of the time t. But this is only half of the meaſure of the velocity which the accelerating force generates during that unit of time. For this reaſon we did not expreſs the accelerating force by an ordinary equation, but uſed the ſymbol $\doteqdot$. In this caſe, therefore, of uniform action, we may expreſs the accelerating force by $a = \frac{2\,s}{t^2}$.

The following theorem is of ſtill more extenſive uſe in all dynamical diſquiſitions.

85
Moſt general meaſure of accelerating force.

Accelerating forces are proportional to the momentary increments of the ſquares of the velocities directly, and as the ſpaces along which they are uniformly acquired inverſely.

Let A′B, A′C, and AD (fig. 14.), be three lines, deſcribed in the ſame or equal times by the uniform action of accelerating forces; the motions along theſe lines will be uniformly accelerated, and the lines themſelves will be proportional to the forces, and may be employed as their meaſures. On the greateſt of them AD, deſcribe the ſemicircle ABCD, and apply the other two lines A′B, A′C as chords AB, AC. Draw EB, FC perpendicular to AD. Take any ſmall portions B b, C c of AB and AC, and draw b e, c f perpendicular to AD, and E h and F k parallel to AB and AC.

Then, becauſe the triangles DAB and BAE are ſimilar, we have $AD : AE = AD^2 : AB^2$. And becauſe AD is to AB as the velocity generated at D is to the velocity generated at B (the times being equal), we have AD to AE as the ſquare of the velocity at D to the ſquare of the velocity at B; which we may expreſs thus:

$$AD : AE = V^2, D : V^2, B.$$

For the ſame reaſons we have alſo

$$AD : AF = V^2, D : V^2, C. \quad \text{Therefore}$$
$$AE : AF = V^2, B : V^2, C.$$

But becauſe in any uniformly accelerated motion, the ſpaces are as the ſquares of the acquired velocities, we have alſo

$$AE : A\,e = V^2, B : V^2\,b, \text{ and}$$
$$AF : A\,f = V^2, C : V^2\,c.$$

Therefore E e is to F f as the increment of the ſquare of the velocity acquired in the motion along B b to the increment of the ſquare of the velocity acquired along C c.

But, by ſimilarity of the triangles ABD and E e h, we have

$$AB : AD = E\,e : E\,h; \text{ and, in like manner,}$$
$$AD : AC = F\,k : F\,f. \quad \text{Therefore}$$
$$AB : AC = E\,e \times F\,k : F\,f \times E\,h.$$

Now AB and AC are proportional to the forces which accelerate the body along the lines A′B and A′C; E e and F f are proportional to the increments of the ſquares of the velocities acquired in the motions along the portions B b and C c; and E h and F k are equal to thoſe portions reſpectively. The ratio of AB to AC is compounded of the direct ratio of E e to F f; and the inverſe ratio of E h to F k. The propoſition is therefore demonſtrated.

The proportion may be expreſſed thus:

$AB : AC = \frac{E\,e}{E\,h} : \frac{F\,f}{F\,k}$, and may be expreſſed by the proportional equation $AB \doteqdot \frac{E\,e}{E\,h}$ or, ſymbolically, $a \doteqdot \frac{\dot{(v^2)}}{s}$.

$\dot{v}v$ is but one-half of the increment of v^2.

REMARK. Becauſe the motion along any of theſe three lines is uniformly accelerated, the relation between ſpaces, times, and velocities, may be repreſented by means of the triangle ABC (fig. 15.); where AB repreſents the time, BC the velocity, and ABC the ſpace. If BC be taken equal to AB, the triangle is half of the ſquare ABCF of the velocity BC; and the triangle ADE is half of the ſquare ADEG of the velocity DE. Let D d and B b be two moments of time, equal or unequal. Then D d e E and B b c C are half the increments of the ſquares of the velocities DE and BC, acquired during the moments D d and B b. It was demonſtrated, that the ratio of the area D d e E to the area B b c C is compounded of the ratio of DE to BC, and the ultimate ratio of D d to B b. But D d and B b are reſpectively equal to ε e and × c. Therefore D d e E is to B b c C, in the ratio compounded of the ratio of DE to BC, and the ultimate ratio of ε e to × c. If we repreſent DE and BC by V and v, then ε e and × c muſt be repreſented by V' and v', the increments of V and v; and then the compounded ratio will be the ratio of VV' to $v\,v'$; and if we take the ultimate ratio of the moments, and conſequently the ultimate ratio of the increments of the velocities, we have the ratio of $V\dot{V}$ to $v\,\dot{v}$. If, therefore, V^2 and v^2 repreſent the ſquares of the velocities, $V\dot{V}$ and $v\,\dot{v}$ will repreſent not the increments of thoſe ſquares, but half the increments of them.

We may now repreſent this propoſition concerning accelerating forces by the proportional equation $a \doteqdot \frac{\dot{v}v}{s}$; and we muſt conſider this as equivalent with $a = \frac{V^2 - v^2}{2\,(S - s)}$; keeping always in mind, that a, V, and v, relate to the ſame units of time and ſpace, and that a is that number of units of the ſcale on which S and s are meaſured, which is run over in *one* unit of time.

Meaſure of gravity conſidered as an accelerating force.

This will be more clearly conceived by taking an example. Let us aſcertain the accelerative power of gravity, ſuppoſing it to act uniformly on a body. Let the ſpaces be meaſured in feet and the time in ſeconds. It is a matter of obſervation, that when a body has fallen 64 feet, it has acquired a velocity of 64 feet per ſecond: and that when it has fallen 144 feet, it has acquired the velocity of 96 feet per ſecond. We want to determine what velocity gravity communicated to it by acting on it during one ſecond. We have $V^2 = 9216$, and $v^2 = 4096$; and therefore $V'^2 - v^2 = 5120$. $S = 144$, and $s = 64$, and $S - s = 80$, and $2\,(S - s) = 160$. Now $a = \frac{5120}{160}, = 32$. Therefore gravi-

ty

ty has generated the velocity 32 feet per ſecond by acting uniformly during one ſecond.

86. *The augmentation of the ſquare of the velocity is proportional to the force and to the ſpace jointly.* For, becauſe $a = \frac{v\dot{v}}{\dot{s}}$, we have $a\dot{s} = v\dot{v}$.

Thus we learn, that a given force acting uniformly on a body along a given ſpace, produces the ſame increment of the ſquare of the velocity, whatever the previous velocity may have been. Alſo, in the ſame manner as we formerly found that the augmentation of the velocity was proportioned to the time during which the force has acted, ſo the augmentation of the ſquare of the velocity is proportional to the ſpace along which it has acted.

Theorems reſpecting retarding forces. It is pretty plain, that all that we have ſaid of the uniform action of an *accelerating* force may be affirmed of a *retarding force*, taking a diminution or decrement of velocity in place of an increment. A uniformly retarded motion is that in which the decrements of velocity in equal times are equal. and the whole decrements are proportional to the whole times of action. Such a motion is the indication of a conſtant or invariable force acting in a direction oppoſite to that of the motion. We conceive this to be the caſe when an arrow is ſhot perpendicularly upwards; its weight is conceived as a force continually preſſing it perpendicularly downwards.

In ſuch motions, however great the initial velocity may be, the body will come to reſt; becauſe a certain determined velocity will be taken from the body in each equal ſucceſſive moment, and ſome multiple of this will exceed the initial velocity. Therefore the velocity will be extinguiſhed before the end of a time that is the ſame multiple of the time in which the velocity was diminiſhed by the quantity above mentioned. It is no leſs evident, that the time in which any velocity will be extinguiſhed by an oppoſing or retarding force, is equal to the time in which the ſame force would generate this velocity in the body previouſly at reſt. Therefore,

87. 1. The times in which different initial velocities will be extinguiſhed by the ſame oppoſing force are proportional to the initial velocities.

88. 2. The diſtances to which the body will go till the extinction of its velocity are as the ſquares of the initial velocities.

3. They are alſo as the ſquares of the times elapſed.

89. 4. The diſtance to which a body, projected with any velocity, will go till its motion be extinguiſhed by the uniform action of a retarding force, is one half of the ſpace which it would deſcribe uniformly during the ſame time with the initial velocity.

Forces generally variable in their intenſity. It very rarely happens, that the force which accelerates the body acts uniformly, or with an unvaried intenſity. The attraction of a magnet, for example, increaſes as the iron approaches it. The preſſure of a ſpring diminiſhes as it unbends. The impulſe of a ſtream of water or wind diminiſhes as the impelled ſurface retires from it by yielding. Therefore the effects of accelerating forces are very imperfectly explained, till we have ſhewn what motions reſult from any given variation of force, and how to diſcover the variation of force from the obſerved motion. This laſt queſtion is perhaps the moſt important in the ſtudy of mechanical nature. It is only thus that we learn what is uſually called *the nature of a mechanical force.* This chiefly conſiſts in the relation ſubſiſting between the intenſity of the force and the diſtance of the ſubſtance in which it reſides. Thus the nature of that power which produces all the planetary motions, is conſidered as aſcertained when we have demonſtrated that its preſſure or intenſity is inverſely as the ſquare of the diſtance from the body in which it is ſuppoſed to reſide.

Acceleration expreſſes ſome relation of the velocity and time. This relation may be geometrically expreſſed in a variety of ways. In figure 13. the uniform acceleration or the unvaried relation between the velocity and the time is very aptly expreſſed by the conſtant ratio of the ordinates and abſciſſes of the triangle $a\,g\,\nu$. The ratio of $d\,\delta$ to $a\,d$ is the ſame with that of $c\,\varepsilon$ to $a\,e$, or that of $f\,\varphi$ to $a\,f$, &c.; or the ratio of the increment of velocity $\varpi\,\varkappa$ to the increment of the time $\beta\,\varpi$ or $b\,c$, or that of $i\,\varphi$ to $\varepsilon\,i$, &c. This ratio $\varpi\,\varkappa : \beta\,\varpi$ is equivalent to the ſymbol $\frac{\dot{v}}{\dot{t}}$

But when the ſpaces deſcribed in a varied motion are repreſented by the areas bounded by a curve line $b\,k\,o$, we no longer have that conſtant ratio of the increments of the ordinates and abſciſſes.

90 Their meaſures in ſuch caſes how obtained? Theorems of moſt extenſive uſe. Therefore in order to obtain meaſures of the accelerating forces, or at leaſt of their proportions, let the abſciſſa $a\,e\,g$ (fig. 13.) of the line $b\,k\,o$ again repreſent the time of a motion. But let the areas bounded by parallel ordinates now repreſent the velocities, that is, let the whole area increaſe during the time $a\,g$ at the ſame rate with the velocities of the motion along the line AG. In this caſe the ordinates $b\,i$, $c\,k$, $d\,l$, &c. will be as the accelerations at the inſtants b, c, d, &c. or in the points B, C, D, &c.

This is demonſtrated in the ſame way as the former propoſition (n° 72.). If the accelerating force be ſuppoſed conſtant during any two equal moments $b\,c$ and $f\,g$, the rectangles $b\,c\,p\,t$ and $f\,g\,x\,s$ would expreſs the increments of velocity uniformly acquired in equal times, and their baſes $c\,p$ and $f\,s$ would have the ratio of the accelerations, or of the accelerating forces. But as the velocities expreſſed by the figure increaſe faſter than the times during every moment, the force at the inſtant c is to the force at the inſtant f in a greater ratio than that of $c\,p$ to $f\,s$; but, for ſimilar reaſons, it is in a leſs ratio than that of $c\,q$ to $f\,r$; and therefore (as in the other propoſition) the force at the inſtant c is to the force at the inſtant f as $c\,k$ to $f\,n$.

91. *Cor.* Becauſe $c\,p$ is to $f\,s$ in the ratio compounded of the direct ratio of the rectangle $c\,p\,t\,b$ to the rectangle $f\,s\,x\,g$, and the inverſe ratio of the altitude $b\,c$ to the altitude $f\,g$; and becauſe theſe rectangles are proportional to the increments of velocity, and the ultimate ratio of the altitudes is the ultimate ratio of the moments or increments of the time—we muſt ſay, that *the accelerating forces (that is, their intenſities or preſſures producing acceleration) are directly as the increments of velocity, and inverſely as the increments of the times:* Which propoſition may be expreſſed, in regard to two accelerations A and a, by this analogy:

$$A : a = \frac{\dot{V}}{\dot{T}} : \frac{\dot{v}}{\dot{t}}.$$

Or by the proportional equation $a \doteq \frac{\dot{v}}{\dot{t}}$. Alſo $a\,\dot{t} \doteq \dot{v}$, and $\int a\,\dot{t} = v'$. And thus do theſe theorems extend even to the caſes where there cannot be obſerved an immediate meaſure, either of velocity or of acceleration; becauſe neither the ſpace nor the velocity increaſes uniformly.

See *Barrow's Lect. Geometr.* paſſim.

The theorem $a \doteq \frac{\dot{v}}{\dot{t}}$ is employed when we would diſcover the variation in the intenſity of ſome natural power. We obſerve the motion and repreſent it by a figure analogous to fig. 13. where the abſciſſa repreſents the times, and the area is made to increaſe at the ſame rate with the ſpaces deſcribed. Then the ordinates will repreſent the velocities, or have the proportion of the velocities. Then we may draw a ſecond curve on the other ſide of the ſame abſciſſa, ſuch that the areas of this laſt curve ſhall be proportioned to the ordinates of the firſt. The ordinates of this laſt curve are proportional to the accelerating forces.

92. On the other hand, when we know from other circumſtances that a force, varying according to ſome known law, acts on a body, we can determine its motion. The intenſity of the force in every inſtant being known, we can draw a line ſo related to another line repreſenting the time that the ordinates ſhall be proportional to the forces: The areas will be proportional to the velocities. We can draw another curve to the ſame abſciſs, ſuch that the ordinates of this ſhall be proportional to the areas of the other, that is, to the velocities of the motion. The areas of this ſecond curve will be proportional to the ſpaces deſcribed.

93

All theſe theorems relate to *changes* of velocity; by which means they indicate *immediately* the operation of natural powers.

We muſt now obſerve, that all that has been ſaid concerning the effects of accelerating forces continually varying, relates to *changes* of motion, independent of what the abſolute motions may be. The areas of the line whoſe ordinates repreſent the velocities do not neceſſarily repreſent the ſpaces deſcribed, but the change made on the ſpaces deſcribed in the ſame time, not the motions, but the changes of motion. If, indeed, the body be ſuppoſed to be at reſt when the forces begin to act, theſe areas repreſent the very ſpaces that are paſſed over, and the ordinates are the very velocities. In every caſe, however, the accelerations are the real increments of the velocities.

This circumſtance gives a great extenſion to our theorems, and enables us to aſcertain the diſturbances of any ſpecies of regular motion, apart from the motions themſelves, and thus avoid a complication which would frequently be inextricable in any other way. And this proceſs, which is merely mathematical, is perfectly conformable to mechanical principles. It is in fact an application of the doctrine of the compoſition of motion; a doctrine rigidly demonſtrated when we meaſure a mechanical force by the *change* of motion which it produces. Acceleration is the continual compoſition of a new motion with the motion already produced.

No finite change of velocity can be produced in an inſtant by any accelerating force.

We may learn from this inveſtigation of the value of an accelerating force, that no finite change of velocity is effected in an inſtant by the action of an accelerating force. When the fig. 13. is uſed for the ſcale of accelerations, and they are repreſented by the ordinates of the line *h k o*, the increment of velocity is repreſented by an area, that is, by a ſlip of the whole area; which ſlip muſt have ſome altitude, or muſt occupy ſome portion of the abſciſſa which repreſents time. Some portion of time, however ſmall it may be, muſt elapſe before any meaſurable addition can be made to the velocity. The velocity muſt change *continually*. As no motion can be conceived as inſtantaneous, becauſe this would be to conceive, that in one inſtant the moving particle is in every point of its momentary path; ſo no velocity can change, by a finite quantity, in one inſtant; becauſe this would be to conceive, that in that inſtant the particle had all the intervening velocities. The inſtant of change is at once the laſt inſtant of the preceding velocity, and the firſt of the ſucceeding, and therefore muſt belong to both. This cannot be conceived, or is abſurd. As a body, in paſſing from one part of ſpace to another, muſt paſs in ſucceſſion through all the intermediate places; ſo, in paſſing from one velocity to another, it muſt in ſucceſſion have all the intermediate velocities. It muſt be *continually* accelerated; we muſt not ſay *gradually*, however ſmall the ſteps.

But to return from this digreſſion:

94

More convenient manner of conſidering the action of forces, and more frequently coming into view.

The moſt frequent caſes which come under examination do not ſhew us the relation between the forces and times, but the relation between the forces and ſpaces. Thus, when a piece of iron is in the neighbourhood of a magnet, or a planet is conſidered in the neighbourhood of the ſun, a force is acting on it in every point of its path, and we have diſcovered that the intenſity of this force varies in a certain proportion. Thus, a ſpring varies in its preſſure as it unbends; gunpowder preſſes leſs violently as it expands, &c. &c.

Our knowledge is generally confined to ſome ſuch effect as this. We know, that while a body is moving along a line ADE (fig. 16.), it is urged forward by a force, of which the intenſity varies in the proportion of the ordinates BF, CG, DH, EI, &c. of the line FGHI.

To inveſtigate the motion or change of motion produced by the action of this force, let CD be ſuppoſed a very ſmall portion of the ſpace s, which we may expreſs by s'. Draw GK perpendicular to DH. Then, if we ſuppoſe that the force acts with the unvaried intenſity CG through the whole ſpace CD, the rectangle CDKG will expreſs half of the increment of the ſquare of the velocity (n° 85). We may ſuppoſe that the force acts uniformly along the adjoining ſmall ſpace D*r* with the intenſity DH. The rectangle DH *o r* will in like manner expreſs another half increment of the ſquare of the velocity. And in like manner we may obtain a ſucceſſion of ſuch increments. The aggregate or ſum of them all will be half the difference between the ſquare of the velocity at B and the ſquare of the velocity at E.

If we employ f to expreſs the indetermined or variable intenſity of the accelerating force, and v to expreſs the variable velocity, and v' its increment *uniformly* acquired; then the rectangle CDKG will be expreſſed by $f\,s'$. We have ſeen that this is equal to $v\,v'$. Therefore, in every caſe where we can tell the aggregate of all the quantities $f\,s$, it is plain that we will obtain half the difference between the ſquares of the velocities in B and E, on the ſuppoſition that the intenſity of the force was conſtant along each little ſpace, and

varied

varied by ſtarts. Then, by increaſing the number, and diminiſhing the magnitude, of thoſe little portions of the ſpace without end, it is evident that we terminate in the expreſſion of the real ſtate of the caſe, *i. e.* of a force varying continually; and that in this caſe the aggregate of theſe rectangles occupies the whole area AEIF, and is equivalent to the fluent of $f\dot{s}$, or to the ſymbol $\int f s$, uſed by the foreign mathematicians to expreſs this fluent, which they indeed conceive as an aggregate of ſmall rectangles $f s'$. And we ſee that this area expreſſes half of the augmentation of the ſquare of the velocity. Therefore,

95 Moſt important theorem (*Newton's Principia*, I. 39.)

If the abſciſſa AE (fig. 16.) *of a line* FGI *is the path along which a body is urged by any accelerating force, and if the ordinates* BF, CG, DH, *&c. are proportional to the forces acting on the points* B, C, D, *&c. the intercepted areas* BCGF, BEIF, *&c. are proportional to the augmentations of the ſquare of the velocity.*

Obſerve that the areas BCGF and DEIH are alſo proportional to the augmentations made on the ſquares of the velocities in B and D.

Obſerve alſo, that it is indifferent what may have been the original velocity. The action of the forces repreſented by the ordinates make always the ſame addition to its ſquare; and this addition is half the ſquare of the velocity which thoſe forces would generate in the body by impelling it from reſt in the point A.

96. Laſtly, on this head, obſerve, that we can ſtate what conſtant or variable force will make the ſame augmentation of the ſquare of the velocity by impelling the body uniformly along the ſame ſpace BE; or along what ſpace a given force muſt impel the body, in order to produce the ſame increaſe of the ſquare of its velocity. In the firſt caſe, we have only to make a rectangle BENφ, equal to the area BEIF, and then Bφ is the intenſity of the conſtant force wanted. In the ſecond caſe, in which the force EO is given, we muſt make the rectangle AαOE equal to the area BEIF, and AE is the ſpace required.

97 Converſe. The converſe of this propoſition, *viz. If the areas are as the increments of the ſquare of the velocity, the ordinates are, as the forces*, is eaſily demonſtrated in the ſame way; for if the elementary areas CDKG and EIM*e* repreſent increments of the ſquares of the velocity, the accelerating forces are in the ratio compounded of the direct ratio of theſe rectangles and the inverſe ratio of their altitudes, becauſe theſe altitudes are the increments of the ſpace (n° 85.). Now the baſe CG of the rectangle CDKG, is to the baſe EI of the rectangle EIM*e* in the ſame compounded ratio; therefore the force in C is to the force in E as CG to EI.

98 *Scales* of force, velocity, acceleration, time, &c. The line *h k o* (fig. 13.) was called by Dr Barrow (who firſt introduced this extenſive employment of motion into geometry), the SCALE *of velocities*; and the line FHL (fig. 16.) was named by him the *ſcale of accelerations*. Hermann, in his *Phoronomia*, calls it the *ſcale of forces*. We ſhall retain this name, and we may call *h k o* of fig. 13. the *ſcale of* accelerations, when the areas repreſent the velocities. Sir Iſaac Newton added another ſcale of very great uſe, viz. a ſcale of times. It is conſtructed as follows.

99. Let ABE (fig. 16.) be the line along which a body is accelerated, and let FHI be the ſcale of forces, that is, having its ordinates FB, HD, IE, &c. proportional to the forces acting at B, D, E, F, &c.; let *f h i* be another line ſo related to ABE, that C*g* is to E*i* in the inverſe ſubduplicate ratio of the area BFGC to the area BFIE; or, to expreſs it more generally, let the ſquares of the ordinates to the line *f g i* be inverſely, as the areas of the line FHI intercepted between theſe ordinates and the firſt ordinate drawn through B; then the times of the bodies moving from a ſtate of reſt in B are as the intercepted areas of the curve *f g i*.

For let CD and E*e* be two very ſmall portions of the ſpace deſcribed in equal times. They will be ultimately as the velocities in C and E. The area FBCG is to the area FBEI as the ſquare of E*i* to the ſquare of C*g* (by conſtruction); but the area FBCG is to FBEI as the ſquare of the velocity at C is to the ſquare of the velocity at E (by the propoſition); therefore the ſquare of the velocity at C is to the ſquare of the velocity at E as the ſquare of E*i* to the ſquare of C*g*; therefore E*i* is to C*g* as the velocity at C to the velocity at E, that is, as CD to E*e*: but ſince $Ei : Cg = CD : Ee$, we have $Ei \times Ee = Cg \times CD$, and the elementary rectangles C*g k* D and E*i m e* are equal, and may repreſent the equal moments of time in which CD and E*e* were deſcribed. Thus the areas of the line *f g l* will repreſent or expreſs the times of deſcribing the correſponding portions of the abſciſſa..

We may expreſs the nature of this ſcale more briefly thus. Let BE be the ſpace deſcribed with any varied motion, and *f g l* a curve, ſuch that its ordinates are inverſely as the velocities in the different points of the abſciſſa, then the area will be as the times of deſcribing the correſponding portions of the abſciſſa.

100 Examples of the application of n° 95. In all the caſes where our mathematical knowledge enables us to aſſign the values of the ordinates of the figure 16, we can obtain the law of action of the forces, or the nature of the force; and where we can aſſign the value of the areas from our knowledge of the proportions of the ordinates or forces, we can aſcertain the velocities of the motion. We ſhall give an example or two, which will ſhew the way in which we avail ourſelves of the geometrical properties of figure, in order to aſcertain the effects of mechanical forces.

1. Let the accelerating force which impels the body along the line AB be conſtant, and let the body be previouſly at reſt in B; the line which bounds the ordinates that repreſent the forces muſt be ſome line φHN parallel to AB. The area BDHφ is to the area BENφ as the ſquare of the velocity at D to the ſquare of the velocity at E. Theſe areas, having equal baſes DH and EN, are as their altitudes BD and BE; that is, the ſpaces deſcribed are as the ſquares of the acquired velocities. And we ſee that this characteriſtic mark of uniformly accelerated motion is included in this general propoſition.

101 Example ſecond of peculiar importance. 2. Let us ſuppoſe that the body is impelled from A (fig. 17.) towards the point C, by a force proportional to its diſtance from that point. This force may be repreſented by the ordinates DA, EB, *e b*, &c. to the ſtraight line DC. We may take any magnitude of theſe ordinates; that is, the line DC may make any angle with AC. It will ſimplify the inveſtigation if we make the firſt force AD = AC. About C deſcribe the circle AH*a*, cutting the ordinate EB in F; let *e b* be another ordinate, cutting the circle in *f* very near

to F; draw CH perpendicular to AC, and make the arch $Hb = fF$, and draw bc parallel to HC; join FC and DH, and draw Fg perpendicular to fb. Let IML be another ordinate.

The area DABE is to the area DAKL as the ſquare of the velocity at B to the ſquare of the velocity at K. But DABE is the exceſs of the triangle ADC above the triangle EBC, or it is half of the exceſs of the ſquare of CA or CF above the ſquare of CB, that is, half the ſquare of BF. In like manner, the area DAKL is equal to half the ſquare of KM; but halves have the ſame ratio as the integers; therefore the ſquare of BF is to the ſquare of KM as the ſquare of the velocity at B to the ſquare of the velocity at K; therefore the velocity at B is to the velocity at K as BF is to KM. The velocities are proportional to the ſines of the arches of the quadrant AFH deſcribed on AC.

Cor. 1. The final velocity with which the body arrives at C, is to the velocity in any other point B as radius to the ſine of the arch AF.

Cor. 2. The final velocity is to the velocity which the body would acquire by the uniform action of the initial force at A as 1 to $\sqrt{2}$; for the rectangle DACH expreſſes the ſquare of the velocity acquired by the uniform action of the force DA; and this is double of the triangle DAC; therefore the ſquares of theſe velocities are as 1 and 2, and the velocities are as $\sqrt{1}$ and $\sqrt{2}$, or as 1 to $\sqrt{2}$.

Cor. 3. The time of deſcribing AB is to the time of deſcribing AC as the arch AF to the quadrant AFH.

102. For when the arch Ff is diminiſhed continually, it is plain that the triangle fiF is ultimately ſimilar to CFB, by reaſon of the equal angles Cib (or CFB) and fiF, and the right angles CBF and fFi; therefore the triangles fgF and CBF are alſo ſimilar. Moreover, Bb is equal to Fg, Ff is equal to bH, which is ultimately equal to cC; therefore ſince the triangles fgF and CFB are ſimilar, we have $Fg : Ff = FB : FC, = FB : HC$; therefore Bb is to cC as FB to HC, that is, as the velocity at B to the velocity at C; therefore Bb and cC are deſcribed in equal moments when indefinitely ſmall; therefore equal portions Ff, bH, of the quadrant correſpond to equal moments of the accelerated motion, along the radius AC; and the arches AF, FM, MH, &c. are proportional to the times of deſcribing AB, BK, KC, &c.

Cor. 4. The time of deſcribing AC with the unequally accelerated motion, is to the time of deſcribing it uniformly with the final velocity as the quadrantal arch is to the radius of a circle; for if a point move in the quadrantal arch ſo as to be in F, f, M, H, &c. when the body is in B, b, K, C, it will be moving uniformly, becauſe the arches are proportional to the times of deſcribing thoſe portions of AC; and it will be moving with the velocity with which the body arrives at C, becauſe the arch bH is ultimately $= Cc$. Now if two bodies move uniformly with this velocity, one in the arch AFH, and the other in the radius AC, the times will be proportional to the ſpaces uniformly deſcribed; but the time of deſcribing AFH is equal to the time of the accelerated motion along AC; therefore the propoſition is manifeſt.

103. *Cor.* 5. If the body proceed in the line Ca, and be retarded in the ſame manner that it was accelerated along AC, the time of deſcribing AC uniformly with the velocity which it acquires in C is to the time of deſcribing ACa with the varied motion, as the diameter of a circle to the circumference; for becauſe the momentary retardations at K′, B′, &c. are equal to the accelerations at K and B, &c. the time of deſcribing ACa is the ſame with that of deſcribing AHa uniformly with the greateſt velocity. That is, to the time of deſcribing AC uniformly as AHa to AC, or as the circumference of a circle to the diameter. Therefore, &c. *N. B.* In this caſe of retarding forces it is convenient to repreſent them by ordinates K′L, B′E, aD′, lying on the other ſide of the axis ACa; and to conſider the areas bounded by theſe ordinates as ſubtractive from the others. Thus the ſquare of the velocity at K′ is expreſſed by the whole area DACK′L′D, the part C′K′L being negative in reſpect of the point DAC. This obſervation is general (See alſo Optics, nº 125, *Encycl.*)

Cor. 6. The time of moving along KC, the half of AC, by the uniform action of the force at A, is to that of deſcribing ACa by the varied action of the force directed to C, and proportional to the diſtance from it, as the diameter of a circle to the circumference; for when the body is uniformly impelled along KC by the conſtant force IK, the ſquare of the velocity acquired at C is repreſented by half the rectangle IKCH, and therefore it is equal to the velocity which the variable force generates by impelling it along AC (by the way, an important obſervation). The body will deſcribe AC uniformly with this velocity in the ſame time that it is uniformly accelerated along KC. Therefore by *Cor.* 5. the propoſition is manifeſt.

Cor. 7. If two bodies deſcribe AC and KC by the action of forces which are every where proportional to the diſtances from C, their final velocities will be proportional to the diſtances run over, and the times will be equal.

For the ſquares of the final velocities are proportional to the triangles ADC, LKC, that is, to AC^2, KC^2, and therefore the velocities are as AC, KC. The times of deſcribing AC and KC uniformly, with velocities proportional to AC and KC, muſt be equal; and theſe times are in the ſame ratio (*viz.* that of radius to $\frac{1}{4}$th of the circumference) to the times of deſcribing AC and KC with the accelerated motion. Therefore, &c.

Thus, by availing ourſelves of the properties of the circle, we have diſcovered all the properties or characters of a motion produced by a force always directed to a fixed point, and proportional to the diſtance from it.

Some of theſe are remarkable, ſuch as the laſt corollary; and they are all important; for there are innumerable caſes where this law of action obtains in Nature. It is nearly the law of action of a bow ſtring, and of all elaſtic bodies, when their change of figure during their mutual action is moderate; and it has been by the help of this propoſition, firſt demonſtrated in a particular caſe by Lord Brouncker and Mr Huyghens, that we have been able to obtain preciſe meaſures of time, and conſequently of actual motions, and conſequently of any of the mechanical powers of Nature. It is for this reaſon, as well as for the eaſy and perſpicuous employment of the mathematical method of proceeding, that we have ſelected it.

Inſtead of giving any more particular caſes, we may obſerve

Of Accelerating and Retarding Forces.

obſerve in general, that if the intenſity of the force be proportional to any power whoſe index is $n - 1$ of the diſtance, and if a be the diſtance from the fixed point at which the body begins to be accelerated, and x its diſtance from that point in any part of the motion, the velocity will be $\doteqdot \sqrt{a^n - x^n}$. This is very plain, becauſe the increment CGHD of the area of fig. 16. which is alſo the increment of the ſquare of the velocity, is $\doteqdot x^{n-1}\dot{x}$, and the area is $\doteqdot x^n$; and the whole area, correſponding to the diſtance a, is a^n. Therefore the portion of the area lying beyond the diſtance x is $a^n - x^n$. This is as the ſquare of the velocity, and therefore the velocity is as the ſquare root $\sqrt{a^n - x^n}$ of this quantity.

This propoſition, $f\dot{s} \doteqdot v\dot{v}$, or $f \doteqdot \frac{v\dot{v}}{\dot{s}}$, is the 39th of the firſt book of Newton's *Principia*, and is perhaps the moſt important in the whole doctrine of dynamics, whether employed for the inveſtigation of forces or for the explanation of motions. It furniſhes the moſt immediate data for both purpoſes, but more eſpecially for the laſt. By its help Sir Iſaac Newton was able to point out the numerous diſturbances of the planetary motions, and to ſeparate them from each other; thus unravelling, as it were, that moſt intricate motion in which all are blended together. He has given a moſt wonderful ſpecimen of its application in his Lunar Theory.

We now are able to explain all the puzzling facts which were adduced by Leibnitz and his partiſans in ſupport of their meaſure of the forces of bodies in motion. We ſee why four ſprings, equally bent, communicate but a double velocity, and nine ſprings but a triple velocity; why a bullet moving twice as faſt will penetrate an earthen rampart to a quadruple depth, &c. &c.

Conſervatio virium vivarum.

This theorem alſo gives a moſt perſpicuous explanation of the famous doctrine called *conſervatio virium vivarum*. When perfectly elaſtic bodies act on each other, it is found that the ſum of the maſſes multiplied by the ſquares of the velocities is always the ſame. This has been ſubſtituted, with great encomiums, by the German philoſophers in place of Des Cartes's principle, that the quantity of motion in the univerſe, eſtimated in one direction, remains always the ſame. They are obliged, however, to acknowledge, that in the actions of perfectly hard bodies, there is always a loſs of *vis viva*, and therefore have denied the exiſtence of ſuch bodies But there is the ſame loſs in the mutual actions of all ſoft or ductile, or even imperfectly elaſtic, bodies; and they are miſerably puzzled how to explain the fact; but both the *conſervatio* and the *amiſſio* are neceſſary conſequences of this theorem.

In the colliſion of elaſtic bodies, the whole change of motion is produced during the ſhort time that the bodies are compreſſed, and while they regain their figure. When this is completed, the bodies are at the ſame diſtance from each other as when the mutual action began. Therefore the preceding body has been accelerated, and the following body has been retarded, along equal ſpaces; and in every point of this ſpace the accelerating and the retarding force has been equal. Conſequently the ſame area of fig. 17. expreſſes the change made on the ſquare of the velocity of both bodies. Therefore, if V and U are the velocities before colliſion, and v and u the velocities after colliſion, of the two bodies A and B, we muſt have $A \times \overline{V^2 - v^2} = B \times \overline{u^2 - V^2}$, and therefore $A \times V^2 + B \times U^2 = A \times v^2 + B \times u^2$.

Of Accelerating and Retarding Forces.

But in the other claſs of bodies, which do not completely regain their figure, but remain compreſſed, they are nearer to each other when their mutual action is ended than when it began. The foremoſt body has been accelerated along a ſhorter ſpace than that along which the other has been retarded. The mutual forces have, in every inſtant, been equal and oppoſite. Therefore the area which expreſſes the diminution of the ſquare of the velocity, muſt exceed the area expreſſing the augmentation by a quantity that is always the ſame when the permanent compreſſion is the ſame; that is, when the relative motion is the ſame. $A \times \overline{V^2 - v^2}$ muſt exceed $B \times \overline{u^2 - U^2}$, and $A \times V^2 + B \times U^2$ muſt exceed $A \times v^2 + B \times u^2$.

This ſame theorem is of the moſt extenſive uſe in all practical queſtions in mechanic arts; and without it mechanics can go no farther than the mere ſtatement of equilibrium.

Hiſtory of n° 95. is curious.

Hermann, profeſſor of mathematics at Pavia, one of the ornaments of the mathematical claſs of philoſophers, has given a pretty demonſtration of this valuable propoſition in the *Acta Eruditorum Lipſiæ* for 1709; and ſays, that having ſearched the writings of the mathematicians with great care, he found himſelf warranted to ſay, that Newton was the undoubted author, and boaſts of his own as the firſt ſynthetical demonſtration. The purpoſe of this aſſertion was not very apparent at the time; but long after, in 1746, when Hermann's papers, preſerved in the town-houſe of Pavia, were examined, in order to determine a diſpute between Maupertuis and Koenig about the claim to the diſcovery of *the principle of leaſt action*, letters of Leibnitz's were found, requeſting Hermann to ſearch for any traces of this propoſition in the writings of the mathematicians of Europe. Leibnitz was by this time the envious detractor from Newton's reputation; and could not but perceive, that all his contorted arguments for his doctrine received a clear explanation by means of this propoſition, in perfect conformity to the uſual meaſure of moving forces. Newton had diſcovered this theorem long before the publication of the *Principia*, and even before the diſcovery of the chief propoſition of that book in 1666; for in his Optical Lectures, the materials of which were in his poſſeſſion in 1664, he makes frequent uſe of a propoſition founded on this (ſee n° 42.) We may here remark, that Hermann's demonſtration is, in every ſtep, the ſame with Dr Barrow's demonſtration of it as a theorem merely geometrical, without ſpeaking of moving forces (ſee *Lect. Geomtr.* xi. p. 85. edit. 16), but giving it as an inſtance of the transformation of curves, which he calls SCALES of velocity, of time, of acceleration, &c. It is very true that Barrow, in theſe mathematical lectures, approached very near to both of Newton's diſcoveries, the fluxionary geometry, and the principles of dynamics; and the junto on the continent, who were his continual detractors, charge him with impudent plagiariſm from Dr Barrow, and even ſay that he has added nothing to the diſcoveries of his teacher. But ſurely Dr Barrow was the beſt judge of this matter;

ter; and ſo far from reſenting the uſe which Newton has made of what he had taught him, he was charmed with the genius of the *juvenis ſpectatiſſimus* his ſcholar, and of his own accord gave him his profeſſorial chair, and ever after lived in the utmoſt harmony and friendſhip with him. Nay, it would even appear, from ſome expreſſions in thoſe very lectures, that Dr Barrow owed to young Newton the firſt thought of making ſuch extenſive uſe of motion in geometry. We recommend this work of Barrow's to the ſerious peruſal of our readers, who wiſh to acquire clear notions of the ſcience of motion, and an elegant taſte in their mechanical diſquiſitions. After all the cultivation of this ſcience by the commentators and followers of Newton, after the *Phoronomia* of Hermann, the *Mechanica* of Euler, the *Dynamique* of D'Alembert, and the *Mechanique Analytique* of De la Grange, which are undoubtedly works of tranſcendent merit and utility, the *Principia* of Newton will ſtill remain the moſt pleaſing, perſpicuous, and elegant ſpecimen of the application of mathematics to the ſcience of *univerſal mechanics*, or what we call DYNAMICS.

The two fundamental theorems $f \dot{t} = \dot{v}$, and $f \dot{s} = v \dot{v}$, enable us to ſolve every queſtion of motion accelerated or retarded by the action of the mechanical powers of nature. But the employment of them may be greatly expedited and ſimplified by noticing two or three general caſes which occur very frequently.

104
Similar inſtants and points, what?

Theſe may be called ſimilar inſtants of time, and *ſimilar points of ſpace which divide given portions of time*, and *of ſpace in the ſame ratio.* Thus the middle is a ſimilar inſtant of an hour or of a day, and is the ſimilarly ſituated point of a foot or of a yard. The beginning of the 21ſt minute, and of the 9th hour, are ſimilar inſtants of an hour and of a day. The beginning of the 5th inch, and of the 2d foot, are ſimilar points of a foot and of a yard.

105
Similar actions, what?

Forces may be ſaid to act ſimilarly when their intenſities in ſimilar inſtants of time, or in ſimilar points of ſpace, are in a conſtant ratio. Thus in fig. 17. when one body is impelled towards C from A, and another from K, each with a force proportional to the diſtance of every point of its motion from C, theſe forces may be ſaid to act ſimilarly along the ſpaces AC and KC, or during the times repreſented by the quadrantal arches AFH, KNO. The following propoſitions on ſimilar actions will be found very uſeful on many occaſions; but we muſt premiſe a geometrical lemma.

106. If there be two lines EFGH (fig. 18.), *e f g h*, ſo related to their abſciſſes AD, *a d*, that the ordinates IK, *i k*, drawn from ſimilar points I and *i* of the abſciſſes, are in the conſtant ratio of AE to *a e*; then the area ADHE is to the area *a d h e* as the rectangle of $AD \times AE$ to the rectangle $ad \times ae$.

For let each abſciſſa be divided into the ſame number of equal and very ſmall parts, of which let CD and *c d* be one in each. Inſcribe the rectangles CGID, *c g i d*. Then becauſe the number of parts in each axis is the ſame, the lengths of the portions CD and *c d* will be proportional to the whole abſciſſes AD and *a d*. And becauſe C and *c* are ſimilar points CG is to *c g* as AE is to *a e*. Therefore $CD \times CG : cd \times cg = AD\ AE : ad \times ae$ This is true of each pair of correſponding rectangles; and therefore it is true of their ſums. But when the number of theſe rectangles is increaſed, and their breadth diminiſhed without end, it is evident that the ultimate ratio of the ſum of all the rectangles, ſuch as CDHG to the ſum of all the rectangles *c d h g*, is the ſame with that of the area ADHE to the area *a d h e*, and the propoſition is manifeſt.

107 *If two particles of matter are ſimilarly impelled during given times, the changes of velocity are as the times and as the forces jointly.*

Let the times be repreſented by the ſtraight lines ABC (fig. 19.) and *a b c*, and the forces by the ordinates AD, BE, CF, and *a d*, *b e*, *c f*. Then if B and *b* are ſimilar inſtants (ſuppoſe the middles) of the whole times, we have $BE : be = AD : ad$. Therefore, by the lemma, the area ACDF is to *a c f d* as $AC \times AD$ to $ac \times ad$. But theſe areas are proportional to the velocities (n° 72), and the propoſition is demonſtrated. For the ſame reaſon the change of velocity during the time AB is to the change during *a b* as $AB \times AD$ to $ab \times ad$.

Cor. 1. If the times and forces are reciprocally proportional, the changes of velocity are equal; and if the forces are inverſely as the times, the changes of velocity are equal.

108. *If two particles be ſimilarly urged along given ſpaces, the changes made on the ſquares of the velocities are as the forces and ſpaces jointly.*

For if AC (fig. 19.) and *a c* are the ſpaces along which the particles are impelled, and the forces are as the ordinates AD and *a d*, the areas ACFD and *a c f d* are as the changes on the ſquares of the velocities. But theſe areas are as $AC \times AD$, and $ac \times ad$. Therefore, &c.

Cor. 2. If the ſpaces are inverſely as the forces, the changes of the ſquares of the velocities are equal; and if theſe are equal, the ſpaces are inverſely as the forces.

Cor. 3. If the ſpaces, along which the particles have been impelled from a previous ſtate of reſt, are directly as the forces, the velocities are alſo as the forces. For, becauſe the changes of the ſquares of the velocities are as the ſpaces and forces jointly, they are in this caſe as the ſquares of the forces or of the ſpaces; but the changes of the ſquares of the velocities are in this caſe the whole ſquares of the velocities; therefore the ſquares of the velocities are as the ſquares of the forces, and the velocities are as the forces. *N. B.* This includes the motions repreſented in fig. 17.

109. *If two particles be ſimilarly impelled along given ſpaces, from a ſtate of reſt, the ſquares of the times are proportional to the ſpaces directly, and to the forces inverſely.*

Let ABC (fig. 19.) *a b c* be the ſpaces deſcribed, and AD, *a d*, the accelerating forces at A and *a* Let V, B expreſs the velocity at B, and *v*, *b* the velocity at *b*.

Let GHK and *g h k* be curves whoſe ordinates are inverſely as the velocities at the correſponding points of the abſciſſa. Theſe curves are therefore exponents of the times (n° 99.) Then, becauſe the forces act ſimilarly, we have, by the laſt theorem, $AC \times AD : ac \times ad = V^2, B : v^2, b, = hb^2 : HB^2$. Therefore $HB : hb = \sqrt{ac \times ad} : \sqrt{AC \times AD}$, and therefore in a conſtant ratio. Call this the ratio of *m* to *n*. But, ſince the ordinates of the lines GHK, *g h k* are inverſely as the velocities, the areas are as the times (n° 99); and

Of Accelerating and Retarding Forces.

and ſince theſe ordinates are in the conſtant ratio of m to n, the areas are in the ratio of AC × m to ac × n. Therefore (calling the times of the motions T and t), we have

$$T : t = m\,AC : n\,ac;\text{ and therefore}$$
$$T^2 : t^2 = m^2 \times AC^2 : n^2 \times ac^2.\quad\text{But}$$
$$m^2 : n^2 = ac \times ad : AC \times AD.\quad\text{Therefore}$$
$$T^2 : t^2 = ac \times ad \times AC^2 : AC \times AD \times ac^2,$$
$$\text{Or } T^2 : t^2 = ad \times AC : AD \times ac.$$
$$\text{Or } T^2 : t^2 = \frac{AC}{AD} : \frac{ac}{ad}.$$

The attentive reader will obſerve that theſe three propoſitions give a great extenſion to the theorems which were formerly deduced from the nature of uniformly accelerated motion, or of uniform action of the forces, and were afterwards demonſtrated to obtain in the momentary action of forces any how variable.

The firſt of the three propoſitions, $V : v = F \times T : f \times t$, is the extenſion of the theorem $f \times \dot{t} = \dot{v}$. The ſecond, $V^2 : v^2 = F \times S : f \times s$, is the extenſion of the theorem $f \times \dot{s} = v\,\dot{v}$. And the third, $T^2 : t^2 = \frac{S}{F} : \frac{s}{f}$, is the extenſion of $f = \frac{\dot{s}}{(t^2)^{\cdot}}$, or of $f \times (t^2) = \dot{s}$. Theſe theorems hold true of all *ſimilar* actions; and only for this reaſon, are true of uniformly accelerated motions, or uniform actions.

Aggregate of many equal accelerating forces.

There remains one thing more to be ſaid concerning the action of accelerating forces. Their magnitude is aſcertained by their effect. Therefore that is to be conſidered as a double force which produces a double quantity of motion. Therefore when a body A contains twice the number of equal atoms of matter, and acquires the ſame velocity from the action of the force F that another body a, containing half the number of atoms, acquires from the action of a force f, we conceive F to be double of f. That this is a legitimate inference appears clearly from this, that we conceive the ſenſible weight of a body, or that preſſure which it exerts on its ſupports, as the aggregate of the equal preſſure, of every atom, accumulated perhaps on one point; as when the body hangs by a thread, and, by its intervention, pulls at ſome machine. Without inquiring in what manner, or by what intervention, this accumulation of preſſure is brought about, we ſee clearly that it reſults from the equal accelerating force of gravity acting immediatly on each atom. When this weight is thus employed to move another body by the intervention of the thread, which is attached to one point perhaps of that body, it puts the whole into motion, generating a certain velocity v in every atom, by acting uniformly during the time t. We conceive each atom to have ſuſtained the action of an equal accelerating force, whoſe meaſure is $\frac{v}{t}$. Without conſidering how this force is exerted on each atom, or by what it is immediately exerted, or how it is diffuſed through the body from the point to which the weight of the other body is applied by means of the thread; we ſtill conſider it as the aggregate of the action of gravity on each atom of that other body. Moreover, attending only to the motion produced by it, and perhaps not knowing the weight of the impelling body, we meaſure it, as a moving force, by conſidering it as the aggregate of the forces propagated to each atom of the impelled body, and meaſured by $\frac{v}{t}$. If we know that the impelled body contains the number m of atoms, the aggregate of forces is $m\frac{v}{t}$, or $\frac{mv}{t}$.

Of Accelerating and Retarding Forces.

But ſince we meaſure forces by the quantity of motion which they produce, we muſt conceive, that when the ſame force is applied to a body which conſiſts of n particles, and produces the velocity u, by acting uniformly during the ſame time t, the force $n\frac{u}{t}$ is equal to the force $m\frac{v}{t}$.

110 Moving force, motive force, vis motrix, as diſtinguiſhed from accelerating force.

Sir Iſaac Newton found it abſolutely neceſſary, in the diſquiſitions of natural philoſophy, to keep this circumſtance of acceleration clear of all notions of quantity of matter, or other conſiderations, and to contemplate the affections of motion only. He therefore conſidered $\frac{v}{t}$ as the true original meaſure of accelerating force, and $m\frac{v}{t}$ as an aggregate. He therefore calls the aggregate a *vis motrix*, a *moving force*, meaſured by the *quantity of motion* that it generates. And he confines the term *accelerating force* to the quantity $\frac{v}{t}$, meaſured by the *acceleration* or *velocity* only. It would be convenient, therefore, alſo to confine the ſymbol f to $m\frac{v}{t}$, and to retain the ſymbol a for expreſſing the accelerating force $\frac{v}{t}$.

This appellation of *motive force* is perfectly juſt and ſimple; for we may conceive it as the ſame with the accelerating force which produces the velocity m times v in one particle, by acting on it uniformly during the time t. This motion of one particle having the velocity $m\,v$, is the ſame with that of m particles having each the velocity v.

If therefore a motive force f acts on a body conſiſting of m particles, the accelerating force a is $= \frac{f}{m}\frac{v}{t}$.

Therefore the three laſt propoſitions concerning the ſimilar, the uniform, or the momentary actions of *moving* forces, when expreſſed in the moſt general terms, are,

$$v' \doteqdot \frac{f}{m\,t'}$$
$$vv' \doteqdot \frac{f\,s'}{m},\ \text{or } v\dot{v} = \frac{f\,\dot{s}}{m}$$
$$t^2 \doteqdot \frac{m\,s'}{f}.$$

Of Deflecting Forces.

111 Deflecting forces.

When we obſerve the direction of a body to change, we unavoidably infer the agency of a force which acts in a direction that does not coincide with that of the body's motion; and we may diſtinguiſh this circumſtance by calling it a DEFLECTING FORCE. We have already ſhewn how to eſtimate and meaſure this deflecting force, by conſidering it as competent to the pro-

production of that motion which, when compounded with the former motion, will produce the new motion (n° 44.) Now, as all changes of motion are really compoſitions of motions or forces, it is evident that we ſhall explain the action of deflecting forces when we ſhew this compoſition.

Alteration of deflections are continual, and produce curvilineal motions.

We may almoſt venture to ſay *à priori*, that all deflections muſt be continual, or exhibit curvilineal motions: for as no finite velocity, or change of velocity, can be produced in an inſtant by the action of an accelerating force, no polygonal or angular deflection can be produced; becauſe this is the compoſition of a finite velocity produced in an inſtant. Deflective motions are all produced by the compoſition of the former motion, having a finite velocity, with a tranſverſe motion continually accelerated from a ſtate of reſt. Of this we can form a very diſtinct notion, by taking the ſimpleſt caſe of ſuch accelerated motion, namely, an uniformly accelerated motion.

112
Example Determination of the path,

Let a body be moving in the direction AC (fig. 20.) with any conſtant velocity, and when it comes to A, let it be expoſed to the action of an accelerating force, acting uniformly in any other direction AE. This alone would cauſe the body to deſcribe AE with a uniformly accelerated motion, ſo that the ſpaces AD, AE would be as the ſquares of the times in which they are deſcribed. Therefore, if AB be the ſpace which it would have deſcribed uniformly in the time that it deſcribes AD by the action of the accelerating force, and AC the ſpace which it would have deſcribed uniformly while it deſcribes AE by the action of the accelerating force—nothing more is wanted for aſcertaining the real motion of the body but to compound the uniform motion in the direction AC with the uniformly accelerated motion in the direction AE. AD is to AE as the ſquare of the time of deſcribing AD to the ſquare of the time of deſcribing AE; that is, as the ſquare of the time of deſcribing AB to the ſquare of the time of deſcribing AC; that is, as AB^2 to AC^2 (by reaſon of the uniform motion in AC). This compoſition is performed by taking the ſimultaneous points B, D, and the ſimultaneous points C, E, and completing the parallelograms ABFD, ACGE. The body will be found in the points F and G in the inſtants in which it would have been found at B and C by the uniform motion, or in D and E by the accelerated motion. In the ſame manner may be found as many points of the real path as we pleaſe. It is plain that theſe points will be in a line AFG, ſo related to AE that $AD : AE = DF^2 : EG^2$; or ſo related to the original motion AC, that $AB^2 : AC^2 = BF : CG$, &c. This line is therefore a parabola, of which AE is a diameter, DF and EG are ordinates, and which touches AC in A.

And of the motion in this path.

Having thus aſcertained the path of the body, we can alſo aſcertain the motion in that path; that is, the velocity in any point of it. We know that the velocity in the point G is to the velocity of the uniform motion in the direction AC as the tangent TG is to the ordinate EG; becauſe this is the ultimate ratio of the momentary increment of the arch AFG to the momentary increment of the ordinate EG. Thus is the velocity in every point of the curve determined. We have taken it for granted, that the line of projection touches the path, and that the direction in every point is that of the tangent. To ſuppoſe that the curve, in any portion of it, coincides with the tangent, is to ſuppoſe that the body is not deflected; that is, is not acted on by a tranſverſe accelerating force: And to ſuppoſe that the tangent makes a finite angle with any part of the path, is to ſuppoſe that the deflection is not continual, but by ſtarts—both of which are contrary to the conditions of the caſe. No ſtraight line can be drawn between the direction of the body and the ſucceeding portion of the path, otherwiſe we muſt again ſuppoſe that the deflection is ſubſultory, and the motion angular.

113.

But while the inveſtigation is ſo eaſy when the direction and intenſity of the deflecting force in every point of the curve are known, the inveſtigation of the deflecting force from the obſerved motion is by no means eaſy. The obſerved curvilineal motion always ariſes from a compoſition of a uniform motion in the tangent with ſome tranſverſe motion. But the ſame curvilineal motion may be produced by compounding the uniform motion in the tangent with an infinity of tranſverſe motions; and the law of action will be different in theſe tranſverſe motions according as their directions differ. We muſt learn, not only the intenſity of the deflecting force, and the law of its variation, but alſo its direction in every point of the curve. It is not eaſy to find general rules for diſcovering the direction of the tranſverſe force; moſt commonly this is indicated by extrinſic circumſtances. The deflecting force is frequently obſerved to reſide in, or to accompany, ſome other body. It may be preſumed, therefore, that it acts in the direction of the line drawn to or from that body; yet even this is uncertain. The moſt general rule for this inveſtigation is to obſerve the place of the body at ſeveral intervals of time before and after its paſſing through the point of the curve, where we are intereſted to find its preciſe direction. We then draw lines, joining thoſe places with the places of the tangent where the body would have been by the uniform motion only. We ſhall perhaps obſerve theſe lines of junction keep in parallel poſitions: we may be aſſured that the direction of the tranſverſe force is the ſame with that of any of theſe lines. This is the caſe in the example juſt now given of a parabolic motion. But when theſe lines change poſition, they will change it gradually; and their poſition in the point of contact is that to which their poſitions on both ſides of it gradually approximate.

But all this is deſtitute of the preciſion requiſite in philoſophical diſcuſſion. We are indebted to Sir Iſaac Newton for a theorem which aſcertains the direction of the tranſverſe force with all exactneſs, in the caſes in which we moſt of all wiſh to attain mathematical accuracy, and which not only opened the acceſs to thoſe diſcoveries which have immortaliſed his name, but alſo pointed out to him the path he was to follow, and even marked his firſt ſteps. It therefore merits a very particular treatment.

114
Newton's fundamen tal theore for the di rection of deflectin force.

If a body deſcribes a curve line ABC, DEF (fig. 21.) lying in one plane; and if there be a point S ſo ſituated in this plane that the line joining it with the body deſcribes areas ASB, ASC, ASD, &c. proportional to the times in which the body deſcribes the arches AB, AC, AD, &c. the force which deflects the body from rectilineal motion is continually directed to the fixed point S.

Let us firſt ſuppoſe that the body deſcribes the polygon ABCDEF, &c. formed of the chords AB, BC, CD, DE, EF, &c. of this curve: and (for greater ſimplicity of argument) let us conſider areas deſcribed in equal ſucceſſive times; that is, let us ſuppoſe that the triangles ASB, BSC, CSD, &c. are equal, and deſcribed in equal times. Make B *c* = AB, and draw *c* S.

Areas ÷ to he times ndicate entral orces. Had the motion AB ſuffered no change in the point B, the body would have deſcribed B*c* in the equal moment ſucceeding the firſt: but it deſcribes BC. The body has therefore been deflected by an external force; and BC is the diagonal of a parallelogram (n° 45, 46.), of which B *c* is one ſide, and *c* C is another. The deflecting force will be diſcovered, both in reſpect of direction and intenſity, by completing the parallelogram B *c* C *b*. B *b* is the ſpace which the deflecting force would have cauſed the body to deſcribe in the time that it deſcribes B *c* or BC. Becauſe B *c* is equal to BA, the triangles BS*c*, BSA are equal. But (by the nature of the motion) BSA is equal to BSC. Therefore the triangles BSC and BS*c* are equal. They are alſo on the ſame baſe BS; therefore they lie between the ſame parallels, and C*c* is parallel to SB. But *c* C is parallel to B *b*. Therefore B *b* coincides with BS, and the deflecting force at B is directed toward S. By the ſame argument, the deflecting force at the angles D, E, F, &c. is directed to S.

Now, let the ſides of the polygon be diminiſhed, and their number increaſed without end. The demonſtration remains the ſame; and continues, when the polygon finally coaleſces with the curve, and the deflection is continual.

When areas are deſcribed proportional to the times, equal areas are deſcribed in equal times; and therefore the deflection is always directed to S. Q. E. D.

entre of eflection. entre of orces. entral orces. The point S may, with great propriety of language, be called the CENTRE OF DEFLECTION, or THE CENTRE OF FORCES; and forces which are thus continually directed to one fixed point, may be diſtinguiſhed from other deflecting forces by the name CENTRAL FORCES.

adius vec- or. The line joining the centre of forces with the body, and which may be conceived as a ſtiff line, carrying the body round, is uſually named the RADIUS VECTOR.

115 entral for- es produce reas pro- ortional to ne times. The converſe of this propoſition, viz. that if the deflecting forces be always directed to S, the motion is performed in one plane, in which S is ſituated, and areas are deſcribed proportional to the times—is eaſily demonſtrated by reverſing the ſteps of this demonſtration. The motion will be in the plane of the lines SB and B *c*; becauſe the diagonal BC of the parallelogram of forces is in the plane of the ſides. Areas are deſcribed proportional to the times; for C *c* being parallel to SB, the triangles SCB and S *c* B are equal; and therefore SCB and SAB are equal, &c. &c.

116 elocity is nverſely a- ne perpen- icular om the entre. *Cor.* 1. When a body deſcribes areas round S proportional to the times, or when it is continually deflected toward S, or acted on by a tranſverſe force directed to S, the velocities in the different points A and E of the curve are inverſely proportional to the perpendiculars S*r* and S*t*, drawn from the centre of forces to the tangents in thoſe points; that is, to the perpendiculars from the centre on the momentary directions of the motion: For ſince the triangles ASB, ESF are equal, their baſes AB, EF are inverſely as their altitudes S*r*, S*t*. But theſe baſes, being deſcribed in equal times, are as the velocities; and they ultimately coincide with the tangents at A and E.

117. *Cor.* 2. If $B\alpha$ and $F\epsilon$ be drawn perpendicular to SA and SE, we have $SA \times B\alpha = SE \times F\epsilon$, and $SA : SE = F\epsilon : B\alpha$: For $SA \times B\alpha$ is double of the triangle BSA, and $SE \times F\epsilon$ is double of the equal triangle SFE.

118 Angular velocity is inverſely as the ſquare f the diſtance from the centre of forces. *Cor.* 3. The angular velocity round S, that is, the magnitude of the angle deſcribed in equal times by the radius vector, is inverſely proportional to the ſquare of the diſtance from S. For when the arches AB, EF are diminiſhed continually, the perpendiculars $B\alpha$ and $F\epsilon$ will ultimately coincide with arches deſcribed round S with the radii SB and SF. Now the magnitude of an angle is proportional to the length of the arch which meaſures it directly, and to the radius of the arch inverſely. In any circle, an arch of two inches long meaſures twice as many degrees as an arch one inch long; and an arch an inch long contains twice as many degrees of a circle whoſe radius is twice as ſhort. Therefore, ultimately, the angle ASB is to the angle ESF as $B\alpha$ to $F\epsilon$, and as SF to SB jointly; that is, as $B\alpha \times SF$ to $F\epsilon \times SB$. But $B\alpha : F\epsilon = SE : SA$ (*Cor.* 2.) Therefore $ASB : ESF = SE \times SF : SB \times SA$, $=$ ultimately $SE^2 : SB^2$.

This corollary gives us an oſtenſible mark, in many very important caſes, of the action of a deflecting force being always directed to a fixed point. We are often able to meaſure the angular motion when we cannot meaſure the real velocities.

Intimate connection of dynamics and the higher geometry. Having thus diſcovered the chief circumſtances which enable us to aſcertain the direction of the deflecting force, we proceed to inveſtigate the quantity of this deflective determination in the different points of a curvilineal motion. This is a more difficult taſk. The momentary effect of the deflecting force is a ſmall deviation from the tangent; and this deviation is made with an accelerated motion. The law of this acceleration regulates the curvature of the path, and is to be determined by it. We may be allowed to obſerve by the way, that it appears clearly from the form in which Newton has preſented all his dynamical theorems, that we are indebted to theſe problems for the immenſe improvement which he has made in geometry by his invention of fluxions. The purpoſes he had in view ſuggeſted to his penetrating mind the means for attaining them; and the connection between dynamics and geometry is ſo intimate, that the ſame theorems are in a manner common to both. This is particularly the caſe in all that relates to curvature. Or ſhall we ſay that the geometry of Dr Barrow ſuggeſted the dynamical theorems to Newton? We have ſeen how the curvature of a parabola is produced by a force acting uniformly. The *momentary* action of all finite forces may be conſidered as uniform; and therefore the curvature will be that of ſome portion of ſome parabola; but it will be difficult to determine the preciſe degree without ſome farther help. We are beſt acquainted with the properties of the circle, and will have the cleareſt notions of the curvature of other curves by comparing them with circles.

Meaſure of curvature. The curvature of a circular arch of given length is ſo much greater as its radius is ſhorter; for it will contain ſo many more degrees in the ſame length; and therefore the change of direction of its extremities is ſo much greater. Curvatures may always be meaſured by the length of the arch directly and the radius inverſely.

119 Evolution and involution of curves.

Suppoſe a thread made faſt at one end of a material curve ABCD (fig 22), and applied to it in its whole length. Taking hold of its extremity D, unfold it gradually from the curve DCBA; the extremity D will deſcribe another curve D *c b a*. This geometrical operation is called the Evolution of curves, and D *c b a* is called the Evolute of DCBA, which is called the Involute of D *c b a*. Perhaps this denomination has been given from the geneſis of the area or ſurface contained by the two lines, which is folded up and unfolded ſomewhat like a fan. When the deſcribing point is in *b*, the thread *b* B is, undoubtedly, the momentary radius of a circle *e b f*, whoſe centre is B, the point of the involute which it is juſt going to quit. The momentary motion of *b* is the ſame, whether it is deſcribing an arch of the evolute paſſing through *b*, or an arch of a circle round the centre B. The ſame line *b t*, perpendicular to the thread *b* B, touches the circle *e b f* and the curve D *b a* in the point *b*. This circle *e b f* muſt lie within the curve D *b a* on the ſide of *b* B toward *a*; becauſe on this ſide the momentary radius is continually increaſing. For ſimilar reaſons, the circle *e b f* lies without the curve on the other ſide of *b* B. Therefore the circle *e b f* both touches and cuts the curve D *b a* in the point *b*. Moreover, becauſe every portion of the curve between *b* and D is deſcribed with radii that are ſhorter than *b* B, it muſt be more incurvated than any portion of the circle *e b f*. For ſimilar reaſons, every portion of the curve between *b* and *a* muſt be leſs incurvated than this circle; therefore the circle has that preciſe degree of curvature that belongs to the curve in the point *b*; it is therefore called the

Circle of curvature. Equicurve circle.

Equicurve Circle, or the Circle of Curvature, and B is called the centre, and B *b* the Radius of Curvature. It is eaſy to perceive that no circle can be deſcribed which ſhall touch the curve in *b*, and come between it and the circle *e b f*; for its centre muſt be in ſome point *i* of the radius *b* B. If *i b* be leſs than B *b*, it muſt fall within the curve on both ſides of *b*, and if *i b* is greater than B *b*, the circle muſt fall without the curve on both ſides of B *b*. The circle *e b f* lies cloſer to the curve, has cloſer contact with it than any other, and has therefore got the whimſical name of Osculating Circle; and this ſort of contact was called Osculation.

This view of the geneſis of curve lines is of particular uſe in dynamical diſcuſſions. It exhibits to the eye the perfect ſameneſs of the momentary motion, and therefore of the momentary deflection, in the curve and in the equicurve circle, and leaves the mind without a doubt but that the forces which produce the one will produce the other. A great variety of curves may be deſcribed in this way. If perpendiculars be drawn to the curve D *b a* in every point, they will interſect each other, each its immediate neighbour, in the circumference of the curve DBA: and geometry teaches us how to find the curve DBA which ſhall produce the curve D *b a* by evolution. See Evolution and Involution, *Supplement*.

It is a matter worthy of remark, that the path of a body that is deflected from rectilineal motion by a *finite* force, varying according to any law whatever, may always be deſcribed by evolution. This includes almoſt every caſe of the action of deflecting forces; none being excepted but when, by the oppoſite action of different forces, the body is in equilibrio in one ſingle point of its path.

Our taſk is now brought within a very narrow compaſs, namely, to meaſure the deflection in the arch of a circle.

Had the motion repreſented in fig. 21. been polygonal, it is plain that the deflecting force in the point B is to that in the point E as the diagonal B *b* of the parallelogram ABC *b* to the diagonal E *i* of the parallelogram DEF *i*; therefore let ABCZY be a circle paſſing through the points A, B, and C, and let the radius vector BS cut the circumference in Z; draw AZ, CZ, and the diagonal AC, which neceſſarily biſects and is biſected by the diagonal B *b*. The triangles *b* BC and CBZ are ſimilar; for the angle C *b* B is equal to the alternate angle AB *b* or ABZ, which is equal to the ACZ, ſtanding on the ſame chord AZ. And the angle CB *b*, or CBZ, is equal to CAZ, ſtanding on the ſame chord CZ; therefore the remaining angle *b* CB is equal to the remaining angle AZC; therefore ZA is to AC as BC to B *b*, and B *b* $= \frac{AC \times BC}{AZ}$. In like manner E *i* $= \frac{DF \times EF}{Dz}$.

Now let the points A and C continually approach, and ultimately coaleſce with B; it is evident that the circle ABCZY is ulimately the equicurve or coinciding circle at the point B, and that AS ultimately coaleſces with, and is equal to, BS, and that AC × BC is ultimately $2\,BC^2$; therefore ultimately B *b* : E *i* $= \frac{2BC^2}{BZ} : \frac{2EF^2}{Ez}$, or $= \frac{BC^2}{\frac{1}{2}BZ} : \frac{EF^2}{\frac{1}{2}Ez}$.

Measure of deflecting forces.

Now BC and EF being deſcribed in equal times, are as the velocities: B *b* and E *i* are the meaſures of the velocities which the deflective forces at B and E would generate in the time that the body deſcribes BC or EF, and are therefore the meaſures of thoſe forces. *They are as the ſquares of the velocities directly, and inverſely as thoſe chords of the equicurve circles which have the directions of the deflection.*

Obſerve, that B *b* or E *i* is the third proportional to half of the chord and the arch deſcribed; for B *b* : BC $= BC : \frac{BZ}{2}$.

It is evident that as the arches AB, BC, continually diminiſh, AC is ultimately parallel to the tangent B *r*, and BO is equal to the actual deflection from the tangent. The triangles BOC and AOZ are ſimilar, and BO $= \frac{OC^2}{OZ}$, or ultimately $= \frac{BC^2}{BZ}$. We may meaſure the forces by the actual deflections, becauſe they are the halves of the meaſures of the generated velocities; and we may ſay that

120 Measure of deflection.

The actual momentary deflection from the tangent is a third proportional to the deflective chord of the equicurve circle and the arch deſcribed during the moment.

Caution.

Either of theſe meaſures may be taken, but we muſt take care not to confound them. The firſt is the moſt proper, becauſe the change produced on the body (which is the *immediate* effect and meaſure of the force) is the determination, left inherent in it, to move with a certain velocity. This is the meaſure alſo which we obtain by means of the differential or fluxionary calculus; but the other meaſure muſt be obtained when our immediate object is to mark the actual path of the body. What is now delivered coincides with what was more briefly ſtated in ASTRONOMY, *Suppl.* n° 16. and is repeated in this place, becauſe the ſteps of this demonſtration, which is Newton's, ſo naturally terminate in the equicurve circle, and give at once the immediate meaſure of the deflecting force: at the ſame time the reader muſt perceive that this meaſure does not depend on the force being always directed to one centre; it is enough that the two ſides of the polygon, in immediate ſucceſſion, are deſcribed in equal times. This is neceſſary in order that ABC *b* may be a parallelogram, and that the diagonals AC and B *b* may mutually biſect each other.

Thus have we obtained a meaſure of deflecting force, and, in the moſt important caſes, a method of diſcovering its direction. It only remains to point out the relation between the intenſity of the force, the curvature of the path, and the velocity of the motion. Theſe three circumſtances have a neceſſary connection; for we ſee that the intenſity is expreſſed by certain values of the other two in the formula $f \doteq \frac{\text{Arch}^2}{\frac{1}{2}\text{Chord}}$, or $f = \frac{2\,\text{BC}}{\text{BZ}}$. The deflective velocity B *b* is acquired in the time that the body deſcribes BC; therefore the deflective velocity is to the velocity in the curve as B *b* to BC. The velocity B *b* is acquired by an accelerated motion along BO; for while, by progreſſive motion, the body deſcribes BC, it deflects from the tangent through a ſpace equal to the half of B *b*, becauſe the momentary action of the deflecting force may be conſidered as uniform. The progreſſive velocity BC may be generated by the ſame force, uniformly acting through a ſpace greater than BC; call this ſpace x. The ſpaces along which a body muſt be uniformly impelled in order to acquire different velocities, are as the ſquares of thoſe velocities; therefore $\text{B}\,b^2 : \text{BC}^2 = \text{B}\,o : x$; but $\text{B}\,b : \text{BC} = \text{BC} : \frac{1}{2}\,\text{BZ}$; therefore $\text{B}\,b^2 : \text{BC}^2 = \text{B}\,b : \frac{1}{2}\,\text{BZ}$, and $\text{B}\,b : \frac{1}{2}\,\text{BZ} = \text{B}\,o : x$, and $\text{B}\,b : \text{B}\,o = \frac{1}{2}\,\text{BZ} : x$; but B *o* is ½ of B *b*; therefore x is ¼ of BZ; that is,

121. *The velocity in any point of a curvilineal path, is that which the deflecting forces in that point would generate in the body by impelling it uniformly along one fourth part of the deflective chord of the equicurve circle.* If the velocity increaſe, the chord of the equicurve circle muſt increaſe; that is, the path becomes leſs incurvated. If the force be increaſed, the curvature will alſo increaſe, for the chord of curvature will be leſs.

There is another general obſervation to be made on the velocity of a curvilineal motion, which greatly aſſiſts us in our inveſtigations.

122 Compariſon of orbital motion with direct approach to the centre.

If a body deſcribes a curve by the action of a force always directed to a fixed point, and varying according to any proportion whatever of the diſtances from that point, and if another body, acted on by the ſame centripetal force, move toward the centre in a ſtraight line, and if in any one caſe of equal diſtances from the centre of force the two bodies have equal velocities, they will have equal velocities in every other caſe of equal diſtances from the centre.

Let one body be impelled from A (fig. 23.) toward C along the ſtraight line AVDEC, and let another be deflected along the curve line VIK *k*. About the centre C deſcribe concentric arches ID, KE, very near to each other, and cutting the curve in I and K, and the line AC in D and E; draw IC, cutting KE in N, and draw NT perpendicular to the arch IK of the curve, and complete the parallelogram ITNO. Let the bodies be ſuppoſed to have equal velocities at I and at D.

Then, becauſe the centripetal forces are ſuppoſed to be the ſame for both bodies when they are at equal diſtances, the accelerating forces at D and I may be repreſented by the equal lines DE and IN; but the force IN is not wholly employed in accelerating the body along the arch IK, but, acting tranſverſely, it is partly employed in incurvating the path. It is equivalent to the two forces IO and IT, of which only IT accelerates the body. Now IKN is a right-angled triangle, as is alſo the triangle INT; and they are ſimilar; therefore IN : IT = IK : IN, or DE : IT = IK : DE; that is, the force which accelerates the body along DE is to the force which accelerates the body along IK as the ſpace IK is to the ſpace DE; therefore (n° 86.) the increment of the ſquare of the velocity acquired along DE is equal to the increment of the ſquare of the velocity acquired along IK. But the velocities at D and I were equal, and conſequently their ſquares were equal; and theſe having received equal increments, therefore the ſquares of the velocities at E and K are equal, and the velocities themſelves are equal. And ſince this is the caſe in all the correſponding points of the line AC and the curve VIK, the velocities at all equal diſtances from C will be equal.

It it evident that the concluſion will be the ſame, if the bodies, inſtead of being accelerated by approaching the centre in the ſtraight line AC, and in the curve VIK, are moving in the oppoſite directions from E to A, or from I to V, and are therefore retarded by the centripetal force.

123 Retarded curvilineal motion always accompanied by receſs from the centre.

Cor. Hence it follows, that if a body be projected from any point, ſuch as V, of the curve, in a line tending ſtraight from the centre, with the velocity which it had in that point of the curve, it would go to a diſtance VA, ſuch, that if it were impelled along AV by the centripetal force, it would acquire its former velocity in the point V; alſo in any point between V and A it will have the ſame velocity in its receſs from the centre that it has there in its approach to the centre.

The line BLFG, whoſe ordinates are as the intenſities of the centripetal force in A, V, D, E, or in A, V, I, K, may be called the SCALE or EXPONENT of force; the areas bounded by the ordinates AB, VL, DF, EG, &c. drawn from any two points of the axis, are as the ſquares of the velocity acquired by acceleration along the intercepted part of the axis, or in any curvilineal path, while the body approaches the centre, or which are loſt while the body retires from it. When we can compute theſe areas we obtain the velocities (ſee n° 102.).

We are now in a condition to ſolve the chief problem in the ſcience of dynamics, to which the whole of it is, in a great meaſure, ſubſervient. The problem is this,

Let a body be projected with a known velocity from a

124 Inverſe problem of centripetal forces.

a given point and in a given direction, and let it be under the influence of a mechanical force, whoſe direction, intenſity, and variation, are all known: it is required to determine its path, and its motion in this path, for any given time?

This problem is ſuſceptible of three diſtinct claſſes of conditions, which require different inveſtigation.

1. The force may act in one conſtant direction; that is, in parallel lines.

2. The force may be always directed to a fixed point.

3. It may be directed to a point which is continually changing its place.

1. When the force acts in parallel lines, the problem is ſolved by compounding the rectilineal accelerated motion which the force would produce in its own direction with the uniform motion which the projection alone would have produced. The motion muſt be curvilineal, when the accelerating force is tranſverſe, in any degree whatever, to the projectile motion; and the curvilineal path muſt be concave on that ſide to which the deflecting force tends; for the force is ſuppoſed to act inceſſantly. The place of the body will be had for any time, by finding where the body would have been at the end of that time by each force acting alone, and by completing the parallelogram. Thus, ſuppoſe a body projected along AB (fig. 20.) while it is continually acted on by a force whoſe direction is AD. Let D and B be the places where the body would be at the end of a given time. Then the body will at the end of that time be in F, the oppoſite angle of the parallelogram ABFD. But it has not deſcribed the diagonal AF; becauſe its motion has been curvilineal, as we ſhall find by determining its place at other inſtants of this time.

The velocity in any point F is found by firſt determining the velocity at D, and making DT to DF as the velocity at D to the velocity at B (that is, the velocity of projection, becauſe the motion along AB is uniform). Then draw TF. Then AB is to TF as the conſtant velocity of projection to the velocity at F. We have ſeen already (n° 112—119.) that TF is a tangent to the curve in F. Hence we may determine the velocity at F in another way. Having determined the form of the path in the way already deſcribed, by finding its different points, draw the tangent F *d*, cutting the line DA in *d*. Then the velocity at A is to that at F as AB to *d* F. Hence alſo we ſee, that the velocities in every point of the curve are proportional to the portion of the tangents at thoſe points which are intercepted between *any* two lines parallel to AD.

Either of theſe methods for aſcertaining the velocity, in this caſe of parallel deflections, will in general be eaſier than the general method in n° 121. by the equicurve circle.

It was thus that Galileo diſcovered the parabolic motion of heavy bodies.

Inverſe problem of centripetal forces.

2 We muſt conſider the motions of bodies affected by centripetal or centrifugal forces, always tending to one fixed point. This is the celebrated *inverſe problem of centripetal forces*, and is the 42d propoſition of the firſt book of Newton's *Principia*. We ſhall give the ſolution after the manner of its illuſtrious author; becauſe it is elementary, in the pureſt ſenſe of the word, keeping in view the two leading circumſtances, and theſe only, namely, the motion of approach and receſs from the centre, and the motion of revolution. By this judicious proceſs, it becomes a pattern by which more refined, and, in ſome reſpects, better ſolutions ſhould be modelled. At the ſame time we ſhall ſupply ſome ſteps of the inveſtigation which his elegant conciſeneſs has made him omit.

125. Let a body, which tends to C (fig. 24.) with a force proportional to the ordinates of the exponent BLFG, having the axis CA, be projected from V in the direction VQ, with the velocity which the centripetal force would generate in it by accelerating it along AV. It is required to determine the path or orbit VIKI of the body, and its place I in this orbit, at the end of the aſſigned time T?

Suppoſe the thing done, and that I is the place of the body. About the centre C, with the diſtances CV and CI, deſcribe the circles YV and ID. Draw CIX to the circumference, and draw the ordinate DF of the exponent of forces, producing it toward *x*, and produce the ordinate VL toward *a*. Let V *t* be the diſtance to which the body would go along the tangent VQ in the time T, and join *t* C. Let this be ſuppoſed done for every point of the curve. Let *a i k* and *a x y* be two curves ſo related to the curve VIK, that the ordinate DF cuts off an area V *a i* D equal to the orbital ſector VCI, and an area V *a x* D equal to the circular ſector VCX.

Then, becauſe the velocity of projection is given, the diſtance V *t* is known, and the area of the triangle VC *t*. But this is equal to the area VCI, by the laws of central forces (n° 115.). Therefore the area V *a i* D is given. Alſo, becauſe the area VCI increaſes in the proportion of the time, the area V *a i* D increaſes at the ſame rate. Therefore having theſe ſubſidiary curves *a i k*, *a x y*, the problem is ſolved as follows:

Draw an ordinate D *i*, cutting off an area V *a i* D proportional to the time, and deſcribe a circle DIR. Then draw a line CX, cutting off a ſector VCX, equal to the area V *a x* D cut off by the ordinate D *i x*. This line will cut the circle DR in the point I, which is the point of the orbit that was demanded.

But the chief difficulty of the problem conſiſts in the deſcription of the two ſubſidiary curves *a i k* and *a x y*, into which the lines VIK and VXY are tranſformed. We attain this conſtruction by reſolving the motion in the arch of the orbit into two motions, one of which is in the direction of the tranſverſe force, or of the radius vector, and the other is in the direction of revolution, or perpendicular to the radius.

Let V *k* and IK be two very ſmall arches deſcribed in equal moments, and therefore ultimately in the ratio of the velocities in V and I (n° 73.). Deſcribe the circle KE, cutting IC in N. Draw KC and *k* C, and *k n* perpendicular to VC.

The element ICK of the orbit is $= \frac{\text{IC} \times \text{KN}}{2}$, or to $\frac{1}{2}$ IC × KN. This is equal to the element D *i k* E of the area V *a i* D, or to D *i* × DE, or to D *i* × IN. Therefore IN : KN = $\frac{1}{2}$ IC : D *i*, or 2 IN : KN = IC : D *i*, and D *i* $= \frac{\text{IC} \times \text{KN}}{2\ \text{IN}}$.

Now let A *l ſ g h* be the exponent of the velocities, that

that is (n° 86.), let $V l^2$ be to $D f^2$ as ABLV to ABFD, or $V l : D f = \sqrt{ABLV} : \sqrt{ABFD}$. Make $V v$ and $I i$ in the tangents reſpectively equal to $V l$ and $D f$. Draw $v u$ and $i o$ perpendicular to VC and IC, and $v m$ perpendicular to LV produced. Let $m r z$ be an equilateral hyperbola, having VC, ZC, for its aſſymptotes, and cutting FD produced in r. Then the ordinates $V m$, $D r$, are inverſely proportional to CV, CD, or $V m : D r = CD : CV, = CI : CV$. But becauſe the momentary ſectors $VC k$ and ICK are equal, $k n : KN = CI : CV$. Therefore,

$V m : D r = k n : KN$

but $V v : V m = V k : k n$

and $I i \text{ (or } D f) : V v = IK : V k$

therefore $I i : D r = IK : KN$

but $I i : i o = IK : KN$, by ſim. triang.

Therefore $D r = i o$, and $i o : V m = VC : CI$.

Alſo, by ſimilarity of triangles, $I o : i o = IN : KN$, and $2 I o : i o = 2 IN : KN$.

Now it was ſhewn, that in order that the ſpace $D i k E$ may be equal to the ſpace ICK, we muſt have

$2 IN : KN = IC : D i$

or $2 I o : i o = IC : D i$

but $i o : V m = VC : IC$

therefore $2 I o : V m = VC : D i$

and $D i = \frac{VC \times V m}{2 I o}$.

Having obtained $D i$, we eaſily get $D x$; for the ultimate ratio of ICK to XCY is that of IC^2 to VC^2. Therefore make

$IC^2 : VC^2 = D i : D x$.

Thus are the points of the two ſubſidiary curves $a i k$, $a x y$, determined.

The rectangle $VC \times V m$ is a conſtant magnitude; and is given, becauſe VC is given, and $V m$ is the given velocity $V l$, diminiſhed in the ratio of radius to the ſine of the given angle CVQ.

But the line $2 I o$ is of variable magnitude, but it is alſo given, by means of known quantities. $I o^2$ is $= I i^2 - i o^2 = D f^2 - D r^2$, and $I o = \sqrt{D f^2 - D r^2}$. Moreover, $D f^2 = ABFD$, and $D r^2 = \frac{VC^2 \times V m^2}{IC^2}$. Therefore $2 I o = 2 \sqrt{ABFD - \frac{VC^2 \times V m^2}{IC^2}}$, expreſſed in known quantities, becauſe ABFD is known from the nature of the centripetel force.

Let the indeterminate diſtance CI or CD be $= x$, and let the ordinate DF, expreſſing the force, be y. Let VC be a, and $V m$ be c, and let $a b$ be a rectangle equal to the whole area of the exponent of force lying between the ordinate AB and the ordinate CZ, ſo that $a b - \int y \dot{x}$ may repreſent the indeterminate area ABFD.

We have $D i = \frac{a c}{2 \sqrt{a b - \int y \dot{x} - \frac{a^2 c^2}{x^2}}}$

and $D x = \frac{a^3 c}{2 x^2 \sqrt{a b - \int y \dot{x} - \frac{a^2 c^2}{x^2}}}$.

Remark. We have hitherto ſuppoſed that the velocity of projection is acquired by acceleration along AV. But this was merely for greater ſimplicity of argument, and that the final values of $D i$ and $D x$ might be eaſier conceived. In whatever way the velocity is acquired, it will ſtill be true, that when in any point V we make $V l$ to $V m$ as the momentary increment $V k$ of the arch is to the perpendicular $k n$ on the radius vector, we ſhall have in every other point, ſuch as I, the line $D f$ to the line $D r$ as the increment IK of the arch to KN. And in the final equation $D f$ will ſtill be expreſſed by $\sqrt{a b - \int y \dot{x}}$.

126. *Cor.* 1. The angle which the path of the projectile makes with the radius vector is determined by this ſolution; for $I i$ is to $i o$ as radius to the ſine of this angle; which ſine is therefore $= \frac{a c}{x \sqrt{a b - \int y \dot{x}}}$.

127 Apſides determined; *Cor.* 2. When the magnitude $\frac{a c}{x}$ is equal to $\sqrt{a b - \int y x}$, the path is perpendicular to the radius vector, and the body is a tone of the apſides of its orbit, and begins to recede from the centre after having approached to it, or begins to approach after having receded.

128 And curvature. *Cor.* 3. The curvature of the orbit VIK is alſo determined in every point; for the curvature of any line is inverſely as the radius of the equicurve circle, and this is to the chord which paſſes through C as radius to the ſine of the angle $CI i$. Becauſe the velocity in any point I is $= \sqrt{ABFD}$, and is equal to what the centripetal force at I would produce, by impelling the body along ¼th of the deflective chord of the equicurve circle, we have this chord $= 4 \frac{ABFD}{DF}$. Or we obtain it by taking a third proportional to the momentary deflection and the momentary arch of the curve, or by other proceſſes of the higher geometry, all proceeding on the quantities furniſhed in this inveſtigation.

129 Newton the inventor. Such is the ſolution of this celebrated problem given by Sir Iſaac Newton, who may juſtly be called the inventor of the ſcience of which it is the chief reſult, as well as of the geometry, by help of which it is proſecuted. For we cannot give this glory to Galileo; for his ſimple problem of the motion of bodies affected by uniform and parallel gravity, however juſt and elegant his ſolution may be, was peculiar; and the ſame muſt be ſaid of Mr Huyghens's doctrine of centrifugal forces. Beſides, theſe theorems had been inveſtigated by Newton ſeveral years before, *ſua matheſi facem preferente*, as corollaries which he could not paſs unnoticed, from his general method. This is proved by letters from Huyghens. Newton's inveſtigation is extremely, but elegantly, conciſe, and is one of the beſt exertions of his ſagacious mind.

130 Hiſtory of this problem. Whether we conſider this problem as a piece of mere mathematical ſpeculation, or attend to its conſequences, which include the whole of the celeſtial motions in all their extent and complication, we muſt allow it to be highly intereſting, and likely to engage much attention in the period of ardent inquiry which cloſed the laſt century. Accordingly, it was no ſooner known, by the publication of the *Mathematical Principles of Natural Philoſophy* in 1686, than it occupied the talents of the moſt eminent mathematicians; and many ſolutions were publiſhed, ſome of which differ conſiderably from Newton's; ſome are more expeditious, and better fitted for computation. Of theſe, the moſt remarkable

for originality and ingenuity are thoſe of de Moivre, Hermann, Keill, and Stewart. The laſt differs moſt from the methods purſued by others. M'Laurin's propoſitions on this ſubject, and in that part of his fluxions which treats of curvature, are highly valuable, claſſing the chief affections of curvilineal motions geometrically, as they are ſuggeſted by the fluxionary method; and then ſhewing, in a very inſtructive manner, the connection between theſe mathematical affections of motion and the powers of nature which produce them. This part of his excellent work is a fine example of the real nature of all inquiries in dynamics; ſhewing that it differs from geometry little more than in the language, in which the word *force* is ſubſtituted for *acceleration*, *retardation*, or *deflection*. We recommend the careful peruſal of theſe propoſitions to all who wiſh to have clear conceptions of the ſubject. Dr John Keill and Dr Horſeley (biſhop of Rocheſter) have given particular treatiſes on the motions of bodies deflected by centripetal forces inverſely proportional to the cubes of the diſtances; induced by the ſingular motions which reſult from this law of action, and the multitude of beautiful propoſitions which they ſuggeſt to the mathematician. Newton, indeed, firſt perceived both of theſe peculiarities, and has begun this branch of the general problem. He firſt demonſtrated the deſcription of the logarithmic and hyperbolic ſpirals, and indicated a variety of curious recurring elliptical ſpirals, which would be deſcribed by means of this force, and ſhewing that they are all ſuſceptible of accurate quadrature. Several of thoſe authors affect to conſider their ſolutions as more perfect than Newton's, and as more immediately indicating the remarkable properties of ſuch motions; and alſo affect to have deduced them from different and original principles. But we cannot help ſaying, that their claims to ſuperiority are very ill founded; there is not a principle made uſe of in their ſolutions which was not pointed out by Newton, and employed by him. The appearance of originality ariſes from their having taken a more particular concern in ſome general property of curvilineal motions; ſuch as the curvature, the centrifugal force, &c. and the making that the leading ſtep of their proceſs. But Newton's is ſtill the beſt; becauſe it is ſtrictly elementary, aiming at the two leading circumſtances, the motion to or from the centre, and the motion of revolution round that centre. To theſe two purpoſes he adapted his two ſubſidiary curves. This procedure became Newton, *pater, et rerum inventor*, who was teaching the world, and who might ſay,

Avia Pieridum peragro loca, nullius ante
Trita pede——

Singular boaſt of John Bernoulli.

Is it not ſurpriſing, that 25 years after the publication of Newton's *Principia*, a mathematician on the continent ſhould publiſh a ſolution in the Memoirs of the French academy, and boaſt that he had given the firſt demonſtration of it? Yet John Bernoulli did this in 1710. Is it not more remarkable that this ſhould be preciſely the ſolution given by Newton, beginning from the ſame theorem, the 40th I. Prin. following Newton in every ſtep, and uſing the ſame ſubſidiary lines? Yet ſo it is. Bernoulli actually reduces the whole to two functions; namely, $\frac{a\,c}{\sqrt{a\,b-\int\varphi\,\dot{x}-\frac{a^2\,c^2}{x^2}}}$ and $\frac{a^2\,c}{\sqrt{a\,b\,x^4-\int\varphi\,x^4-a^2\,c^2\,x^2}}$; which laſt is plainly the ſame with Newton's $\frac{Q\times CX^2}{A^2\sqrt{ABDF-Z^2}}$; becauſe Newton's $\frac{Q}{A}$ is the ſame with $\frac{a\,c}{x}$, and Newton's $A^2\sqrt{ABFD-Z^2}$ is the ſame with $x^2\sqrt{a\,b-\int\varphi\,\dot{x}-\frac{a^2\,c^2}{x^2}}$, which Bernoulli has changed (apparently to hide the borrowing) into $\sqrt{a\,b\,x^4-\int\varphi\,x^4\,\dot{x}-a^2\,c^2\,x^2}$. This publication of Bernoulli is perhaps the moſt impudent piece of literary *robbery*, for theft is too mild a term, that has ever appeared; and is the more deſerving of ſevere reprehenſion, becauſe it is full of reflections on the ſimple and ſupremely elegant method of Newton. It is hardly conceivable that a perſon of Bernoulli's conſummate mathematical knowlege was ſo much blinded by the mechanical procedure of the ſymbolical calculus (which indeed is rarely accompanied by any ideas of the ſubject in hand) as not to perceive the perfect ſameneſs of his ſolution. No; he ſhews, from time to time, that the phyſical ideas of motion and force were preſent to his mind; for he affects to ſhew, that all Newton's brighteſt diſcoveries, ſuch as the proportionality of the areas and times, &c. flow as corollaries from his procedure.

Bernoulli's chief boaſt in this diſſertation is, that *now* philoſophers may be aſſured that the planets will always deſcribe conic ſections; a truth of which they had not as yet received any proof: becauſe, ſays he, Newton's argument for it in the corollary of the 13th propoſition is inconcluſive, and becauſe he had not been able to accommodate his demonſtration of the 41ſt and 42d propoſition to the particular caſe of the planetary gravitation. Two aſſertions that border on inſolence. Newton's demonſtration in the corollary of the 13th propoſition is juſt, founded on the principle on which the very demonſtration of the 42d, adopted by Bernoulli, proceeds, and without which that demonſtration is of no force; namely, that a body in given circumſtances of ſituation, velocity, direction, and centripetal force, can deſcribe no other figure than what it really deſcribes. Newton did not accommodate the demonſtration of the 42d propoſition to the planetary motions, becauſe he had already demonſtrated the nature of their orbits; but mentions the caſe of a force proportional to the reciprocal of the cubes of the diſtance; not as a deduction from the 42d, but becauſe it *was not* a deduction from it, and admitted a very ſingular and beautiful inveſtigation by methods totally and eſſentially different.

Bernoulli alſo ſays, that Newton's ſolution does not give us the notion of a continuous path, as his own does, but only informs us how to aſcertain points of this path. This is the boldeſt of all his aſſertions. Bernoulli uſes the differential calculus. It is the *eſſential* character of this calculus that it exhibits, and *can* exhibit, nothing but detached points. This is undeniable. And this has been objected to Newton's firſt propoſition. But Newton's fluxionary *geometry*, of which the calculus exhibits only elements (being the ſame with the differential), ſuppoſes oncluſion. ſuppoſes the continuity of all magnitudes; and when applied to dynamics, is no ſubſtitution whatever, but the *ipſa corpora*. This geometry offered itſelf to the mind of Newton, the accompliſhed and darling ſcholar of Barrow, whoſe geometry flaſhed on Newton's mind as the torch which was to ſhew him the ſteps of this yet untrodden path.

We truſt that our readers will not be diſpleaſed with our repeated endeavours to defend our great philoſopher from the injurious attacks that have been made on him. During his own illuſtrious life, while he was diffuſing light and knowledge around him, and never contended for fame, happy in being the inſtructor of mankind, he was injured by thoſe who envied his reputation, while they derived their chief honours from being his beſt commentators. Now, ſince he has left this world, he has been more groſsly injured by thoſe who avail themſelves of that very reputation: and who, by crude and contemptible inferences from his doctrine of elaſtic undulations, and groſs miſrepreſentations of his notions of an etherial fluid, have pretended to ſupport a ſyſtem of materialiſm; and thus have ſet Newton at the head of the atheiſtical ſect, which he held in abhorrence. For our part, we always think with pleaſure on the wonderful energy of that great mind; becauſe it gives us a foretaſte of thoſe pleaſures that await the wiſe and good, when the ſorrows flowing from the infirmities, the vices, and the arrogant vanity of man, are paſt;

Utque in hoc infelici campo,
Ubi luctus regnat, et pavor,
Mortalibus prorſus non abſit ſolatium.
Hujus enim ſcripta evolvas,
Mentemque tantarum rerum capacem
Corpori caduco ſuperſtitem credas.

132 ncluſion. It cannot be expected that, in the narrow limits preſcribed to a work like ours, we can proceed to conſider the various departments of this celebrated problem. We are only giving the outlines of the general doctrines of dynamics; and we have beſtowed more time on thoſe which are purely elementary than ſome readers may think they deſerve. We were anxious to give juſt conceptions of the fundamental principles of dynamics; becauſe we know that nothing elſe can intitle it to the name of a demonſtrative ſcience, and becauſe we ſee much indiſtinctneſs and uncertainty, and a general vagueneſs or want of preciſion, in ſeveral elementary works which are put into the hands of perſons entering on the ſtudy. This leads to errors of more conſequence than a perſon is apt to think; becauſe they affect our leading thoughts of mechaniſm itſelf, and our notions of the intimate nature of the viſible univerſe.

133 ſons for ſſions. But we muſt conclude the article with this great problem. Many very general doctrines of dynamics remain untouched; all, namely, that relate to the rotative motion of rigid bodies, and all that relate to the mutual action of bodies on each other in the way of impulſe.

The rotative motions, with the doctrine of mechanic momenta, have been conſidered at large in the article Rotation of the *Encycl. Britan.*; and we propoſe to offer ſome important conſiderations on the ſame ſubject in our ſupplement to the articles Machine and Mechanics. In the article Impulsion will be conſidered ſuch doctrines as are truly general, and independent of the ſpecific differences of the bodies. Dynamics profeſſes to involve no notions but thoſe of force, and its Concluſion. marks and meaſures.

Notwithſtanding theſe great omiſſions, we muſt obſerve that no new principle remains to be conſidered. We have given all that are neceſſary; and there is no queſtion that occurs in the caſes omitted, which cannot be completely anſwered by means of the propoſitions already eſtabliſhed. We have taught how to diſcover the exiſtence and agency of a mechanical force, to meaſure and characteriſe it, and then to ſtate what will be its various effects, according to the circumſtances of the caſe.

134 Univerſal reaction is a law of the material world. Proceeding by theſe principles, men have diſcovered an univerſal fact, that every action of one body on another is accompanied by an equal reaction of that other on the firſt, in the oppoſite direction; that is, to expreſs it in the language of dynamics, "all the phenomena which make us infer that the body A poſſeſſes a force by which it changes the motion of the body B, ſhew, at the ſame time, that B poſſeſſes a force by which it makes an equal and oppoſite alteration in the motion of A." This, however, is not a doctrine of abſtract dynamics: it does not flow from our idea of force; therefore it was not included in our liſt of the Laws of Motion. It is a part of the mechanical hiſtory of nature, juſt as the law of univerſal gravitation is; and it might be called the law of Universal Reaction. Sir Iſaac Newton has, in our humble apprehenſion, deviated from his accuſtomed logical accuracy, when he admits, as a third *axiom* or law of motion, that reaction is always equal and contrary to action. It is a phyſical law, in as far as it is *obſerved* to obtain through the whole extent of the ſolar ſyſtem. But Newton himſelf did not, in the ſubſequent part of his noble work, treat it as a logical axiom; that is, as a law of human thought with reſpect to motion: for he labours with much ſolicitude, and with equal ſagacity, to prove, by *fact and obſervation*, that it really obtains through the whole extent of the ſolar ſyſtem; and it is in this diſcovery that his chief claim to unequalled penetration and diſcernment appears.

135 Impulſion explained by it; Availing ourſelves of this fact, we, with very little trouble, ſtate all the laws of impulſion. The body A, for example, moving to the weſtward at the rate of eight feet per minute, overtakes the double body B, moving at the rate of four feet per minute. What muſt be the conſequence of their mutual impenetrability, and of the equality and contrariety of action and reaction? Their motions muſt be ſuch that both ſuſtain equal and oppoſite changes. They muſt give, in ſome way or other, *this* indication of poſſeſſing equal and oppoſite forces. This will be the caſe if, when the changes are completed, A and B move on in contact at the rate of four feet per minute: for here A has produced in each half of B a change of motion two; and therefore a totality of change equal to four. This is the effect, the mark, the meaſure, of the *impulſive* force of A; for it is the whole *impulſion*. B has produced in A a change of motion four, equal to the former, and in the oppoſite direction. This is the effect, mark, and meaſure, of the *repulſive* force of A; for it is the whole *repulſion*. And this is all that we obſerve in the colliſion of two lumps of clay; and the obſervation is one of the facts on which the reality of the phyſical law of equal action and reaction is founded: and we can make no farther inference from *this* fact.

But the event might have been very different. A and B may be two magnets floating on corks on water, with their north poles fronting each other. We know, by other means, that they really poſſeſs forces by which they equally repel each other. The dynamical principles already eſtabliſhed tell us alſo what muſt happen in this caſe. That both conditions of equal reaction and ſenſible repulſion may be fulfilled, A muſt come to reſt, and B muſt move forward at the rate of four feet per minute. The ſame thing muſt happen in the meeting of perfectly elaſtic bodies, ſuch as billiard balls. If elaſticities are known to be imperfect in any degree, our dynamical principles will ſtill ſtate the effect of their colliſion, in conformity to the law of equal reaction.

136 And rotation. In like manner, all the motions of rotation are explained or predicted by means of the ſame principles of dynamics applied to the force of coheſion. This is conſidered as a moving force, becauſe, when the attraction of a magnet acts on a bit of iron attached to one end of a long lath floating on water, the whole lath is moved, although the magnet does not act on it at all: ſome other force acts on it; it is its coheſion; which is therefore a moving force, and the ſubject of dynamical diſcuſſion.

137. And thus it appears that theſe ſubjects do not come neceſſarily, nor, perhaps, with ſcientific propriety, under the category of dynamics, but are parts of the mechanical hiſtory of nature. Yet, did a work like ours give room in this place, the ſtudy of mechanical nature might be conſiderably improved by giving a ſyſtem of ſuch *general* doctrines as involve no other notions but thoſe of force and its meaſures, and the hypotheſis of equal reaction. Some very general, nay univerſal, conſequences of this combination might be eſtabliſhed, which would greatly aſſiſt the mechanician in the ſolution of difficult and complicated problems. Such is the propoſition, that *the mutual actions of bodies depend on their relative motions only, and require no knowledge of their real motions.* This principle ſimplifies in a wonderful manner the moſt difficult and the moſt frequent caſes of action which nature preſents to our view; but at the ſame time gives a ſevere blow to human vanity, by forcing us to acknowledge that we know nothing of the real motion of any thing in the univerſe, and never ſhall know any thing of it till our intellectual conſtitution, or our opportunities of obſervation, are completely changed.

138. Mr D'Alembert has made this principle ſtill more ſerviceable for extricating ourſelves from the immenſe complication of actions that occurs in all the ſpontaneous phenomena of nature, by preſenting it to us in a different form, which more diſtinctly expreſſes what may be called the *elements* of the actions of bodies on each other. His propoſition is as follows (*ſee his Dynamique*, page 73.):

D'Alembert's general principle of dynamics. "In whatever manner a number of bodies change their motions, if we ſuppoſe that the motion which each body would have in the following moment, if it were perfectly free, is decompoſed into two others, one of which is the motion which it really takes in conſequence of their mutual actions, the other will be ſuch, that if each body were impreſſed by this force alone (that is, by the force which would produce this motion) the whole ſyſtem of bodies would be in equilibrio."

This is almoſt ſelf-evident; for if theſe ſecond conſtituent forces be not ſuch as would put the ſyſtem in equilibrio, the other conſtituent motions could not be thoſe which the bodies really take by the mutual action, but would be changed by the firſt.

For example, let there be three bodies P, Q, R, and let the forces A, B, C, act on them, ſuch as would give them the velocities p, q, r, in any directions whatever, producing the momenta, or quantities of motion, $P\times p$, $Q\times q$, $R\times r$, which we may call A, B, C, becauſe they are the proper meaſures of the moving force. Let us moreover ſuppoſe, that, by ſtriking each other, or by being any how connected with each other, they cannot take theſe motions A, B, and C, but really take the motions a, b, and c. It is plain that we may conceive the motion A impreſſed on the body P, to be compoſed of the motion a, which it really takes, and of another motion α. In like manner, B may be reſolved into b, which it takes, and another β; and C into c and κ. The motions will be the ſame, whether we act on P with the force A, or with the two forces a and α; whether we act on Q with the force B, or with b and β; and on R with the force C, or with c and κ. Now by the ſuppoſition, the bodies actually take the motions a, b, and c; therefore the motions α, β, and κ, muſt be ſuch as will not derange the motions a, b, and c; that is to ſay, that if the bodies had only the motions α, β, and κ, impreſſed on them, they would deſtroy each other, and the ſyſtem would remain at reſt.

Mr D'Alembert has applied this propoſition with great addreſs and ſucceſs to the very difficult queſtions that occur in the motions and actions of fluids, and many other moſt difficult problems, ſuch as the preceſſion of the equinoxes, &c. The cauſe of its utility is, that in moſt caſes it is not difficult to find what forces will put a ſyſtem in equilibrio; and, combining theſe with the known extraneous forces whoſe effects we are intereſted to diſcover, we obtain the motions which really follow the mutual action of the bodies.

This is not, properly ſpeaking, a principle: it is a form in which a general fact may be conceived. In the ſame way the celebrated mathematician De la Grange obſerved, that a ſyſtem of bodies acting on each other in any way, is in equilibrio, if there be impreſſed on its parts forces in the inverſe proportion of the velocities which each body takes in conſequence of their action or connection; and he expreſſes this univerſal fact by a very ſimple formula; and calling this alſo a principle, he ſolves every queſtion with eaſe and neatneſs, by reducing it to the inveſtigation of thoſe velocities. In this way he has written a complete ſyſtem of dynamics, to which he gives the title of *Mechanique Analytique*, full of the moſt ingenious and elegant ſolutions of very intereſting and difficult problems; and all this without drawing a line or figure, but accompliſhing the whole by algebraic operations.

139. But this is not teaching mechanical philoſophy; it is merely employing the reader in algebraic operations, each of which he perfectly underſtands in its quality of an algebraic or arithmetical operation, and where he may have the fulleſt conviction of the juſtneſs of his procedure. But all this may be (and, in the hands of an expert algebraiſt, it generally is), without any notions, diſtinct or indiſtinct, of the things, or the proceſſes of reaſoning that are repreſented by the ſymbols made uſe of. It is preciſely like the occupation of a banker's clerk when he carries his eye up and down the columns of pounds ſhillings and pence, calculates the compound intereſt, reverſionary values, &c.

It

onclufion.

ifadvan-ges of t e mbolical ethod.

It were well if this were all, although it greatly diminiſhes the pleaſure which an accompliſhed mathematician might receive; but this total abſence of ideas expoſes even the moſt eminent analyſt to frequent riſks of paralogiſm and phyſical abſurdity. Euler, who was perhaps the moſt expert algebraiſt of the laſt century, making uſe of the Newtonian theorem for aſcertaining the motion of a body impelled along a ſtraight line AC (fig. 24) by a centripetal force, by comparing it with the motion in an ellipſe, of which the ſhorter axis was diminiſhed till it vaniſhed altogether, expreſſes his ſurpriſe at finding, that when he computes the place of the body for a time ſubſequent to that of its arrival at C, the body is back again, and in ſome place between C and A; in ſhort, that the body comes back again to A, and plays backward and forward. He ſays that this is ſomewhat wonderful, and ſeems inconſiſtent with ſound reaſon: "*ſed analyſi magis fidendum.*" It muſt be ſo. And he goes on to another problem.

In like manner Mr Maupertuis, an accompliſhed man and good philoſopher and geometer, finding the ſymbol MVS, or the quantity of matter, multiplied by the velocity and by the diſtance run over during the action, always preſent itſelf to him as a mathematical *minimum* in the actions of bodies on each other; he was amuſed by the obſervation, and preſumed that there was ſome reaſon for it in the nature of things. Finding that it gave him very neat ſolutions of many elementary problems in dynamics, he thought of trying whether it would aſſiſt him in accounting for the conſtant ratio of the ſines of incidence and refraction; he found that it gave an immediate and very neat ſolution. This problem had, before his time, occupied the minds of Des Cartes and Fermat. Each of theſe gentlemen ſolved the problem by ſaying, that the light did not take the *ſhorteſt* way from a point in the air to a point under water, but the *eaſieſt* way, in conformity with the acknowledged economy of nature and conſummate wiſdom of its adorable Author. But how was this the eaſieſt way, the courſe that economiſed the labour of nature? One of theſe gentlemen proved it to be ſo, if light move faſter in air than in water; the other proved it to be ſo, if light move faſter in water than in air. Both could not be right. Maupertuis was convinced that he had diſcovered what it was that nature was ſo chary of, and grudged to waſte—it was MVS! Therefore MVS can mean nothing but labour; nothing but natural exertion, mechanical action; therefore MVS is the proper meaſure of action. He kept this great diſcovery a profound ſecret; and, being Preſident of the Royal Academy of Berlin, he propoſed for the annual prize queſtion, "Are the laws of motion neceſſary or contingent truths?" He could not compete for the prize, by the laws of the Academy; but before the time of deciſion, he publiſhed at Paris his *Diſſertation on the Principle of the leaſt Action;* in which he pointed out the ſingular fact of MVS being always a minimum; and therefore, in fact, the object of nature's economical care. He ſolved a number of problems by making the minimum ſtate of $\frac{f v \dot{s}}{m}$ a condition of the problems; and, to crown the whole, ſhewed that the laws of motion which obtain in the univerſe could not be but what they are, becauſe this economy was worthy of infinite wiſdom; and *therefore* any other laws were impoſſible. The reputation of Maupertuis was already eſtabliſhed as a good mathematician and a worthy and amiable man, and he was a favourite of Frederic. The principle of leaſt action became a mode; and it drew attention for ſome time, till it went out of faſhion. It is no mechanical principle, but a neceſſary mathematical truth, as any perſon muſt ſee who recollects that v is the ſame with $\dot{s}$, and that f is the ſame with $m \dot{v}$.

Concluſion.

Great advantages of the geometrical method.

To avoid ſuch paralogiſms and ſuch whims, we are convinced that it is prudent to deviate as little as poſſible in our diſcuſſions from the *geometrical* method. This has ſurely the advantage of keeping the real ſubject of diſcuſſion cloſe in view; for motion includes the notion of lines, with all their qualities of magnitude and poſition. It is needleſs to take a repreſentative when the original itſelf is in our hands, and affords a much more comprehenſible object than one of its abſtract qualities, mere magnitude. Let any perſon candidly compare the lunar theory by Mayer or Euler with that by its illuſtrious inventor Sir Iſaac Newton, and ſay which of the two is moſt luminous and moſt pleaſing to the mind. No perſon will deny that theſe later performances are incomparably more adapted to all practical purpoſes, and lead to corrections which it would be extremely difficult and tedious to inveſtigate geometrically; but it muſt be acknowledged, at the ſame time, that *till this be done*, we have no idea whatever of the deviation of the track which this correction aſcertains from the path which the moon would follow, independent of the diſturbance expreſſed by the correction. In like manner, Dan. Bernoulli, by mixing as much as poſſible the linear method with the algebraic, in his diſſertations on muſical chords, made the beautiful diſcovery of the ſecondary trochoids, and demonſtrated the co-exiſtence of the harmonic ſounds in a full muſical note. Let the accompliſhed mathematician puſh forward our knowledge of dynamics by the employment of the ſymbolical analyſis; but let him be followed as cloſe as poſſible by the geometer, that we may not be robbed of ideas, and that the ſtudent may have light to direct his ſteps. But,—*manum e tabula.*

nano-eter.

Dynamometer.

DYNANOMETER, an inſtrument for aſcertaining the relative muſcular ſtrength of men and other animals. That it would be deſirable to know our relative ſtrengths at the different periods of life, and in different ſtates of health, will hardly be denied; and there can be no doubt but that it would be highly uſeful to have a portable inſtrument by which we could aſcertain the relative ſtrength of horſes or oxen intended for the plough or the waggon. Such an inſtrument was invented, many years ago, by Graham, and improved by Deſaguliers; but being conſtructed of wooden work it was too bulky to be portable, and therefore it was limited in its uſe.

M. Leroy of the Academy of Sciences at Paris conſtructed a much more convenient Dynanometer than Graham's, conſiſting of a metal tube, 10 or 12 inches in length, placed vertically on a foot like that of a candleſtick, and containing in the inſide a ſpiral ſpring, having above it a graduated ſhank terminating in a globe. This ſhank, together with the ſpring, ſunk into the tube in proportion to the weight acting upon it, and thus pointed in degrees the ſtrength of the perſon who preſſed on the ball with his hand.

This was a very ſimple conſtruction, and, we think, a good one; but it did not ſatisfy Buffon and Gueneau. Theſe two philoſophers wiſhed not merely to aſcertain the muſcular force of a finger or a hand, but to eſtimate that of each limb ſeparately, and of all the parts of the body. They therefore employed M. Regnier to contrive a new *dynamometer;* and the account which he gives * of his attempts to fulfil their wiſhes is calculated to enhance the difficulty of the enterprize. The inſtrument, however, which he conſtructed, is not ſuch as appears to us to have required any uncommon ſkill in mechanics, or any very great ſtretch of thought. It conſiſts chiefly of an elliptical ſpring, 12 inches in length, rather narrow, and covered with leather that it may not hurt the fingers when compreſſed by the hands. This ſpring is compoſed of the beſt ſteel well welded and tempered, and afterwards ſubjected to a ſtronger effort than is likely to be ever applied to it either by men or animals, that it may not loſe any of its elaſticity by uſe.

The effects of this machine are eaſily explained. If a perſon compreſſes the ſpring with his hands, or draws it out lengthwiſe by pulling the two extremities in contrary directions, the ſides of the ſpring approach towards each other; and it has an apparatus (we do not think a very ſimple one) appended to it, conſiſting of an index and ſemicircular plate, by which the degree of approach, and conſequently of effort, employed, is aſcertained with great accuracy. The author gives a tedious deſcription of other appendages, by means of which horſes or oxen may be employed to compreſs the ſpring. But as any mechanic may deviſe means for this purpoſe, we do not think it worth while to tranſcribe that deſcription. The Engliſh reader will find a full account of the whole apparatus in the 4th number of the very valuable miſcellany intitled *The Philoſophical Magazine.* The principle of the contrivance conſiſts in the elliptical ſpring, of which we confeſs ourſelves unable to perceive the ſuperiority to the ſpiral ſpring of M. Leroy, though the author ſees it very clearly.

DYSENTERY. See Medicine-*Index*, Encycl.—For the cure of this diſeaſe we have the following ſimple preſcription by Dr Perkins and Dr B. Lynde Oliver, of the State of Maſſachuſetts in North America.

Saturate any quantity of the beſt vinegar with common marine ſalt; to one large table-ſpoonful of this ſolution add four times the quantity of boiling water; let the patient take of this preparation, as hot as it can be ſwallowed, one ſpoonful once in half a minute until the whole is drank: this for an adult. The quantity may be varied according to the age, ſize, and conſtitution of the patient. If neceſſary, repeat the doſe once in ſix or eight hours. Conſiderable evacuations I conceive (ſays Dr Parkins) to be not only unneceſſary, but injurious, as they ſerve to debilitate and prolong the diſeaſe. A tea of plantain, or ſome other cooling ſimple drink, may be uſeful; and if a thirſt for cyder be diſcovered, it may be gratified. Carefully avoid keeping this preparation in veſſels partaking of the qualities of lead or copper, as the poiſon produced by that means may prove dangerous. The ſucceſs of the remedy depends much on preparing and giving the doſe as above directed.—The ſimplicity of this treatment renders it the more valuable, as all perſons have it in their power to avail themſelves of its uſe.

Dr Perkins ſays, that he has found it uſeful in agues, diarrhœas, and the yellow fever.

E.

EARTH, in chemiſtry. See Chemistry-*Index* in this Supplement.

Earth, in aſtronomy and geography. See *Encyclopædia.*

Earth, in ancient philoſophy, one of the elements, the ſubſtance of which this globe is compoſed. To aſcertain the denſity of that ſubſtance, many experiments have been made; but perhaps none more ingenious than thoſe of Mr Cavendiſh, which are detailed at full length in Part II. of the Tranſactions of the Royal Society of London for 1798. They were projected by the late Rev. John Michell, F. R. S. but he did not live to carry them into effect. After his death, the apparatus came to the Rev. F. J. H. Wollaſton, Jackſonian Profeſſor at Cambridge, who transferred them to Mr Cavendiſh. The apparatus contrived for making ſenſible the attraction of ſmall quantities of matter, and which has been improved by Mr Cavendiſh, is very ſimple: it conſiſts of a wooden arm 6 feet long, ſuſpended by the middle in an horizontal poſition by a ſlender wire 40 inches long; to each extremity is hung a leaden ball about two inches in diameter; and the whole is incloſed in a wooden caſe to defend it from the wind.

As no more force is required to turn this balance on its centre than is neceſſary to twiſt the ſlender ſuſpending wire, the ſmalleſt degree of attraction of a leaden weight or weights, a few (eight) inches in diameter, brought near to the ſmall ſuſpended ball or balls of the balance, will be ſufficient to move it ſenſibly aſide.

To determine from hence the denſity of the earth, all that is neceſſary is, to aſcertain what force is required to draw the arm aſide through a given ſpace, and then to have recourſe to calculation.

To prevent any diſturbance from currents that might be produced within the box that contained the balance, by even the difference of temperature that might be occaſioned

caſioned by heat being communicated by the bodies of the experimenters to one ſide of it more than another, it was ſupported in the middle of a cloſe room; the operators, from adjoining apartments, viewed the operation through holes in the wall by means of teleſcopes; and the apparatus had a ſtrong light thrown upon its two ends (an opening being left at each end of the box for the purpoſe) by means of two lamps, alſo in the adjoining apartments, the rays from which were likewiſe made to paſs through the holes formed in the wall.

The two large balls were ſuſpended from a beam near the cieling, which could be moved in an horizontal direction, by means of a ſtring and pulley, ſo as to be brought near to the ſmall balls of the balance, or made to recede again, without requiring any perſon to be in the room.

From this deſcription it will be eaſily ſeen, that on the two large balls being brought near to the two ſmall ones, but on oppoſite ſides of each, that their forces may not counteract each other—the ſmall ſuſpending wire of the balance muſt be twiſted by the movements of the arms, occaſioned by attraction, which carries the ſmall towards the large balls; and that the wire, endeavouring to untwiſt itſelf, will again in its turn carry the ſmall balls away from the large ones. Vibrations are thus occaſioned, which would continue a long time before the ſmall balls would ſettle between the firſt point of reſt and the large balls: but it is not neceſſary to wait for this; an ivory ſcale at each end of the balance enables the experimenters, by means of their teleſcopes, to ſee the two extreme diviſions to which the ſmall balls move in their vibrations, and thus to determine the middle point. The time neceſſary for each vibration is alſo noticed.

A full account of theſe experiments, and of the calculations founded on them, would be little intereſting to the great majority of our readers. We ſhall therefore only mention the reſult. By a mean of the experiments the denſity of the earth comes out 5·48 times greater than that of water.

By the experiments made by Dr Maſkelyne on the attraction of the hill Schehallien, the denſity of the earth was computed to be only 4½ times that of water. The difference of reſult, therefore, is almoſt one-fifth, which no doubt muſt leſſen our confidence in either ſet of experiments, or in the principle on which they were deviſed.

Earth-Worm (ſee Lumbricus, *Encycl.*), is an animal which occaſions ſuch deſtruction in gardens, by gnawing the tender roots of ſhrubs and plants, that various methods have been propoſed for remedying this evil. One of the lateſt, and that which promiſes to prove the moſt ſucceſsful, is given by M. Socoloff in the fifth volume of the New Tranſactions of the Imperial Academy of Sciences at Peterſburgh. As the deſtructive power of quick lime, heightened by a fixed alkali, which corrodes or diſſolves all the tender parts of animals, has been long known, it occurred to our author that this mixture would be the beſt means for accompliſhing the object which he had in view. He therefore took three parts of quicklime, newly made, and two parts of a ſaturated ſolution of fixed alkali in water, and thence obtained a ſomewhat milky liquor ſufficiently cauſtic, highly hoſtile and poiſonous to earthworms and other ſmall animals; for as ſoon as it touched any part of their bodies, it occaſioned in them violent ſymptoms of great uneaſineſs. If this liquor be poured into thoſe holes in which the earth-worms reſide under ground, they immediately throw themſelves out as if driven by ſome force; and, after various contortions, either languiſh or die. If the leaves of plants or fruit trees frequented by the voracious caterpillars, which are ſo deſtructive to them, be ſprinkled over with this liquor, theſe inſects ſuddenly contract their bodies and drop to the ground. For though Nature has defended them tolerably well by their hairy ſkins from any thing that might injure their delicate bodies, yet as ſoon as they touch with their feet or mouths leaves which have been moiſtened by this liquor, they become as if it were ſtupified, inſtantly contract themſelves, and fall down.

With regard to plants or corn, theſe ſuſtain no injury from the liquor, becauſe it has no power over the productions of the vegetable kingdom, as our author has fully learned from experience; or if any hurt is to be ſuſpected, all the danger will be removed by the firſt ſhower that falls. This liquor may be procured in abundance in every place where lime is burnt. If the lime be freſh, one part of it infuſed into about ſeventy parts of common water will produce real lime-water. The want of the fixed alkali may be ſupplied by boiling wood-aſhes in water, and thickening the ley by evaporation.

This liquor might be employed alſo to kill bugs and other domeſtic inſects; but on account of its ſtrong lixivious ſmell, M. Socoloff thinks it could not be uſed with ſafety in houſes that are inhabited. Nothing, however, more ſpeedily or more effectually deſtroys bugs, as our author ſays he has repeatedly experienced, than the oily pickle that remains in caſks in which ſalted herrings have been packed.

EAU de Luce, a fragrant alkaline liquor which was ſome years ago in great repute, eſpecially among the fair ſex, and of which the leading perfection is, that it ſhall poſſeſs and retain a milky opacity.

Mr Nicholſon, in the ſecond number of his valuable journal, tells us, that being informed by a philoſophical friend, that the uſual recipes for making this compound (ſee Chemistry, *Encycl.* n° 1037.) do not ſucceed, and that the uſe of maſtic in it has hitherto been kept a ſecret, he made the following trials to procure a good eau de luce.

One dram of the rectified oil of amber was diſſolved in four ounces of the ſtrongeſt ardent ſpirit of the ſhops; its ſpecific gravity being .840 at 60 degrees of Fahrenheit. A portion of the clear ſpirit was poured upon a larger quantity of fine powdered maſtic than it was judged could be taken up. This was occaſionally agitated without heat; by which means the gum reſin was for the moſt part gradually diſſolved. One part of the oily ſolution was poured into a phial, and to this was added one part of the ſolution of maſtic. No opacity or other change appeared. Four parts of ſtrong cauſtic volatile alkali were then poured in, and immediately ſhaken. The fluid was of a denſe opake white colour, affording a ſlight ruddy tinge when the light was ſeen through a thin portion of it. In a ſecond mixture, four parts of the alkali were added to one of the ſolution of maſtic; it appeared of a leſs denſe and more yellowiſh white than the former mixture. More of the gum reſinous ſolution was then poured in; but it ſtill appeared leſs opaque than that mixture. It was ruddy by tranſmitted light. The laſt experiment was repeated with the oily ſolution inſtead of that of maſtic. The white was much leſs denſe than either of the foregoing compounds, and the requiſite opacity was not given by augmenting the doſe of the oily ſolution. No ruddineſs nor other remarkable appearance was ſeen by tranſmitted light. Theſe mixtures were left at repoſe for two days; no ſeparation appeared in either of the compounds containing maſtic; the compound conſiſting of the oily ſolution and alkali became paler by the ſeparation of a cream at the top.

It appears, therefore, that the firſt of theſe three mixtures, ſubject to variation of the quantity of its ingredients, and the odorant additions which may be made, is a good eau de luce.

In a ſubſequent number of the ſame Journal, we have the following recipe by one of the author's correſpondents, who had often proved its value by experience. "Digeſt ten or twelve grains of the whiteſt pieces of maſtic, ſelected for this purpoſe and powdered, in two ounces of alcohol; and, when nearly diſſolved, add twenty grains of elemi (See Amyris, *Encycl.*). When both the reſins are diſſolved, add ten or fifteen drops of rectified oil of amber, and fifteen or twenty of eſſence of bergamot: ſhake the whole well together, and let the fæces ſubſide. The ſolution will be of a pale amber colour. It is to be added in very ſmall portions to the beſt aqua ammoniæ puræ, until it aſſumes a milky whiteneſs, ſhaking the phial well after each addition, as directed by Macquer. The ſtrength and cauſticity of the ammoniac are of moſt eſſential conſequence. If, upon the addition of the firſt drop or two of the tincture, a denſe opaque coagulated precipitate is formed, not much unlike that which appears on dropping a ſolution of ſilver into water ſlightly impregnated with common ſalt, it is too ſtrong, and muſt be diluted with alcohol. A conſiderable proportion of the tincture, perhaps one to four, ought to be requiſite to give the liquor the proper degree of opacity."

EAVES Board, or Eaves-Lath, a thick feather-edged board, uſually nailed round the eaves of a houſe for the lowermoſt tiles, ſlate, or ſhingles, to reſt upon.

ECLIPSAREON, an inſtrument invented by Mr Ferguſon for ſhewing the phenomena of eclipſes; as their time, quantity, duration, progreſs, &c.

ECLIPTIC. See *Encycl.* both under Ecliptic and in Astronomy-*Index*. It was obſerved in Astronomy, *Encycl.* n° 407. that the obliquity of the ecliptic has been found gradually to decreaſe. This was obſerved, among others, by *La Lande*, who, in the third edition of his aſtronomy, reckoned the ſecular diminution of this obliquity at 50 ſeconds. From a new examination, however, of ancient obſervations, he has ſince found reaſon to eſtimate it at only 36 ſeconds; but whether this be perfectly accurate, is very doubtful. The mean obliquity was determined for the 1ſt of January 1793, with circular inſtruments, by *Mechain* at Barcelona, and *Piazzi* at Palermo, to be 23° 27′ 53″.3. Yet the obſervation of the ſummer ſolſtice of 1796, by *Mechain* and *Le Français*, gave 11 ſeconds more; which was juſtly conſidered as a perplexing circumſtance. But, as one of the ableſt of our literary journaliſts obſerves, might not this difference ariſe from the uncertainty of our tables of refraction, as affected by the hygroſcopic variations of the atmoſphere?

Ecliptic Bounds, or *Limits*, are the greateſt diſtances from the nodes at which the ſun or moon can be eclipſed, namely, near 18 degrees for the ſun, and 12 degrees for the moon.

Smeaton's Account of the Edyſtone Light-houſe.

EDYSTONE Rocks, ſo remarkable for the light-houſe built on them, obtained their name from the great variety of contrary ſets of the tide or current in their vicinity. They are ſituated nearly S. S. W. from the middle of Plymouth Sound, according to the true meridian. The diſtance from the port of Plymouth is nearly 14 miles, and from the promontory called *Ram-head* about 10 miles. They are almoſt in the line, but ſomewhat within it, which joins the Start and the Lizard points; and as they lie nearly in the direction of veſſels coaſting up and down the channel, they were neceſſarily, before the eſtabliſhment of a light houſe, very dangerous, and often fatal to ſhips under ſuch circumſtances. Their ſituation, likewiſe, with regard to the Bay of Biſcay and Atlantic ocean, is ſuch, that they lie open to the ſwells of the Bay and ocean from all the ſouth-weſtern points of the compaſs: which ſwells are generally allowed by mariners to be very great and heavy in thoſe ſeas, and particularly in the Bay of Biſcay. It is to be obſerved, that the ſoundings of the ſea from the ſouth-weſtward toward the Edyſtone are from 80 fathoms to 40, and everywhere till you come near the Edyſtone the ſea is full 30 fathoms in depth; ſo that all the heavy ſeas from the ſouth-weſt come uncontrouled upon the Edyſtone rocks, and break on them with the utmoſt fury.

The force and height of theſe ſeas is increaſed by the circumſtance of the rocks ſtretching acroſs the Channel, in a north and ſouth direction, to the length of above 100 fathoms, and by their lying in a ſloping manner toward the ſouth-weſt quarter. This *ſliving* of the rock, as it is technically called, does not ceaſe at low water, but ſtill goes on progreſſively; ſo that, at 50 fathoms weſtward, there are 12 fathoms water; nor do they terminate altogether at the diſtance of a mile. From this configuration it happens, that the ſeas are ſwelled to ſuch a degree in ſtorms and hard gales of wind, as to break on the rocks with the utmoſt violence.

The effect of this ſlope is likewiſe ſenſibly felt in moderate, and even in calm weather; for the libration of the water, cauſed in the Bay of Biſcay in hard gales at ſouth-weſt, continues in thoſe deep waters for many days, though ſucceeded by a calm; inſomuch, that when the ſea is to all appearance ſmooth and even, and its ſurface unruffled by the ſlighteſt breeze, yet thoſe librations ſtill continuing, which are called the *ground-ſwell*, and meeting the ſlope of the rocks, the ſea breaks upon them in a frightful manner, ſo as not only to obſtruct any work being done on the rock, but even the landing upon it, when, figuratively ſpeaking, you might go to ſea in a walnut ſhell. A circumſtance which ſtill farther increaſes the difficulty of working on the rock is, there being a ſudden drop of the ſurface of the rock, forming a ſtep of about four and a half, or five feet high; ſo that the ſeas, which in moderate weather come ſwelling to this part, meet ſo ſudden a check that they frequently fly to the height of 30 or 40 feet.

Notwithſtanding theſe difficulties, it is not ſurpriſing that the dangers to which navigators were expoſed by the Edyſtone rocks ſhould make a commercial nation deſirous of having a light-houſe on them. The wonder is, that any one ſhould be found hardy enough to undertake the building. Such a man was firſt found in in the perſon of *Henry Winſtanley* of Littlebury in Eſſex, Gent. who, in the year 1696, was furniſhed by the maſter, wardens, and aſſiſtants, of the Trinity-houſe of Deptford-ſtrond with the neceſſary powers to carry the deſign into execution.

Mr Winſtanley had diſtinguiſhed himſelf in a certain branch of mechanics, the tendency of which is to raiſe wonder and ſurpriſe. He had at his houſe at Littlebury a ſet of contrivances, ſuch as the following: Being taken into one particular room of his houſe, and there obſerving an old ſlipper careleſsly lying on the floor; if, as was natural, you gave it a kick with your foot, up ſtarted a *ghoſt* before you. If you ſat down in a certain chair, a couple of arms would immediately claſp you in, ſo as to render it impoſſible to diſentangle yourſelf till your attendant ſet you at liberty. And if you ſat down in a certain arbour by the ſide of a canal, you were forthwith ſent out *afloat* to the middle of the canal, from whence it was impoſſible for you to eſcape till the manager returned you to your former place.—Whether thoſe things were ſhewn to ſtrangers at his houſe for money, or were done by way of amuſement to thoſe that came to viſit the place, is uncertain, as Mr Winſtanley is ſaid to have been a man of ſome property; but it is at leaſt certain, that he eſtabliſhed a place of public exhibition at Hyde Park-corner, called *Winſtanley's water-works*, which were ſhewn at ſtated times at one ſhilling each perſon. The particulars of thoſe water-works are not now known; but, according to the taſte of the times, we muſt naturally ſuppoſe a great variety of *jets d'eau*, &c.

Theſe particulars are at preſent of no other importance than that they ſerve to give a ſketch of the talents and turn of mind of the original undertaker, and to account for the whimſical kind of buildings which he erected on the Edyſtone; from the deſign of which, it ſeems as if it were not ſufficient for his enterpriſing genius to erect a building on the ſpot, where, of all others, it was leaſt likely to ſtand unhurt; but that he would alſo give it an elevation, in appearance the moſt liable to ſubject it to damage from the violence of the wind and waves.

This ingenious man entered upon his great undertaking in 1696, and completed it in ſomething more than four years. The firſt ſummer was occupied with making 12 holes in the rock, and in faſtening 12 great irons, which were to hold the work that was afterward to be done. The next ſummer was ſpent in making a ſolid body, or round pillar, 12 feet high and 14 feet in diameter. In the third year, the aforeſaid pillar or work was made good at the foundation, from the rock, to 16 feet in diameter; and all the work was raiſed, which, to the vane, was 80 feet high. Being all finiſhed, with the lantern, and all the rooms that were in it, we "ventured (ſays Mr Winſtanley) to lodge there ſoon after midſummer, for the greater diſpatch of this work: but the firſt night the weather came bad, and ſo continued, that it was eleven days before any boats could come near us again; and not being acquainted with the height of the ſeas riſing, we were almoſt all the time drowned with wet, and our proviſions in as bad a condition, though we worked night and day, as much as poſſible, to make ſhelter for ourſelves."

Mr Winſtanley, however, ſucceeded in ſetting up the light on the 14th of November in that year (1698); but he was detained till within three days of Chriſtmas before he could return to ſhore, being almoſt at the laſt extremity for want of proviſions.

In the fourth year, obſerving the effects that the ſea produced on the houſe, burying the lantern at times, although more than 60 feet high, Mr Winſtanley encompaſſed the aforeſaid building early in the ſpring with a new work of four feet thickneſs from the foundation, making all ſolid for near 20 feet high; and taking down the upper part of the firſt building, and enlarging every part in its proportion, he raiſed it 40 feet higher than it was at firſt: Yet, he obſerves, "the ſea, in times of ſtorms, flies in appearance *one hundred feet above the vane*, and at times doth cover half the ſide of the houſe and the lantern as if it were under water."

No material occurrences concerning this building happened till November 1703, when the fabric, needing ſome repairs, Mr Winſtanley went down to Plymouth to ſuperintend the work. And "we muſt not wonder (ſays Mr Smeaton), if, from the preceding accounts of the violence of the ſeas, and the ſtructure of the light-houſe, the common ſenſe of the public led them to ſuppoſe this building would not be of long duration. The following is an anecdote which I received to the ſame effect from ſo many perſons that I can have no doubt of the truth of it: Mr Winſtanley being among his friends previous to his going off with his workmen on account of thoſe reparations, the danger being intimated to him, and that one day or other the light-houſe would certainly be overſet; he replied, "He was ſo very well aſſured of the ſtrength of his building, he ſhould only wiſh to be there in the greateſt ſtorm that ever blew under the face of the heavens, that he might ſee what effect it would have on the ſtructure."—It happened that Mr Winſtanley was but too amply gratified in this wiſh; for while he was there with his workmen and light-keepers, that dreadful ſtorm began which raged moſt violently on the 26th of November 1703, in the night; and of all the accounts of the kind which hiſtory furniſhes us with, we have none that has exceeded this in Great Britain, or was more injurious or extenſive in its devaſtation. The next morning, November 27th, when the violence of the ſtorm was ſo much abated that it could be ſeen whether the light-houſe had ſuffered by it, nothing appeared ſtanding, but, upon a nearer inſpection, ſome of the large irons by which the work was fixed upon the rock; nor were any of the people, or any of the materials of the building, ever found afterwards, ſave only part of an iron chain, which had got ſo faſt jambed into a chink of the rock, that it could never afterwards be diſengaged till it was cut out in the year 1756."

Thus periſhed Mr Winſtanley, together with his building: but ſo great was the utility of that building while it ſtood, that the public could not fail to be deſirous of having another in its place. Accordingly, in 1706, an act of parliament of the 4th of Queen Anne was paſſed, for the better enabling the maſter, &c. of the Trinity-houſe of Deptford-ſtrond to rebuild the ſame. By this act, the duties payable by ſhipping paſſing the light-houſe were veſted in the corporation of the Trinity-houſe, who were empowered to grant a leaſe to ſuch undertaker or undertakers as they ſhould approve. In conſequence, they agreed with a Captain *Lovel* or *Lovet* for a term of 99 years, commencing from the day on which a light ſhould be exhibited, and continuing ſo long as that exhibition ſhould laſt during the ſaid term. On this foundation Captain Lovet engaged Mr John Rudyerd to be his engineer or architect and ſurveyor.

It does not appear that Mr Rudyerd was bred to any mechanical buſineſs or ſcientific profeſſion, being at that time a ſilk mercer on Ludgate-hill; nor is it known that, in any other inſtance, he had diſtinguiſhed himſelf by any mechanical performance before or after. His want of perſonal experience, however, was in a degree aſſiſted by Mr Smith and Mr Norcutt, both ſhipwrights in the King's yard at Woolwich.

It is not, as Mr Smeaton obſerves, very material in what way this gentleman became qualified for the execution of his work; it is ſufficient that he directed the performance in a maſterly manner, and ſo as perfectly to anſwer the end for which it was intended. He ſaw the errors in the former building, and avoided them; inſtead of a polygon he choſe a circle for the outline of his building, and carried up the elevation in that form. His principal aim appears to have been *uſe* and *ſimplicity;* and indeed, in a building ſo ſituated, the former could hardly be acquired in its full extent without the latter. He ſeems to have adopted ideas the very reverſe of his predeceſſor; for all the unwieldy ornaments at top, the open gallery, the projecting cranes, and other contrivances, more for ornament and pleaſure than uſe, Mr Rudyerd laid totally aſide. He ſaw, that how beautiful ſoever ornaments might be in themſelves, yet when they are improperly applied and out of place, by affecting to ſhew a taſte, they betray ignorance of its firſt principle, *judgment;* for whatever deviates from propriety is erroneous, and at beſt inſipid.

It is impoſſible for us to give an accurate account of the conſtruction of Mr Rudyerd's light-houſe. We can only ſay, in general terms, that it was altogether built of wood; for the courſes of moorſtone, which Mr Rudyerd, adverting to the maxim, that *weight* is beſt reſiſted by *weight*, introduced into the ſolid part of his building, muſt be conſidered as being of the nature of ballaſt; the weight of theſe amounted to above 270 tons. The main column of the building conſiſted of one ſimple figure, being an elegant fruſtum of a cone, unbroken by any projecting ornament, or any thing on which the violence of the ſtorms could lay hold; meaſuring, excluſively of its ſloping foundation, 22 feet and eight inches on its largeſt circular baſe; 61 feet high above that circular baſe; and 14 feet and three inches in diameter at the top: ſo that the circular baſe was ſomewhat greater than one-third of the total height, and the diameter at the top was leſs than two-thirds of the baſe at the greateſt circle. On the flat roof of this main column, as a platform, Mr Rudyerd fixed his lantern, which was an octagon of ten feet and ſix inches diameter externally The mean height of the window-frames of the lantern above the balcony floor was nearly nine feet; ſo that the elevation of the centre of the light above the higheſt ſide of the baſe was 70 feet; that is, lower than the centre of Mr Winſtanley's ſecond lantern by ſeven feet, but higher than that of his firſt by 24 feet. The width of Mr Rudyerd's lantern was, however, nearly the ſame as that of Mr Winſtanley's ſecond: but inſtead of the towering ornaments of iron-work, and a vane that roſe above the top of the cupola no leſs than 21 feet, Mr Rudyerd judiciouſly contented himſelf with finiſhing his building with a round ball of two feet and three inches diameter, which terminated at three feet above the top of his cupola. The whole height of Mr Rudyerd's light-houſe, from the loweſt ſide to the top of the ball, was 92 feet, on a baſe of 23 feet and four inches, taken at a medium between the higheſt and loweſt part of the rock that it covered. The whole building was completed in the year 1709, three years from its commencement.

This great work, after having braved the elements for forty-ſix years, was burnt to the ground in 1755. On the 2d of December of that year, when the light-keeper, then on the watch, went, about two o'clock in the morning, into the lantern, to ſnuff the candles according to cuſtom, he found it in a ſmoke; and in ſpite of all that he and his companions could do, the whole edifice was on fire in the compaſs of little more than eight hours, and in a few days was burnt to its foundation. The three light-men were with much difficulty got on ſhore, when one of them immediately ran off, and has never ſince been heard of. Another, who had been dreadfully burned by melted lead, of which, according to his own account, he had ſwallowed a quantity, lingered in agony for twelve days, and then expired. His ſtomach being opened, there was found in it a ſolid piece of lead of a flat oval form, which weighed ſeven ounces and five drachms; and thus was verified an aſſertion which, to the ſurgeon and others who attended him, appeared altogether incredible, *viz.* that any human being could live after receiving melted lead into the ſtomach.

On the deſtruction of Mr Rudyerd's light-houſe, Mr Smeaton (ſee SMEATON in this Supplement) was recommended by Lord Macclesfield, then preſident of the Royal Society, as the fitteſt perſon in England to build another. It was with ſome difficulty that he was able to perſuade the proprietors that a ſtone building, properly conſtructed, would in all reſpects be preferable to one of wood; but having at laſt convinced them, he turned his thoughts to the ſhape which was moſt ſuitable to a building ſo critically ſituated. Reflecting on the ſtructure of the former buildings, it ſeemed a material improvement to procure, if poſſible, an enlargement of the baſe, without increaſing the ſize of the *waiſt*, or that part of the building which is between the top of the rock and the top of the ſolid work. Hence he thought a greater degree of ſtrength and ſtiffneſs would be gained, accompanied with leſs reſiſtance to the acting power. On this occaſion, the natural figure of the waiſt or bole of a large ſpreading oak occurred to Mr Smeaton.

" Let us (ſays he) conſider its particular figure.—Connected with its roots, which lie hid below ground, it riſes from the ſurface with a large ſwelling baſe, which at the height of one diameter is generally reduced by an elegant curve, concave to the eye, to a diameter leſs by at leaſt one third, and ſometimes to half its original baſe. From thence, its taper diminiſhing more ſlowly, its ſides by degrees come into a perpendicular, and for ſome height form a cylinder. After that, a preparation of more circumference becomes neceſſary, for the ſtrong inſertion and eſtabliſhment of the principal boughs, which produces a ſwelling of its diameter.—Now we can hardly doubt but that every ſection of the tree is nearly of an equal ſtrength in proportion to what it has to reſiſt; and were we to lop off its principal boughs, and expoſe it in that ſtate to a rapid current of water, we ſhould find it as capable of reſiſting the action of the heavier fluid, when diveſted of the greater part of its clothing, as it was that of the lighter, when all its ſpreading ornaments were expoſed to the fury of the wind: and hence we may derive an idea of what the proper ſhape of a column of the greateſt ſtability ought to be, to reſiſt the action of external violence, when the quantity of matter is given of which it is to be compoſed."

The next thing to be conſidered was, how the blocks of ſtone could be bonded to the rock, and to one another, in ſo firm a manner as that not only the whole together, but every individual piece, when connected with what preceded, ſhould be proof againſt the greateſt violence of the ſea. For this purpoſe, cramping was the firſt idea, but was rejected on account of the great quantity of iron which was neceſſary, and from the trouble and loſs of time which would attend that operation. In its place was ſubſtituted the method of dovetailing. From ſome ſpecimens which Mr Smeaton had ſeen in Belidor's deſcription of the ſtone floor of the great ſluice at Cherburgh, (where the tails of the upright headers are cut into dovetails for their inſertion into the maſs of rough maſonry below,) he was led to think, that if the blocks themſelves were, both inſide and outſide, formed into large dovetails, they might be managed ſo as to lock one another together, being primarily engrafted into the rock; and in the round or entire courſes above the top of the rock, they might all proceed from, and be locked to, one large centre ſtone. Theſe particulars being digeſted in his own mind, he explained his deſign by the help of drawings; with which, after mature deliberation, the proprietors were perfectly ſatisfied; and declared, that the ſcheme was not only in itſelf practicable, but, as appeared to them, the only means of doing the buſineſs effectually.

During this time Mr Smeaton had never viſited the rock on which he was to be employed: he therefore reſolved to go to Plymouth early in the ſpring of 1756, that he might loſe no opportunity of viewing it. At Plymouth he met Mr Joſias Jeſſop, to whom he was referred for information and aſſiſtance, and who afterwards proved of great ſervice: he was not only an approved workman in his branch as a ſhipwright, but a competent draughtſman and an excellent modeller; 'in which laſt (ſays the author) he was accurate to a great degree: he therefore appeared to be a very fit perſon to overlook the exact execution of a deſign given.' Mr Jeſſop, like others, expreſſed his doubts that a ſtone building could ſtand on the Edyſtone: but they were removed by the propoſed mode of its conſtruction.—As Mr Smeaton was impatient to go to the rock, he ſeized the firſt opportunity that ſeemed to promiſe any chance of landing on it. On the 2d of April he got within a ſtone's throw of it, but could not land: on the 5th he was more fortunate; he now landed, and ſtaid on the rock for two hours and a half. This time was employed in taking a general view of the whole. No remains of the houſe could be perceived either on the rock, or about it, except the greateſt part of the iron branches that had been fixed by Mr Rudyerd; and ſome of the moorſtones were diſcerned lying in the bottom of the gut. Such traces were alſo obſerved of the ſituation of the irons fixed by Mr Winſtanley, as to render it no very difficult taſk to make out his plan, and the poſition of the edifice; whence it appeared very probable, that Mr Winſtanley's building was overſet altogether, and that it had torn up a portion of the rock itſelf, as far as the irons had been faſtened in it. With regard to the ſteps, which were ſaid to have been cut in the rock by Mr Rudyerd, the traces of only five were remaining; theſe were faintly cut, and without much regularity. It was next tried in what degree the rock was workable; and Mr Smeaton had the ſatisfaction of finding every thing ſucceed to his wiſhes.

Having thus determined that there was no impracticability in fixing a ſtone building, it became of the greateſt importance to ſecure a more ſafe and certain landing on the rock; as it would frequently happen, while the veſſels were lying off the rock, waiting for a favourable time to enter the gut, that tides might change, ground ſwells come on, winds ſhift, and ſtorms ariſe, which would of courſe make it deſirable to return to Plymouth, if poſſible, though the purpoſe of the voyage was unperformed. In addition to this, when veſſels had got with ſome facility into the gut, they frequently could not get out again without extreme danger: for as the larger ſort had not room to turn in it, they were in reality obliged to go out ſtern forward; the Sugar-loaf rock being ſo critically placed, with ſhallow water on both ſides of it, that it prohibits a thorough paſſage. It was true, indeed, that by the ſkill and expertneſs of thoſe ſeamen who had frequently attended the ſervice of the Edyſtone, not only row boats, but the attendant veſſels, after having delivered their cargoes, had been carried quite through, at the top of an high tide, with a fair wind and ſmooth water: but this was not an experiment to be commonly repeated. The two voyages which Mr Smeaton had made were in a ſmall ſailing veſſel of about ten or twelve tons burden, which was built for the ſervice, and called the Edyſtone Boat. It occurred to him, that while the light houſe was ſtanding, if the boat had been ſtaved on the rocks while lying in the gut, there was a poſſibility of the men being ſaved by getting into the houſe, as the light-keepers would have been ready to throw out a rope to their aſſiſtance: but that if any accident of the kind were to happen now that the houſe was down, and no protection nor ſhelter to be had, there was little chance of their eſcape;—and theſe conſiderations being likely to caſt a damp on every exertion to land, he determined to go out no more without another ſailing boat to attend.

The weather being unfavourable for viſiting the rock, all exertions were uſed to forward the work on ſhore; and, firſt, a work-yard was choſen in a field adjacent to Mill Bay, about a mile weſt from Plymouth. The next object was to procure moor ſtone, or granite; and with this view the author viſited Hingſtone Downs, and obſerved the manner of working the ſtone, which is curious. He next went to Lanlivery, near Fowey harbour, from which place the ſtone-work for the late light-houſe had been furniſhed.

During this time he had made five voyages to the rock with little ſucceſs: the event of the laſt had ſtrongly pointed out, that the much greater tonnage of the ſtone which muſt be neceſſary to be carried out and fixed, in caſe of a ſtone building, than was requiſite in the compoſitions of his predeceſſors, would make the uncertainty and delay which they had deſcribed as being attendant on their voyages, in order to fix their work, bear far heavier on the ſcheme; and would thus occaſion the whole time of the performance to be lengthened. It appeared, therefore, that had a veſſel been fixed within a quarter of a mile, or ſome ſuch competent diſtance from the rocks, and which ſhould be capable of lodging the workmen, all their tools and looſe materials, the ſeveral pieces of wrought ſtone only excepted, that then the workmen might, by means of ſmall row-boats or yawls, have effected a landing both of themſelves and of their materials, and have been at work on the rock during the greateſt part of thoſe days which otherwiſe, as voyagers, they would have loſt in fruitleſs endeavours to get to the place of action. Agreeably to this opinion, it was propoſed to build a ſtrong and very well found ſloop of about fifty tons, with iron chains for mooring her on the rocky ground near the Edyſtone. A veſſel was in fact afterward moored in this ſituation: but it was one not built for the ſervice, but originally intended to have been ſtationed as a temporary floating light during the rebuilding of the light-houſe.

Mr Smeaton now made a ſixth voyage to the rock, on which he employed himſelf for nineteen hours in taking ſuch dimenſions as would enable him to make an accurate model of its ſurface. He likewiſe attempted a ſeventh voyage: but being unable to reach the Edyſtone, he bore away for Falmouth, in order to examine the moor-ſtone works at Conſtantine in that neighbourhood. From the difficulties which occurred here, as well as at other places, he was convinced that a ſufficient quantity of moor-ſtone could not be readily and expeditiouſly procured, in order to complete the whole building; and that he muſt therefore confine the moorſtone to the outſide, as being more durable, and content himſelf with the uſe of Portland, or ſome other free-working ſtone, for the inſide work. In conſequence, after making three more voyages to the rock, and completing all the obſervations which he was deſirous of taking there, he viſited the iſle of Portland in his return to London, and made the neceſſary agreements for carrying on his work.

On his arrival in London, Mr Smeaton again met the proprietors, from whom he experienced the greateſt liberality and confidence: they declared, that as he was now apprized of what was to be done, they left both the time and the means of its accompliſhment to him.

‘ On this occaſion (he obſerves), I found myſelf totally unfettered; and perhaps no reſolution of the proprietors ever more conduced to the ultimate ſucceſs of the work than this, which ſet me ſo much at liberty. Had they been of the ſame temper and diſpoſition of by far the greateſt part of thoſe who have employed me, both before and ſince, their language would have been, Get on, Get on, for God's ſake get on! the public is in expectation; get us ſomething ſpeedily to ſhew, by which we may gain credit with the public!—This, however, was not their tone, which I looked upon as a happy earneſt from the proprietors in the outſet.’

During his ſtay in London, he reſolved, as an abſolutely neceſſary preliminary ſtep, to form models of the rock, both in its preſent ſtate and as cut to the intended ſhape for receiving the building. Connected with the laſt was a model of the building itſelf, ſhewing diſtinctly how the work was to be adapted to each ſeparate ſtep in the aſcent of the rock, and particularly exhibiting the conſtruction of the firſt entire courſe after riſing to the level of the upper ſurface of the rock: to this a ſolid being fitted, the model ſhewed the external form of the whole building, including the lantern; while, by a ſection on paper, the whole inſide work was repreſented. Theſe models, as well, indeed, as moſt of the material parts of the buſineſs, were the entire work of Mr Smeaton's own hands. After exhibiting theſe to the Lords of the Admiralty, who expreſſed their warmeſt approbation, he returned to Plymouth on the 23d of July 1756.

On his arrival at Plymouth, he found that Mr Jeſſop had completely fitted up, for preſent ſervice, the ſloop, which had before been uſed as an attendant; as well as the Edyſtone boat, and a large yawl, with ſails and oars. Another ſeaman was now taken into the ſervice, which made the number of the crew ſix. The Neptune Buſs, which had been built for the purpoſe of exhibiting a temporary light, but which was afterward moored near to the rock, was arrived: but as her deſtination was not known, all orders for mooring-chains were ſuſpended, and Mr Smeaton was obliged to content himſelf with preparing cables in the beſt manner that he could for mooring the ſloop in that ſituation. As the weather was unfavourable, he had but one opportunity of viſiting the rock; he therefore applied vigorouſly to prepare every thing on ſhore. The firſt buſineſs was to eſtabliſh the working companies, which were to conſiſt of two complete ſets of hands, to relieve each other by turns; ſo that, whenever winds and tides would permit, the work might be purſued by day and night. In his diſtribution and management of theſe people he appears to have acted with great judgment. He made choice of, and agreed with, Mr Thomas Richardſon, a maſter maſon of Plymouth, to act as foreman of one of the companies; and alſo with William Hill, who had been ſome time foreman to another maſter maſon of the ſame place, to act as the other foreman. He likewiſe entered three maſons, and nine tinners (Corniſh miners), as a company, to go out with Mr Richardſon to take the firſt turn, or week, commencing from Saturday the 31ſt of July. Mr Jeſſop was appointed general aſſiſtant. The wages of the foremen, while at ſea, were to be 5 s. per day certain; and for every hour ſpent on the rock, the farther premium of 1 s.—but when employed in the work-yard or otherwiſe on ſhore, their wages were to be 3 s. 6 d. per day. The wages of the maſons were to be 2 s. 6 d. per day certain at ſea, with a premium of 9 d. per hour; and the tinners were to have 2 s. per day certain at ſea, and 8 d. per hour. In the work-yard, or at ſhore, the maſons were to have 20d. and the tinners 18d. per day, and to be paid for over-time when required to work;—and that the ſeamen might not want inducement to do their utmoſt in landing the workmen at the Edyſtone as early as poſſible at every opportunity, and in ſupplying them with what was neceſſary for keeping them at work, over and above their weekly wages, which were ſettled at 8 s. per week, they were all to receive a premium for every landing on the rock; the maſter ſeamen having 2s. 6 d. and the ordinary men 2s. to make their advantage equivalent to that of the other workmen, in whatever ſervice the ſeamen, who were conſtantly on duty, were employed. Mr Jeſſop, as general aſſiſtant, was to have 10s. 6d. per day at ſea, and 5 s. per day on land; and every one was to ſupply himſelf with victuals.—Mr Smeaton likewiſe agreed for half an acre of ground on the weſt ſide of Mill-bay for

a

a work-yard, as before mentioned, which he marked out, and ordered to be fenced with boards. At this time arrived Mr John Harriſon, who was to act as clerk to the Edyſtone works, with whom a plan was digeſted for keeping the accounts and correſpondence; and for the diſtinct noting of ſo great a variety of articles, it was found expedient to open fourteen different books.

Matters being thus ſettled on ſhore, and the weather having become more promiſing, Mr Richardſon and his company embarked in the ſloop, with her ground tackle on board, attended by the author and Mr Jeſſop, and having the yawl alſo properly manned. Having landed on the rock, Mr Smeaton proceeded to fix the centre, and to lay down the lines of the intended work on its ſurface; and being followed by Mr Richardſon, he, with ſharp picks, left indelible traces of thoſe lines, ſo as that the workmen might proceed on them whenever they ſhould be able to land. The roughneſs of the ſea, however, ſoon rendered it adviſable to return to the ſloop; and from the ſame cauſe it was thought unſafe to attempt to moor her that evening. On the next day, the wind continued to blow very freſh; but on the following they were able to moor the ſloop: and every one being anxious to make a beginning, the whole company landed on the rock, and immediately began the work, which was purſued for about four hours, when they were driven off by the ſea. On the following day, all hands landed before ſun-riſe, and worked, during that tide, for ſix hours; and in the afternoon's tide they again landed, and continued the work, by the help of links, till ten o'clock at night. They purſued this courſe for ſome time with very little interruption, working, at an average, for about five hours in each tide.

The weather had now been fair from Auguſt 27th to the 14th of September; and in this ſpace they had worked for 177 hours on the rock. During this interval, alſo, Mr Jeſſop had prevented a weſt Indiaman homeward bound, and a man of war's tender, from driving on the rocks, to which they were approaching, though they themſelves were not aware of it. On the 16th, the work on the rock was in the following ſituation: The loweſt new ſtep (the moſt difficult to work, becauſe the loweſt), with its dovetails, was quite completed.—The ſecond ſtep was rough bedded, and all its dovetails ſcapelled out.—The third ſtep (being the loweſt in Mr Rudyerd's work) was ſmooth bedded, and all the dovetails roughed out.—The fourth was in the like ſtate.—The fifth was rough bedded, and its dovetails were ſcapelled out; and the ſixth was ſmooth bedded, and all the dovetails roughed out.—Laſtly, the top of the rock, the greateſt part of the bulk whereof had been previouſly taken down as low as it could be done with propriety, was now to be reduced to a level with the upper ſurface of the ſixth ſtep; the top of that ſtep being neceſſarily to form a part of the bed for the ſeventh or firſt regular courſe: ſo that what now remained, was to bring the top of the rock to a regular floor by picks; and from what now appeared (as all the upper parts that had been damaged by the fire were cut off) the new building was likely to reſt on a baſis even more ſolid than the former lighthouſes had done.

The equinoctial winds that were now reigning, afforded little proſpect of doing much more work on the rock for this ſeaſon: for though a more moderate interval of weather might be expected, yet that muſt be employed in weighing the Buſs's moorings. To prevent the neceſſity of this, however, it was an object of conſideration, whether they could not diſpenſe with that operation, and thereby have a little more time for work on the rock. Mr Smeaton's contrivance for this purpoſe was admirable; but it was rendered vain by the bad ſailing of the buſs. After overcoming many difficulties, the buſs with Mr Smeaton on board was driven at a great rate towards the bay of Biſcay, in danger every hour of being ſwallowed up by the waves or daſhed in pieces on the rocks of Scilly. At laſt, on Friday morning the 26th of November, they reached Plymouth Sound, and relinquiſhed all thoughts of returning to their work on the rock that ſeaſon.

The winter therefore of 1756, and the following ſpring, were employed in preparing materials for the outwork: the maſonry particularly required great attention. It was a deſirable object to uſe large and heavy pieces of ſtone in the building; yet their ſize muſt neceſſarily be limited by the practicability of landing them with ſafety. Now ſmall veſſels only could deliver their cargoes alongſide of this hazardous rock; and theſe could not deliver very large ſtones, becauſe the ſudden riſing and falling of the veſſels in the gut amounted frequently to the difference of three or four feet, even in moderate weather; ſo that in caſe after a ſtone was raiſed from the floor of the veſſel, her gunwale ſhould take a ſwing, ſo as to hitch under the ſtone, one of a very large magnitude muſt, on the veſſel's riſing, infallibly ſink her. From this conſideration, it was determined that ſuch ſtones ſhould be uſed as did not much exceed a ton weight; though occaſionally particular pieces might amount to two tons. That they might attain a certainty in putting the work together on the rock, the ſtones of each courſe were tried together in their real ſituation with reſpect to each other; and they were ſo exactly marked, that every ſtone, after the courſe was taken aſunder, could be replaced in the identical poſition in which it lay on the platform, within the fortieth part of an inch:—nor was this judged ſufficient; for every courſe was not only tried ſingly together on the platform and marked, but the courſe above it was put on it, and marked in the ſame way; ſo that every two contiguous courſes might fit each other on the outſide, and prevent an irregularity in the outline. This degree of accuracy might ſeem ſuperfluous: but as the nature of the building required the workmen to be in a condition to reſiſt a ſtorm at every ſtep, it became neceſſary to fix the centre ſtone firſt, as being leaſt expoſed to the ſtroke of the ſea; and in order to have ſure means of attaching all the reſt to this, and to one another, it was indiſpenſable that the whole of the two courſes ſhould be tried together; in order that, if any defect appeared at the outſide, by an accumulation of errors from the centre, it might be rectified on the platform.

Another circumſtance, to which Mr Smeaton was particularly attentive, and concerning which his remarks are very valuable, was to aſcertain the moſt proper compoſition for water cements. In making mortar for buildings expoſed to water, *tarras* had been moſt eſteemed: but ſtill there were objections to its uſe. Mr Smeaton was therefore induced to try the *terra puzzolana*, found in Italy, as a ſubſtitute for *tarras*. Fortunately there was a quantity of it in the hands of a merchant at Plymouth, which had been imported as a venture from Civita Vecchia, when Weſtminſter-bridge was building; and which he expected to have ſold for that work to a good advantage, but failed in his ſpeculation: for having found that *tarras* anſwered their purpoſe, neither commiſſioners, engineers, nor contractors, would trouble themſelves to make a trial of the other material. This was found in every reſpect equal to *tarras*, as far as concerned the hardening of water-mortar, if not preferable to it; and if made into a mortar with lime produced from a ſtone found at Aberthaw, on the coaſt of Glamorganſhire, it exceeded, in hardneſs, any of the compoſitions commonly uſed in dry work; and in wet and dry, or wholly wet, was far ſuperior to any which Mr Smeaton had ſeen, inſomuch that he did not doubt its making a cement that would equal the beſt merchantable Portland ſtone in ſolidity and durability.

Theſe preliminary arrangements being ſettled, they proceeded, on the 3d of June 1757, to carry out the Neptune buſs, and to begin the work. After getting up the moorings (a work of no ſmall difficulty and ſome danger), and after fixing the fender-piles, the ſhears, windlaſs, &c. the firſt ſtone was landed, got to its place, and fixed, on Sunday the 12th of June; and on the next day the firſt courſe was completed. On the 14th, the ſecond courſe was begun: but, in conſequence of a freſh gale, the workmen were obliged to quit the rock, after ſecuring every thing as well as poſſible. Such was the violence of the gale, that it was impracticable for the boats to get out of the gut, otherwiſe than by paſſing the Sugar-loaf rock, in which they providentially ſucceeded. On the 18th, they were again as ſuddenly driven from their work, and ſeveral pieces of ſtone were waſhed away by the violence of the ſea. In the night of the 6th of July, the watch on the deck of the buſs eſpied a ſail on the rocks, and one of the yawls was ſent to her relief, which brought back the whole crew, ſeveral of whom were in their ſhirts, and in great diſtreſs. It was a ſnow of about 130 tons burthen, which was returning in ballaſt from Dartmouth; but not knowing exactly where they were, they had miſtaken the rocks for ſo many fiſhing-boats, till it was too late to clear them; and on the veſſel's ſtriking, ſhe filled ſo quickly, that the boat floated on deck before they could get into it.

During this time the building went on, though its progreſs was retarded by various interruptions and accidents; till, at the latter end of Auguſt, when the ſeventh courſe was nearly finiſhed, a violent ſtorm aroſe, which carried away the ſhears and triangles, together with two of the largeſt ſtones which had been left chained on the rock! yet notwithſtanding theſe and various other difficulties, the ninth courſe was completed by the end of September.

"Being now arrived at the eve of October (ſays Mr Smeaton), I maturely conſidered our ſituation; and finding that we had been 18 days in completing the laſt courſe, whereas the former one was begun and finiſhed in five, though the weather, both on ſhore and above head, had remained to all appearance much the ſame; I from thence concluded it to be very probable, we might not get another courſe completed in the compaſs of the month of October: So that when I reflected on the many diſaſters that we had ſuffered laſt year by continuing out to the month of November, and how little work we in reality did after this time, it appeared to me very problematical whether we might be able, with every poſſible exertion, to get another courſe finiſhed this ſeaſon; and conſidering how very ineligible it was to have a courſe lie open during the winter in this ſtage of the work, and that we had now got three complete courſes eſtabliſhed above the top of the rock, the ſum of whoſe height was four feet ſix inches; and that we could not leave the work in a more defenſible ſtate, whether as relative to the natural violence of the ſea, or the poſſibility of external injuries—from theſe conſiderations, it appeared to me highly proper to put a period to the outwork of the preſent ſeaſon."

At the commencement of the following year, 1758, the weather proved very tempeſtuous till March; and on viſiting the rock, they diſcovered that the great buoy on the moorings had been carried away; nor were the mooring chains, though ſought with the greateſt perſeverance, recovered till the middle of May. In conſequence of this delay, and from other accidents, the tenth courſe of the building was not completed till the 5th of July. From this time, the progreſs was without any very material interruption; ſo that on the 26th of September the 25th courſe, being the firſt of the ſuperſtructure, was finiſhed. The work was now ſo far advanced, that Mr Smeaton made a propoſal to the Trinity Board and to the proprietors, of exhibiting a light during the enſuing winter; and for this purpoſe he continued his operations longer than he otherwiſe would have done, in order to complete the firſt room, and make it habitable; but foul weather coming on, he was obliged to quit the rock, and returned to Plymouth. A ſtorm enſued; and, on the next morning, looking out with his teleſcope, he could diſcern the houſe with the ſea breaking over it, but nothing of the buſs. On the following day, the air being more clear, he had a diſtinct view of the building; but the buſs was really gone. This was a day of double regret, as it likewiſe brought a negative on his propoſal for exhibiting a light from the houſe during the winter. The buſs had run into Dartmouth harbour; ſhe was brought home; and the work on the rock being ſecured againſt the winter, the operations of the third ſeaſon were cloſed.

During the early part of 1759, Mr Smeaton was employed in London in forming and making out the neceſſary deſigns for the iron rails of the balcony, the caſt iron, the wrought iron, and the copper works for the lantern, together with the plate glaſs work. It was not till the 22d of June that he arrived at Plymouth. As the moorings had been again loſt, new chains were provided, and the buſs was once more fixed in her ſituation. On the 5th of July he landed on the rock, and found every thing perfectly ſound and firm, without the leaſt perceptible alteration, excepting that the cement, uſed in the firſt year, now in appearance approached the hardneſs of the moorſtone; and that uſed in the laſt year had the full hardneſs of Portland; but on hauling up the ſtones for the next circle from the ſtore-room, where they had been depoſited, he had the mortification to find only ſeven inſtead of eight. It was imagined that a body of falling water, making its way through the open ribs of the centre, had waſhed this ſtone out of the ſtore-room door, though it weighed between four and five hundred weight.

The progreſs of the work, however, was now ſuch, that

that a whole room, with its vaulted cover, was built complete in ſeven days.

On the 17th of Auguſt the main column was completed.

On the 27th Mr Richardſon and his company left the Edyſtone, and gave an account that they had lived in it ſince the 23d, having found it much more warm than the buſs's hold and cabin.

They had now finiſhed every thing belonging to the maſonry. The work of the cupola was going on briſkly in the yard at Mill-bay, though it was retarded by the ſucceſſive illneſſes of the two principal copperſmiths. However, by the exertions of Mr Smeaton, who was himſelf ready to work at every buſineſs, all matters were put in ſuch forwardneſs, that by the 8th of September there was nothing to prevent the frame of the lantern from being fixed in its place but bad weather. It was not till the 15th that the weather permitted the boats to deliver their cargoes. The 16th was remarkably fine; ſo that by the evening the whole frame of the lantern was ſcrewed together, and fixed in its place. On the 17th, which was alſo exceedingly fine, the cupola was brought out, and the ſhears and tackle were ſet up for hoiſting it.

“ This (ſays Mr Smeaton) perhaps may be accounted one of the moſt difficult and hazardous operations of the whole undertaking; not ſo much on account of its weight, being only about 11 cwt. as on account of the great height to which it was to be hoiſted clear of the building, and ſo as, if poſſible, to avoid ſuch blows as might bruiſe it. It was alſo required to be hoiſted a conſiderable height above the balcony floor; which, though the largeſt baſe that we had for the ſhears to ſtand on, was yet but 14 feet within the rails, and therefore narrow in proportion to their height. About noon the whole of our tackle was in readineſs; and in the afternoon the Weſton (boat) was brought into the gut, and in leſs than half an hour her troubleſome cargo was placed on the top of the lantern without the leaſt damage. During the whole of this operation it pleaſed God that not a breath of wind diſcompoſed the ſurface of the water, and there was the leaſt ſwell about the rocks I had obſerved during the ſeaſon.

“ Tueſday, September 18th, in the morning, I had the ſatisfaction to perceive the Edyſtone boat, on board of which I expected the ball to be; and which being double gilt, I had ordered the carriage of it to be carefully attended to. The wind and tide were both unfavourable to the veſſel's getting ſoon near us; therefore, being deſirous to get the ball ſcrewed on before the ſhears and tackle were taken down, one of the yawls was diſpatched to bring it away. This being done, and the ball fixed, the ſhears and tackle were taken down, which took up nearly as much time as was employed in ſetting them up; that is, near 12 hours each, in the whole, to do the work of an hour.—I muſt obſerve, that by choice I ſcrewed on the ball with mine own hands, that in caſe any of the ſcrews had not held quite tight and firm, the circumſtance might not have been ſlipped over without my knowledge; being well aware, that even this part would at times come to a conſiderable ſtreſs of wind and ſea, and which could not be replaced without ſome difficulty in caſe any thing ſhould fail.—It may not be amiſs to intimate to thoſe who may in future have to perform the ſame operation, that the ſcaffold on which this was done conſiſted of four boards only, well nailed together, at ſuch diſtances as to permit it to be lifted over the ball when done with. It reſted on the cupola, encompaſſing its neck; and Roger Cornthwaite, one of the maſons, placed himſelf on the oppoſite ſide upon it, to balance me while I moved round to fix the ſcrews.”

Reſpecting the diſpoſition of the internal part of the edifice, Mr Smeaton fixed the beds in the uppermoſt room, and the fire-place, which conſtituted the kitchen, in the room below it; whereas, in the late houſe, the upper room was the kitchen, and the beds were placed in one of the rooms below: the conſequence of which was, that the beds and bedding were generally in a very damp and diſagreeable ſtate. The preſent diſpoſition has perfectly anſwered the end propoſed, as nothing can be more completely dry than the two habitable rooms.

On the 1ſt of October, every thing being finiſhed, and the chandeliers hung, there was nothing to hinder a trial by lighting the candles in the day-time. Accordingly 24 candles were put into their proper places, and were continued burning for three hours, during which time it blew a hard gale; and a fire being kept at the ſame time in the kitchen, they both operated without any interference; not any degree of ſmoke appearing in the lantern nor in any of the rooms: and by opening the vent-holes, which had been made in the bottom of the lantern for occaſional uſe, it could be kept quite cool; whereas, in the late light-houſe, it uſed to be ſo hot, eſpecially in the ſummer, as to give much trouble by the running of the candles.

All being thus in readineſs, and a conductor, in caſe of lightning, being adapted to the building, notice was given to the Trinity-houſe that the light would be exhibited on the 16th of October 1759. The ſeaſon of the year being now advanced to that which was always very precarious, the Neptune buſs was unmoored, and on the 9th of October ſhe came to an anchor in Plymouth harbour.—“ And thus (ſays Mr Smeaton), after innumerable difficulties and dangers, was a happy period put to this undertaking, without the loſs of life or limb to any one concerned in it, or accident, by which the work could be ſaid to be materially retarded.”

With regard to ſubſequent occurrences, it is truly obſerved, that the beſt account is, that after a trial of 40 years, which have elapſed ſince the finiſhing of the building, it ſtill remains in its original good condition. A few particulars are however intereſting. On the 19th of October Mr Smeaton, with Mr Jeſſop, &c. viſited the houſe, and, landing, found all well. Henry Edwards, one of the light-keepers, gave an account that they lighted the houſe as they were directed, and found the lights to burn ſteadily, notwithſtanding it blew very hard; that they had the greateſt ſeas on the days immediately preceding the lighting; and that then the waves broke up ſo high, that had they not been thrown off by the cove courſe, they would have endangered breaking the glaſs in the lantern; that when the ſeas broke the higheſt, they had experienced a ſenſible motion; but that, as it was barely perceptible, it had occaſioned them neither fear nor ſurpriſe.

During his ſtay at Plymouth, in the times of ſtormy weather, Mr Smeaton took ſeveral opportunities of viewing the light-houſe with his teleſcope from the Hoa, and alſo from the garriſon; both which places were ſufficiently elevated to ſee the baſe of the building, and the whole of the rock at low water in clear weather;

ther; and though he had many occaſions of viewing the unfiniſhed building when buried in the waves in a ſtorm at ſouth-weſt, yet having never before had a view of it under this circumſtance in its finiſhed ſtate, he was aſtoniſhed to find that the account given by Mr Winſtanley did not appear to be at all exaggerated. At intervals of a minute, and ſometimes of two or three, when a combination happened to produce one overgrown wave, it would ſtrike the rock and the building conjointly, and fly up in a white column, enwrapping it like a ſheet, riſing at leaſt to double the height of the houſe, and totally intercepting it from the ſight; and this appearance being momentary, both as to its riſing and falling, he was enabled to judge of the comparative height very nearly by the comparative ſpaces, alternately occupied by the houſe and by the column of water in the field of the teleſcope.

The year 1759 concluded with ſome very ſtormy weather; and in January 1760, Mr Jeſſop viſited the houſe, but could not land. He got a letter, however, from Henry Edwards, acquainting him that there had been ſuch very bad weather that the ſea frequently ran over the houſe; ſo that for 12 days together they could not open the door of the lantern nor any other. He ſaid, "the houſe did ſhake as if a man had been up in a great tree. The old men were almoſt frighted out of their lives, wiſhing they had never ſeen the place, and curſing thoſe that firſt perſuaded them to go there. The fear ſeized them in the back; but rubbing them with oil of turpentine gave them relief." He farther mentioned, that on the 5th of December, at night, they had a very great ſtorm; ſo that the ladder, which was laſhed below the entry door, broke looſe, and was waſhed away. Alſo, on the 13th, there was ſo violent a ſtorm of wind that he thought the houſe would overſet; and at midnight the ſea broke one pane of glaſs in the lantern. They had a very melancholy time of it, having alſo had a great deal of thunder and lightning.—"The ſtorms (obſerves Mr Smeaton) which the building has now ſuſtained without material damage, convince us, and every one, of the ſtability of the ſtone light-houſe, except thoſe (who are not a few) who had taken a notion that nothing but *wood* could reſiſt the ſea upon the Edyſtone rocks; who ſaid, that though they allowed it was built very ſtrong, yet if ſuch a ſtorm as had deſtroyed Winſtanley's light-houſe was again to happen, they doubted not but it muſt ſhare the ſame fate. The year 1762 was uſhered in with ſtormy weather, and indeed produced a tempeſt of the firſt magnitude; the rage of which was ſo great, that one of thoſe who had been uſed to predict its downfal was heard to ſay, If the Edyſtone light-houſe is ſtanding now, it will ſtand till the day of judgment. And, in reality, from this time, its exiſtence has been ſo entirely laid out of mens minds, that whatever ſtorms have happened ſince, no inquiry has ever been made concerning it."

For the length of this detail we cannot bring ourſelves to make any apology. If there be a few of our readers to whom it may appear tedious, we are perſuaded that there are many more to whom it will be in a high degree intereſting; while ſuch of them as are engineers will derive inſtruction even from this very abridged hiſtory of the Edyſtone light-houſe.

EFFECTION, denotes the geometrical conſtruction of a propoſition. The term is alſo uſed in reference to problems and practices, which, when they are deducible from, or founded upon, ſome general propoſitions, are called the *geometrical effection* of them.

ELASTICITY. In addition to the article in the *Encyclopædia*, ſee, in this *Supplement*, the view of Boscovich's theory of natural philoſophy, n° 26.

ELECTIONS, or Choice, ſignify the ſeveral different ways of taking any number of things propoſed, either ſeparately, or as combined in pairs, in threes, in fours, &c.; not as to the order, but only as to the number and variety of them. Thus, of the things a, b, c, d, e, &c. the elections of

one thing are (a,) $1 = 2^1 - 1$,
two things are (a, b, ab,) $3 = 2^2 - 1$,
three things are (a, b, c, ab, ac, bc, abc,) $7 = 2^3 - 1$,
&c.; and of any number n, all the elections are $2^n - 1$; that is, one leſs than the power of 2 whoſe exponent is n, the number of ſingle things to be choſen, either ſeparately or in combination.

ELECTRICITY.

We cannot but be ſomewhat ſurpriſed that, among the many attempts which have been made by the philoſophers of Britain to explain the wonderful phenomena which are claſſed under this name, no author of eminence, beſides the Hon. Mr Cavendiſh and Lord Mahon, have availed themſelves of their ſuſceptibility of mathematical diſcuſſion; and our wonder is the greater, becauſe it was by a mathematical view of the ſubject, in the phenomena of attraction and repulſion, that the celebrated philoſopher Franklin was led to the only knowledge of electricity that deſerves the name of ſcience; for we had ſcarcely any leading facts, by which we could claſs the phenomena, till he publiſhed his theory of *poſitive* and *negative*, or *plus* and *minus*, electricity. This is founded entirely on the phenomena of attraction and repulſion. Theſe furniſh us with all the indications of the preſence of the mighty agent, and the marks of its kind, and the meaſures of its force. Mechanical force accompanies every other appearance; and this accompaniment is regulated in a determinate manner. Many of the effects of electricity are ſtrictly mechanical, producing local motion in the ſame manner as magnetiſm or gravitation produce it. One ſhould have expected that the countrymen of Newton, prompted by his ſucceſs and his fame, would take to this mode of examination, and would have endeavoured to deduce, from the laws obſerved in the action of this motive force, an explanation of other wonderful phenomena, which are inſeparably connected with thoſe of attraction and repulſion.

But this has not been the caſe, if we except the labours of the two philoſophers above mentioned, and a few very obvious poſitions, which muſt occur to all the inventors and improvers of electrometers, batteries, and other things of meaſurable nature.

This view has, however, been taken of the ſubject by a philoſopher of unqueſtioned merit, Mr Æpinus of the Imperial Academy of St Peterſburgh. This gentleman,

gentleman, ſtruck with the reſemblance of the electrical properties of the tourmalin to the properties of a magnet, which have always been conſidered as the ſubject of mathematical diſcuſſion, fortunately remarked a wonderful ſimilarity in the whole ſeries of electrical and magnetical attractions and repulſions, and ſet himſelf ſeriouſly to the claſſification of them. Having done this with great ſucceſs, and having maturely reflected on Dr Franklin's happy thought of plus and minus electricity, and his conſequent theory of the Leyden phial, he at laſt hit on a mode of conceiving the whole ſubject of magnetiſm and electricity, that bids fair for leading us to a full explanation of all the phenomena; in as far, at leaſt, as it enables us to claſs them with preciſion, and to predict what will be the reſult of any propoſed treatment. He candidly gives it the modeſt name of a hypotheſis.

This was publiſhed at St Peterſburg in 1759, under the title of *Theoria Electritatis et Magnetiſmi*, and is unqueſtionably one of the moſt ingenious and brilliant performances of the eighteenth century. It is indeed moſt ſurpriſing that it is ſo little known in this country. This, we imagine, has been chiefly owing to the very ſlight and almoſt unintelligible account which Dr Prieſtley has given of it in his hiſtory of electricity; a work which profeſſes to comprehend every thing that has been done by the philoſophers of Europe and America for the advancement of this part of natural ſcience, and which indeed contains a great deal of inſtructive information, and, at the ſame time, ſo many looſe conjectures and inſignificant obſervations, that the reader (eſpecially if acquainted with the Doctor's character as an unwearied bookmaker) reaſonably believes that he has let nothing ſlip that was worthy of notice. We do not pretend to account for the manner in which Dr Prieſtley has mentioned this work, ſo much, and ſo deſervedly celebrated on the continent. We cannot think that he has read it ſo as to comprehend it; and imagine, that ſeeing ſo much algebraic notation in every page, and being at that time a novice in mathematical learning, he contented himſelf with a few ſcattered paragraphs which were free of thoſe embaraſſments; and thus could only get a very imperfect notion of the ſyſtem. The Hon. Mr Cavendiſh has done it more juſtice in the 61ſt volume of the Philoſophical Tranſactions, and conſiders his own moſt excellent diſſertation only as an extenſion and more accurate application of Æpinus's theory. That we have not an account of this expoſition of the Franklinian theory of electricity in our language, is a material want in Britiſh literature; and we truſt, therefore, that our readers will be highly pleaſed with having the ingenious diſcoveries of the great American philoſopher put into a form ſo nearly approaching to a ſyſtem of demonſtrative ſcience.

We propoſe, therefore, in this place, to give ſuch a brief account of Æpinus's theory of electricity, as will enable the reader to reduce to a very ſimple and eaſily remembered law all the phenomena of electricity which have any cloſe dependence on the mechanical effects of this powerful agent of Nature; referring for a demonſtration of what is purely mathematical to Sir Iſaac Newton's Principia, and the Diſſertation by Mr Cavendiſh already mentioned, except in ſuch important articles as we think ourſelves able to preſent in a new, and, we hope, a more familiar form. We do not mean, in this place, to give a ſyſtem of philoſophical electricity, nor even to narrate and explain the more remarkable phenomena. Of theſe we have already given a vaſt collection in the article ELECTRICITY, *Encycl.* We confine ourſelves to the phenomena which may be called *mechanical*, producing meaſurable motion as their *immediate* effect; and thus giving us a principle for the mathematical examination of the cauſe of electrical phenomena. We ſhall conſider the reader as acquainted with the other phyſical effects of electricity, and ſhall frequently refer to them for proofs.

Moreover, as our intention is merely to give a ſynoptical view of this elaborate and copious performance of Mr Æpinus, hoping that it will excite our countrymen to a careful peruſal of ſo valuable a work, we ſhall omit moſt of the algebraic inveſtigations contained in it, and preſent the concluſions in a more familiar, and not leſs convincing form. At the ſame time we will inſert the valuable additions made by Mr Cavendiſh, and many important particulars not noticed by either of thoſe gentlemen.

HYPOTHESIS OF ÆPINUS.

1 Hypotheſis. THE phenomena of electricity are produced by a fluid of peculiar nature, and therefore called the ELECTRIC FLUID, having the following properties:

2 1. Its particles repel each other, with a force decreaſing as the diſtances increaſe.

3 2. Its particles attract the particles of ſome ingredient in all other bodies, with a force decreaſing, according to the ſame law, with an increaſe of diſtance; and this attraction is mutual.

4 3. The electric fluid is diſperſed in the pores of other bodies; and moves, with various degrees of facility, through the pores of different kinds of matter. In thoſe bodies which we call *non-electrics*, ſuch as water or metals, it moves without any perceivable obſtruction; but in glaſs, roſins, and all bodies called *electrics*, it moves with very great difficulty, or is altogether immoveable.

5 4. The phenomena of electricity are of two kinds; 1. Such as ariſe from the actual motion of the fluid from a body containing more into one containing leſs of it. 2. Such as do not immediately ariſe from this transference, but are inſtances of its attraction and repulſion.

Theſe things being ſuppoſed, certain conſequences neceſſarily reſult from them, which ought to be analogous to the obſerved phenomena of electricity, if this hypotheſis be complete, or ſome farther modification of the aſſumed properties is neceſſary, in order to make the analogy perfect.

6 Plate XXIV. Suppoſe the body A (fig. 1.) to contain a certain quantity of fluid. Its particles adjoining to the ſurface, ſuch as P, are attracted by the particles of common matter in the body, but repelled by the other particles of the fluid. The totality of the attractive forces acting on P may be equal to the totality of the repulſive forces, or may be unequal. If theſe two ſums are equal, P is in equilibrio, and has no tendency to change its place. But there may be ſuch a quantity of fluid in the body, that the repulſions of the fluid exceed the attractions of the common matter. In this caſe, P has a tendency to quit the body, or there is an expulſive force acting on it, and it *will* quit the body if it be moveable.

moveable. Becauſe the ſame muſt be admitted in reſpect of every other particle of moveable fluid, it is plain that there will be an efflux, till the attraction of the common matter for the particles of fluid is equal to the repulſion of the remaining fluid. On the other hand, if the primitive repulſion of the fluid acting on the particle P be leſs than the attractions of the common matter, there will be the ſame, or at leaſt a ſimilar, ſuperiority of attraction acting on the fluid reſiding in the circumambient bodies; and there will be an influx from all hands, till an equilibrium be reſtored.

7 Natural quantity, why ſo called.

Hence it follows, that there may always be aſſigned to any body ſuch a quantity of fluid that there ſhall be no tendency either to efflux or influx. But if the quantity be increaſed, and nothing prevent the motion, the redundant fluid will flow out; and if the proper quantity be diminiſhed, there will be an influx of the ſurrounding fluid, if not prevented by ſome external force. This may be called the body's NATURAL QUANTITY; becauſe the body, when left to itſelf, will always be reduced to this ſtate.

8. If two bodies A and B, contain each its natural quantity, they will not exert any ſenſible action on each other; for, becauſe the fluid contained in B is united by attraction to the common matter, and is alſo repelled by the fluid in A, it neceſſarily follows that the whole body B is repelled by the fluid in A. But, on the other hand, the matter in A attracts the fluid in B, and conſequently attracts the whole body B: Similar action is exerted by B on A. Theſe contrary forces are either equal, and deſtroy each other, or unequal, and one of them prevails. This equality or inequality evidently depends on the quantity of fluid contained in one or both of the bodies (n° 7.) Now it is known that bodies left entirely to themſelves neither attract nor repel; and it follows from the hypothetical properties of the fluid, that if there be either a redundancy or deficiency of fluid, there will be an efflux or influx, till the attractions and repulſions balance each other. Therefore the internal ſtate of two bodies which neither attract nor repel each other, is that where each contains its natural quantity of electric fluid.

9. In order, therefore, to conceive diſtinctly the ſtate of a body containing its natural quantity, and to have a diſtinct notion of this natural quantity, we muſt ſuppoſe that the quantity of fluid competent to a particle of matter in A repels the fluid competent to a particle of matter in B, juſt as much as it attracts that particle of matter; and alſo, that the fluid belonging to a particle of matter in A, repels the fluid belonging to a particle of matter in B, juſt as much as the particle of matter in A attracts it. Thus the whole fluid in the one repels the whole fluid in the other as much as it attracts the whole matter.

Since this muſt be conceived of every particle of common matter in a body, we muſt admit, that when a body is in its natural ſtate, the quantity of electric fluid in it is proportional to the quantity of matter, every particle being united with an equal quantity of fluid. This, however, does not neceſſarily require that different kinds of matter, in their natural or ſaturated ſtate, ſhall contain the ſame proportion of fluid. It is ſufficient that each contains ſuch a quantity, uniformly diſtributed among its particles, that its repulſion for the fluid in another body is equal to its attraction for the common matter in it. It is, however, more probable, for reaſons to be given afterwards, that the quantity of electric fluid attached, or competent, to a particle of all kinds of matter is the ſame.

We ſhall now conſider more particularly the immediate reſults of this hypotheſis, in the moſt ſimple caſes, from which we may derive ſome elementary propoſitions.

10 Electric phenomena ariſe from redundancy or deficiency in fluid total or partial.

Since our hypotheſis is accommodated to the fact, that bodies in their natural ſtate, having their natural quantity of electric fluid, are altogether inactive on each other, by making this natural quantity ſuch, that its mutual repulſion exactly balances its attraction for the common matter—it follows, that we muſt deduce all the electric phenomena from a redundancy or deficiency of electric fluid. This accordingly is the Franklinian doctrine. The redundant ſtate of a body is called by Dr Franklin POSITIVE OR PLUS ELECTRICITY, and the deficient ſtate is called NEGATIVE OR MINUS ELECTRICITY.

A body may contain more than its natural quantity, or leſs, in every part, or it may be redundant in one place and deficient in another. Theſe different conditions will exhibit different appearances, which muſt be conſidered firſt of all.

11 Action of the redundant fluid or matter how computed.

Let the body (fig. 1.) be ſuppoſed in its natural ſtate throughout, which we ſhall generally expreſs by ſaying that it is SATURATED; and let us expreſs the quantity of fluid required for its ſaturation by the ſymbol Q. Let P be a ſuperficial particle of the fluid. It is attracted by the common matter of the body (which we ſhall in future call ſimply the *matter*), and it is repelled equally by the fluid. Let us call the attraction a, and the repulſion r. Then the force with which the ſuperficial particle is attracted by the body, muſt be $= a - r$, and $a - r$ muſt be $= 0$, becauſe $a = r$. Let the quantity f of fluid be added to the body, and uniformly diſtributed through its ſubſtance. Then, becauſe we muſt admit that the action is in proportion to the quantity of acting fluid, and this is now $Q + f$, we have $Q : Q + f = r : \frac{\overline{Q + f} \times r}{Q}$; and therefore P is repelled by the whole fluid with the force $\frac{\overline{Q+f} \times r}{Q}$, or $\frac{Qr}{Q} + \frac{fr}{Q}$, or $r + \frac{fr}{Q}$. But it is attracted by the common matter in the ſame manner as before, that is, with a force $= a$. Therefore the whole action on P is $= a - r - \frac{fr}{Q}$. But $a - r = 0$. Therefore the whole action on P is $= -\frac{fr}{Q}$; that is, P is repelled with the force $\frac{fr}{Q}$.

This will perhaps be as diſtinctly conceived by recollecting, that as much of the fluid as was neceſſary for ſaturation, that is, the quantity Q, puts the particle P in equilibrio; and therefore we need only conſider the action of the redundant fluid f. To find the repulſive force of this, ſay $Q : f = r : \frac{fr}{Q}$, and prefix the ſign —; becauſe we are to conſider attractions as poſitive, and repulſions as negative, quantities.

Unleſs, therefore, the particle P be withheld by ſome other

12 tes of a ly cau- r efflux influx.

ther force, it will quit the body, being expelled by a force $\frac{fr}{Q}$. And as every ſuperficial particle is in a ſimilar ſituation, we ſee that there will be an efflux from an overcharged body, till all the redundant fluid has quitted it. This efflux will indeed gradually diminiſh as the expelling force $\frac{fr}{Q}$ diminiſhes; that is, as f diminiſhes, but will never ceaſe till f be reduced to nothing. But if there be either an external force acting on the ſuperficial fluid in the oppoſite direction, or ſome internal obſtruction to its motion, the efflux will ſtop when the remaining expelling force is juſt in equilibrio with this external force, or this obſtruction.

13. On the other hand, if the body contains leſs than its natural quantity of fluid, there will be an influx from without; for if there be a deficiency of fluid $= f$, the particle P will be repelled with the force $\frac{\overline{Q-f}\times r,}{Q}$ $= r - \frac{fr}{Q}$. It is attracted with the force a; and therefore the whole action is $= a - r + \frac{fr}{Q}, = + \frac{fr}{Q}$ (becauſe $a - r = 0$); that is, P is attracted with the force $\frac{fr}{Q}$. Fluid will therefore enter from all quarters, as long as there is any deficiency of the quantity neceſſary for ſaturation, unleſs it be oppoſed by ſome external force, or hindered by ſome internal obſtruction.

When there is a deficiency of fluid, there is a redundancy of matter, ſuch that its attraction for external fluid is equal to the repulſion of a quantity f of fluid. This confirms the aſſumption in nº 10, that *the action of a body on the electric fluid depends entirely on the redundant fluid, or the redundant matter of the body.*

14 w bodies ideo- trics or -elec- s.

The efflux or influx may be prevented, either by ſurrounding the body with ſubſtances, through the pores of which the fluid cannot move at all, or by the body itſelf being of this conſtitution. And thus we ſee, that the very circumſtance of being impervious to the fluid, or completely permeable, renders the body capable or incapable of permanently exhibiting electrical phenomena, if ſurrounded by permeable bodies. This circumſtance alone, therefore, is ſufficient to conſtitute the difference between *electrics per ſe*, and *non-electrics*.—Here, then, is a numerous claſs of phenomena, which receive an explanation by this hypothetical conſtitution of the electric fluid. All electrics *per ſe* are bodies fit for confining electricity in bodies which are rendered capable (by whatever means) of producing electrical phenomena; and no conductor, or ſubſtance which allows the electricity to paſs through it, can be made electric by any of the means which produce that effect in *inſulators*. And it is well known that the electricity of electrics is vaſtly more durable than that of non-electrics in ſimilar ſituations. It is true, indeed, that an electric, which has been excited ſo as to exhibit electric phenomena with great vivacity, loſes this power very quickly if plunged into water, or any other conducting body. But this is owing to the redundancy or deficiency being quite ſuperficial, ſo that the parts which are diſpoſed to give out or to take in the fluid are in immediate contact with the conducting matter. That the redundancy or deficiency is ſuperficial, follows from this hypotheſis; for when the ſurface is overcharged by the means employed for exciting, the impermeability of the electric *per ſe* prevents this redundant fluid from penetrating to any depth; and when the ſurface has been rendered deficient in fluid, the ſame impermeability prevents the fluid from expanding from the interior parts, ſo as to contribute to the repleniſhing the ſuperficial ſtratum with fluid. If, indeed, we could fall on any way of overcharging the interior parts of a glaſs ball, or of abſtracting the natural quantity from them, it is highly probable, that it would continue to attract or repel even after it had been plunged in water. Although the ſurrounding water would inſtantly take off the fluid redundant contained in the very ſurface, the repulſion of the fluid in the internal parts would ſtill be ſenſible; nay, if a very ſmall permeability be ſuppoſed, the body would again become overcharged at the ſurface; juſt as we ſee, that when we plunge a red-hot ball of iron into water, and take it out again immediately, it is black on the ſurface, and may be touched with the finger; but in half a minute after, it again becomes red hot. Perhaps this may be accompliſhed with a globe of ſealing wax, which is permeable while liquid, by electrifying it in a particular way while in that ſtate, and allowing it to freeze. But the reader is not far enough advanced in the hypotheſis to underſtand the proceſs which muſt be followed. He cannot but recollect, however, many examples in coated glaſs, &c. where the electricity is moſt pertinaciouſly retained by a ſurface in very cloſe contact with conductors.

15 Conſequences of unequable diſtribution of fluid. 1. Action on external fluid.

Let us now ſuppoſe a body NS (fig. 2.) containing in the half NA a quantity f of redundant fluid, and in the half AS let there be a deficiency g of fluid; that is, let there be a quantity of matter unſaturated, and ſuch as will attract fluid as much as the quantity g of fluid would repel it. Let the fluid neceſſary for the ſaturation of each half of NS be Q, as before. Let the attraction of the whole matter of NA for a particle of fluid at N be a; and let r be the repulſion exerted on the ſame particle N by the whole uniformly diſtributed fluid in NA, and let r' be the repulſion exerted by the *ſame quantity* of fluid in the remote part SA. Then the force with which the particle N or S is attracted by the merely ſaturated body NS muſt be $= a - r - r'$. This is evidently nothing, if the body be in its natural ſtate. But as NA contains the redundant fluid f, and SA is deficient by the quantity g, the whole action muſt be $a - \frac{\overline{Q+f}\times r}{Q}$ $- \frac{\overline{Q-g}\times r'.}{Q}$ But becauſe $a - r - r' = o$, the action becomes $= \frac{gr' - fr}{Q}$, or becauſe r is greater than r', the particle N is repelled with the force $\frac{fr - gr'.}{Q}$ In like manner the particle S is attracted with the force $\frac{gr - fr'}{Q}$.

16 2. Action on the contained fluid.

In the mean time, a particle C, ſituated at the middle, muſt be in equilibrio, if the body be in its natural ſtate, being equally attracted, and alſo equally repelled, on both ſides. But as we ſuppoſe that NA is overcharged

ged with the quantity f, C muſt be repelled in the direction CS with the force $\frac{fr}{Q}$. And if we alſo ſuppoſe that AS is deficient by the quantity g, C is attracted in the direction CS with a force $\frac{gr}{Q}$. Therefore, on the whole, it is urged in the direction CS with the force $\frac{fr+gr}{Q}$, or $\frac{\overline{f+g}\times r}{Q}$.

17 It will be uniformly diffuſed, unleſs obſtructed.

Hence we learn, that as long as there is any redundancy in AN, and deficiency in AS, there is a tendency of the redundant fluid to move from N toward S; and, if the body be altogether permeable by the electric fluid, we cannot have a permanent ſtate till the fluid is ſimilarly diſtributed, and equally divided, between the two halves of NS. Therefore a ſtate like that aſſumed in this example cannot be permanent in a conducting body, unleſs an external force act on it; but it may ſubſiſt in a non-conductor, and in a leſſer degree, in all imperfect conductors.

18 Nature of the obſtruction.

It is neceſſary, in this place, to conſider a little the nature of that reſiſtance which muſt be aſſigned to the motion of the electric fluid through the pores of the body. If it reſemble the reſiſtance oppoſed by a perfect fluid, ariſing ſolely from the inertia of its particles, then there is no inequality of force ſo minute but that it will operate a uniform diſtribution of the fluid, or at leaſt a diſtribution which will make the exceſs of the mutual attractions and repulſions preciſely equal and oppoſite to the external force which keeps it in any ſtate of unequal diſtribution. But it may reſemble the reſiſtance to the deſcent of a parcel of ſmall ſhot diſſeminated among a quantity of grain, or the reſiſtance to motion through the pores of a plaſtic or ductile body, ſuch as clay or lead. Here, in order that a particle may change its place, it muſt overcome the tenacity of the adjoining particles of the body. Therefore, when an unequal diſtribution has been produced by an external force, the removal or alteration of that force will not be followed by an equable diſtribution of the fluid. In every part there will remain ſuch an inequality of diſtribution, that the want of equilibrium between the electric attractions or repulſions is balanced by the tenacity of the parts.

19. We learn farther from the foregoing propoſitions, that a particle at N is leſs repelled than if the part AS were overcharged as AN is: for in that caſe, it would be expelled by a force $\frac{f\times\overline{r+r'}}{Q}$, which is much greater than $\frac{fr-gr'}{Q}$. And, in like manner, the particle S is attracted with leſs force than it would be if NA were equally undercharged with SA.

20. The condition of the body now deſcribed may be changed by different methods. The redundant fluid in AN may flow into AS, where it is deficient, till the whole be uniformly diſtributed; or fluid may eſcape from AN, and fluid may enter into AS, till the body be in its natural ſtate. The firſt method will be ſo much the ſlower as the body is leſs permeable, or more remarkably *electric per ſe*; and the ſecond method will be ſlower than if the whole body were overcharged or undercharged.

21. What we have been now ſaying of a body NS that is overcharged at one end, and undercharged at the other, and capable of retaining this ſtate, is applicable, in every particular, to two conducting bodies NA and SA′, having a non-conducting body Z interpoſed between them, as in fig. 3. All the formulas, or expreſſions of the forces which tend to expel or to draw in fluid, are the ſame as before. Perhaps this is the beſt way of forming to ourſelves a diſtinct notion of the body that is redundant in fluid at one end, and deficient at the other. And we perceive, that the ſtate of the two bodies, ſeparated by the electric Z, will be more permanent when one is overcharged, and the other undercharged, than if both are either over or undercharged.

22 A body may be inactive, or neutral, where it i redundant or deficie

It muſt be remarked, that the quantities f and g were taken at random. They may be ſo taken, that the force with which the fluid tends to eſcape at N, or to enter at S, may be nothing, or may even be changed to their oppoſite. Thus, in order that there may be no tendency to eſcape from N, we have only to ſuppoſe $gr'-fr=0$, or $g:f=r:r'$, and $g=\frac{fr}{r'}$. In this caſe, the particle at N is as much attracted by the redundant matter in SA as it is repelled by the redundant fluid in NA.

23 Condition neceſſary for this.

When the extremity N is rendered inactive in this manner, the condition of the other extremity S is conſiderably changed. To diſcover this condition, put $\frac{fr}{r'}$ in place of g in the formula $\frac{gr-fr'}{Q}$, which expreſſes the attraction for a particle at S, and we obtain $\frac{f\times\overline{r^2-r'^2}}{Qr'}$.

24. On the other hand, we may have the redundancy and deficiency ſo balanced, that there ſhall be no tendency to influx at S. For this purpoſe, we muſt make $g=\frac{fr'}{r}$. When this obtains at S, the action at N will be had by putting $\frac{fr'}{r}$ in place of g in the formula $\frac{fr-gr'}{Q}$, and this will give us $\frac{f\times\overline{r'^2-r^2}}{Qr}$ for the force repelling a particle at N.

25. When the tendency to efflux or influx is induced in this manner, by a due proportion of the redundancy and deficiency of electric fluid, the part of the body where this obtains is by no means in its natural ſtate, and may contain either more or leſs than its natural quantity. But it neither acts like an overcharged nor like an undercharged body, and may therefore be called NEUTRAL. The reader, who is converſant with electrical experiments, will recollect numberleſs inſtances of this, and will alſo recollect that they are important ones. Such, for example, is the caſe with the plates and covers of the electrophorus. Theſe circumſtances, therefore, claim particular attention.

26. As the quantities f and g may be ſo choſen, that the appartus ſhall be *neutral*, either at S or at N; they may likewiſe be ſo, that either end ſhall exhibit either the appearance of *redundancy* or *deficiency*. Thus, inſtead of neutrality at N, we may have repulſion, as at the firſt, by making g leſs in any degree than $\frac{fr}{r'}$. If, on the contrary, g be greater than $\frac{fr}{r'}$, the extremity N, tho' overcharged, will attract fluid. In like manner, if g be

be leſs than $\frac{fr'}{r}$, the extremity S, although undercharged, will repel fluid.—We may make the following general remarks.

27 oth ends nnot be eutral at ıce.

1. Both extremities N and S cannot be neutral at the ſame time: for ſince the neutrality ariſes from the increaſed quantity of redundancy or deficiency at the other extremity, ſo as to compenſate for its greater diſtance, the activity of that extremity muſt be proportionably greater on the fluid adjoining to its ſurface, whether externally or internally. When an overcharged extremity is rendered neutral, the other extremity attracts fluid more ſtrongly; and when a deficient extremity is rendered neutral, the other repels fluid more ſtrongly. All theſe elementary corollaries will be fully verified afterwards, and give clear explanations of the moſt curious phenomena.

2. We have been ſuppoſing that the redundant fluid is uniformly ſpread, and that the body is divided into equal portions; but this was merely to ſimplify the procedure and the formulæ. The reader muſt ſee that the general concluſions are not affected by this, and that ſimilar formulæ will be obtained, whatever is the diſpoſition of the fluid. We cannot tell in what manner the redundant fluid is diſpoſed, even in a body of the ſimpleſt form, till we know what is the variation of its attraction and repulſion by a change of diſtance; and even when this has been diſcovered, we find it difficult in moſt caſes, and impoſſible in many, to aſcertain the mode of diſtribution. We ſhall learn it in ſome important caſes, by means of various phenomena judiciouſly ſelected.

28. A body may be conſidered in many diviſions, in ſome of which the fluid is redundant, and in others deficient. We may expreſs the repulſion of the whole of this body in the ſame way as we expreſs that of a body conſidered in two diviſions, uſing the letters f, g, h, &c. to expreſs the quantities of redundant or deficient fluid in each portion, while Q expreſſes the quantity neceſſary for ſaturating each of them; and the repulſion at different diſtances may be expreſſed by r, r', r'', r''', &c. as they are more and more remote; and we may expreſs their action as attractive or repulſive by prefixing the ſign + or —. Thus the attraction may be $\frac{(fr - gr' + hr'' - ir''')}{Q}$, &c.

29 nſible actions of ectrical dies.

Having obtained the expreſſions of the inviſible actions of electrified bodies on the fluid within them, or ſurrounding them, let us now conſider their ſenſible actions on other bodies, producing motion, or tendencies to motion.

Here it is obvious that the mechanical phenomena exhibited are what may be called *remote* EFFECTS of the acting forces. The immediate effects, or the mutual actions of the particles, are not obſerved, but hypothetically inferred. The tangible matter of the body is put in motion, in conſequence of its connection with the fluid reſiding in the body, which fluid is the only ſubject of the action of the other body.

In conſidering theſe phenomena, we ſhall content ourſelves with a more general view of the actions which take place between the fluid or tangible matter of the one body, and the fluid or matter of the other, ſo as to gain our purpoſe by more ſimple formulæ than thoſe hitherto employed. They were premiſed, however, becauſe we *muſt* have recourſe to them on many very important particular occaſions.

30. Let there be two bodies, A and B, in their natural ſtate. Let the tangible matter in A be called M, and let the fluid neceſſary for its ſaturation be called F, and let m and f be the tangible matter and the fluid in B. Let the mutual action between a ſingle particle of fluid and the matter neceſſary for its ſaturation be expreſſed by the indeterminate ſymbol z, becauſe it varies by a change of diſtance.

The actions are mutual and equal. Therefore when the motion of B by the action of A is determined, the motion of A is alſo aſcertained. We ſhall therefore only conſider how A is affected. 1. Every particle of fluid in A tends toward every particle of matter in B with the force z. The whole tendency of A toward B may therefore be expreſſed by z, multiplied by the product of F and m. 2. Every particle of fluid in A is repelled by every particle of fluid in B, with the ſame force z. 3. Every particle of matter in A is attracted by every particle of fluid in B, with the ſame force. We may expreſs this more purely and briefly thus:

1. F tends *toward m* with the force $+ Fmz$
2. F tends *from f* with the force $- Ffz$
3. M tends *toward f* with the force $+ Mfz$

Therefore the ſenſible tendency of A to or from B will be $= z \times \overline{Fm + Mf - Ff}$. But, by the hypotheſis, the attraction of a particle of the fluid in A for a particle of the matter in B, is equal to its repulſion for the particle or parcel of the fluid attached or competent to that particle of matter. Therefore the attraction Fmz is balanced by the repulſion Ffz. Therefore there remains the attraction of the matter in A for the fluid in B unbalanced, and the body A will tend toward the body B with the force Mfz, or B attracts A with the force Mfz. A muſt therefore move toward B. And, by the 3d law of motion, B muſt move toward A with equal force.

31 Completion of the hypotheſis of Æpinus.

But the fact is, that no tendency of any kind is obſerved between bodies in their natural ſtate. The hypotheſis, therefore, is not complete. If we abide by it, as far as it is already expreſſed, we muſt farther ſuppoſe, that there is ſome repulſive force exerted between the bodies to balance the attraction of M for f. Mr Æpinus, therefore, ſuppoſes, that every particle of tangible matter repels another particle as much as it attracts the fluid neceſſary for its ſaturation. The whole action of B on A will now be $= z \times \overline{Fm - Ff - Mm + Mf}$. Fmz is balanced by Ffz, and Mmz by Mfz, and no exceſs remains on either ſide.

32 Objections anſwered.

Æpinus acknowledges that this circumſtance appeared to himſelf to be hardly admiſſible; it ſeeming inconceivable that a particle in A ſhall repel a particle in B, or tend from it, electrically, while it attracts it, or tends toward it, by planetary gravitation. We cannot conceive this; but more attentive conſideration ſhewed him, that there is nothing in it contrary to the obſerved analogy of natural operations. We muſt acknowledge, that we ſee innumerable inſtances of inherent forces of attraction and repulſion; and nothing hinders us from referring this lately diſcovered power to the claſs of primitive and fundamental powers of nature. Nor is there any difficulty in reconciling this repulſion with univerſal gravitation; for while bodies are in their natural ſtate,

ſtate, the electric attractions and repulſions preciſely balance each other, and there is nothing to diſturb the phenomena of planetary gravitation; and when bodies are not in their natural electrical ſtate, it is a fact that their gravitation is diſturbed. Although we cannot conceive a body to have a tendency to another body, and at the ſame time a tendency from it, when we derive our notion of theſe tendencies entirely from our own conſciouſneſs of effort, endeavour, *conatus*, *niſus accedendi ſeu recedendi*, nothing is more certain than that bodies exhibit at once the appearances which we endeavour to expreſs by theſe words. We can bring the north poles of two magnets near each other, in which caſe they recede from each other; and if this be prevented by ſome obſtacle, they preſs on this obſtacle, and ſeem to endeavour to ſeparate. If, while they are in this ſtate, we electrify one of them, we find that they will now approach each other; and we have a diſtinct proof that both tendencies are in actual exertion by varying their diſtances, ſo that one or other force may prevail; or by placing a third body, which ſhall be affected by the one but not by the other, &c. We do not underſtand, nor can conceive in the leaſt, how either force, or how gravity, reſides in a body; but the effects are paſt contradiction. It muſt be granted, therefore, that this additional circumſtance of Æpinus's hypotheſis has nothing in it that is repugnant to the obſerved phenomena of Nature.

N. B. It is not neceſſary to ſuppoſe (although Mr Æpinus does ſuppoſe it), that every atom of tangible matter repels every other atom. It will equally explain all the phenomena, if we ſuppoſe that every particle contains an atom or ingredient having this property, and that it is this atom alone which attracts the particles of electrical fluid. The material atoms having this property, and their correſponding atoms of fluid, may be very few in compariſon with the number of atoms which compoſe the tangible matter. Their mutual ſpecific action being very great in compariſon with the attraction of gravitation (as we certainly obſerve in the action of light), all the phenomena of electricity will be produced without any ſenſible effect on the phenomena of gravitation, even although neither the electric fluid nor its ally, this ingredient of tangible matter, ſhould not gravitate. But this ſuppoſition is by no means neceſſary.

Since we call that the natural electrical ſtate of bodies in which they do not affect each other, and the hypothetical powers of the fluid are accommodated to this condition, we may conſider any body that has more than its natural quantity as conſiſting of a quantity of matter ſaturated with fluid, and a quantity of redundant fluid ſuperadded; and an undercharged body may be conſidered as conſiſting of a quantity of matter ſuperadded. The ſaturated matter of theſe two bodies will be totally inactive on another body in its natural ſtate, and will neither attract nor repel it, nor be attracted nor repelled by it; therefore the action of the overcharged body will depend entirely on the redundant fluid; and that of the undercharged body will depend entirely on the redundant matter; therefore we need only conſider them as conſiſting of this redundant fluid or matter, agreeably to what was ſaid in more vague terms in n° 10. and 13. This will free us from the complicated formulæ which would otherwiſe be neceſſary for expreſſing all the actions of the fluid and tangible matter of two bodies on each other. The reſults will be ſufficiently particular for diſtinguiſhing the ſenſible action of bodies in the chief general caſes: but in ſome particular and important caſes, it is abſolutely neceſſary to employ every term.

33 General e preſſion (ſymbolical) of the mutual action.

1. Suppoſe two bodies A and B, containing the quantities F and f' of redundant fluid, it is plain that their mutual action is expreſſed by $F' \times f' + z$, and that it is a repulſion; for ſince every particle of redundant fluid in A repels every particle of redundant fluid in B with the force z; and ſince F' and f' are the numbers of ſuch particles in each, the whole repulſion muſt be expreſſed by the product of theſe numbers.

2. In like manner, two bodies A and B, containing the redundant matter M' and m', will repel each other with the force $M' m' z$. 34.

3. And two bodies A and B, one of which A contains the redundant fluid F', and the other B contains the redundant matter m', will attract each other with the force $F m' z$. 35.

4. It follows from theſe premiſes, that if either of the bodies be in its natural ſtate, they will neither attract nor repel each other; for, in ſuch a caſe, one of the factors F', or f', or M', or m', which is neceſſary for making a product, is wanting. This may be perceived independent of the mathematical formula; for if A contain redundant fluid, and B be in its natural ſtate, every particle of the redundant fluid in A is as much repelled by the natural fluid in B as it is attracted by the tangible matter. 36.

37 Seeming paradox.

The three firſt propoſitions agree perfectly with the known phenomena of electricity; for bodies repel each other, whether both are poſitively or both are negatively electrified, and bodies always attract each other when the one is poſitively and the other negatively electrified. But the fourth caſe ſeems very inconſiſtent with the moſt familiar phenomena. Dr Franklin and all his followers aſſert, on the contrary, that electrified bodies, whether poſitive or negative, always attract, and are attracted, by all bodies which are in their natural ſtate of electricity. But it will be clearly ſhewn preſently, that they are miſtaken, and that Franklin's theory neceſſarily ſuppoſes the truth of the fourth propoſition, otherwiſe two bodies in their natural ſtate could not be neutral or inactive, as any one may perceive on a very ſlight examination by the Franklinian principles. It will preſently appear, with the fulleſt evidence; and, in the mean time, we proceed to explain the action of bodies which are overcharged in ſome part, and undercharged in another.

38 Action of a body having the fluid unequably diſpoſed.

Let the body B (fig. 4.) be overcharged in the part B *n*, and undercharged in the part B *s*, and let f' and m' be the redundant fluid and common matter in thoſe parts; let A be overcharged, and contain the redundant fluid F; let z and z' expreſs the intenſity of action correſponding with the diſtances of A from the overcharged and undercharged parts of B; the part B *n* repels A with the force $F' f' z$, while the part B *s* attracts it with the force $F' m' z$: A will therefore be attracted or repelled by B, according as $F' m' z'$ is greater or leſs than $F' f' z'$; that is, according as $m' z'$ is greater or leſs than $f' z$. This, again, depends on the proportion of f' to m', and on the proportion of z to z'. The firſt depends on many external circumſtances, which may occaſion a greater or leſs redundancy or deficiency of electrical fluid; the ſecond depends

pends entirely on the law of electric attraction and repulſion, or the change produced in its intenſity by a change of diſtance. As we are, at preſent, only aiming at very general notions, it is enough to recollect, that all the electric phenomena, and indeed the general analogy of nature, concur in ſhewing that the intenſity of both forces (attraction and repulſion) decreaſes by an increaſe of diſtance; and to combine this with that circumſtance of the hypotheſis which ſtates the repulſion to be equal to the attraction at the ſame diſtance; therefore both forces vary by the ſame law, and we have z always greater than z. The viſible action of B on A (which, by the 3d law of motion, is accompanied by a ſimilar action of A on B) may be various, even with one poſition of B, and will be changed by changing this poſition.

afes of
nſible re-
ulſion.

1. We may ſuppoſe that B contains, on the whole, its natural quantity, but that part of it is abſtracted from B *s*, and is crowded into B *n*. This is a very common caſe, as we ſhall ſee preſently, and it will be expreſſed in our formula by making $f' = m'$. In this caſe, therefore, we have $F' f z$ greater than $F m' z$, becauſe z is greater than z'. A will therefore be repelled by B, and will repel it; and the repulſion will be $F' f' \times \overline{z - z'}$.

f attrac-
on.

It is evident that if A be placed on the other ſide of B, the appearances will be reverſed, and the bodies will attract each other with the force $F' f' \times \overline{z - z'}$.

It is alſo plain, that if A be as much undercharged as we have ſuppoſed it overcharged, all the appearances will be reverſed; if on the undercharged ſide of B, it will be repelled; and if on the overcharged ſide of B, it will be attracted.

39
f neutra-
ty.

2. If the redundancy and deficiency in the two portions of B be inverſely proportional to the forces, ſo that $F' : m' = z' : z$, we ſhall have $f' z = m' z'$, and $m' = \frac{f' z}{z'}$. In this caſe theſe two actions balance each other, and A is neither attracted nor repelled when at this preciſe diſtance from the overcharged ſide of B. B may be ſaid to be NEUTRAL with reſpect to A, although A and the adjoining ſide of B are both overcharged.

40
odies neu-
ral at one
nd are
ore ac-
ve at the
ther.

But if A be placed at the ſame diſtance on the other ſide of B, the effect will be very different: For becauſe $m' = \frac{f' z}{z'}$, and $m' z'$ is now changed into $m' z$, and $f' z$ into $f z'$, we have the action on $A = F' \times \left(\frac{f' z}{z'} - f' z'\right), = F' f' \times \frac{z^2 - z'^2}{z'}$; that is, A is ſtrongly attracted.

In like manner, f' and m' may be ſo proportioned, that when A, containing redundant fluid, is placed near the undercharged end of *s* B, it ſhall neither be attracted nor repelled, B becoming neutral with regard to A at that preciſe diſtance. For this purpoſe m' muſt be $= \frac{f z'}{z}$. And if A be now placed at the ſame diſtance on the other ſide of B, it will be repelled with the force $F' f' \times \frac{z^2 - z'^2}{z}$.

Thus, when the overcharged end is rendered neutral to an overcharged body, the other end ſtrongly attracts it; and when the undercharged end is rendered neutral to the ſame body, the overcharged end ſtrongly repels it.

Similar appearances are exhibited when A is undercharged.

Theſe caſes are of frequent occurrence, and are important, as will appear afterwards.

41.

It is eaſy now to ſee what changes will be made on the action of B on A, by changing the proportion of f' and m'. If m' be made greater than $\frac{f'' z}{z}$, A will be attracted in the ſituation where it was formerly neutral; and if m' be made leſs, A will be repelled, &c. &c.

Therefore, when we obſerve B to be neutral, or attractive, or repulſive, we muſt conclude that m' is equal to $\frac{f z}{z'}$, or greater or leſs than it, &c.

We have been thus minute, that the reader may perceive the agreement between this action on a body containing redundant fluid, and the action on the ſuperficial fluid formerly conſidered in nº 21, 22, 23, 24. When theſe things are attended to, we ſhall explain, with great eaſe, all the curious phenomena of the electrophorus.

42
Neutrality
generally
limited to a
preciſe diſ-
tance. Im-
portant in-
formation
obtained
from this.

There is another circumſtance to be attended to here, which will alſo explain ſome electrical appearances that ſeem very puzzling. We limited the inactivity of B to a certain preciſe diſtance of the body A. This inactivity required that m' ſhould be $= \frac{f z}{z'}$. If A be brought nearer, both z and z' are increaſed. If they are both increaſed in the ſame proportion, the value of $\frac{z}{z'}$ will be the ſame as before, and the body A will neither be attracted nor repelled at this new diſtance. But if z increaſe faſter than z', we ſhall have $f' z$ greater than $m' z'$, and A will be repelled; and if z increaſes more ſlowly than z', A will be attracted by bringing it nearer. The contrary effects will be obſerved if A be removed farther from the overcharged end of B. This explains many curious phenomena; and thoſe phenomena become inſtructive, becauſe they enable us to diſcover the law of electric action, by ſhewing us the manner in which it diminiſhes by a change of diſtance. Electricians cannot but recollect many inſtances, in which the motion of the electrometer appeared very capricious. The general fact is, that when an overcharged pith ball is ſo ſituated near the overcharged ſide of the electrophorus as to be neutral, it is repelled when brought nearer, but attracted when removed to a greater diſtance. This ſhews that z increaſes faſter than z' when A is brought nearer to B. Now, ſince the bodies may be again rendered neutral at a greater diſtance than before, and the ſame appearances are ſtill obſerved, it follows, that the law of action is ſuch, that *every* diminution of diſtance cauſes z to increaſe faſter than z'. We ſhall find this to be valuable information.

43
Action
when the
fluid is un-
equably diſ-
poſed in
both bodies.

Let us, in the laſt place, inquire into the ſenſible effect on A when it alſo is partly overcharged and partly undercharged. This is a much more complicated caſe, and is ſuſceptible of great variety of external appearances, according to the degrees of redundancy and deficiency, and according to the kind of electricity (poſitive or negative) of the ends which front each other.

First,

Firſt, then, let the overcharged end of A (fig. 5.) fron the undercharged end of B, they being overcharged in N and *n*, but undercharged in S and *s*. Let F and *f* be the quantity of fluid natural to each; and let F′ and *f*′ be the redundancy in N and *n*, and M′ and *m*′ the deficiency in S and *s*. Moreover, let Z and Z′ repreſent the intenſity of actions of a particle in N on a particle in *n* and *s*; and let *z* and *z*′, repreſent the actions of a particle in S on a particle in *n* and in *s*; or, in other words, let Z, Z′, *z*, *z*′, repreſent the intenſity of action between particle and particle, correſponding to the diſtances N *s*, N *n*, S *s*, S *n*.

Proceeding in the ſame manner as in the former examples, we eaſily ſee, that the action of B on A is $= \frac{F' m' Z - F' f' Z' - M' m' z + M' f' z'}{F f}$; the attractions are conſidered as poſitive quantities, having the ſign + prefixed to them, and the repulſions are negative, having the ſign —.

This action will be either attractive or repulſive, according as the ſum of the firſt and laſt terms of the numerator exceeds or falls ſhort of the ſum of the ſecond and third: And the value of each term will be greater or leſs, according to the quantity of redundant fluid and matter, and alſo according to the intenſity of the electric action. It would require ſeveral pages to ſtate all thoſe poſſible varieties. We ſhall therefore content ourſelves at preſent with ſtating the ſimpleſt caſe; becauſe a clear conception of this will enable the reader to form a pretty diſtinct notion of the other poſſible caſes; and alſo, becauſe this caſe is very frequent, and is the moſt uſeful for the explanation of phenomena.

We ſhall ſuppoſe, that the redundant part of each body is juſt as much overcharged as the deficient part is undercharged; ſo that $F = M'$, and $f' = m'$. In this caſe, the formula becomes $\frac{F' f' (Z - Z' - z + z'}{F f}$.

Uſeful repreſentation of the mutual forces by ordinates to a curve.

Here we ſee that the ſenſible or external effect on A depends entirely on the law of electric action, or the variation of its intenſity by a change of diſtance. If the ſum of Z and *z*′ exceed the ſum of Z′ and *z*, A will be attracted; but if $Z + z'$ be leſs than $Z' + z$, A will be repelled. This circumſtance ſuggeſts to us a very perſpicuous method of expreſſing theſe actions between particle and particle, ſo that the imagination ſhall have a ready conception of the circumſtance which determines the external complicated effect of this internal action. This will be obtained by meaſuring off from a fixed point of a ſtraight line portions reſpectively equal to the diſtances N *s*, N *n*, S *s*, and S *n*, between the points of the two bodies A and B, where we ſuppoſe the forces of the redundant fluid and redundant matter to be concentrated, and erect ordinates having the proportion of thoſe forces. If the law of action be known, even though very imperfectly, we ſhall ſee, with one glance, of which kind the movements or tendencies of the bodies will be. Thus, in fig. 5. drawing the line C *z*, take $C p = N s$, $C q = N n$, $C r = S s$, and $C t = S n$, and erect the ordinates P *p*, Q *q*, R *r*, and T *t*. If the electric action be like all the other attractions and repulſions which we are familiarly acquainted with, decreaſing with an increaſe of diſtance, and decreaſing more ſlowly as the diſtances are greater, theſe ordinates will be bounded by a curve PQRTZ, which has its convexity turned toward the axis. We ſhall preſently get full proof that this is the caſe here; but we premiſe this general view of the ſubject, that we may avoid the more tedious, but more philoſophical, proceſs of deducing the nature of the curve from the phenomena now under conſideration.

45
General character of the ſcal of electric force.

This conſtruction evidently makes the pair of ordinates P *p*, Q *q*, equidiſtant with the pair R *r*, T *t*. Alſo, P *p*, R *r*, and Q *q*, T *t*, are equidiſtant pairs. It is no leſs clear, that the ſum of P *p* and T *t* exceeds the ſum of Q *q* and R *r*. For if C *z* be biſected in V, and V *v* be drawn perpendicular to it, cutting the ſtraight lines PT and QR in *x* and *y*, then *x v* is the half ſum of P *p* and T *t*, and *y v* is the half ſum of Q *q* and R *r*. Moreover, if Q *m* and T *n* are drawn parallel to the baſe, we ſee that P *m* exceeds R *r*; and, in general, that if any pair of equiſtant ordinates are brought nearer to C, their difference increaſes, and *vice verſa*. Alſo, if two pairs of equidiſtant ordinates be brought nearer to C, each pair by the ſame quantity, the difference of the neareſt pair will increaſe more than the difference of the more remote pair. And this will hold true, although the firſt of the remote pair ſhould ſtand between the two ordinates of the firſt pair. If the reader will take the trouble of conſidering theſe ſimple conſequences with a little attention, he will have a notion of all the effects that are to be expected in the mutual actions of the two bodies, ſufficiently preciſe for our preſent purpoſe. We ſhall give a much more accurate account of theſe mathematical truths in treating the article Magnetism, where preciſion is abſolutely neceſſary, and where it will be attended with the greateſt ſucceſs in the explanation of phenomena.

Now let us apply this to our preſent purpoſe. *Firſt*, then, When the overcharged end of A is turned toward the undercharged end of B, A muſt be attracted; for $P p + T t$ is greater than $Q q + R r$. 46.

Secondly, This attraction muſt increaſe by bringing the bodies nearer; for this will increaſe the difference between P *m* and R *n*. 47.

Thirdly, The attraction will increaſe by increaſing the length either of A or of B (the diſtance N *s* remaining the ſame); for by increaſing the length of A, which is repreſented by *pr* or *q t*, R *r* is more diminiſhed than T *t* is. In like manner, by increaſing B, whoſe length is repreſented by *p q* or *r t*, we diminiſh Q *q* more than T *t*. 48.

49
Uſe of this picture of the forces.

On the other hand, if the overcharged end of B front the overcharged end of A, their mutual action will be

$$\frac{F' f' (- P p + Q q + R r - T t),}{F f}$$

and A will be repelled, and the repulſion will increaſe or diminiſh, by change of diſtance or magnitude, preciſely in the ſame manner that the attractions did. It is hardly neceſſary to obſerve, that all theſe conſequences will reſult equally from bringing an apparatus ſimilar to that repreſented in fig. 3. near to another of the ſame kind; and that they will be various according to the poſition and the redundancy or deficiency of the two parts of each apparatus.

50
Curious phenomena which ſhould reſult from the hypotheſis reſembling magnetiſm.

If the body B of fig. 5. is not at liberty to approach toward A, nor to recede from it, and can only turn round its centre B, it will arrange itſelf in a certain determinate poſition with reſpect to that of A. For example, if the centre B (fig. 7.) be placed in the line paſſing through S and N of the body A, B will arrange itſelf in the ſame ſtraight line: for if we forcibly give it another poſition, ſuch as s B n, N will attract s and repel n, and theſe actions will concur in putting B into the poſition s' B n'. S, however, will repel s and attract n; and theſe forces tend to give the contrary poſition. But S being more remote than N, the former forces will prevail, and B will take the poſition s' B n'.

If the centre B be placed ſomewhere on the line AD, drawn through a certain point of the body NAS (which will be determined afterwards), at right angles to NAS, the body B will aſſume the poſition n' B s', parallel to NAS, but ſubcontrary. For if we forcibly give it any other poſition n B s, it is plain that N repels n and attracts s, while S attracts n and repels s. Theſe four forces evidently combine to turn the body round its centre, and cannot balance each other till B aſſume the poſition n' B s', where n' is next to S, and s' is next to N.

rm of
e electric
ridian.

If the centre of B have any other ſituation, ſuch as B′, the body will arrange itſelf in ſome ſuch poſition as n' B′ s'. It may be demonſtrated, that if B be infinitely ſmall, ſo that the action of the end of A on each of its extremities may be conſidered as equal, B will arrange itſelf in the tangent BT of a curve NB′S, ſuch that if we draw NB, SB, and from any point T of the tangent draw TE parallel to BN, and TF parallel to B′S, we ſhall have BE to BF, as the force of S to the force of N. This arrangement of B will be ſtill more remarkable and diſtinct if N be an overcharged ſphere, and S an undercharged one, and both be inſulated. We muſt leave it to the reader's reflection to ſee the changes which will ariſe from the inequality of the redundancy and deficiency in A or B, or both, and proceed to conſider the conſequences of the mobility of the electric fluid. Theſe will remove all the difficulty and paradox that appears in ſome of the foregoing propoſitions.

51
nſe-
ence
nda-
ntal) of
mobili-
of the
id in the
res of bo-
a.

Let the body A (fig. 4.) contain redundant fluid, and let B be in its natural ſtate, but let the fluid in A be fixed, and that in B perfectly moveable; it is evident that the redundant fluid in A will repel the moveable fluid in B, toward its remote extremity n, and leave it undercharged in s. The fluid will be rarefied in s, and conſtipated in n. We need only conſider the mutual actions of the redundant fluid and redundant matter. It is plain that things are now in the ſituation deſcribed in n° 15.: A muſt be attracted by B, becauſe $f' = m'$, and z is greater than z'. The attractive force is $F' f' \times (z - z')$.

dies con-
ning the
ural
ncity, in
natural
e, at-
ct and
attract
by elec-
ied bo-

Thus we ſee that the hypotheſis is accommodated to the phenomena in the caſe in which it appeared to differ ſo widely from it. Had the fluid been immoveable, the mutual actions would have ſo balanced each other that no external effects would have appeared. But now the greater vicinity of the redundant matter prevails, A is attracted by B, and, the actions being all mutual, B is attracted by A, and approaches it.

52
dchange
ſtate of
ſe bo-
, which
eaſes
action.

We have ſuppoſed that the fluid in A is immoveable; but this was for the ſake of greater ſimplicity. Suppoſe it moveable. Then, as ſoon as the uniform diſtribution of the fluid in B is changed, and B becomes undercharged at s, and overcharged at n, there are forces acting on the fluid in A, and tending to change its ſtate of diſtribution. The redundant matter in S attracts the redundant fluid in A more than the more remote redundant fluid in n repels it, becauſe z' is leſs than z. This tends to conſtipate the redundant fluid of A in the nearer parts, and render N more redundant, and S leſs redundant in fluid than before. It is plain that this muſt increaſe their mutual action, without changing its nature. It can be ſtrictly demonſtrated, that however ſmall the redundancy in A may be, it can never be rendered deficient in its remote extremity by the action of the unequally diſpoſed fluid in B, if the fluid in B be no more nor leſs than its natural quantity. It is alſo plain that this change in the diſpoſition of the fluid in A muſt increaſe the ſimilar change in B. It will be ſtill more rarefied in s, and condenſed in n; and this will go on in both till all is in equilibrio. When things are in this ſtate, a particle of fluid in B is in equilibrio by the combined action of ſeveral forces. The particle B is propelled toward n by the action of the redundant fluid in A. But it is urged toward S by the repulſion of the redundant fluid on the ſide of n, and alſo by the attraction of the redundant matter on the ſide of s; and the repulſion of the redundant fluid in A muſt be conceived as balancing the united action of thoſe two forces reſiding in B.

53
General notion of the forced diſpoſition of electric fluid in a body.

Hence we may conclude, that the denſity of the fluid in B will increaſe gradually from s to n. It will be extremely difficult to obtain any more preciſe idea of its denſity in the different parts of B, even although we knew the law of action between ſingle particles.

This muſt depend very much on the form and dimenſions of B; for any individual particle ſuſtains the ſenſible action of all the redundant fluid and redundant matter in it, ſince we ſuppoſe it affected by the more remote fluid in A. All that we can ſay of it in general is, that the denſity in the vicinity of s is leſs than the natural denſity; but in the vicinity of n it is greater; and therefore there muſt be ſome point between s and n where the fluid will have its natural denſity. This point may be called a NEUTRAL point. We do not mean by this that a particle of ſuperficial fluid will neither be attracted nor repelled in this place. This will not always be the caſe (although it will never be *greatly* otherwiſe); nor will the variation of the denſity in the different parts of B be proportional to the force of A on thoſe parts. Some eminent naturaliſts have been of this opinion; and, having made experiments in which it appeared to be otherwiſe, they have rejected the whole theory. But a little reflection will convince the mathematician, that the ſum of the internal forces which tend to urge a particle of fluid from its place, and which are balanced by the action of A, are *not* proportional to the variations of denſity, although they increaſe and decreaſe together. We ſhall take the proper opportunity of explaining thoſe experiments; and will alſo conſider ſome ſimple, but important caſes, where we think the law of diſtribution of the fluid aſcertained with tolerable preciſion.

Neutral point.

If we ſuppoſe, on the other hand, that A is undercharged, the redundant matter in A will attract the moveable fluid in B, and will abſtract it from the remote extremity, and crowd it into the adjacent extremity. Moreover, the fluid now becoming redundant in the nearer extremity of B, will act more ſtrongly on the moveable fluid in A than the more remote redundant matter of B; and thus fluid will be propelled toward the remote ſide of A, which will become now undercharged;

charged in its nearer ſide, and leſs undercharged in its remote ſide than if B were taken away. This muſt increaſe the inequability of diſtribution of the fluid in B, and both will be put farther from their natural ſtate; but A will never become overcharged in its remote extremity.

Things being in this ſtate, it is plain that A and B will mutually attract each other in the ſame manner, and with the ſame force, as when A was as much overcharged as it is now undercharged.

54
Electric atmoſphere is not adequate to the explanation of the phenomena.

Thus, then, we ſee how the attraction obtains, whether A be over or undercharged. A fact which Dr Franklin could never explain to his own ſatisfaction; nor will it ever be explained conſiſtently with the acknowledged principles and obſerved laws of mechanics by any perſon who employs elaſtic atmoſpheres for this purpoſe. It is indeed a ſufficient objection to the employment of ſuch electric or other atmoſpheres, that the ſame extent of attraction and repulſion between the particles of the atmoſphere is neceſſary, as is employed here between the particles of the fluid reſiding in the body; and therefore they ceaſe to give any explanation, even although their ſuppoſed actions were legitimately deduced from their conſtitution. This is by no means the caſe. Let any perſon examine ſeriouſly the *modus operandi* of the electric atmoſpheres employed by Lord Mahon (the only perſon who has written mathematically on the ſubject), and he will ſee that the whole is nothing but figurative language, without any diſtinct perception of what is meant by theſe atmoſpheres, as diſtinct from the fluid moveable in the conducting bodies, or any perception how the unequal denſity of theſe atmoſpheres protrudes the fluid along the conductor. Beſides, it is well known that a conducting wire becomes poſitive at one end, and negative at the other, by the mere vicinity of an overcharged or undercharged body, and this in an inſtant, although it be ſurrounded with ſealing-wax, or other non-conductors, to any thickneſs: in this caſe there can be no atmoſpheres to operate on the included fluid. To this we may add Dr Franklin's judicious experiment of whirling an electrified ball many times round his head, with great rapidity, by means of a ſilk line, without any ſenſible diminution of its electricity. It is not conceivable that an electric atmoſphere could remain attached to the ball; nor could it be inſtantaneouſly formed round the ball, in every point of its motion, ſo as to be operative the moment he ſtopped it and tried it; for this would have exhauſted or greatly diminiſhed the electricity of the ball); whereas that ſagacious philoſopher affirms (and any perſon will find it true), that when the air is dry, he did not obſerve the electricity more diminiſhed than that of another ball which remained all the while in the ſame place.

55
Induced electricity.

Let the overcharged body A (fig. 6.) be brought near the ends of two oblong conductors B and C in their natural ſtate, and lying parallel to each other; the fluid will be propelled toward their remote ends N, *n*, where it will be condenſed, while it will be rarefied in the ends S and *s*, adjacent to A. Both will be attracted by A, and will attract it. But the redundant fluid in NB will repel the redundant fluid in *n* C; and the redundant matter in SB will repel the redundant matter in *s* C. For this reaſon the bodies B and C will repel each other, and will ſeparate; but SB attracts *n* C, and NB attracts *s* C; and on this account the bodies ſhould approach: but the diſtances of the attracting parts being greater than thoſe of the repelling parts, the repulſions muſt prevail, and the bodies muſt really ſeparate.

It is equally clear that the very ſame *ſenſible* appearance will reſult from bringing an undercharged body near the ends of B and C, although the internal motions are juſt the oppoſite to the former.

If another body D, electrified in the ſame way with A, be brought near the oppoſite ends of B and C, it will prevent or diminiſh the internal motions, and it ſhould therefore prevent or diminiſh the external effects.

If another conducting body be brought near to the end *s* of C that fronts A, it will be affected as C is, and the end *f* will repel *s*; but if it be brought near the remote end, as is the caſe with the body F, it will attract this remote end. As the body A, containing more or leſs than its natural ſhare of electric fluid, affects every other body, while they do not (when out of its neighbourhood) affect each other, it is uſually ſaid to be the electrified body, and the others are ſaid to be electrified by it; and ſince theſe bodies, when perfect conductors, cannot retain their power of exhibiting electrical appearances (ſee nº 17.), it will be convenient to diſtinguiſh this laſt electrical ſtate by a particular name. We ſhall call it ELECTRICITY BY POSITION, OR INDUCED ELECTRICITY. It is induced by poſition with regard to the permanently electrical body.

56
Conſeque
ces of ob
ſtruction

We have ſuppoſed, in theſe laſt propoſitions, that the fluid was perfectly moveable in B, and, at laſt, alſo, in A: but let us examine the conſequences of ſome obſtruction to this motion. Without entering into a minute enquiry on this head, we may ſtate the obſtruction as uniform, and ſuch that a certain ſmall force is neceſſary for cauſing a particle of fluid to get through between two particles of the common matter, juſt as we conceive to happen in tenacious bodies of uniform texture (ſee nº 18.).

It is evident, that when an overcharged body A (fig. 4. or 5.) is brought near ſuch an imperfect conductor B, the fluid cannot be ſo copiouſly propelled to the remote extremity *n*. We may conceive the ſtate of diſtribution by taking a conſtant quantity from the intenſities of the force of A at every point of B. This circumſtance alone ſhews us that there will not be ſo unequable a diſtribution of the fluid, and therefore *there will not be ſuch a ſtrong attraction between imperfect as between perfect conductors.* But beſides this, we ſee that an incomparably longer time muſt elapſe before things come to a ſtate of equilibrium. Each particle of fluid employs time to overcome the obſtacle to its motion, and it cannot advance till after the ſucceeding ones, each eſcaping in its turn, have again come up with the foremoſt. An important conſequence reſults from this. The neutral point, where the fluid is of the natural denſity, will not be ſo far from the other body as it would have been without theſe obſtructions; and this point will be a conſiderable while of advancing along the imperfect conductor. At the firſt approach of the overcharged electric, the near extremity of the imperfect conductor becomes a little undercharged, and the neutral point advances from the very extremity a ſmall way, the diſplaced fluid being crowded a little before it, and giving way by degrees

as

as its foremoſt particles get paſt the obſtructions. The motion forward takes place over a conſiderable extent at the very firſt; namely, in that part of the conductor where the propelling power of the neighbouring electric is juſt able to puſh a particle over the obſtruction. As the propulſion goes on, the neutral point muſt gradually advance, and at laſt reach a certain diſtance, determined by the degree of the obſtruction. It is plain, that the final accumulation at the remote end of the imperfect conductor will be leſs than in a perfect conductor, and the neutral point will be nearer to the other end.

57 Irregular diſtribution. There is another remarkable conſequence of the obſtruction. It muſt always happen that, at the beginning of the action, the greateſt conſtipation will not be towards the remote extremity, but in a place much nearer to the diſturbing cauſe. Beyond this, the conſtipation will diminiſh. As time elapſes during this operation, this conſtipated fluid acts on the fluid beyond it by repulſion, and may do this with ſufficient force to diſplace ſome of it, and render a part of the imperfect conductor deficient, with a ſmall conſtipation beyond it. This may, in like manner, produce a rarefaction farther on, followed by another condenſation; and this may be frequently repeated when the obſtruction is very great, and the repulſion of the overcharged body very great alſo. This can be ſtrictly demonſtrated in ſome very ſimple caſes, but the demonſtration is very tedious: As the reſult, however, is of the firſt importance in the theory of electricity, and ſerves to explain ſome of the moſt abſtruſe phenomena, we wiſh the reader to have ſome ſtronger ground of confidence than the above bare aſſertion. He may obſerve ſimilar effects of cauſes preciſely ſimilar. If we dip the end of a flat ruler into water, and if, after allowing the water to become perfectly ſtill, we move the ruler gently along in a direction perpendicular to the face, we ſhall obſerve a ſingle wave heap up before the ruler, and keep before it, all the reſt of the water before it remaining ſtill: but if we do the ſame thing in a veſſel of clammy fluid, eſpecially if the clammy part is ſwimming on the ſurface of a more perfect fluid, like a cream, we ſhall obſerve a ſeries of ſuch waves to curl up before the ruler, and form before it in ſucceſſion; and if we have previouſly ſpotted the ſurface of the cream, we ſhall ſee that it is not the ſame individual waves that are puſhed before the ruler, but that they are ſucceſſively formed out of different parts of the ſurface, and that the particles which, at one time, form the ſummit of a wave, are, immediately after, at the bottom, &c. In like manner, when a cannon is fired in clear air, at no great diſtance, we hear a ſingle ſnap; but, in a thick fog, we hear the ſnap both preceded and followed by a quivering noiſe, reſembling the ruſhing of a fluttering wind, which laſts perhaps half a ſecond. A ſlight reflection on theſe facts will ſhew that they are neceſſary reſults of the mechanical laws of ſuch obſtruction.

Several neutral points. The conſequence of this mode of action muſt be, that an imperfect conductor may have more than one neutral point, and more than one overcharged and undercharged portion, ſo that its action on diſtant bodies may be extremely various. The formula of n° 28. was accommodated to this caſe, and will be found to have very curious reſults. Another body may be placed in the direction of the axis, and will be attracted at one diſtance, repelled when this diſtance is increaſed, and again attracted when at a ſtill greater diſtance, &c. &c.

Suppoſe the obſtruction not to be conſiderable: The immediate operation of the neighbouring overcharged body will be the production of an undercharged part in the adjoining extremity, an overcharged part beyond this, an undercharged portion farther on, &c. In a little while theſe will ſhift along the conductor; one after another will diſappear at the farther end, and the body will have at laſt but one neutral point. A greater obſtruction will leave the body, finally, with more than one neutral point, and their ultimate number will be greater in proportion as the obſtruction to the fluid's motion is ſuppoſed greater.

58 Induced electricity, rendered permanent. Now, let the overcharged body, the cauſe of this unequal diſtribution, be removed. We have ſeen, n° 17. that when a body contains its natural quantity of fluid, but unequally diſtributed, there is a force acting on every particle, and tending to reſtore the original equable diſtribution; and that ſuch a force remains as long as there is any inequality in this reſpect. If, therefore, there be no obſtruction, the uniform diſtribution will take place immediately; for it is well known, that the ſpeed with which electricity is propagated is immenſe. The elaſticity, or the attractive and repulſive forces, muſt be very great indeed when compared with any that we know, except, perhaps, the force which impels the particles of light. The electricity, therefore, of a perfect conductor, that is, its power of acting on other bodies in the ſame way that an original electric acts on them, muſt be quite momentary, and ceaſe as ſoon as the inducing cauſe is removed. The conductor is electrical merely in conſequence of its poſition. Hence the propriety of our denominations. Nothing material is ſuppoſed in this theory to be communicated from the overcharged body: Nay, this theory teaches, that the ſenſible electricity of the overcharged body is augmented in ſome reſpects; for it becomes more overcharged in the part neareſt to the conductor. Indeed it becomes leſs overcharged on the other end, and will act leſs forcibly on that ſide than if the conductor were away. It may be remarked here (it ſhould have been mentioned in n° 5 .) that when F is preſented in the manner ſhewn in fig. 6. the body B becomes more ſtrongly overcharged at the end remote from A, and more ſtrongly undercharged at the end next to A, than when F is away. The contrary *may* happen, by preſenting a body in the manner of E. We wiſh theſe particulars to be kept in mind. In the mean time, all theſe circumſtances are neceſſary conſequences of the ſuppoſition, that nothing is communicated from A to B or C. The electricity induced on perfect conductors is momentary, requiring the continual preſence of a body that is electrified in ſome way or other.

But the caſe is quite otherwiſe in imperfect conductors. When the overcharged, or otherwiſe electrical body A is removed, the forces which tend to reſtore the uniform diſtribution of the fluid immediately operate, and muſt reſtore it in part. They cannot, however, do it completely: For when the force which urges any particle from an overcharged to an undercharged part, is juſt in equilibrio with the obſtruction, it will remain, juſt as a number of grains of ſmall ſhot may lie, uniformly mixed with a maſs of clammy fluid, or, as ſuch fluids retain heavy mud, in a ſtate of equable or inequable diffuſion. If the reſiſtance ariſe merely from the inertia of the tangible matter, there is no force ſo ſmall but it will in time reſtore the uniform diſtribution. But this cannot be the caſe in ſolid bodies. Their particles exert lateral forces, by which they maintain themſelves in particular ſituations: theſe muſt be overcome by *ſuperior* forces.

We ſhould therefore expect, that imperfect conductors will retain part of their inequable conſtitution; and, *in conſequence of this*, their power of affecting other bodies like electrics; that is, their Electricity. For we muſt obſerve (having neglected to do it in the beginning), that the term *electricity* is as often uſed to expreſs this power of producing electrical phenomena as it is uſed for expreſſing a ſubſtance ſuppoſed to be the original cauſe of all theſe appearances. It is neceſſary to keep this diſtinction in mind; becauſe there are many phenomena which clearly indicate the transference of this cauſe, and they muſt not be confounded with others, where the exhibition of electric phenomena is evidently propagated to a diſtance. We muſt not always ſuppoſe, that when the electric appearances are exhibited in an inſtant at the far end of a wire 4½ miles long, the ſame numerical particles of the electric fluid have moved over this ſpace. We muſt diſtinguiſh thoſe caſes where this muſt be granted from thoſe in which it certainly has not happened. Of theſe there are innumerable inſtances.

59 Imperfect conductors are neceſſarily idio-electrics.

We have now to obſerve, that by this theory the ſingle circumſtance of perfect and imperfect conducting power is ſufficient for eſtabliſhing the whole difference between idio-electrics and non-electrics. The idio-electrics are ſuſceptible of excitation in various ways, and retain their electricity; and this may be done in any part of them without affecting the reſt in any remarkable degree. This cannot be done in perfect conductors, plainly *becauſe they are perfect conductors*. Any inequality of diſtribution of the electric fluid, which is all that is neceſſary for rendering them electric, is immediately deſtroyed by its uniform diffuſion. We can have no direct proof of their incapability of excitation; but if they can be excited, they cannot ſhew it. We doubt, however, their excitability; becauſe the appearances in the excitation of electrics ſeem to indicate, that oppoſite ſtates of two bodies are neceſſary previous to the appearance of electricity. This is impoſſible in perfect conductors. By this theory, therefore, perfect conductors are neceſſarily non-electrics; and non-conductors are neceſſarily (if excitable) idio-electrics.

With reſpect to the particular phenomena which may be expected on the removal of the original electric; it may juſt be remarked, that the electric appearances of the imperfect conductor will go off in the contrary order to that of their indication. The accumulation and deficiency will diminiſh gradually, and the neutral point or points will gradually approach the end which had fronted the original electric. The imperfect conductor will be finally left with one or more neutral points, according to the magnitude of the obſtructions, and the force which had been employed in its electrification: And their final ſtate will be ſo much the more inequable, and conſequently they will retain ſo much the greater electric powers, as they are leſs perfect conductors.

60 Electrics are only ſuperficially ſo.

The laſt obſervation which we ſhall make on this head at preſent is, that whether electrified by induction, or by friction, or moſt other modes of excitation, the electrification will be nearly ſuperficial in bodies which conduct very imperfectly; and bodies which are altogether impervious (if there be any ſuch) muſt have the accumulation or deficiency altogether at their ſurface. If a glaſs globe be ſuch a body, it will hardly be poſſible to electrify it to any depth; and all that we can expect is alternate ſtrata of overcharged and undercharged glaſs. If theſe ſtrata are once formed, they tend greatly to make the body retain its ſuperficial electricity. A ſuperficial ſtratum of redundant fluid, tending, by the mutual repulſion of its particles, to eſcape, is retained by the ſtratum of redundant matter immediately below it: And the almoſt inſuperable obſtruction prevents the fluid of the ſtratum beyond this from coming up to ſupply the vacancy. If we can fall on any contrivance to produce ſuch deficient ſtrata within the glaſs, we ſhall make it much more retentive and capable of holding faſt a much greater quantity. We have already mentioned ſomething of this in n° 14. and we recommend the caſe to the attentive conſideration of the reader.

61 Compariſon of the theory with experiment.

Thus have we given a ſketch of the leading doctrines of this elegant theory of Mr Æpinus, all legitimately deduced from the circumſtances aſſumed in the hypotheſis concerning the *mechanical* properties of that ſubſtance which he calls *the electric fluid*. Let us now ſee with what ſucceſs this hypotheſis may be applied to account for the phenomena. It would have been more philoſophical to have arranged the phenomena, and from the compariſon to have deduced the hypotheſis. But this would have required much more room than can be afforded in a Work like ours.

We preſume, that many of our readers, namely, all ſuch as are already converſant with electrical phenomena and with electric experiments, have ſeen, as we went along, the perfect agreement of the hypotheſis with the various phenomena of attraction and repulſion, and all thoſe which are uſually claſſed under the name of electric atmoſpheres: and we are confident, that when they compare the conſequences that ſhould neceſſarily reſult from ſuch a fluid with the legitimate conſequences of the mechanical action of elaſtic atmoſpheres, they will acknowledge the great ſuperiority of this hypotheſis in point of ſimplicity, perſpicuity, and analogy with other general operations of nature. To ſuch readers it would not be neceſſary to ſtate any farther compariſon; but there are many who have not yet formed any diſtinct *ſyſtematic* view of the appearances called *electrical*. We do not know any way of giving ſuch a view of them as by means of this hypotheſis; and we may venture to ſay, that it will enable the ſtudent of Nature to claſs them all, with hardly a ſingle exception. After which, the hypotheſis may be thrown aſide by the faſtidious philoſopher; and the uſeful claſſification, and general laws of the electric phenomena, will remain ready foundations for a more perfect theory. For the ſake of ſuch readers, therefore, we ſhall take a ſhort review of thoſe general appearances which are accompanied by attractions and repulſions, and compare them with this Æpinian theory.

We ſhall not at preſent conſider the various modes of excitation, although this theory alſo affords much inſtruction

ſtruction on the ſubject, but confine ourſelves entirely to the facts which are moſt immediately dependent on it, and ſhould be employed to ſupport or overturn it; and we ſhall ſuppoſe the reader acquainted with moſt parts of the common apparatus; ſuch as electrometers, inſulation, &c. We alſo preſume that he knows, that when a ſmall pith-ball has been electrified by touching a piece of glaſs which has been excited by rubbing with dry flannel, it will repel another body ſo electrified; and that balls, which have received their electricity in this manner from ſealing-wax excited by the ſame rubber, alſo repel each other; but that balls, thus electrified by glaſs, attract thoſe which are electrified by ſealing-wax.

The following ſimple apparatus will ſerve for all the experiments which are neceſſary for eſtabliſhing the theory:

62
pparatus
eceſſary
r this
compari-
n.

1. Two ſlender glaſs rods A (fig. 8.), having a braſs ball B at the end, about a quarter of an inch in diameter, ſuſpending a very ſmall and delicate pith-ball electrometer C.

2. Some electrometers (fig. 9.), conſiſting of two pieces of ruſh pith, about four inches long, nicely ſuſpended, and hanging parallel, and almoſt in contact with each other. It is proper to have them as ſmooth as poſſible, and neatly rounded at the ends, to prevent unneceſſary diſſipation.

3. Some pith-ball electrometers (fig. 10.), whoſe threads are of ſilk, about four inches long, and ſome with flaxen threads moiſtened with a ſolution of ſome deliqueſcent ſalt, that they may be always in a good conducting ſtate.

4. Several braſs conductors (fig. 11.), each ſupported on an inſulating ſtalk and foot. They ſhould be about an inch and half or two inches long, and about three-fourths of an inch in diameter, with round ends, and well poliſhed, to prevent all diſſipation. The foot muſt be ſo narrow as to allow them to touch each other at the ends.

5. Two balls (fig. 12.), one of glaſs, and the other of glaſs coated with ſealing-wax, each furniſhed with an inſulating handle, the other end of which may be occaſionally ſtuck into a foot, or into the ſide of a block of wood, which can be ſlid up or down on a wooden pillar, and fixed at any height. Theſe balls ſhould be about three inches in diameter. They muſt be excited by rubbing with dry warm flannel.

6. Some little pieces of gilt card (fig. 13.), about two inches long, half an inch broad, and rounded at the ends, and made as ſmooth as poſſible. Each muſt have a dimple ſtruck in the middle with a poliſhed blunt point, ſo that it will traverſe freely like a mariner's needle when ſet on a glaſs point, rounded in the flame of a lamp. More artificial needles may be made of ſome light wood, having ſmall cork balls at the ends, all gilt and poliſhed, and turning, in like manner, on glaſs ſtalks: alſo ſome ſimilar needles made of ſealing-wax, one end of each being black, and the other red.

The mechanical phenomena of electricity may be expreſſed in a few ſimple propoſitions. The moſt general fact that we know, and from which all the reſt may be deduced, is the following:

If any body A is electrified, by any means whatever, and if another body B is brought into its neighbourhood, the laſt becomes electrical by poſition.

63
A neutral body attracted, becauſe rendered electrical by induction.

Set the braſs conductors in a row, touching each other, as repreſented in fig. 11. by A, B, C; and let a pith-ball electrometer, having ſilk threads, be ſet near one end of the conductors. Excite one of the globes, by rubbing it with dry flannel. When this is brought near the end of the conductor, the pith-ball will approach the other end. But the globe muſt not be brought ſo near as to cauſe the pith-ball to ſtrike againſt the other end. On removing the globe, the pith-ball will move off and hang perpendicularly. The ſame effect is produced by both globes.

Thus the mere vicinity of the electric renders the conductor electric, and the electricity ceaſes on removing the globe. This is perfectly conformable to the theory, whether we ſuppoſe the fluid to be made redundant or deficient at the remote end of the conductor. If one ſhould aſcribe the approach of the pith-ball to the immediate action of the globe, it is ſufficient to obſerve, that if the ball be ſuſpended near the *ſide* of the conductor, it will approach the conductor, ſhewing that it is affected by the conductor, and not by the globe.

State of diſtribution aſcertained experimentally.

Let the globe be held in the poſition D (fig. 12), about ſix inches from the conductor, and a little above the line of its axis. Take the glaſs rod (fig. 8.), and bring its knob into contact with the under ſide of the remote end *c* of the conductor. The balls of the electrometer will ſeparate, ſhewing that they are electrified in the ſame manner, and repel each other. Slide the braſs knob along the under ſide of the conductors, quite to the end *a*. The balls will gradually collapſe as the knob approaches a point near the middle of the conductors, where they will hang parallel. Paſſing this point, they will again ſeparate, and moſt of all when the knob is at *a*. In this ſituation they will deviate toward the globe, and will be directed ſtraight toward it, if it be held too near, or in the direction of the axis. This would diſturb the experiment, and muſt be avoided. Theſe phenomena are conformable to the account given of the diſpoſition of the fluid in the conductor. The electrometer may be conſidered as making a part of the conductor; and when its threads hang parallel, it is in its natural ſtate, having its fluid of its natural denſity. This, however, cannot be ſtrictly true, according to the theory; becauſe the balls of the electrometer muſt be conſidered as more remote from the electric, and their electrical ſtate muſt correſpond to a point of the conductor more remote than that where the knob of the electrometer touches it. This will be more remarkably the caſe as the threads are longer. Accordingly, an electrometer with very long threads will never collapſe. The place of the neutral point cannot be accurately aſcertained in this way. Lord Mahon imagined that its ſituation B was determined (in his experiments with a long conductor) to be ſuch, that D *c* was harmonically divided in B and *a*; and he finds this to be agreeable to the reſult of an electric atmoſphere whoſe denſity is inverſely proportional to the ſquare of the diſtance. But we cannot deduce this from his narration of the experiment. He gives no reaſon for his ſelection of the point D, nor tells us the form and dimenſions of the electric employed, nor takes into account the action of the fluid in the long conductor. It is evident that no computation can be inſtituted, even on his Lordſhip's principles, till all this be done. We have

Lord Mahon's determination of the neutral point not warranted by his explanation.

always found that the neutral point was farther from the electric, in proportion as the conductor was ſmaller, and when the electricity was ſtronger; and that the differences in this reſpect were ſo very conſiderable, that no dependence could be had on this experiment for determining the law of action. It ſhould be ſo, both according to Lord Mahon's and Mr Æpinus's theory. But to proceed with our examination:

Having touched the end *c* of the conductor with the knob of the electrometer, bring it away. The balls will continue to repel each other, and they are attracted by any body that is in its natural ſtate. Touch the ſame end with the knob of the other electrometer, and bring it alſo away; the balls of the two electrometers will be found to repel each other: but if one has touched the conductor at *c*, and the other has touched it at *a*, the electrometers will ſtrongly attract each other. All this is quite conformable to the theory. If the fluid has been compreſſed at *c*, and therefore the balls of that electrometer are overcharged, they muſt repel each other, and repel any other body electrified in the ſame way. They muſt attract and be attracted by any natural body. But the balls of the other electrometer having touched the conductor at *a*, muſt be undercharged, and the redundant fluid of the one muſt attract the redundant matter of the other.

If the conductor has been electrified by the vicinity of excited glaſs, the electrometer which touched it in the remote end *c*, will be repelled by a piece of excited glaſs, but attracted by excited ſealing wax. The electrometer which touched the conductor in *a* will be attracted by excited glaſs, and repelled by excited ſealing-wax. The contrary will be obſerved if the conductor has had its electricity induced on it by the vicinity of the globe covered with ſealing-wax. This is a complete proof that Mr Dufuy's doctrine of *vitreous* and *reſinous* electricity is unfounded. Both kinds of electricity are produced in a conducting body, without any material communication, by mere juxta-poſition to a body poſſeſſed of either the vitreous or the reſinous electricity.

64
Conſtant diſtinctions of redundancy and deficiency.

We have not yet mentioned any reaſons which indicate which end of the conductor is electrical by the redundancy of electric fluid, nor is the reader prepared for ſeeing their force. It is generally believed that the remote end of a conductor which is electrified by glaſs, excited by rubbing it with flannel or amalgamated leather, is electrical by redundancy. No difference has been obſerved in the attractions and repulſions. But there are other marks of diſtinction which are conſtant, and undoubtedly ariſe from a difference in the mode of action of thoſe of mechanical forces. If, while the excited glaſs globe remains at D, a glaſs mirror, foiled as uſual with tin-leaf, be made to touch the remote end of the conductor, and ſlowly drawn tranſverſely, ſo that the conductor draws a line as it were acroſs it—this mirror being laid down with the foiled ſide undermoſt, the duſt, which ſettles on it in the courſe of a day or two, will be chiefly collected along this line, ſomewhat in the form of the fibres of a feather. But if the conductor was rendered electrical by the globe covered with ſealing-wax, the duſt will be collected along this line in little ſpots like a row of beads. The appearances will be reverſed if the mirror has been paſſed acroſs the end of the conductor which is neareſt to the excited electric. In ſhort, in whatever way the drawing point has been electrified, if it repel a ball which has touched excited glaſs, the line will be feathered; but if it attract ſuch a ball, the line will be ſpotted. There are many ways of making this appearance much more remarkable (ſee Electricity, *Encycl.* Sect. viii. n° 48.) than this; but we have mentioned it on this occaſion, becauſe the circumſtances which occaſion the difference, whatever it is, are the moſt ſimple poſſible. Nothing is communicated; and therefore the effect muſt ariſe from the unnatural ſtate of a ſubſtance or power reſiding in the body. If it be a ſubſtance *ſui generis*, the electric action muſt ariſe from a different diſtribution of this ſubſtance; from a redundancy and deficiency of it in the different portions of the conductor. Without pretending as yet to ſay which is redundant, we ſhall ſuppoſe, with Dr Franklin, that the electricity of excited glaſs is ſo; and we ſhall uſe the words *redundant* and *poſitive* to diſtinguiſh this electricity from the other. This is merely that we may, on many occaſions, conſiderably abbreviate language.

The different electrical ſtates of the different portions of the conductor may be ſeen in another way, which is perhaps more ſimple and unexceptionable than that already narrated. While the globe remains at D, take the two extreme pieces A and C aſide; or, if only two pieces have been uſed, draw the remote piece farther away. Now remove the excited globe. When we examine A ſeparately, we ſhall find it wholly negative, or undercharged, ſtrongly repelling a ball electrified by ſealing-wax, and attracting a ball electrified by glaſs. The other piece C exhibits poſitive electricity, attracting and repelling what A repelled and attracted. If only three pieces of the conductor have been employed, the middle piece B is generally poſitive; but this in a very faint degree.

If all the pieces be again joined, they are void of electricity. If, inſtead of ſuch conductors, a row of metal balls, ſuſpended by ſilk lines, are employed, one of them may generally be found without any ſenſible electricity, when ſeparated from the reſt, having been the neutral part of the row while united.

Theſe very ſimple facts ſhew, as completely as can be wiſhed, that if the electric phenomena depend on a fluid moveable in the pores of the body, the conſtitution given it by Mr Æpinus is adequate to the explanation. We may now venture to aſſert, that every other phenomenon of attraction and repulſion will be found in exact conformity with the legitimate conſequences of this conſtitution of the electric fluid.

65
In the induction of electricity nothing is communicated. Inherent powers are excited.

That nothing is communicated from the electric will appear ſtill more forcibly by the following experiment: Let a conductor be rendered electrical in the way now deſcribed, and touch either extremity of it with the little electrometer, and obſerve attentively the divergency of its threads. Now approach its remote extremity with another conducting body, ſuch as a ſingle piece of thoſe conductors, it will be rendered electrical; as may be diſcovered by a delicate electrometer. Obſerve carefully whether the electrometer in contact with the firſt conductor be affected:—it will generally be found to ſpread its threads wider. It will *certainly* be thus affected if the other conductor be very long and bulky, or touched by the hand; or if, inſtead of this ſecond conductor, we approach the firſt with the extended palm

palm of the hand. As the ſecond conductor was rendered electrical, ſo, undoubtedly, is the hand alſo: and its electrification has not deprived the firſt conductor of any of its electric power, but, on the contrary, has increaſed it. And this augmentation of its power is equally ſenſible at both ends: For an electrometer at the other end will alſo diverge more when the hand is brought near the remote end. This theory explains this in the moſt ſatisfactory manner. The firſt conductor renders the ſecond electric, by propelling its fluid to a greater diſtance. The ſecond conductor now acts on the fluid that is moveable in the firſt, and cauſes a greater accumulation in its end which is fartheſt from the electric; that is, renders it more electric.

s.

Suppoſe that, inſtead of employing an excited globe of glaſs, we had made uſe of a conducting body, ſlightly overcharged. Thus if we employ the conductor A, overcharged, to induce electricity on C; this will produce the ſame general effect on our ſet of conductors. But if we have previouſly examined the force of the redundant body, by ſuſpending a pith-ball near it, and obſerving its deviation from the perpendicular, we may ſometimes be led to think that it has imparted ſomething to the other body. For if the other body and the pith-ball be on oppoſite ſides of the redundant body, the pith-ball will fall a little; indicating a diminution of electric force. But this *ſhould happen* according to the theory; for it was ſhewn, in nº 52. that the conſtipation in the remote end of the overcharged body will be diminiſhed, and along with this, its action on the pith ball. We ſhould find the electricity of the other end, next the conductor, increaſed, could we find an eaſy way of examining it; but an electrometer applied there will be too much affected by the conductor.

The ſame concluſions may be drawn from the following facts: Hang up a ruſh-pith electrometer. Approach it below with a body ſlightly electrified. The legs of the electrometer immediately diverge, though attracted by the electrified body. Hold the hand above the electrometer, and they will diverge ſtill more; touch the top of it, and they ſpread yet farther. Hold the electrified body (very weakly electrified) above the electrometer, ſo that its legs may diverge a little. Hold the hand above the electrified body; the legs of the electrometer will come nearer each other.

Theſe appearances are obſerved whether the electric be poſitive or negative. We need not take up time in explaining this by the theory, its agreement is ſo obvious.

ectric
edles po-
ity and
tricity.

Laſtly, on this head, if, in place of a fixed conductor, we uſe one of the needles of gilt card, ſet on its pivot, and if we then approach it with another conducting body, in the manner repreſented by E and C of fig. 6. we ſhall obſerve that end of the needle to avoid the other body; but if we bring them together, in the manner repreſented by F and B, they will attract each other. The attraction will be greater when the body F is long; and moſt of all when it communicates with the ground. Theſe phenomena are therefore in perfect conformity with the theory; but it may ſometimes happen that E will attract the end of C that is neareſt to A, and E will be electrified poſitively if A be poſitive. This ſeems inconſiſtent with the theory; and, accordingly, it has been adduced by Volta againſt Lord Mahon's account of the electrical ſtate of a conductor in a ſituation ſimilar to that of C. But the theory of Æpinus ſhews the poſſibility of this caſe. When E is very long, or when it is held in the hand, it is rendered *much more* undercharged than the adjacent part of C; and the fluid in the remoter, but not much remoter, part of C is ſtrongly attracted by the copious redundant matter in the near end of E, and is brought back again, and paſſes over into E, in the way to be deſcribed immediately The caſe is rare, and it will not happen at any conſiderable diſtance from the neutral point of C. If, indeed, E touch the near end of C before A is brought near, the approach of A will cauſe fluid to paſs into E immediately, and C will be left undercharged on the whole.

The reader, who is at all converſant with electrical experiments, will be ſenſible, that theſe experiments are delicate, requiring the greateſt dryneſs of air, and every attention to prevent the diſſipation of electricity during the performance. This, by changing the ſtate of the conductors and electrometers, will frequently occaſion irregularities. The electrometers are moſt apt to change in this reſpect, it being ſcarcely poſſible to make them perfectly ſmooth and free from ſharp angles. It may therefore happen, that when the conductors have affected them *for ſome time*, by the action of the diſturbing electric, the removal of this electric will not cauſe the electrometers to hang perpendicular; they will often be attracted by the conductors, and often repelled; but the intelligent experimenter, aware of theſe circumſtances, will know what allowances to make.

67
Phenomena
of imperfect conductors
greatly corroborate
the theory.

The theory obtains a ſtill more complete ſupport from a compariſon with ſimilar experiments made with imperfect conductors. If, in place of the ſeries A, B, C, of metalline conductors, we employ cylinders of glaſs or ſealing wax, or even dry wood or marble, and electrometers with ſilk threads in place of the ruſh-pith electrometers, we ſhall find all the appearances to be ſuch as the theory enables us to predict. If, for example, we uſe a ſingle cylinder A of glaſs, we ſhall find that the neighbourhood of the electric D ſcarcely induces any electricity on A. The electrometer will hardly exhibit the ſmalleſt attraction, and its motions will be almoſt entirely ſuch as ariſe from the immediate influence of the electric body D. A cylinder of very dry wood will be more affected by the electric D; and a circumſtance of theoretical importance is very diſtinctly obſerved, namely, the gradual ſhifting of the neutral point. It will be found to advance along the cylinder for a very long while, when every circumſtance is very favourable, the air very dry, and the wood almoſt a nonconductor; and its final ſituation will be found much nearer to the electric than in the braſs conductor. Several inſtructive experiments of this kind may be found in a treatiſe publiſhed in 1783 by Dr Thomas Milner at Maidſtone in Kent, entitled, "Experiments and Obſervations on Electricity." The author does not profeſs to advance any new doctrines, but only to exhibit experiments ſcientifically arranged for forming a ſyſtem. He ſupports the Franklinian ſyſtem as it was generally underſtood at that time; but is much embarraſſed for the explanation of the repulſion of negative electrics. The Æpinian correction of this theory did not offer itſelf to his mind.

68
Irregularities.

We need not go over the ſame ground again with imperfect conductors. It is well known that ſuch bodies

dies are more weakly attracted and repelled; that the balls of an electrometer with linen threads diverge vaſtly more when an electrified body is held below it, than if the threads are ſilken: that ſuch electrometers frequently exhibit very capricious appearances from the ſlow but real progreſs of the electricity along the threads. Theſe anomalies will be better underſtood when we explain the diſſipation of electricity along imperfect conductors.

69 Induced electricity of imperfect conductors is really permanent.

A very eſſential deduction from the theory is, that the electricity induced on an imperfect conductor muſt have ſome permanency. This is fully confirmed by experiment. But the remarkable inſtances of this particular cannot be produced till we be better acquainted with the methods of producing great accumulations of fluid. It is enough to obſerve at preſent, that a permanent electricity may always be obſerved at the junction of the conductors with their inſulating ſtalks. The braſs conductor A ceaſes to be electric as ſoon as the excited globe is removed; but the very top of the glaſs ſtalk on which it is ſupported will ſenſibly affect a delicate electrometer for a long while after. The following pretty experiment ſhews this permanency very diſtinctly. Set one of the ſealing-wax needles on its pivot, and place it between two inſulated metal ſpheres of conſiderable ſize, at ſuch a diſtance from both as not to receive a ſpark. Electrify theſe balls moderately, one of them poſitively, and the other negatively, and keep them thus electrified for ſome hours by renewing their electrification. The needle quickly arranges itſelf in the line adjoining the two ſpheres, juſt as a magnetic needle will do when placed between two magnets whoſe diſſimilar poles front each other. Any gentle force will derange the needle; but it will vibrate like a magnetic needle, and finally ſettle in its former poſition. When this has been continued ſome time, that end of the needle which pointed to the poſitive globe will be found negative, and the other will be found poſitive, if examined with an electroſcope. And now, if the two globes be removed, this little needle will remain electrical for entire days in dry froſty weather, and its ends will approach any body that is brought near it (taking care not to come too cloſe); and the end which pointed to the poſitive globe will avoid a piece of rubbed ſealing wax, but will approach a piece of rubbed glaſs; but the other end will be affected in the oppoſite way. In ſhort, it proves an electric needle with a poſitive and negative pole.

If two ſmall inſulated balls are moderately electrified, and placed about ſix inches aſunder, this needle, when carried round them, will arrange itſelf exactly as a magnetic needle does when carried round a magnet of the ſame length. If the ſame trial be made with the needle of gilt card, it will arrange itſelf in the ſame manner that a ſoft iron needle arranges itſelf near a magnet, but either end will turn indifferently to either globe.

Electrical meridians.

If a thin glaſs plate, coated with red ſealing wax, be ſet on the poſitive and negative globes, and we ſprinkle (from a conſiderable height) a fine powder of black ſealing wax, and then pat the plate gently with a glaſs rod ſo as to agitate it a little, the particles of wax powder will gradually arrange themſelves into curve lines, diverging from the point over one of the globes, and converging to the point over the other, preciſely like the curves formed by iron-filings ſprinkled on a paper held over a magnet. Each little rag of wax becomes electrical by poſition, acquires two poles, and the poſitive pole of one attracts the negative pole of another; and they adhere in a certain determinate poſition, nearly a tangent to the curve, which was mentioned in n° 50, and indicates the law of magnetic action. When in this ſtate, if a hot brick be held over the plate till the wax ſoften a little, the particles of black wax will adhere to the red coating, and give us a permanent ſpecimen of the action.

70

It is well known that liquid ſealing wax is a conductor. The writer of this article filled a glaſs tube with powdered ſealing wax, and melted it, and then expoſed it, in its melted ſtate, to the influence of a poſitive and a negative globe, hoping to make a powerful and permanent electric needle, which ſhould have two poles, and exhibit a ſet of phenomena reſembling thoſe of magnetiſm. Accordingly he, in ſome meaſure, ſucceeded, by keeping the globes continually electrified for ſeveral hours, till the wax was quite cold. It had two diſtinct poles, and preſerved this property, *even though plunged in water, and while immerſed in the water;* but he was greatly diſappointed as to the degree of its electricity. It juſt affected a ſenſible electrometer at the diſtance of ſix inches from either pole. It was conſiderably ſtronger than if it had not been melted during the impregnation, but by no means in the degree that he expected. It retained ſome electricity for about ſix weeks, although lying neglected among conducting bodies. After its power ſeemed quite extinct, he was melting it again in order to renew it. Some light fibrous things chanced to be near it. While it was ſoftening, it became very ſenſibly electrical, cauſing theſe fibres to bend towards it, and even to cling to the tube. We ſhall ſee by and bye, that he was miſtaken in expecting more remarkable appearances, and that the theory, when properly applied, does not promiſe them. Having thus eſtabliſhed (as we think) this theory on ſufficient foundations for making it a very perſpicuous way of explaining the phenomena of induced electricity, we proceed to compare it with the ſecond general fact in electricity.

71 Electricit by comm nication

Prop. II. When an inſulated body B is brought very near an electrified body A, a ſpark is obſerved to paſs between them, accompanied with a noiſe (which we ſhall call the electric Snap), and B is now electrified permanently, and the electricity of A is diminiſhed.

Although this be one of the moſt familiar facts in electricity, it will be proper to conſider its attending circumſtances in a way that connects it with what we have now learned concerning electricity by poſition.

Let the inſulated body A (fig. 14.) be furniſhed with a cork-ball, hanging by a ſilk thread from a glaſs ſtalk connected with A; let B be fitted up in the ſame manner; let A be electrified weakly, and its degree of electricity be eſtimated by the inclination of the ball *towards* A: ſince B is not electrified, its electrometer will hang perpendicular; but when it approaches A (keeping the electrometers on the remote ſides of both), its electrometer will approach it, and the electrometer of A will gradually approach the perpendicular. When the bodies are brought very near, a ſpark is ſeen between them; and, at that inſtant, the electrometer of B comes

B comes much nearer to it, and that of A drops farther from it. If they be now ſeparated, their electrometers will retain their new poſitions with very little change, and B will now manifeſt the ſame kind of electricity with A.

Such is the appearance when A has been but weakly electrified. Bringing B near A, the fluid in B is drawn to the remote ſide, if A be overcharged, or drawn to the ſide neareſt to A, if A has been undercharged. B acts on its electrometer in conſequence of the change made in the diſpoſition of its fluid. The electrometer is attracted. In the mean time, the change made in the diſpoſition of the fluid in B affects the moveable fluid in A. If A was overcharged, the adjacent ſide of B becomes undercharged, and its redundant matter, attracting the fluid in A, condenſes it in the adjacent ſide, abſtracting part of the redundant fluid from that ſide which is next to the pith-ball. Then the joint action of the whole redundant fluid in A on the pith-ball is diminiſhed.

ſt hap- abrupt-

As there is now an attraction in the redundant fluid in A for the redundant matter on the adjacent ſide of B, it is reaſonable to ſuppoſe that when this attraction, joined to the repulſion of the redundant fluid behind it, is able to overcome the attraction which connects it with the ſuperficial particles of the matter, it will then eſcape and fly into B: but this will not happen gradually, but at once, as ſoon as the expelling force has ariſen to a very conſiderable intenſity. We cannot ſay what is the preciſe augmentation that is neceſſary; but we can clearly ſee, that however great the attraction for the adjoining particles may be, while the particle is ſurrounded by them on *all* ſides, it will yield to the ſmalleſt inequality of force, becauſe the particles before it attract as much as thoſe behind it; but when it is juſt about to quit the laſt or ſuperficial particles of A, a much greater force is now neceſſary. It can be ſtrictly demonſtrated, that when the mutual tendency is inverſely as the ſquare of the diſtance, the action of a particle placed immediately without a ſphere of ſuch matter is double of its action when ſituated in the very ſurface *. A *ſaltus* of this kind muſt obtain whatever be the law of electric attraction. We ſhall ſee other cauſes alſo which ſhould prevent the eſcape of redundant fluid, and alſo its admiſſion, till the impelling force is encreaſed in a certain abrupt degree.

72. These obſervations muſt ſuffice at preſent to explain the deſultory nature of this tranference, if there be really a transference. That this has happened, may be confidently inferred from the ſudden diminution of the electricity of A, indicated by the ſudden fall of its electrometer; but it is more expreſsly eſtabliſhed, that there has been a transference by the change produced on B. It is now permanently electrified, and its electricity is of the ſame kind with that of A, poſitive or negative according as A is poſitive or negative. And now we are enabled to explain the third general fact in electricity.

73 arted tricity duces ual re ion.

PROP. III. When a body has imparted electricity to another, it conſtantly repels it, unleſs that other has afterwards imparted all its electricity to other bodies. This fact, from which there is no exception, is an immediate conſequence of the theory. Before the transference ſuppoſed by it, B was in its natural ſtate; after the transference, both bodies contain redundant fluid, or redundant matter; therefore they muſt mutually repel.

We may now take another form of the experiment, which will be much more convincing and inſtructive. Let A be electrified poſitively, or by redundancy, and let its electrometer be attached to it by a conducting ſtalk, and have a flaxen thread; let this be the caſe alſo with the electrometer of B; then the appearances ſhould happen in the following order: When A is made to approach B, the electrometer of B muſt gradually riſe, diverging *from* B; becauſe the fluid condenſed on the ſide remote from A, and in the electrometer, will act more ſtrongly on it than the deſerted matter on the other ſide of B; and when the ſudden transference is made, and B is wholly overcharged, its electrometer will immediately riſe much higher, and muſt remain at that height, nearly, when A is removed. On the other hand, the electrometer attached to the remote ſide of A muſt deſcend, by reaſon of the change made in the diſpoſition of the fluid in A by the induced electrical ſtate of B: and when a conſiderable portion of the redundant fluid in A paſſes into B, the electrometer of A muſt ſudenly ſink much lower, and remain in that ſtate when B is removed.

Transference of a peculiar ſubſtance highly probable.

Many circumſtances of this phenomenon corroborate our belief of a real transference of matter. The cauſe of electric action reſided formerly in A alone; it now reſides alſo in B. The larger that B is, the greater is the diminution of A's electric power, and the ſmaller is the power acquired by B. It perfectly reſembles, in this reſpect, the communication of ſaltneſs, ſweetneſs, &c. by mixing a ſolution of ſalt or ſugar with different quantities of water; and the evidence of a transference of a ſubſtance, the cauſe of electric attractions and repulſions, is at leaſt as cogent as the evidence of the transference of heat, when we mix hot water with a quantity of cold, or when a hot ſolid body is applied to the ſide of a cold one. We alſo ſee ſo many chemical and other changes produced by this communication of electricity, that we can hardly refuſe admitting that *ſome material ſubſtance* paſſes from one body to another, and, in its new ſituation, exerts its attractions and repulſions, and produces all their effects.

We may deduce the following corollaries; all of which are exactly conformable to the phenomena, ſerving ſtill more to confirm the juſtneſs of the theory.

74 Degrees of vivacity proportioned to the quantity imparted.

1. A certain quantity of what poſſeſſes theſe powers of attraction and repulſion is neceſſary for giving a determined vivacity to the appearances. Another ſpark muſt paſs between the bodies, *only if they be brought ſtill nearer*, and their electrometers muſt riſe and fall ſtill farther. For by the firſt transference of electric fluid into B, the expelling power of A is diminiſhed, and the ſuperior attraction of the redundant matter in the adjacent ſide of B is alſo counteracted by the repulſion of the fluid which has entered into it; therefore no more will follow unleſs theſe forces be encreaſed, at leaſt to their former degree. When this addition has been made to B, and this abſtraction from A, their reſpective electrometers muſt be affected. All this is in perfect conformity to experience.

75 Communication moſt remarkable in conductors.

2. All the phenomena of communicated electricity muſt be more remarkable in proportion to the conducting power of the bodies. A very imperfect conductor,

puſcles Alem- , t. 1.

ductor, ſuch as glaſs or ſealing wax, will impart or receive fluid only between the very neareſt parts; whereas a metalline body is inſtantly affected through its whole extent. This deduction is perfectly agreeable to the whole train of electric experiments. The finger receives a ſtrong ſpark from a large metalline electrified body, which diſcharges *every part of it* of a portion of its electricity. But an excited globe, which ſhews, by its action on a diſtant body, as great a degree of electricity, will give only a very ſmall ſpark; and it is found not to be affected at any conſiderable diſtance from the point of its ſurface from which the transference was made. The whole electricity of a perfect conductor is diſcharged by touching it; but a non-conductor will ſucceſſively give ſparks, if touched in many different parts; and it may be ſeen by a nice electrometer, that each contact takes away the electricity only from a very ſmall ſpace round it: and it is further highly deſerving of notice, that ſome time after a ſpark has been obtained from a particular ſpot of the electric, a ſecond ſpark may be obtained from it, the electricity of the neighbouring parts having been gradually diffuſed through it.

76 Inſulation neceſſary for electric appearances.

3. If an electrified conducting body touch any thing communicating with the ground by perfect conductors, all its electricity muſt diſappear, and none can appear in the body touched by it; for the maſs of the earth bears ſuch an unmeaſurable proportion to that of the greateſt body that we can electrify, that when the redundancy or deficiency is divided between them, it muſt be imperceptible in both.

77. Hence the neceſſity of *inſulation*, as it is called, or the ſurrounding by non-conductors every body which we would have exhibit electric appearances. We muſt refer the reader to the article Electricity in the *Encycl.* for all the obſervations on this head, and the reaſons of preference given to certain ſubſtances to be employed for inſulating ſupports. But we muſt conſider, in its proper place, the manner in which the electric fluid is diſſipated by imperfectly inſulating ſubſtances; a ſubject intimately connected with the theory.

78 An electrified body attracts and then repels any unelectrified body.

4. Any unelectrified body will be firſt attracted by an electrified body, will touch it, and will then be repelled. The neutral body is rendered electrical by induction. It is, *in conſequence of this*, attracted, comes near enough to receive a ſpark, or even touches it, and is then electrified by communication; and, *in conſequence of this*, it is repelled. This is confirmed by an endleſs train of experiments. It was firſt taken notice of (we think) by Sir Iſaac Newton. Otho Guericke, a gentleman of Magdeburgh, to whom we owe the air pump, mentions many inſtances of the repulſion, but did not obſerve that it was an univerſal law. Newton was ſo ſtruck with it as to engage in a conſiderable train of experiments in the early part of his life, while meditating on the power of gravity; but even his ſagacious mind did not obſerve the whole proceſs of nature in his experiments. He obſerved, that the light bodies which roſe and adhered to the rubbed plate of glaſs were ſoon after repelled by it; but did not obſerve that the ſame piece would again riſe to the glaſs after it had touched the table. This fact is now the foundation of many experiments, which the itinerant electricians vie with each other in rendering very amuſing. We may render them inſtructive. Take away the middle conductor B (fig. 11.), and hang in its place a cork ball by a long ſilk thread. As ſoon as the electric body D is brought near to A, the ball is attracted by its remote end, comes into contact, is repelled by it, and attracted by the adjacent end of C, touches it, is faintly repelled by it, and again attracted by A; and the operation is repeated ſeveral times. When all has ceaſed, remove C, and alſo the electric D. C is found to have the ſame electricity with D, and A has the oppoſite electricity. The proceſs is too obvious to need any detailed application of the theory. The cork ball was the carrier of fluid from A to C if D was electric by redundancy, or from C to A if D was undercharged. If inſtead of removing C when the vibrations of the ball have ceaſed, we bring D a little nearer, they will be renewed, and after ſome time will again ceaſe. The reaſon is plain. The carrier ball had brought the conductor A into a ſtate of equilibrium with the action of D. But this action is now increaſed, and the effects are renewed. If we now remove D, the ball will vibrate between A and C with great rapidity for a conſiderable time before the vibrations come to an end; and we ſhall find their number to be the ſame as before. The cauſe of this is alſo obvious from the theory. We may ſuppoſe A to be negative, and C poſitive. One of them will attract the ball into contact, and will repel it, having put it into an electric ſtate oppoſite to that of the other conductor. It now becomes a carrier of fluid from the poſitive to the negative conductor, till it nearly reſtore both to their primitive ſtate of neutrality.

79 Irregularities frequent—Why.

There is frequently a ſeeming capricioufneſs in thoſe attractions and repulſions. A pith ball, or a down feather, hung by ſilk, will cling to the conductor, or otherwiſe electrified body, and will not fly off again, at leaſt for a long while. This only happens when thoſe bodies are ſo dry as to be almoſt non-conductors. They acquire a poſitive and negative pole, like an iron nail adhering to a magnet, and are not repelled till they become almoſt wholly poſitive or negative. It never happens with conducting light bodies.

80 Electric a tion, like gravitati is not hi red by the inter ofition non-conductors.

5. It ſhould follow from the theory, that the electric attractions and repulſions will not be prevented by the intervention of non-conducting ſubſtances in their neutral ſtate. Accordingly, it is a fact, that the interpoſition of a thin pane of glaſs, let it be ever ſo extenſive, does not hinder the electrometer from being affected. Alſo, if an inſulated electric be covered with a glaſs bell, an electrometer on the outſide will be affected. Nay, a metal ball, covered to any thickneſs with ſealing wax, when electrified, will affect an electrometer in the ſame way as when naked. We cannot ſee how theſe facts can be explained by the action of electric atmoſpheres. It is indeed ſaid, that the atmoſphere on one ſide of the glaſs produces an atmoſphere on the other; but we have no explanation of this production. If the interpoſed plate be a non-conductor, how does the one atmoſphere produce the other? It muſt produce this effect by acting at a diſtance on the particles which are to form this atmoſphere. Of what uſe, then, is the atmoſphere, even if thoſe atmoſpheres could effect the obſerved motions of the electrometer in conſiſtency with the laws of mechanics? The atmoſpheres only ſubſtitute millions of attractions or repulſions in place of one. We muſt obſerve, however, that the motions of

of the electrometer are modified, and ſometimes greatly changed, by the interpoſed non-conducting plate; but this is owing to the electricity induced on the plate. If the electric is poſitive, the adjacent ſurface of the plate becomes faintly negative, and the ſide next the electrometer ſlightly poſitive. This affects the electrometer even more than the more remote electric does. That this is the cauſe of the difference between the ſtate of the electrometer when the plate is there and when it is removed, will appear plainly by breathing gently on the glaſs plate to damp it, and give it a ſmall conducting power. This will make ſome change in the poſition of the electrometer. Continue this more and more, till the plate will no longer inſulate. The changes produced on the electrometer's poſition will form a regular ſeries, till it is ſeen to aſſume the very poſition which it would have taken had the plate been braſs. Then, conſidering thoſe changes in a contrary order, and ſuppoſing the ſeries continued a little farther, we ſhall always find that it leads to the poſition which it would have taken when no plate whatever is interpoſed. We conſider this as an important fact, ſhewing that the electric action is ſimilar to gravitation, and that there is no more occaſion for the intervention of an atmoſphere for explaining the phenomena of electricity than for explaining thoſe of gravitation.

g.

6. Since non-electrics are conductors, and ſince electrics may be excited by friction with a non-electric, it follows, that if this non-electric be inſulated, and ſeparated from the electric, it will exhibit ſigns of electricity; but when they are together, there muſt not appear any marks of it, however ſtrong the excitation may be. We do not pretend to comprehend diſtinctly the manner in which friction, or the other modes of excitation, operate in changing the connection between the particles of the fluid and thoſe of the tangible matter; nor is this explained in any electric theory that we know: but if we are ſatisfied with the evidences which we have for the exiſtence of a ſubſtance, whoſe preſence or abſence is the cauſe of the electric phenomena, we muſt grant that its uſual connection with the tangible matter of bodies is changed in the act of excitation, by friction, or by any other means. In the caſe of friction producing poſitive electricity on the ſurface of the electric, we muſt ſuppoſe that the act of friction cauſes one body to emit or abſorb the fluid more copiouſly than the other, or perhaps the one to emit and the other to abſorb. Whichever is the caſe, the adjoining ſurfaces muſt be in oppoſite ſtates, and the one muſt be as much overcharged as the other is undercharged. When the bodies (which we may ſuppoſe to have the form of plates) are joined, and the one exactly covers the other, the aſſemblage muſt be inactive; for a particle of moveable fluid, ſituated anywhere on the ſide of the overcharged plate, will be as much attracted by the undercharged ſurface of the remote plate as it is repelled by the overcharged ſurface of the near plate. The ſurfaces are equal, and equally electric, and act on either ſide with equal intenſity; and they are coincident. Therefore their actions balance. The action is expreſſed by the formula of n° 43; namely, $F' m' \times \overline{z - z'}$; and $z - z'$ is $= 0$, by reaſon of the equal diſtances of theſe ſurfaces from the particle of exterior fluid.

But let the plates be ſeparated. Part, and probably the greateſt part, of the redundant fluid on one of the rubbed ſurfaces will fly back to the other, being urged both by the attraction of the redundant matter and the repulſion of its own particles. But the electric, being electric becauſe, and only becauſe, it is a non-conductor, muſt retain ſome, or will remain deprived of ſome, in a ſtratum a little within the ſurface. The two plates muſt therefore be left in oppoſite ſtates, and the conducting, or non electric plate, if inſulated before ſeparation, muſt now exhibit electric action.

All this is exactly agreeable to fact. We alſo know that electrics may be excited by rubbing on each other; and if of equal extent, and equally rubbed, they exhibit no electric powers while joined together; but when parted, they are always in oppoſite ſtates. The ſame thing happens when ſulphur is melted in a metal diſh, or when Newton's metal is melted in a glaſs diſh. While joined, they are moſt perfectly neutral; but manifeſt very ſtrong oppoſite electricities when they are ſeparated. This completely diſappears when they are joined again, and reappears on their ſeparation, even after being kept for months or years in favourable circumſtances. We have obſerved the plates of talc, and other laminated foſſils, exhibit very vivid electricity when ſplit aſunder.

82
Principles of the conſtruction of electric machines.

Attention to theſe particulars enables us to conſtruct machines for quickly exciting vivid electricity on the ſurface of bodies, and for afterwards exhibiting it with continued diſpatch. The whirling globe, cylinder, or plate, firſt employed by Mr Haukſbee, for the ſolitary purpoſe of examining the electricity of the globe, was moſt ingeniouſly converted by Hauſen, a German profeſſor, into a rapid collector and diſpenſer of electricity to other bodies, by placing an inſulated prime conductor cloſe to that part of the ſurface of the globe which had been excited by friction. Did our limits give us room, we ſhould gladly enlarge on this ſubject, which is full of moſt curious particulars, highly meriting the attention of the philoſopher: But it might eaſily occupy a whole volume; and we have ſtill before us the moſt intereſting parts of the mechanical department of electricity, and ſhall hardly find room for what is eſſentially requiſite for a clear and uſeful comprehenſion of it. We muſt therefore requeſt our readers to have recourſe to the original authors, who have conſidered the excitation by friction minutely. And we particularly recommend the very careful peruſal of Beccaria's Diſſertations on it, comparing the phenomena, in every ſtep, with this theory of Æpinus. Much valuable information is alſo obtained from Mr Nicholſon's Obſervations, of which an abſtract is given in the article ELECTRICITY in the *Encyclopædia Britannica*. The Æpinian theory will be found to connect many things, which, to an ordinary reader, muſt appear ſolitary and accidental.

83
Evidences of the materiality of the electric fluid.

Seeing that this very ſimple hypotheſis of Æpinus ſo perfectly coincides in its legitimate conſequences with all the general phenomena of attraction and repulſion, and not only with thoſe that are ſimple, but even ſuch as are compounded of many others—we may liſten, without the imputation of levity, to the other evidences which may be offered for the materiality and mobility of the cauſe of thoſe mechanical phenomena. Such evidences are very numerous, and very perſuaſive. We have ſaid that the tranſference of electricity is deſultory, and that the change made in the electric ſtate of the communicating bodies is always conſiderable. It appears to keep ſome ſettled ratio to the whole electric power of the body. When the form of the parts where the communication takes place, and other circumſtances, remain the ſame, the transference increaſes with the ſize of the bodies; and all the phenomena are more vivid in proportion. When the conductor is very large, the ſpark is very bright, and the ſnap very loud.

Snap,

1. This ſnap alone indicates ſome material agent. It is occaſioned by a ſonorous undulation of the air, or of ſome elaſtic fluid, which ſuddenly expands, and as ſuddenly collapſes again. But ſuch is the rapidity of the undulation, that when it is made in cloſe veſſels it does not exiſt long enough, in a very expanded ſtate, to affect the column of water, ſupported in a tube by the elaſticity of the air, for the purpoſe of a delicate thermometer or barometer; juſt as a muſket ball will paſs through a looſe hanging ſheet of paper without cauſing any ſenſible agitation.

Spark, and heat.

2. The ſpark is accompanied by intenſe heat, which will kindle inflammable bodies, will melt, explode, and calcine metals.

Chemical effects.

3. The ſpark produces ſome very remarkable chemical effects. It calcines metals even under water or oil; it renders Bolognan phoſphorus luminous: It decompoſes water, and makes new compoſitions and decompoſitions of many gaziform fluids; it affects vegetable colours; it blackens the calces of biſmuth, lead, tin, luna cornea; it communicates a very peculiar ſmell to the air of a room, which is diſtinct from all others; and in the calcination of metals, it changes remarkably the ſmells with which this operation is uſually accompanied: it affects the tongue with an acidulous taſte; it agitates the nervous ſyſtem.—When we compare theſe appearances with ſimilar chemical and phyſiological phenomena, which naturaliſts never heſitate in aſcribing to the action of material ſubſtances, transferable from one body, or one ſtate of combination, to another, we can ſee no greater reaſon for heſitating in aſcribing the electric phenomena to the action of a material ſubſtance; which we may call *a fluid*, on account of its connected mobility, and *the electric fluid*, on account of its diſtinguiſhing effects. We are well aware, that theſe evidences do not amount to demonſtration; and that it is poſſible that the electric phenomena, as well as many chemical changes, may reſult from the mere difference of arrangement, or poſition, of the ultimate particles of bodies, and may be conſidered as the reſult of a change of modes, and not of things. But in the inſtances we have mentioned, this is extremely improbable.

This is therefore aſſumed.

We therefore venture to aſſume the exiſtence of this ſubſtance, which philoſophers have called *the electric fluid*, as a propoſition abundantly demonſtrated; and to affirm, on the authority of all the above-mentioned facts, that its mechanical character is ſuch as is expreſſed in Mr Æpinus's hypotheſis.

We proceed, therefore, to explain the moſt intereſting phenomena of electricity from theſe principles.

84

Diſtribution of it depends on its law of action.

We have ſeen that, in a perfect conductor, in its natural ſtate, the electric fluid is uniformly diſtributed, and cannot remain in any other condition. We are particularly intereſted to know how it is diſtributed in an overcharged or undercharged body, and how this is affected by the circumambient non-conducting air. It is evident that much depends on this. The tendency to eſcape, and particularly the tendency to transference from one body to another, muſt be greateſt where the fluid is moſt conſtipated. We know that it tends remarkably to diſſipate from all protuberances, edges, and long bodies, and that it is impoſſible to confine it in a body having very acute far-projecting points; and, what is more paradoxical, it is hardly poſſible to prevent its entering into a body furniſhed with a ſharp point. The ſmalleſt reflection muſt ſuggeſt to our imagination, that a perfectly moveable fluid, whoſe particles mutually repel, even at conſiderable diſtances, and which is confined in a veſſel from which it cannot eſcape, muſt be compreſſed againſt the ſides of the veſſel, and be denſer there than in the middle of the veſſel. But in what proportion its denſity will diminiſh as we recede from the walls of the veſſel, muſt depend on the change of electric repulſion by an increaſe of diſtance. The intenſity varies in the proportion of ſome function of the diſtance, and may be expreſſed by the ordinates of a curve, on whoſe axis the diſtances are meaſured. But we are ignorant of this function. We muſt therefore endeavour to diſcover it, by obſerving a proper ſolution of phenomena. Having made ſome approximation to this diſcovery, ſuch as ſhall give riſe to a *probable conjecture* concerning the function which expreſſes the intenſity of electric repulſion, mathematics will then enable us to ſay how the fluid muſt be diſtributed (at leaſt in ſome ſimple and inſtructive caſes) in a perfectly conducting body ſurrounded by the air, and what will be its action on another body. Thus we ſhall obtain oſtenſible reſults, which we can compare with experiments. The writer of this article made many experiments with this view above 30 years ago, and flatters himſelf that he has not been unſucceſsful in his attempts. Theſe were conducted in the moſt obvious and ſimple manner, ſuggeſted by the reaſonings of Mr Æpinus; and it was with ſingular pleaſure that, ſome years after, he peruſed the excellent diſſertation of Mr Cavendiſh in the Philoſophical Tranſactions, vol. 61. where he obtained a much fuller conviction of the truth of the concluſion which he had drawn, in a ruder way, from more familiar appearances. Mr Cavendiſh has, with ſingular ſagacity and addreſs, employed his mathematical knowledge in a way that opened the road to a much farther and more ſcientific proſecution of the diſcovery, if it can be called by that name. After this, Mr Coulomb, a diſtinguiſhed member of the French Academy of Sciences, engaged in the ſame reſearch in a way ſtill more refined; and ſupported his concluſions by ſome of the moſt valuable experiments that have been offered to the public. We ſhall now give a very brief account of this argument: and have premiſed theſe hiſtorical remarks; becauſe the writer, although he had eſtabliſhed the general concluſion, and had read an account of his inveſtigation in a public ſociety in 1769, in which it was applied to the moſt remarkable facts then known in electricity, has no claim to the more elaborate proofs of the ſame doctrine, which is given in ſome of the following paragraphs. Theſe are but an application of Mr Cavendiſh's more cautious and general mathematical procedure, to the function which the writer apprehends to be ſufficiently eſtabliſhed by obſervation.

Proceſs for diſcovering this law.

The moſt unexceptionable experiments with which we can begin, ſeem to be the repulſions obſervable between

tween two *ſmall* ſpheres. Whatever be the law of diſtribution of the particles in a ſphere, the general action of its particles on the particles of another ſphere will follow a law which will not differ much from the law of action between two particles, if the diameters of the ſpheres be ſmall in proportion to their diſtance from each other. The inveſtigation was therefore begun with them. But the ſubject required an electrometer ſuſceptible of compariſon with others, and that could exhibit abſolute meaſures. The one employed was made in the following manner; and we give it to the public as a valuable philoſophical inſtrument.

85
Comparable electrometer.

Fig 15. repreſents the electrometer in front. A is a poliſhed braſs ball, $\frac{1}{4}$th of an inch in diameter. It is fixed on the point of a needle three inches long, as ſlender as can be had of that length. The other end of the needle paſſes through a ball of amber or glaſs, or other firm non-conducting ſubſtance, about half or three-fourths of an inch in diameter; but the end muſt not reach quite to the ſurface, although the ball is completely perforated. From this ball riſes a ſlender glaſs rod FEL, three inches long from F to E, where it bends at right angles, and is continued on to L, immediately over the centre of the ball A. At L is fixed a piece of amber C, formed into two parallel cheeks, between which hangs the ſtalk DCB of the electrometer. This is formed by dipping a ſtrong and dry ſilk thread, or fine cord in melted ſealing-wax, and holding it perpendicular till it remain covered with a thin coating, and be fully penetrated by it. It muſt be kept extended, that it may be very ſtraight; and it muſt be rendered ſmooth, by holding it before a clear fire. This ſtalk is faſtened into a ſmall cube of amber, perforated on purpoſe, and having fine holes drilled in two of its oppoſite ſides. The cheeks of the piece C are wide enough to allow this cube to move freely between them, round two fine pins, which are thruſt thro' the holes in the cheeks, and reach about half way to the ſtalk. The lower part of the ſtalk is about three inches long, and terminates in a gilt and burniſhed cork-ball (or made of thin metal), a quarter of an inch in diameter. The upper part CD is of the ſame length, and paſſes through (with ſome friction) a ſmall cork-ball. This part of the inſtrument is ſo proportioned, that when FE is perpendicular to the horizon, and DCB hangs freely, the balls B and A juſt touch each other. Fig. 16. gives a ſide perſpective view of the inſtrument. The ball F is fixed on the end of the glaſs rod FI, which paſſes perpendicularly through the centre of a graduated circle GHO, and has a knob handle of boxwood on the farther end I. This glaſs rod turns ſtiffly, but ſmoothly, in the head of the pillar HK, &c. and has an index NH, which turns round it. This index is ſet parallel to the line LA, drawn through the centre of the fixed ball of the electrometer. The circle is divided into 360 degrees, and 0 is placed uppermoſt, and 90 on the right hand. Thus the index will point out the angle which LA makes with the vertical. It will be convenient to have another index, turning ſtiffly on the ſame axis, and extending a good way beyond the circle.

This inſtrument is uſed in the following manner: A connection is made with the body whoſe electricity is to be examined, by ſticking the point of the connecting wire into the hole at F, till it touch the end of the needle; or, if we would merely electrify the balls A and B, and then leave them inſulated, we have only to touch one of them with an electrified body. Now, take hold of the handle I, and turn it to the right till the index reach 90. In this poſition, the line LA is horizontal, and ſo is CB; and the moveable ball B is reſting on A, and is carried by it. Now electrify the balls, and gently turn the handle backwards, bringing the index back toward 0, &c. noticing carefully the two balls. It will happen that, in ſome particular poſition of the index, they will be obſerved to ſeparate. Bring them together again, and again cauſe them to ſeparate, till the exact poſition at ſeparation is aſcertained. This will ſhew their repulſive force in contact, or at the diſtance of their centres, equal to the ſum of their radii. Having determined this point, turn the inſtrument ſtill more toward the vertical poſition. The balls will now ſeparate more and more. Let an aſſiſtant turn the long index ſo as to make it parallel to the ſtalk of the electrometer, by making the one hide the other from his view. The mathematical reader will ſee that this electrometer has the properties aſcribed to it. It will give abſolute meaſures: for by poizing the ſtalk, by laying ſome grains weight on the cork-ball D, till it becomes horizontal and perfectly balanced, and computing for the proportional lengths of BC and DC, we know exactly the number of grains with which the balls muſt repel each other (when the ſtalk is in a horizontal poſition), in order *merely to ſeparate*. Then a very ſimple computation will tell us the grains of repulſion when they ſeparate in any oblique poſition of the ſtalk; and another computation, by the reſolution of forces, will ſhew us the repulſion exerted between them when AL is oblique, and BC makes any given angle with it. All this is too obvious to need any farther explanation. The reaſon for giving the connection between A and C ſuch a circuitous form, was to avoid all action between the fixed and the moveable part of the electrometer, except what is exerted between the two balls A and B. The needle AF, indeed, may act a little, and might have been avoided, by making the horizontal axis FI to join with A: but as it was wanted to make the inſtrument of more general uſe, and frequently to connect it with an electrical machine, a battery, or a large body, no mode of connection offered itſelf which would not have been more faulty in this reſpect. The ueateſt and moſt compendious form would have been to attach the axis FI to C, and to make CA and CB ſtiff metalline wires, in the ſame manner as Mr Brookes's electrometer is made. But as the whole of their lengths would have acted, this conſtruction would have been very improper in the inveſtigation of the law of electric repulſion. As it now ſtands, we imagine that it has conſiderable advantages over Mr Brookes's conſtruction; and alſo over Mr De Luc's comparable electrometer, deſcribed in his Eſſays on Meteorology. It has even advantages over Mr Coulomb's incomparably more delicate electrometer, which is ſenſible, and *can meaſure* repulſions which do not exceed the 50,000 of a grain; for the inſtrument which we have deſcribed will meaſure the *attractions* of the oppoſitely electrified bodies; a thing which Mr Coulomb could not do without a great circuit of experiments. For inſtead of making the ball B *above* A, by inclining the inſtrument to the right hand, we may incline it to the left; and then, by electrifying one of the balls poſitively, and the other negatively, when at a great diſtance from each other, their mutual attraction will cauſe them to approach; CB will deviate from the vertical toward A; and we can compute the force by means of this deviation.

We muſt remind the perſon who would make obſervations with this inſtrument, that every part of it muſt be ſecured againſt diſſipation as much as poſſible, by varniſhing all its parts, by having all angles, points, and roughneſſes removed, and by chooſing a dry ſtate of the air, and a warm room; and, becauſe it is impoſſible to prevent diſſipation altogether, we muſt make a previous courſe of experiments, in a variety of circumſtances, in order to determine the diminution per minute correſponding to the circumſtances of the experiments that are to be made with further views.

We truſt that the reader will accept of this particular account of an inſtrument which promiſes to be of conſiderable ſervice to the curious naturaliſt; and we now proceed with an account of the concluſions which have been drawn from obſervations made with it.

Here we could give a particular narration of ſome of the experiments, and the computations made from them; but we omit this, becauſe it is really unneceſſary. It ſuffices to ſay, that the writer has made many hundreds, with different inſtruments, of different ſizes, ſome of them with balls of an inch diameter, and radii of 18 inches. Their coincidence with each other was far beyond his expectation; and he has not one in his notes which deviate from the medium $\frac{1}{8}$th of the whole force, and but few that have deviated $\frac{1}{12}$th. The deviations were as frequently in exceſs as in defect. His cuſtom was to meaſure all the forces by a linear ſcale, and expreſs them by ſtraight lines erected as ordinates to a baſe, on which he ſet off the diſtances from a fixed point; he then drew the moſt regular curve that he could through the ſummits of theſe ordinates. This method ſhews, in the moſt palpable manner, the coincidence or irregularity of the experiments.

86 Spheres, when electrified, repel with a force proportional to $\frac{1}{x^2}$;

The reſult of the whole was, that the mutual repulſion of two ſpheres, electrified poſitively or negatively, was very nearly in the inverſe proportion of the ſquares of the diſtances of their centres, or rather in a proportion ſomewhat greater, approaching to $\frac{1}{x^{2,06}}$. No difference was obſerved, although one of the ſpheres was much larger than the other; and this circumſtance enables us to make a conſiderable improvement on the electrometer. Let the ball A be made an inch in diameter, while B is but $\frac{1}{3}$th of an inch. This greatly diminiſhes the proportion of the irregular actions of the reſt of the apparatus of the whole force, and alſo diminiſhes the diſſipation when the general intenſity is the ſame.

87 And attract according to the ſame law.

When the experiments were repeated with balls having oppoſite electricities, and which therefore attracted each other, the reſults were not altogether ſo regular, and a few irregularities amounted to $\frac{1}{6}$th of the whole; but theſe anomalies were as often on one ſide of the medium as on the other. This ſeries of experiments gave a reſult which deviated as little as the former (or rather leſs) from the inverſe duplicate ratio of the diſtances; but the deviation was in defect as the other was in exceſs.

We therefore think that it may be concluded, that the action between two ſpheres is exactly in the inverſe duplicate ratio of the diſtance of their centres, and that this difference between the obſerved attractions and repulſions is owing to ſome unperceived cauſe in the form of the experiment.

88 Attractions and repulſions are equal at equal diſtances.

It muſt be obſerved alſo, that the attractions and repulſions, with the ſame denſity and the ſame diſtances, were, to all ſenſe, equal, except in the forementioned anomalous experiments. The mathematical reader will ſee that the above-mentioned irregularities are imperfections of experiment, and that the gradations of this function of the diſtances are too great to be much affected by ſuch ſmall anomalies. The indication of the law is preciſe enough to make it worth while to adopt it, in the mean time, *as a hypotheſis*, and then to ſelect, with judgment, ſome legitimate conſequences which will admit of an exact compariſon with experiment, on ſo large a ſcale, that the unavoidable errors of obſervation ſhall bear but an inſignificant proportion to the whole quantity. We ſhall attempt this: and it is peculiarly fortunate that this obſerved law of action between two ſpheres gives the moſt eaſy acceſs to the law of action between the particles which compoſe them; for Sir Iſaac Newton has demonſtrated (and it is one of his moſt precious theorems), that if the particles of matter act on each other with a force which varies in the inverſe duplicate ratio of the diſtances, then ſpheres, conſiſting of ſuch particles, and of equal denſity at equal diſtances from the centre, alſo act on each other with forces varying in the ſame proportion of the diſtances of their centres. He demonſtrates the ſame thing of hollow ſpherical ſhells. He demonſtrates that they act on each other with the ſame force as if all their matter were collected in their centres. And, laſtly, he demonſtrates, that if the law of action between the particles be different from this, the ſenſible action of ſpheres, or of hollow ſpherical ſhells, will alſo be different (ſee *Principia*, I. Prop. 74, &c. alſo ASTRONOMY, *Encycl.* 307.)

89 Electric action is inverſely as the ſquare of the diſtance.

Therefore we may conclude, that the law of electric attraction and repulſion is ſimilar to that of gravitation, and that each of thoſe forces diminiſhes in the ſame proportion that the ſquare of the diſtance between the particles increaſe. We have obtained much uſeful information from this diſcovery. We have now full confirmation of the propoſitions concerning the mutual action of two bodies, each overcharged at one end and undercharged at the other. Their evidence before given amounted only to a reaſonable probability; but we now ſee that the curve line, whoſe ordinates repreſent the forces, is really convex to the abſciſſa, and that $Z + z'$ is always greater than $Z' + z$; from which circumſtance all the reſt follows of courſe.

90 Diſpoſition of ſuch fluid when redundant or deficient.

Let us now enquire into the manner in which the redundant fluid, or redundant matter, is diſtributed in bodies; the proportion in which it ſubſiſts in bodies communicating with each other; the tendencies to eſcape; the forces which produce a transference, &c. &c.

In the courſe of this enquiry, a continual reference will be made to the following elementary propoſition:

91 Lemma.

Let ABD (fig. 17.) be the baſe of a cone or pyramid, whoſe vertex is P, and axis PC; and let *abd* be another ſection of it by a plane parallel to the baſe; let theſe two circles, or ſimilar polygons, conſiſt of matter or fluid of equal and uniform denſity; and let P be a particle of fluid or matter; the attraction or repulſion of this particle for the whole matter or fluid in the figure ABD is equal to its attraction or repulſion for the

the whole matter or fluid in *a b d*. For the attraction for a particle in ABD is to the attraction for a particle ſimilarly placed in *a b d* as Pc^2 to PC^2; and the number of particles in ABD is to that of thoſe in *a b d* as PC^2 to Pc^2; therefore the whole attraction for ABD is to that for *a b d* as $Pc^2 \times PC^2$ to $PC^2 \times Pc^2$, or in the ratio of equality.

Cor. 1. The ſame will be true of the action of plates of equal thickneſs and equal denſity; or, in general, having ſuch thickneſs and denſity as to contain quantities of matter or fluid proportional to their areas.

2. The action of all ſuch ſections made by parallel planes, or by planes equally inclined to their axis, are equal.

3. The tendency of a particle P to a plane, or plate of uniform thickneſs and denſity, and infinitely extended, or to a portion of it bounded by the ſame pyramid, is the ſame, at whatever diſtance it be placed from the plate, and it is always perpendicular to it.

4. This tendency is proportional to the denſity and thickneſs of the plate or plates jointly.

It is only in two or three ſimple caſes that we can propoſe to ſtate with preciſion what will be the diſpoſition and action of the electric fluid in bodies; but we ſhall ſelect thoſe that are moſt inſtructive, and connected with the moſt remarkable and important phenomena.

92 Diſpoſition in parallel plates,

Let A *a d* D (fig. 18.) and E *e h* H repreſent the ſections of a part of two infinitely extended parallel plates (which we ſhall call A and E), conſiſting of ſolid conducting matter, in which the electric fluid can move without any obſtruction, but from which it cannot eſcape.

When both are over-charged,

Firſt, Let them be both overcharged, A containing the quantity *r* of redundant fluid, and E containing the quantity *s*, and let *r* be greater than *s*.

The fluid will be diſpoſed in the following manner:

1. There will be two ſtrata, A *a b* B and G *g h* H, adjoining to the remote ſurfaces, in each of which the quantity $\frac{r+s}{2}$ will be crowded together as cloſe as poſſible.

2. Adjoining to the interior ſurface (that is, the ſurface neareſt to E) of the plate A, there will be a ſtratum C *c d* D, containing the quantity $\frac{r-s}{2}$ crowded together.

3. The adjacent ſide of E will have a ſtratum E *e f* F, juſt ſufficient for containing the quantity $\frac{r-s}{2}$ at its natural denſity. This ſtratum will be entirely exhauſted of fluid.

4. The ſpaces B *b c* C and F *f g* G will be in their natural ſtate.

For a particle of fluid in the ſpace B *b c* C is urged in the direction *a d* by the force $\frac{r+s}{2}$ (n° 91, 3.), and in the direction *d a* by the force $\frac{r-s}{2}$, therefore it is, on the whole, urged in the direction *a d* with the force *s*, which will balance the repulſion of the redundant fluid in the other plate. A particle of fluid in the ſpace F *f g* G is repelled in the direction *h e* by a force $\frac{r+s}{2}$ by the fluid in G *g h* H, and it is attracted in the ſame direction by the redundant matter in E *e f* F, with the force $\frac{r-s}{2}$. Theſe make a force *r* which balances the repulſion *r* of the other plate. No other diſpoſition will be permanent; for if a particle be taken out from either ſtratum A *a b* B or C *c d* D into the ſpace between them, the repulſion from that ſtratum which it quitted is leſſened, and the repulſion of the oppoſite ſtratum, joined to that of the other plate, will drive it back again. The ſame thing holds with reſpect to the fluid in the other plate.

93. *Cor.* 1. If the two plates be equally overcharged, all the redundant fluid will be crowded on the remote ſurfaces, and the adjacent ſurfaces will be in the natural ſtate.

94 When they are under-charged,

In the *ſecond* place, let the plates be undercharged, and let *r* be the fluid wanting in A, and *s* the fluid wanting in E, and let *s* be greater than *r*; then,

1. The ſtrata adjoining to A *a* and H *h* will be completely exhauſted of fluid, and the redundant matter in each will be ſuch as would be ſaturated by $\frac{r+s}{2}$.

2. The ſtratum C *c d* D will contain redundant fluid $\frac{s-r}{2}$, crowded cloſe.

3. The ſtratum E *e f* F will be deprived of fluid, and the quantity abſtracted is $\frac{s-r}{2}$.

4. The ſpaces B *b c* C and F *f g* G are in the natural ſtate.

The demonſtration is the ſame as in the former caſe.

95 When they are in oppoſite ſtates,

Thirdly, Let A be overcharged, and E undercharged, A containing the redundant fluid *r*, and E wanting the fluid *s*; and let *r* be greater than *s*. Then,

1. The ſtrata A *a b* B and G *g h* H contain the redundant fluid $\frac{r-s}{2}$, crowded cloſe.

2. The ſtratum C *c d* D contains the quantity $\frac{r+s}{2}$, crowded cloſe.

3. The ſtratum E *e f* F is exhauſted, and wants the quantity $\frac{r+s}{2}$.

4. The reſt is in the natural ſtate.

96, *Cor.* 2. If the redundant fluid in A be juſt ſufficient to ſaturate the redundant matter in E, the two remote ſurfaces will be in their natural ſtate, all the redundant fluid in A being crowded into the ſtratum C *c d* D, and all the redundant matter being in E *e f* F.

This diſpoſition will be the ſame, whatever is the diſtance or thickneſs of the plates, unleſs the redundant fluid in A be more than can be contained in the whole of E when crowded cloſe.

97 Preſſure and tendency to eſcape.

When the two plates are overcharged, the fluid preſſes their remote ſurfaces with the force $\frac{\overline{r+s}^2}{4}$, and would eſcape with that force if a paſſage were opened. It would enter the remote ſurfaces of two undercharged plates with the ſame force; and, in either caſe, it would run from the inner ſurface of one to the adjacent ſurface of the other, with the force $\frac{\overline{r-s}^2}{4}$.

If one be overcharged and the other undercharged, fluid would eſcape from the remote ſurface with the force

force $\frac{\overline{r-s}^2}{4}$, and would run through a canal between them with the force $\frac{\overline{r+s}^2}{4}$.

Mutual actions.

They repel or attract each other with the force $\overline{r+s}^2$ according as they are both over or undercharged, or as one is overcharged and the other undercharged.

This example of parallel plates, infinitely extended, is the ſimpleſt that can be ſuppoſed. But it cannot obtain under our obſervation; and in all caſes which we can obſerve, the fluid cannot be uniformly ſpread in any ſtratum, but muſt be denſer near the edges, or near the centre, as they are overcharged or undercharged.

98 Diſpoſition in a ſphere.

Let ABD (fig. 19.) repreſent a ſphere of perfectly conducting matter, overcharged with electric fluid, which is perfectly moveable in its pores, but cannot eſcape from the ſphere. Let it be ſurrounded by conducting matter ſaturated with moveable fluid. It is required to determine the diſpoſition of the fluid within and without this ſphere.

Sir Iſaac Newton has demonſtrated (*Princ.* I. 70.) that a particle *p*, placed anywhere within this ſphere, is not affected by any matter that is without the concentric ſpherical ſurface *p q r* in which itſelf is ſituated, therefore not affected by what is between the ſurfaces ABD and *p q r*. He alſo demonſtrates, that the matter within the ſurface *p q r* acts on the particle *p* in the ſame manner as if the whole of it were collected in the centre C.

Hence it follows, that the redundant fluid will be all conſtipated as cloſe as poſſible within the external ſurface of the ſphere, forming a ſhell of a certain minute thickneſs, between the ſpherical ſurfaces ABD and *abd*; and all that is within this (that is, nearer the centre C) will be in its natural ſtate.

With reſpect to the diſtribution of the fluid in the ſurrounding matter, which we ſuppoſe to be infinitely extended, we muſt recollect that this ſhell of conſtipated redundant fluid repels any external particle of fluid in the ſame manner as if all were collected at C. Hence it is evident, that the fluid in the ſurrounding matter will be repelled, and, being moveable, it will recede from this centre; and there will be a ſpace all round the ſphere ABD which is undercharged, forming a ſhell between the concentric ſurfaces ABD and αβδ. This ſhell will contain ſuch a quantity of redundant matter, that its attraction for a particle of fluid is equal to the repulſion of the ſhell of fluid crowded internally on the ſurface ABD. All beyond this ſurface αβδ will be in its natural ſtate; for this redundant matter acts on a particle of fluid, ſituated farther from the centre, in the ſame manner as if all this redundant matter were collected in the centre C. So does the redundant fluid in the conſtipated ſhell. Therefore their actions balance each other, and there is no force exerted on any particle of fluid beyond this deficient ſhell. This deficient ſhell will not affect the fluid in the ſphere *a b d* by Newton's demonſtration. No other diſpoſition will be permanent. But farther: This undercharged ſhell muſt be completely exhauſted: for a particle of fluid placed between ABD and αβδ will be more repelled by the fluid in the crowded ſhell within the ſurface ABD, than it is attracted by the redundant matter of its own ſhell that is leſs remote from the centre; and it is not affected by what is more remote from the centre. Therefore the fluid without the ſphere ABD cannot be in equilibrio, unleſs the ſhell between ABD and αβδ be not only rarefied, but altogether exhauſted of fluid.

If the ſphere be undercharged, the ſpace between ABD and *a b d* will be entirely exhauſted of fluid, and there will be a ſhell αβδ of redundant matter ſurrounding the ſphere. All within *a b d*, and all without αβδ, will be in its natural ſtate. It is unneceſſary to repeat the ſteps of the ſame demonſtration.

This valuable propoſition is by the Hon. Mr Cavendiſh.

99 Conſequences of this diſpoſition.

This would be the diſpoſition in and about a glaſs globe filled and ſurrounded with an ocean of water, and having redundant fluid within it, on the ſuppoſition that glaſs is impervious to the electric fluid. But it would not affect an electrometer, even ſuppoſing that the movements of the electrometer could be effected under water. Suppoſe the globe of water to be ſurrounded with air, and that the fluid is diſpoſed in both in the manner here deſcribed; it will be perfectly neutral in its action on any electrometer ſituated in the air. But, by reaſon of the almoſt total immobility of the fluid in pure dry air, this ſtate cannot ſoon obtain; and, till it obtain, the conſtipated ſhell within the glaſs muſt repel the fluid in an electrometer more than the partially rarefied ſhell of air, which ſurrounds the glaſs, attracts it. By the gradual retiring of the fluid in the ſurrounding air from the globe, the attraction of the deſerted matter will come nearer to equality with the repulſion of the conſtipated ſhell within the glaſs, and the globe will appear to have loſt fluid. Yet it may retain all the redundant fluid which it had at the firſt. Therefore we are not to imagine that a body ſimilar to this globe has no redundant electric fluid, or only a ſmall quantity, becauſe we obſerve it inactive, or nearly ſo.

100 Verified by the phenomena. Electric Well explained.

Thus we ſee, as we proceed, that the Æpinian theory is adequate to the explanation of the phenomena. But we ſee it much more remarkably in a very familiar and amuſing experiment, uſually called the ELECTRIC WELL. See ELECTRICITY, *Encycl.* Sect. x. 4.

To ſee it in perfection, make a glaſs veſſel of globular ſhape, with a narrow mouth, ſufficiently wide, however, to admit an electrometer ſuſpended to the end of a glaſs rod of a crooked form, ſo that the electrometer can be preſented to any part of the inſide. Smear the outſide of the globe with ſome tranſparent clammy fluid, ſuch as ſyrup. Set it on an inſulating ſtand (a wine glaſs), and electrify it poſitively. Hold the electrometer near it, anywhere without, and it will be ſtrongly affected. Its deviations from the perpendicular (if the ball of the electrometer has alſo been electrified) will indicate a force inverſely as the ſquare of the diſtance from the centre of the globe, pretty exactly, if the thread of the electrometer is of ſilk. Now let down the electrometer into the inſide of the globe. It will not be affected in any ſenſible degree, nor approach or avoid any body that is lying within the globe. The electrometer may be held in all parts of the globe, and when brought out again, is perfectly inactive and neutral. But if the balls of the electrometer be touched with a wire, while hanging free within the globe, they will, on withdrawing the wire, repel each other; and when taken out, they will be found negatively electrified.

fied. The experiment ſucceeds as well with a metal globe; nay, even although the mouth be pretty wide; in which caſe, there is not a perfect balance of action in every direction. The electrometer may be made to touch the bottom of the globe, or anywhere not too near the mouth, without acquiring any ſenſible electricity; but if we touch the outſide with the electrometer, it will inſtantly be electrified and ſtrongly repelled. Deep cylinders, and all round veſſels with narrow mouths, exhibit the ſame faintneſs of electricity within, except near the brims, although ſtrongly electric without; and even open metal cups have the interior electricity much diminiſhed.

101
Electric bodies are only ſuperficially ſo.

Reflecting on this valuable propoſition of Mr Cavendiſh, we ſee clearly why an overcharged electric is only ſuperficially ſo; and that this will be the caſe even although we attempt to accumulate a great quantity of electricity in it, by melting it in a thin glaſs globe, and electrifying it while liquid, and keeping up the accumulating force till it becomes quite cold. The preſent writer, not having conſidered the ſubject with that judicious accuracy that Mr Cavendiſh exerted, had hopes of producing a powerful and permanent electric in this way, and was mortified and puzzled by the diſappointment, till he ſaw his miſtake on reading Mr Cavendiſh's diſſertation.

Cautions in certain experiments.

Theſe obſervations alſo point out a thing which ſhould be attended to in our experiments for diſcovering the electricity excited in the ſpontaneous operations of nature, as in chemical compoſition and decompoſition, congelation, fuſion, evaporation, &c. It has been uſual to put the ſubſtances into glaſs, or other non-conducting veſſels, or into veſſels which conduct very imperfectly. In this laſt caſe eſpecially, the very faint electricity which is produced, inſtantly forms a compenſation to itſelf in the ſubſtance of the veſſel, and the apparatus becomes almoſt neutral, although there may have been a great deal of electricity excited. It will be proper to conſider, whether the nature of the experiment will admit of metalline veſſels. In the experiments on metalline ſolutions, the beſt method ſeems to be, to make the veſſel itſelf the ſubſtance that is to be diſſolved.

102
Electricity more nearly proportional to the ſurface than to the quantity of matter.

For ſimilar reaſons we may collect, without a more minute examination, that bodies of all ſhapes, when overcharged, will have the redundant fluid much denſer near the ſurface than in the interior parts; and denſer in all elevations, bumps, projections, angles, and near the ends of oblong bodies; and that, in general, the quantity of redundant fluid, or redundant matter, will be much more nearly proportional to the ſurfaces of bodies than to their quantities of matter. All this is fully proved by experience. The experiment of the electrified chain is a very beautiful one. Lay a long metal chain in an inſulated metal diſh furniſhed with an electrometer. Let one end be held an inch or two above the coil by a ſilk thread. Electrify the whole, and obſerve the divergency of the electrometer; then, gradually drawing up the chain from the coil, the electrometer will gradually fall lower, and lowering the chain again will gradually raiſe it.

103. We now ſee with how little reaſon Lord Mahon concluded that the point of his conductor, obſerved to be neutral, correſponded with his theory; namely, one of the media of a harmonic diviſion. We ſee no reaſon for beginning the computation at the extremity of the prime conductor. It certainly ſhould not have been from the extremity. Had the prime conductor been a ſingle globe, it ſhould have begun from the centre of this globe. If it was of the uſual form, with an outſtanding wire, terminated by a large ball, the action of the body of the conductor ſhould certainly have been taken into the account. In ſhort, almoſt any point of the long conductor might have been accommodated to his Lordſhip's theory.

104. We might now proceed to inveſtigate the diſtribution of the electric fluid in bodies expoſed to the action of others, and particularly in the oblong conductors made uſe of in our preparatory propoſitions. The problem is determinate, when the length and diameter of cylindric conductors are given; but even when the electric employed for inducing the electricity is in the form of a globe, we muſt employ functions of the diſtances that are pretty complex, and oblige us to have recourſe to ſecond fluxions. The mutual actions of two oblong conductors, of conſiderable diameters, give a problem that will occupy the firſt mathematicians; but which is quite improper for this ſcanty abſtract. Nor is a minute knowledge of the diſpoſition of the fluid of very important ſervice. We may therefore content ourſelves with a general repreſentation of the ſtate of the fluid in the following manner, which will give us a pretty diſtinct notion how it will act in moſt caſes:

General repreſentation of the diſpoſition of the fluid.

Let A (fig. 20.) be an overcharged ſphere, and BC a conducting cylindric or priſmatic body; draw $b\,c$ parallel to BC, and erect perpendiculars B b, C c, P p, &c. to repreſent the equable denſity of the fluid, when the conductor is in its natural ſtate; but let B d, C r, P s, &c. repreſent the unequal denſities in its different points, while in the vicinity of the overcharged ſphere. Theſe ordinates muſt be bounded by a line $d\,n\,r$, which will cut the line $b\,c$ in the point n of the perpendicular, drawn from the neutral point N of the conductor. The whole quantity of fluid in the conductor is repreſented by the parallelogram BC $c\,b$; which muſt therefore be equal to the ſpace BC $r\,n\,d$: the redundant fluid in any portion CP or PN is repreſented by the ſpaces $c\,r\,t\,p$, or $t\,p\,n$; and the redundant matter, or deficient fluid, in any portion BQ, is repreſented by $b\,d\,v\,q$. The action of this body on any body placed near it, depends entirely on the area contained between this curve line and its axis $b\,c$. The only circumſtance that we can aſcertain with reſpect to this curve is, that *the variations of curvature* in every point are proportional to the forces exerted by the ſphere A; and are therefore inverſely as the ſquares of the diſtances from A. This property will be demonſtrated by and bye. The place of n, and the magnitude of the ordinates, will vary as the diameter of the conductor varies. We ſhall conſider this a little more particularly in ſome caſes which will occur afterwards. We may conſider the ſimpleſt caſe that can occur; namely, when the conductor is, like a wire, of no ſenſible diameter, nay, as containing only one row of particles.

In a very ſlender canal the fluid muſt be almuſt equally diſtributed.

Let AE (fig. 21.) be ſuch a ſlender conducting canal; and let B b, C c, E e, &c. repreſent the denſity of the fluid which occupies it, being kept in this ſtate of inequable denſity by the repulſion for ſome overcharged body. A particle in C is impelled in the direction CE by all the fluid on the ſide of A, and in the

direction

direction CA by all the fluid on the ſide of E. The moving force, therefore, ariſes from the difference of theſe repulſions. When the diameter of the canal is conſtant, this ariſes only from the difference of denſity. The force of the element adjacent to E may therefore be expreſſed by the exceſs of D d above C c, and the action at the diſtance CD jointly. Therefore, drawing $\beta c \varepsilon$ parallel to AE, this force of the element E will be expreſſed by $\frac{d\delta}{c\delta^2}\dot{x}$, repelling the particle in the direction CA. If CF be taken equal to CD, the force of the element at F will be expreſſed by $\frac{f\varphi}{c\gamma^2}\dot{x}$, or $\frac{f\varphi}{c\delta^2}\dot{x}$, alſo impelling the particle in the direction CA. The joint action of theſe two elements therefore is $\frac{d\delta+f\varphi}{c\delta^2}\dot{x}$. If $b c e$ were a ſtraight line, we ſhould have $d\delta+f\varphi$ always proportional to $c\delta$; and it might be expreſſed by $m\times c\delta$; m being a number expreſſing what part of $c\delta$ the ſum of $d\delta$ and $f\varphi$ amounts to (perhaps $\frac{1}{10}$th, or $\frac{1}{20}$th, or $\frac{1}{30}$th, &c.). But in the caſe expreſſed in the figure, $d\delta$ does not increaſe ſo faſt as $c\delta$, and $f\varphi$ increaſes faſter than $c\delta$. However, in the immediate neighbourhood of any point C, we may expreſs the accelerating force tending towards A by $\frac{mc\delta}{c\delta^2}\dot{x}$, without any ſenſible error; that is, by $m\frac{\dot{x}}{x}$; that is, by the fluxion of the area of a hyberbola HD′G, having CC′ and CK for its aſſymptotes; and the whole action of the fluid between F and D, on the particle C, will be expreſſed by the area C′CDD′H. Hence it follows, that the action of the ſmalleſt conceivable portion of the canal immediately adjoining to C on both ſides, or the difference of the actions of the two adjoining elements, is equal to the action of all beyond it. This ſhews, that the ſtate of compreſſion is hardly affected by any thing that is at a ſenſible diſtance from C; and that the denſity of the fluid, in an indefinitely ſlender canal, is, to all ſenſe, uniform. The geometer will alſo ſee, that the ſecond fluxion of D d is proportional to the force of the diſtant body. We learn, therefore, ſo much of the nature of the curve $b c e$.—(*Coulomb*).

We are now in a condition to examine the communication of electricity by means of conducting canals (which is one of the moſt important articles of the ſtudy,) having found that the fluid, in a very ſlender canal, is very nearly of uniform denſity throughout.

106 Communication and transference by canals.

There can be no doubt but that, if a body B (fig. 22.) be overcharged or undercharged, any other body C, which communicates with it by a conducting canal, will alſo be overcharged or undercharged. It is as evident, that if a body, in any ſtate of electricity, be in the neighbourhood of an overcharged or undercharged body A, while it communicates with C by a canal leading from the ſide moſt remote from A, fluid will be driven from B into C, or abſtracted from C into B.

107 By crooked canals.

It is not, however, ſo clear, that when the canal leads from the ſide neareſt to A (as in fig. 23.), fluid will be driven from B into C. We conceive the fluid to be moveable in the body and in this canal, but not to eſcape from it. Its motion, therefore, in this caſe, ſhould, in the opinion of Mr Cavendiſh, reſemble the running of water in a ſyphon by the preſſure of the air. While the repulſion of the redundant fluid in A allows the bend of the ſyphon neareſt to A to retain fluid, a current ſhould take place from B along the ſhort leg, in conſequence of the ſuperior action on the fluid in the long leg. But if the repulſion of A can drive the fluid out of the bend between B and F, Mr Cavendiſh thinks, that it does not appear that fluid will come up from B in oppoſition to the repulſion of A, and then run along to D. But fluid does not move, in either of theſe caſes, on the principle of a ſyphon; becauſe there is nothing to hinder the fluid from expanding in the part EDF. And we are rather diſpoſed to think, that it will always move from B, over the bend, to C; For even if the fluid can be completely driven out of the bend EF, it muſt be done by degrees, and the fluid in the long leg will, from the very beginning of the action of A, be more moved from its place than that in the ſhort leg; and therefore will yield to the compreſſion, which acts tranſverſely, and, by thus yielding more toward F than toward E, the fluid will ruſh through the contracted part, and go into C. We do not ſay this with full confidence; but are thus particular, on account of an important uſe that may be made of the experiment. For if the body A be undercharged, fluid will certainly be attracted from C, and paſs over the bend into B, however great the action of A may be. Perhaps this may be ſo contrived, therefore, as to decide the long agitated queſtion, *Whether the electricity of excited glaſs be plus or minus?* If it be found that this apparatus, being preſented to the rubber of an electrical machine, diminiſhes the poſitive electricity of C, and increaſes that of B; but that, preſenting the ſame apparatus to the prime conductor, makes little change—we may conclude, that the electricity of the prime conductor is poſitive. We have tried the experiment, paying attention to every circumſtance that ſeemed likely to inſure ſucceſs; but we have always found hitherto, that the apparatus was equally affected by both electricities.

Propoſal for diſcovering redundancy of fluid.

We muſt now conſider the action of electrified bodies on the canals of communication; becauſe this will give us the eaſieſt method of aſcertaining the proportion in which the expelling fluid is diſtributed between them. For when two bodies communicate by a canal, and have attained a permanent ſtate, we muſt conceive that their oppoſite actions on the fluid moveable along this canal are in equilibrio, or are equal. This will generally be a much eaſier problem than their action on each other, ſince we have ſeen a little ago, that the fluid in a ſlender canal is of uniform denſity very nearly. A very few examples of the moſt important of the ſimple caſes muſt ſuffice.

108 Action of a plate on a rectilineal canal.

Therefore let AC a (fig. 24.) repreſent the edge of a thin conducting circular plate, to which the ſlender canal CP is perpendicular in the centre. It is required to determine the action of the matter or fluid, uniformly ſpread over this plate, on the fluid moveable in the canal PC?

109. 1. Required the action of a particle in A on the fluid in the whole canal? Join AP; and call CP x, AP y, and AC r; and let f expreſs the intenſity of action at the diſtance 1, or the unit of the ſcale on which the lines are meaſured.

The action of A on P, in the direction AP, is $\frac{f}{y^2}$. This,

This, when eſtimated in the direction CD, is reduced to $\frac{f}{y^2} \times \frac{x}{y}$; and is therefore $= f \frac{x}{y^3}$. Therefore the fluxion of the action, in the direction CP, on the whole canal, is $f \frac{x}{y^3} \dot{x} = f \frac{y \dot{y}}{y^3}$ (becauſe $x : y = \dot{y} : \dot{x}$) $= f \times \frac{\dot{y}}{y^2}$. The variable part of the fluent is $= f \frac{-1}{y}$, and the complete fluent is $= f \left(\mathrm{C} - \frac{1}{y} \right)$, where C is a conſtant quantity, accommodated to the nature of the caſe. Now, the action muſt vaniſh when the canal vaniſhes, or when $x = 0$, and $y = r$. Therefore $\mathrm{C} - \frac{1}{r} = 0$, and $\mathrm{C} = \frac{1}{r}$; and the general expreſſion of the action is $f \left(\frac{1}{r} - \frac{1}{y} \right), = f \frac{y - r}{ry}$, expreſſing the action of a particle in the circumference of the plate on the fluid in the whole canal CP.

2. Required the action of the plate, whoſe diameter is A a, on the particle P?

110 . On a ſin- le particle n the ca- al.

Let a repreſent the area of a circle, whoſe diameter is $= 1$. Then $a r^2$ is the area of the plate, and $2 a r \dot{r}$ is the fluxion of this area: becauſe $r : y = \dot{y} : \dot{r}$, $2 a r \dot{r}$ is $= 2 a y \dot{y}$. Therefore the fluxion of the action of the plate on the particle P is $f \times 2 a y \dot{y} \times \frac{x}{y^3} = 2 f a x \times \frac{\dot{y}}{y^2}$. The fluent of this has for its variable part $2 f a x \times \frac{-1}{y}$ (for when the particle P is given, x does not vary). This is $= 2 f a \times \frac{-x}{y}$. To complete this fluent, we muſt add a conſtant quantity, which ſhall make the fluent $= 0$ when the particle P is at an infinite diſtance; and therefore when $x = y$. Therefore $\frac{y}{y} - \frac{x}{y} = 0$, or $1 - \frac{x}{y} = 0$, or $\mathrm{C} = 1$; and the complete fluent for the whole plate is $2 f a \left(1 - \frac{x}{y} \right)$.

111. The meaning of this expreſſion may not occur to the reader: For $1 - \frac{x}{y}$ is evidently an abſtract number; ſo is a. Therefore the expreſſion appears to have no reference to the ſize of the plate. But this agrees with the obſervation in n° 91. where it was ſhewn that, provided the angle of the cone or pyramid remained the ſame, the magnitude of the baſe made no change in its attraction or repulſion for a particle in the vertex.

It will appear by and bye, that $1 - \frac{x}{y}$ is a meaſure or function of a certain angle of a cone.

Cor. If PC be very ſmall in proportion to AC, the action is nearly the ſame as if the plate were infinite: For when the plate is infinite, $\frac{x}{y}$ is $= 0$, and the action is $= 1$, whatever is the diſtance (ſee n° 91—93.) Therefore, when x is very ſmall in compariſon of r, and conſequently of y, $1 - \frac{x}{y}$ is very nearly $= 1$.

112 2. On the whole canal.

3. To find the action of the plate on the whole column?

The fluxion of this muſt be $= 2 f a \times \left(1 - \frac{x}{y} \right) \dot{x}$, or $2 f a \left(\dot{x} - \frac{x \dot{x}}{y} \right)$, or $2 f a \times (\dot{x} - \dot{y})$; becauſe $\dot{y} = \frac{x \dot{x}}{y}$. The fluent of this has for its variable part $2 f a \times (x - y)$. A conſtant quantity muſt be added, which ſhall make it $= 0$ when the column $= 0$; that is, when $y = r$, and $x = 0$; that is, $\mathrm{C} - r = 0$, and $\mathrm{C} = r$. Therefore the complete fluent is $= 2 f a \, (x + r - y$.

113 Geometrical expreſſion of theſe actions.

Thus we have arrived at a moſt ſimple expreſſion of the attraction or repulſion of a plate for ſuch a column, or for portions of ſuch a column. And it is moſt eaſily conſtructed geometrically, ſo as to give us a ſenſible image of this action of eaſy conception and remembrance. It is as follows: Produce PC till CK = CA, and about the centre P deſcribe the arch AI, cutting CK in I. Then $2 f a \times$ IK is evidently the geometrical expreſſion of the attraction or repulſion. This is plainly a cylinder, whoſe radius is a unit of the ſcale, and whoſe height is twice IK.

In like manner, by deſcribing the arch Ai round the centre p, we have $2 f a \times i$ K for the action of the plate on the ſmall column Cp; and $2 f a \times$ Ii is the action of the plate on the portion Pp.

The general meaning of the expreſſion $2 f a \times$ IK is, that the action of the whole plate on the column PC is the ſame as if all the fluid in the cylinder $a \times 2$ IK, were placed at the diſtance 1 from the acting particle.

From this propoſition may be eaſily deduced ſome very uſeful corollaries by the help of the geometrical conſtruction.

1. If PC be very great in compariſon with AC, the action is nearly the ſame as if the column were infinitely extended; for in this caſe IK is very nearly = CK, the difference being to the whole nearly as AC to twice AP. 114.

115 Important corollary.

2. If, in addition to this laſt condition, another column pC be very ſmall in compariſon of AC, then the action on PC is to that on pC very nearly as pC to AC. For it will appear that iK : IK = pC : AC very nearly. It is exactly ſo when CP : CA = CA : Cp; and it will always be in a greater proportion than that of pC to IK.

This will be found to be a very important obſervation.

The redundant fluid has hitherto been ſuppoſed to be uniformly ſpread over the plate: but this cannot be; becauſe its mutual repulſion will cauſe it to be denſer near the circumference. We have not determined, by a formula of eaſy application, what will be the variation of denſity. Therefore let us conſider the reſult of the extreme caſe, and ſuppoſe the whole redundant fluid to be crowded into the circumference of the plate, as we ſaw that it muſt be on the ſurface of a globe.

116 Action of a circumference on a canal.

In this caſe, the action on the fluid in the canal will be $f a \left(r - \frac{r^2}{y} \right)$. For the area of the plate is $a r^2$, and the action of a particle in the circumference on the whole canal was ſhewn (nº109.) to be $f\left(\frac{y-r}{ry}\right)$. Therefore the action of the whole fluid crowded into the circumference is $f\,a\,r^2\times\frac{y-r}{ry}, = f\,a\,r\frac{y-r}{y}$. It may be repreſented as follows: Deſcribe the quadrant CbBE, cutting AP and Ap in B and b. Draw BD and $b\,d$ parallel to PC. Then PB $= y-r$, and DC $= r\frac{y-r}{y}$. Therefore the action is repreſented by f multiplying a cylinder, whoſe radius is 1 and height is DC. In like manner, dC is the height of the cylinder correſponding to the column pC, and Dd the height correſponding to Pp.

117. *Cor.* 1. When CP is very great in compariſon with CA, the point D is very near to A, and I is very near to C, and CD is to IK nearly in the ratio of equality. In this caſe the action of the fluid, uniformly ſpread over the plate, is nearly double of the action of the ſame fluid crowded round the circumference; for they are as cylinders, having the ſame baſes and heights in the ratio of 2 IK to DC, which is nearly the ratio of 2 to 1.

118. 2. On the other hand, when the column pC is very ſhort, the action of the fluid ſpread uniformly over the plate is to its action, when crowded round the circumference, nearly in the ratio of 4 AC to pC. For theſe actions are in the ratio of $2fa\times i$K to $1fa\times d$C, or as 2 iK to dC, or nearly as 2 pC to dC, or more nearly as 2 $b\,d$ to dC. But Cd : $b\,d$ = $b\,d$: bA + Ad, or nearly = $b\,d$: 2 CA. Therefore Cd : 2$b\,d$ = pC : 4 CA nearly.

119. Hence we ſee that the action on ſhort columns is much more diminiſhed by the receſs of the redundant fluid toward the circumference than that on long columns. Therefore, any external electric force which tends to ſend fluid along this canal, and from thence to ſpread it over the plate, will ſend into the plate a greater quantity of fluid than if the fluid remained ultimately in a ſtate of uniform diſtribution over its ſurface; and that the odds will be greater when the canal is ſhort.

120 Equivalent centre of action.

Laſtly, on this ſubject. If KL be taken equal to AP, or PL be equal to KI, the repulſion which all the fluid in the plate, collected in K, would exert on the fluid in the canal CL, is equal to the repulſion which the ſame fluid, conſtipated in the circumference, would exert on the column CP. For we have ſeen that the action of a particle in A, on the whole column PC, when eſtimated in the direction PC, is $\frac{y-r}{yr}$; and it is well known that the action of a particle in K for the column CL is $\frac{1}{\text{KC}}-\frac{1}{\text{KL}}$, or $\frac{1}{r}-\frac{1}{y}, = \frac{y-r}{yr}$. Therefore the action of the whole fluid, collected in the circumference, on the column CP, is equal to that of the ſame fluid, collected in K, on the columns CL.

121. *Cor.* 1. If the column CP is very long in proportion to AC or KC, the actions of the fluids in theſe two different ſituations are very nearly the ſame. The action of the fluid collected in K exceeds its action when collected in A only by its action on the ſmall and remote column LP. The action of all the fluid collected at K on the column CP, is eaſily had by taking Cl = KP. It is equal to the action of the ſame fluid placed in A on the column Cl.

Cor. 2. The action of all the fluid uniformly ſpread, exerted on the column CP, is to the action of the ſame fluid collected in K, exerted on the column CL, as 2 IK to CD. 122.

123. If the column CP is very great in proportion to AC, the half breadth of the plate, the action in the firſt caſe is very nearly double of the action in the other caſe, and is exactly in this proportion if CP is of infinite extent.

124 Action of a ſpherical ſurface, or ſhell, or ſolid, on the ſame canal.

Cor. 3. If CNO be a ſpherical ſurface or ſhell of the ſame thickneſs and diameter as the plate Aa, and containing redundant fluid of the ſame uniform denſity, the action of this fluid on the column CL is double of the action of the fluid uniformly ſpread over the plate on the column CP, and quadruple of the action of the fluid collected in the circumference: for the action is the ſame as if all were collected in the centre K, and the ſurface of the ſphere is four times that of the plate, and therefore they are as IK to 2 CD.

Let us now conſider the comparative actions of different plates or ſpheres on the canals.

125 Action of two plates, or two ſpheres, are as their diameters, when the canals are infinitely long.

If two circular plates, DE, de (fig. 25.), or two ſpherical ſhells, ABO, $a\,b\,o$, of equal diameters and thickneſs with the plates, and containing redundant fluid of equal denſity, communicate with infinitely extended ſtraight canals OP, $o\,p$, paſſing through their centres perpendicular to their ſurfaces, alſo containing fluid uniformly diſtributed and of equal denſity—the repulſions will be as the diameters. For the repulſion of the ſpherical ſurfaces is the ſame as if all the fluid were collected at their centres; and the repulſion of the fluid uniformly ſpread over the ſurfaces of the plates is double of its repulſion if collected at the centres of theſe ſpheres; it follows, that the repulſions of the plates are proportional to thoſe of the ſpheres. But becauſe the repulſion of a plate whoſe radius is r was ſhewn to be $= 2a\times\overline{r+x-y}$, and when the column is infinitely extended, x is equal to y, and $\overline{r+x-y} = r$, it follows, that the repulſions of the plates are as $2a\times$R and $2a\times r$, or proportional to their diameters. Therefore the repulſions of the ſpheres are in the ſame proportion.

126. *Cor.* 1. If the canals are very long in proportion to the diameters of the plates or ſpheres, the repulſions are nearly in the ſame proportion.

127 The proportion of the greateſt action is diminiſhed if the canals are ſhort.

Cor. 2. But as the lengths of the canals diminiſh, the repulſions approach to equality; for it was ſhewn, that when the canal was very ſmall, the repulſion was to that for an infinite column as the length of the canal to the radius of the plate. Therefore if the radius of the greater plate be (for example) double of that of the ſmaller, and the little column be $\frac{1}{10}$th of the radius, it will be $\frac{1}{10}$th of the radius of the ſmaller plate. Now $\frac{1}{10}$th of half the repulſion is equal to $\frac{1}{10}$th of the double repulſion. Alſo, in the caſe of the ſpheres, the repulſion of a particle at the ſurface is as the quantity of fluid directly, and as the ſquare of the radius inverſely; but when the denſity is the ſame in both ſhells, the quantity is as the ſurface, or as the ſquare of the radius. Therefore the repulſions are equal.

Cor. 3. If the denſity of the fluid in two ſpherical ſhells be inverſely as the diameters, the repulſions for an

128
Actions of two ſpheres are equal if the denſity be inverſely as the diameters;

infinitely extended column of fluid are equal; for each repels as if all the fluid was collected in the centre. Therefore, if the denſity, and conſequently the quantity, be varied in any proportion, the repulſion will vary in the ſame proportion. The repulſions will now be as $CO \times \frac{1}{CO}$ to $co \times \frac{1}{co}$, or in the ratio of equality.

129
Or if the quantity of redundant fluid be as the diameters.

Cor. 4. When the quantities of redundant fluid in two ſpheres are proportional to their diameters, their repulſions for an infinitely extended canal are equal: for if this redundant fluid is conſtipated in the ſurfaces of the ſpheres, as it always will be when they conſiſt of conducting matter, the denſities are as the diameters inverſely, becauſe the ſurfaces are as the ſquares of the diameters. Therefore, by the laſt corollary their actions on an infinitely extended canal are equal. But in ſpheres of nonconducting matter it may be differently diſpoſed, in concentric ſhells of uniform denſity. This makes no change in the action on the fluid that is without the ſphere, becauſe each ſhell acts on it as if it were all collected in the centre. Therefore the repulſions are ſtill equal.

130
Two ſpheres overcharged in this proportion are in equilibrio if communicating by a very long canal.

Cor. 5. Two overcharged ſpheres, or ſpherical ſhells, OAB, *oab* (fig. 26.), communicating by an infinitely extended canal of conducting matter, contain quantities of redundant fluid proportional to their diameters; for their actions on the fluid in the interjacent canal muſt be in equilibrio, and therefore equal. This will be the caſe only when the quantities of fluid are in the proportion of their diameters.

When the canals are very long in proportion to the diameters of the ſpheres, the proportion of the quantities of redundant fluid will not greatly differ from that of the diameters.

131.

Cor. 6. When the ſpheres of conducting matter are thus in equilibrio, the preſſures of the fluid on their ſurfaces are inverſely as their diameters; for the repulſion of a particle at the ſurface is the ſame with the tendency of that particle from the centre of the ſphere, the actions being mutual. Now this is proportional to the quantity of redundant fluid directly, and to the ſquare of the diſtance from the centre inverſely, that is, to the diameter directly, and to the ſquare of the diameter inverſely, that is, to the diameter inverſely.

Tendency of the fluid to eſcape is inverſely as the diameter.

Hence it follows, that the tendency to eſcape from the ſpheres is inverſely as the diameter, all other circumſtances being the ſame: for in as far as the eſcape proceeds from mere electric repulſion, it muſt follow this proportion. But there are evident proofs of the co-operation of other phyſical cauſes. We obſerve chemical compoſitions and decompoſitions accompanying the eſcape of electric fluid, and its influx into bodies: we are ignorant how far, and in what manner, theſe operations are affected by diſtance. Boſcovich ſhews moſt convincingly, that the action of a particle (of whatever order of compoſition), on external atoms and particles, is ſurpriſingly changed by a change in the diſtance and arrangement of its component atoms. A conſtipation, therefore, to a certain determined degree and lineal magnitude, may be neceſſary for giving occaſion to ſome of thoſe chemical operations that accompany, and perhaps occaſion, the eſcape of the electric fluid. If this be the caſe (and it is *demonſtrable* to be poſſible, if the operations of Nature be owing to attractions and repulſions), the eſcape *muſt* be deſultory. It is actually ſo; and this confirms the opinion.

The public is indebted to Mr Cavendiſh for the preceding theorems on the action of ſpheres and circular plates. He has given them in a more abſtract and general form, applicable to any law of electric action which experience may warrant. We have accommodated them to the inverſe duplicate ratio of the diſtances, as a point ſufficiently eſtabliſhed; and we hope that we have rendered them more ſimple and perſpicuous. We have availed ourſelves of Mr Coulomb's demonſtration of the uniform denſity in the canal, without which the theorems could not have been demonſtrated. The minute quantity of the fluid in the canal can have no ſenſible effect on the diſpoſition or proportion of the fluid in the plates or ſpheres.

This propoſition agrees with hydroſtatical laws.

It may be thought that the laſt corollary, reſpecting the equilibrium of two ſpheres, is not agreeable to hydroſtatical principles, which require the equality of the two forces which balance each other at the orifices of the ſlender cylindric canal; whereas, in that corollary, the forces at the extremities of the canal are inverſely as the diameters of the ſpheres or plates. This would be a valid objection, if the compreſſing forces acted only on the extremities of the canals; but they act on every particle through their whole length. It is not, therefore, the preſſure at one end of the canal that is in equilibrio with the preſſure at the other end, by the interpoſition of the fluid. It is the preſſure at one end, together with the ſum of all the intermediate preſſures in that direction, that is in equilibrio with all the preſſure in the oppoſite direction. The preſſures at the ends are only parts of the whole oppoſite preſſures; they are the firſt in each account. In this manner a ſlender pipe, having a ball at each end, may be kept filled with mercury, while lying horizontal, if the air in each ball is of equal denſity. But if it be raiſed perpendicular to the horizon, it cannot remain filled from end to end, unleſs the air of the ball below be made ſo elaſtic by condenſation, that its preſſure on the lower orifice of the pipe exceed the preſſure of the air in the upper ball on the other orifice by a force equal to the weight of the mercury, that is, to the aggregate of the action of gravity on each particle of mercury in the pipe. Therefore the repulſions of the ſpheres that we are ſpeaking of are in equilibrio by the intervention of the fluid in the canal, in perfect conſiſtency with the laws of hydroſtatical preſſure.

Mr Cavendiſh has purſued this ſubject much farther, and has conſidered the mutual action of more than two bodies, communicating with each other by canals of moveable fluid uniformly denſe. But as we have not room for the whole of his valuable propoſitions, we ſelected thoſe which were elementary and leading theorems, or ſuch as will enable us to explain the moſt important phenomena. They are alſo ſuch, as that the attentive reader will find no difficulty in the inveſtigation of thoſe which we have omitted.

132
General propoſition with reſpect to the ſtate of communicating bodies.

Mr Cavendiſh's moſt general propoſition is as follows:

When an overcharged body communicates, by a canal of *very great* length, ſtraight or crooked, with two or more ſimilar bodies, alſo at a very great diſtance from each other, and all are in electric equilibrium, and conſequently each body overcharged in a certain determined proportion, depending on its magnitude, if any two of theſe bodies are made to communicate in the ſame manner, their degrees of electricity are ſuch, that no fluid will paſs from one to the other, their mutual actions on the fluid in this canal being alſo in equilibrio. He brings out this by induction and combination of the ſingle caſes, each of which he demonſtrates by means of the following theorem:

133 It is indifferent whether the canal be ſtraight or crooked.

The action of an overcharged ſphere ACB (fig. 25.) on the fluid in the whole of a canal df P that is oblique, tending to impel the fluids in the direction of that canal, is equal to its action on the fluid in the whole of the rectilineal canal CP. Let hi be a minute portion of the ſtraight canal, and fd the portion of the crooked canal which is equidiſtant from the centre C of the ſphere; draw the radii Cf, Cd, and the concentric arches hf, id, cutting fC in g; and draw ge perpendicular to fd; the force acting on ih, impelling it toward P, may be repreſented by hi. The ſame force acting on df, in the direction cf, muſt therefore be expreſſed by gf. This, when eſtimated in the direction of the canal df, is reduced to ef; but it is exerted on each particle of df. Now $df : gf = gf : ef$, and $df \times ef = gf^2, = gf \times hi$; therefore the whole force on df, in the direction df, is equal to the force on ih, in the direction ih. Hence the truth of the propoſition is manifeſt.

We beg the curious reader to apply this to the caſe in hand, and he will find that the moſt complicated caſes may all be reduced to the ſimple ones which we have demonſtrated to be ſtrictly true when the bodies are ſpheres or plates, and the canals infinitely long, and which are very nearly true when the canals are *very long*, and the bodies ſimilar: And we now proceed to one compound caſe more, which includes all the moſt remarkable phenomena of electricity.

134 Curious and very important caſe of four plates.

Let HK, AB, DF, and LM (fig. 27.), be four parallel and equal circular plates, two of which, HK and AB, communicate by a canal GC of indefinite extent, joining their centres, and perpendicular to their planes; let DF and LM be connected in the ſame manner, and let the two canals be in one ſtraight line; let the plate HK be overcharged, and the plate LM juſt ſaturated. It is required to determine the diſpoſition and proportion of the electric fluid in the plates which will make this condition of HK and LM poſſible and permanent, every thing being in equilibrio?

The plate HK being overcharged, and communicating with AB, AB muſt be overcharged in the ſame manner; and being alſo equal to HK, it muſt be overcharged in the ſame degree, containing an equal quantity of redundant fluid diſpoſed in the ſame manner. To ſimplify the inveſtigation, we ſhall firſt ſuppoſe that the redundant fluid is uniformly ſpread over the ſurfaces of both.

When the plates HK and AB are in this ſtate, let the plates DF and LM be brought near them, as is repreſented in the figure, CE being the diſtance of the centres of AB and DF. It is evident that the redundant fluid in AB will act on the natural moveable fluid in DF, and drive ſome of it along the canal EN, and render LM overcharged. Take off this redundant fluid in LM. This will diminiſh or annihilate the repulſion which it was beginning to exert on the canal EN; therefore more fluid will come out of DF, and again render LM overcharged. The redundant fluid in LM may again be taken off, in leſs quantity than before, as is plain. Do this repeatedly till no more can be taken off. But this will undoubtedly render DF undercharged, and it will now contain redundant matter. This will act on the fluid in the canal GC, and abſtract it from G; therefore fluid will come out of HK into AB. HK will be leſs overcharged than before, and AB will be more overcharged. But the now increaſed quantity of redundant fluid in AB will act more ſtrongly on the moveable fluid in DF, and drive more out of it. This will leave more redundant matter in it than before, and this will act as before on the fluid in the canal GC. This will go on, by repeatedly touching LM, till at laſt all is in equilibrio. Or this ultimate ſtate may be produced at once by allowing LM to communicate with the ground. And now, in this permanent ſtate of things, HK contains a certain quantity of redundant fluid; AB contains a greater quantity; DF contains redundant matter; and LM contains its natural quantity. The demand of the problem therefore is to determine the proportion of the redundant fluid in HK to that in AB, and the proportion of the redundant fluid in AB to the deficiency of fluid in DF. The dynamical conſiderations which determine theſe proportions are, *1ſt*, The repulſion of the redundant fluid in AB, for the fluid in the canal EN, muſt be preciſely equal to the attraction of the redundant matter in DF for the ſame fluid in the canal; for LM, being ſaturated, is neutral. *2d*, The repulſion of the redundant fluid in HK, for the whole fluid in the canal GC, muſt balance the exceſs of the repulſion of the redundant fluid in AB above the attraction of the redundant matter in DF for the ſame.

Let the redundant fluid in AB be $= f$.
the redundant matter in DF $= m$.
the redundant fluid in HK $= F$.

Becauſe HK and AB are equal, there can be no doubt but that the fluid in thoſe plates would be ſimilarly diſpoſed; and it is highly probable, that if AB be very near DF, the redundant fluid in AB, and the redundant matter in DF, will alſo be diſpoſed nearly in the ſame manner. This will appear plainly when we conſider with attention the forces acting between a very ſmall portion of AB and the correſponding portion of DF. The probability that this is the caſe is ſo evident, that we apprehend it unneceſſary to detail the proofs. We ſhall afterwards conſider ſome circumſtances which ſhew that the diſpoſition in the three plates will (though nearly ſimilar) be nearer to a ſtate of uniform diſtribution than if only AB and HK had been in action. Aſſuming therefore this ſimilarity of diſtribution, it follows, that their actions on the fluid in the canals will be ſimilar, and nearly proportional to their quantities.

Therefore let 1 be to n as the repulſion of the fluid in AB, for the fluid that would occupy CE, is to its repulſion for the fluid in EN or CG.

Then the action of AB on EN is $f \times \overline{n - 1}$, and the action of DF on EN is mn; therefore, becauſe the plate LM is inactive, the actions of AB and DF on EN muſt balance each other, and $f \times \overline{n - 1} = mn$, and $m = f \times \frac{n - 1}{n}$.

The

The repulſion of f for the fluid in CG is $f n$. The attraction of m for it is $m \times \overline{n-1}$; and becauſe $m = f \times \frac{n-1}{n}$, the attraction of m for the fluid in CG is $f \times \overline{\frac{n-1}{n}} \times \overline{n-1}$. Therefore the repulſion of f is to the attraction of m as $f n$ to $f \times \frac{\overline{n-1}^2}{n}$, or as $f n^2$ to $f \times \overline{n-1}^2$, or as n^2 to $\overline{n-1}^2$. Call the repulſion of f r, and the attraction of m a.

We have $r : a = n^2 : \overline{n-1}^2$

and $r : r - a = n^2 : n^2 - (n-1)^2 = n^2 : 2n - 1$.

Therefore, becauſe the repulſion of F is equal to this exceſs of r above a, we have $n^2 : 2n - 1 = f : \mathrm{F}$, and $\mathrm{F} = f\frac{2n-1}{n^2}$, or $f = \mathrm{F}\frac{n^2}{2n-1}$. Therefore, if n^2 is much greater than $2n - 1$, the quantity of redundant fluid in AB will be much greater than the quantity in HK.

135
Prodigious
ccumula-
ion of re-
dundant
luid;

Now, when the electric action is inverſely as the ſquare of the diſtance, and EC is very ſmall in compariſon with AC, we have ſeen (n° 115.) that $1 : n$ nearly $= \mathrm{CE} : \mathrm{CA}$, or that n is nearly $\frac{\mathrm{AC}}{\mathrm{EC}}$. When this is the caſe, and conſequently n is a conſiderable number, we may take the number $\frac{n^2}{2n}$ for $\frac{n^2}{2n-1}$ without any great error. In this caſe f is equal to $\mathrm{F} \times \frac{n}{2}$ very nearly. Suppoſe CA to be ſix inches, and CE to be $\frac{1}{20}$th of an inch; this will give $n = 120$, and $f = 60\,\mathrm{F}$; or, more exactly, $\mathrm{F} = \frac{n^2}{2n-1} = \frac{14{,}400}{239}$; $= 60\frac{1}{4}$. If, inſtead of the plate HK, we employ a globe of the ſame diameter, f will be but half of this quantity, or $f = \mathrm{F} \times \frac{n}{4}$ (n° 123, 124.)

136
And evacu-
ation:

It alſo appears, that when the plates AB and DF are very near to each other, and conſequently n a large number, the deficiency in DF is very nearly equal to the redundancy in AB. In the example now given, m is $\frac{59}{60}$ of f, being $= f \times \overline{n-1}$.

137
Yet no very
ſenſible ap-
pearance.

Yet this great deficiency in DF does not make it electrical on the ſide toward LM. It is juſt ſo much evacuated that a particle of fluid at its ſurface has no tendency to enter or to quit it.

Laſtly, this great quantity of fluid collected in AB does not render it more electrical than HK.

In general, things are in the condition treated of in n° 22, 23, &c.

The attentive reader will readily ſee, that this account of the apparatus of four plates is only an approximation to the condition that readily obtains under our obſervation. Our canals are not of indefinite length, nor occupied by fluid that is diſtributed with perfect uniformity; nor is the fluid uniformly ſpread over the ſurface of the plates. He will alſo ſee, that the real ſtate of things, as they occur in our experiments, tends to diminiſh the great diſproportion which this imaginary ſtatement determines. But when the canals are very long in compariſon with the diameters of the plates, and AB is very near to DF, the difference from this determination is inconſiderable. We ſhall note theſe differences when we conſider the remarkable phenomena that are explained by them.

In the mean time, we ſhall juſt mention ſome ſimple conſequences of the preſent combination of plates.

138
Method
of deſtroy-
ing this
great accu-
mulation:
1. By de-
grees;

Suppoſe AB touched by a body. Electric fluid will be communicated; but by no means all the redundant fluid contained in AB: only as much will quit it as will reduce it to a neutral ſtate, if the body which touches it communicates with the ground; that is, till the attraction in the redundant matter in DF attracts fluid on the remote ſide of AB as much as the redundant fluid left in AB repels it. When this has been done, DF is no longer neutral; for the repulſion of AB for the fluid in EN is now diminiſhed, and therefore the attraction of DF will prevail. If we now touch DF, it may again become neutral with reſpect to EN; but AB will now repel again the fluid in CG, and again be electric on that ſide by redundancy. Touching AB a ſecond time takes more fluid from it, and DF again becomes electric by deficiency, and attracts fluid on that ſide.—And thus, by repeatedly touching AB and DF alternately, the great accumulation of fluid in AB may be exhauſted, and the nearly equal deficiency in DF may be made up.

139
2. All at
once.

But this may be done in a much more expeditious way. Suppoſe a ſlender conducting canal $a\,b\,d$ brought very near to the outſides of the plates, the end a being near to A, and the end d to D. The vicinity of a to A cauſes the fluid in $a\,b$ to recede a little from a by the repulſion of the redundant fluid in AB. This will leave redundant matter in a, which will ſtrongly attract the redundant fluid from A, and a may receive a ſpark. But the conſequence, even of a nearer approach of the fluid to the outward ſurface of A, will render the correſponding part of DF more attractive, and the retiring of fluid from a along $a\,b$ will puſh ſome of its natural fluid toward d; and thus A becomes more diſpoſed to give out, and a to take it in, while d is diſpoſed to emit, and D to attract. Thus every circumſtance favours the paſſage of the whole, or almoſt the whole, redundant fluid to quit AB at A, to go along $a\,b\,d$, and to enter into DF at D.

140
The plates
ſtrongly at-
tract each
other.

It is plain that there muſt be a ſtrong tendency in the fluid in AB to go into DF, and that the plates muſt ſtrongly attract each other. A particle of fluid ſituated between them tends toward DF with a force, which is to the ſole repulſion of AB nearly as twice the redundant fluid in it to what it would contain if electrified to the ſame degree while ſtanding alone.

With this particular and remarkable caſe of induced electricity, we ſhall conclude our explanation of Mr Æpinus's Theory of Electric Attraction and Rupulſion. The reader will recollect, that we began the conſideration of the diſpoſition of the electric fluid in bodies, in order to deduce ſuch legitimate conſequences of the hypothetical law of action as we could compare with the phenomena.

141
Method of
examining
the validity
of this the-
ory.

Theſe compariſons are abundantly ſupplied by the preceding paragraphs, particularly by n° 74, 75, 76; by n° 130, and by n° 134.

Let a ſmooth metal ſphere be electrified poſitively in any manner whatever, and then touch it with a ſmall one in its natural ſtate. The redundant fluid is divided between them in a proportion which the theory determines with accuracy. By the theory alſo the redundant fluid in both acts as if collected in the centre. Therefore the proportion of the repulſions is determined. Theſe can be examined by our electrometer. But as this menſuration may be ſaid to depend on the truth of the theory, we may examine this independent of it Let the balls be equal. Then the redundant fluid is divided equally between the bodies, whatever be the law of action. Therefore obſerve the electrometer, as it is affected by the electrified body, both before and after the communication. This will give the poſitions of the electrometer which correſpond to the quantities 2 and 1.

142 Graduation of electrometer. Take off the electricity of one of the balls by touching it, and then touch the other ball with it. This will reduce to $\frac{1}{2}$ the original quantity $\frac{1}{2}$, and therefore to $\frac{1}{4}$th of the original quantity. This will determine the value of another poſition of the electrometer. In like manner, we obtain $\frac{1}{8}$th, $\frac{1}{16}$th, &c. &c. Then, by touching a ball containing 1 with a ball containing $\frac{1}{2}$, we get a poſition for $\frac{3}{1}$, $\frac{3}{2}$, $\frac{3}{8}$, &c. Proceeding in this way, we graduate our electrometer independently of all theory, and can now examine the electricity of bodies with confidence. The writer of this article took this method of examining his electrometer, not having then ſeen Mr Cavendiſh's diſſertation, which gives another mode of meaſurement. He had the ſatisfaction of obſerving, in the firſt place, that the poſitions of the inſtrument, which unqueſtionably indicated 1, $\frac{1}{2}$, $\frac{1}{4}$, &c. were preciſely thoſe which ſhould indicate them if electric repulſion be inverſely as the ſquares of the diſtances. Having thus examined the electrometer, it was eaſy to give to balls any propoſed degree of electricity, and then make a communication between balls of very different diameters. The electrometer informed us when the repeated abſtractions by a ſmall ball reduced the electricity of a large ball to $\frac{1}{2}$, $\frac{1}{4}$, &c. This ſhewed the proportion of electricity contained in balls of different diameters. This was alſo found to be ſuch as reſulted from an action in the inverſe duplicate ratio of the diſtances.

143. Long after this, Mr Cavendiſh's inveſtigation pointed out the proportion of the redundant electric fluid in balls of different ſizes joined by long wires; in n° 130, &c. theſe were examined—and found to be ſuch as were ſo indicated by the electrometer.

144. And, laſtly, the mode of accumulating great quantities of fluid by means of parallel plates, gave a third way of confronting the hypothetical law with experiment. The argument was no leſs ſatisfactory in this caſe; but the examination required attention to particulars not yet mentioned, which made the proportions between the fluid in HK and AB (fig 27.) widely different from thoſe mentioned in the preceding paragraphs. Theſe circumſtances are among the moſt curious and important in the whole ſtudy, and will be conſidered in their place.

145 The law of electric action is well determined. We reſt therefore with confidence on the truth of the law of electric action, aſſumed by us as a principle of explanation and inveſtigation. It is quite needleſs and unprofitable to give any detail of the numerous experiments in which we confronted it with the phenomena. The ſcrupulous reader will get ample ſatisfaction from the excellent experiments of Mr Coulomb with his delicate electrometer. He will find them in the Memoirs of the Academy of Sciences of Paris for 1784, 1785, 1786, and 1787. Some of them are of the ſame kind with thoſe employed by the writer of this article; others are of a different kind; and many are directed to another object, extremely curious and important in this ſtudy, namely, to diſcover how the electric fluid is diſpoſed in bodies; and a third ſet are directed to an examination of the manner in which the electric fluid is diſſipated along imperfect conductors.

But we have already drawn this article to a great length, and muſt bring it to an end, by explaining ſome very remarkable phenomena, namely, the operation of the Leyden phial, the operation of the electrophorus, and the diſſipation of electricity by ſharp points and by imperfect conductors.

146 Of the Leyden phial. The obſervations of Mr Watſon on the neceſſity of connecting the rubber of an electrical machine with the ground, might have ſuggeſted to philoſophers the doctrine of *plus* and *minus* electricity, eſpecially after the valuable diſcoveries of Mr Symmer and Cigna. A ſerious conſideration of theſe general facts would have led to the theory of coated glaſs almoſt at its firſt appearance. But the hiſtorical fact was otherwiſe; and a conſiderable time elapſed betwen the firſt experiments with charged glaſs by Kleiſt, and the clear and ſatisfactory account given by Dr Franklin, of all the eſſential parts of the apparatus, and the probable procedure of nature in the phenomenon. The impermeability of glaſs by the electric fluid, and the conſequent abſtraction of it from the one ſide while it was accumulated on the other, ſuggeſted to his acute mind the leading principle of electrical philoſophy; namely, that all the phenomena ariſe from the redundancy or deficiency of electric fluid, and that a certain quantity of it reſides naturally in all bodies in a ſtate of uniform diſtribution, and, in this ſtate, produces no ſenſible effect. This was, in his hands, the inlet to the whole ſcience; and the greateſt part of what has been ſince added is a more diſtinct explanation how the redundancy or deficiency of electric fluid produces the obſerved phenomena. Dr Franklin deduced this leading principle from obſerving, that as faſt as one ſide of a glaſs plate was electrified poſitively, the other ſide appeared negative, and that, unleſs the electricity of that ſide was communicated to other bodies, the other ſide could be no farther electrified. Having formed this opinion, the old obſervations of Watſon, Symmer, and Cigna, were explained at once, and the explanation of the Leyden phial would have come in courſe. It is for theſe reaſons, as much as for the important diſcovery of the ſameneſs of electricity and of thunder, that Dr Franklin ſtands ſo high in the rank of philoſophers, and is juſtly conſidered as the author of this department of natural ſcience. Whatever credit may be due to the chemical ſpeculations of De Luc, Wilcke, Winkler, and many others, who have attempted to aſſociate electricity with other operations of nature, by reſolving the electric fluid into its conſtituent parts, all their explanations preſuppoſe a mathematical and mechanical doctrine concerning the mode of action of the ingredients, which will either account for the total inactivity of the compound, or which will explain, in the very ſame manner, the action of the compound itſelf: yet all ſeem to

to content themſelves with a vague and indiſtinct notion of this preliminary ſtep, and have allowed themſelves to ſpeak of electrical atmoſpheres, and ſpheres of activity, and ſuch other creatures of the mind, without once taking the trouble of conſidering whether thoſe aſſumptions afforded any real explanation. How different was Newton's conduct. When he diſcovered that the planets attracted each other in the inverſe duplicate ratio of the diſtances, and that terreſtrial gravity was an inſtance of the ſame force, and that *therefore* the deflection of the earth was the effect of the accumulated weight of all its parts; he did not raſhly affirm this of the planets, till he examined what would be the effect of the accumulated attraction in the abovementioned proportion.

147. Mr Æpinus has the honour of firſt treading in the ſteps of our illuſtrious countryman; and he has done it with ſingular ſucceſs in the explanation of the phenomena of attraction and repulſion, as we have already ſeen. In no part of the ſtudy has his ſucceſs been ſo conſpicuous as in the explanation of the curious and important phenomena of the Leyden phial. It only remained for him to account for the accumulation of ſuch a prodigious quantity of this agent as was competent to the production of effects which ſeemed to exceed the ſimilar effects in other caſes, out of all proportion. Indeed, the diſproportion is ſo great, as to make them appear to be of a different and incomparable nature. Dr Wilſon's experiments in the pantheon are therefore precious, by ſhewing that nothing was wanted for the production of all the effects of the Leyden phial but a ſurface ſufficiently extenſive for containing a vaſt quantity of fluid, and ſo perfectly conducting as to admit of its ſimultaneous and rapid transference. Therefore we aſſert that one of the chief merits of Mr Æpinus's theory is the ſatisfactory explanation of the accumulation of this vaſt quantity of fluid in a ſmall ſpace. We truſt, therefore, that our readers will peruſe it with pleaſure. But we muſt here obſerve, that Mr Æpinus has not expreſsly done this in his work which we have already made ſo much uſe of, nor in any other that we know of. He has gone no farther than to point out to the mathematicians, that his hypotheſis is adequate to the accounting for any degree of accumulation whatever. This he does in that part of his work which contains the formulæ of n° 38, 39, 40, 41, &c. And he afterwards ſhews, that all the phenomena of attraction and repulſion which are obſerved in the charged jar are preciſely ſuch as are neceſſary conſequences of his theory.

148 Theory of charged glaſs completed by Mr Cavendiſh.

It is to the Hon. Mr Cavendiſh that we are indebted for the ſatisfactory, the complete (and we may call it *the popular*), explanation of all the phenomena. Forming to himſelf the ſame notion of the mechanical properties of the electric fluid with Mr Æpinus, he examined, with the patience, and much of the addreſs, of a Newton, the action of ſuch a fluid on the fluid around it, and the ſenſible effects on the bodies in which it reſided; the diſpoſition of it in a conſiderable variety of caſes; and particularly its action on the fluid contained in ſlender canals and in parallel plates;—till he arrived at a ſituation of things ſimilar to the Leyden phial. And he then pointed out the preciſe degree of accumulation that was attainable, on different ſuppoſitions concerning the law of electric action in general. We have given an abſtract of this inveſtigation accommodated to the inverſe duplicate ratio of the diſtances.

149. From this it appears (n° 135), that whatever quantity of electric fluid we can put into a circular plate 12 inches in diameter, by ſimple communication with the prime conductor of an electrical machine, we can accumulate 60 times as much in it by bringing the plate within $\frac{1}{10}$th of an inch of another equal plate which communicates with the ground; and it appears in n° 139, that all this accumulated fluid may be transferred in an inſtant to the other plate (which is ſhewn to be almoſt equally deprived of fluid), by connecting the two plates by a ſmall wire.

But as it was alſo ſhewn in that paragraph, that the force with which the accumulated fluid was attracted by the redundant matter in the other plate was exceedingly great, and conſequently its tendency to eſcape was proportionably increaſed; this accumulation cannot be obtained unleſs we can prevent this ſpontaneous transference.

150 Inexplicable by material atmoſpheres.

Here the non-conducting power of idio-electrics, without any diminution, the action of the electric fluid on fluid or matter on the other ſide of them, comes to our aid, and we at once think of interpoſing a plate of glaſs, or wax, or roſin, or any other electric, between our conducting plates. Such is the immediate ſuggeſtion of a perſon's mind who entertains the Æpinian notion of the electric fluid; and ſuch, we are convinced, is the thought of all who imagine that they underſtand the phenomena of the Leyden phial. But thoſe who attempt to explain electric action by means of what they call electric atmoſphere of variable denſity or intenſity, are not intitled to make any ſuch inference, nor to expect any ſuch phenomena as the Leyden phial exhibits. Electricity, they ſay, acts by the intervention of atmoſpheres: Therefore, whatever allows the propagation of this action (conceive it in any manner whatever), allows the propagation of theſe agents; and whatever does not conduct electric action, does not conduct the agents. Interpoſed glaſs ſhould therefore prevent all action on the other plate. This is true, even although it were poſſible (which we think it is not) to form a clear notion of the free paſſage of this material atmoſphere in an inſtant, and this without any diminution of its quantity, and conſequently of its action, by the diſplacement of ſo much of it by the ſolid matter of the body which it penetrates. Yet without this undiminiſhed action of the electrified plate on the fluid, and on the matter, beyond the glaſs, and on the canal by which its fluid may be driven off into the general maſs—no ſuch accumulation can take place; and if the phenomena of the Leyden phial are agreeable to the reſults of the Æpinian hypotheſis, all explanation by atmoſpheres muſt be abandoned. Indeed when the partiſans of the atmoſpheres attempt to explain their conceptions of them, they do not appear to differ from what are called *ſpheres of activity* (a phraſe firſt uſed by Dr Gilbert of Colcheſter, in his celebrated work *De Magnete et Corporibus Magneticis*): and ſpheres of activity will be found nothing more than a figurative expreſſion of ſome indiſtinct conception of *action in every direction*. When we uſe the words *attraction* and *repulſion*, we do not ſpeak a whit more figuratively than when we uſe the general word *action*. Theſe terms are all figurative, only *attraction* and *repulſion* have the advantage

vantage of ſpecifying the *direction* in which we conceive the *action* to be exerted.

It therefore becomes ſtill more intereſting to the philoſopher to compare the phenomena of CHARGED GLASS with the Æpinian theory. They afford an *experimentum crucis* in the queſtion about electric atmoſpheres.

151 Phenomena of charged glaſs explained.

Let G (fig. 28.) repreſent the end of a prime conductor, furniſhed with Henley's electrometer. Let AB repreſent a round plate of tinfoil, paſted on a pane of glaſs which exceeds the tinfoil about two inches all round. The pane is fixed in a wooden foot, that it may ſtand upright, and be ſhifted to any diſtance from the conductor. DF repreſents another plate of the ſame dimenſions as AB, in the centre of which is a wire EN, having a ſmall ball on the end N, to which is attached a Canton's electrometer. This wire paſſes through the wooden ball O, faſtened to the inſulating ſtand P. The glaſs pane muſt be very clean, dry, and warm. Connect the conductor G with AB by a wire reaching to the centre C. Turn the cylinder of the electrical machine ſlowly, till the electrometer riſe to 30° or 40°, and note the number of turns. Take off the electricity; and having taken away the connecting wire GC, turn the machine again till the electrometer riſe to the ſame height. The difference in the number of turns will give ſome notion of the expenditure of fluid neceſſary for electrifying the plate of tinfoil alone. This will be found to be very trifling when the electricity is in ſo moderate a degree. It is proper, however, to keep to this moderate degree of electrification, becauſe when it is much higher, the diſſipation from the edges of the plate is very great. Replace the wire, and again raiſe the electrometer to 30°. Now bring forward the plate DF, keeping it duly oppoſite and parallel to AB, and taking care not to touch it. It will produce no ſenſible change on the poſition of the electrometer till it come within four or three inches of the glaſs pane; and even when we bring it much nearer (if a ſpark do not fly from the glaſs pane to DF), the electrometer HG will ſink but two or three degrees, and the electrometer at N will be little affected. Now remove the plate DF again to the diſtance of two or three feet, and attach to its ball N a bit of chain, or ſilver or gold thread, which will trail on the table. Again, raiſe the electrometer to 30°, and bring DF gradually forward to AB. The electrometer HG will gradually fall down, but will riſe to its former height, if DF be withdrawn to its firſt ſituation. It is ſcarcely neceſſary to ſhew the conformity of this to the theory contained in n° 134, 135, &c. As the plate DF approaches, the redundant fluid in AB acts on the fluid in DF, and drives it to the remote end of the wire EN, as was ſhewn by the divergency of the balls at N; and then an accumulation begins in AB, and the electrometer HG falls in the ſame manner as if part of the fluid in the prime conductor were communicated to AB. When DF communicates with the ground, the electrometer at N cannot ſhew any electricity, but much more fluid is now driven out of DF, in proportion as it is brought nearer to AB. Inſtead of connecting AB immediately with the prime conductor, let the wire GC have a plate at the end G, of the ſame dimenſions as AB, having an electrometer attached to the ſide next to AB. Let this apparatus of two plates be electrified anyhow, and note the divergency of the electrometer at H, before DF, communicating with the ground, is brought near it, and then attend to the changes. We ſhall find the divergency of this electrometer correſpond with the diſtance of DF very nearly as the theory requires.

152 State of the coatings.

While the plates AB and DF are near each other, eſpecially when DF communicates with the ground, if we hang a pith-ball between them by a ſilk thread, it will be ſtrongly attracted by the plate which is neareſt to it, whether DF or AB; and having touched it, it will be briſkly repelled, and attracted by the glaſs pane, which will repel it after contact, to be again attracted and repelled by DF; and thus bandied between the plates till all electricity diſappear in both, the electrometer attached to H deſcending gradually all the while.

153. As all theſe phenomena are more remarkable in proportion as the plates are brought nearer, they are moſt of all when DF is applied cloſe to the glaſs pane. And if, in this ſituation, we take any accurate method for meaſuring the intenſity of the electricity in the plate HG, before the approach of DF, we ſhall find the diminution, occaſioned by its coming into full contact with the pane, conſiderably greater than what is pointed out in n° 135. When we employed plates of 12 inches diameter, paſted on a pane one fortieth of an inch in thickneſs, we found the diminution not leſs than 199 parts of 200; and we found that it required at leaſt 200 times the revolution of the cylinder to raiſe the electrometer to the ſame height as before. This compariſon is not ſuſceptible of great accuracy, by reaſon of many circumſtances, which will occur to an electrician. But in all the trials we have made, we are certain that the accumulation greatly exceeded that pointed out by the Æpinian theory as improved by Mr Cavendiſh. And we muſt here obſerve, that we found this ſuperiority more remarkable in ſome kinds of glaſs than others, and more remarkable in ſome other idioelectrics. We think that, in general, it was moſt remarkable in the coarſe kinds of glaſs, provided they were uniformly tranſparent. We found it moſt remarkable in ſome common glaſs which had exfoliated greatly by the weather; but we alſo found that ſuch glaſſes were very apt to be burſt by the charge. The hardeſt and beſt London crown-glaſs ſeemed to accumulate leſs than any other; and a coloured glaſs, which when viewed by reflection ſeemed quite opake, but appeared brown by tranſmitted light, admitted an accumulation *greatly* exceeding all that we have tried; but it could not be charged much higher without the certainty of being burſt. This diverſity in the accumulation, which may be made in different kinds of glaſs, hinders us from comparing the *abſolute* accumulations aſſigned by the theory with thoſe which experiment gives us. But though we cannot make this compariſon, we can make others which are equally ſatisfactory. We can diſcover what proportion there is between the accumulation in glaſs of the ſame kind, as it may differ in thickneſs and in extent of ſurface. Uſing mirror glaſs, which is of uniform and meaſurable thickneſs, and very flat plates, which come into accurate or equable contact—we found that the accumulation is inverſely as the thickneſs of the plates; but with this exception, that when two plates were uſed inſtead of a plate of double thickneſs, the diminution by the increaſe of thickneſs was not nearly in the proportion of this increaſe. Inſtead

ſtead of being reduced to one half, it was more than two-thirds; and in the kind called Dutch plate, the diminution was inconſiderable.

154
rong at-
action be-
ween
em.

The experiments with the Dutch and other double plates, ſuggeſted another inſtructive and pretty experiment. Obſerving theſe plates to cohere with conſiderable force, it was thought worth while to meaſure it; which was attempted in this manner: Two very flat braſs plates AB, DF (fig. 29.) furniſhed with wires and balls, were ſuſpended. about three inches aſunder, by ſilk threads, as repreſented in the figure. At G was attached a very fine ſilver wire, which hung very looſe between it and the prime conductor, without coming near the table. Another was attached to N, which touched the table. A plate of mirror glaſs was ſet between them, as ſhewn by QR. When this apparatus was electrified, the threads of ſuſpenſion immediately began to deviate from the perpendicular, and the plates to approach the glaſs pane and each other. The pane was carefully ſhifted, ſo as to be kept in the exact middle between them. This reſult ſhewed very plainly the preſſure of the fluid on one of the plates, and the mutual attraction of the redundant matter and redundant fluid. This increaſed as the accumulation increaſed; and it was attempted to compare the attraction with the accumulation, by comparing the deviation of the ſuſpending threads with that of the electrometer attached to the prime conductor; but we could not reconcile the ſeries (which, however, was extremely regular) with the law of electric action. This harmony was probably diſturbed by the force employed in raiſing the ſilver wires. When more flexible ſilver threads were uſed, much was loſt by diſſipation from the roughneſs of the thread. We did not think of employing a fine flaxen thread moiſtened: but, indeed, an agreement was hardly to be expected; becauſe theory teaches us, that the diſtribution of the redundant fluid in AB will be extremely different from the diſtribution of the redundant matter in DF, till the plates come very near each other. The accumulation in AB depends greatly on the law of diſtribution, being leſs (with any degree of redundancy) when the fluid is denſer near the centre of the plate. Other circumſtances concurred to diſturb this trial; but the theory was abundantly confirmed by the experiment, which ſhewed the ſtrong attraction ariſing from the accumulation. This was ſo great, that although the plates were only three inches in diameter, and the glaſs pane was $\frac{1}{12}$ of an inch thick, and the threads deviated about 18 degrees from the perpendicular—it required above an ounce weight, hung on the wire EN, to ſeparate the plates from the glaſs.

155
)iſcharge;
ow it is
ffected.

The experienced electrician need not be told, that by bringing the two ends of a bent wire in contact with the two plates (firſt touching DF with it) diſcharges the apparatus, and cauſes the plates to drop off from the pane. But he may farther obſerve, that if there be attached to each end of the diſcharging wire a downy feather, and if he firſt bring the end near the plate DF, and obſerve the feather to be not at all, or but a very little, affected, and if he then bend round the other end toward the plate AB, *both feathers* will immediately ſtretch out their fibres to the plates, and cling faſt to them, long before the diſcharging ſpark is ſeen. This is a fine proof of the proceſs of diſcharge, which begins by the induction of electricity on the ends of the diſcharging wire; firſt, negative electricity on the end that approaches A, and, in the ſame inſtant, oppoſite electricities at D and the adjoining end of the wire.

156
Beautiful and inſtructive experiment by Profeſſor Richmann.

The following obſervation of Profeſſor Richmann of St Peterſburgh (the gentleman who fell a ſacrifice to electrical ſtudies by a thunder ſtroke from his apparatus) is extremely inſtructive and amuſing. Let a glaſs pane be coated on both ſides, and furniſhed with a ſmall electrometer attached to the coatings. It is repreſented as if ſeen edgewiſe in fig. 30. Let it be charged poſitively (that is, by redundancy) by the coating AB, while DF communicates with the ground. The electrometer A a will ſtand out from the plate, and D d will hang down cloſe by its coating, as long as DF communicates with the ground. But as the electricity gradually diſſipates by communication to the contiguous air, the ball a will gradually, but very ſlowly, fall down. We may judge of the intenſity of the remaining electricity by the deviation of the electrometer, and we may conceive this deviation divided into degrees, indicating not angles, but intenſities, which we conceive as proportional to the redundancy or deficiency which occaſion them.

If we take away the communication with the ground, we ſhall obſerve the ball a fall down very ſpeedily, and then more ſlowly, till it reach about half of its firſt elevation. The ball d will at the ſame time riſe to nearly the ſame height; the angle between the two electrometers continuing nearly the ſame as at firſt. When a has ceaſed to riſe, both balls will very ſlowly deſcend, till the charge is loſt by diſſipation. If we touch DF during this deſcent, d will immediately fall down, and a will as ſuddenly riſe nearly as much; the angle between the electrometers continuing nearly the ſame. Remove the finger from DF, and a will fall, and d will riſe, to nearly their former places; and the ſlow deſcent of both will again continue. The ſame thing will happen if we touch AB; a will fall down cloſe to the plate, and d will riſe, &c. And this alternate touching of the coatings may be repeated ſome hundreds of times before the plate be diſcharged. If we ſuſpend a crooked wire $v\ m\ u$, having two pith balls v and u from an inſulated point m above the plate, it will vibrate with great rapidity, the balls ſtriking the coatings alternately; and thus reſtoring the equilibrium by ſteps. Each ſtroke is accompanied by a ſpark.

Theory of it.

All theſe phenomena are not only conſequences of the theory, but their meaſures agree preciſely with the computations deduced from the formulæ in nº 22, 23, 24, accommodated to the caſe by means of nº 135 and 136, as we have verified by repeated trials. But it would occupy much room to trace the agreement here, and would fatigue ſuch readers as are not familiarly converſant with fluxionary calculations. The inquiſitive reader will get full conviction by peruſing Epinus's Eſſay, Appendix i. A very diſtinct notion may be conceived of the whole proceſs, by ſuppoſing that in a minute AB loſes $\frac{1}{10}$th of the unbalanced redundancy actually in it, and conſequently diminiſhes as much in its action. It will be proved afterwards, that the diſſipations in equal times are really in proportion to the ſuperficial repulſions then exerted. We may alſo ſuppoſe, that the action of the redundant fluid, or redundant matter, in either coating, on the external fluid contiguous to it, is to its action on the fluid contiguous to the

the other coating in the conſtant proportion of 10 to 9. We ſelect this proportion for the ſimplicity of the computation. Then the difference of theſe actions is always $\frac{1}{10}$th of the full action on the fluid contiguous to it. This is alſo an exact ſuppoſition in ſome particular caſe, depending on the breadth of the coating and the thickneſs of the pane.

Now, let the primitive unbalanced repulſion between AB and the contiguous fluid of the electrometer be 100, while DF communicates with the ground. The ball *a* will ſtand at 100; the ball *d* will hang touching DF. Then *a*, by loſing $\frac{1}{10}$th, retains only 90, and would ſink to 90°: But as this deſtroys the equilibrium on the other ſide, fluid will enter into DF, ſo as to reduce the deficiency $\frac{1}{10}$th. Therefore nine degrees of fluid will enter; and its action on *a* will be the ſame as if $\frac{9}{10}$ths of 9, or 8,1 had been reſtored to AB. Therefore *a* will riſe from 90 to 98,1; or it will ſink in one minute from 100 to 98,1.

But if we have cut off the communication of DF with the ground, this quantity of fluid cannot come into DF; and the quantity which really comes into it from the air will be to that which eſcapes from A as the attraction on the ſide of DF to the repulſion on the ſide of AB. By the diminution of the repulſion $\frac{1}{10}$th, and the want of 9 degrees of fluid in DF to balance it, DF acquires an attraction for fluid which may be called 9. Therefore, ſince $\frac{1}{10}$th of the primitive repulſion of AB has diſſipated 10 meaſures of fluid in the minute, the attraction of DF will cauſe it to acquire $\frac{1}{10}$th of 9, or 0,9, from the air in the ſame minute. At the end of the minute, therefore, there remains an unbalanced attraction for fluid = 8,1; and conſequently an unbalanced repulſion between the redundant matter in DF, and that in the ball *d*. Therefore *d* will riſe to 8,1. But *a* cannot now be at 98,1; becauſe DF has not acquired 9 meaſures of fluid, but only $\frac{9}{10}$ths of one meaſure. Therefore *a*, inſtead of riſing from 90 to 98,1, will only riſe to 90 + $\frac{9}{10}$ths × $\frac{9}{10}$ths; that is, to 90,81.

At the cloſe of the minute, therefore, *a* is at 90,81, and *d* is at 8,1, and their diſtance is 98,91. In the next minute, AB will loſe $\frac{1}{10}$th of the remaining unbalanced electricity of that ſide, and DF will now acquire a greater proportion than before; becauſe its former unbalanced attraction gets an addition equal to $\frac{9}{10}$ths of the loſs of AB. This will make a larger compenſation in the action on *a*, and *a* will not fall ſo much as before. And becauſe in the ſucceeding minutes the attraction of DF for fluid is increaſing, and the repulſion of AB is diminiſhing, the compenſation in the action on *a*, by the increaſed attraction of DF, continues to increaſe, and the deſcent of *a* grows continually ſlower; conſequently a time muſt come, when the repulſion of AB for fluid is to the attraction of DF for it, nearly in the proportion of 10 to 9. When this ſtate obtains, *d* will riſe no more; becauſe the receipt of fluid by DF, being now $\frac{9}{10}$ths of the loſs by AB, it will exactly compenſate the additional attraction of DF for fluid, occaſioned by that loſs. The next loſs by AB not being ſo great, and the next receipt by DF continuing the ſame, by reaſon of its undiminiſhed attraction, there will be a greater compenſation in the action on *a*, which will prevent its deſcending ſo faſt; and there will be more than a compenſation for the additional attraction of DF for fluid: that is, the fluid which has now come into DF will render it, and alſo the ball *d*, leſs negative than before; and therefore they will not repel ſo ſtrongly. Therefore *d* muſt now deſcend. It is evident, that ſimilar reaſons will ſtill ſubſiſt for the ſlow deſcent of *a*, and the ſlower deſcent of *d*, till all redundancy and deficiency are at an end.

This maximum of the elevation of *d* happens when *a* has deſcended about one half of its elevation; that is, when the unbalanced repulſion of AB is reduced to about one-half. For if one-half of the unbalanced fluid be really taken out of AB, and if DF can get no ſupply whatever, it muſt acquire an attraction correſponding to $\frac{9}{10}$ths of this; and if the ſupply by the air be now opened to it, things will go on in the way already deſcribed, till all is diſcharged.

This account of the proceſs is only an approximation; becauſe we have ſuppoſed the changes to happen in a deſultory manner, as in the popular way of explaining the acceleration of gravity. The riſe of *d* is not at an end till the attraction of DF for fluid is to the repulſion of AB as 19 to 20.

But if we interrupt this progreſs in any period of it, by touching DF, we immediately render it neutral, and *d* falls quite down, in conſequence of receiving a complete ſupply of fluid. But this muſt change the ſtate of AB, and cauſe it to riſe $\frac{9}{10}$ths of the deſcent of *d*. As *a* and *d* were nearly at an equal height before DF was touched, it is plain that *a* will riſe to nearly twice its preſent height; after which, the ſame ſeries of phenomena will be repeated as ſoon as the finger is removed from DF.

If, inſtead of touching DF, we touch AB, the ſame things muſt happen; *a* muſt fall down, and *d* muſt riſe to nearly twice its preſent height, and all will go on as before, after removing the finger. Laſtly, if inſtead of allowing either ſide to touch the *ground* alternately, we only touch it with a *ſmall inſulated body*, ſuch as the wire with the balls *v* and *u*, the ball attached to the ſide touched ſinks, till the electricity is ſhared between the coating and the wire with balls. The ball attached to the other coating riſes $\frac{9}{10}$ths of the ſinking of the firſt ball. The crooked wire ball is now repelled by the coating which it touched, and the other ball is brought near to the other coating, and muſt be attracted by it, becauſe the electricities are oppoſite. This operation evidently tends to transfer the redundant fluid *by degrees* to the ſide where it is deficient. It needs no explanation. We ſhall only mention a thing which we have always obſerved, without being able to account for it. The vibration of the wire acquires a certain rapidity, which continues for a long while, and ſuddenly accelerates greatly, and immediately afterwards ceaſes altogether.

This pretty experiment of Profeſſor Richmann will be found very inſtructive; and will enable us to underſtand the operation of the electrophorus, and to ſee the great miſtake of thoſe who ſay that it is perfectly ſimilar to a diſcharged glaſs plate.

157
Electric action *e diſtanti* demonſtrated.

Thus, then, we ſee, that all the claſſes of phenomena, connected with attraction and repulſion, are preciſely ſuch as would reſult from the action of a fluid ſo conſtituted. The complete undiminiſhed action of the cauſe of thoſe phenomena on the other ſide of the interpoſed non-conductor of that cauſe is demonſtrated, and all

all explanation by the mechanical action of material elaſtic atmoſpheres of variable denſity muſt be abandoned, and the infinitely ſimpler explanation by the attractive and repulſive forces of the fluid itſelf muſt be preferred.

So happily does the Franklinian theory of poſitive and negative electricity explain the phenomena, when a ſuitable notion is formed of the manner of action of this fluid. We cannot but think that this is attained, when, to the general doctrine of Æpinus, we add the ſpecification of the law of action, ſo fully verified by the experiments of Mr Coulomb, which are in the hands of the public, and are of that ſimple nature that any careful experimenter can convince himſelf of their accuracy (See n° 144.) We may therefore proceed with ſome confidence, and apply this doctrine even to caſes where experiment does not offer itſelf for proof.

158
Franklin miſtaken in ſuppoſing that a charged plate contains its natural quantity of fluid.

Dr Franklin affirms that electric fluid cannot be thrown into one ſide of the coated pane unleſs it be abſtracted from the other; and that therefore the charged glaſs contains no more than it did before charging. We indeed find that we cannot *charge* the inſide, if the outſide do not communicate with the ground. He proves it alſo by ſaying, that if a perſon, when inſulated, diſcharges a glaſs through his own body, he is not found electrified: And he infers, as a neceſſary conſequence of this, that a ſeries of any number of jars may be charged by the ſame turns of a machine, if we make the outſide of the firſt communicate with the inſide of the ſecond, and the outſide of the ſecond with the inſide of the third; and ſo on; and the outſide of the laſt communicate with the ground. Having made the trial, and having found that more turns of the machine were neceſſary, he attributes this to diſſipation into the air by the communication. But our theory teaches us otherwiſe. We learn from it, that the redundant matter in the plate DF is leſs than the redundant fluid in AB, in the proportion of $n - 1$ to n; and therefore the redundant fluid in the overcharged ſide of the next plate is no greater. The charge or redundancy in the mth jar of the ſeries will therefore be $\left.\overline{\frac{n - 1}{n}}\right|^{m}$. Thus, if n, or the charge of the firſt jar, be 60, the charge of the 10th jar will be nearly 51. Although a coated plate cannot be *charged* unleſs one of the coatings communicate with the ground, it may be *electrified* as much as one of the coatings can be alone. And this is ſeen in our attempt to charge it: For as ſoon as we attempt to electrify one ſide, the other is electrified alſo; for it gives a ſpark which no unelectrified body will do. Alſo, when we diſcharge a jar by an inſulated diſcharger, we always leave it electrical in the ſame way with the body from which it was charged. If a man is not found electrified after having diſcharged a jar through his own body, it is owing to the great ſurface of his body, which reduces the ſimple electrification of a ſide of the jar to a very inſignificant and inſenſible quantity.

159
iſtake of ilcke's.

Wilcke (and we believe Franklin before him) maintains, that when the jar has been charged, by connecting one ſide with the prime conductor, and the other with the rubber, it is neutral and inactive on both ſides. But this is not ſo; and a ſlight reflection might have convinced them that it cannot be ſo: if it were, the jar could not be diſcharged. Each ſide, while connected with the machine, muſt be in the condition of the part with which it is connected, and in a diſpoſition to take or give. If the trial be carefully made, it will be found to be *equally active* on both ſides; and the diſcharging rod, having down on its ends, will ſhew this in an unequivocal manner, and ſhew that its condition differs in this reſpect from that of a jar charged in the ordinary way. It is in the maximum ſtate of Richmann's plate, deſcribed in n° 156. when d riſes no more.

160
Charge one jar by the diſcharge of another.

In diſcharging a jar A, if inſtead of the outſide communicating with the inſide by a wire, we make it communicate with the inſide of a ſecond jar B, while the outſide of B is made to communicate with the inſide of A, we ſhall find be charged by the diſcharge of A; and that the diſcharge of A is not complete, the charge 2^2 always remaining, whatever may have been the magnitude of n.

161
Important inference.

We may infer from this experiment, that when a ſhock is given to a number of perſons a, b, c, &c. we are not to conclude, that the fluid which comes into the deficient ſide of the jar is the ſame which came out of the redundant ſide. The whole, or perhaps only a part, of the moveable fluid in the perſon a goes into b, replacing as much as has paſſed from b into c, &c. Indeed, where the canal is a ſlender wire, we may grant that great part of the individual particles of fluid which were accumulated on the inſide of the jar have gone into the outſide. Perhaps the quantity transferred, even in what we call *a very great diſcharge*, may be but a ſmall proportion of what naturally belongs to a body. This may be the reaſon why a charge will not melt more than a certain length of wire. Mr Cavendiſh aſcribes this to the greater obſtruction in a longer wire; but this does not appear ſo probable. A greater obſtruction would occaſion a longer delay of the transference; and therefore the action of the ſame quantity would be longer continued. He proves, that a metal wire conducts many hundred times faſter than water; yet, when water is diſſipated by a diſcharge, it is found to have actually conducted a *much greater* proportion of the whole charge. We aſcribe it chiefly to this, that, in a ſhort wire, the quantity transferred exceeds the whole quantity belonging to the wire.

162
Leyden phial like a coated pane.

It is ſurely needleſs to prove that the theory of the Leyden phial is the ſame with that of the coated pane. The only difference is, that we are not ſo able to tell the diſpoſition of the accumulated fluid, and the evacuated matter, in every figure. When the phial is of a globular form, and of uniform thickneſs, with an exceedingly ſmall neck, we then knew the diſpoſition more accurately than in a plate. The redundant fluid is then uniformly diſtributed. If we could inſure the uniformity of thickneſs, ſuch a phial would be an excellent UNIT for meaſuring all other charges by; but we can neither inſure this (by the manner of working glaſs), nor meaſure its want of uniformity: whereas we can have mirror plate made of preciſely equal thickneſs, and meaſure it. This, therefore muſt be taken as our unit.

163
Excellent method for verifying the theory.

And here we remark, that this gives us the moſt perfect of all methods for comparing our theory with experiment. We muſt take two plates, of the ſame glaſs and the ſame thickneſs, but of different dimenſions of coated ſurface. We muſt charge both by very long conducting wires on both ſides, and then meaſure

how

how often the charge of the one is contained in the other. Mr Cavendiſh has given an unexceptionable method of doing this independent of all theory. As it applies equally to jars, however irregular, we ſhall take it altogether.

Meaſure of a charge

When a jar is charged, obſerve the electrometer connected with it, and immediately communicate the charge to another equal jar (the perfect equality being previouſly aſcertained by the methods, which will appear immediately). Again note the electrometer. This will give the elevation, which indicates one-half, independent of all theory. Now electrify a jar, or a row of equal jars, to the ſame degree with the firſt, and communicate the charge to a coated mirror plate, diſcharging the plate after each communication, till the electrometer reaches the degree which indicates one-half. This ſhews how often the charge of the plate is contained in that of the jar or row of jars.

Let the charge of the plate be to that of the jars as x to 1. Then, by each communication, the electricity is diminiſhed in the proportion of $\overline{1 + x}$ to 1. If m communications have been made, it will be reduced in the proportion of $\overline{1 + x}^m$ to 1. Therefore $\overline{1 + x}^m = 2$, and $1 + x = \sqrt[m]{2}$, and $x = \sqrt[m]{2} - 1$.

When x is ſmall in proportion to 1, we ſhall be very near the truth, by multiplying the number of communications by 1,444, and ſubtracting 0,5 from the product. The remainder ſhews how often the charge of the plate is contained in that of the jars, or $\frac{1}{x}$.

Thus may the perfect equality of two jars be aſcertained; and the one which exceeds, on trial, may be reduced to equality by cutting off a little of the coating. An electrician ſhould have a pair of ſmall jars or phials ſo adjuſted. It will ſerve to diſcover in a minute or two the mark of one-half electricity for any electrometer, and for any degree; as alſo for meaſuring jars, batteries, ſhocks, &c. much more accurately than any other method: becauſe ſuch phials, conſtructed as we ſhall deſcribe immediately, may be made ſo neutral, and ſo retentive, that the quantity which diſſipates during the handling becomes quite inſignificant in proportion to the quantity remaining; whereas, in all experiments with electrometers, conſtructed with the moſt curious attention, the diſſipations are great in proportion to the whole, and are capricious.

164. It was chiefly by this method that the writer of this article, having read Mr Cavendiſh's paper, compared the meaſures given by experiment with thoſe which reſult from an action in the inverſe duplicate ratio of the diſtance. When the charges were moderate, the coincidence was perfect; when the charges were great, the large plates contained a little more. This is plainly owing to their being leſs diſpoſed to diſſipate from the edges.

165

Maxims for conſtructing jars, batteries, &c.

We may now follow with ſome confidence the practical maxims deducible from the theory for the conſtruction of this accumulating apparatus. The theory preſcribes a very conducting coating, in cloſe and uninterrupted contact: It preſcribes an extenſive ſurface, and a thin plate of idio-electric ſubſtance. Accordingly all theſe are in fact attended by a more powerful effect. Metal is found to be far preferable to water, which was firſt employed, having been ſuggeſted by the original experiments of Gray, Kleiſt, and Cunæus. A continuous plating is preſcribed, in preference to ſome methods commonly practiſed; ſuch as filling the jar with braſs duſt, or gold leaf, or covering its ſurface with filings ſtuck on with gum water, or coating the inſide with an amalgam of mercury and tin. This laſt appears, by reflection from the outſide, to give a very continuous coating; but if we hold the jar between the eye and the light, we may perceive that it is only like the covering with a cobweb. Yet there are caſes where theſe imperfect coatings only are practicable, and ſome rare ones where they are preferable.

Hint for medical exhibition of electricity.

In the medical exhibition of electricity, where the purpoſe intended is ſuppoſed to require the transfuſion of a great quantity of the electric fluid, any thing that can diminiſh the irritating ſmartneſs of the ſpark is deſirable. This is greatly effected by thoſe imperfect coatings. Small ſhocks, which convey the ſame quantity of fluid with the ſharp pungent and alarming ſpark from a large ſurface, are quite ſoft and inoffenſive, greatly reſembling the ſpaſmodic quivering, ſometimes felt in the lip or eye-lid, and will not alarm the moſt fearful patient.

166

How to prevent the burſting of jars by high charges,

Cloſe contact of the metallic coating is obſerved to increaſe the effect of the charge. But it is alſo found that it greatly increaſes the riſk of burſting the glaſs by ſpontaneous diſcharge through its ſubſtance. An experienced electrician (we think it is Mr Brookes of Norwich) ſays, that ſince he has employed paper covered with tinfoil, with the paper next the glaſs, inſtead of the foil itſelf, he has never had a jar burſt; whereas the accident had been very frequent before. The theory juſtifies this obſervation. Paper is an imperfect conductor, even when ſoaked with flour paſte; and the transfuſion, though rapid, is not inſtantaneous nor deſultory, but begins faintly, and ſwells to a maximum. It operates on the glaſs, like gradual warming, inſtead of the ſudden application of great heat.

167

Very curious obſervation by Mr Cuthbertſon.

Mr Cuthbertſon, an excellent artiſt in all electrical apparatus, and inventor of the beſt air-pump, has made a curious obſervation on this ſubject. He ſays that he has uniformly obſerved, that jars take a much greater charge (nearly one-third), if the inſide be conſiderably damped, by blowing into it with a tube reaching to the bottom (*Nicholſon's Journal*, March 1799).—We muſt acknowledge, that we can form no diſtinct conception of what Mr Cuthbertſon calls *an undulation of the elaſtic atmoſphere*. We do not know whether he means that the atmoſphere is actually undulating as water, or as air in the production of ſound, its parts being in a reciprocating motion; or whether he only means that this atmoſphere conſiſts of quieſcent ſtrata, alternately denſer and rarer. Nor can we form any notion how either of theſe undulations contributes to the exploſion, or prevents it. We are really but very imperfectly acquainted with that part of the ſcience which ſhould determine the preciſe accumulation that produces the deſultory transference. We mentioned one neceſſary conſequence of the action inverſely as the ſquare of the diſtance, which has ſome relation to this queſtion, *viz.* that a particle, making part of a ſpherical ſurface, is twice as much repelled when it has juſt quitted the ſurface, as when it made part of it, provided its place be immediately ſupplied. And another circumſtance has been frequently mentioned, *viz.* that a greater, and perhaps much greater, force is neceſſary for enabling a particle

particle of fluid to quit the laſt ſeries of particles of the ſolid matter than for producing almoſt any conſtipation. But we are not certain that theſe circumſtances are of ſufficient influence to explain the whole of the event. *Valeant quantum valere poſſint.* Yet we are of opinion that Mr Cuthbertſon has aſſigned the true cauſe, namely, the imperfect coating of the inſide of the glaſs. When we come to the explanation of the eſcape of electricity along imperfect conductors, we hope that it will appear, that the diſpoſition to eſcape muſt be greatly diminiſhed by a charge, which diſpoſes the fluid ſo, that in no place the conſtipation is remarkably greater than in another part very near it, and the denſity changes everywhere ſlowly.

168 Beſt forms for jars, &c.

With reſpect to the form of the coated glaſs, the theory preſcribes that which will occaſion ſuch a diſtribution of the electric fluid as ſhall make its repulſion for the fluid in the canal which connects it with the prime conductor as little as poſſible. In this reſpect it would ſeem that a plate is the beſt, and a globe the worſt: but if both are very thin, the difference cannot be conſiderable. Our experience, however, ſeems to indicate the oppoſite maxim as the moſt proper. We have uniformly found a globe to be far preferable to a plate of the ſame thickneſs, and that a plate was generally the weakeſt form. It muſt be owned that we have not yet been able to aſcertain by the theory what is the exact diſtribution of the redundant fluid in a plate. In a ſphere it muſt be uniformly ſpread over the ſurface. We muſt alſo aſcribe part of the inferiority of the plate to its greater tendency to diſſipation from the edges. If a plate be coated in a ſtar-like form, with ſlender projecting points, we ſhall obſerve them luminous in the dark, almoſt at the beginning of the accumulation; and the plate will diſcharge itſelf by theſe points, over the uncoated part, before it has attained any conſiderable ſtrength. Thoſe forms are leaſt expoſed to this deterioration which have the leaſt circumference to the ſame quantity of ſurface. We have always found that a ſquare coating will not receive a more powerful charge without exploding than a circular one of the ſame breadth, although it contains a fourth more ſurface; and this although any viſible eſcape from the angles be prevented by covering the outline with ſealing wax. Of all forms, therefore, a globe, with a very narrow, but long neck, is the moſt retentive. But it is very difficult to coat the inſide of ſuch a veſſel. The balloons uſed in chemical diſtillations make excellent jars, and can be eaſily coated internally when the neck will admit the hand. The thinneſt of tinfoil may be uſed, by firſt paſting it on paper, and then applying it either with the foil or the paper next the glaſs. It ſhould be cut into guſſets, as in the covering of terreſtrial globes; and they ſhould be put on overlapping about half an inch. The middle of the bottom is then coated with a circular piece. The great bottles for holding the mineral acids are alſo good jars, but inferior to the balloons, becauſe they are very thick in the bottom, and for ſome diſtance from it. A box of balloons contains more effective ſurface than an equal box of jars of the ſame diameter and height of coating.

169 Compendious battery.

The moſt compendious battery may be made in the following manner: Chooſe ſome very flat and thin panes of the beſt crown glaſs, coat a circle (*a b c d*), (fig. 31.) in the middle of both ſurfaces, ſo as to leave a ſufficient border uncoated for preventing a ſpontaneous diſcharge; let each of them have a narrow ſlip of tinfoil *a* reaching from the coating to the edge on one ſide, and a ſimilar ſlip *c* leading to the oppoſite edge on the other ſide. Lay them on each other, ſo that the ſlips of two adjoining plates may coincide. Connect all the ends of theſe ſlips on one ſide together by a ſlip of the ſame foil, or a wire which touches them all. Then, connecting one of theſe collecting ſlips with the prime conductor, and the other with the ground, we may charge and diſcharge the whole together. If the panes be round, or exact ſquares, we may employ as few of them together as we pleaſe, by ſetting the whole in an open frame, like an old-faſhioned plate-warmer; and then turning the ſet which we would employ together at right angles to the reſt. This evidently detaches the two parcels from each other. This battery may be varied in many ways; and if the whole is always to be employed together, we may make it extremely retentive, by covering the uncoated border of the plate with melted pitch, and, while it is ſoft, preſſing down its neighbour on it till the metallic coatings touch. For greater variability this may be done in parcels of the whole.

170 Another.

On the ſame principle, a moſt compendious battery may be made by alternate layers of tinfoil and hard varniſh, or by coating plates of very clear and dry Muſcovy glaſs. But theſe muſt be uſed with caution, leſt they be burſt by a ſpontaneous diſcharge; in which caſe we cannot diſcover where the flaw has happened. They make a ſurpriſing accumulation, without ſhewing any vivid electricity.

171 Portable jar.

We have made a very fine electric phial for carrying about, by forming tin-plate (iron plate tinned) into ſomewhat of a phial ſhape, with a long neck. We then covered this with a coating of fine ſealing wax, about $\frac{1}{10}$th of an inch thick, quite to the end of the neck, and coated the ſealing wax, all but the neck, with tinfoil. It is plain that the ſealing wax is the coated idio-electric, and that the tin-plate phial ſerves for an inner coating and wire. The diſſipation is almoſt nothing if the neck be very ſmall; and it only requires a little caution to avoid burſting by too high a charge. Even this may be prevented by coating the ſealing wax ſo near to the end of the neck, that a ſpontaneous diſcharge muſt happen before the accumulation is too great.

172 Importance of a cloſe diſcharge.

It is well known that the diſcharge happens when the diſcharging balls are at a conſiderable diſtance from each other; therefore only ſo much is diſcharged as correſponds to that diſtance. This is one cauſe of the reſiduum of a diſcharge which ſometimes is pretty conſiderable. Some experiments require the very utmoſt force of the charge. It is therefore proper to make the diſcharge as cloſe and abrupt as poſſible. But the moſt rapid approach that we can make of the diſcharger is nothing in compariſon with the velocity with which the fluid ſeems to fly off, and will therefore have but ſmall influence in making a more inſtantaneous and complete diſcharge. Theory points out the following method: Let a very thick plate of glaſs (half an inch), of ſeveral inches diameter, be put between the diſcharging balls, which ſhould, in this caſe, be ſmall, and let theſe balls be ſtrongly preſſed againſt it by a ſpring. While the charge is going on, a very ſmall part of the glaſs plate, round

round the points of contact, will receive a weak and uſeleſs charge; but this will not hinder the battery from acquiring the ſame intenſity of charge. When this is completed, let the intervening glaſs plate be briſkly withdrawn. The diſcharge will begin with an intenſity which is unattainable in the ordinary manner of proceeding.

173 Lateral exploſion. Much has been ſaid of the lateral exploſion. It appears, that in ſome of the prodigious transferences of electricity that have taken place in the diſcharge of great ſurfaces through wires barely ſufficient to conduct them, flaſhes of light are thrown off laterally; but the moſt delicate electrometer, it is ſaid, is not affected. The fact is not accurately narrated; we have always obſerved a very delicate electrometer to be affected. The paſſage of ſuch a quantity of fluid is almoſt equivalent to the co-exiſtence of it in any given ſection of the wire; but it remains there for ſo ſhort a time, that, acting as an accelerating force, it cannot produce a very ſenſible motion. It is like the diſcharging a piſtol ball through a ſheet of paper hanging looſely. It goes through it without very ſenſibly agitating it.

174 Propoſal for diſcovering which is redundant electricity. It has ſometimes appeared to us probable that, by means of this lateral exploſion, the direction of the current may be diſcovered. Let the jar *a b* (fig. 32.) be diſcharged by a wire *a c d e b*, interrupted at *c d* by the coating of a very thin plate of talc; let the coating alſo be very thin. There muſt be *ſome* obſtruction to the motion, which muſt cauſe the fluid to preſs on the ſides or ſurfaces of the coating, juſt as the obſtruction to the motion of water in a pipe (ariſing from friction, or even from material obſtacles in the pipe) cauſes the water to preſs on the ſides of the pipe. Therefore if a wire κ ε connect the other coating with the ground, we ſhould expect that fluid will be expelled along this wire, and a charge be given to the plate of talc. Now whether the courſe in this apparatus be from *b* to *a*, or from *a* to *b*, if any charge be acquired by *c d*, it will *probably* be poſitive in *c d*, and negative in κ δ; for it is electric fluid that is ſuppoſed to paſs: therefore we ſhould always have one ſpecies of electricity, whether *a* has been charged by glaſs or by ſealing wax; and this ſpecies will indicate which is poſitive. We have ſaid "*probably*"—for it is not impoſſible that it may be otherwiſe. If the abſtraction at *d* be ſuppoſed more powerful than the ſupplying force at *c*, the ſame obſtruction may perhaps keep the plate *c d* in an *abſorbing* ſtate, juſt as water deſcending in a vertical pipe, into which it is preſſed by a very ſmall head of water in the ciſtern, inſtead of preſſing the ſides of the pipe, rather draws them inwards, as is well known. This ſeems, at any rate, an intereſting experiment; for we muſt acknowledge, that there ſtill hangs a myſterious curtain before a theory which deduces ſo much from the preſence of a ſubſtance which we have never been able to exhibit alone, and where we do not know when it abounds and when it is deficient. It is like the phlogiſton of Stahl, or the caloric of Lavoiſier. It will be proper to uſe the thinneſt plate of talc to be charged, and to connect it with another coated plate of half the diameter, or leſs, in order to increaſe the accumulation. It ſeems by no means a deſperate caſe.

The theory of coated glaſs now explained, might have been treated with more preciſion, and the formulæ deduced in the beginning of this article might have been employed for ſtating the ſum total of the acting forces, and thus demonſtrating with preciſion the truth of the general reſult; and indeed it was with ſuch a view that they were premiſed: but they would have been conſiderably complicated in the preſent caſe; for however thin we ſuppoſe the tinfoil coatings to be, it is evident from nº 92, &c. that each coating will conſiſt of three ſtrata; of which the two outermoſt are active, and muſt have their forces ſtated, and the ſtatement of the force of each ſtratum would have conſiſted of three terms. This would have been very embarraſſing to ſome readers; and the force of the concluſion would not, after all, have been much more convincing than we hope the above more looſe and popular account has been.

175 Does the charge reſide in the coatings or in the glaſs? We have hitherto conſidered the non-electric coatings only, and have not attended to what may chance to obtain in the ſubſtance of the coated electrics themſelves. May not part, at leaſt, of the redundant fluid be lodged in one ſuperficial ſtratum of the glaſs? or, if it do not penetrate it, may it not adhere to the ſurface, and drive off from the other ſurface, or ſtratum, a part of what naturally adheres to it? Till Dr Franklin's notions on the ſubject became prevalent, no perſon doubted this. The electric was ſuppoſed to contain or to accumulate in its ſurface all the electricity that we know. But the firſt ſuggeſtion of Dr Franklin's experiments certainly was, that the electric plate or veſſel acted merely as an obſtacle, preventing the fluid from flying from the body where it was redundant to that where it was deficient. It is therefore an important queſtion in the ſcience, whether the glaſs or electric concerned in theſe phenomena ſerve any other purpoſe beſides the mere prevention of the redundant fluid from flying to the negative plate?

176 It is in the glaſs. Now it appears, at the very firſt, that this is the caſe. For if a glaſs be coated only on one ſide, and be electrified on that ſide, we obtain a ſtrong ſpark from the other ſide by bringing the knuckle near it: and this may be obtained for ſome time from one ſpot of that ſurface; and after this we get no more from that ſpot, but get ſparks, with the ſame vivacity, and in the ſame number, from any other ſpot that is oppoſite to the coating on the other ſide. In this manner we can obtain a ſucceſſion of ſparks from every inch of ſurface oppoſite to the coating, and from no other part. But what puts this queſtion beyond all doubt, is, that if we now lay a metal coating on the ſurface from which the ſparks have been drawn in this manner, and make a communication between the two metallic coatings, by means of a bent wire, we obtain a perfect diſcharge. To complete the proof, we need only obſerve that this experiment ſucceeds whether the glaſs has been electrified by excited glaſs or by excited ſealing-wax. Therefore the coated ſurface may receive the electric fluid by the coating, as we ſee plainly that it is abſtracted by the coating. The uſe of the coatings may be nothing more than to act as conductors to every part of the ſurface of the electric. None of theſe thoughts eſcaped the penetrating and ſagacious mind of Dr Franklin. He immediately put it to the teſt of experiment; and, laying a moveable metallic coating on both ſurfaces, he found the glaſs charge perfectly well. He lifted off the coatings; which operation was accompanied by flaſhes

flaſhes of light between the metallic coverings and the glaſs from which he ſeparated them. Having removed the coatings, he applied others, completed the circle, and obtained a perfect diſcharge, not diſtinguiſhable from what he would have obtained from the firſt coatings.

177 Charged glaſs acquires redundant and deficient ſtrata.

Thus it was demonſtrated, that the glaſs plate itſelf acquired by charging a redundant ſtratum on one ſide, and a deficient ſtratum on the other ſide; and we now ſee, at once, the reaſon why the accumulation turns out greater than what is determined by the theory. The diſtance between the redundant and deficient ſtratum is leſs than the thickneſs of the glaſs; and this, perhaps, is an unknown proportion.

This precious experiment of Dr Franklin was repeated by every electrician, and varied in a thouſand ways. No philoſopher has carried this reſearch farther than Beccaria; and he has given ground for a moſt important diſcovery in the mechanical theory, namely, that the charged glaſs has ſeveral ſtrata, of inconceivable thinneſs, alternately redundant and deficient in electric fluid; and that by continuing the electrification, theſe ſtrata penetrate deeper into the glaſs, and probably increaſe in number. We have not room here to give even an account of his experiments, and muſt refer the philoſophical and curious reader to that part of his valuable Treatiſe where he treats of what he calls *vindicating* or *recovering electricity;* as alſo to a paper by Mr Henly in Phil. Tranſ. for 1766, giving account of experiments on Dutch plates by Mr Lane. The general form of the experiment is this. He puts two plates together; he coats the outer ſurfaces, and charges and diſcharges them as one thick plate. Their inner touching ſurfaces are found ſtrongly electrical after the diſcharge, having oppoſite electricities, and changing theſe electricities, by repeated ſeparations and replacings, in a way ſeemingly very capricious at firſt ſight, but which the attentive reader will find to be according to fixed laws, and agreeably to the ſuppoſition that the ſtrata gradually ſhift their places within the glaſs, very much reſembling what we obſerve on a long glaſs rod which we would render electric by induction. In this caſe, as was obſerved in n° 57. there are obſerved more than one neutral point, &c.

178. Mr Cavendiſh endeavours to give us ſome notion of the diſpoſition of the fluid in the ſubſtance of the glaſs in the following manner: Having ſeparated the coated plate from the machine and from the ground, ſuppoſe a little of the redundant fluid in $B\beta\delta D$ (fig. 33.) equal to the fluid wanting in $E\varepsilon\varphi F$. If we now ſuppoſe all the redundant fluid to be lodged in $b\beta\delta d$, and $e\varepsilon\varphi f$ to hold all the redundant matter, and the two coatings to be in their natural ſtate, a particle p, placed in the middle of the ſurface bd, will be nearly as much attracted by $\varepsilon ef\varphi$ as it is repelled by $b\beta\delta d$ (exactly ſo if the plates were infinitely extended); and if the coating be removed, keeping parallel and oppoſite to the ſurface that it quits, there will be very little, if any, tendency to fly from the glaſs to the coating: there will rather be ſome diſpoſition in the fluid to quit the coating and fly to the glaſs; becauſe the repulſion of $b\beta\delta d$ is more diminiſhed than the attraction of $\varepsilon ef\varphi$. (n° 42.) But the difference will be very ſmall indeed. (*N. B.* the reſult would be very different if electric action followed a different law. Were it as $\frac{1}{d^3}$, the coating would be much overcharged; and were it as $\frac{1}{d}$, it would be very much undercharged). Now the fact is, that when the coating is carefully removed, it is poſſeſſed of very little electricity, not more than may reaſonably be ſuppoſed to run into it by bringing away one part before another. It is impoſſible to keep it mathematically parallel.

Hence we may conclude that the greateſt part of the redundant fluid is lodged in the glaſs if the plates be thin, and the redundant fluid bear but a ſmall proportion to the natural quantity. Similar reaſoning ſhews that the greateſt part of the deficiency is in the other ſide of the glaſs; and that therefore the coatings are very nearly in their natural ſtate, and merely ſerve the purpoſe of conducting.

We have employed coatings of conſiderable thickneſs, having holes through them, oppoſite to which was ſome gold leaf of the heavieſt ſort, and almoſt free of cracks. We have examined the ſtate of the bottom of thoſe pits in Mr Coulomb's manner, and always found them void of electricity.

179 Conjecture about the burſting of jars.

Thus we learn that glaſs, and probably all other electrics, acquire redundant and deficient ſtrata as well as the moſt perfect conductors, at the ſame time that they may be impervious to the fluid; and we get ſome mode of conceiving how the rupture happens by a ſtrong charge. This may very probably happen when the ſtrata have formed, in alternate order, ſo deep in the glaſs, that a ſtratum, in which the fluid is crowded cloſe together, may become contiguous to one deprived altogether of fluid. We cannot, however, ſay with confidence, what *ſhould* be the effect of this ſtate of things; or of one conſtipated ſtratum coming in contact with another.

This view of the condition of charged glaſs explains (we think) ſeveral phenomena which ſeem not well underſtood by electricians.

180 Several phenomena explained.

The reſiduum of a diſcharge is frequently owing to a charge extending beyond the coating, where the action is conſiderably irregular, or different from what it would be if the plates were infinitely extended. This *outline* charge is taken up by the coated part after a very little while, and may again be diſcharged. But it alſo frequently ariſes from another ſtratum (much thinner, as it will always be) than the exterior one, coming to the ſurface ſome time after the firſt diſcharge, and being now in a condition for being diſcharged. It explains the ſparkling that is perceived *in ſucceſſion* between the parts of a jar that is coated in ſpots, during the charge, and the very ſenſible reſiduum of the charge of ſuch a veſſel. It explains the phenomena of Beccaria's *Electricitas Vindex* (ſee ELECTRICITY, *Encycl.* n° 48.), and the great difference that may be found in the different kinds of glaſs in this reſpect. It explains the great difference between the ſenſation occaſioned by a ſpark from a perfectly conducting ſurface of conſiderable extent, and that occaſioned by a ſhock, which conveys the ſame quantity of fluid accumulated in a ſmall ſurface of glaſs. The diſcharge of the firſt is almoſt inſtantaneous, while that of the laſt requires a ſmall moment of time, and is therefore leſs deſultory

and

and abrupt. The one is pungent and ſtartling; but the other is ſofter in the firſt inſtant, and ſwells to a maximum. Therefore, in the medical employment of electricity, when the purpoſe is to be affected by the transfuſion of a great quantity of electric fluid, we ſhould recommend very ſmall ſhocks from a very large ſurface of coated glaſs, very faintly electrified, in place of ſtrong ſparks. Patients of irritable conſtitutions are frequently alarmed by the quickneſs and pungency of ſtrong ſparks: but if the balls of Lane's ſhock-meaſurer be ſet ſo cloſe as to give four or five ſhocks in each turn of a ſeven inch cylinder, the ſhocks are not even diſagreeable. The balls ſhould be made of fine cupelled ſilver: in which caſe, the ſurface will never be hurt by the greateſt diſcharge; whereas the diſcharge of four ſquare feet of coated glaſs will raiſe ſuch a roughneſs on the ſurface of braſs as will cauſe it to ſputter, and deſtroy entirely the regularity of the expenditure of fluid. The ſame conſideration ſhould make us prefer a jar coated entirely with amalgam. This cob-web coating gives a greater ſoftneſs to the ſhock. Laſtly, we ſee why a powerful and permanent electricity was not produced in the tube filled with melted ſealing wax, and treated as mentioned in n° 101. The redundancy and deficiency intended to be produced could only be ſuperficial. And becauſe the wax cooled by degrees from the ſurface to the axis, and the wax is a conductor while liquid, it muſt have taken a charge at laſt; and therefore muſt appear but faintly electrical.

181. This account of the ſtate of charged glaſs promiſes us ſome aſſiſtance in our attempts to conceive what paſſes in the excitation of glaſs by friction. It appears from Beccaria's experiments, that the redundant fluid is lodged in the ſame manner in both caſes; for by rubbing one ſide of a glaſs tumbler, while points were preſented to the oppoſite ſurface, and were connected with a wire that communicated with the ground, he gave it a powerful charge.

182
The quantity of fluid in a body may be exceeding great.

It is obſerved, that when the laminæ of a piece of Muſcovy glaſs are ſeparated, by pulling them aſunder without inſerting any inſtrument between them, they are electrical when ſeparated; one being poſitive, and the other negative. Muſt we not conclude from this, that when conjoined they were in the ſtate of charged glaſs? If we take this view of it, a body may contain a prodigious quantity of electric fluid without exhibiting any appearance of it. Mr Nicholſon found, by a very fair computation from his experiments, that a cubic inch of talc, when ſplit into plates of 0,011 of an inch in thickneſs, and coated with gold leaf, gave a ſhock equal to the emptying 45 conductors, each ſeven inches in diameter and three feet long, electrified ſo that each gave a ſpark at nine inches diſtance. Now, the whole of this was moveable fluid, and no more than what the talc contains when unelectrified: for no more comes into the poſitive ſide than goes out of the negative ſide. Nay, there is no probability that the quantity moveable in our experiments bears a conſiderable proportion to the natural quantity. The quantity of moveable fluid in a man's body is therefore very great: and Lord Mahon is well authoriſed to ſay, that the ſudden diſplacing of this quantity in a *returning ſtroke*, which has been occaſioned by a diſcharge of a cloud in a very diſtant place, is fully adequate to the production of the moſt violent effects. But his Lordſhip has not attended to the circumſtance, that no ſuch diſplacement can happen. The accumulation that can be made in the human body is only ſuperficial; and therefore, altho' the whole fluid of a man's body may change its place, it will not change it with the rapidity that ſeems neceſſary for the violent effects of electricity, except in the very points of communication with the ſurrounding bodies.

183. We have now ſeen in what ſenſe the idio-electrics may be ſaid to be impervious to the electric fluid. It is moved in them only to very ſmall and imperceptible diſtances. When a conſiderable ſtratum is diſcharged, the fluid does not come from the extremity of it to the point of diſcharge through the glaſs, but through the coating. And when alternate ſtrata of redundant fluid and redundant matter are formed, the particles in each ſhift their places very little, moving perpendicularly to the ſtratum.

184
The impermeability of electrics denied by ſome.

Even this degree of obſtruction has been denied by ſome very active electricians, who have multiplied experiments to prove that the fluid paſſes freely through glaſs, and that the theory of coated electrics is totally different from what Franklin imagines. Mr Lyons of Dover has publiſhed a numerous liſt of ſingular experiments, which he has made with this view, with much trouble, and no ſmall expence. They may all be reduced to this: A wire is brought from the outſide of a phial, charged by the knob, and terminates in a ſharp point at a ſmall diſtance from a thin glaſs plate (it is commonly introduced into a glaſs tube, having a ball at the end, and the point of the wire reaches to the centre of the ball); and another wire is connected with the diſcharging rod, and alſo comes very near (and frequently cloſe) to the other ſide of the glaſs, oppoſite to the pointed wire. With this apparatus he obtains a diſcharge; and therefore ſays that the glaſs is permeable to electricity. But he does not narrate all the circumſtances of the experiment. We have repeated all of them that have any real difference (for moſt of them are the ſame fact in different forms), and we have obtained diſcharges: But they were all very incomplete, except when the glaſs was perforated, which happened very frequently. The diſcharge was never made with a full, bright, undivided ſpark, and loud ſnap; but with ſputtering, and trains of ſparks, continued for a very ſenſible time; and the phial was never deprived of a conſiderable part of its charge: and (which Mr Lyons has taken no notice of) the glaſs is found to be charged, negative on the ſide connected with the poſitive ſide of the phial, and poſitive on the other. This charge was communicated to the glaſs over a pretty conſiderable ſurface round the points immediately oppoſite to the wires. This is quite conformable to the experiments of Dr Franklin and Beccaria, who charged a tumbler by graſping it with the hand, and preſenting the inſide to a point electrified by the prime conductor. The whole experiment is analogous to the one narrated in n° 176.

185
Bars touched like magnets for electricity.

We may conclude our obſervations on coated glaſs with mentioning a curious experiment. A flat ſtick of fine ſealing wax, warmed till it bent pretty readily, was rendered permanently electrical, with a poſitive and negative pole, in a manner analogous to the double touch of magnets. A ſmall jar was taken, having a hemiſphere on the end of its inſide wire, and another on the end

end

end of a ſtiff wire projecting from the outer coating, and then turned up parallel to the inſide wire; ſo that the two hemiſpheres ſtood equally high, and about three inches aſunder. This jar was electrified ſo weakly, as to run no riſk of a ſpontaneous diſcharge. The flat faces of the two hemiſpheres were now applied to the flat ſide of the ſealing wax, and were moved to and fro along it, overpaſſing both ends about an inch with each hemiſphere. The experiment was very troubleſome; for the phial often diſcharged itſelf along the ſurface of the ſealing wax, and all was to begin again. But, by continuing this operation till the ſealing wax grew quite cold and hard, it acquired a very ſenſible electriciſm, which laſted ſeveral weeks when kept with care; but ſtill it was not much more ſenſible than that of the ſealing wax, which congealed between two globes oppoſitely electrified.

186 ectro- iorus. After this application of the theory to the phenomena of coated glaſs, it will not be neceſſary to employ much time in its application to the electrophorus. The general propoſitions from n° 14. to 25. and their companions in n° 38—43, will enable us to ſtate with preciſion (when combined with the law of electric action) the actions of every part of this apparatus; and conſiderable aſſiſtance will be derived from a careful conſideration of our analyſis of Profeſſor Richmann's experiment in n° 156. But we muſt content ourſelves with a general, popular view of theſe particulars, which may be ſufficient for making us underſtand what will be the *kind*, and ſomewhat of the *intenſity*, of the action of its different parts.

The electrophorus conſiſts of three parts. The chief part is the cake ABCD (fig. 34.) of ſome electric; ſuch as gum lac, ſealing wax, pitch, or other reſinous compoſition. This is melted on ſome conducting plate, DCFE, and allowed to congeal; in which ſtate it is found to be negatively electric. Another conducting plate GHBA is laid on it, and may be raiſed up by ſilk lines, or any inſulating handle. We ſhall call ABCD the CAKE, DCFE the SOLE, and GHBA the COVER.

The general appearances not having been ſo ſcientifically claſſed in the article ELECTRICITY as could be wiſhed, we ſhall here narrate them, very briefly, in a way more ſuited to our purpoſe. In comparing the theory with obſervation, it will be proper to make all the three parts of conſiderable thickneſs, and of no great breadth. Although this diminiſhes greatly the moſt remarkable of the actions, it leaves them ſufficiently vivid, and it greatly increaſes the ſmaller changes which are inſtructive in the compariſon. The general facts are,

enome- thereof. 1. If the ſole has been inſulated during the congelation of the electric, till all is cold and hard, the whole is found negatively electric, and the finger draws a ſpark from any part of it, eſpecially from the ſole. If allowed to remain in this ſituation, its electricity grows gradually weaker, and at laſt diſappears: but it may be excited again by rubbing the cake with dry warm flannel, or, which is the beſt, with dry and warm cat or hare fur. If the cover be now ſet on the cake by its inſulating handle, but without touching the cover, and again ſeparated from the cake, no electricity whatever is obſerved in the cover.

2. But if it be touched while on the cake, a ſharp pungent ſpark is obtained from it; and if, at the ſame time, the ſole be touched with the thumb, a very ſenſible ſhock is felt in the finger and thumb.

3. After this, the electrophorus appears quite inactive, and is ſaid to be *dead*; neither ſole nor cover giving any ſign of electricity. But,

4. When the cover is raiſed to ſome diſtance from the cake (keeping it parallel therewith), if it be touched while in this ſituation, a ſmart ſpark flies, to ſome diſtance, between it and the finger, more remarkably from the upper ſide, and ſtill more from its edge, which will even throw off ſparks into the air, if it be not rounded off. As this diminiſhes the deſired effects, it is proper to have the edge ſo rounded. This ſpark is not ſo ſharp as the former, and reſembles that from any electrified conductor.

5. The electricity of the cover, while thus raiſed, is of the oppoſite kind to that of the cake, or is poſitive.

6. The electricity of the cover while lying on the cake is the ſame with that of the cake, or negative.

7. The appearances n° 2, 3, 4, may be repeated for a very long time without any ſenſible diminution of their vivacity. The inſtrument has been known to retain its power undiminiſhed even for months. This makes it a ſort of magazine of electricity, and we can take off the electricity of the cake and of the cover as charges for ſeparate jars, the cover, when raiſed, charging like the prime conductor of an ordinary electrical machine; and, when ſet on the cake, charging it like the rubber. This cauſed the inventor, Mr Volta, to give it the name of ELECTROPHORUS.

8. If the ſole be inſulated before putting on the cover, the ſpark obtained from the cover is not of that cutting kind it was before: but the ſame ſhock will be felt if both cake and cover be touched together.

9. If the cover be again raiſed to a conſiderable height, the ſole will be found electrical, and its electricity is that of the cake, and oppoſite to that of the cover.

10. After touching both cover and ſole, if the cover be raiſed and again ſet down, without touching it while aloft, the whole is again inactive.

11. If both cover and ſole be made inactive when joined, they ſhew oppoſite electricities when ſeparated, the ſole having the electricity of the cake.

12. If both cover and ſole be made inactive when ſeparate, they both ſhew the oppoſite to the electricity of the cake when joined.

187 Diſpoſition of the fluid. Let us now attend to the diſpoſition of the electrical fluid in the different parts of the inſtrument in their various ſituations, and to the forces which operate mutually between them. *N. B.* Experiments for examining this inſtrument are beſt made by ſetting the three plates vertically, ſupported on glaſs ſtalks, with leaden feet, to ſteady them. A very ſmall electrometer may be attached to the outer ſurfaces of the cover and ſole.

If the extent of the plates were incomparably greater than their thickneſs, we may infer from n° 92, &c. that the redundant fluid and matter would be diſpoſed in parallel ſtrata, and that the actions would be the ſame at all diſtances. But ſince this is not the caſe, the diſpoſition of the fluid will be ſomewhat different; and whatever it is, the action of any ſtratum will be diminiſhed by an increaſe of diſtance. The following deſcription cannot be very different from the truth:

I. The cake grows negative by cooling; and if it

188 Explanation of the *primitive ſtate.* were alone, it would have a negative ſuperficial ſtratum on both ſides, of greater thickneſs near the edges; and the fluid would probably grow denſer by degrees to the middle, where it would have its natural denſity. This diſpoſition may be inferred from n° 92, 93, and 98. But it cools in conjunction with the ſole, and the attraction of the redundant matter in the cake; for the moveable fluid in the ſole diſturbs its uniform diffuſion in the ſole, and cauſes it to approach the cake. And becauſe this, in all probability, happens while the cake is ſtill a conductor, the diſpoſition of its fluid will be different from that deſcribed above, and the final diſpoſition of the fluid in the cake and ſole will reſemble that deſcribed in n° 95, where the plates E and A repreſent the cake and ſole. But becauſe we do not know preciſely the gradation of denſity, and aim only at general notions at preſent, it will be ſufficient to conſider the cake and ſole as divided into two ſtrata only; one redundant in fluid, and the other deficient, neglecting the neutral ſtratum that is interpoſed between them in each. The cake, then, conſiſts of a ſtratum $ABbaA$ containing redundant matter, and a ſtratum $abCD$ containing redundant fluid: and the ſole has a ſtratum $DCnm$ containing redundant fluid, namely, all that belongs naturally to the ſpace DCFE, and a ſtratum $mnFE$ containing redundant matter. This may be called the PRIMITIVE STATE of the cake and ſole; and if once charged by communication with unelectrified bodies, it can never be recovered again without ſome new excitement.

189 *Common ſtate.* II. If the ſole be touched by any body communicating with the ground, fluid will come in, till the repulſion of the redundant fluid in the ſole for a ſuperficial particle y is equal to the attraction of the redundant matter in the cake for the ſame particle. What has been ſaid concerning infinitely extended plates rendered neutral on one ſide, may ſuffice to give us a notion of the preſent diſpoſition of the fluid in the ſole. The under ſurface will be neutral, and the fluid will increaſe in denſity toward the ſurface DC. The ſole contains more than its natural quantity of fluid, but is neutral by the balance of oppoſite forces. Let it now be inſulated. This diſpoſition of fluid may be called the *common ſtate* of the electrophorus.

190. III. Let the cover GHBA be laid on it. The particle z, at the upper ſurface of the cover, muſt be more attracted by the redundant matter in the ſtratum $ABba$ than it is repelled by the redundant fluid in the remoter ſtrata; for the fluid in the cake is leſs than what belongs to it in its natural ſtate, and therefore z is attracted by the cake. The redundant fluid which has come into the remote ſide of the ſole is leſs than what would ſaturate the redundant matter of the cake, becauſe it only balances the exceſs of the remote action of this matter above the nearer action of the compreſſed fluid in the ſole; and this ſmaller quantity of redundant fluid acts on z at a greater diſtance than that of the redundant matter in the cake. On the whole, therefore, the particle z, lying immediately within the ſurface GH, is attracted; therefore ſome will move toward the cake, and its natural ſtate of uniform diffuſion through the cover will be changed into a violent ſtate, in which it will be compreſſed on the ſurface AB, being abſtracted from the ſurface GH. It will now have a ſtratum $GgpH$, containing redundant matter, and another $gpBA$, containing redundant fluid. But this will diſturb the arrrangement which had taken place in the ſole, and had rendered it neutral on the under ſurface. We do not attend to the fluid in the cake, but conſider it as immoveable; for any motion which it can get will be ſo ſmall, that the variations of its action will be altogether inſignificant. The particle y, ſituated in that ſurface, will be more repelled by the compreſſed fluid in the ſtratum $gpCA$ than it is attracted by the equivalent, but more remote redundant matter in $GHpg$. Fluid is therefore diſpoſed to quit the ſurface EF, and the ſole appears poſitively electric; very little indeed, if the cover be thin. All this may be obſerved by attaching a ſmall Canton's electrometer to the lower ſurface of the ſole, or by touching the ſole with the electrometer of fig. 8. and then trying its electricity by rubbed wax or glaſs.

191. IV. A particle of fluid z, placed immediately without the ſurface GH, will be more attracted by the deficient ſtratum $GHpg$ and by $ABba$ than it is repelled by the redundant ſtrata beyond them, and the cover muſt be ſenſibly negative. This is the common ſtate of the whole inſtrument after ſetting on the cover. It is ſlightly poſitive on the lower ſurface of the ſole, and much more ſenſibly negative on the upper ſurface of the cover. A ſmart ſpark will therefore be ſeen between it and the finger, fluid will enter, till the attraction of the redundant matter in $ABba$ is balanced by the repulſion of the redundant fluid in DCFE.

192 *Dead ſtate.* V. A ſpark will now be obtained from the ſole, becauſe it was faintly poſitive before, and there has been added the action of the fluid which has entered into the cover. The fluid in the ſole is therefore diſpoſed to fly to any body preſented to it. But when this has happened, the equilibrium at the ſurface GH is deſtroyed. and that ſurface again becomes negative, and will attract fluid, although the cover already contains more than its natural quantity. A ſmall ſpark will therefore be ſeen between the cover and any conducting body preſented to it. By touching it, the neutrality or equilibrium is reſtored at GH; but it is deſtroyed again at EF, which will again give a poſitive ſpark, which, in its turn, again leaves GH negative. This will go on for ever, in a ſeries of communications continually diminiſhing, ſo as ſoon to become inſenſible, if the three parts of the electrophorus be thin. This makes it proper to make them otherwiſe, if the inſtrument be intended for illuſtrating the theory.

At laſt the equilibrium is completed at the ſurfaces GH and EF, and both are neutral in relation to ſurrounding bodies, although both the cover and ſole contain more than their natural ſhare of electric fluid. We may call this the NEUTRAL or DEAD ſtate of the electrophorus.

193 *Charged ſtate.* This ſtate may be produced at once, inſtead of doing it by theſe alternate touches of GH and EF. If we touch at once both theſe ſurfaces, we have a bright, pungent ſpark, and a ſmall ſhock. If this be the object of the experiment, the ſtate N° IV. which gives occaſion to it, may be called the CHARGED ſtate of the electrophorus.

When the inſtrument has thus been rendered neutral in relation to ſurrounding bodies, it is plain that it may continue in this ſtate for any length of time without any diminution of its capability of producing the other phenomena,

phenomena, provided only that no fluid paſs from the cover to the cake. We do not *fully* underſtand what prevents this communication, nor indeed what prevents the rapid eſcape from an overcharged body into the air. This cauſe, whatever it be, operates here; and the beſt way of preventing the diſſipation, or the abſorption by the cake, is to keep the electrophorus with its cover on. It will come into this neutral ſtate by diſſipation from the ſole, and abſorption by the cover, in no very long time; and after this, will remain neutral, retaining its power with great obſtinacy, eſpecially if the cake and plates are very thin.

194 Charging or ive ſtate. VI. If the cover be now removed to a diſtance, both parts of the apparatus will ſhew ſtrong marks of electricity. The cover contains much redundant fluid, and muſt appear ſtrongly poſitive, and will give a bright ſpark, which may be employed for any purpoſe. It may be employed for charging a jar poſitively by the knob, if we juſt touch the cover with the knob. The ſole will attract fluid, or be negative, although it contain more than its natural quantity of fluid, and it will take a ſpark. The ſole therefore, in the abſence of the cover, may be employed to charge a jar negatively by the knob. By touching it with the finger, or with the knob of a jar held in the hand, it is reduced to the common ſtate deſcribed in N° II.; and now all the former experiments may be repeated. We may call this the ACTIVE or the CHARGING ſtate.

lectrophorus not magazine electricity, but a llecting achine. This ſtate of the apparatus has cauſed it to get the name *Electrophorus*. Volta, its undoubted inventor, called it *Electroforo perpetuo*; for it *appears*, as has been already obſerved, to contain a magazine of electricity. The cover, when removed, will charge a jar held in the hand poſitively; and having done this ſervice, it will charge a jar negatively when again ſet on the cake. The ſole, in the abſence of the cover, will charge a third jar negatively; and then, when the cover, after being touched, is ſet down again, it will charge a fourth jar poſitively. It will not be difficult to contrive a ſimple mechaniſm, connected with the motion of the cover, which ſhall connect the joined parts with two jars, and ſhall connect them, when ſeperated, with two others; and thus charge all the four with great expedition. All this is done without any new excitation of the electrophorus. But it is by no means a *magazine* of electricity which it gradually expends: it is a COLLECTOR of electricity from the ſurrounding bodies, which it afterwards imparts to others, and may be employed to diſcharge jars in the ſame gradual manner as to charge them.

195. VII. If the electrophorus is not inſulated, a ſhock may ſtill be obtained, by firſt touching the ſole, and then, without removing the finger, touching the cover: but this will not be ſo ſmart as when the negative cover is touched at the ſame time that we touch the ſole, more highly poſitive than when it communicates with the ground. The difference muſt, however, be almoſt imperceptible when the pieces are thin.

196. VII. If the electrophorus is not inſulated, the cover, when put on, will give a ſpark in the manner already mentioned, and it will be ſomewhat ſtronger than when it is inſulated; becauſe the fluid is allowed to eſcape from the ſole, and does not obſtruct the entry into the cover. If we then, without removing the finger from the cover, touch the ſole, nothing is felt; but if we firſt touch the ſole, and, without removing the finger from it, touch the cover, we obtain a ſhock. This is evident from the theory. By this ſeries of alternate touches, the period of the electrophorus is completed. The electrophorus is charged, or rendered neutral, by touching the plates when joined; then, by touching both when ſeparated, the whole is reduced to the common ſtate. When ſeparated, from being in the neutral ſtate, they have oppoſite electricities, the ſole ſhewing that of the cake. When brought together, each in the common ſtate, they have oppoſite electricities, the cover ſhewing that of the cake.

197 How it may be recreated. IX. When, by long expoſure to the air without its cover, the electrophorus has loſt its virtue, it may be brought again into an active ſtate in a variety of ways. Its ſurface may be rendered negative by friction with dry cat or hare ſkin, or warm flannel. It may be rendered negative by ſetting on it a jar charged negatively on the inſide, and then touching the knob with any thing communicating with the ground. This is the moſt expeditious method, and will give it a high degree of excitation, if the jar be of ſize, and if the electrophorus be covered with a plate of tinfoil which comes into contact all over its ſurface. This however requires the previous charging of the jar; therefore it will be as expeditious and effectual to connect this ſurface with the rubber of an electrical machine. We had almoſt forgotten to remark, that the effects of bringing the cover edgewiſe to the cake follow clearly from the theory, as will appear to the attentive reader without further explanation.

198 It is not ſimilar to a charged pane. The electrophorus has been compared to a charged plate of coated glaſs. It is true that it *may be brought* into an external ſtate which very much reſembles a charged pane; namely, when the cover, in its natural ſtate, is ſet on the electrophorus in its natural ſtate: and accordingly it gives a ſhock, and the two exterior ſurfaces become neutral; but the internal conſtitution, and the acting forces, are totally and *eſſentially* different. The two coatings of the pane would not, when ſeparated, exhibit the appearances of the electrophorus; nor, when touched in their disjoined ſtate, will they pruduce the ſame effects when joined. In the operation of coated glaſs, the conſtant or invariable part, the glaſs is not the *agent*, it is merely the *occaſion* of the action, by *allowing* the accumulation. In the electrophorus, the electric, which is the conſtant invariable part, is the *agent producing* the accumulation. The electrophorus is an original, and a very ingenious and curious electrical machine. Nothing has ſo much contributed to ſpread ſome general, though ſlight, acquaintance with the mechanical principles of electricity. The numerous dabblers in natural knowledge had been diverted from ſcientific purſuit by the variety of the ſingular and amuſing effects of electricity, and had really attained very little connected knowledge. The effects of the electrophorus *forced* this knowledge on them; becauſe no uſe can be made of it without a pretty clear conception of the diſpoſition of the electricity, and the kind and intenſity of the actions. It is therefore moſt ungrateful in the experimenters who have attained better views, to attempt to rob Mr Volta of the real merit of diſcovery, by ſhewing that its effects are ſimilar to thoſe of Mr Symmer's ſtockings, or of Cigna's plates, or of Franklin's charged or diſcharged glaſs panes. And the attempt

tempt deſtroys itſelf: for it ſhews the ignorance or inattention of its author; for the ſimilarity is not real, as will appear clear to any perſon who will examine things minutely and ſcientifically, proceeding in this examination on ſuppoſitions ſimilar to thoſe which we employed in the analyſis of Richmann's experiment. It was indeed in ſubſerviency to this examination that we entered into the detail of that experiment, it being a ſimpler caſe. The accurate examination of Richmann's experiment requires the fluxionary calculus in its refined form. In the preſent queſtion five acting ſtrata are to be conſidered, which renders the formulæ very complicated, and indeed intractable, unleſs we make the plates extremely thin; which, fortunately, is the beſt form of the inſtrument. We have completed this mathematical analyſis; and the popular view here given is the reſult of that computation.

199 *Condenſator of electricity.* The electricians are no leſs obliged to Mr Volta for another machine, or inſtrument, from which the ſtudy of Nature's operations has derived, or may derive, immenſe advantages. We mean the CONDENSER or COLLECTOR of electricity. We refer to the article ELECTRICITY in the *Encyclopædia* for a deſcription of the inſtrument, and ſome account of its effects and properties. The general effect is to render ſenſible an accumulation or deficiency of electric fluid ſo ſlight that it will not affect the moſt delicate electrometer; and it produces (at leaſt in the opinion of Mr Volta) this effect, by employing for the ſole of an electrophorus a body which is an imperfect conductor, ſuch as a plate of well dried marble, or well dried, but not baked, wood; or even a conducting body, covered with a bit of dry taffety or other ſilk. Mr Volta, Cavallo, and others, who have written a great deal on the ſubject, have attempted to ſhew how theſe ſubſtances are preferable (and they certainly are preferable in a high degree) to more perfect inſulators: but not having taken pains to form preciſe notions of the diſpoſition and action of the electric fluid in the ſituations afforded by the inſtrument, their reaſonings have not been very clear. We think that an adequate conception of the eſſentials of the propoſed inſtrument may be acquired by means of the following conſiderations:

200. Furniſh the cover of an electrophorus with a graduated electrometer, which indicates the proportional *degrees of electricity*; electrify it poſitively to any degree, ſuppoſe ſix, while held in the hand, at ſome diſtance, right over a metal plate lying on a wine glaſs as an inſulating ſtand, but communicating with the ground by a wire. Bring it gradually down toward the plate. Theory teaches, and we know it by experiment, that the electrometer will gradually ſubſide, and perhaps will reach to 2° before the electricity is communicated in a ſpark. Stop it before this happens. In this ſtate the attraction of the lying plate produces a compenſation of four degrees of the mutual repulſion of the parts of the cover, by conſtipating the fluid on its under ſurface, and forming a deficient ſtratum above. This needs no farther explanation after what has been ſaid on the charging of coated glaſs plates. Now we can ſuppoſe that the eſcape of the fluid from this body into the air begins as ſoon as electrified to the degree 6, and that it will fly to the lying plate with the degree 2, if brought nearer. If we can prevent this communication to the lying plate, by interpoſing an electric, we may electrify the cover again, while ſo near the metal plate, to the degree 6, before it will ſtream off into the air. If it be now removed from the lying plate, the fluid would raiſe the electrometer to 10, did it not immediately ſtream off; and an electric excitement of any kind which could only raiſe this body to the degree 6 by its intenſity, will, by this apparatus, raiſe it to the degree 10, if only copious enough in extent. If we do the ſame thing when the wire is taken away which connects the lying plate with the ground, we know that the ſame diminution of the electricity of the other plate cannot be produced by bringing it down into the neighbourhood of the lying plate (ſee nº 134, &c. 151, &c.)

Theory thereof. Here we ſee the whole theory of Mr Volta's condenſer. He ſeems to have obſcured his conceptions of it by having his thoughts running upon the electrophorus lately invented by him, and is led into fruitleſs attempts to explain the advantages of the imperfect conductor above the perfect inſulator. But the apparatus is altogether different from an electrophorus, and is more analogous in its operations to a coated plate not charged nor inſulated on the oppoſite ſide; and ſuch a coated plate lying on a table is a complete condenſer, if the upper coating be of the ſame ſize with the plate of the condenſer. All the directions given by Mr Volta for the preparation of the imperfect conductors ſhew, that the effect produced is to make them as perfect conductors as poſſible for any degree of electricity that exceeds a certain ſmall intenſity, but ſuch as ſhall not ſuffer this very weak electricity to clear the firſt ſtep of the conduit. The marble muſt be thoroughly dried, and even heated in an oven, and either uſed in this warm ſtate, or varniſhed, ſo as to prevent the reabſorption of moiſture. We know that marble of ſlender dimenſions, ſo as to be completely dried throughout, will not conduct till it has again become moiſt. A thick piece of marble is rendered ſo, ſuperficially only, and ſtill conducts internally. It is then in the beſt poſſible ſtate. The ſame may be ſaid of dry unbaked wood. Varniſhing the upper ſurface of a piece of marble or wood is equivalent to laying a thin glaſs plate on it. Now this method, or covering the top of the marble, or of a book, or even the table, with a piece of clean dry ſilk, makes them all the moſt perfect condenſators. This juſt view of the matter has great advantages. It takes away the myſterious indiſtinctneſs and obſcurity which kept the inſtrument a quackiſh tool, incapable of improvement. We can now make one incomparably better and more ſimple than any propoſed by the very ingenious inventor. We need only the ſimple moveable plate. Let this be varniſhed on the under ſide with a moderately thick coat of the pureſt and hardeſt *vernis de Martin*, or coach-painters varniſh; and we have a complete condenſator by laying this on a table. If it be connected by a wire with the ſubſtance in which the weak and imperceptible electricity is excited, it will be raiſed (provided there be enough of it of that ſmall intenſity) in the proportion of the thickneſs of the varniſh to the fourth part of the diameter of the plate. This degree of condenſation will be procured by detaching the connecting wire from the inſulating handle of the condenſer, and then raiſing the condenſer from the table. It will then give ſparks, though the original electricity could not ſenſibly affect a flaxen fibre.

It muſt be particularly noted, that it can produce this condenſation only when there is fluid to condenſe; that is, only when the weak electricity is diffuſed over a greater ſpace than the plate of the condenſer. In this way it is a moſt excellent collector of the weak atmoſpheric electricity, and of all diffuſed electricity. But to derive the ſame advantage from it *in many very intereſting caſes*, ſuch as the inquiry into the electricity excited in many operations of Nature on ſmall quantities of matter, we muſt have condenſers of various ſizes, ſome not larger than a ſilver penny. To conſtruct theſe in perfection, we muſt uſe the pureſt and hardeſt varniſh, of a kind not apt to crack, and highly coercive. This requires experiment to diſcover it. Spirit varniſhes are the moſt coercive; but by their difference of contraction by cold from that of metals, they ſoon appear froſty, and when viewed through a lens, they appear all ſhivered: They are then uſeleſs. Oil varniſhes have the requiſite toughneſs, but are much inferior in coercion. We have found amber varniſh inferior to copal varniſh in this reſpect, contrary to our expectation. On the whole, we ſhould prefer the fineſt coach-painters varniſh, new from the ſhop, into which a pencil has never been dipped: and we muſt be particularly careful to clear our pencils of moiſture and all conducting matter, which never fails to taint the varniſh. We ſcarcely need remark, that the coat of varniſh on theſe ſmall condenſers ſhould be very thin, otherwiſe we loſe all the advantage of their ſmallneſs.

201 avallo's nprovement hereof. Mr Cavallo has ingeniouſly improved Volta's condenſer by connecting the moveable plate, after removal, with a ſmaller condenſer. The effect of this is evident from nº 130. But the ſame thing would have been generally obtained by uſing the ſmall condenſer at firſt, or by uſing a ſtill thinner coat of varniſh.

202. It will readily occur to the reader, that this inſtrument is not inſtantaneous in its operation, and that the application muſt be continued for ſome time, in order to collect the minute electricity which may be excited in the operations of nature. He will alſo be careful that the experiment be ſo conducted that no uſeleſs accumulation is made anywhere elſe. When we expect electricity from any chemical mixture, it never ſhould be made in a glaſs veſſel, for this will take a charge, and thus may abſorb the whole excited electricity, accumulating it in a neutral or inſenſible ſtate. Let the mixture be made in veſſels of a conducting ſubſtance, inſulated with as little contact as poſſible with the inſulating ſupport; for here will alſo be ſomething like a charge. Suſpend it by ſilk threads, or let it reſt on the tops of three glaſs rods, &c.

203 ennet's *ubler* of lectricity. After this account of the Leyden phial, electrophorus, and condenſer, it is ſurely unneceſſary to employ any time in explaining Mr Bennet's moſt ingenious and uſeful inſtrument called the *doubler of electricity*. The explanation offers itſelf ſpontaneouſly to any perſon who underſtands what has been ſaid already. Mr Cavallo has with induſtry ſearched out all its imperfections, and has done ſomething to remove them, by ſeveral very ingenious conſtructions, minutely deſcribed in his Treatiſe on Electricity. Mr Bennet's original inſtrument may be freed, we imagine, as far as ſeems poſſible, by uſing a plate of air as the intermedium between the three plates of the doubler. Stick on one of the plates three very ſmall ſpherules made from a capillary tube of glaſs, or from a thread of ſealing wax. The other plate being laid on them, reſts on mere points, and can ſcarcely receive any friction which will diſturb the experiment. Mr Nicholſon's beautiful mechaniſm for expediting the multiplication, has the inconveniency of bringing the plates towards each other edgewiſe, which will bring on a ſpark or communication ſooner than may be deſired: but this is no inconvenience whatever in any philoſophical reſearch; becauſe, before this happens, the electricity has become very diſtinguiſhable as to its kind, and the degree of multiplication is little more than an amuſement. The ſpark may even ſerve to give an indication of the original intenſity, by means of the number of turns neceſſary for producing it. If the fine wires, which form the alternate connections in ſo ingenious a manner, could be tipped with little balls to prevent the diſſipation, it would be a great improvement indeed. An alternate motion, like that of a pump-handle, might be adopted with advantage. This would allow the plates to approach each other face to face, and admit a greater multiplication, if thought neceſſary.

204 Diſſipation of electricity from ſharp points. One of the moſt remarkable facts in electricity is the rapid diſſipation by ſharp points, and the impoſſibility of making any conſiderable accumulation in a body which has any ſuch, projecting beyond other parts of its ſurface. The diſſipation is attended with many remarkable circumſtances, which have greatly the appearance of the actual eſcape of ſome material ſubſtance. A ſtream of wind blows from ſuch a point, and quickly electrifies the air of a room to ſuch a degree, that an electrometer in the fartheſt corner of the room is affected by it. This diſſipation in a dark place is, in many inſtances, accompanied by a bright train of light diverging from the point like a firework. Dr Franklin therefore was very anxious to reconcile this appearance with his theory of plus and minus electricity, but does not expreſs himſelf well ſatisfied with any explanation which had occurred to him. From the beginning, he ſaw that he could not conſider the ſtream of wind as a proof of the eſcape of the electric fluid, becauſe the ſame ſtream is obſerved to iſſue from a ſharp negative point; which, according to his theory, is not diſperſing, but abſorbing it. Mr Cavendiſh has, in our opinion, given the firſt ſatisfactory account of this phenomenon.

205. To ſee this in its full force, the phenomenon itſelf muſt be carefully obſerved. The ſtream of wind is plainly produced by the eſcape of ſomething from the point itſelf, which hurries the air along with it; and this draws along with it a great deal of the ſurrounding air, eſpecially from behind, in the ſame manner as the very ſlender thread of air from a blow-pipe hurries along with it the ſurrounding air and flame from a conſiderable ſurface on all ſides. It is in this manner that it gathers the whole of a large flame into one maſs, and, at laſt, into a very point. If the ſmoke of a little roſin thrown on a bit of live coal be made to riſe quietly round a point projecting from an electrified body, continually ſupplied from an electrical machine, the vortices of this ſmoke may be obſerved to curl in from all ſides, along the wire, forming a current of which the wire is the axis, and it goes off completely by the point. But if the wire be made to paſs through a cork fixed in the bottom of a wide glaſs tube, and if its point project not beyond the mouth of the tube,

the afflux of the air from behind is prevented, and we have no ſtream; but if the cork be removed, and the wire ſtill occupy the axis of the tube, but without touching the ſides, we have the ſtream very diſtinctly; and ſmoke which riſes round the far end of the tube is drawn into it, and goes of at the point of the wire. Now it is of importance to obſerve, that whatever prevents the formation of this ſtream of wind prevents the diſſipation of electricity (for we ſhall not ſay eſcape of electric fluid) from the point. If the point project a quarter of an inch beyond the tube, or if the tube be open behind, the ſtream is ſtrong, and the diſſipation ſo rapid, that even a very good machine is not able to raiſe a Henly's electrometer, ſtanding on the conductor, a very few degrees. If the tube be ſlipped forward, ſo that the point is juſt even with its mouth, the diſſipation of electricity is next to nothing, and does not exceed what might be produced by ſuch air as can be collected by a ſuperficial point. If the tube be made to advance half an inch beyond the point which it ſurrounds, the diſſipation becomes inſenſible. All theſe facts put it beyond a doubt that the air is the cauſe, or, at leaſt, the occaſion of the diſſipation, and carries the electricity off with it, in this manner rendering electrical the whole air of a room. The problem is reduced to explain how the air contiguous to a ſharp electrified point is electrified and thrown off.

Theory of it. It was demonſtrated in n° 130, that two ſpheres, connected by an infinitely extended, but ſlender conducting canal, are in electrical equilibrium, if their ſurfaces contain fluid in the proportion of their diameters. In this caſe, the ſuperficial denſity of the fluid and its tendency to eſcape are inverſely as the diameters (n° 130). Now if, in imagination, we gradually diminiſh the diameter of one of the ſpheres, the tendency to eſcape will increaſe in a greater proportion than any that we can name We know, that when the prime conductor of a powerful table-machine has a wire of a few inches in length projecting from its end, and terminating in a ball of half an inch in diameter, we cannot electrify it beyond a certain degree; for when arrived at this degree, the electricity flies off in ſucceſſive burſts from this ball. Being much more overcharged than any other part of the body, the air ſurrounding the ball becomes more overcharged by communication, and is repelled, and its place ſupplied by other air, not ſo much overcharged, which ſurrounded the other parts of the body, and is preſſed forwards into this ſpace by the general repulſion of the conductor and the confining preſſure of the atmoſphere; otherwiſe, being alſo overcharged, it would have no tendency to come to this place. Half a turn of the cylinder is ſufficient to accumulate to a degree ſufficient for producing one of theſe exploſions, and we have two of them for every turn of the cylinder, A point may be compared to an incomparably ſmaller ball. The conſtipation of the fluid, and its tendency to eſcape, muſt be greater in the ſame unmeaſurable proportion. This denſity and mutual repulſion cannot be diminiſhed, and muſt even be increaſed, by the matter of the wire forming a cone of which the point is the apex; therefore, if there were no other cauſe, we muſt ſee that it is almoſt impoſſible to confine a collection of particles, mutually repelling, and conſtipated, as theſe are in a fine point.

206 Electricity unites chemically with air. But the chief cauſe ſeems to be a certain chemical union which takes place between the electric fluid and a correſponding ingredient of the air. In this ſtate of conſtipation, almoſt completely ſurrounded by the air, the little maſs of fluid muſt attract and be attracted with very great force, and more readily overcome the force which keeps the electrified fluid attached to the laſt ſeries of particles of the wire. It unites with the air, rendering it electric in the higheſt degree of redundancy. It is therefore ſtrongly repelled by the maſs of conſtipated fluid which ſucceeds it within the point. Thus is the electrified air continually thrown off, in a ſtate of electrification, that muſt rapidly diminiſh the electricity of the conductor. Hence the uninterrupted flow, without noiſe or much light, when the point is made very fine. When the point is blunt, a little accumulation is neceſſary before it attains the degree neceſſary for even this minute exploſion; but this is ſoon done, and theſe little exploſions ſucceed each other rapidly, accompanied by a ſputtering noiſe, and trains of bright ſparks. The noiſe is undoubtedly owing to the atoms of the highly electrified fluid. Theſe are, in all probability, rarefied of a ſudden, in the act of electrification, and immediately collapſe again in the act of chemical union, which cauſes a ſonorous agitation of the air. This electrified air is thus thrown off, and its place is immediately ſupplied by air from behind, not yet electrified, and therefore ſtrongly drawn forward to the point, from which they are thrown off in their turn. This rapid expanſion and ſubſequent collapſing of the air is verified by the experiments of Mr Kinnerſly, related by Dr Franklin, and is ſeen in numberleſs experiments made with other views in later times, and not attended to. Perhaps it is produced by the great heat which accompanies, or is generated in the transference of electricity; and it is of the ſame kind with what occaſions the burſting of ſtones, ſplitting of trees, exploding of metals, &c. by electricity. The expanſion is either inconſiderable, or it is ſucceſſively produced in very ſmall portions of the ſubſtance expanded; for when metal is exploded in cloſe veſſels, or under water, there is but a minute portion of gazeous matter produced; and in the diſſipation by a very fine point, ſufficiently great to give full employment to a powerful machine, the ſtream of wind is but very faint, and nine-tenths of this has been dragged along by the really electrified thread of wind in the middle.

From a collation of all the appearances of electricity, we muſt form the ſame conception of the forces which operate round a point that is negatively electrified, not diſperſing, but drawing in electric fluid. It is more completely undercharged than any other part of a body, and attracts the fluid in the ſurrounding air, and the air in which it is retained, with incomparably greater force. It therefore deprives the contiguous air of its fluid, and then repels it, and then produces a ſtream like the overcharged point.

207. If a conducting body be brought near to any part of an overcharged body, the fronting part of the firſt is rendered undercharged; and this increaſes the charge of the oppoſite part of the overcharged body. It becomes more overcharged in that part, and ſooner attains that degree of conſtipation that enables the fluid to quit the ſuperficial ſeries of particles, and to electrify ſtrongly the contiguous air. The exploſion is therefore made in this part in preference to any other; and the

the air thus exploded is ſtrongly attracted by the fronting part of the other body, and muſt fly thither in preference to any other point. If, moreover, the fronting part of A be prominent or pointed, this effect will be produced in a ſuperior degree; and the current of electrified air, which will begin very early, will increaſe this diſpoſition to transference in this way by rarefying the air; a change which the whole courſe of electric phenomena ſhews to be highly favourable to this transference, although we cannot perhaps form any very adequate notion how it contributes to this effect. This ſeems to be the reaſon why a great exploſion and ſnap, with a copious transference of electricity, is generally preceded by a hiſſing noiſe like the ruſhing of wind, which ſwells to a maximum in the loud ſnap itſelf.

208. If two prominences, preciſely ſimilar, and electrified in the contrary way to the ſame degree, are preſented to each other, we cannot ſay from which the current ſhould take its commencement, or whether it ſhould not equally begin from both, and a general diſperſion of air laterally be the effect; but ſuch a ſituation is barely poſſible, and muſt be infinitely rare. The current will begin from the ſide which has ſome ſuperiority of propelling force. We are diſpoſed to think that this current of material electrified ſubſtance muſt ſuffer great change during its paſſage, by mixing with the current in an oppoſite electrical ſtate coming from the other body. Any little maſs of the one current muſt ſtrongly attract a contiguous maſs of the other, and certain changes ſhould ſurely ariſe from this mixture. Theſe may, in their turn, make a great change in the *mechanical* motions of the air; and, inſtead of producing a *quaqua verſum* diſperſion of air from between the bodies, as ſhould reſult from the meeting of oppoſite ſtreams, it may even produce a collapſing of the air by the mutual ſtrong attractions of the little maſſes. Many valuable experiments offer themſelves to the curious inquirer. Two little balls may be thus preſented to each other, and a ſmoke may be made with roſin to occupy the interval between them. Motions may be obſerved which have certain analogies that would afford uſeful information to the mechanical inquirer. There muſt be ſomething of this mixture of currents in all ſuch transferences, and the moſt minute differences in the condition of a little parcel of the air may greatly affect the future motions. The moſt promiſing form of ſuch experiment would be to uſe two points of the ſame ſubſtance, ſhape, and ſize, and electrified to the ſame degree in oppoſite ſenſes.

aracter-
c differ-
ces of po-
ve and
gative
ctricity.

After all care has been taken to inſure ſimilarity, there remains one eſſential difference, that *the one current is redundant in electric fluid, and the other deficient*. This circumſtance *muſt* produce characteriſtic differences of appearance. And are there not ſuch differences? Is not the pencil and the ſtar of light a characteriſtic difference? And does not this well-ſupported fact greatly corroborate the opinion of Dr Franklin, that the electric phenomena reſult from the redundancy and deficiency of *one* ſubſtance, and not from two diſtinct ſubſtances operating in a ſimilar manner? For the diſtinction in appearance is a mechanical diſtinction. Motion, direction, velocity, are perceivable in it. Locomotive forces are concerned in it; but they are ſo implicated with forces which probably reſemble chemical affinities, hardly operating beyond contact, that to extricate their effects from the complicated phenomenon ſeems a deſperate problem. There is ſome hitherto inexplicable chemical compoſition and decompoſition taking place in the transference of electricity. Of this a numerous train of obſervations made ſince the dawn of the pneumatic chemiſtry leaves us no room to doubt. The emerſion or production of light and heat is a remarkable ſign and proof. Now *this takes place along the whole path of transference*; therefore the proceſs is by no means completed at the point from which the active cauſe proceeds; and although there be certain appearances that are pretty regular, they are ſtill mixed with others of the moſt capricious anomaly. The zigzag form of the moſt condenſed ſpark, totally unlike, by its ſharp angles, to any motions producible by accelerating forces, which motions are, without exception, curvilineal, makes us doubt exceedingly whether the luminous lines which we obſerve are ſucceſſive appearances of the ſame matter in different places, or whether they be not rather ſimultaneous, or nearly ſimultaneous, coruſcations of different parcels of matter in different places, indicating chemical compoſitions taking place almoſt at once; and this becomes more probable, when we reflect on what has been ſaid already of the jumbling of oppoſite currents; ſuch mixtures ſhould be expected. We have ſeen a darted flaſh of lightning which reached (in a direction nearly parallel to the horizon) above three miles from right to left; and it ſeemed to us *to be co-exiſtent*; we could not ſay at which end it began. The thunder began with a loud crack, and continued with a moſt irregular rumbling noiſe about 15 ſeconds, and ſeemed equal on both hands. We imagine that it was really a ſimultaneous ſnap, in the whole extent of the ſpark, but of different ſtrength in different places; different portions of the ſonorous agitation were propagated to the ear in ſucceſſion by the ſonorous undulations of air, cauſing it to ſeem a lengthened ſound. Such would be the appearance to a perſon ſtanding at one end of a long line of ſoldiers who diſcharge their firelocks at one inſtant. It will ſeem a running fire, of different ſtrength in different parts of the line, if the muſkets have been unequally loaded. It is inconceivable that this long zigzag ſpark can mark the track of an individual maſs of electrified air. The velocity and momentum would be enormous, and would ſweep off every thing in its way, and its path could not be angular. The ſame muſt be aſſerted of the ſtreams of light in our experiments. The velocity is ſo unmeaſurable that we cannot tell its direction. There may be very little local motion, juſt as in the propagation of ſound, or of a wave on the ſurface of water. That particular change of mutual ſituation among the adjoining atoms which occaſions chemical ſolution or precipitation may be produced in an inſtant, over a great extent, as we know that a parcel of iron filings, lying at random on the ſurface of quickſilver, will, in one inſtant, be arranged in a certain manner by the mere neighbourhood of a magnet. Is not this like the ſimultaneous precipitation of water along the whole path of a diſcharge?

But ſtill there muſt be ſome cauſe which gives theſe ſimultaneous coruſcations a ſituation with reſpect to each other, that has a certain regularity. Now the luminous *trains* (for they are not uniform *lines* of light) of almoſt continuous ſparks which are arranged between a poſitive and a negative point, ſeem to us to indicate emanation from the poſitive, and reception by the negative point. The general line has a conſiderable reſemblance to the path of a body projected from the poſitive point, repelled by it, and attracted by the negative point. This will appear to the mechanician on a very little reflection. If the curve were completely viſible, it would ſomewhat reſemble thoſe drawn between P and N in fig. 35. PABN overpaſſes the point N, and comes to it from behind; P *a b* N lies within the other, and arrives in a direction nearly perpendicular to the axis; P α BN deſcribes a ſtraight line, and arrives in the direction PN. As the chemical compoſition advances, the light is diſengaged or produced, and therefore the appearances are more rare as we advance farther in the direction in which they are produced; and there would perhaps be no appearance at all at the point where the motion ends, were it not that the few remaining parcels, where the compoſitions or decompoſitions have not been completed, are crowded together at the negative point, *incomparably* more than in any other part of the track. We think that theſe conſiderations offer ſome explanation of the appearance of the pencil and ſtar, which are ſo uniformly characteriſtic of the poſitive and negative electricities; but we ſee many grounds of uncertainty and doubt, and offer it with due diffidence.

210 Lichtenberg's electric writing affords diſtinctive marks of + and —

The curious figures obſerved by Mr Lichtenberg, formed by the duſt which ſettles on a line drawn on the face of a mirror by the poſitive and by the negative knobs of a charged jar, are alſo uniformly characteriſtic of the two electricities. Theſe are mechanical diſtinctions, indicating certain differences of accelerating forces. We muſt refer the curious reader to Lichtenberg's Diſſertations in the *Gottingen Commentaries*; to the *Publication of the Haarlem Society*; to the *Gotha Magazine*; to *Diſſertations by Spath* at Altdorff, and other German writers.

211 Diſſipation of electricity into the air is proportional to the denſity.

It only remains for us to take notice of the general laws of the diſſipation of electricity into the air, and along imperfect inſulators. On this ſubject we have ſome valuable experiments of Mr Coulomb, publiſhed in the Memoirs of the Academy of Sciences of Paris for 1785.

Theſe experiments were made with the aſſiſtance of an electrometer of a particular conſtruction, which ſhall be deſcribed under the article ELECTROMETER.

The general reſult of Mr Coulomb's experiments was, that the momentary diſſipation of moderate degrees of electricity is proportional to the degree of electricity at the moment. He found that the diſſipation is not ſenſibly affected by the ſtate of the barometer or thermometer; nor is there any ſenſible difference in bodies of different ſizes or different ſubſtances, or even different figures, provided that the electricity is very weak.
