SUPPLEMENT

TO THE THIRD EDITION OF THE

ENCYCLOPÆDIA BRITANNICA,

OR, A

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN TWO VOLUMES.

Illuſtrated with Fifty Copperplates.

By GEORGE GLEIG, LL. D. F.R.S. Edin.

NON IGNORO, QUÆ BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUÆ NON OPTIMA,
ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.——*Cicero.*

VOL. I.

THE SECOND EDITION, WITH IMPROVEMENTS.

Edinburgh:
PRINTED FOR THOMSON BONAR, PARLIAMENT-SQUARE;
BY *JOHN BROWN*, ANCHOR CLOSE, EDINBURGH.

1803.

[Entered in Stationers Hall.]

TO THE KING.

SIR,

It proceeds from no vain confidence in my own abilities, that I presume to solicit for this WORK *the Protection of a* MONARCH, *who is not more exalted in station, than he is distinguished, among the Potentates of the Earth, by his Taste in Literature, and his Patronage of Science and the Arts.*

In conducting to its conclusion the ENCYCLOPÆDIA BRITANNICA, *I am conscious only of having been uniformly influenced by a sincere desire to do Justice to those Principles of Religion, Morality, and Social Order, of which the Maintenance constitutes the Glory of Your* MAJESTY'S *Reign, and will, I trust, record Your Name to the latest Posterity, as the* Guardian of the Laws and Liberties of Europe.

The French Encyclopédie *has been accused, and justly accuſed, of having disseminated, far and wide, the seeds of Anarchy and Atheism. If the* ENCYCLOPÆDIA BRITANNICA *shall, in any degree, counteract the tendency of that pestiferous Work, even these two Volumes will not be wholly unworthy of Your* MAJESTY'S *Patronage; and the Approbation of my* SOVEREIGN, *added to the consciousness of my own upright intentions, will, to me, be an ample reward for the many years of labour which I have employed on them, and on the Volumes to which they are Supplementary. I am,*

SIR,

YOUR MAJESTY'S

Most faithful Subject,

And most devoted Servant,

STIRLING,
Dec. 10. 1800.

GEORGE GLEIG.

SUPPLEMENT

TO THE

ENCYCLOPÆDIA BRITANNICA.

ABACISCUS, in architecture, the ſame with Abacus; for which, ſee *Encyclopædia*.

ABATIS, or Abattis, is, in military language, the name of a kind of retrenchment made of felled trees. When the emergency is ſudden, the trees are merely laid lengthwiſe beſide each other, with their branches pointed towards the enemy, to prevent his approach, whilſt the trunks ſerve as a breaſtwork before thoſe by whom the abatis is raiſed. When the abatis is meant for the defence of a paſs or entrance, the boughs of the trees are generally ſtripped of their leaves and pointed; the trunks are planted in the ground; and the boughs are interwoven with each other. It is needleſs to add, that the cloſer the trees are laid or planted together, the more ſecure is the defence which they afford; and if, when they are planted, a ſmall ditch be dug towards the enemy, and the earth thrown up properly againſt the lower part of the abatis, it will be very difficult to paſs it if well defended.—*Simes's Military Guide.*

ABBREVIATION of fractions, in arithmetic and algebra, is the reducing of them to lower terms; which is done by dividing the numerator and denominator by ſome number or quantity which will divide both without leaving a remainder of either.

ABERRATION, in optics (in Encycl.), refers the reader to the article Optics, nº 17, 136, 173. It ſhould have referred him to Optics, nº 17, and 251—256.

Aberration of the Viſual Ray, is a phenomenon, of which, though ſome account of it has been given in the Encyclopædia (ſee Aberration, in aſtronomy; and the article Astronomy, nº 337.), one of the moſt candid of our correſpondents requires a fuller explanation. If ſuch an explanation be requiſite to him, it muſt be much more ſo to many others; and we know not where to find, or how to deviſe, one which would be more ſatisfactory, or more familiar, than the following by Dr Hutton.

"This effect (ſays he) may be explained and familiarized by the motion of a line parallel to itſelf, much after the manner that the compoſition and reſolution of forces are explained. If light have a progreſſive motion, let the proportion of its velocity to that of the earth in her orbit be as the line BC to the line AC; then, by the compoſition of theſe two motions, the particle of light will ſeem to deſcribe the line BA or DC, inſtead of its real courſe BC; and will appear in the direction AB or CD, inſtead of its true direction CB. So that if AB repreſent a tube, carried with a parallel motion by an obſerver along the line AC, in the time that a particle of light would move over the ſpace BC, the different places of the tube being AB, *ab*, *cd*, CD; and when the eye, or end of the tube, is at A, let a particle of light enter the other end at B; then when the tube is at *ab*, the particle of light will be at *e* exactly in the axis of the tube; and when the tube is at *cd*, the particle of light will arrive at *f*, ſtill in the axis of the tube; and, laſtly, when the tube arrives at CD, the particle of light will arrive at the eye or point C, and conſequently will appear to come in the direction DC of the tube, inſtead of the true direction BC: and ſo on, one particle ſucceeding another, and forming a continued ſtream or ray of light in the apparent direction DC. So that the apparent angle made by the ray of light with the line AE is the angle DCE, inſtead of the true angle BCE; and the difference BCD, or ABC, is the quantity of the aberration."

Plate II. fig. 1.

Aberration of the Planets, is equal to their geocentric motion, or, in other words, to the ſpace which each appears to move as ſeen from the earth, during the time that light employs in paſſing from the planet to the eye of the obſerver. Thus the ſun's aberration in longitude is conſtantly 20″, that being the ſpace actually moved by the earth, but apparently by the ſun in 8 minutes and 7 ſeconds, the time in which light paſſes from the ſun to the earth. If then the diſtance of any planet from the earth be known, the time which light employs in paſſing from the planet to the earth muſt likewiſe be known; for as the diſtance of the ſun is to the diſtance of the planet, ſo is 8 minutes and 7 ſeconds to that time; and the planet's geocentric motion in that time is its aberration, whether it be in longitude, latitude, right aſcenſion, or declination. See Astronomy in this Supplement.

ABOAB, ceſſes levied, in India, under different denominations, beyond the ſtandard rent.

ABSCISS, Absciſse, or *Abſciſſa*, is a part cut off from a ſtraight line, and terminated at ſome certain point by an ordinate to a curve; as AP (fig. 2.), or BP (fig. 3.) The abſciſs may commence either at the vertex of the curve, or at any other fixed point; and it may be taken either upon the axis or upon the diameter

Plate II.

meter of the curve, or upon any other line drawn in a given poſition. Hence there are on the ſame given line or diameter an infinite number of variable abſciſſes, terminated all at one end by the ſame fixed point. In the common parabola (fig. 4.), each ordinate PQ has but one abſciſs AP. In the ellipſe or circle (fig. 2.), the ordinate has two abſciſſes lying on the oppoſite ſides of it. In general, to each ordinate a line of the ſecond kind, or a curve of the firſt kind, may have two abſciſſes; a line of the third order, three; a line of the fourth order, four; and ſo on.

ABSORPTION, in ANATOMY and PHYSIOLOGY, has been ſufficiently explained under theſe articles in the Encyclopædia; but there is another abſorbing power poſſeſſed by different ſubſtances, which is worthy of attention, becauſe it is only by our knowledge of it that we can adapt our clothing to the various climates of the earth. The power to which we allude is that of different ſubſtances; ſuch as wool, cotton, ſilk, and linen, to abſorb or attract moiſture from the atmoſphere. On this ſubject the reader will find ſome very inſtructive experiments detailed (in Encycl.), where perhaps he may not have looked for them, under the title FLANEL.

ABSURDUM, a term made uſe of by mathematicians when they demonſtrate any truth, by ſhowing that its contrary is impoſſible, or involves an abſurdity. Thus Euclid demonſtrates the truth of the fourth propoſition of the firſt book of his Elements, by ſhowing that its contrary implies this obvious abſurdity—"that two ſtraight lines may incloſe a ſpace."

This mode of demonſtration is called *reductio ad abſurdum*, and is every whit as concluſive as the direct method; becauſe the contrary of every falſehood muſt be truth, and of every truth, falſehood.

The young geometrician, however, does not, we believe, feel himſelf ſo perfectly ſatisfied with a demonſtration of this kind, as with thoſe which, proceeding from a few ſelf-evident truths, conducts him directly, by neceſſary conſequences, to the truth of the propoſition to be proved. The reaſon is, that he has not yet learned to diſtinguiſh accurately between the words *falſe* and *impoſſible*, *different* and *contrary*. Many *different* aſſertions may be made relating to the ſame thing, and yet be all true or all falſe; but it is impoſſible to make two aſſertions directly *contrary* to each other, of which the one ſhall not be true and the other falſe. Thus, "ſnow is white," "ſnow is cold," are different aſſertions relating to the ſame thing, and both true; as, "ſnow is black," "ſnow is red," are both falſe: but let it be remembered, that of the firſt and ſecond, and of the third and fourth of theſe aſſertions, neither is directly *contrary* to the other; nor is any one of them, abſtractly conſidered, *impoſſible*, or ſuch as a blind man, who had never felt nor heard of ſnow, might not believe upon ordinary teſtimony. But were all the men in Europe to tell a native of the interior parts of Africa that ſnow is a thing at once *white and not white, cold and not cold*, the woolly-headed ſavage would know as well as the moſt ſagacious philoſopher, that of theſe *contrary* aſſertions the one *muſt be true* and the other *muſt be falſe*. Juſt ſo it is with reſpect to Euclid's fourth propoſition. Had he proved its truth by ſhowing that its contrary involves this propoſition, that "the diagonal of a ſquare is commenſurate with its ſide," the ſkilful geometrician would indeed have admitted the demonſtration, becauſe he knows well that the diagonal of a ſquare is *not* commenſurate with its ſide; but the tyro in geometry would have been no wiſer than before. He knew from the beginning, that the propoſition and its contrary cannot both be true; but which of them is true, and which falſe, ſuch a demonſtration could not have taught him, becauſe he is ignorant of the incommenſurability of the diagonal and ſide of a ſquare. No man, however, is ignorant, that two ſtraight lines cannot incloſe a ſpace; and ſince Euclid ſhows that the contrary of his propoſition implies this abſurdity, no man of common ſenſe can entertain a doubt but that the propoſition itſelf muſt be true.

ACCELERATED MOTION.
ACCELERATING FORCE. } See (Encycl.) ACCELERATION; and MECHANICS, Sect. VI.—and (this Supplement) DYNAMICS.

ACTION is a term which has been ſufficiently explained in the Encyclopædia; but ſince that article was written, queſtions have been agitated reſpecting *agents*, *agency*, and *action*, which, as they have employed ſome of the moſt eminent philoſophers of the age, and are connected with the deareſt intereſts of man, are certainly entitled to notice in this place.

It is the opinion of Dr Reid, and we have adopted it (ſee METAPHYSICS, nº 109, &c. Encycl.), that no being can be an *agent*, or perform an *action*, in the proper ſenſe of the word, which does not poſſeſs, in ſome degree, the powers of will and underſtanding. If this opinion be juſt, it is obvious, that what are called the powers of nature, ſuch as *impulſe*, *attraction*, *repulſion*, *elaſticity*, &c. are not, ſtrictly ſpeaking, *powers* or *cauſes*, but the effects of the agency of ſome active and intelligent being; and that *phyſical cauſes*, to make uſe of common language, are nothing more than *laws* or *rules*, according to which the *agent* produces the effect.

This doctrine has been controverted by a writer whoſe acuteneſs is equalled only by his virtues; and we ſhall conſider ſome of his objections to it in another place (ſee CAUSE): but a queſtion of a different kind falls under our preſent conſideration; and perhaps the anſwer which we muſt give to it, may go far to remove the objections to which we allude.

Can an agent operate where, either by itſelf or by an inſtrument, it is not preſent? We think not; becauſe agency, or the exertion of power, muſt be the agency of ſomething. The conſtitution of the human mind compels us to attribute every action to ſome *being*; but if a being could act in *one* place from which it is abſent, it might do the ſame in a ſecond, in a third, and in all places; and thus we ſhould have action without an agent: for to be abſent from all places is a phraſe of the ſame import as not to exiſt. But if a living and intelligent being cannot act but where it is either immediately or inſtrumentally preſent, much leſs ſurely can we attribute events of any kind to the agency of an abſent and inanimated body. Yet it has been ſaid, that "we have every reaſon, which the nature of the ſubject and of our own faculties can admit of, to believe, that there are among things inanimate ſuch relations, that they may be mutually cauſes or principles of change to one another, without any exertion of *power*, or any operation of an agent, ſtrictly ſo called. Such relations, for aught that we know, may take place among bodies at great diſtances from one another, as well as among bodies really or ſeemingly in actual contact; and they may vary both in degree and in kind, according to the diſtances between the bodies."

That any thing ſhould be a cauſe or principle of change to another, without the exertion of *power* or the operation of an agent, appears to us a palpable contradiction; and we could as eaſily conceive any two ſides of a triangle to be not greater than the third ſide, as reconcile ſuch a propoſition to that faculty of our minds by which we diſtinguiſh truth from falſehood. When we ſee one body the apparent cauſe of change in another body, we cannot poſſibly entertain a doubt of the *exertion of power;* but whether that power be in the body apparently producing the change, or in a diſtinct agent, is a queſtion to which an anſwer will not ſo readily be found. That it is in a diſtinct agent, we are ſtrongly inclined to believe, not only by the received doctrine concerning the inertia of matter, which, though it has been frequently controverted, we have never ſeen diſproved, but much more by conſidering the import of an obſervation frequently introduced to prove the direct contrary of our belief. "We cannot be charged (ſays the writer whom we have juſt quoted) with maintaining the abſurdity, that there may be an effect without a cauſe, when we refer the fall of a ſtone to the ground, and the ebbing and flowing of the ſea, to the *influence* of the earth on the ſtone, and of the ſun and moon on the ocean, according to the principle of general gravitation."

We admit the truth of this obſervation, provided the influence of the ſun and moon on the ocean be poſſible; but, to us at leaſt, it appears impoſſible, and is certainly inconceiveable. The influence of the ſun and moon can here mean nothing but the *action* or *operation* of the ſun and moon; but if theſe two bodies be inanimate, they cannot *act* at all, in the proper ſenſe of the word; and whatever they be, it is obvious that they cannot act *immediately* on an object at ſuch a diſtance from them as the earth and the ocean. If they be the agents, they muſt operate by an inſtrument, as we do when moving objects to which our hands cannot reach; but as it has been ſhewn elſewhere (ſee Metaphysics, n° 199. and Optics, n° 63. Encycl.), that neither air nor æther, nor any other material inſtrument which has yet been thought of, is ſufficient to account for the phenomena of attraction and repulſion, it is ſurely much more rational to conclude, that the ebbing and flowing of the ſea are produced, not by the influence of the ſun and moon, but by the power of ſome diſtinct agent or agents.

What thoſe agents are, we pretend not to ſay. If the Supreme Being himſelf be the immediate author of every change which takes place in the corporeal world, it is obvious that he acts by fixed rules, of which many are apparent to the moſt heedleſs obſerver, whilſt the diſcovery of others is reſerved for the reward of the judicious application of the faculties which he has given us. If he employs inferior agents to carry on the great operations of nature, it is ſurely not difficult to conceive that the powers of thoſe agents which were derived from him, may by him be reſtrained within certain limits, and their exerciſe regulated by determined laws, in ſuch a manner as to make them produce the greateſt benefit to the whole creation. Nor let it be thought an objection to this theory, that the changes which take place among bodies at great diſtances from each other, vary both in degree and in kind according to the diſtances; for this variation, which we acknowledge to be a fact, appears to us wholly unaccountable upon any other hypotheſis than that which attributes the different changes to agents diſtinct from the bodies themſelves. Did we perceive all the particles of matter, at all diſtances, tending towards each other by a fixed law, we might be led to conſider mutual attraction as an *eſſential* property of that ſubſtance, and think no more of inquiring into its cauſe, than we think of inquiring into the cauſe of extenſion. But when we find that the ſame particles, which at one diſtance ſeem to attract each other, are at a different diſtance kept aſunder by a power of repulſion, which no force, with which we are acquainted, is able to overcome, we cannot attribute the *principle* or *cauſe* of theſe changes to brute matter, but muſt refer it to ſome other agent exerting power according to a fixed law.

It is the faſhion at preſent to deſpiſe all metaphyſical inquiries as abſtruſe and uſeleſs: and on this account we doubt not but ſome of our readers will turn away from this diſquiſition with affected diſguſt, whilſt the petulant and unthinking chemiſt, proud of poſſeſſing the ſecrets of his ſcience, will deem it ſuperfluous to inquire after any other natural agents than thoſe of which he has been accuſtomed to talk. But with the utmoſt reſpect for the diſcoveries made by modern chemiſts, which we acknowledge to be both numerous and important, we beg leave to obſerve, that though theſe gentlemen have brought to light many events and operations of nature formerly unknown, and have ſhown that thoſe operations are carried on by eſtabliſhed laws, none of them can ſay with certainty that he has diſcovered a ſingle agent. The moſt enlightened of them indeed pretend not to have diſcovered in one department of ſcience more than Newton diſcovered in another; for they well know that agents and agency cannot be ſubjected to any kind of phyſical experiments. Our very notions of theſe things are derived wholly from our own conſciouſneſs and reflection; and when it is conſidered what dreadful conſequences have in another country reſulted from that pretended philoſophy which excludes the agency of mind from the univerſe, it is ſurely time to inquire whether our conſciouſneſs and reflection do not lead us to refer real agency to mind alone. Let this be our apology both to the real and to the affected enemies of metaphyſics for endeavouring to draw their attention to the preſent queſtion. It is a queſtion of the utmoſt importance, as well to ſcience as to religion: and if the laws of human thought decide it, as we have endeavoured to ſhow that they do, we may without heſitation affirm, that the impious philoſophy of France can never gain ground but among men incapable of patient thinking.

ADAMAS, a name given, in aſtrology, to the moon.

ÆOLUS, in mechanics, a ſmall machine invented by Mr Tidd for refreſhing or changing the air in rooms when it becomes too hot or otherwiſe unfit for reſpiration. The æolus is ſo contrived as to ſupply the place of a ſquare of glaſs in the window, where it works, with very little noiſe, like the ſails of a wind-mill or a ſmoke-jack.

AEROLOGY is a branch of ſcience which was detailed in the Encyclopædia at ſufficient length, and according to the principles which were then generally admitted by chemiſts. Subſequent experiments, however, have ſhown, that ſome of thoſe principles are erroneous, and of courſe that ſome of the opinions advanced in the article AEROLOGY are inconſiſtent with facts. Theſe opinions muſt be corrected; but inſtead of ſwelling this volume with a new article AEROLOGY, we apprehend that it will be more acceptable to our ſcientific readers to refer them for thoſe corrections to the article CHEMISTRY in this Supplement.

AFGHANS, are a people in India who inhabit a province of CABUL or CABULISTAN (ſee Encycl.), and have always been connected with the kingdoms of Perſia and Hindoſtan. They boaſt of being deſcended of Saul the firſt king of Iſrael; of whoſe advancement to the royal dignity they give an account which deviates not very widely from the truth. They ſay indeed, that their great anceſtor was raiſed from the rank of a ſhepherd, not for any princely qualities which he poſſeſſed, but becauſe his ſtature was exactly equal to the length of a rod which the angel Gabriel had given to the prophet Samuel as the meaſure of the ſtature of him whom God had deſtined to fill the throne of Iſrael.

SAUL, whoſe deſcent, according to ſome of them, was of Judah, and according to others of Benjamin, had, they ſay, two ſons, BERKIA and IRMIA, who ſerved David, and was beloved by him. The ſons of Berkia and Irmia were AFGHAN and USBEC, who, during the reigns of David and Solomon, diſtinguiſhed themſelves, the one for his corporeal ſtrength, and the other for his learning. So great indeed was the ſtrength of *Afghan*, that we are told it ſtruck terror even into demons and genii.

This hero uſed frequently to make excurſions to the mountains, where his progeny, after his death, eſtabliſhed themſelves, lived in a ſtate of independence, built forts, and exterminated infidels. When the ſelect of creatures (the appellation which this people give to *Mahomet*) appeared upon earth, his fame reached the *Afghans*, who ſought him in multitudes under their leaders *Khalid* and *Abdul Reſpid*, ſons of *Walid*; and the prophet honouring them with this reception—"Come, O *Muluc*, or Kings!" they aſſumed the title of *Melic*, which they retain to this day.

The hiſtory, from which this abſtract is taken, gives a long and unintereſting detail of the exploits of the Afghans, and of their zeal in overthrowing the temples of idols. It boaſts of the following monarchs of their race who have ſat upon the throne of *Dehli*: Sultan BEHLOLE, *Afghan* LODI, Sultan SECANDER, Sultan IRBAHIM, SHIR SHAH, ISLAM SHAH, ADIL SHAH SUR. It alſo numbers the following kings of *Gaur* deſcended of the Afghan chiefs: SOLAIMAN *Shah Gurzani*, BEYAZID *Shah*, and KUTB *Shah*; beſides whom, their nation, we are told, has produced many conquerors of provinces. The Afghans are ſometimes called *Solaimani*, either becauſe they were formerly the ſubjects of SOLOMON king of Iſrael, or becauſe they inhabit the mountains of Solomon. They are likewiſe called PATANS, a name derived from the *Hindi* verb *Paitna* "to ruſh," which was given to them by one of the Sultans whom they ſerved, in conſequence of the alacrity with which they had attacked and conquered his enemies. The province which they occupy at preſent was formerly called *Roh*; and hence is derived the name of the *Rohillas*. The city which was eſtabliſhed in it by the *Afghans* was called by them *Paiſhwer* or *Paiſher*, and is now the name of the whole diſtrict. The ſects of the Afghans are very numerous; of which the principal are, *Lodi*, *Lohouni*, *Sur*, *Serwani*, *Yuſufzihi*, *Bangiſh*, *Dilazaui*, *Khetti*, *Yaſin*, *Kail*, and *Beloje*. They are *Muſulmans*, partly of the *Sunni*, and partly of the *Shiek* perſuaſion.

Though they are great boaſters, as we have ſeen, of the antiquity of their origin, and the reputation of their race, other *Muſulmans* reject their claim, and conſider them as of modern, and even of baſe, extraction.

This is probably a calumny; for it ſeems inconſiſtent with their attention to the purity of their deſcent—an attention which would hardly be paid by a people not convinced of their own antiquity. They are divided into four claſſes. The firſt is the *pure* claſs, conſiſting of thoſe whoſe fathers and mothers were *Afghans*. The ſecond claſs conſiſts of thoſe whoſe fathers were *Afghans* and mothers of another nation. The third claſs contains thoſe whoſe mothers were *Afghans* and fathers of another nation. The fourth claſs is compoſed of the children of women whoſe mothers were *Afghans* and fathers and huſbands of a different nation. Perſons who do not belong to one of theſe claſſes are not called *Afghans*.

This people have at all times diſtinguiſhed themſelves by their courage, both ſingly and unitedly, as principals and auxiliaries. They have conquered for their own princes and for foreigners, and have always been conſidered as the main ſtrength of the army in which they ſerved. As they have been applauded for virtues, they have alſo been reproached for vices, having ſometimes been guilty of treachery, and of acting the baſe part even of aſſaſſins.

Such is the account of the Afghans publiſhed in the ſecond volume of the Aſiatic Reſearches. It was tranſlated from a Perſian abridgment of a book written in the Puſhto language, and called *The Secrets of the Afghans*, and communicated by Henry Vanſittart, Eſq; to Sir William Jones, then preſident of the Aſiatic Society. Their claim to a deſcent from Saul king of Iſrael, whom they call MELIC TALUT, is probably of not a very ancient date; for the introduction of the angel Gabriel with his rod, gives to the whole ſtory the air of one of thoſe many fictions which Mahomet borrowed from the later rabbins. Sir William Jones, however, though he ſurely gave no credit to this fable, ſeems to have had no doubt but the Afghans are deſcendants of Iſrael. "We learn (ſays he) from ESDRAS, that the ten tribes, after a wandering journey, came to a country called *Arſareth*, where we may ſuppoſe they ſettled: now the *Afghans* are ſaid by the beſt *Perſian* hiſtorians to be deſcended from the *Jews*. They have traditions among themſelves of ſuch a deſcent; and it is even aſſerted, that their families are diſtinguiſhed by the names of *Jewiſh* tribes, although ſince their converſion to *Iſlam*, they ſtudiouſly conceal their origin from all whom they admit not to their *ſecrets*. The *Puſhto* language, of which I have ſeen a dictionary, has a manifeſt reſemblance to the *Chaldaick*; and a conſiderable diſtrict under their dominion is called *Hazareth* or *Hazaret*, which might eaſily have been changed into the word uſed by ESDRAS. I ſtrongly recommend an inquiry into the literature and hiſtory of the *Afghans*."

It is to co-operate with this accompliſhed ſcholar that we have inſerted into our Work this ſhort account of that ſingular people; and it is with pleaſure that, upon the authority of Mr Vanſittart, we can add, that a very particular account of the *Aſghans* has been written by the late Hafiz Rahmat *Khan*, a chief of the *Rohillahs*, from which ſuch of our readers as are oriental ſcholars may derive much curious information.

ALBATEGNI, an Arabic prince of Batan in Meſopotamia, was a celebrated aſtronomer, about the year of Chriſt 880, as appears by his obſervations. He is alſo called *Muhammed ben Geber Albatani*, *Mahomet the ſon of Geber*, and *Muhamedes Aractenſis*. He made aſtronomical obſervations at Antioch, and at Racah or Aracta, a town of Chaldea, which ſome authors call a town of Syria or of Meſopotamia. He is highly ſpoken of by Dr Halley, as *vir admirandi acuminis, ac in adminiſtrandis obſervationibus exercitatiſſimus*.

Finding that the tables of Ptolemy were imperfect, he computed new ones, which were long uſed as the beſt among the Arabs: theſe were adapted to the meridian of Aracta or Racah. Albategni compoſed in Arabic a work under the title of *The Science of the Stars*, compriſing all parts of aſtronomy, according to his own obſervations and thoſe of Ptolemy. This work, tranſlated into Latin by Plato of Tibur, was publiſhed at Nuremberg in 1537, with ſome additions and demonſtrations of Regiomontanus; and the ſame was reprinted at Bologna in 1645, with this author's notes. Dr Halley detected many faults in theſe editions.—*Phil. Tranſ.* for 1693, N° 204.

In this work Albategni gives the motion of the ſun's apogee ſince Ptolemy's time, as well as the motion of the ſtars, which he makes one degree in 70 years. He made the longitude of the firſt ſtar of Aries to be 18° 2′; and the obliquity of the ecliptic 23° 35′. And upon Albategni's obſervations were founded the Alphonſine tables of the moon's motions; as is obſerved by Nic. Muler, in the *Tab. Friſicæ*, p. 248.

ALDERAIMIN, a ſtar of the third magnitude, in the right ſhoulder of the conſtellation Cepheus.

ALFRAGAN, Alfergani, or *Fargani*, a celebrated Arabic aſtronomer, who flouriſhed about the year 800. He was ſo called from the place of his nativity, Fergan, in Sogdiana, now called Maracanda, or Samarcand, anciently a part of Bactria. He is alſo called *Ahmed* (or *Muhammed*) *ben-Cothair*, or *Katir*. He wrote the Elements of Aſtronomy in 30 chapters or ſections. In this work the author chiefly follows Ptolemy, uſing the ſame hypotheſis, and the ſame terms, and frequently citing him. Of Alfragan's work there are three Latin tranſlations, of which the laſt and beſt was made by Golius, profeſſor of mathematics and oriental languages in the univerſity of Leyden. This tranſlation, which was publiſhed in 1669, after the death of Golius, is accompanied with the Arabic text, and with many learned notes on the firſt nine chapters, which would undoubtedly have been carried to the end, had the tranſlator lived to complete his plan.

ALGORAB, a fixed ſtar of the third magnitude, in the right wing of the conſtellation Corvus.

ALHAZEN, an Arabian aſtronomer, who flouriſhed in Spain about the beginning of the 12th century. See Astronomy, n° 6. *Encycl.*

ALMAMON, was a philoſopher and aſtronomer, who, in the beginning of the 9th century, aſcended the throne of the caliphs of Bagdat. He was the ſon of Harun Al-Raſhid, and grandſon of Almanſor. His name is otherwiſe written *Mamon*, *Almaon*, *Almamun*, *Alamoun*, or *Al-Maimon*. Having been educated with great care, and with a love for the liberal ſciences, he applied himſelf to cultivate and encourage them in his own country. For this purpoſe he requeſted the Greek emperors to ſupply him with ſuch books on philoſophy as they had among them; and he collected ſkilful interpreters to tranſlate them into the Arabic language. He alſo encouraged his ſubjects to ſtudy them; frequenting the meetings of the learned, and aſſiſting at their exerciſes and deliberations. He cauſed Ptolemy's Almageſt to be tranſlated in 827, by Iſaac Ben-honain, and Thabet Ben-korah, according to Herbelot, but, according to others, by Sergius, and Alhazen the ſon of Joſeph. In his reign, and doubtleſs by his encouragement, an aſtronomer of Bagdat, named Habaſh, compoſed three ſets of aſtronomical tables.

Almamon himſelf made many aſtronomical obſervations, and determined the obliquity of the ecliptic to be then 23° 35′ (or 23° 33′ in ſome manuſcripts), but Voſſius ſays 23° 51′ or 23° 34′. He alſo cauſed ſkilful obſervers to procure proper inſtruments to be made, and to exerciſe themſelves in aſtronomical obſervations; which they did accordingly at Shemaſi in the province of Bagdat, and upon Mount Caſius near Damus.

Under the auſpices of Almamon alſo a degree of the meridian was meaſured on the plains of Sinjar or Sindgiar (or, according to ſome, Fingar), upon the borders of the Red Sea; by which the degree was found to contain 56⅔ miles, of 4000 coudees each, the coudee being a foot and a half: but it is not known what foot is here meant, whether the Roman, the Alexandrian, or ſome other. Riccioli makes this meaſure of the degree amount to 81 ancient Roman miles, which value anſwers to 62,046 French toiſes; a quantity more than the true value of the degree by almoſt one-third. Finally, Almamon revived the ſciences in the Eaſt to ſuch a degree, that many learned men were found, not only in his own time, but after him, in a country where the ſtudy of the ſciences had been long forgotten. This learned king died near Tarſus in Cilicia, by having eaten too freely of ſome dates, on his return from a military expedition, in the year 833.

ALOE dichotoma, in botany, called by the Dutch *Kooker-boom* or *Quiver tree*, is a native of the ſouthern parts of Africa, and ſeems to be a ſpecies of the Agave or *American aloe* (ſee Agave, Encycl.) It is thus deſcribed by Le Vaillant in his *New Travels into the Interior Parts of Africa*: "The *aloe dichotoma* riſes to the height of 25 or 30 feet; its trunk is ſmooth, and the bark white. When young, and the trunk not more than four or five feet long, it terminates with a ſingle tuft of leaves, which, like thoſe of the ananas, ſpread and form a crown, from the midſt of which all its flowers iſſue. As it grows older, it puſhes out lateral branches, perfectly regular and ſymmetrical, each of which has at its extremity a crown ſimilar to that of the young plant. The kooker-boom thrives much better on mountains than in the plain. Inſtead of long roots penetrating deep into the earth, like thoſe of other trees, it has but a very ſlight one by which it is fixed to the ſoil. Accordingly, three inches of mould are

ſufficient

ſufficient to enable it to grow upon the very rocks, and attain its utmoſt beauty; but its root is ſo feeble a ſupport, that I could throw down the largeſt with a ſingle kick of my foot. The hordes on the weſt make their quivers of the trunk of this tree when young, whence is derived the name given it by the planters."

It becomes not us, ſitting in our chamber, to controvert a fact in natural hiſtory, of the reality of which we never had an opportunity of judging; nor would it be proper, on account of our own ſcepticiſm, to ſuppreſs the narrative of a traveller, who corrects the narratives of former travellers in terms which nothing ſhould have dictated but the conſciouſneſs of his own invariable veracity. Yet we hope to be pardoned for expreſſing our ſurpriſe that, in any part of the world, trees ſhould be found in great numbers 25 or 30 feet high, and ſhooting out many branches, which have yet ſo looſe a hold of the ground, that the largeſt of them may be thrown down by the ſingle kick of a man's foot. The reader's ſurpriſe will probably equal our's, when he is informed that the author ſaw one of theſe trees of which the trunk was ten feet four inches in circumference, whilſt its branches overſhadowed a ſpace of more than 100 feet in diameter! This tree he aſſures that he could have *kicked* over. The country, according to his account, is not exempted from ſtorms. He is himſelf a French philoſopher. What a pity then is it that he did not explain to thoſe, who have not had the benefit of being enlightened in that ſchool, upon what principle of mechanics or ſtatics the tree could reſiſt the violence of the elements till it arrived at ſo enormous a ſize?

ALPHONSUS X. king of Leon and Caſtile (ſee *Encycl.*) This prince underſtood aſtronomy, philoſophy, and hiſtory, as if he had been only a man of letters; and compoſed books upon the motions of the heavens, and on the hiſtory of Spain, which are highly commended. "What can be more ſurpriſing (ſays Mariana), than that a prince, educated in a camp, and handling arms from his childhood, ſhould have ſuch a knowledge of the ſtars, of philoſophy, and the tranſactions of the world, as men of leiſure can ſcarcely acquire in their retirements? There are extant ſome books of Alphonſus on the motions of the ſtars, and the hiſtory of Spain, written with great ſkill and incredible care." In his aſtronomical purſuits he diſcovered that the tables of Ptolemy were full of errors; and thence he conceived the firſt of any the reſolution of correcting them. For this purpoſe, about the year 1240, and during the life of his father, he aſſembled at Toledo the moſt ſkilful aſtronomers of his time, Chriſtians, Moors, and Jews, when a plan was formed for conſtructing new tables. This taſk was accompliſhed about 1252, the firſt year of his reign; the tables being drawn up chiefly by the ſkill and pains of Rabbi Iſaac Hazan, a learned Jew, and the work called the *Alphonſine Tables*, in honour of the prince, who was at vaſt expences concerning them. He fixed the epoch of the tables to the 30th of May 1252, being the day of his acceſſion to the throne. They were printed for the firſt time in 1483, at Venice, by Radtoldt, who excelled in printing at that time. This edition is extremely rare: there are others of 1492, 1521, 1545, &c.

In the Encyclopædia it is ſaid, that the charge of impiety brought againſt this prince was *unjuſt*. This was ſaid too confidently, becauſe we know not of any direct proof of his innocence. All that has been ſaid for him by Dr Hutton, one of his ableſt apologiſts, amounts to nothing more than a high degree of probability that the charge was carried by much too far. The charge itſelf was, that Alphonſus affirmed, "that if he had been of God's privy-council when he made the world, he would have adviſed him better." Mariana, however, ſays only in general, that Alphonſus was ſo bold as to blame the works of Providence, and the conſtruction of our bodies; and he ſays that this ſtory concerning him reſted only upon a vulgar tradition. The Jeſuit's words are curious: "Emanuel, the uncle of Sanchez (the ſon of Alphonſus), in his own name, and in the name of other nobles, deprived Alphonſus of his kingdom by a public ſentence; which that prince merited, for daring ſeverely and boldly to cenſure the works of Divine Providence, and the conſtruction of the human body, as tradition ſays he did. Heaven moſt juſtly puniſhed the folly of his tongue." Though the ſilence of ſuch an hiſtorian as Mariana, in regard to Ptolemy's ſyſtem, ought to be of ſome weight, yet we cannot think it improbable, that if Alphonſus did paſs ſo bold a cenſure on any part of the univerſe, it was on the celeſtial ſphere, and meant to glance upon the contrivers and ſupporters of that ſyſtem. For, beſides that he ſtudied nothing more, it is certain that at that time aſtronomers explained the motions of the heavens by intricate and confuſed hypotheſes, which did no honour to God, nor anywiſe anſwered the idea of an able workman. So that, from conſidering the multitude of ſpheres compoſing the ſyſtem of Ptolemy, and thoſe numerous eccentric cycles and epicycles with which it is embarraſſed, if we ſuppoſe Alphonſus to have ſaid, "that if God had aſked his advice when he made the world, he would have given him better counſel," the boldneſs and impiety of the cenſure will be greatly diminiſhed.

Such is the apology made by Dr Hutton for this royal aſtronomer of Spain; and we hope, for the honour of ſcience, that it is well founded. Still it leaves Alphonſus guilty of great irreverence of language, which is to us wholly unaccountable, if it be really true that he read the Bible fourteen times. We have ſeen impiety indeed break out lately from very eminent aſtronomers of a neighbouring nation; but theſe men read not the Bible, nor any thing elſe, but the dreams of the eternal ſleepers.

ALTERNATE ANGLES. See GEOMETRY (*Encycl.*), Part I. 35.

ALTERNATE Ratio, or *Proportion*, is the ratio of the one antecedent to the other, or of one conſequent to the other, in any proportion, in which the quantities are of the ſame kind. So if A : B : : C : D, then alternately, or by alternation A : C : : B : D.

ALTITUDE, PARALLAX OF, is an arch of a vertical circle, by which the true altitude, obſerved at the centre of the earth, exceeds that which is obſerved on the ſurface. See PARALLAX (*Encycl.*) and ASTRONOMY (*Suppl.*)

ALTITUDE of the Nonageſimal, is the altitude of the 90th degree of the ecliptic, counted upon it from where it cuts the horizon, or of the middle or higheſt point of it which is above the horizon, at any time; and is equal to the angle made by the ecliptic and horizon where they interſect at that time.

ltitude,
Alum.

Altitude of the Cone of the Earth's or Moon's Shadow, the height of the ſhadow of the body made by the ſun, and meaſured from the centre of the body. To find it ſay, As the tangent of the angle of the ſun's apparent ſemidiameter is to radius; ſo is 1 to a fourth proportional, which will be the height of the ſhadow in ſemidiameters of the body.

ALUM is a ſalt ſo uſeful in commerce and the arts, that the knowledge of its component parts, and of the beſt method of preparing it, muſt be of importance. In the article CHEMISTRY (Encycl.), the opinions which were then held reſpecting its compoſition, and the practice which was generally followed in its preparation, have been detailed at full length; but ſome of theſe opinions have ſince been controverted, and if they be erroneous, it muſt be expedient to vary in ſome degree the mode of preparation. In particular, the opinion that it is merely an exceſs of acid which prevents the formation of alum by evaporation of the ley, has been ſhown to be falſe by Citizen *Vauquelin*, who contends, of courſe, that the addition of putrid urine to the ley is a very bad practice.

This eminent chemiſt had long ſuſpected, that the cryſtallization of alum is not prevented by an exceſs of acid, and that pot-aſh is not of uſe ſimply to ſaturate this acid, but to perform an office of more importance. To bring his ſuſpicions to the teſt of experiment, he diſſolved very pure ALUMINE in ſulphuric acid of equal purity, and evaporated the ſolution to dryneſs, for the purpoſe of expelling the ſuperabundant acid. He then rediſſolved the dry and pulverulent reſidue in water, and reduced the ſolution to different degrees of ſpecific gravity, with a view to ſeize the point moſt favourable to cryſtallization; but with every poſſible precaution he could obtain nothing but a magma (ſee MAGMA), formed of ſaline plates, without conſiſtence or ſolidity. This ſolution, however, though it conſtantly refuſed to afford cryſtallized alum alone, afforded it immediately by the addition of a few drops of the ſolution of pot-aſh; and as he had employed theſe two ſubſtances in the requiſite proportion, the reſt of the ſolution, to the very end, afforded pure alum, without any mixture of ſulphat of pot-aſh.

Into another portion of the ſame ſolution of pure alumine, he dropped the ſame quantity of carbonat of ſoda as he had added of that of pot-aſh to the former; but no cryſtallization was formed, even by the help of evaporation, nor did lime and barytes poduce any better effect. But if the common opinion that pot-aſh, in the formation of alum, is of uſe only to abſtract the exceſs of acid, be true, ſoda; lime, barytes, and all the ſubſtances which by a more powerful force would take this acid from alum, ought to give the ſame reſult. Another argument preſented itſelf, which ſeemed deciſive: If the alkalies, pot-aſh, and ammoniac, do nothing more than unite to the ſuperabundant acid of the alum, the ſulphats of pot-aſh and of ammoniac ought not to occaſion any change in pure alum in its acidulated ſtate; whereas if theſe alkalies enter as a conſtituent part into the alum, and are neceſſary to its exiſtence, they ought to produce the ſame effects as pure pot-aſh or ammoniac. He therefore added to a third portion of the ſolution of ſulphat of alumine before-mentioned ſome drops of the ſolution of ſulphat of pot-aſh; immediately upon which octahedral cryſtals of alum were formed. The ſulphat of ammoniac preſented the ſame effect.

Alum.

This reſult gave ſtill greater confirmation to his firſt notions, though it did not yet afford a demonſtration perfectly without objection; for it might have happened that the two ſalts he made uſe of might determine the cryſtallization of the alum, ſimply by abſorbing the ſuperfluous acid, of which they are very greedy; but to determine this poſſible fact, he mixed in the uncryſtallizable ſolution of alumine ſome ſulphat of pot-aſh with exceſs of acid, and obtained a cryſtallization no leſs abundant than with the neutral ſulphat of pot-aſh.

This laſt experiment leaves therefore no doubt with regard to the influence and mode of action of pot-aſh and ammoniac in the fabrication of alum; and this action is ſtill more ſtrongly confirmed by the examination of the alums which have been formed by the proceſſes above related; for in this manner it is proved that they contain conſiderable quantities of the ſulphats of pot-aſh and ammoniac.

Theſe experiments led M. Vauquelin to an examination of the different alums of commerce, of which he found not one that did not afford ſulphat of pot-aſh, or of ammoniac, or of both. His methods of analyſis are very accurate; but to detail them at length would ſwell this article to little purpoſe. To ſuch of our readers as are not chemiſts they would hardly be intelligible; and the experienced chemiſt will deviſe methods of analyſis for himſelf. It may be proper, however, to obſerve, that M. Vauquelin proved, to his own ſatisfaction, that the ſulphat of pot-aſh, or of ammoniac, is neceſſary to render alum capable of being precipitated by its earth, or to cauſe it to paſs, as it were, to the earthy ſtate (A). He proved likewiſe, that ſuch aluminous waters as do not contain pot-aſh, may remain, as long as may be deſired, on their materials, without being ſaturated with too great a quantity of earth, or ſuffering alum to precipitate.

From the whole of his experiments our author drew the following concluſions, which he conſiders as of importance to the arts, to chemiſtry, and to natural hiſtory.

1. It is not, at leaſt in the greateſt number of circumſtances, the exceſs of acid which impedes the cryſtallization of alum, but it is the want of pot-aſh or ammoniac: For it is difficult to imagine that the ſulphuric acid could remain diſengaged after ſo long remaining upon alumine in a ſtate of extreme diviſion, and always ſuperabundant. It is true that the aluminous waters redden the vegetable tinctures; but this property is not owing to a diſengaged acid. This portion of acid is a conſtituent part of theſe waters; and it appears to have more affinity with the neutral ſulphat of alumine than with a new quantity of this earth at the temperature of the atmoſphere.

2. The ſulphat of pot-aſh may be uſed, as well as pure pot-aſh, to cauſe the cryſtallization of alum. It even

---

(A) It may be proper to notice, that Scheele ſeems to have known this long before, and that he mentions it expreſsly in his paper on *Pyrophorus*.

even has the advantage over the latter ſalt, becauſe if the aluminous waters do not really contain a diſengaged acid, the pot-aſh, in its combination, will precipitate a portion of alumine, and diminiſh the product of the boiling; whereas the ſulphat of pot-aſh does not produce the ſame effect; but if the lixiviums contain diſengaged acid, which muſt very ſeldom be the caſe, it is not converted into alum by the ſulphat of pot-aſh, and is loſt with regard to the product. Our author therefore is of opinion, that when the waters really contain an exceſs of acid, or a very oxided ſulphat of iron, the uſe of pot-aſh is preferable to that of the ſulphat of pot-aſh. But when economy is an object, that in many places it would be profitable to uſe the ſulphat of pot-aſh; becauſe it is a ſalt indirectly produced in many manufactories, where of courſe it may be obtained for nothing. In particular, the reſidues of the diſtillation of aquafortis by the ſulphuric acid would be excellent for this operation, and much preferable to putrid urine, becauſe this fluid always contains phoſphoric ſalts, which decompoſe a portion of the ſulphat of alumine, and conſiderably diminiſh the product.

3. Alumine cannot be uſed in the treatment of mother waters, as Bergman propoſes. This earth is incapable of favouring the cryſtallization of alum, beſides which, it decompoſes a portion of alum by the aſſiſtance of ebullition; in which circumſtance it ſeizes the acid neceſſary to its ſolution, and precipitates it in the form of that powder which is called alum ſaturated with its earth.

4. Many alum ores muſt naturally contain pot-aſh, becauſe perfect alum is often obtained from the firſt cryſtallization of new alum waters without the addition of this alkali. It is true that an objection may be made with regard to the wood uſed in calcining theſe ores, which may be ſuppoſed to have furniſhed the alkali; but it is not probable that the ſmall quantity of wood employed, in compariſon to the quantity of ore and the alum it affords, could ſupply enough of pot-aſh for the cryſtallization.

5. All the earths and ſtones which have given, or ſhall hereafter afford, by analyſis with the ſulphuric acid, perfect alum without addition of pot-aſh, muſt contain this alkali naturally. For it is well proved, that alum cannot exiſt without pot-aſh or ammoniac; and as there is little probability that this laſt ſhould be found combined in earths or ſtones, unleſs perhaps in very rare caſes, we may almoſt conſtantly be aſſured, when alum is obtained from any of theſe ſubſtances, that its formation was effected by pot-aſh. The quantity of alum will immediately ſhow in what proportion this alkali exiſted in the ſubſtances analyſed.

6. The alum of commerce ought not to be conſidered as a ſimple ſalt, but as a combination in the ſtate of a triple and ſometimes quadruple ſalt of ſulphat of alumine, ſulphat of pot-aſh, or of ammoniac. Among theſe laſt we may diſtinguiſh two ſpecies; the one without exceſs of acid, inſoluble in water and inſipid, being what is improperly called alum ſaturated with its own earth; and the other, which contains an exceſs of acid ſoluble in water, very ſapid and aſtringent, is the common alum.

There is likewiſe a pure ſulphat of alumine, very aſtringent, very difficult of cryſtallization, in the form of brilliant pearl-coloured plates without conſiſtence, and which cannot be rendered inſoluble by the addition of a new quantity of its baſe. This laſt ſalt may with the greateſt propriety be called the ſulphat of alumine.

7. It follows from the comparative analyſis, and the knowledge acquired reſpecting the different ſtates of the combination of alumine with the ſulphuric acid united at the ſame time with other baſes, that we muſt diſtinguiſh ſeven ſtates in this combination, and that it is neceſſary to expreſs them according to the rules of the methodical nomenclature. Here follow the ſeries, the nature, and the names of theſe ſeven ſulphats of alumine.

1. Sulphat of alumine, or the artificial combination of ſulphuric acid and alumine. This ſalt is aſtringent; it cryſtallizes in laminæ or flexible leaves, ſoluble in water. It has never been deſcribed nor named by chemiſts. 2. Acid ſulphat of alumine is the foregoing ſalt, with exceſs of acid, from which it differs by reddening blue vegetable colours. It is eaſily made by diſſolving that ſalt in the ſulphuric acid, but it is not eaſy to convert this into the neutral ſulphat of alumine but by boiling it a long time with its earth. This ſalt, like the firſt, has not been deſcribed. 3. Saturated ſulphat of alumine and of pot-aſh is the alum of the chemiſts ſaturated with its earth. It is pulverulent, inſipid, inſoluble, not cryſtallizable, and is eaſily converted into true alum by the addition of ſulphuric acid. 4. The acid ſulphat of alumine and of pot-aſh greatly reſembles common alum, and is eaſily prepared chemically; but M. Vauquelin found no alum but that of La Tolfa, which is exactly of the ſame nature with it. 5. The acid ſulphat of alumine and of ammoniac has all the properties of alum, and may be uſed for the ſame purpoſes; but though it is eaſily made in the laboratories, our author never found it pure in commerce. 6. The acid ſulphat of alumine, pot-aſh, and ammoniac. It is remarkable enough, ſays M. Vauquelin, that this ſhould be the nature of the alum moſt frequently made in the arts, and that to expreſs its combination ſo many words ſhould be neceſſary. This, however, may be avoided, by reſerving the name of alum to this ſubſtance, which will be ſufficient to diſtinguiſh it perfectly. 7. The acidulous ſulphat of alumine and of pot-aſh, our author ſays, he is leſs acquainted with than with the preceding ſeries. The name by which he characterizes it was ſuggeſted to him, and he thinks it proper, becauſe by adding to the ſolution a ſmall quantity of pot-aſh more than is neceſſary to obtain octahedral cryſtals, it manifeſtly paſſes to the cubic form.

From theſe deductions, the phyſician, the chemiſt, and the manufacturer, with whom the uſes of alum are greatly multiplied, will hereafter poſſeſs a knowledge of the ſubſtance they employ, and may appreciate its effects on the animal economy, and other bodies to which it is ſo frequently applied. See *Annales de Chimie*, xxii. 258, and *Nicholſon's Journal*, Vol. I. p 318, &c.

ALUMINE, one of the ſimple earths. See CHEMISTRY in this *Supplement*.

AMICABLE NUMBERS have been defined, and the firſt pair of them given in the Encyclopædia. The ſecond pair of amicable numbers are 17296 and 18416; and the third pair are 9363584 and 9437056.

Dr Hutton informs us, that theſe three pairs of amicable numbers, with the properties from which they receive

micable,
Amſter-
dam.

ceive their name, were found out by F. Schooten, as appears from Sect. ix. of his *Exercitationes Mathematicæ*. To find the firſt pair, he puts $4x$ and $4yz$, or a^2x and a^2yz for the two numbers, where $a=2$; then making each of theſe equal to the ſum of the aliquot parts of the other, gives two equations, from which are found the values of x and z, and conſequently, aſſuming a proper value for y, the two amicable numbers themſelves $4x$ and $4yz$.

In like manner for the other pairs of ſuch numbers; in which he finds it neceſſary to aſſume $16x$ and $16yz$, or a^4x and a^4yz for the ſecond pair, and $128x$ and $128yz$ or a^7x and a^7yz for the third pair.

Schooten then gives this practical rule, from Deſcartes, for finding amicable rules, viz. aſſume the number 2, or ſome power of the number 2, ſuch that if unity or 1 be ſubtracted from each of theſe three following quantities, viz. from 3 times the aſſumed number, alſo from 6 times the aſſumed number, and from 18 times the ſquare of the aſſumed number, the three remainders may be all prime numbers; then the laſt prime number being multiplied by double the aſſumed number, the product will be one of the amicable numbers ſought, and the ſum of its aliquot parts will be the other. That is, if a be put $=$ the number 2, and n ſome integer number, ſuch that $3a^n-1$, and $6a^n-1$, and $18a^{2n}-1$ be all three prime numbers; then is $\overline{18a^{2n}-1}\times 2a^n$ one of the amicable numbers; and the ſum of its aliquot parts is the other.

AMSTERDAM and St Paul, are two iſlands in the South Sea, lying in the ſame degree of longitude, and generally confounded with each other. The Dutch navigators have given the name of *Amſterdam* to the northern, and of *St Paul* to the ſouthern iſland, and Captain Cook conforms to that appellation. Moſt other Engliſh navigators, and particularly Meſſrs Cox and Mortimer, with Sir George Staunton, reverſe the names, calling the ſouthern iſland Amſterdam, and the other St Paul. At this ſouthern iſland the Lion man of war ſtopped on her voyage to China with Lord Macartney, the late ambaſſador to the court of Pekin, which gave an opportunity to the men of ſcience in the train of the ambaſſador to examine the iſland with more ſkill and attention than probably it had ever been examined before.

Dr Gillan, who was appointed phyſician to the embaſſy, as well for his knowledge of chemiſtry as for his medical ſkill, is confident that the iſland of Amſterdam is the product of ſubterraneous fire, as it bears in every part of it evident marks of volcanic eruption. "On the weſt and ſouth-weſt ſides (ſays he) there are four ſmall cones regularly formed, with craters in their centres, in which the lava and other volcanic ſubſtances have every appearance of recent formation. The heat continues ſtill ſo great, and ſuch a quantity of elaſtic vapours iſſues through numberleſs crevices, that there can be no doubt of their having been very lately in a ſtate of eruption. In a thermometer placed upon the ſurface, the quickſilver roſe conſtantly to 180 degrees, and when ſunk a little into the aſhes, it advanced to 212 degrees. It certainly would have riſen ſtill higher; but the ſcale being graduated only to the point of boiling water, and the length of the tube proportioned to that extent, the thermometer was immediately withdrawn, leſt the increaſing expanſion of the quickſilver ſhould burſt the glaſs. The ground was felt tremulous under the feet; a ſtone thrown violently upon it returned a hollow ſound; and the heat was ſo intenſe for a conſiderable diſtance around, that the foot could not be kept for a quarter of a minute in the ſame poſition without being ſcorched. But the great crater on the eaſtern ſide, now full of water, is by far the largeſt here, or perhaps elſewhere, and is of an aſtoniſhing ſize, conſiderably exceeding in diameter thoſe of Etna or Veſuvius. The quantity of matter to be thrown up, which required ſo wide an orifice for its paſſage, and the force with which ſuch matter was impelled, in order to overcome the reſiſtance of the ſuperincumbent earth and ſea, muſt have been indeed prodigious.

Amſter-
dam.

"This vaſt crater, according to the uſual method of computing the antiquity of volcanoes, muſt have been formed at a very remote period. The lava all around its ſides is much decompoſed, and has mouldered into duſt, which lies on the ſurface in many parts to a conſiderable depth. The decompoſition has ſupplied a rich ſoil for the long graſs growing on the ſides of the crater, and has even ſpread over moſt parts of the iſland. The fibrous roots of the graſs, extending in all directions through the decompoſed lava and volcanic aſhes, and mixed in a decaying ſtate with the vegetable mould, produced from the annual putrefaction of the leaves and ſtalks, have formed a layer of ſoil ſeveral feet deep all over the iſland. But as it has nothing except its own weight to compreſs it together, it is of a light ſpongy texture, with very little cohesion, and in many places furrowed and interſected by the ſummer rains, and the torrents occaſioned by the melting of the ſnow which lies upon it in the winter, from three to four feet thick, in all thoſe places where the ſubterraneous heat is not great enough to prevent its accumulation. In ſome parts theſe furrows and cavities are deeper than the level of the common channel; hence they ſerve the purpoſe of ſmall natural reſervoirs. The water flows into them from all the neighbouring ground; and as their ſides are ſhaded, and almoſt covered over by the leaves of the long graſs, growing from their edges in oppoſite directions, the rays of the ſun are excluded, and very little is loſt by evaporation. Theſe reſervoirs, however, are very ſmall, and but few in number; the largeſt could not contain more than three or four hogſheads of water; and there is none elſe to be found, except in the ſprings on the ſides of the large crater.

"The ſoil everywhere being light and ſpongy, and full of holes, formed in it by ſea-birds for neſts, is very troubleſome to walk upon; the foot breaks through the ſurface, and ſinks deep at every ſtep; a circumſtance which renders the journey acroſs the iſland uncommonly fatiguing, although it be ſcarcely three miles from the edge of the great crater to the oppoſite weſt ſide. There is one place near the centre of the iſland, extending about 200 yards in length, and ſomewhat leſs in breadth, where particular caution is neceſſary in walking over it. From this ſpot a hot freſh ſpring is ſuppoſed to derive its ſource, finding its way through the interſtices of the lava to the great crater, and burſting out a little above the water covering its bottom. The heat in this upper ſpot is too great to admit of vegetation. The ſurface is covered with a kind of mud or paſte formed from the aſhes, moiſtened by ſteam conſtantly riſing from below. When the mud is removed, the vapour iſſues forth with violence, and in ſome parts copiouſly. This mud is ſo hot, that a gentleman who inadvertently ſtepped into it had his foot ſeverely ſcalded by it. The ſame cauſes which have prevented vegetation on this ſpot, have had the ſame effect on the four cones recently thrown up. Their ſurfaces are covered with aſhes only; nor is there the leaſt appearance even of moſs on the ſurrounding lava, for the production of which there does not appear to have elapſed a ſufficient length of time ſince the cones were formed: but this is not the caſe with the lava of the great primary crater; for in thoſe parts of it where the edges are more perpendicular, and where conſequently the mouldering decompoſed earth, having no baſis to ſupport it, ſlides down the ſides of the rock, pretty long moſs was generally found growing upon it. All the ſprings or reſervoirs of hot water, except one only, were brackiſh. One ſpring derives its ſource from the high ground and ridges of the crater. The water in it, inſtead of boiling upwards through the ſtones and mud, as in the other ſprings, flows downward with a conſiderable velocity, in a ſmall collected ſtream. Its temperature has been found not to exceed 112 degrees. The hand could be eaſily kept in it for a conſiderable time. It is a pretty ſtrong chalybeate. The ſides of the rock whence it iſſues, and of the cavity into which it falls, are incruſted with ochre depoſited from it.

" When the great crater is viewed from the high ground, it appears to have been originally a perfect circle, but to have been encroached upon by the ſea on the eaſtern ſide, where the flood tide ſtrikes violently. The rocks of lava which formed the edge of the crater on that ſide have fallen down. The depth of the water in the crater is about 170 feet, rendering the whole height of the crater, from the bottom to its upper ridge, nearly if not quite 900 feet. The lofty rocks forming this ridge are the higheſt parts of the iſland, which ſeems to have been originally produced by the melted lava flowing down on all ſides from hence. Thus there is a gradual ſlope from the edges of the crater to the ſea; and the lava, though very irregular, and lying in mixed ruin and confuſion immediately around the crater, aſſumes a more uniform appearance at ſome diſtance, layer reſting regularly upon layer, with a gradual declivity the whole way down to the ſea. This diſpoſition of the layers is particularly obſervable in the weſt ſide, where they happen to terminate in an abrupt precipice. The eruptions that took place at different periods appear here diſtinctly marked by the different layers that are found with regular diviſions between them; the glaſſy lava being undermoſt, the compact next, the cellular lava next above, over it the volcanic aſhes and lighter ſubſtances, and a layer of vegetable mould covering the whole."

The iſland appears indeed in ſuch a ſtate of volcanic inflammation, that from the ſhips decks at night were obſerved, upon the heights of the iſland, ſeveral fires iſſuing out of the crevices of the earth, more conſiderable, but in other reſpects reſembling ſomewhat the nightly flames at Pietra Mala, in the mountains between Florence and Bologna, or thoſe near Bradley in Lancaſhire, occaſioned by ſome of the coal-pits having taken fire. In the day nothing more than ſmoke could be perceived.

The length of the iſland from north to ſouth is upwards of four miles, its breadth from eaſt to weſt about two miles and a half, and its circumference eleven miles, comprehending a ſurface of about eight ſquare miles, or 5120 acres, almoſt the whole of which is covered with a fertile ſoil. The iſland is inacceſſible except on the eaſt ſide, where the great crater forms a harbour, the entrance to which is deepening annually, and might by the aid of art be made fit for the paſſage of large ſhips. The tides run in and out at the rate of three miles an hour, and riſe perpendicularly eight or nine feet on the full and change of the moon; a northerly wind making the higheſt tide. The water is eight or ten fathoms deep cloſe to the edge of the crater; and in the baſon formed by the crater itſelf, the variation of the compaſs was found to be nineteen degrees and fifty minutes weſtward of the north pole.

On the iſland, which has no native inhabitants, were found three Frenchmen and two natives of England, who at the end of the American war had emigrated to Boſton. The whole five had come laſt from the Iſle of France in the Indian Ocean, and had been left on the iſland of Amſterdam, about five months before the arrival of the Lion, for the purpoſe of procuring a cargo of 25,000 ſeal-ſkins for the Canton market, which, as they had already procured 8000, they hoped to complete in about ten months more. The veſſel which brought them from the Iſle of France was gone to Nootka Sound, with a view of bringing a quantity of ſea-otter ſkins to China; and afterwards of calling for the cargo of ſeal-ſkins at this place, to be carried to China likewiſe; proceeding thus alternately to Nootka and Amſterdam iſland as long as the owners ſhould find their account in it.

The ſeals, whoſe ſkins are thus an article of commerce, are found here in greater numbers in the ſummer than in the winter, when they generally keep in deep water, and under the weeds, which ſhelter them from the inclemency of the weather. In the ſummer months they come aſhore, ſometimes in droves of 800 or 1000 at a time, out of which about 100 are deſtroyed, that number being as many as five men can ſkin and peg down to dry in the courſe of a day. Little of the oil which theſe animals might furniſh is collected, for want of caſks to put it in; part of the beſt is boiled, and ſerves thoſe people inſtead of butter. The ſeal of Amſterdam is the *phoca urſina* of Linnæus. The female weighs uſually from 70 to 120 pounds, and is from three to five feet in length, but the male is conſiderably larger. In general they are not ſhy: ſometimes they plunge into the water inſtantly upon any one's approach, but at other times remain ſteadily on the rocks, bark, and rear themſelves up in a menacing poſture; but the blow of a ſtick upon the noſe ſeemed ſufficient to diſpatch them. As the ſkins alone were the objects wanted, the carcaſes were left on the ground to putrefy at leiſure, ſtrewed in ſuch numbers as to render it difficult to avoid trading on them in walking along. The people thus employed were remarkable for the ſqualor and filth of their perſons, clothes, and dwelling; yet none of them ſeemed deſirous of leaving the place before the buſineſs they came upon ſhould be completed. One of them, an Engliſhman, who had been a conſiderable time upon the iſland on a former adventure, gave but an unfavourable account of the weather during the winter months, which are always

boiſterous,

boiſterous, with hail and ſnow; but in ſummer he acknowledged it to be very fine.

The ſea ſupplies this iſland with great varieties of excellent fiſh, particularly a kind of cod, which was equally reliſhed whether freſh or ſalted. Cray fiſh were in ſuch abundance on the bar acroſs the entrance into the crater, that at low water they might be taken with the hand; and at the anchorage of the ſhips, when baſkets, in which were proper baits, were let down into the ſea, they were in a few minutes drawn up filled with cray fiſh. This circumſtance is the more extraordinary, that in the ſame place were found abundance of ſharks and dog fiſh of uncommon ſize, which are known to be ſo voracious and ſuch enemies to all other fiſh. The baſon of the crater abounds with tench, bream, and perch; and the perſon who with a hook and line has caught any of theſe fiſh in the cold water of the baſon, may with a ſlight motion of his hand let them drop into the adjoining hot ſpring already mentioned, in which they will be boiled and rendered fit for eating in the ſpace of fifteen minutes. This was often practiſed by the gentlemen of the embaſſy, and furniſhed them at once with a ſingular amuſement and a highly reliſhed repaſt.

Of all the birds which frequent this iſland, ſo extraordinary in its origin, formation, and appearance, not one is common to the ſame degree of latitude in the northern hemiſphere. Of the larger kind were ſeveral ſpecies of the *albatroſs;* on examining one of which, diſtinguiſhed by the name of *exulans*, it was found, that inſtead of having only the rudiments of a tongue, as naturaliſts generally ſuppoſe, it had one equalling half the length of the bill. Another large bird is likewiſe common here, called the great *black petrel*, or *procellaria equinoctialis* of Linnæus. It is the determined enemy of the albatroſs, as well as of the *blue petrel* of Amſterdam, or *procellaria forſteri.* This blue petrel, which is about the ſize of a pigeon, conſtitutes the principal food of the ſeal catchers on the iſland. During the day-time they hide themſelves in the ground, in order to eſcape, if poſſible, their deſtroyer the black petrel. At night they come abroad, and thence are termed *night birds* by the people at Amſterdam; but being fond of flocking to any light, they fall into another ſnare laid for them by the ſeal-catchers, who kindle torches to attract them, and then kill them in multitudes. The pretticſt of the feathered tribe, inhabiting or viſiting Amſterdam, is the ſilver bird, or *ſterna hirundo,* about the ſize of a large ſwallow or ſwift, with a forked or ſwallow tail. The bill and legs are of a bright crimſon colour, the belly white, and the back and wings of a bluiſh aſh colour. This bird ſubſiſts chiefly on ſmall fiſh, which it picks up as they are ſwimming over the ſurface of the water.

This ſingular iſland lies in 38°.42′ S. Lat. and in 76° 54′ E. Long. from Greenwich. St Paul's, or the iſland lying in ſight and to the northward, differed in appearance materially from Amſterdam. It preſented no very high land, or any riſing in a conic form; and ſeemed to be overſpread with ſhrubs or trees of a middling ſize. It was ſaid to abound with freſh water, but to have no good anchorage near it, nor any place of eaſy landing.—*Sir George Staunton's Account of an Embaſſy to the Emperor of China.*

ANACLASTIC curves, a name given by M. de Mairan to certain apparent curves formed at the bottom of a veſſel full of water, to an eye placed in the air; or the vault of the heavens, ſeen by refraction through the atmoſphere.

ANAPHORA, in aſtrology, the ſecond houſe, or that part of the heavens which is 30 degrees from the horoſcope. The term *anaphora* is alſo ſometimes applied promiſcuouſly to ſome of the ſucceeding houſes, as the 5th, the 8th, and the 11th. In this ſenſe *anaphora* is the ſame as *epanaphora*, and ſtands oppoſed to *cataphora.*

ANASTROUS signs, in aſtronomy, a name given to the *duodecatemoria*, or the twelve portions of the ecliptic, which the ſigns poſſeſſed anciently, but have ſince deſerted by the preceſſion of the equinox.

ANCHOR of a ship, is an inſtrument which, as it is commonly made, has been ſufficiently deſcribed in the Encyclopædia. An improvement, however, has been propoſed on its conſtruction by Mr James Stuard of the pariſh of St Anne, Middleſex, who obtained a patent for his invention, dated Feb. 1796.

The whole of this invention conſiſts in making the anchor with one fluke or arm inſtead of two, and contriving to load that fluke or arm in ſuch a manner as to make it always fall the right way. With this view Mr Stuard would have the ſhank of the anchor made very ſhort, that it may *cant* the more when ſuſpended by the cable; and he would have the arm and it made of bars in one length, that there may be no ſhoot or joining in the whole inſtrument. The bend of the ſhank and arm he would have rounded, and not angular as in the common anchor; and on this bend he would have a ſmall ſhackle, or two plates with a ſmall bolt between them, for the buoy-rope to be made faſt to. Inſtead of wood, he propoſes for the ſtock of the anchor a bar of wrought iron, loaded or covered at the ends with knobs of caſt iron; and he would have the palm of the fluke or arm either to be compoſed entirely of caſt iron, or to be a caſt iron ſhell filled with lead. This weight of the palm, the ſhortneſs of the ſhank, and the ſtructure of the ſtock, will no doubt make the anchor fall the right way; which, having no upper fluke, will never be tripped by the cable taking hold of it on the ſhip's ſwinging, nor will it prove ſo dangerous as the common anchor to ſuch veſſels as may happen to ground by it.

ANDERSON (Alexander), an eminent mathematician, was born at Aberdeen towards the end of the 16th century. Where he was educated, or under what maſters, we have not learned; probably he ſtudied the belles lettres and philoſophy in the univerſity of his native city, and, as was the practice in that age of all who could afford it, went afterwards abroad for the cultivation of other branches of ſcience. But wherever he may have ſtudied, his progreſs in ſcience muſt have been rapid; for, early in the 17th century, we find him profeſſor of mathematics in the univerſity of Paris, where he publiſhed ſeveral ingenious works; and among others, 1. *Supplementum Apollonii Redivivi; ſive analyſis problematis hactenus deſiderati ad Apollonii Pergæi doctrinam* ϖερι νευϛιων, *a Marino Ghetaldo Patritio Raguſino hujuſque, non ita pridem reſtitutam. In qua exhibetur mechanice æqualitatum tertii gradus ſive ſolidarum, in quibus magnitudo omnino data, æquatur homogeneæ ſub altero tantum coefficiente ignoto. Huic ſubnexa eſt variorum problematum practice,* Paris, 1612, in 4to.—2. Αιτιολογια: *Pro Zetetico Apolloniani problematis a ſe jam pridem edito in* *ſupplemento Apollonii Redivivi. Ad clariſſimum et ornatiſſimum virum Marinum Ghetaldum Patritium Raguſinum. Paris, 1615, in 4to.—4. Vieta's *Angulares Sectiones;* to which he added demonſtrations of his own. Our profeſſor was couſin-german to Mr David Anderſon of Finſhaugh, a gentleman who alſo poſſeſſed a ſingular turn for mathematical knowledge. This mathematical genius was hereditary in the family of the Anderſons; and from them it ſeems to have been tranſmitted to their deſcendants of the name of Gregory, who have for ſo many generations been eminent in Scotland as profeſſors either of mathematics, or, more lately, of the theory and practice of phyſic. The daughter of the David Anderſon juſt mentioned, was the mother of the celebrated James Gregory, inventor of the reflecting teleſcope; and obſerving in her ſon, while yet a child, a ſtrong propenſity to mathematical ſtudies, ſhe inſtructed him in the elements of that ſcience herſelf. From the ſame lady deſcended the late Dr Reid of Glaſgow, who was not leſs eminent for his knowledge of mathematics than for his writings as a metaphyſician.

The preciſe dates of Alexander Anderſon's birth and death, we have not learned either from Dempſter, Mackenzie, or Dr Hutton, who ſeems to have uſed every endeavour to procure information; nor are ſuch of his relations as we have had an opportunity of conſulting, ſo well acquainted with his private hiſtory as we expected to find them.

ANHINGA, in ornithology, a ſpecies of the pelicanus, conſiſts of four known varieties: two peculiar to America, one to Senegal, and the fourth to the region about the Cape of Good Hope. This laſt is thus deſcribed by Le Vaillant in his New Travels into the Interior Parts of Africa.

Plate III.

"The denomination of *Slange-Hals-Voogel*, given to it by the Hottentots, characteriſes the anhinga in a very ſimple and accurate manner. Buffon, who was ſtruck with the conformation peculiar to birds of this kind, has delineated them by a ſimilar expreſſion. 'The anhinga (ſays he) exhibits a reptile grafted on the body of a bird.' Indeed there is no perſon who, upon ſeeing the head and neck only of an anhinga, while the reſt of the body is hid among the foliage of the tree on which it is perched, would not take it for one of thoſe ſerpents accuſtomed to climb and reſide in trees; and the miſtake is ſo much the eaſier, as all its tortuous motions ſingularly favour the illuſion. In whatever ſituation the anhinga may be ſeen, whether perched on a tree, ſwimming in the water, or flying in the air, the moſt apparent and remarkable part of its body is ſure to be its long and ſlender neck, which is continually agitated by an oſcillatory motion, unleſs in its flight, when it becomes immoveable and extended, and forms with its tail a perfectly ſtraight and horizontal line.

"The true place which nature ſeems to have aſſigned to the anhingas, in the numerous claſs of the palmipedes, is exactly between the cormorant and the grebe. They partake indeed equally of both theſe genera of birds, having the ſtraight ſlender bill and the long neck of the latter; while they approach the former by the conformity of their feet, the four toes of which are joined by a ſingle membrane. They partake alſo of the cormorant by their flight; having like it the wings larger and fitter for the purpoſe than thoſe of the grebe, which are ſhort and weak. The tail of the anhinga is extremely long; a characteriſtic very ſingular and remarkable in a water fowl, and which ought, it would ſeem, to render them totally diſtinct from diving birds, which in general have little or no tail. By this trait they approach ſtill nearer to the cormorants; for tho' the tails of the latter are ſhorter, the tails of both have a great reſemblance to each other, ſince their quills are equally ſtrong, elaſtic, and proper to form a rudder when theſe fowls ſwim through the water in purſuit of fiſh, which conſtitute their principal nouriſhment. When the anhinga ſeizes a fiſh, he ſwallows it entire if it be ſmall enough, and if too large he carries it off to a rock or the ſtump of a tree, and fixing it under one of his feet, tears it to pieces with his bill.

"Though water is the favourite element of this bird, it builds its neſt and rears its young on rocks and trees; but it takes great care to place them in ſuch a manner, that it can precipitate them into a river as ſoon as they are able to ſwim, or the ſafety of the little family may require it."

The male anhinga differs from the female, which is ſmaller, in having the whole under part of the body, from the breaſt to the root of the tail, of a beautiful black, while the latter has the ſame parts of a yellow iſabella colour. It has alſo, on each ſide of its neck, a white ſtripe, which extends from the eye to the middle of its length, and interſects a reddiſh ground. A very ſingular characteriſtic, common to all the anhingas, is that of having the feathers of the tail deeply ſtriated, and as it were ribbed. It is a very ſagacious bird, eſpecially when ſurpriſed ſwimming; for its head is the only part which it expoſes above the water; and if the ſportſman once miſs that part, the anhinga plunges out of ſight entirely, and never more ſhows itſelf but at very great diſtances, and then no longer at a time than is abſolutely neceſſary for breathing.

ANTECEDENTAL CALCULUS. See CALCULUS in this Supplement.

ANTES, in architecture, ſmall pilaſtres placed at the corners of buildings.

ANTICS, in architecture, figures of men and animals placed as ornaments to buildings.

ANTICUM, in architecture, a porch; alſo that part of a temple which lies between the body of the temple and the portico, and is therefore called the outer temple.

ANTIMETER, or REFLECTING SECTOR, an inſtrument invented by Mr William Garrard, for the purpoſe of meaſuring angles, particularly ſmall ones, with a greater degree of accuracy than can be done by Hadley's quadrant or by the ſextant.

The frame of this inſtrument is ſimilar to that of Hadley's quadrant, having two radii, a limb, and braces; but with this difference, that the further radius is produced upwards of four inches beyond the centre of motion of the index; and the great ſpeculum, or what is called the index-glaſs in Hadley's quadrant, being placed there, is called the *upper centre*. In this inſtrument there is no proviſion for the back obſervation.

Antimeter. The horizon-glaſs is like that in Hadley's quadrant; there are two ſight vanes, to ſuit two different ſituations of the large ſpeculum or object glaſs: theſe vanes are adapted to receive a ſmall teleſcope. On the centre of the index, where the index-glaſs of Hadley's quadrant is fixed, is a braſs or bell-metal ſemicircle, two inches in diameter, and one-eighth of an inch thick: this ſemicircle is ſcrewed faſt to the index, in ſuch a manner that the axis of the index is a tangent to it. On the upper centre are two circular braſs plates, which revolve concentrically, either together or ſeparately. The under plate has a lever, or part perpendicular to the plane of the inſtrument, projecting downwards, a little beyond the lower centre: this lever is acted upon by the ſemicircular plate at the lower centre, to which it is always kept cloſe by a ſpring on the other ſide. In the upper of the above mentioned circular plates are two circular perforations or ſlits, through one of which a ſcrew takes into the head of the inſtrument, and through the other a ſcrew takes into the lower moveable plate. The large ſpeculum is faſtened to the upper plate; and by the above mentioned ſcrews the poſition of this glaſs may be altered. A circular plate is fixed to the lower centre by three pillars: in its centre is a nut to admit a ſcrew, by which the plate carrying the large ſpeculum may be faſtened here occaſionally.

The ſcale on the limb is divided into 45 equal parts or degrees, and not into half degrees, as is the caſe in Hadley's quadrant, by reaſon of the double reflection. Theſe diviſions are numbered in a retrograde order; zero being at the extremity of the further radius. Although the limb contains 45 degrees, yet the greateſt angle which can be meaſured, the large ſpeculum remaining fixed to the circular plate, is 10° 18′ 21″.8; the diſtance between the two centres being four inches, and the radius of the ſemicircle one inch. Agreeable to theſe dimenſions, the inventor has given a table exhibiting the value of each primary diviſion on the limb; he hath alſo given a more ample table, adapted to a diſtance between the centres of three times the radius of the ſemicircle, which he ſays hath been found the moſt convenient in practice. If an angle greater than 10° 18′ is wanted, it may be meaſured by the method of *anticipation*, as the inventor calls it, which is as follows: Let the ſcrew which faſtens the two circular plates on the upper centre be made faſt, and looſen the ſcrew which faſtens the upper circular plate to the inſtrument: Now adjuſt the glaſſes by the uſual method; bring forward the index to any given diviſion on the limb, and make it faſt; alſo faſten the ſcrew which was before looſe, and looſen the other ſcrew; then bring the index to zero, and proceed as before.

The inventor gives the following directions for adjuſting and uſing the inſtrument.

The firſt thing to be attended to is, to ſet the horizon-glaſs perpendicular to the plane of the inſtrument, which is performed as follows: Hold the inſtrument with its plane perpendicular to the horizon, and look over backwards into the glaſs and beyond it. If the limb of the inſtrument appears in a right line with its reflection, the glaſs is upright; but if it does not appear ſo, looſen or tighten the little ſcrew on the foot of the glaſs until it be adjuſted: Then with the inſtrument, as in taking an altitude, look through the ſight vane or teleſcope at ſome diſtant object, with the index fixed in any intended ſituation; the two ſcrews at the upper centre being looſe, turn the glaſs about till the ſame object appears nearly in the ſame part of the horizon-glaſs: Next hold it in a horizontal poſition, and adjuſt the object-glaſs or large ſpeculum with the ſcrews which are behind and before, on the foot of it, till the object and its reflection are ſeen in the ſame horizontal line. Laſtly, with the inſtrument upright, turn the tangent-ſcrew belonging to the horizon-glaſs at the back of the inſtrument, until there be a perfect coincidence of the object and its reflection that way, and the adjuſtments are complete.

ANTIPARALLELS, in geometry, are thoſe lines which make equal angles with two other lines, but contrariwiſe; that is, calling the former pair the firſt and ſecond lines, and the latter pair the third and fourth lines, if the angle made by the firſt and third lines be equal to the angle made by the ſecond and fourth, and contrariwiſe the angle made by the firſt and fourth equal to the angle made by the ſecond and third; then each pair of lines are antiparallels with reſpect to each other, viz. the firſt and ſecond, and the third and fourth. So, if AB and AC be any two lines, Plate II. fig. 5. and FC and FE be two others, cutting them ſo,

that the angle B is equal to the angle E,
and the angle C is equal to the angle D;

then BC and DE are antiparallels with reſpect to AB and AC; alſo theſe latter are antiparallels with regard to the two former. It is a property of theſe lines, that each pair cuts the other into proportional ſegments, taking them alternately,

viz. AB : AC : : AE : AD : : DB : EC,
and FE : FC : : FB : FD : : DE : BC.

APERTURE, in optics, has been defined in the Encyclopædia, but no rule was given there for finding a juſt aperture. As much depends upon this circumſtance, our optical readers will be pleaſed with the following practical rule given by Dr Hutton in his Mathematical Dictionary. "Apply ſeveral circles of dark paper, of various ſizes, upon the face of the glaſs, from the breadth of a ſtraw to ſuch as leave only a ſmall hole in the glaſs; and with each of theſe, ſeparately, view ſome diſtant object, as the moon, ſtars, &c. then that aperture is to be choſen through which they appear the moſt diſtinctly.

"Huyghens firſt found the uſe of apertures to conduce much to the perfection of teleſcopes; and he found by experience (*Diopt.* prop. 56.), that the beſt aperture for an object-glaſs, for example of 30 feet, is to be determined by this proportion, as 30 to 3, ſo is the ſquare root of 30 times the diſtance of the focus of any lens to its proper aperture: and that the focal diſtances of the eye-glaſſes are proportioned to the apertures. And M. Auzout ſays he found, by experience, that the apertures of teleſcopes ought to be nearly in the ſub-duplicate ratio of their lengths. It has alſo been found by experience, that object-glaſſes will admit of greater apertures, if the tubes be blacked within ſide, and their paſſage furniſhed with wooden rings.

"It is to be noted, that the greater or leſs aperture of an object-glaſs, does not increaſe or diminiſh the viſible area of the object; all that is effected by this is the admittance of more or fewer rays, and conſequently the more or leſs bright the appearance of the object. But the largeneſs of the aperture or focal diſtance cauſes the

the irregularity of its refractions. Hence, in viewing Venus through a teleſcope, a much leſs aperture is to be uſed than for the moon, or Jupiter, or Saturn, becauſe her light is ſo bright and glaring. And this circumſtance ſomewhat invalidates and diſturbs Azout's proportion, as is ſhown by Dr Hook, Phil. Tranſ. N° 4."

APOCATASTASIS, or, as it ſhould be written, Apokatastasis, is a Greek word employed in the language of aſtronomers, to denote the period of a planet, or the time it takes to return to that point of the zodiac whence it ſet out.

APOTOME, is a term employed by Euclid to denote the difference between two lines or quantities which are only commenſurable in power. Such is the difference between 1 and $\sqrt{2}$, or the difference between the ſide of a ſquare and its diagonal. The doctrine of apotomes in lines, as delivered by this ancient mathematician in the tenth book of his Elements, is a very curious ſubject, and has always been admired by ſuch as underſtood it. The firſt algebraical writers in Europe, ſuch as Lucas de Burgo, Cardan, Tartalea, Stifelius, &c. employed a conſiderable portion of their works on an algebraical expoſition of that which led them to the doctrine of ſurd quantities.

APPARENT conjunction of the planets, is when a right line, ſuppoſed to be drawn through their centres, paſſes through the eye of the ſpectator, and not through the centre of the earth. And, in general, the apparent conjunction of any objects, is when they appear or are placed in the ſame right line with the eye.

Apparent Diameter of a planet or other heavenly body, is not the real length of the diameter of that body, but the angle which it ſubtends at the eye, or under which it appears.

Apparent Diſtance, is that which we judge an object to be from us when ſeen afar off; and which is almoſt always very different from the true diſtance.

Apparent Figure, is the figure or ſhape under which an object appears when viewed at a diſtance; and is often very different from the true figure. Thus a ſtraight line, viewed at a diſtance, may appear but as a point; a ſurface, as a line; and a ſolid, as a ſurface.

Apparent Motion, is either that motion which we perceive in a diſtant body that moves, the eye at the ſame time being either in motion or at reſt; or that motion which an object at reſt ſeems to have, while the eye itſelf only is in motion.

Apparent Place of a Planet, &c. in aſtronomy, is that point in the ſurface of the ſphere of the world where the centre of the luminary appears from the ſurface of the earth.

APPARITION, in aſtronomy, denotes a ſtar's or other luminary's becoming viſible, which before was hid. So, the heliacal riſing, is rather an apparition than a proper riſing.

1 Arch defined.

ARCH, in building, is an artful diſpoſition and adjuſtment of ſeveral ſtones or bricks, generally in a bow-like form, by which their weight produces a mutual preſſure and abutment; ſo that they not only ſupport each other, and perform the office of an entire lintel, but may be extended to any width, and made to carry the moſt enormous weights.

2 Hiſtory of architecture connected with arches.

In thoſe mild climates which ſeem to have been the firſt inhabited parts of this globe, mankind ſtood more in need of ſhade from the ſun than of ſhelter from the inclemency of the weather. A very ſmall addition to the ſhade of the woods ſerved them for a dwelling. Sticks laid acroſs from tree to tree, and covered with bruſhwood and leaves, formed the firſt houſes in thoſe delightful regions. As population and the arts improved, theſe huts were gradually refined into commodious dwellings. The materials were the ſame, but more artfully put together. At laſt agriculture led the inhabitants out of the woods into the open country. The connection between the inhabitant and the ſoil became now more conſtant and more intereſting. The wiſh to preſerve this connection was natural, and fixed eſtabliſhments followed of courſe. Durable buildings were more deſirable than thoſe temporary and periſhable cottages—ſtone was ſubſtituted for timber.

But as theſe improved habitations were gradual refinements on the primitive hut, traces of its conſtruction remained, even when the choice of more durable materials made it in ſome meaſure inconvenient. Thus it happened, that while a plain building, intended for accommodation only, conſiſted of walls, pierced with the neceſſary doors and windows, an ornamented building had, ſuperadded to theſe eſſentials, columns, with the whole apparatus of entablature, borrowed from the wooden building, of which they had been eſſential parts, gradually rendered more ſuitable to the purpoſes of accommodation and elegance.

3 Origin of Greek architecture

This view of ornamental architecture will go far to account for ſome of the more general differences of national ſtyle which may be obſerved in different parts of the world. The Greeks borrowed many of their arts from their Aſiatic neighbours, who had cultivated them long before. It is highly probable that architecture travelled from Perſia into Greece. In the ruins of Shuſhan, Perſepolis, or Tchilminar, are to be ſeen the firſt models of every thing that diſtinguiſhes the Grecian architectures. There is no doubt, we ſuppoſe, among the learned, as to the great priority of theſe monuments to any thing that remains in Greece; eſpecially if we take into account the tombs on the mountains, which have every appearance of greater antiquity than the remains of Perſepolis. In thoſe tombs we ſee the whole *ordonnance* of column and entablature, juſt as they began to deviate from their firſt and neceſſary forms in the wooden buildings. We have the architrave, frize, and corniche; the far-projecting mutules of the Tuſcan and Doric orders; the modillions no leſs diſtinct; the rudiments of the Ionic capital; the Corinthian capital in perfection, pointing out the very origin of this ornament, viz. a number of long graceful leaves tied round the head of the column with a fillet (a cuſtom which we know to have been common in their temples and banqueting rooms). Where the diſtance between the columns is great, ſo that each had to ſupport a weight too great for one tree, we ſee the columns cluſtered or fluted, &c. In ſhort, we ſee every thing of the Grecian architecture but the ſloped roof or pediment; a thing not wanted in a country where it hardly ever rains.

4 Egyptian

The ancient Egyptian architecture ſeems to be a refinement on the hut built of clay or unburnt bricks mixed with ſtraw; every thing is maſſive, clumſy, and timid; ſmall intercolumnations, and hardly any projections.

5 Arabian, and

The Arabian architecture ſeems a refinement on the tent. A moſque is like a little camp, conſiſting of a number of little bell tents, ſtuck cloſe together round a great one. A caravanſeray is a court ſurrounded by a row of ſuch tents, each having its own dome. The Greek church of St Sophia at Conſtantinople has imitated this in ſome degree; and the copies from it, which have been multiplied in Ruſſia as the ſacred form for a Chriſtian church, have adhered to the original model of cluſtered tents in the ſtricteſt manner. We are ſometimes diſpoſed to think that the painted glaſs (a faſhion brought from the Eaſt) was in imitation of the painted hangings of the Arabs.

6 Chineſe ar- hitecture. The Chineſe architecture is an evident imitation of a wooden building. Sir Geo. Staunton ſays, that the ſingular form of their roofs is a *profeſſed* imitation of the cover of a ſquare tent.

In the ſtone-buildings of the Greeks, the roofs were imitations of the wooden ones; hence the lintels, flying corniches, ceilings in compartments, &c.

Plate I. 7 Origin of he arch. The pediment of the Greeks ſeems to have ſuggeſted the greateſt improvement in the art of building. In erecting their ſmall houſes, they could hardly fail to obſerve occaſionally, that when two rafters were laid together, from the oppoſite walls, they would, by leaning on each other, give mutual ſupport, as in fig. 1. Nor is it unlikely that ſuch a ſituation of ſtones as is repreſented in fig. 2. would not unfrequently occur by accident to maſons. This could hardly fail of exciting a little attention and reflection. It was a pretty obvious reflection, that the ſtones A and C, by overhanging, leaned againſt the intermediate ſtone B, and gave it ſome ſupport, and that B cannot get down without thruſting aſide A and C, or the piers which ſupport them. This was an approach to the theory of an arch; and if this be combined with the obſervation of fig. 1. we get the diſpoſition repreſented in fig. 3. having a perpendicular joint in the middle, and the *principle of the arch* is completed. Obſerve that this is quite different from the principle of the arrangement in fig. 2. In that figure the ſtones act as wedges, and one cannot get down without thruſting the reſt aſide; the ſame principle obtains in fig. 4. conſiſting of five arch ſtones; but in fig. 3. the ſtones B and C ſupport each other by their mutual preſſure (independent of their own weight), ariſing from the tendency of each lateral pair to fall outwards from the pier. This is the principle of the arch, and would ſupport the key-ſtone of fig. 4. although each of its joints were perpendicular, by reaſon of the great friction ariſing from the horizontal thruſt exerted by the adjoining ſtones.

This was a moſt important diſcovery in the art of building; for now a building of any width may be roofed with ſtone.

8 recian. We are diſpoſed to give the Greeks the merit of this diſcovery; for we obſerve arches in the moſt ancient buildings of Greece, ſuch as the temple of the ſun at Athens, and of Apollo at Didymos; not indeed as roofs to any apartment, nor as parts of the ornamental deſign, but concealed in the walls, covering drains or other neceſſary openings; and we have not found any *real* arches in any monuments of ancient Perſia or Egypt. Sir John Chardin ſpeaks of numerous and extenſive ſubterranean paſſages at Tchilminar, built of the moſt exquiſite maſonry, the joints ſo exact, and the ſtones ſo beautifully dreſſed, that they look like one continued piece of poliſhed marble: but he nowhere ſays that they are arched; a circumſtance which we think he would not have omitted—no arched door or window is to be ſeen. Indeed one of the tombs is ſaid to be arch-roofed, but it is all of one ſolid rock. No trace of an arch is to be ſeen in the ruins of ancient Egypt; even a wide room is covered with a ſingle block of ſtone. In the pyramids, indeed, there are two galleries, whoſe roofs conſiſt of many pieces; but their conſtruction puts it beyond doubt that the builder did not know what an arch was: for it is covered in the manner repreſented in fig. 5. where every projecting piece is more than balanced behind, ſo that the whole awkward maſs could have ſtood on two pillars. The Greeks therefore ſeem entitled to the honour of the invention. The arched dome, however, ſeems to have ariſen in Etruria, and originated in all probability from the employment of the augurs, whoſe buſineſs it was to obſerve the flight of birds. Their ſtations for this purpoſe were *templa*, ſo called *a templando*, "on the ſummits of hills." To ſhelter ſuch a perſon from the weather, and at the ſame time allow him a full proſpect of the country around him, no building was ſo proper as a dome ſet on columns; which accordingly is the figure of a temple in the moſt ancient monuments of that country. We do not recollect a building of this kind in Greece except that called the *Lanthern of Demoſthenes*, which is of very late date, whereas they abounded in Italy. In the later monuments and coins of Italy or of Rome, we commonly find the Etruſcan dome and the Grecian temple combined; and the famous pantheon was of this form, even in its moſt ancient ſtate.

9 It was uſed at firſt only in bridges and aqueducts. It does not appear that the arch was conſidered as a part of the *ornamental* architecture of the Greeks during the time of their independency. It is even doubtful whether it was employed in roofing their temples. In none of the *ancient* buildings where the roof is gone, can there be ſeen any rubbiſh of the vault, or mark of the ſpring of the arch. It is not unfrequent, however, after the Roman conqueſts, and may be ſeen in Athens, Delos, Palmyra, Balbek, and other places. It is very frequent in the magnificent buildings of Rome; ſuch as the Coliſeum, the baths of Diocleſian, and the triumphal arches, where its form is evidently made the object of attention. But its chief employment was in bridges and aqueducts; and it is in thoſe works that its immenſe utility is the moſt conſpicuous: For by this happy contrivance a canal or a road may be carried acroſs any ſtream, where it would be almoſt impoſſible to erect piers ſufficiently near to each other for carrying lintels. Arches have been executed 130 feet wide, and their execution demonſtrates that they may be made four times as wide.

10 Difficulty of conſtructing it. As ſuch ſtupendous arches are the greateſt performances of the maſonic art, ſo they are the moſt difficult and delicate. When we reflect on the immenſe quantity of materials thus ſuſpended in the air, and compare this with the ſmall coheſion which the firmeſt cement can give to a building, we ſhall be convinced that it is not by the force of the cement that they are kept together: they ſtand faſt only in conſequence of the proper balance of all their parts. Therefore, in order to erect them with a well-founded confidence of their durability, this balance ſhould be well underſtood and judiciouſly employed. We doubt not but that this was underſtood in ſome degree by the engineers of antiquity.

ty; but they have left us none of their knowledge. They muſt have had a great deal of mechanical knowledge before they could erect the magnificent and beautiful buildings whoſe ruins ſtill enchant the world; but they kept it among themſelves. We know that the Dionyſiacs of Ionia were a great corporation of architects and engineers, who undertook, and even monopolized, the building of temples, ſtadiums, and theatres, preciſely as the fraternity of maſons in the middle ages monopolized the building of cathedrals and conventual churches. Indeed the Dionyſiacs reſembled the myſtical fraternity now called free maſons in many important particulars. They allowed no ſtrangers to interfere in their employment; they recogniſed each other by ſigns and tokens; they profeſſed certain myſterious doctrines, under the tuition and tutelage of Bacchus, to whom they built a magnificent temple at Teos, where they celebrated his myſteries as ſolemn feſtivals; and they called all other men profane, becauſe not admitted to theſe myſteries. But their chief myſteries and moſt important ſecrets ſeem to be their mechanical and mathematical ſciences, or all that academical knowledge which forms the regular education of a civil engineer. We know that the temples of the gods and the theatres required an immenſe apparatus of machinery for the celebration of ſome of their myſteries; and that the Dionyſiacs contracted for thoſe jobs, even at far diſtant places, where they had not the privilege of building the edifice which was to contain them. This is the moſt likely way of explaining the very ſmall quantity of mechanical knowledge that is to be met with in the writings of the ancients. Even Vitruvius does not appear to have been of the fraternity, and ſpeaks of the Greek architects in terms of reſpect next to veneration. The *Collegium Murariorum*, or incorporation of maſons at Rome, does not ſeem to have ſhared the ſecrets of the Dionyſiacs.

11
Skill and myſteries of the Dionyſiacs.

12
The art of building arches underſtood in the middle ages

The art of building arches has been moſt aſſiduouſly cultivated by the aſſociated builders of the middle ages of the Chriſtian church, both Saracens and Chriſtians, and they ſeem to have indulged in it with fondneſs: they multiplied and combined arches without end, placing them in every poſſible ſituation.

13
Better than by the Greeks and Romans.

Having ſtudied this branch of the art of building with ſo much attention, they were able to erect the moſt magnificent buildings with materials which a Greek or Roman architect could have made little or no uſe of. There is infinitely more ſcientific ſkill diſplayed in a Gothic cathedral than in all the buildings of Greece and Rome. Indeed theſe laſt exhibit very little knowledge of the mutual balance of arches, and are full of groſs blunders in this reſpect; nor could they have reſiſted the ſhock of time ſo long, had they not been almoſt ſolid maſſes of ſtone, with no more cavity than was indiſpenſably neceſſary.

14
Defects of the church of St Sophia at Conſtantinople.

Anthemius and Iſidorus, whom the Emperor Juſtinian had ſelected as the moſt eminent architects of Greece for building the celebrated church of St Sophia at Conſtantinople, ſeem to have known very little of this matter. Anthemius had boaſted to Juſtinian, that he would outdo the magnificence of the Roman pantheon, for he would hang a greater dome than it aloft in the air. Accordingly he attempted to raiſe it on the heads of four piers, diſtant from each other about 115 feet, and about the ſame height. He had probably ſeen the magnificent vaultings of the temple of Mars the Avenger, and the temple of Peace at Rome, the thruſts of which are withſtood by two maſſes of ſolid wall, which join the ſide walls of the temple at right angles, and extend ſidewiſe to a great diſtance. It was evident that the walls of the temple could not yield to the preſſure of the vaulting without puſhing theſe immenſe buttreſſes along their foundations. He therefore placed four buttreſſes to aid his piers. They are almoſt ſolid maſſes of ſtone, extending at leaſt 90 feet from the piers to the north and to the ſouth, forming as it were the ſide walls of the croſs. They effectually ſecured them from the thruſts of the two great arches of the nave which ſupport the dome; but there was no ſuch proviſion againſt the puſh of the great north and ſouth arches. Anthemius truſted for this to the half dome, which covered the ſemicircular eaſt end of the church, and occupied the whole eaſtern arch of the great dome. But when the dome was finiſhed, and had ſtood a few months, it puſhed the two eaſtern piers with their buttreſſes from the perpendicular, making them lean to the eaſtward, and the dome and half dome fell in. Iſidorus, who ſucceeded to the charge on the death of Anthemius, ſtrengthened the piers on the eaſt ſide, by filling up ſome hollows, and again raiſed the dome. But things gave way before it was cloſed; and while they were building in one part it was falling in in another. The pillars and walls of the eaſtern ſemicircular end were much ſhattered by this time. Iſidorus ſeeing that they could give no reſiſtance to the puſh which was ſo evidently directed that way, erected ſome clumſy buttreſſes on the eaſt wall of the ſquare which ſurrounded the whole Greek croſs, and was roofed in with it, forming a ſort of cloiſter round the whole. Theſe buttreſſes, ſpanning over this cloiſter, leaned againſt the piers of the dome, and thus oppoſed the thruſts of the great north and ſouth arches. The dome was now turned for the third time, and many contrivances were adopted for making it extremely light. It was made offenſively flat; and, except the ribs, it was roofed with pumice ſtone; but, notwithſtanding theſe precautions, the arches ſettled ſo as to alarm the architects, and they made all ſure by filling up the whole from top to bottom with arcades in three ſtories. The loweſt arcade was very lofty, ſupported by four noble marble columns, and thus preſerved, in ſome meaſure, the church in the form of a Greek croſs. The ſtory above formed a gallery for the women, and had ſix columns in front, ſo that they did not bear fair on thoſe below. The third ſtory was a dead wall filling up the arch, and pierced with three rows of ſmall ill-ſhaped windows. In this unworkmanlike ſhape it has ſtood till now, and is the oldeſt church in the world; but it is an ugly miſhapen maſs, more reſembling an overgrown potter's kiln, ſurrounded with furnaces pieced and patched, than a magnificent temple. We have been thus particular in our account of it, becauſe this hiſtory of the building ſhows that the ancient architects had acquired no diſtinct notions of the action of arches. Almoſt any maſon of our time would know, that as the ſouth arch would puſh the pier to the eaſtward, while the eaſt arch puſhed it to the ſouthward, the buttreſs which was to withſtand theſe thruſts muſt not be placed on the ſouth ſide of the pier, but on the ſouth-eaſt ſide, or that there muſt be an eaſtern as well as a ſouthern buttreſs. No ſuch blunders are to be ſeen

15

in a Gothi
church.

in a Gothic cathedral. Some of them appear, to a careleſs ſpectator, to be very maſſive and clumſy; but when judiciouſly examined, they will be found very bold and light, being pierced in every direction by arcades, and the walls are divided into cells like a honeycomb, ſo that they are very ſtiff, while they are very light.

16 Dr Hooke's principle of arches

About the middle, or rather towards the end, of laſt century, when the Newtonian mathematics opened the road to true mechanical ſcience, the conſtruction of arches engroſſed the attention of the firſt mathematicians. The firſt hint of a principle that we have met with is Dr Hooke's aſſertion, that the figure into which a chain or rope, perfectly flexible, will arrange itſelf when ſuſpended from two hooks, is, when inverted, the proper form for an arch compoſed of ſtones of uniform weight. This he affirmed on the ſame principle which is made uſe of in the Encyclopædia Britannica in the article Roof, § 25. viz. that the figure which a flexible feſtoon of heavy bodies aſſumes, when ſuſpended from two points, is, when inverted, the proper form for an arch of the ſame bodies, touching each other in the ſame points; becauſe the forces with which they mutually preſs on each other in this laſt caſe, are equal and oppoſite to the forces with which they pull at each other in the caſe of ſuſpenſion.

This principle is ſtrictly juſt, and may be extended to every caſe which can be propoſed. We recollect ſeeing it propoſed, in very general terms, in the St James's Chronicle in 1759, when plans were forming for Blackfriar's Bridge in London; and ſince it is perhaps equal, in practical utility, to the moſt elaborate inveſtigations of the mathematicians, our readers will not be diſpleaſed with a more particular account of it in this place.

17 Explained,

Let ABC (fig. 6.) be a parcel of magnets of any ſize and ſhape, and let us ſuppoſe that they adhere with great force by any points of contact. They will compoſe ſuch a flexible feſtoon as we have been ſpeaking of, if ſuſpended from the points A and C. If this figure be inverted, preſerving the ſame points of contact, they will remain in equilibrio. It will indeed be that kind of equilibrium which will admit of no diſturbance, and which may be called a *tottering equilibrium*. If the form be altered in the ſmalleſt degree, by varying the points of contact (which indeed are points in the *figure of equilibration*), the magnets will no more recover their former poſition than a needle, which we had made to ſtand on its point, will regain its perpendicular poſition after it has been diſturbed.

But if we ſuppoſe planes de, fg, hi, &c. drawn, that the points of mutual contact a, b, c, each biſecting the angle formed by the lines that unite the adjoining contacts (fg, for example, biſecting the angle formed by ab, bc), and if we ſuppoſe that the pieces are changed for others of the ſame weights, but having flat ſides, which meet in the planes de, fg, hi, &c. it is evident that we ſhall have an arch of equilibration, and that the arch will have ſome ſtability, or will bear a little change of form without tumbling down: for it is plain that the equilibrium of the original feſtoon obtained only in the points a, b, c, of contact, where the preſſures were perpendicular to the touching ſurfaces; therefore if the curve a, b, c, ſtill paſſes through the touching ſurfaces perpendicularly, the conditions that are required for equilibrium ſtill obtain. The caſe is quite ſimilar to that of the ſtability of a body reſting on a horizontal plane. If the perpendicular through the centre of gravity falls within the baſe of the body, it will not only ſtand, but will require ſome force to puſh it over. In the original feſtoon, if a ſmall weight be added in any part, it will change the form of the curve of equilibration a little, by changing the points of mutual contact. This new curve will gradually ſeparate from the former curve as it recedes from A or C. In like manner, when the feſtoon is ſet up as an arch, if a ſmall weight be laid on any part of it, it will bring the whole to the ground, becauſe the ſhifting of the points of contact will be juſt the contrary to what it ſhould be to ſuit the new curve of equilibration. But if the ſame weight be laid on the ſame part of the arch now conſtructed with flat joints, it will be ſuſtained, if the new curve of equilibration ſtill paſſes through the touching ſurfaces.

Theſe concluſions, which are very obviouſly deducible from the principle of the feſtoon, ſhew us, without any further diſcuſſion, that the longer the joints are, the greater will be the ſtability of the arch, or that it will require a greater force to break it down. Therefore it is of the greateſt importance to have the arch ſtones as long as economy will permit; and this was the great uſe of the ribs and other apparent ornaments in the Gothic architecture. The great projections of thoſe ribs augmented their ſtiffneſs, and enabled them to ſupport the unadorned copartments of the roof, compoſed of very ſmall ſtones, ſeldom above ſix inches thick. Many old bridges are ſtill remaining, which are ſtrengthened in the ſame way by ribs.

Having thus explained, in a very familiar manner, the ſtability of an arch, we proceed to give the ſame popular account of the general application of the principle.

18 And applied.

Suppoſe it to be required to aſcertain the form of an arch which ſhall have the ſpan AB (fig. 7.), and the height F 8, and which ſhall have a road-way of the dimenſions CDE above it. Let the figure ACDEB be inverted, ſo as to form a figure $AcdeB$. Let a chain of uniform thickneſs be ſuſpended from the points A and B, and let it be of ſuch a length that its lower point will hang at, or rather a little below, f, correſponding to F. Divide AB into a number of equal parts, in the points 1, 2, 3, &c. and draw vertical lines, cutting the chain in the correſponding points 1, 2, 3, &c. Now take pieces of another chain, and hang them on at the points 1, 2, 3, &c. of the chain AfB. This will alter the form of the curve. Cut or trim theſe pieces of chain, till their lower ends all coincide with the inverted road-way cde. The greater lengths that are hung on in the vicinity of A and B will pull down theſe points of the chain, and cauſe the middle point f (which is leſs loaded) to riſe a little, and will bring it near to its proper height.

It is plain that this proceſs will produce an arch of perfect equilibration; but ſome farther conſiderations are neceſſary for making it exactly ſuit our purpoſe. It is an arch of equilibration for a bridge, that is ſo loaded that the weight of the arch-ſtones is to the weight of the matter with which the haunches and crown are loaded, as the weight of the chain AfB is to the ſum of the weights of all the little bits of chain very nearly. But this proportion is not known beforehand; we muſt therefore proceed in the following manner: Adapt to the curve produced in this way a thickneſs of the arch-ſtones as great as are thought ſufficient to enſure ſtability ; then compute the weight of the arch ſtones, and the weight of the gravel or rubbiſh with which the haunches are to be filled up to the road-way. If the proportion of theſe two weights be the ſame with the proportion of the weights of chain, we may reſt ſatisfied with the curve now found ; but if different, we can eaſily calculate how much muſt be added equal to, or taken from, each appended bit of chain, in order to make the two proportions equal. Having altered the appended pieces accordingly, we ſhall get a new curve, which may perhaps require a very ſmall trimming of the bits of chain to make them fit the road-way. This curve will be infinitely near to the curve wanted.

We have practiſed this method for an arch of 60 feet ſpan and 21 feet height, the arch-ſtones of which were only two feet nine inches long. It was to be loaded with gravel and ſhivers. We made a previous computation, on the ſuppoſition that the arch was to be nearly elliptical. The diſtance between the points 1, 2, 3, &c. were adjuſted, ſo as to determine the proportion of the weights of chain agreeable to the ſuppoſition. The curve differed conſiderably from an ellipſe, making a conſiderable angle with the verticles at the ſpring of the arch. The real proportion of the weights of chain, when all was trimmed ſo as to ſuit the road-way, was conſiderably different from what was expected. It was adjuſted. The adjuſtment made very little change in the curve. It would not have changed it two inches in any part of the real arch. When the proceſs was completed, we conſtructed the curve mathematically. It did not differ ſenſibly from this mechanical conſtruction. This was very agreeable information ; for it ſhewed us that the firſt curve, formed by about two hours labour, on a ſuppoſition conſiderably different from the truth, would have been ſufficiently exact for the purpoſe, being in no place three inches from the accurate curve, and therefore far within the joints of the intended arch-ſtones. Therefore this proceſs, which any intelligent maſon, though ignorant of mathematical ſcience, may go through with little trouble, will give a very proper form for an arch ſubject to any conditions.

19
The chief defect of the curve found according to this principle.

The chief defect of the curve found in this way is a want of elegance, becauſe it does not ſpring at right angles to the horizontal line ; but this is the caſe with all curves of equilibration, as we ſhall ſee by and by. It is not material: for, in the very neighbourhood of the piers, we may give it any form we pleaſe, becauſe the maſonry is ſolid in that place ; nay, we apprehend that a deviation from the curve of equilibration is proper. The conſtruction of that curve ſuppoſes that the preſſure on every part of the arch is vertical ; but gravel, earth, and rubbiſh, exert ſomewhat of a hydroſtatical preſſure laterally in the act of ſettling, and retain it afterwards. This will require ſome more curvature at the haunches of an arch to balance it ; but what this lateral preſſure may be, cannot be deduced with confidence from any experiments that we have ſeen. We are inclined to think that if, inſtead of dividing the horizontal line AB in the points 1, 2, 3, &c. we divide the chain itſelf into equal parts, the curve will approach nearer to the proper form

20
Theory founded on this principle.

After this familiar ſtatement of the general principle, it is now time to conſider the theory founded on it more in detail. This theory aims at ſuch an adjuſtment of the poſition of the arch-ſtones to the load on every part of the arch, that all ſhall remain in equilibrio, although the joints be perfectly poliſhed, and without any cement. The whole may be reduced to two problems. The firſt is to determine the vertical preſſure or load on every point of a line of a given form, which will put that line in equilibrio. The ſecond is to determine the form of a curve which ſhall be in equilibrio when loaded in its different points, according to any given law.

The whole theory is deducible from § 27. of the article Roof. The fundamental propoſition in that ſection ſtates the proportions between the various preſſures or thruſts which are exerted at the angles of an aſſemblage of beams or other pieces of ſolid heavy matter, freely moveable about thoſe angles, as ſo many joints, but retaining their poſition by the equilibrium of thoſe preſſures. It is there demonſtrated, "that the thruſt at any angle, if eſtimated in a horizontal direction, is the ſame throughout, and may be repreſented by any horizontal line BT, fig. 8. (Roofs, fig. 10 Pl. CCCCXL); and that if a vertical line QTS be drawn through T, the thruſt exerted at any angle D by the piece CD, in its own direction, will then be repreſented by BR, drawn parallel to CD ; and in like manner, that the thruſt in the direction ED is repreſented by BS, &c. ; and, laſtly, that the vertical thruſts or loads, at each angle B, C, D, by which all theſe others preſſures are excited, are repreſented by the portions QC, CR, RS, of the vertical intercepted by thoſe lines ; that is, all theſe preſſures are to the uniform horizontal thruſt as the lines which repreſent them are to BT. The horizontal thruſt, therefore, is a very proper unit, with which we may compare all the others. Its magnitude is eaſily deduced from the ſame propoſition ; for QS is the ſum of all the vertical preſſures of the angles, and therefore repreſents the weight of the whole aſſemblage. Therefore as QS is to BT, ſo is the weight of the whole to the horizontal thruſt.

21
Accommodated to the conſtruction of an arch vault,

To accommodate this theory to the conſtruction of a curvilineal arch vault, let us firſt ſuppoſe the vault to be polygonal, compoſed of the cords of the elementary arches. Let AVE (fig. 9.) be a curvilineal arch, of which V is the vertex, and VX the vertical axis, which we ſhall conſider as the axis or abſciſſa of the curve, while any horizontal line, ſuch as HK, is an ordinate to the curve. About any point C of the curve as a centre deſcribe a circle BLD, cutting the curve in B and D. Draw the equal cords CB, CD. Draw alſo the horizontal line CF, cutting the circle in F. Deſcribe a circle BCDQ paſſing through B, C, D. Its centre O will let in a line COQ, which biſects the angle BCD ; and C *d*, which touches this circle in C, will biſect the angle *b* C *d*, formed by the equal cords BC, CD. Draw CLP perpendicular to *c b*, and DP perpendicular to CD, meeting CL in P. Through L draw the tangent GLM, meeting CD in G, and the vertical line CM in M. Draw the tangent F *a*, cutting the cords BC, CD, in *b* and *d*, and the tangent to the circle BCDQ in *c*. Laſtly, draw *d* N parallel to *b c*.

From what is demonſtrated in § 27. of the article Roof, it appears, that if BC, CD be two pieces of an equilibrated heavy polygon, and if CF repreſent the horizontal thruſt in every angle of the polygon, C *d* and

C *b*

Arch. C*b* will ſeverally repreſent the thruſts exerted by the pieces DC, BC, and that *bd*, or CN, will repreſent the weight lying on the angle BCD, by which thoſe thruſts are balanced.

As the reader may not have the article Roof at hand, this equilibrium may be recalled to his remembrance in the following manner: Produce *d*C to *o*, ſo that C*o* may be equal to C*d*. Draw *bn* to the vertical parallel to *d*B, and join *no*. It is evident that *bno*C is a parallelogram, and that *n*C (= *bd*) = CN. Now the thruſt or ſupport of the piece BC is exerted in the direction C*b*, while that of DC is exerted in the direction C*o*. Theſe two thruſts are equivalent to the thruſt in the diagonal C*n*; and it is with this compound thruſt that the load or vertical preſſure CN is in *immediate* equilibrium.

22 And demonſtrated. Becauſe *b*CL, NCF, are right angles, and FCL is common to both, the angles *b*CF and MCL are equal. Therefore the right angled triangles *b*CF and MCL are ſimilar. And ſince CF is equal to CL, *cb* is equal to CM. It is evident that the triangles GCM and *d*CN are ſimilar. Therefore CG : C*d* = CM : CN, = C*b* : CN. Therefore we have $\mathrm{CN} = \frac{\mathrm{C}b \times \mathrm{C}d}{\mathrm{CG}}$. But becauſe CDP and CLG are right angles, and therefore equal, and the angle GCP is common to the two triangles GCL, PCD, and CD is equal to CL, we have CG equal to CP. Therefore $\mathrm{CN} = \frac{\mathrm{C}b \times \mathrm{C}d}{\mathrm{CP}}$. Alſo, ſince CDP is a right angle, DP meets the diameter in Q, the oppoſite point of the circumference, and the angle DQC is equal to DC*d*, or DC*b* (becauſe *b*C*d* is biſected by the tangent), that is, to PCQ (becauſe the right angles *b*CP, *c*DO are equal, and *c*DP is common). Therefore PQ is equal to PC; and if PO be drawn perpendicular to CQ, it will biſect it, and O is the centre of the circle BCDQB.

Now let the points B and D continually approach to C (by diminiſhing the radius of the ſmall circle), and ultimately coincide with it. It is evident that the circle BCDQ is ultimately the equicurve circle, and that PC ultimately coincides with OC, the radius of curvature. Alſo $\mathrm{C}b \times \mathrm{C}d$ becomes ultimately $\mathrm{C}c^2$. Therefore CN, the vertical load on any point of a curve of equilibration, is $= \frac{\mathrm{C}c^2}{\text{Rad. Curv.}}$

It is farther evident, that CF is to C*c* as radius to the ſecant of the elevation of the tangent above the horizon. Therefore we have the load on any point of the curve always proportional to $\frac{\text{Sec.}^2\ \text{Elev.}}{\text{Rad. Curv.}}$

This load on every elementary arch of the wall is commonly a quantity of ſolid matter incumbent on that element of the curve, and preſſing it vertically; and it may be conceived as made up of a number of heavy lines ſtanding vertically on it. Thus, if the element E*e* of the curve were lying horizontally, a little parallelogram RE*er* ſtanding perpendicularly on it, would repreſent its load. But as this element E*e* has a ſloping poſition, it is plain that, in order to have the ſame quantity of heavy matter preſſing it vertically, the height of the parallelogram muſt be increaſed till it meets in *ep*, the line R*e* drawn parallel to the tangent EG. It is evident that the angle RE*p* is equal to the angle AEG. Therefore we have ER : E*p* = Rad. : Sec. Elev. Arch,

If therefore the arch is kept in equilibrio by the vertical preſſure of a wall, we muſt have the height of the wall above any point proportional to $\frac{\text{Sec.}^3\ \text{Elev.}}{\text{Rad. of Curv.}}$

Cor. I. If OS be drawn perpendicular to the vertical CS, CS will be half the vertical cord of the equicurve circle. The angle OCS is equal to *c*CF, that is, to the angle of elevation. Therefore 1 : Sec. Elev. = CS : CO, and the ſecant of elevation may be expreſſed by $\frac{\mathrm{CO}}{\mathrm{CS}}$, and its cube by $\frac{\mathrm{CO}^3}{\mathrm{CS}^3}$. Therefore the height of wall is proportional to $\frac{\mathrm{CO}^3}{\mathrm{CS}^3 \times \mathrm{CO}}$, or to $\frac{\mathrm{CO}^2}{\mathrm{CS}^3}$, or $\frac{\mathrm{CO}^2}{\mathrm{CS}^2 \times \mathrm{CS}}$, or to $\frac{\text{Sec.}^2\ \text{of Elev.}}{\text{Vert. Cord of Curv.}}$ 23 Corollaries.

Cor. II. If we make the arch VC = *z*, the abſciſſa VH = *x*, the ordinate HC = *y*, the radius oſculi CO = *r*, and the ½ vertical cord CS = *s*, the height of wall preſſing on any point is proportional to $\frac{\dot{z}^3}{\dot{y}^3 r}$; or to $\frac{\dot{z}^2}{\dot{y}^2 s}$, or $\frac{\dot{x}^2 + \dot{y}^2}{\dot{y}^2 s}$. Therefore, when the equation of the curve is given, and the height of wall on any one point of it is alſo given, we can determine it for any other point: for the equation of the curve will always give us the relation of $\dot{z}$, $\dot{x}$, and $\dot{y}$, and the value of *r* or *s*. This may be illuſtrated by an example or two. For this purpoſe it will generally be moſt convenient to aſſume the height above the vertex V for the unit of computation. The thickneſs of the arch at the crown is commonly determined by other circumſtances. At the vertex the tangent to the arch is horizontal, and therefore the cube of the ſecant is unity or 1. Call the height of wall, at the crown, H, and let the radius of curvature in that point be R, and its half cord R (it being then coincident with the radius), and the height on any other point *h*. We have $\frac{1}{\mathrm{R}} : \frac{\dot{z}^3}{\dot{y}^3 r} = \mathrm{H} : h$, and $h = \mathrm{H} \times \frac{\dot{z}^3}{\dot{y}^3} \times \frac{\mathrm{R}}{r}$. The other formula gives $h = \mathrm{H} \times \frac{\dot{z}^2}{\dot{y}^2} \times \frac{\mathrm{R}}{s}$.

Examp. 1. Suppoſe the arch to be a ſegment of a circle, as in fig. 10. where AE is the diameter, and O the centre. In this arch the curvature is the ſame throughout, or $\frac{\mathrm{R}}{r} = 1$. Therefore $h = \mathrm{H} \times \frac{\dot{z}^3}{\dot{y}^3}$, or $= \mathrm{H} \times$ Cube Sec. Elev. 24 Illuſtrated by examples.

This gives a very ſimple calculus. To the logarithm of H add thrice the logarithm of the ſecant of elevation, The ſum is the logarithm of *h*.

It gives alſo a very ſimple conſtruction. Draw the vertical CS, cutting the horizontal diameter in S. Draw ST, cutting the radius OC perpendicularly in T. Draw the horizontal line T*z*, cutting the vertical in *z*. Join *zo*. Make C*u* = V*v*, and draw *ux* parallel to *zo*. C*c* muſt be made = C*x*. The demonſtration is evident.

It is very eaſy to ſee that if CV is an arch of 60°, and V*v* is $\frac{1}{14}$th of VC, the points *v* and *c* will be on a level; for the ſecant of CV is twice CO, and therefore C*c* is 8 times V*v*, which is $\frac{1}{7}$th of VH.

Arch.

The dotted line $v g c f$ is drawn according to this calculus or conſtruction. It falls conſiderably below the horizontal line in the neighbourhood of c; and then, paſſing very obliquely through c, it riſes rapidly to an unmeaſurable height, becauſe the vertical line through A is its aſſymptote. This muſt evidently be the caſe with every curve which ſprings at right angles with a horizontal line.

It is plain that if vV be greater, all the other ordinates of the curve $v g c f$, reſting on the circumference AVE, will be greater in the ſame proportion, and the curve will cut the horizontal line drawn through v in ſome point nearer to v than c is. Hence it appears that a circular arch cannot be put in equilibrio by building on it up to a horizontal line, whatever be its ſpan, or whatever be the thickneſs at the crown. We have ſeen that when this thickneſs is only $\frac{1}{14}$th of the radius, an arch of 120 degrees will be too much loaded at the flanks. This thickneſs is much too ſmall for a bridge, being only $\frac{1}{23}$th of the ſpan CM, whereas it ſhould have been almoſt double of this, to bear the inequalities of weight that may occaſionally be on it. When the crown is made ſtill thinner, the outline is ſtill more depreſſed before it riſes again. There is therefore a certain ſpan, with a correſponding thickneſs at the crown, which will deviate leaſt of all from a horizontal line. This is an arch of about 54 degrees, the thickneſs at the crown being about one-fourth of the ſpan, which is extravagantly great. It appears in general, therefore, that the circle is not a curve ſuited to the purpoſes of a bridge or an arcade, which requires an outline nearly horizontal.

Examp. 2. Let the curve be a parabola AVE (fig. 11.), of which V is the vertex, and DG the directrix. Draw the diameters DCF, GVN, the tangents CK, VP, and the ordinates VF and CN. It is well known that GV is to DC as VP^2 to CK^2, or as CN^2 to CK^2. Alſo 2 GV is the radius of the oſculating circle at V, and 2 DC is one-half of the vertical cord of the oſculating circle at C. Therefore $\mathrm{CN}^2 : \mathrm{CK}^2$ (or $\dot{y}^2 : \dot{z}^2$) $= \mathrm{R} : s$, and $s = \frac{\dot{z}^2}{\dot{y}^2}\mathrm{R}$. But C$c$, or $b = \mathrm{H} \times \frac{\dot{z}^2\,\mathrm{R}}{\dot{y}^2\,\mathrm{S}}$. Therefore $b = \mathrm{H} \times \frac{\dot{z}^2 \quad \mathrm{R}}{\dot{y}^2 \frac{\dot{z}^2}{\dot{y}^2}\mathrm{R}}, = \mathrm{H} \times \frac{\dot{z}^2\,\mathrm{R}}{\dot{z}^2\,\mathrm{R}}, = \mathrm{H}$. Therefore $\mathrm{C}c = v\mathrm{V}$.

It follows from this inveſtigation, that the back or extrados of a parabolic arch of equilibration muſt be parallel to the arch or ſoffit itſelf; or that the thickneſs of the arch, eſtimated in a vertical direction, muſt be equal throughout; or that the extrados is the ſame parabola with the ſoffit or intrados.

We have ſelected theſe two examples merely for the ſimplicity and perſpicuity of the ſolutions, which have been effected by means of elementary geometry only, inſtead of employing the analytical value of the radius of the oſculatory circle, viz. $\frac{\dot{z}^3}{\dot{y}\ddot{x} - \dot{x}\ddot{y}}$, which would have involved us at leaſt in the elements of ſecond fluxions. We have alſo preferred ſimplicity to elegance in the inveſtigation, becauſe we wiſh to inſtruct the practical engineer, who may not be a proficient in the higher mathematics.

Arch.

The converſe of the problem, namely, to find the form of the arch when the figure of the back of it is given, is the moſt uſual queſtion of the two, at leaſt in caſes which are moſt important and moſt difficult. Of theſe perhaps bridges are the chief. Here the neceſſity of a road-way, of eaſy and regular aſcent, confines us to an outline nearly horizontal, to which the curve of the arch muſt be adapted. This is the moſt difficult problem of the two; and we doubt whether it can be ſolved without employing infinite approximating ſeries inſtead of accurate values.

25
To find the form of an arch when the figure of its back is given.

Let $a v e$ (fig. 12.) be the intended outline or extrados of the arch AVE, and let vQ be the common axis of both curves. From c and C, the correſponding points, draw the ordinates $c b$, CH. Let the thickneſs vV at the top be a, the abſciſſa $v b$ be $= u$, and VH $= x$, and let the equal ordinates $c b$, CH be y, and the arch VC be z.

Then, by the general theorem, $c\mathrm{C} = \frac{\dot{z}^3}{r\dot{y}^3}$, r being the radius of curvature. This, by the common rules, is $= \frac{\dot{z}^3}{\dot{y}\ddot{x} - \dot{x}\ddot{y}}$. This gives us $c\,\mathrm{C} = \frac{\dot{y}\ddot{x} - \dot{x}\ddot{y}}{\dot{y}^3}$, or $= \frac{\dot{y}\ddot{x} - \dot{x}\ddot{y}}{\dot{y}^3} \times \mathrm{C}$; where C is a conſtant quantity, found by taking the real value of cC in V, the vertex of the curve. But it is evident that it is alſo $= a + x - u$. Therefore $a + x - u = \frac{\dot{y}\ddot{x} - \dot{x}\ddot{y}}{\dot{y}^3} \times \mathrm{C}, = \frac{\mathrm{C}}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$.

If we now ſubſtitute the true value of u (which is given, becauſe the extrados is ſuppoſed to be of a known form), expreſſed in terms of y, the reſulting equation will contain nothing but x and y, with their firſt and ſecond fluxions, and known quantities. From this equation the relation of x and y muſt be found by ſuch methods as ſeem beſt adapted to the equation of the extrados.

Fortunately the proceſs is more ſimple and eaſy in the moſt common and uſeful caſe than we ſhould expect from this general rule. We mean the caſe where the extrados is a ſtraight line, eſpecially when this is horizontal. In this caſe u is equal to o.

Example. To find the form of the balanced arch AVE (fig. 13.), having the horizontal line $c v$ for its extrados.

Plate II.

Keeping the ſame notation, we have $u = o$, and therefore $a + x = \frac{\mathrm{C}}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$.

Aſſume $\dot{y} = \frac{\dot{x}}{v}$; then $\frac{\dot{x}}{\dot{y}} = v$, and $\frac{\mathrm{C}}{\dot{y}} \times$ fluxion of $\frac{\dot{x}}{\dot{y}}$, $= \frac{\mathrm{C}v\dot{v}}{\dot{x}}$, that is $a + x = \frac{\mathrm{C}v\dot{v}}{\dot{x}}$. Therefore $a\dot{x} + x\dot{x} = \mathrm{C}v\dot{v}$; and by taking the fluents, we have $2ax + x^2 = \mathrm{C}\,v^2$; and $v = \sqrt{\frac{2ax + x^2}{\mathrm{C}}}$. Conſequently, $\dot{y} = \frac{\sqrt{\mathrm{C}}\,\dot{x}}{\sqrt{2ax \times x^2}}$ (being $= \frac{\dot{x}}{v}$). Taking the fluent of this, we have $y = \sqrt{}\,\mathrm{C} \times \mathrm{L}\,(2ax + 2x^2$
$+ 2$

$+ 2\sqrt{2ax + x^2})$. But at the vertex, where $x = o$, we have $y = \sqrt{C} \times L\,(2a)$. The corrected fluent is therefore $y = \sqrt{C} \times L\,\frac{a + x + \sqrt{2ax + x^2}}{a}$.

It only remains to find the conſtant quantity C. This we readily obtain by ſelecting ſome point of the extrados where the values of x and y are given by particular circumſtances of the caſe. Thus, when the ſpan $2s$ and height h of the arch are given, we have $s = \sqrt{C} \times L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)$, and conſequently $\sqrt{C} = \frac{s}{L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)}$. Therefore

the general value of $y = s \times \frac{L\left(\frac{a + x + \sqrt{2ax + x^2}}{a}\right)}{L\left(\frac{a + h + \sqrt{2ah + h^2}}{a}\right)}$;

$$= \frac{s}{L\,\frac{a+h+\sqrt{2ah+h^2}}{a}} \times L\,\frac{a + x + \sqrt{2ax + x^2}}{a}.$$

As an example of the uſe of this formula, we ſubjoin a table calculated by Dr Hutton of Woolwich for an arch, the ſpan of which is 100 feet, and the height 40; which are nearly the dimenſions of the middle arch of Blackfriars Bridge in London.

y	x	y	x	y	x
0	6,000	21	10,381	36	21,774
2	6,035	22	10,858	37	22,948
4	6,144	23	11,368	38	24,190
6	6,324	24	11,911	39	25,505
8	6,580	25	12,489	40	26,894
10	6,914	26	13,106	41	28,364
12	7,330	27	13,761	42	29,919
13	7,571	28	14,457	43	31,563
14	7,834	29	15,196	44	33,299
15	8,120	30	15,980	45	35,135
16	8,430	31	16,811	46	37,075
17	8,766	32	17,693	47	39,126
18	9,168	33	18,627	48	41,293
19	9,517	34	19,617	49	43,581
20	9,934	35	20,665	50	46,000

The figure for this propoſition is exactly drawn according to theſe dimenſions, that the reader may judge of it as an object of ſight. It is by no means deficient in gracefulneſs, and is abundantly roomy for the paſſage of craft; ſo that no objection can be offered againſt its being adopted on account of its mechanical excellency.

26
efects of
e Caten
an curve.

The reader will perhaps be ſurpriſed that we have made no mention of the celebrated Catenarian curve, which is commonly ſaid to be the beſt form for an arch; but a little reflection will convince him, that although it is the only form for an arch conſiſting of ſtones of equal weight, and touching each other only in ſingle points, it cannot ſuit an arch which muſt be filled up in the haunches, in order to form a road-way. He will be more ſurpriſed to hear, after this, that there is a certain thickneſs at the crown, which will put the Catenaria in equilibrio, even with a horizontal road-way; but this thickneſs is ſo great as to make it unfit for a bridge, being ſuch that the preſſure at the vertex is equal to the horizontal thruſt. This would have been about 37 feet in the middle arch of Blackfriars Bridge. The only ſituation, therefore, in which the Catenarian form would be proper, is an arcade carrying a height of dead wall; but in this ſituation it would be very ungraceful. Without troubling the reader with the inveſtigation, it is ſufficient to inform him that in a Catenarian arch of equilibration the abſciſſa VH is to the abſciſſa $v\,h$ in the conſtant ratio of the horizontal thruſt to its exceſs above the preſſure on the vertex.

27
Inutility of
the common theory
of equilibration.

This much will ſerve, we hope, to give the reader a clear notion of this celebrated theory of the equilibrium of arches, one of the moſt delicate and important applications of mathematical ſcience. Volumes have been written on the ſubject, and it ſtill occupies the attention of mechanicians. But we beg leave to ſay, with great deference to the eminent perſons who have proſecuted this theory, that their ſpeculations have been of little ſervice, and are little attended to by the practitioner. Nay, we may add, that Sir Chriſtopher Wren, perhaps the moſt accompliſhed architect that Europe has ſeen, ſeems to have thought it of little value: for, among the fragments which have been preſerved of his ſtudies, there are to be ſeen ſome imperfect diſſertations on this very ſubject, in which he takes no notice of this theory, and conſiders the balance of arches in quite another way. Theſe are collected by the author of the account of Sir Chriſtopher Wren's family. This man's great ſagacity, and his great experience in building, and, ſtill more his experience in the repairs of old and crazy fabrics, had ſhewn him many things very inconſiſtent with this theory, which appears ſo ſpecious and ſafe. The general facts which occur in the failure of old arches are highly inſtructive, and deſerve the moſt careful attention of the engineer; for it is in this ſtate that their defects, and the proceſs of nature in their deſtruction, are moſt diſtinctly ſeen. We venture to affirm, that a very great majority of theſe facts are irreconcileable to the theory. The way in which circular arches commonly fail, is by the ſinking of the crown and the riſing of the flanks. It will be found by calculation, that in moſt of the caſes it ought to have been juſt the contrary. But the cleareſt proof is, that arches very rarely fail where their load differs moſt remarkably from that which this theory allows. Semicircular arches have ſtood the power of ages, as may be ſeen in the bridges of ancient Rome, and in the numerous arcades which the ancient inhabitants have erected. Now all arches which ſpring perpendicularly from the horizontal line, require, by this theory, a load of infinite height; and, even to a conſiderable diſtance from the ſpringing of the arch, the load neceſſary for the theoretical equilibrium is many times greater than what is ever laid on thoſe parts; yet a failure in the immediate neighbourhood of the ſpring of an arch is a moſt rare phenomenon, if it ever was obſerved. Here is a moſt remarkable deviation from the theory; for, as is already obſerved, the load is frequently not the fourth part of what the theory requires.

Many other facts might be adduced which ſhew great deviations from the legitimate reſults from the theory. We hope to be excuſed, therefore, by the mathematicians for doubting of the juſtneſs of this theory. We do

28 Its defects. do not think it erroneous, but defective, leaving out circumſtances which we apprehend to be of great importance; and we imagine that the defects of the theory have ariſen from the very anxiety of the mechanicians to make it perfect. The arch-ſtones are ſuppoſed to be perfectly ſmooth or poliſhed, and not to be connected by any cement, and therefore to ſuſtain each other merely by the equilibrium of their vertical preſſure. The theory enſures this equilibrium, and this only, leaving unnoticed any other cauſes of mutual action.

The authors who have written on the ſubject ſay expreſsly, that an arch which thus ſuſtains itſelf muſt be ſtronger than another which would not; becauſe when, in imagination, we ſuppoſe both to acquire connection by cement, the firſt preſerves the influence of this connection unimpaired; whereas in the other, part of the coheſion is waſted in counteracting the tendency of ſome parts to break off from the reſt by their want of equilibrium. This is a very ſpecious argument, and would be juſt, if the forces which are mutually exerted between the parts of the arch in its ſettled ſtate were merely vertical preſſures, or, where different, were inconſiderable in compariſon with thoſe which are really attended to in the conſtruction.

But this is by no means the caſe. The forms which the uſes for which arches are erected oblige us to adopt, and the loads laid on the different points of the arch, frequently deviate conſiderably from what are neceſſary for the equilibrium of vertical preſſures. The varying load on a bridge, when a great wagon paſſes along it, ſometimes bears a very ſenſible proportion to the weight of that point of the arch on which it reſts. It is even very doubtful whether the preſſures which are occaſioned by the weight of the ſtuff employed for filling up the flanks really act in a vertical direction, and in the proportion which is ſuppoſed. We are pretty certain that this is not the caſe with ſand, gravel, fat mould, and many ſubſtances in very general uſe for this purpoſe. When this is the caſe, the preſſures ſuſtained by the different parts of the arch are often very inconſiſtent with the theory—a part of the arch is overloaded, and tends to fall in, but is prevented by the cement. This part of the arch therefore acts on the remoter parts by the intervention of the parts between, employing thoſe intermediate parts as a kind of levers to break the arch in a remote part, juſt as a lintel would be broken. We apprehend that a mathematician would be puzzled how to explain the ſtability of an arch cut out of a ſolid and uniform maſs of rock. His theory conſiders the mutual thruſts of the arch ſtones as in the direction of the tangents to the arch. Why ſo? becauſe he ſuppoſes that all his poliſhed joints are perpendicular to thoſe tangents. But in the preſent caſe he has no exiſting joints; and there ſeems to be nothing to direct his imagination in the aſſumption of joints, which, however, are abſolutely neceſſary for employing his theory, becauſe, without a ſuppoſition of this kind, there ſeems no conceiving any mutual abutment of the arch ſtones. Aſk a common, but intelligent, maſon what notion he forms of ſuch an arch? We apprehend that he will conſider it as no arch, but as a lintel, which may be broken like a wooden lintel, and which reſiſts entirely by its coheſion. He will not readily conceive that, by cutting the under ſide of a ſtone lintel into an arched form, and thus taking away more than half of its ſubſtance, he has changed its nature of a lintel, or given it any additional ſtrength. Nor would there be any change made in the way in which ſuch a maſs of ſtone would reſiſt being broken down, if nothing were done but forming the under ſide into an arch. If the lintel be ſo laid on the piers that it can be broken without its parts puſhing the piers aſide (which will be the caſe if it lies on the piers with horizontal joints), it will break like any other lintel; but if the joints are directed downwards, and converging to a point within the arch, the broken ſtone (ſuppoſe it broken at the crown by an overload in that part) cannot be preſſed down without forcing the piers outwards. Now, in this mode of acting, the mind cannot trace any thing of the ſtatical equilibrium that we have proceeded on in the foregoing theory. The two parts of the broken lintel ſeem to puſh the piers aſide in the ſame manner that two rafters puſh outwards the walls of a houſe, when their feet are not held together by a tie-beam. If the piers cannot be puſhed aſide (as when the arch abuts on two ſolid rocks), nothing can preſs down the crown which does not cruſh the ſtone.

This concluſion will be ſtrictly true if the arch is of ſuch a form that a ſtraight line drawn from the crown to the pier lies wholly within the ſolid maſonry. Thus if the vault conſiſt of two ſtraight ſtones, as in fig. 1. or if it conſiſt of ſeveral ſtones, as in fig. 14. diſpoſed in two ſtraight lines, no weight laid on the crown can deſtroy it in any other way but by cruſhing it to powder.

29 When it i to be calle into the ai of the bui der. But when ſtraight lines cannot be drawn from the overloaded part to the firm abutments through the ſolid maſonry, and when the coheſion of the parts is not able to withſtand the tranſverſe ſtrains, we muſt call the principles of equilibrium to our aid; and in order to employ them with ſafety, we muſt conſider how they are modified by the excitement of the cohering forces.

The coheſion of the ſtones with each other by cement or otherwiſe, has, in almoſt every ſituation, a bad effect. It enables an overload at the crown to break the arch near the haunches, cauſing thoſe parts to riſe, and then to ſpread outwards, juſt as a Manſarde or Kirb roof would do if the truſs beam which connects the heads of the lower rafters were ſawn through. This can be prevented only by loading that part more than is requiſite for equilibrium. It would be prudent to do this to a certain degree, becauſe it is by this coheſion that the crown always becomes the weakeſt part of the arch, and ſuffers more by any occaſional load.

We expect that it will be ſaid in anſwer to all this, that the coheſion given by the ſtrongeſt cement that we can employ, nay, the coheſion of the ſtone itſelf, is a mere nothing in compariſon with the enormous thruſts that are in a ſtate of continual exertion in the different parts of an arch. This is very true; but there is another force which produces the ſame effect, and which increaſes nearly in the proportion that thoſe thruſts increaſe, becauſe it ariſes from them. This is the friction of the ſtones on each other. In dry freeſtone this friction conſiderably exceeds one half of the mutual preſſure. The reflecting reader will ſee that this produces the ſame effect, in the caſe under conſideration, that coheſion would do; for while the arch is in the act of failing, the mutual preſſure of the arch-ſtones is acting with full force, and thus produces a friction more than

adequate

adequate to all the effects we have been ſpeaking of.

30 ocefs of : break- of an h.

When theſe circumſtances are conſidered, we imagine that it will appear that an arch, when expoſed to a great overload on the crown (or indeed on any part), divides, of itſelf, into a number of parts, each of which contains as many arch-ſtones as can be pierced (ſo to ſpeak) by one ſtraight line, and that it may then be conſidered as nearly in the ſame ſituation with a polygonal arch of long ſtones butting on each other like ſo many beams in a Norman roof (ſee Roof, n° 49.), but without their braces and ties. It tends to break at all thoſe angles; and it is not ſufficiently reſiſted there, becauſe the materials with which the flanks are filled up have ſo little coheſion, that the angle feels no load except what is immediately above it; whereas it ſhould be immediately loaded with all the weight which is diffuſed over the adjoining ſide of the polygon. This will be the caſe, even though the curvilineal arch be perfectly equilibrated. We recollect ſome circumſtances in the failure of a conſiderable arch, which may be worth mentioning. It had been built of an exceedingly ſoft and friable ſtone, and the arch ſtones were too ſhort. About a fortnight before it fell, chips were obſerved to be dropping off from the joints of the archſtones about ten feet on each ſide of the middle, and alſo from another place on one ſide of the arch, about twenty feet from its middle. The maſons in the neighbourhood prognoſticated its ſpeedy downfal, and ſaid that it would ſeparate in thoſe places where the chips were breaking off. At length it fell; but it firſt ſplit in the middle, and about 15 or 16 feet on each ſide, and alſo at the very ſpringing of the arch. Immediately before the fall a ſhivering or crackling noiſe was heard, and a great many chips dropped down from the middle between the two places from whence they had dropped a fortnight before. The joints opened above at thoſe new places above two inches, and in the middle of the arch the joints opened below, and in about five minutes after this the whole came down. Even this movement was plainly diſtinguiſhable into two parts. The crown ſunk a little, and the haunches roſe very ſenſibly, and in this ſtate it hung for about half a minute. The arch ſtones of the crown were hanging by their upper corners. When theſe ſplintered off, the whole fell down.

We apprehend that the procedure of nature was ſomewhat in this manner. Straight lines can be drawn within the arch-ſtones from A (fig. 15.) to B and D, and from thoſe points to C and E. Each of the portions ED, DA, AB, BC, reſiſt as if they were of one ſtone, compoſing a polygonal vault EDABC. When this is overloaded at A, A can deſcend in no other way than by puſhing the angles B and D outwards, cauſing the portions BC, DE, to turn round C and E. This motion muſt raiſe the points B and D, and cauſe the arch-ſtones to preſs on each other at their *inner* joints *b* and *d*. This produced the copious ſplintering at thoſe joints immediately preceding the total downfal. The ſplintering which happened a fortnight before aroſe from this circumſtance, that the lines AB and AD, along which the preſſure of the overload was propagated, were tangents to the ſoffit of the arch in the points F, H, and G, and therefore the ſtrain lay all on thoſe corners of the arch-ſtones, and ſplintered a little from off them till the whole took a firmer bed. The ſubſequent phenomena are evident conſequences of this diſtribution and modification of preſſure, and can hardly be explained in any other way; at leaſt not on the theoretical principles already ſet forth: for in this bridge the loads at B and D were very conſiderably greater than what the equilibrium required; and we think that the firſt obſerved ſplintering at H, F, and G, was moſt inſtructive, ſhowing that there was an extraordinary preſſure at the inner joints in thoſe places, which cannot be explained by the uſual theory.

Not ſatisfied with this ſingle obſervation, after this way of explaining it occurred to us, and not being able to find any ſimilar fact on record, the writer of this article got ſome ſmall models of arches executed in chalk, and ſubjected them to many trials, in hopes of collecting ſome general laws of the internal workings of arches which finally produce their downfal. He had the pleaſure of obſerving the above mentioned circumſtances take place very regularly and uniformly, when he overloaded the models at A. The arch always broke at ſome place B conſiderably beyond another point F, where the firſt chipping had been obſerved. This is a method of trial that deſerves the attention both of the ſpeculatiſt and the practitioner.

If theſe reflections are any thing like a juſt account of the procedure of nature in the failure of an arch, it is evident that the ingenious mathematical theory of equilibrated arches is of little value to the engineer. We ventured to ſay as much already, and we reſted a good deal on the authority of Sir Chriſtopher Wren. He was a good mathematician, and delighted in the application of this ſcience to the arts. He was a celebrated architect; and his reports on the various works committed to his charge, ſhow that he was in the continual habit of making this application. Several ſpecimens remain of his own methods of applying them. The roof of the theatre of Oxford, the roof of the cupola of St Paul's, and in particular the mould on which he turned the inner dome of that cathedral, are proofs of his having ſtudied this theory moſt attentively. He flouriſhed at the very time that it occupied the attention of the greateſt mechanicians of Europe; but there is nothing to be found among his papers which ſhows that he had paid much regard to it. On the contrary, when he has occaſion to deliver his opinion for the inſtruction of others, and to explain to the Dean and Chapter of Weſtminſter his operations in repairing that collegiate church, this great architect conſiders an arch juſt as a ſenſible and ſagacious maſon would do, and very much in the way that we have juſt now been treating it: (See *Account of the Family of Wren*, p. 356, &c.) Supported therefore by ſuch authority, we would recommend this way of conſidering an arch to the ſtudy of the mathematician; and we would deſire the experienced maſon to think of the moſt efficacious methods for reſiſting this tendency of arches to riſe in the flanks. Unfortunately there ſeems to be no preciſe principle to point out the place where this tendency is moſt remarkable.

We are therefore highly pleaſed with the ingenious contrivance of Mr Mylne, the architect of Blackfriars Bridge in London, by which he determines this point with preciſion, by making it impoſſible for the overloaded arch to ſpring in any other place. Having thus confined

confined the failure to a particular ſpot, he with equal art oppoſes a reſiſtance which he believes to be ſufficient; and the preſent condition of that noble bridge, which does not in any place ſhow the ſmalleſt change of ſhape, proves that he was not miſtaken. Looking on this work as the firſt, or at leaſt the ſecond, ſpecimen of maſonic ingenuity that is to be ſeen in the world, we imagine that our readers will be pleaſed with a particular account of its moſt remarkable circumſtances.

31 Conſtruction of Blackfriars Bridge. Plate III.

The ſpan *k a* (fig. 16.) of the middle arch is 100 feet, and its height OV is 40, and the thickneſs KV of the crown is ſix feet ſeven inches. Its form is nearly elliptical; the part AVZ being an arch of a circle whoſe centre is C, and radius 56 feet, and the two lateral portions A *k* B and Z *a* E being arches deſcribed with a radius of 35 feet nearly. The thickneſs of the pier at *a b* is 19 feet. The thickneſs of the arch increaſes from the crown V to Y, where it is eight or nine feet. All the arch-ſtones have their joints directed to the centres of their curvature. The joints are all joggled, having a cubic foot of hard ſtone let half way into each. By this contrivance the joints cannot ſlide, nor can any weight laid on the crown ever break the arch in that part, if the piers do not yield; for a ſtraight line from the middle of KV to the middle of the joint YI is contained within the ſolid maſonry, and does not even come near the inner joints of the arch-ſtones. Therefore the whole reſiſts like one ſtone, and can be broken only by cruſhing it. The joint at Z is very nearly perpendicular to a line YF drawn to the outer edge of the foundation of the pier. By this it was intended to take off all tendency of the preſſure on the joint *d* Z to overſet the pier; for if we ſuppoſe, according to the theory of equilibration, that this preſſure is neceſſarily exerted perpendicularly to the joint, its direction paſſes through the fulcrum at F, round which it is thought that the pier muſt turn in the act of overſetting. This precaution was adopted in order to make the arch quite independent of the adjoining arches; ſo that although any of them ſhould fall, this arch ſhould run no riſk.

Still farther to ſecure the independence of the arch, the following conſtruction was practiſed to unite it into one maſs, which ſhould riſe altogether. All below the line *a b* is built of large blocks of Portland ſtone, dovetailed with ſound oak. Four places in each courſe are interrupted by equal blocks of a hard ſtone called *Kentiſh rag*, ſunk half way in each courſe. Theſe act as joggles, breaking the courſes, and preventing them from ſliding laterally.

The portion *a* Y of the arch is joggled like the upper part. The interior part is filled up with large blocks of Kentiſh rag, forming a kind of courſed rubble-work, the courſes tending to the centres of the arch. The under corner of each arch-ſtone projects over the one below it. By this form it takes faſt hold of the rubble-work behind it. Above this rubble there is conſtructed the inverted arch I *e* G of Portland ſtone. This arch ſhares the preſſure of the two adjoining arches, along with the arch-ſtones in Y *a* and in G *b*. Thus all tend together to compreſs and keep down the rubble-work in the heart of this part of the pier. This is a very uſeful precaution; for it often happens, that when the centres of the arches are ſtruck, before the piers are built up to their intended height, the thruſt of the arches ſqueezes the rubble-work horizontally, after the mortar has ſet, but before it has dried and acquired its utmoſt hardneſs. Its bond is broken by this motion, and it is ſqueezed up, and never acquires its former firmneſs. This is effectually prevented by the preſſure exerted by the back of the inverted arch.

Above this counter arch is another maſs of courſed rubble, and all is covered by a horizontal courſe of large blocks of Portland ſtone, butting againſt the back of the arch-ſtone ZI and its correſponding one in the adjoining arch. This courſe connects the feet of the two arches, preſerves the rubble-work from too great compreſſion, and protects it from ſoaking water. This laſt circumſtance is important; for if the water which falls on the road-way is not carried off in pipes, it ſoaks through the gravel or other rubbiſh, reſts on the mortar, and keeps it continually wet and ſoft. It cannot eſcape through the joints of good maſonry, and therefore fills up this part like a funnel.

Suppoſing the adjoining arch fallen, and all tumbled off that is not withheld by its ſituation, there will ſtill remain in the pier a maſs of about 3500 tons. The weight of the portion VY is about 2000 tons. The directions of the thruſts RY and YF are ſuch, that it would require a load of 4500 tons on VY to overturn the pier round F. This exceeds VY by 2500 tons; a weight incomparably greater than any that can ever be laid on it.

Such is the ingenious conſtruction of Mr Mylne. It evidently proceeds on the principles recommended above; principles which have occurred to his experience and ſagacious mind during the courſe of his extenſive practice. We have ſeen attempts by other engineers to withſtand the horizontal thruſts of the arch by means of counter arches inſerted in the ſame manner as here, but extending much farther over the main arch; but they did not appear to be well calculated for producing this effect. A counter arch ſpringing from any point between Y and V has no tendency to hinder that point from riſing by the ſinking of the crown; and ſuch a counter arch will not reſiſt the preciſely horizontal thruſt ſo well as the ſtraight courſe of Mr Mylne.

32 Origin o the Goth arches.

The great incorporation of architects who built the cathedrals of Europe departed entirely from the ſtyles of ancient Greece and Rome, and introduced another, in which arcades made the principal part. Not finding in every place quarries from which blocks could be raiſed in abundance of ſufficient ſize for forming the far-projecting corniches of the Greek orders, they relinquiſhed thoſe proportions, and adopted a ſtyle of ornament which required no ſuch projections: and having ſubſtituted arches for the horizontal architrave or lintel, they were now able to erect buildings of vaſt extent with ſpacious openings, and all this with very ſmall pieces of ſtone. The form which had been adopted for a Chriſtian temple occaſioned many interſections of vaultings, and multiplied the arches exceedingly. Conſtant practice gave opportunities of giving every poſſible variety of theſe interſections, and taught the art of balancing arch againſt arch in every variety of ſituation. An art ſo multifarious, and ſo much out of the road of ordinary thought, could not but become an object of fond ſtudy to the architects moſt eminent for ingenuity

nuity and invention. Becoming thus the dupes of their own ingenuity, they were fond of diſplaying it even when not neceſſary. At laſt arches became their principal ornament, and a wall or ceiling was not thought dreſſed out as it ſhould be till filled full of mock arches, croſſing and butting on each other in every direction. In this proceſs in their ceilings they found that the projecting mouldings, which we now call the Gothic tracery, formed the chief ſupports of the roofs. The plane ſurfaces included between thoſe ribs were commonly vaulted with very ſmall ſtones, ſeldom exceeding ſix or eight inches in thickneſs. This tracery therefore was not a random ornament. Every rib had a poſition and direction that was not only proper, but even neceſſary. Habituated to this ſcientific arrangement of the mouldings, they did not deviate from it when they ornamented a ſmooth ſurface with mock arches; and in none of the highly ornamented *ancient* buildings will we find any falſe poſitions. This is by no means the caſe in many of the modern imitations of Gothic architecture, even by our beſt architects. Ignorant of the directing principle, or not attending to it, in their ſtucco work, they pleaſe the unſkilled eye with pretty radiated figures; but in theſe we frequently ſee ſuch abutments of mouldings as would infallibly break the arches, if theſe mouldings were really performing their ancient office, and ſupporting a vaulting of conſiderable extent. Nay, this began even before the Gothic ſtyle was finally abandoned. Several inſtances are to be found in the highly enriched vaultings of New College, and Chriſt Church in Oxford, in St George's Chapel at Windſor, and Henry the VII's Chapel in Weſtminſter.

33
genera-
of that
le

We call the middle ages rude and barbarous; but there was ſurely much knowledge in thoſe who could execute ſuch magnificent and difficult works. The working drafts which were neceſſary for ſuch varieties of oblique interſections muſt have required conſiderable ſkill, and would at preſent occupy many very expenſive volumes of *maſons jewels* and *carpenters manuals*, and the like. All this knowledge was kept a profound ſecret by the corporation, and on its breaking up we had all to learn again.

There is no appearance, however, that thoſe architects had ſtudied the theory of equilibrated arches. They had adopted an arch which was very ſtrong, and permitted conſiderable irregularities of preſſure—we mean the pointed arch. The very deep mouldings with which it was ornamented, made the arch ſtones very long in proportion to the ſpan of the arch. But they had ſtudied the mutual thruſt of arches on each other with great care; and they contrived to make every invention for this purpoſe become an ornament, ſo that the eye *required* it as a neceſſary part of the building. Thus we frequently ſee ſmall buildings having buttreſſes at the ſides. Theſe are neceſſary in a large vaulted building, for withſtanding the outward thruſt of the vaulting; but they are uſeleſs when we have a flat ceiling within. Pinnacles on the heads of the buttreſſes are now conſidered as ornaments; but originally they were put there to increaſe the weight of the buttreſs: even the great tower, in the centre of a cathedral, which now conſtitutes its great ornament, is a load almoſt indiſpenſably neceſſary, for enabling the four principal columns to withſtand the combined thruſt of the aiſles, of the nave, and tranſepts. In ſhort, the more cloſely we examine the ornaments of this architecture, the more ſhall we perceive that they are eſſential parts, or derived from them by imitation: and the more we conſider the whole ſtyle of it, the more clearly do we ſee that it is all deduced from the reliſh for arcades, indulged in the extreme, and puſhed to the limit of poſſibility of execution.

35
Dome or
cupola

There is another ſpecies of arch which muſt not be overlooked, namely, the Dome or Cupola, with all its varieties, which include even the pyramidal ſteeple or ſpire.

It is evident that the erection of a dome is alſo a ſcientific art, proceeding on the principles of equilibration, and that theſe principles admit and require the ſame or ſimilar modifications, in conſequence of the coheſion and friction of the materials. At firſt ſight, too, a dome appears a more difficult piece of work than a plain arch; but when we obſerve potters kilns and glaſshouſe domes and cones of vaſt extent, erected by ordinary bricklayers, and with materials vaſtly inferior in ſize to what can be employed in common arches of equal extent, we muſt conclude that the circumſtance of curvature in the horizontal direction, or the abutment of a circular baſe, gives ſome aſſiſtance to the artiſt. Of this we have complete demonſtration in the caſe of the cone. We know that a vaulting in the form of a pent roof could not be executed to any conſiderable extent, and would be extremely hazardous, even in the ſmalleſt dimenſions; while a cone of the greateſt magnitude can be raiſed with very ſmall ſtones, provided only that we prevent the bottom from flying out, by a hoop, or any ſimilar contrivance. And when we think a little of the matter, we ſee plainly, that if the horizontal ſection be perfectly round, and the joints be all directed to the axis, they all equally endeavour to ſlide inwards, while no reaſon can be offered why any individual ſtone ſhould prevail. They are all wedges, and operate only as wedges. When we conſider any ſingle courſe, therefore, we ſee that it cannot fall in, even though it may be part of a curve which could not ſtand as a common arch; nay, we ſee that a dome may be conſtructed having the convexity of the curve, by the revolution of which it is formed, turned towards the axis, ſo that the outline is concave. We ſhall afterwards find that this is a ſtronger dome by far than if the convexity were outwards, as in a common arch. We ſee alſo that a cone may be loaded on the top with the greateſt weight, without the ſmalleſt danger of forcing it down, ſo long as the bottom courſe is firmly kept from burſting outwards. The ſtone lanthern on the top of St Paul's cathedral in London weighs ſeveral hundred tons, and is carried by a brick cone of eighteen inches thick, with perfect ſafety, as long as the bottom courſe is prevented from burſting outwards. The reaſon is evident: The preſſure on the top is propagated along the cone in the direction of the ſlant ſide; and, ſo far from having any tendency to break it in any part, it tends rather to prevent its being broken by any irregular preſſure from foreign cauſes.

36
Of eaſier
conſtruction than
a plain
arch.

For the ſame reaſons the octagonal pyramids, which form the ſpires of Gothic architecture, are abundantly firm, although very thin. The ſides of the ſpire of Saliſbury cathedral are not eight inches thick after the octagon is fully formed. It is proper, however, to di-

37
Proper conſtruction of
octagonal
pyramids.

rect the joints to the axis of the pyramid, and to make the courſing joints perpendicular to the ſlant ſide, becauſe the projecting mouldings which run along the angles are the abutments on which the whole pannel depends. A conſiderable art is neceſſary for ſupporting thoſe pannels or ſides of the octagon which ſpring from the angles of the ſquare tower. This is done by beginning a very narrow pointed arch on the ſquare tower at a great diſtance below the top; ſo that the legs of the arch being very long, a ſtraight line may be drawn from the top of the keyſtone of the arch through the whole archſtones of the legs. By this diſpoſition the thruſts ariſing from the weight of theſe four pannels are made to meet on the maſſive maſonry in the middle of the ſides of the tower, at a great diſtance below the ſpringing of the ſpire. This part, being loaded with the great maſs of perpendicular wall, is fully able to withſtand the horizontal thruſt from the legs of thoſe arches. In many ſpires theſe thruſts are ſtill farther reſiſted by iron bars which croſs the tower, and are hooked into pieces of braſs firmly bedded in the maſonry of the ſides.

38
Examples of ſuch conſtruction.

There is much nice balancing of this kind to be obſerved in the highly ornamented open ſpires; ſuch as thoſe of Bruſſels, Mechlin, Antwerp, &c. We have not many of this ſort in Britain. In thoſe of great magnitude, the judicious eye will diſcover that parts, which a common ſpectator would conſider as mere ornaments, are neceſſary for completing the balance of the whole. Tall pinnacles, nay, even pillars carrying entablatures and pinnacles, are to be ſeen ſtanding on the middle of the ſlender leg of an arch. On examination, we find that this is neceſſary, to prevent the arch from ſpringing upwards in that place by the preſſure at the crown. The ſteeple of the cathedral of Mechlin was the moſt elaborate piece of architecture in this taſte in the world, and was really a wonder; but it was not calculated to withſtand a bombardment, which deſtroyed it in 1578.

Such frequent examples of irregular and whimſical buildings of this kind, ſhow that great liberties may be taken with the principle of equilibration without riſk, if we take care to ſecure the baſe from being thruſt outwards. This may always be done by hoops, which can be concealed in the maſonry; whereas, in common arches, theſe ties would be viſible, and would offend the eye.

Plate II.

39
Stability of a dome depends on principles

It is now time to attend to the principle of equilibrium, as it operates in a ſimple circular dome, and to determine the thickneſs of the vaulting when the curve is given, or the curve when the thickneſs is given. Therefore, let B b A (fig. 17.) be the curve which produces the dome by revolving round the vertical axis AD. We ſhall ſuppoſe this curve to be drawn through the middle of all the arch-ſtones, and that the courſing or horizontal joints are every where perpendicular to the curve. We ſhall ſuppoſe (as is always the caſe) that the thickneſs KL, HI, &c. of the arch-ſtones is very ſmall in compariſon with the dimenſions of the arch. If we conſider any portion HA b of the dome, it is plain that it preſſes on the courſe, of which HL is an arch-ſtone, in a direction b C perpendicular to the joint HI, or in the direction of the next ſuperior element βb of the curve. As we proceed downwards, courſe after courſe, we ſee plainly that this direction muſt change, becauſe the weight of each courſe is ſuperadded to that of the portion above it, to complete the preſſure on the courſe below. Through B draw the vertical line BCG, meeting βb, produced in C. We may take $b c$ to preſs the preſſure of all that is above it, propagated in this direction to the joint KL. We may alſo ſuppoſe the weight of the courſe HL united in b, and acting on the vertical. Let it be repreſented by b F. If we form the parallelogram b FGC, the diagonal b G will repreſent the direction and intenſity of the whole preſſure on the joint KL. Thus it appears that this preſſure is continually changing its direction, and that the line, which will always coincide with it, muſt be a curve concave downward. If this be preciſely the curve of the dome, it will be an equilibrated vaulting; but ſo far from being the ſtrongeſt form, it is the weakeſt, and it is the limit to an infinity of others, which are all ſtronger than it. This will appear evident, if we ſuppoſe that b G does not coincide with the curve A b B, but paſſes without it. As we ſuppoſe the arch-ſtones to be exceedingly thin from inſide to outſide, it is plain that this dome cannot ſtand, and that the weight of the upper part will preſs it down, and ſpring the vaulting outwards at the joint KL. But let us ſuppoſe, on the other hand, that b G falls within the curvilineal element b B. This evidently tends to puſh the arch-ſtone inward, towards the axis, and would cauſe it to ſlide in, ſince the joints are ſuppoſed perfectly ſmooth and ſlipping. But ſince this takes place equally in every ſtone of this courſe, they muſt all abut on each other in the vertical joints, ſqueezing them firmly together. Therefore, reſolving the thruſt b G into two, one of which is perpendicular to the joint KL, and the other parallel to it, we ſee that this laſt thruſt is withſtood by the vertical joints all around, and there remains only the thruſt in the direction of the curve. Such a dome muſt therefore be firmer than an equilibrated dome, and cannot be ſo eaſily broken by overloading the upper part. When the curve is concave upwards, as in the lower part of the figure, the line b' C always falls below b B, and the point C below B. When the curve is concave downwards, as in the upper part of the figure, $'b$ C′ paſſes above, or without b B. The curvature may be ſo abrupt, that even b' G′ ſhall paſs without $'b$ B, and the point G′ is above B′. It is alſo evident that the force which thus binds the ſtones of a horizontal courſe together, by puſhing them towards the axis, will be greater in flat domes than in thoſe that are more convex; that it will be ſtill greater in a cone; and greater ſtill in a curve whoſe convexity is turned inwards: for in this laſt caſe the line b G will deviate moſt remarkably from the curve. Such a dome will ſtand (having poliſhed joints) if the curve ſprings from the baſe with any elevation, however ſmall; nay, ſince the friction of two pieces of ſtone is not leſs than half of their mutual preſſure, ſuch a dome will ſtand, although the tangent to the curve at the bottom ſhould be horizontal, provided that the horizontal thruſt be double the weight of the dome, which may eaſily be the caſe if it do not riſe high.

40
Differen from tha of a common arc

Thus we ſee that the ſtability of a dome depends on very different principles from that of a common arch, and is in general much greater. It differs alſo in another very important circumſtance, viz. that it may be open in the middle: for the uppermoſt courſe, by tending

ing equally in every part to ſlide in toward the axis, preſſes all together in the vertical joints, and acts on the next courſe like the key ſtone of a common arch. Therefore an arch of equilibration, which is the weakeſt of all, may be open in the middle, and carry at top another building, ſuch as a lanthern, if its weight do not exceed that of the circular ſegment of the dome that is omitted. A greater load than this would indeed break the dome, by cauſing it to ſpring up in ſome of the lower courſes; but this load may be increaſed if the curve is flatter than the curve of equilibration: and any load whatever, which will not cruſh the ſtones to powder, may be ſet on a truncate cone, or on a dome formed by a curve that is convex toward the axis; provided always that the foundation be effectually prevented from flying out, either by a hoop, or by a ſufficient maſs of ſolid pier on which it is ſet. We have mentioned the many failures which happened to the dome of St Sophia in Conſtantinople. We imagine that the thruſt of the great dome, bending the eaſtern arch outward as ſoon as the pier began to yield, deſtroyed the half dome which was leaning on it, and thus, almoſt in an inſtant, took away the eaſtern abutment. We think that this might have been prevented without any change in the injudicious plan, if the dome had been hooped with iron, as was practiſed by Michael Angelo in the vaſtly more ponderous dome of St Peter's at Rome, and by Sir Chriſtopher Wren in the cone and the inner dome of St Paul's at London.

41
ccellency
the dome
St Paul's.

The weight of the latter conſiderably exceeds 3000 tons, and they occaſion a horizontal thruſt which is nearly half this quantity, the elevation of the cone being about 60°. This being diſtributed round the circumference, occaſions a ſtrain on the hoop $= \frac{7}{2 \times 22}$ of the thruſt, or nearly 238 tons. A ſquare inch of the worſt iron, if well forged, will carry 25 tons with perfect ſafety; therefore a hoop of 7 inches broad and $1\frac{1}{2}$ inches thick will completely ſecure this circle from burſting outwards. It is, however, much more completely ſecured; for beſides a hoop at the baſe of very nearly theſe dimenſions, there are hoops in different courſes of the cone which bind it into one maſs, and cauſe it to preſs on the piers in a direction exactly vertical. The only thruſts which the piers ſuſtain are thoſe from the arches of the body of the church and the tranſepts. Theſe are moſt judiciouſly directed to the entering angles of the building, and are there reſiſted with inſuperable force by the whole lengths of the walls, and by four ſolid maſſes of maſonry in the corners. Whoever conſiders with attention and judgment the plan of this cathedral, will ſee that the thruſts of theſe arches, and of the dome, are incomparably better balanced than in St Peter's church at Rome. But to return from this ſort of digreſſion.

42
eory of
curves
oper for
mes.

We have ſeen that if *b* G, the thruſt compounded of the thruſt *b* C, exerted by all the courſes above HILK, and if the force *b* F, or the weight of that courſe, be everywhere coincident with *b* B, the element of the curve, we ſhall have an equilibrated dome; if it falls within it, we have a dome which will bear a greater load; and if it falls without it, the dome will break at the joint. We muſt endeavour to get analytical expreſſions of theſe conditions. Therefore draw the ordinates *b* δ *b*″, BDB″, C *d* C″. Let the tangents at *b* and *b*″ meet the axis in M, and make MO, MP, each equal to *b c*, and complete the parallelogram MONP, and draw OQ perpendicular to the axis, and produce *b* F, cutting the ordinates in E and *e*. It is plain that MN is to MO as the weight of the arch HA*b* to the thruſt *b c* which it exerts on the joint KL (this thruſt being propagated through the courſe HILK); and that MQ, or its equal *b e*, or δ *d*, may repreſent the weight of the half AH.

Let AD be called x, and DB be called y. Then $be = \dot{x}$, and $eC = \dot{y}$ (becauſe *b c* is in the direction of the element β*b*). It is alſo plain, that if we make $\dot{y}$ conſtant, BC is the ſecond fluxion of x, or $BC = \ddot{x}$, and *b e* and BE may be conſidered as equal, and taken indiſcriminately for $\dot{x}$. We have alſo $bC = \sqrt{\dot{x}^2 + \dot{y}^2}$. Let d be the depth or thickneſs HI of the arch-ſtones. Then $d\sqrt{\dot{x}^2 + \dot{y}^2}$ will repreſent the trapezium HL: and ſince the circumference of each courſe increaſes in the proportion of the radius y, $dy\sqrt{\dot{x}^2 + \dot{y}^2}$ will expreſs the whole courſe. If $\int$ be taken to repreſent the ſum or aggregate of the quantities annexed to it, the formula will be analogous to the fluent of a fluxion, and $\int dy\sqrt{\dot{x}^2 + \dot{y}^2}$ will repreſent the whole maſs, and alſo the weight of the vaulting down to the joint HI. Therefore we have this proportion $\int dy\sqrt{\dot{x}^2 + \dot{y}^2} : dy\sqrt{\dot{x}^2 + \dot{y}^2} = be : bF, = be : CG, = \delta d : CG, = \dot{x} : CG$. Therefore $CG = \frac{dy\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}}$.

If the curvature of the dome be preciſely ſuch as puts it in equilibrium, but without any mutual preſſure in the vertical joints, this value of OG muſt be equal to CB, or to $\ddot{x}$, the point G coinciding with B. This condition will be expreſſed by the equation $\frac{dy\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} = \ddot{x}$, or, more conveniently, by $\frac{dy\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} = \frac{\ddot{x}}{\dot{x}}$. But this form gives only a tottering equilibrium, independent of the friction of the joints and the coheſion of the cement. An equilibrium, accompanied by ſome firm ſtability, produced by the mutual preſſure of the vertical joints, may be expreſſed by the formula $\frac{dy\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} > \frac{\ddot{x}}{\dot{x}}$, or by $\frac{dy\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}} = \frac{\ddot{x}}{\dot{x}} + \frac{\dot{t}}{t}$, where t is ſome variable poſitive quantity, which increaſes when x increaſes. This laſt equation will alſo expreſs the equilibrated dome, if t be a conſtant quantity, becauſe in this caſe $\frac{\dot{t}}{t}$ is $= o$.

Since a firm ſtability requires that $\frac{dy\dot{x}\sqrt{\dot{x}^2 + \dot{y}^2}}{\int dy\sqrt{\dot{x}^2 + \dot{y}^2}}$ ſhall be greater than $\ddot{x}$, and CG muſt be greater than CB: Hence we learn, that figures of too great curvature, whoſe ſides deſcend too rapidly, are improper. Alſo, ſince ſtability requires that we have $\frac{dy\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\ddot{x}}$ greater than $\int dy\sqrt{\dot{x}^2+\dot{y}^2}$, we learn that the upper part of the dome muſt not be made very heavy. This, by diminiſhing the proportion of b F to b C, diminiſhes the angle $c\,b$ G, and may ſet the point G above B, which will infallibly ſpring the dome in that place. We ſee here alſo, that the algebraic analyſis expreſſes that peculiarity of dome-vaulting, that the weight of the upper part may even be ſuppreſſed.

The fluent of the equation $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}=\frac{\ddot{x}}{\dot{x}}+\frac{\dot{t}}{t}$ is moſt eaſily found. It is $\mathrm{L}\int dy\sqrt{\dot{x}^2+\dot{y}^2}=\mathrm{L}\,\dot{x}+\mathrm{L}\,t$, where L is the hyperbolic logarithm of the quantity annexed to it. If we conſider $\dot{y}$ as conſtant, and correct the fluent ſo as to make it nothing at the vertex, it may be expreſſed thus, $\mathrm{L}\int dy\sqrt{\dot{x}^2+\dot{y}^2}-\mathrm{L}\,a=\mathrm{L}\,\dot{x}-\mathrm{L}\,\dot{y}+\mathrm{L}\,t$. This gives us $\mathrm{L}\frac{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}{a}=\mathrm{L}\frac{\dot{x}}{\dot{y}}\,t$, and therefore $\frac{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}{a}=t\frac{\dot{x}}{\dot{y}}$.

This laſt equation will eaſily give us the depth of vaulting, or thickneſs d of the arch, when the curve is given. For its fluxion is $\frac{dy\sqrt{\dot{x}^2+\dot{y}^2}}{a}=\frac{\dot{t}\dot{x}+t\ddot{x}}{\dot{y}}$, and $d=\frac{a\dot{t}\dot{x}+at\ddot{x}}{y\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$, which is all expreſſed in known quantities; for we may put in place of t any power or function of x or of y, and thus convert the expreſſion into another, which will ſtill be applicable to all ſorts of curves.

Inſtead of the ſecond member $\frac{\ddot{x}}{\dot{x}}+\frac{\dot{t}}{t}$, we might employ $\frac{p\ddot{x}}{\dot{x}}$, where p is ſome number greater than unity. This will evidently give a dome having ſtability; becauſe the original formula $\frac{dy\,\dot{x}\sqrt{\dot{x}^2+\dot{y}^2}}{\int dy\sqrt{\dot{x}^2+\dot{y}^2}}$ will then be greater than $\ddot{x}$. This will give $d=\frac{pa\dot{x}^{p-1}\ddot{x}}{y\dot{y}^p\sqrt{\dot{x}^2+\dot{y}^2}}$. Each of theſe forms has its advantages when applied to particular caſes. Each of them alſo gives $d=\frac{a\ddot{x}}{y\dot{y}\sqrt{\dot{x}^2+\dot{y}^2}}$ when the curvature is ſuch as is in preciſe equilibrium. And, laſtly, if d be conſtant, that is, if the vaulting be of uniform thickneſs, we obtain the form of the curve, becauſe then the relation of $\ddot{x}$ to $\dot{x}$ and to y is given.

The chief uſe of this analyſis is to diſcover what curves are improper for domes, or what portions of given curves may be employed with ſafety. Domes are generally built for ornament; and we ſee that there is great room for indulging our fancy in the choice. All curves which are concave outwards will give domes of great firmneſs: They are alſo beautiful. The Gothic dome, whoſe outline is an undulated curve, may be made abundantly firm, eſpecially if the upper part be convex and the lower concave outwards.

The chief difficulty in the caſe of this analyſis ariſes from the neceſſity of expreſſing the weight of the incumbent part, or $\int dy\sqrt{\dot{x}^2+\dot{y}^2}$. This requires the meaſurement of the conoidal ſurface, which, in moſt caſes, can be had only by approximation by means of infinite ſerieſes. We cannot expect that the generality of practical builders are familiar with this branch of mathematics, and therefore will not engage in it here; but content ourſelves with giving ſuch inſtances as can be underſtood by ſuch as have that moderate mathematical knowledge which every man ſhould poſſeſs who takes the name of engineer.

The ſurface of any circular portion of a ſphere is very eaſily had, being equal to the circle deſcribed with a radius equal to the chord of half the arch. This radius is evidently $=\sqrt{x^2+y^2}$.

In order to diſcover what portion of a hemiſphere may be employed (for it is evident that we cannot employ the whole) when the thickneſs of the vaulting is uniform, we may recur to the equation or formula $\frac{dy\,\dot{x}\sqrt{\dot{x}^2-\dot{y}^2}}{\ddot{x}}=\int dy\sqrt{\dot{x}^2+\dot{y}^2}$. Let a be the radius of the hemiſphere. We have $\dot{x}=\frac{ay\dot{y}}{\sqrt{a^2-y^2}}$, and $\ddot{x}=\frac{a^2\dot{y}^2}{\overline{a^2-y^2}|^{\frac{3}{2}}}$. Subſtituting theſe values in the formula, we obtain the equation $y^2\sqrt{a^2-y^2}=\int\frac{a^2 y\dot{y}}{\sqrt{a^2-y^2}}$. We eaſily obtain the fluent of the ſecond member $=a^3-a^2\sqrt{a^2-y^2}$, and $y=a\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$. Therefore if the radius of the ſphere be one, the half breadth of the dome muſt not exceed $\sqrt{-\frac{1}{2}+\sqrt{\frac{5}{4}}}$, or 0,786, and the height will be 618. The arch from the vertex is about 51° 49′. Much more of the hemiſphere cannot ſtand, even though aided by the cement, and by the friction of the courſing joints. This laſt circumſtance, by giving connection to the upper parts, cauſes the whole to preſs more vertically on the courſe below, and thus diminiſhes the outward thruſt; but it at the ſame time diminiſhes the mutual abutment of the vertical joints, which is a great cauſe of firmneſs in the vaulting. A Gothic dome, of which the upper part is a portion of a ſphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very ſtrong, and not ungraceful.

43 Dome of St Peter's at Rome.

But the public taſte has long rejected this form, and ſeems rather to ſelect more elevated domes than this portion of a ſphere; becauſe a dome, when ſeen from a ſmall diſtance, always appears flatter than it really is. The dome of St Peter's is nearly an ellipſoid externally, of which the longer axis is perpendicular to the horizon. It is very ingeniouſly conſtructed. It ſprings from the baſe perpendicularly, and is very thick in this part. After riſing about 50 feet, the vaulting ſeparates into two thin vaultings, which gradually ſeparate from each other. Theſe two ſhells are connected together by thin partitions, which are very artificially dovetailed in both, and thus form a covering which is extremely ſtiff, while it is very light. Its great ſtiffneſs was neceſſary for enabling the crown of the dome to carry the elegant ſtone lanthern

lanthern with ſafety. It is a wonderful performance, and has not its equal in the world; but it is an enormous load in compariſon with the dome of St Paul's, and this even independent of the difference of ſize. If they were of equal dimenſions, it would be at leaſt five times as heavy, and is not ſo firm by its gravity; but as it is connected in every part by iron bars (lodged in the ſolid maſonry, and well ſecured from the weather by having lead melted all round them), it bids fair to laſt for ages, if the foundations do not fail.

Plate II.

If a circle be deſcribed round a centre placed anywhere in the tranſverſe axis AC (fig. 18. N° 1.) of an ellipſe, ſo as to touch the ellipſe in the extremities B, b, of an ordinate, it will touch it internally, and the circular arch Bab will be wholly within the elliptical arch BAb. Therefore, if an elliptical and a ſpherical vaulting ſpring from the ſame baſe, at the ſame angle with the horizon, the ſpherical vaulting will be within the elliptical, will be flatter and lighter, and therefore the weight of the next courſe below will bear a greater proportion to the thruſt in the direction of the curve; therefore the ſpherical vaulting will have more ſtability. On the contrary, and for ſimilar reaſons, an oblate elliptical vaulting is preferable to a ſpherical vaulting ſpringing with the ſame inclination to the horizon. (Fig. 18. N° 2.).

44
menſions
the beſt
m of a
ne.

Perſuaded, that what has been ſaid on the ſubject convinces the reader that a vaulting perfectly equilibrated throughout is by no means the beſt form, provided that the baſe is ſecured from ſeparating, we think it unneceſſary to give the inveſtigation of that form, which has a conſiderable intricacy; and ſhall content ourſelves with merely giving its dimenſions. The thickneſs is ſuppoſed uniform. The numbers in the firſt column of the table expreſs the portion of the axis counted from the vertex, and thoſe of the ſecond column are the lengths of the ordinates.

AD	DB	AD	DB	AD	DB
0,4	100	610,4	1080	2990	1560

465,4	1000	2602	1520	7260	1800

The curve delineated in fig. 19. is formed according to theſe dimenſions, and appears deſtitute of gracefulneſs; becauſe its curvature changes abruptly at a little diſtance from the vertex, ſo that it has ſome appearance of being made up of different curves pieced together. But if the middle be occupied by a lanthern of equal, or of ſmaller weight, this defect will ceaſe, and the whole will be elegant, nearly reſembling the exterior dome of St Paul's in London.

45
antages
ome-
ting.

It is not a ſmall advantage of dome-vaulting that it is lighter than any that can cover the ſame area. If, moreover, it be ſpherical, it will admit conſiderable varieties of figure, by combining different ſpheres. Thus, a dome may begin from its baſe as a portion of a large hemiſphere, and may be broken off at any horizontal courſe, and then a ſimilar or a greater portion of a ſmaller ſphere may ſpring from this courſe as a baſe. It alſo bears being interſected by cylindrical vaultings in every direction, and the interſections are exact circles, and always have a pleaſing effect. It alſo ſprings moſt gracefully from the heads of ſmall piers, or from the corners of rooms of any polygonal ſhape; and the arches formed by its interſections with the walls are always circular and graceful, forming very handſome ſpandrels in every poſition. For theſe reaſons Sir Chriſtopher Wren employed it in all his vaultings, and he has exhibited many beautiful varieties in the tranſepts and the aiſles of St Paul's, which are highly worthy of the obſervation of architects. Nothing can be more graceful than the vaultings at the ends of the north and ſouth tranſepts, eſpecially as finiſhed off in the fine inſide view publiſhed by Gwynn and Wale.

46
Effects of cement and friction in dome vaulting.

We conclude this article with obſerving, that the connection of the parts, ariſing from cement and from friction, has a great effect on dome-vaulting. In the ſame way as in common arches and cylindrical vaulting, it enables an overload on one place to break the dome in a diſtant place. But the reſiſtance to this effect is much greater in dome-vaulting, becauſe it operates all round the overloaded part. Hence it happens that domes are much leſs ſhattered by partial violence, ſuch as the falling of a bomb or the like. Large holes may be broken in them without much affecting the reſt; but, on the other hand, it greatly diminiſhes the ſtrength which ſhould be derived from the mutual preſſure in the vertical joints. Friction prevents the ſliding in of the arch ſtones which produces this mutual preſſure in the vertical joints, except in the very higheſt courſes, and even there it greatly diminiſhes it. Theſe cauſes make a great change in the form which gives the greateſt ſtrength; and as their laws of action are but very imperfectly underſtood as yet, it is perhaps impoſſible, in the preſent ſtate of our knowledge, to determine this form with tolerable preciſion. We ſee plainly, however, that it allows a greater deviation from the beſt form than the other kind of vaulting, and domes may be made to riſe perpendicular to the horizon at the baſe, although of no great thickneſs; a thing which muſt not be attempted in a plane arch. The immenſe addition of ſtrength which may be derived from hooping, largely compenſates for all defects; and there is hardly any bounds to the extent to which a very thin dome-vaulting may be carried, when it is hooped or framed in the direction of the horizontal courſes. The roof of the Halle du Bled at Paris is but a foot thick, and its diameter is more than 200, yet it appears to have abundant ſtrength. It is, on the whole, a noble ſpecimen of architecture.

47
The iron bridge at Sunderland deſcribed.

We muſt not conclude this article without taking notice of that magnificent and elegant arch which has been erected in caſt iron at Weremouth, near Sunderland, in the county of Durham. The inventor and architect is Rowland Burdon, Eſq; one of the repreſentatives of that county in the preſent Parliament.

This arch is a ſegment of a circle whoſe diameter is about 444 feet. The ſpan or cord of the arch is 236 feet, and its verſed ſine or ſpring is 34 feet. It ſprings at the elevation of 60 feet from the ſurface of the river at low water, ſo that veſſels of 200 or perhaps 300 tons burden may paſs under it in the middle of the ſtream, and even 50 feet on each ſide of it.

The ſweep of the arch conſiſts of a ſeries of frames of caſt iron, which butt on each other, in the ſame manner as the vouſſoirs of a ſtone arch. One of theſe frames or blocks (as we ſhall call them in future) is repreſented in fig. 1. as ſeen in front. It is caſt in one piece; and conſiſts of three pieces or arms BC, BC, BC, the middle one of which is two feet long, the upper being ſomewhat more, and the lower ſomewhat leſs, becauſe their extremities are bounded by the radius drawn from the centre of the arch. Theſe arms are four inches ſquare, and are connected by other pieces KL, of ſuch length that the whole length of the block is five feet in the direction of the radius. Each arm has a flat groove on each ſide, which is expreſſed by the darker ſhading, three inches broad and three-fourths of an inch deep. A ſection of this block, through the middle of KL, is repreſented by the light-ſhaded part BBB, in which the grooves are more diſtinctly perceived. Theſe grooves are intended for receiving flat bars of malleable iron, which are employed for connecting the different blocks with each other. Fig. 2 repreſents two blocks united in this manner. For this purpoſe each arm has two ſquare bolt-holes. The ends of the arms being nicely trimmed off, ſo that the three ends butt equally cloſe on the ends of the next block; and the bars of hammered iron being alſo nicely fitted to their grooves, ſo as to fill them completely, and have their bolt holes exactly correſponding to thoſe in the blocks, they are put together in ſuch a manner that the joints or meetings of the malleable bars may fall on the middle between the bolt-holes in the arms. Flat headed bolts of wrought iron are then put through, and keys or forelocks are driven thro' the bolt-tails, and thus all is firmly wedged together, binding each arm between two bars of wrought iron. Theſe bars are of ſuch length as to connect ſeveral blocks.

Plate IV.

In this manner a ſeries of about 125 blocks are joined together, ſo as to form the preciſe curve that is intended. This ſeries may be called a rib, and it ſtands in a vertical plane. The arch conſiſts of ſix of theſe ribs, diſtant from each other five feet. Theſe ribs are connected together ſo as to form an arch of 32 feet in breadth, in the following manner:

Fig. 3. repreſents one of the bridles or croſs pieces which connect the different ribs, as it appears when viewed from below. It is a hollow pipe of caſt iron, four inches in diameter, and has at each end two projecting ſhoulders, pierced with a bolt-hole near their extremities, ſo that the diſtance between the bolt-holes in the ſhoulders of one end is equal to the diſtance between the holes in the arms of the blocks, or the holes in the wrought iron bars. In the middle of the upper and of the under ſide of each end may be obſerved a ſquare prominence, more lightly ſhaded than the reſt. Theſe projections alſo advance a little beyond the flat of the ſhoulders, forming between them a ſhallow notch, about an inch deep, which receives the iron of the arms, where they butt on each other, and thus gives an additional firmneſs to the joint. The manner in which the arms are thus graſped by theſe notches in the bridles is more diſtinctly ſeen in fig. 2. at the letter H in the middle of the upper rail.

The rib having been all trimmed and put together, ſo as to form the exact curve, the bolts are all taken out, and the horizontal bridles are then ſet on in their places, and the bolts are again put in and made faſt by the forelocks. The bolts now paſs through the ſhoulders of the bridles, through the wrought iron bars, and through the caſt iron arm that is between them, and the forelocks bind all faſt together. The manner in which this connection is completed is diſtinctly ſeen in fig. 2. which ſhews in perſpective a double block in front, and a ſingle block behind it. The butting joints of the two front blocks are at the letters E, E, E; the holes in the ſhoulders of the horizontal croſs pieces are at H.

48 Its con- ſtructio ſimple a judiciou

This conſtruction is beautifully ſimple and very judicious. A vaſt addition of ſtrength and of ſtiffneſs is procured by lodging the wrought iron bars in grooves formed in the caſt iron rails; and for this purpoſe it is of great importance to make the wrought iron bars fill the grooves completely, and even to be ſo tight as to require the force of the forelocks to draw them home to the bottom of the grooves. There can be no doubt but that this arch is able to withſtand an enormous preſſure, as long as the abutments from which it ſprings do not yield. Of this there is hardly any riſk, becauſe they are maſſes of rock, faced with about four or five yards (in ſome places only) of ſolid block maſonry. The mutual thruſts of the frames are all in the direction of the rails, ſo that no part bears any tranſverſe ſtrain. We can hardly conceive any force that can overcome the ſtrength of thoſe arms by preſſure or cruſhing them. The manner in which the frames are connected into one rib, effectually ſecures the butting joints from ſlipping; and the accuracy with which the whole can be executed, ſecures us againſt any warping or deviation of a rib from the vertical plane.

But when we conſider the prodigious ſpan of this arch, and reflect that it is only five feet thick, it ſhould ſeem that the moſt perfect equilibration is indiſpenſably neceſſary. It is but like a film, and muſt be ſo ſupple that an overload on any part muſt have a great tendency to bend it, and to cauſe it to riſe in a diſtant part; and this effect is increaſed by the very firmneſs with which the whole ſticks together. The overloaded part acts on a diſtant part, tending to break it with all the energy of a long lever. This can be prevented only by means of the ſtiffneſs of the diſtant part. It is very true, the arch cannot break in the extrados except by tearing aſunder the wrought iron bars which connect the blocks along the upper rail, and each of theſe requires more than a hundred tons to tear it aſunder; yet an overload of five tons on any rib at its middle will produce this ſtrain at twenty feet from the ſides, ſuppoſing the ſides held firm in their poſition. It were deſirable therefore that ſomething were done to ſtiffen the arch at the ſides, by the manner of filling up the ſpandrels, or ſpace between the arch and the road-way. This is filled up in a manner that is extremely light and pleaſing to the eye, namely, by large caſt iron circles, which touch the extrados of the arch and touch the road-way. The road-way reſts on them as on ſo many hoops, while they reſt on the back of the arch, and alſo touch each other laterally. We cannot think that this contributes to the ſtrength of the arch; for theſe hoops will be eaſily compreſſed at the points of contact,

contact, and, changing their ſhape, will oppoſe very little reſiſtance. We think that this part of the arch might have been greatly ſtiffened and ſtrengthened, by connecting it with the road-way by truſſed frames, in the ſame way that a judicious carpenter would have framed a roof. If a ſtrong caſt iron pillar had been made to reſt on the arch at about 20 feet from the impoſt, and been placed in the direction of a radius, the top of this pillar might have been connected by a diagonal bar of wrought iron with the impoſt of the arch, and with the crown of the arch by another ſtring or bar of the ſame materials. Theſe two ties would cauſe the radial pillar to preſs ſtrongly on the back of the arch, and they muſt be torn aſunder before it could bend in that place in the ſmalleſt degree. Suppoſing them of the ſame dimenſions as the bars in the arms, their poſition would give them near ten times the force for reſiſting the ſtrain produced by an overload on the crown.

This beautiful arch contains only 260 tons of iron, of which about 55 are wrought iron. The ſuperſtructure is of wood, planked over a-top. This floor is covered with a coating of chalk and tar, on which is laid the materials for the carriage road, conſiſting of marle, limeſtone, and gravel, with foot-ways of flag ſtones at the ſides. The weight of the whole did not exceed a thouſand tons; whereas the lighteſt ſtone arch which could have been erected would have weighed fifteen thouſand. It was turned on a very light but ſtiff ſcaffolding, moſt judiciouſly conſtructed for the preſervation of its form, and for allowing an uninterrupted paſſage for the numerous ſhips and ſmall craft which frequent the buſy harbour of Sunderland. The mode of framing the arch was ſo ſimple and eaſy, that it was put up in ten days! without an accident; and when all was finiſhed, and the ſcaffolding removed, the arch did not ſenſibly change its form. The whole work was executed in three years, and coſt about L. 26,000.

ARCHITECTURE is an art of ſo much importance, and capable of ſo many embelliſhments, as to have employed the attention and talents of men of ſcience in almoſt every age, and in every country. It is generally thought to have been carried to the utmoſt perfection among the Greeks and Romans; and it has been the aim of the moſt eminent architects of modern times to imitate with fidelity the buildings of thoſe accompliſhed nations. There is, however, another ſpecies of architecture, which was introduced into Europe in the middle ages, and is of ſuch a nature as to ſtrike every unprejudiced obſerver with admiration and aſtoniſhment. The architecture to which we allude has been called, perhaps with little propriety,

Gothic Architecture. It is that which is to be viewed in all our ancient cathedrals, and in other large buildings which have been erected from the middle of the 12th to the beginning of the 16th century. That ſuch edifices have been conſtructed on principles of ſcience, has been ſhewn elſewhere (ſee Roof, *Encycl.* and Arch, in this *Suppl.*): but a queſtion ſtill preſents itſelf to the inquiſitive mind, " How came ſuch ſtructures to be thought of by a people whom we are accuſtomed to call ignorant and barbarous?" This queſtion has occupied the attention of many ingenious men, who have attributed the Gothic ſtyle of building, ſome to neceſſity, and others to an imitation of the works of nature. That, where materials are bad, larger edifices can be erected in the Gothic than in the Grecian ſtyle, has been made ſufficiently evident in the articles to which we have referred; and that neceſſity is the parent of invention, is an adage which has been too long received to be now called in queſtion. But whence came the peculiarities of the Gothic ornaments in building, the pointed arch, and the double row of cluſtered pillars compoſed of ſlender ſhafts, which, reaching from the ground almoſt to the roof of the building, are there ſpread out in all directions, forming the ribs or *groins* of a vaulted roof?

The moſt ſatisfactory ſolution of this queſtion which we have ſeen, is in a memoir publiſhed in the fourth volume of the Tranſactions of the Royal Society of Edinburgh, by Sir James Hall, Bart. with whoſe permiſſion the following abſtract is laid before our readers.

" Although the connection between beauty and utility be ſtill involved in ſuch obſcurity, that we are unable to decide concerning the univerſality of that connection, of one thing we are certain, that, in a work intended to anſwer ſome uſeful purpoſe, whatever viſibly counteracts that purpoſe always occaſions deformity. Hence it is, that, even where ornament is principally intended, the oſtenſibly uſeful object of the work, if it have any ſuch, muſt be provided for, in the firſt place, in preference to every other conſideration.

" But in moſt uſeful works, ſome parts occur, the ſhape of which is quite indifferent with reſpect to the propoſed utility, and which, therefore, the artiſt is at liberty to execute as he pleaſes: a liberty which has opened a wide field to the taſte and invention of ingenious men of every age and country, who have turned their attention to the compoſition of ornaments; and whoſe exertions have been more or leſs influenced by the ſtate of civilization in which they lived. It would ſeem, however, if we may judge by thoſe various efforts, that little has been effected by mere human ingenuity; ſince we ſee that recourſe has been had, almoſt univerſally, to nature, the great and legitimate ſource of beauty; and that ornament has been attained by the imitation of objects, to which ſhe has given a determinate and characteriſtic form.

" Where the materials employed are themſelves poſſeſſed of variety and elegance, the attainment of this object requires little or no alteration of their natural forms. Thus cups are made of ſhells, of cocoa-nuts, or of oſtrich eggs; the character and beauty of which depend upon the natural form of the materials: and in the caſe of the bottles uſed by the Roman Catholic pilgrims, an example occurs of an utenſil, in which the natural form has undergone little or no variation, ſince it conſiſts of the hard outward ſkin of a gourd, of the ſame ſhape in which it grew upon the plant (A). This laſt claſs of forms has been introduced, by imitation, into works compoſed

---

(A) " Even in this caſe, however, the natural form undergoes a certain degree of modification, by the device employed to produce the neck of the bottle. The fruit, while ſmall and tender, is ſurrounded with a ſtring, which remaining during its growth, prevents the part, thus bound, from ſwelling with the reſt."

compoſed of ſhapeleſs materials. Thus we have ſilver cups in the form of thoſe made of ſhells, and fruit-diſhes of ſtoneware in the form of baſkets.

" As ſtone is not naturally poſſeſſed of any peculiar ſhape, and as the uſeful object propoſed, by ſtructures formed of it, may be accompliſhed in various ways, very great latitude is left to the invention of the artiſt. We ſee, accordingly, that in every country where much refinement has been introduced, great pains have been beſtowed in ornamenting ſtone buildings with figures repreſenting various natural objects; whilſt the building itſelf has been executed in imitation of a ſtructure, compoſed of materials which naturally poſſeſs a determinate and characteriſtic form. Such was the method followed by the architects of ancient Greece, who conſtructed temples, and other public edifices, in imitation of a ruſtic fabric, compoſed of ſquare beams, ſupported upon round poſts or ſtems of trees, and who derived the numerous ornaments of that beautiful ſtyle from circumſtances which would naturally take place in ſuch a ſtructure.

" A faint and diſtant reſemblance, however, of the original, has generally been found to anſwer all the end propoſed by the imitation; a reſemblance, which may ſometimes be traced in the general diſtribution of the edifice, ſometimes in its minute parts, and not unfrequently in both.

" But the forms of nature thus introduced have been greatly modified by thoſe of maſonry. For though ſtone is by nature ſhapeleſs, yet, in the courſe of practice, many peculiar forms have been long eſtabliſhed, and currently employed, in working it; ſuch as ſtraight lines, plain ſurfaces, ſquare angles, and various mouldings uſed to ſoften the effect of abrupt terminations: all of which, originating in motives of mechanical convenience, and of ſimple ornament, had, in very early times, been appropriated to maſonry, and conſidered as eſſential in every finiſhed work of ſtone; ſo that, when the imitation of nature was introduced, theſe maſonic forms ſtill maintained their ground, and, being blended with the forms of nature, the two claſſes reciprocally modified each other.

" This combination of art with nature, of which we ſee the moſt perfect example in the Corinthian capital, produces what are called architectonic forms, in which the variety of nature, being ſubjected to the regularity of art, the work acquires that peculiar character which, in a natural object, we conſider as offenſive, under the name of *formality*; but which, in architecture, we admire as a beauty, under the name of *ſymmetry*: thus, we reprobate the formality of an avenue, and praiſe the ſymmetry of a colonnade.

" Such is the nature of architectonic imitation; a device which probably originated in accident, but to which architecture is indebted for its higheſt attainments."

As the ſtone edifices of ancient Greece were conſtructed in imitation of a wooden fabric, compoſed of ſquare beams laid at right angles on round poſts or ſtems of trees, Sir James conceives that the Gothic fabrics with pointed arches have been executed in imitation of a ruſtic dwelling, conſtructed in the following manner: Suppoſe a ſet of round poſts driven firmly into the ground in two oppoſite rows, the interval between the neighbouring poſts in the ſame row being equal to that between the rows, and each poſt being raiſed above the ground to a height equal to three of thoſe intervals; then a ſet of long and flexible rods of willow being applied to each poſt, let them be thruſt into the ground at its baſe, and bound to it by two tyings, one near the ground, and another at two-thirds of its height; the rods being left looſe from this laſt point upwards, and free to be moved in any direction. Let three rods be connected with each outſide corner poſt, and five with each of the others, and let their poſition be ſuch as to cover the inſide of the poſt, ſo that when ſeen from between the rows the lower part of each poſt ſhall be concealed from the view, and preſent the appearance of a bundle of rods (fig 1.)

Plate V.

Things being thus diſpoſed, the ſkeleton of a thatched roof may be formed by means of the looſe ends of the rods. A rod from one of the poſts being ſo bent as to meet a ſimilar one from the poſt immediately oppoſite to it, in the middle of the ſpace between them, let the two rods be made to croſs each other, and let them be bound together at their croſſing (fig. 2.), and we ſhall have the exact form of the Gothic arch The ſame being done with each pair of oppoſite poſts, and a ſet of pointed arches being formed, let them be connected together by means of a ſtraight pole laid upon the forks of the croſſing rods, and bound to each of them, as in fig. 3: then let a looſe rod be brought from each of any two contiguous poſts in the ſame row, ſo as to form a pointed arch, ſimilar to that juſt deſcribed, and nearly of the ſame height. This being done with every two contiguous poſts (fig. 4.), and a new ſet of pointed arches being thus produced, ſtanding oppoſite to each other in pairs, let each pair be bound by a horizontal pole lying on the oppoſite forks, and croſſing the longitudinal pole deſcribed above.

" Two of the rods of each corner poſt, and three of thoſe of each of the others, being thus diſpoſed of, we have one of each corner poſt and two of each middle poſt ſtill to employ, which is done as follows: A pair of theſe unoccupied rods being brought from any two poſts which ſtand diagonally to each other, and made to meet in the middle, not as in the firſt caſe croſſing in an angle, but ſide by ſide, forming a ſemicircle, and joined together after the manner of a hoop; and the ſame being done with every pair of diagonal poſts (fig. 5.), the whole rods will have been employed.

" In this manner a frame would be conſtructed fit to ſupport thatch or other covering; and ſuch a one has probably been often uſed. It would ſeem, however, that, for the ſake of ſtrength, the number of rods has been increaſed in each cluſter, by the introduction, between every two of them, of an additional rod, which riſing with them to the roof, ſtill continues its middle poſition, as they ſpread aſunder, and meets the horizontal pole at an intermediate point. This is ſhown in fig. 6. which is drawn with its covering of thatch; and, from the imitation of a dwelling ſo conſtructed, we may eaſily trace the three leading characteriſtics of Gothic architecture, the pointed arch, the cluſtered column, and the branching roof, as exhibited in fig. 7."

Upon the ſame principles Sir James Hall, with much ingenuity, accounts for the peculiar forms of the Gothic door, the Gothic window, and the pointed ſpire: but it is not our intention to ſuperſede the neceſſity of having recourſe to his memoir, but to excite the deſire of

of our readers to peruſe as well that paper as a larger work which he promiſes on the ſame ſubject, and in which we doubt not but they will find both entertainment and inſtruction. We ſhall conclude this article, therefore, with an experimental proof of the juſtneſs of his hypotheſis.

In the greater part of our late attempts at Gothic architecture, it is allowed by every man of taſte that we have failed. The failure is to be accounted for by the buildings having been conſtructed upon no conſiſtent principle, applicable to every part of them, but upon a ſervile copying of ancient edifices, of which the ſtructure was little underſtood by the copiers. Sir James Hall, however, by applying his theory to practice, has conſtructed a building in this ſtyle, which has far ſurpaſſed, he ſays, his own expectation, and has certainly gained the approbation of every man of taſte and ſcience by whom we have had occaſion to hear it mentioned. "A ſet of poſts of aſh, about three inches in diameter, were placed in two rows, four feet aſunder, and at the interval of four feet in the rows; then a number of ſlender and tapering willow rods, ten feet in length, were applied to the poſts, and, in the manner which we have deſcribed, formed into a frame, which being covered with thatch, produced a very ſubſtantial roof, under which a perſon can walk with eaſe.

"This little ſtructure exhibits, in miniature, all the characteriſtic features of the Gothic ſtyle. It is in the form of a croſs, with a nave, a choir, and a north and ſouth tranſept. The thatch, being ſo diſpoſed on the frame as not to hide the rods of which it is compoſed, they repreſent accurately the pointed and ſemicircular arches, and all the other peculiarities of a groined roof."

ARCTUS, a name given by the Greeks to two conſtellations of the northern hemiſphere, by the Latins called *Ursa Major* and *Minor*, and by us the *Greater* and *Leſſer Bear*.

Binary ARITHMETIC. See *Binary Arithmetic*, Encycl.

Duodecimal Arithmetic, is that which proceeds from 12 to 12, or by a continual ſubdiviſion according to 12. This is greatly uſed by moſt artificers in calculating the quantity of their work; as bricklayers, carpenters, painters, tilers, &c.

Harmonical Arithmetic, is ſo much of the doctrine of numbers as relates to the making the compariſons, reductions, &c. of muſical intervals.

Arithmetic of infinites, is the method of ſumming up a ſeries of numbers, of which the number of terms is infinite. This method was firſt invented by Dr Wallis, as appears by his treatiſe on that ſubject; where he ſhows its uſes in geometry, in finding the areas of ſuperficies, the contents of ſolids, &c. But the method of fluxions, which is a kind of univerſal arithmetic of infinities, performs all theſe more eaſily, as well as a great many other things, which the former will not reach.

Logiſtical Arithmetic, a name ſometimes employed for the arithmetic of ſexageſimal fractions, uſed in aſtronomical computations. Shakerly, in his *Tabulæ Britannicæ*, has a table of logarithms adapted to ſexageſimal fractions, which he calls *logiſtical logarithms*: and the expeditious arithmetic, obtained by means of them, he calls *logiſtical arithmetic*. The term *logiſtical arithmetic*, however, or *logiſtic*, has been uſed by Vieta and others for the rules of computations in algebra.

Political Arithmetic. See *Political Arithmetic*, Encycl.

Sexageſimal Arithmetic. See Arithmetic (*Hiſt.*) Encycl.

Tetractic Arithmetic, is that in which only the four characters 0, 1, 2, 3, are uſed. A treatiſe of this kind of arithmetic is extant by Erhard or Echard Weigel. But both this and binary arithmetic are little better than curioſities, eſpecially with regard to practice; as all numbers are much more compendiouſly and conveniently expreſſed by the common decuple ſcale.

Univerſal Arithmetic, is the name given by Newton to the ſcience of algebra; of which he left at Cambridge an excellenc treatiſe, being the text-book drawn up for the uſe of his lectures, while he was profeſſor of mathematics in that univerſity.

ARITHMETICAL complement, of a logarithm, is what the logarithm wants of 10·00000, &c. and the eaſieſt way to find it is, beginning at the left hand, to ſubtract every figure from 9, and the laſt from 10.

ARTEDI (John), was born in the year 1705, in the province of Angermania, in Sweden. From nature he inherited an ardent paſſion for all branches of natural hiſtory, but he excelled moſt in that branch of it which is termed *itchthyology*. In 1724 he went to ſtudy at the univerſity of Upſal, where ſome years afterwards he gained the friendſhip of the immortal Linnæus, who narrates the principal events of his life in the following animated terms.

"In 1728 (ſays Linnæus) I came from Lund to Upſal. I wiſhed to devote myſelf to medicine. I inquired who, at that univerſity, excelled moſt for his knowledge: every one named Artedi. I was impatient to ſee him. I found him pale, and in great diſtreſs for the loſs of his father, with his thin hair neglected. He reſembled the portrait of Ray the naturaliſt. His judgment was ripe, his thoughts profound, his manners ſimple, his virtues antique. The converſation turned upon ſtones, plants, animals. I was enchanted with his obſervations, equally ingenious and new; for at the very firſt he was not afraid to communicate them to me with the utmoſt frankneſs. I deſired his friendſhip, he aſked mine. From that moment we formed a friendſhip; which we cultivated with the greateſt ardour for ſeven months at Upſal. I was his beſt friend, and I never had any who was more dear to me. How ſweet was that intimacy! With what pleaſure did we ſee it increaſe from day to day! The difference, even of our characters, was uſeful to us. His mind was more ſevere, more attentive; he obſerved more ſlowly, and with greater care. A noble emulation animated us. As I deſpaired of ever becoming as well inſtructed in chemiſtry as he, I abandoned it; he alſo ceaſed to ſtudy botany with the ſame ardour, to which I had devoted myſelf in a particular manner. We continued thus to ſtudy different branches of ſcience; and when one of us excelled the other, he acknowledged him for his maſter. We diſputed the palm in ichthyology; but ſoon I was forced to yield, and I abandoned that part of natural hiſtory to him, as well as the amphibia. I ſucceeded better than he in the knowledge of birds and inſects, and he no longer tried to excel in theſe branches. We marched together as equals in lithology, and the hiſtory of quadrupeds. When one of us made an obſervation, he communicated it to the other: ſcarce a day paſſed in which one did not learn from the other ſome new and intereſting particular. Thus emulation excited our induſtry, and mutual aſſiſtance aided our efforts. In ſpite of the diſtance of our lodgings, we ſaw each other every day. At laſt I ſet out for Lapland; he went to London. He bequeathed to me his manuſcripts and his books.

"In 1735 I went to Leyden, where I found Artedi. I recounted my adventures; he communicated his to me. He was not rich, and therefore was unable to be at the expence of taking his degrees in phyſic. I recommended him to Seba, who engaged him to publiſh his work on fiſhes. Artedi went to join him at Amſterdam.

"Scarcely had I finiſhed my *Fundamenta Botanica*. I communicated it to him; he let me ſee his *Philoſophia Ichthyologica* He propoſed to finiſh as quickly as poſſible the work of Seba, and to put the laſt hand to it. He ſhowed me all his manuſcripts which I had not ſeen. I was preſſed in point of time, and began to be impatient as being detained ſo long. Alas! if I had known this was the laſt time I ſhould ſee him, how ſhould I have prolonged it!

"Some days after, as he returned to ſup with Seba, the night being dark, he fell into the canal. Nobody perceived it, and he periſhed. Thus died, by water, this great ichthyologiſt, who had ever delighted in that element."

Of the works of this eminent naturaliſt there have been two editions, of which the former was publiſhed by Linnæus in 1738, and the latter by Dr Walbaum of Lubeck, in the years 1788, 1789, and 1792. This edition, which is by much the moſt valuable, is in three volumes 4to; of which the firſt contains the hiſtory of the ſcience of ichthyology, commencing ſeveral years before the Chriſtian era, and coming down to the preſent times. The ſecond preſents to the reader the *Philoſophia Ichthyologica* of Artedi, improved by Walbaum, who was benefited by the writings of Monro, Camper, Kætſeuter, and others. Here alſo are added tables containing the ſyſtem of fiſhes by Ray, Dale, Schaeffir, Linnæus, Gowan, Scopola, Klein, and Gronovius. The third volume, which completes the collection of Artedi's works, contains the technical definitions of the ſcience. After the generic and individual characters come the names and Latin phraſes of Artedi; the ſynonymes of the beſt naturaliſts; the vulgar names in Engliſh, German, Swediſh, Ruſſian, Daniſh, Norwegian, Dutch, and Samoyed; the ſeaſon and the countries where every kind is found, their varieties, their deſcription, and obſervations. The modern diſcoveries, even to our own times, are added; ſo that in this part is collected the obſervations of Gronovius, Brunich, Penant, Forſter, Klein, Bloch, Gmelin, Haſſelquiſt, Brouſſonet, Leſke, Buiſh, Linnæus, and other great examiners of nature.

ASTRONOMY

IS a ſcience which has been cultivated from the earlieſt ages, and is converſant about the moſt ſublime objects of inquiry which can employ the mind of man. It has accordingly been treated at great length in the Encyclopædia Britannica; but, in the opinion of ſome of the moſt judicious readers of that work, the compiler of the ſyſtem which is there delivered has failed in his attempt to give a perſpicuous and connected view of the ſcience in its preſent ſtate of improvement. This defect it is our duty to remedy. Our object, therefore, in this ſupplementary article, will be to bring into one point of view the phyſical ſcience which may be derived from the conſideration of the celeſtial motions; that is, to deduce from the general laws of thoſe motions the inferences with reſpect to their ſuppoſed cauſes, which conſtitute the philoſophy of the aſtronomer.

1
Object of this article.

The cauſes of all phenomena are not only inferred from the phenomena, but are characteriſed by them; and we can form no notion of their nature but what we conceive as competent to the phenomena themſelves. The aſtronomical phenomena are aſſumed to be the motions of the *bodies*, which we call the *ſun*, the *planets*, the *comets*, &c. The notion which we expreſs by the word *body* in the preſent caſe, is ſuppoſed to be the ſame with that which we form of other objects around us, to which we give the ſame name; ſuch as ſtones, ſticks, the bodies of animals, &c. Therefore the notion which we have of the cauſes of the celeſtial motions muſt be the ſame with that which we have of the cauſes of motion in thoſe more familiar bodies. All men ſeem to have agreed in giving the name FORCES, or MOVING FORCES, to the cauſes of thoſe familiar motions. This is a figurative or metaphorical term. The true and original meaning of it is, the exertion which we are conſcious of making when we ourſelves put other bodies in motion. Force, when uſed without figure, always ſignifies the exertion of a living and acting thing. We are more intereſted in thoſe productions of motion than in any other, and our recollections of them are more numerous. Hence it has happened that we uſe the ſame term to expreſs the cauſe of bodily motion in general, and ſay that a magnet has force, that a ſpring has force, that a moving body has force.

2
Metaphorical uſe of the term *force*.

Our own force is always exerted by the intervention of our own body; and we find that the ſame exertion by which we move a ſtone, enables us to move another man; therefore we conceive his body to reſemble a ſtone in this reſpect, and that it alſo requires the exertion of force to put it in motion. But when we reflect on our employment of force for producing motion in a body, we find ourſelves puzzled how to account for the motion of our own bodies. Here we perceive no intervening exertion but that of willing to do it; yet we find that we cannot move it as we pleaſe. We alſo find that a greater motion requires a greater exertion. It is therefore to this exertion that the reflecting man reſtrains the term *force*; and he acknowledges that every other uſe of it is metaphorical, and that it is a reſemblance

blance in the ultimate effect alone which diſpoſes us to employ the term in ſuch caſes: but we find no great inconvenience in the want of another term.

We farther find, that our exertion is neceſſary, not only for producing motion where there was none before, but alſo for producing any change of motion; and accurate obſervation ſhews us, that the ſame force is required for changing a motion by any given quantity, as for producing that quantity where there was none before.

Laſtly, we are conſcious of exerting force when we reſiſt the exerted force of another; and that an exertion, perfectly ſimilar to this, will prevent ſome very familiar tendencies to motion in the bodies around us: thus an exertion is neceſſary for carrying a weight, that is, for preventing the fall of that weight.

All theſe reſemblances between the effects of our forcible exertions and the changes of motion which accompany the meeting, and ſometimes the mere vicinity of other bodies, juſtify us in the uſe of this figurative language. The reſemblance is found to be the more perfect as we obſerve it with more care, and, in ſhort, appears to be without exception. Bodies are therefore ſaid to *act* on each other, to *reſiſt* each other, to *reſiſt a change of motion*, &c.

Therefore, wherever we obſerve a change of motion, we infer the exiſtence and exertion of a changing force; and we infer the direction of that exertion from the direction of the change; and the quantity of the exertion, or intenſity of the force, from the quantity of the change.

The ſtudy of the cauſes of the celeſtial motions is therefore hardly different from the ſtudy of the motions themſelves; ſince the agency, the kind, and the degree of the moving force, are immediate inferences from the exiſtence, the kind, and the quantity of the change of motion.

3
Our notion of a moving power.

Our notion of a moving power is that of a power which produces motion, that is, a ſucceſſive change of place. Continuation of the motion produced is therefore involved in the very notion of the production of motion; therefore the continued agency of the moving power, or of any power, is not neceſſary for the continuation of the motion. Motion is conſidered as a ſtate or condition of the body; there is not any exertion of power therefore in the continuation of motion: But every change is indicative of a changing cauſe; and when the change is the ſame, in all its circumſtances, the cauſe is neceſſarily conceived to be the ſame, or equal.

4
Meaſure of moving forces.

The condition of a body, in reſpect of motion, can differ from that of another equal body only in its direction and in its velocity. If the directions are the ſame, the difference of conditions can only be in the difference of velocity. One body has a determination, by which it would deſcribe ten feet uniformly in a ſecond, if nothing changed this determination; the other has a determination, by which it would deſcribe twenty feet in a ſecond. Each of theſe determinations are ſuppoſed to be the effects of forces acting ſimilarly in every reſpect. Therefore theſe determinations are the only meaſures of theſe two forces; that is, moving forces are conceived by us as having the proportion of the velocities which they produce in a body by acting in a manner perfectly ſimilar.

5
Accelerated motion the mark of unvaried action;

We can conceive a force acting equally or unequally. If we ſuppoſe it to act equally or uniformly, we ſuppoſe that in equal times it produces equal effects; that is, equal determinations, or equal changes of determination. We have no other notion of equality or uniformity of action. Therefore it muſt produce equal augmentations or diminutions of velocity in equal times; therefore it muſt produce an *uniformly* accelerated or retarded motion. Uniformly accelerated or retarded motion is, therefore, the mark of uniform or unvaried action. In ſuch a motion, the changes of velocity are proportional to the times from the beginning of the action; and if the motion has begun from reſt, the whole acquired velocities are proportional to the times from the beginning of the motion. In this caſe, the ſpaces deſcribed are as the ſquares of the times from the beginning of the motion; and thus we arrive at an oſtenſible mark of the unvaried action of a moving force, viz. ſpaces increaſing in the duplicate ratio of the times: for ſpace and time are all that we can immediately obſerve in any motion that is continually varying; the velocity or determination is only an inference, on the ſuppoſition that the motion continues unchanged for ſome time, or that all action ceaſes for ſome time.

This abſtract reaſoning is perfectly agreeable to every phenomenon that we can obſerve with diſtinctneſs. Thus we cannot, or at leaſt we do not, conceive the weight of a body to vary its action during the fall. We conſider this weight as the cauſe of the fall—as the moving force—and we conceive it to act uniformly. And, in fact, a body falling freely, deſcribes ſpaces which are proportional, not to the times, but to the ſquares of the times, and the fall is a motion uniformly accelerated. In like manner, the motion of a body riſing in the air, in oppoſition to gravity, is uniformly retarded.

6
And gives a meaſure of the acquired velocity.

This kind of motion alſo gives us a certain meaſure of the acquired velocity, although there is not, in fact, any ſpace obſerved to be uniformly deſcribed during any time whatever. In this motion we know that the final determination, produced by the accumulated or continued action of the unvaried force, is ſuch that the body would deſcribe uniformly twice the ſpace which it has deſcribed with the accelerated motion.

And it is by this method that we obtain the ſimpleſt meaſure of any moving force, and can compare it with another. If we obſerve that by the action of one force (known to be uniform by the ſpaces being proportional to the ſquares of the times) ten feet have been deſcribed in a ſecond, and that by the uniform action of another force eighty feet are deſcribed in two ſeconds, we know that the laſt force is double of the firſt: for in the ſecond motion, 80 feet were deſcribed in two ſeconds, and therefore 20 feet of this were deſcribed in the firſt ſecond (becauſe the motion is uniformly accelerated; and at the end of a ſecond, the firſt body had a determination by which it would deſcribe 20 feet uniformly in a ſecond; and the ſecond body had acquired a determination by which it would have deſcribed 40 feet uniformly in the next ſecond, had not the moving force continued to act on it, and made it really deſcribe 60 feet with an accelerated motion.

Becauſe halves have the ſame proportions with the units of which they are the halves, it is plain that we may take the ſpaces, deſcribed in equal times with motions uniformly accelerated, as meaſures of the forces which have produced thoſe motions. The velocities generated are, however, the beſt meaſures.

7
Meaſure of the velocity produced by action not uniform.

When the actions of forces are not uniform, it is more difficult to learn what is the meaſure of the velocity produced by their accumulated action. But it can be determined with equal accuracy; that is, we can determine what is the velocity which *would have been produced* by the uniform action of the force during the ſame time, and therefore we obtain a meaſure of the force. Mathematicians are farther able to demonſtrate, that if forces vary their continued action in any manner whatever, the proportion of the ſpaces deſcribed by two bodies in equal times approaches nearer and nearer to the proportion of the ſpaces which they would deſcribe in thoſe times by the uniform action of the forces, as the times themſelves are ſmaller; and therefore whenever we can point out the ultimate ratio of the ſpaces deſcribed in equal times, theſe times being diminiſhed without end, we obtain the ratio of the forces.

Plate VI.

Motions may be changed, not only in quantity, by acceleration or retardation, but alſo in direction, by deflecting a body from its former direction. When a body, moving uniformly in the direction AB (fig. 1.), has its motion changed in the point B, and, inſtead of deſcribing BC uniformly in the next moment with the former velocity, deſcribes BD uniformly in that moment, it is plain that the motion BD will be the ſame, whether the body had begun to move in A, or in F, or in G, or in B, provided only that its determination to move, or its velocity, be the ſame in all thoſe points. Complete the parallelogram BCDE. It is well known, that if one force act on the body which would make it deſcribe BC, and another which would make it deſcribe BE, the body will deſcribe BD. Hence we learn, that when a body has the motion BC changed into the motion BD, it has been acted on in the point B by a force which would have cauſed a body at reſt in B to deſcribe BE. Thus we can diſcover the intenſity and direction of the tranſverſe force which produces any deflection from the former direction. In general, the force is that which would have produced in a body at reſt that motion BE, which, when compounded with the former motion BC, produces the new motion BD.

8
Intenſity and direction of deflecting forces.

Theſe two principles, viz. 1ſt, that forces are proportional to the velocities which they produce in the ſame circumſtances, and, 2d, the compoſition of motion or forces, will ſerve for all the phyſical inveſtigations in aſtronomy. All the celeſtial motions are curvilineal, and therefore are inſtances of continual deflection, and of the continual action of tranſverſe or deflecting forces. We muſt therefore endeavour to obtain a general meaſure of ſuch continual deflecting forces.

9
Meaſure of theſe forces obtained.

Let two bodies A and a (fig. 2.) deſcribe in the ſame time the arches AC, $a\,c$ of two circles. They are deflected from the tangents AB, $a\,b$. Let us ſuppoſe that the direction of the deflecting forces is known to be that of the chords AE, $a\,e$ of theſe circles. Let theſe be called the DEFLECTIVE CHORDS. Draw CB, $c\,b$ parallel to AE, $a\,e$, and CD, $c\,d$ parallel to AB, $a\,b$. Join AC, $a\,c$, CE, and $c\,e$. It is plain that the angle BAC is equal to the angle CEA in the alternate ſegment. Therefore ACD is alſo equal to it; and, becauſe the angle CAD is common to the two triangles CAD and EAC, theſe two triangles are ſimilar, and $\mathrm{AD} : \mathrm{AC} = \mathrm{AC} : \mathrm{AE}$, and $\mathrm{AD} = \frac{\mathrm{AC}^2}{\mathrm{AE}}$. For ſimilar reaſons $a\,d = \frac{a\,c^2}{a\,e}$. But AD and $a\,d$ are reſpectively equal to BC and $b\,c$. Therefore $\mathrm{BC} = \frac{\mathrm{AC}^2}{\mathrm{AE}}$, and $b\,c = \frac{a\,c^2}{a\,e}$. Therefore $\mathrm{BC} : b\,c = \frac{\mathrm{AC}^2}{\mathrm{AE}} : \frac{a\,c^2}{a\,e}$, or $\mathrm{BC} : b\,c = \mathrm{AC}^2 \times a\,e : a\,c^2 \times \mathrm{AE}$. But BC and $b\,c$ being reſpectively equal to AD and $a\,d$, are equal to the ſpaces through which the deflecting forces would have impelled the bodies from a ſtate of reſt in the time of deſcribing the arches AC, $a\,c$. Therefore, when theſe times are diminiſhed without end, the *ultimate* ratio of AD and $a\,d$ is the ratio of the forces which deflect the bodies in the points A and a. But it is evident that the ultimate ratio of AC to $a\,c$ is the ratio of the velocity in the point A to the velocity in the point a; becauſe theſe arches are ſuppoſed to be deſcribed in the ſame or equal times. Therefore the deflecting forces, by which bodies are made to deſcribe arches of circles, are to each other as the ſquares of the velocities directly, and as the deflective cords of thoſe circles inverſely. This ratio may be expreſſed ſymbolically thus, $\mathrm{F} : f = \frac{\mathrm{V}^2}{\mathrm{C}} : \frac{v^2}{c}$; or thus, in a proportional equation, $f \doteqdot \frac{v^2}{c}$.

It is eaſy to ſee that in this laſt formula f expreſſes directly the line $b\,c$, or the ſpace through which the body is actually made to deviate from rectilineal motion in the time of deſcribing the arch $a\,c$. It is a third proportional to $a\,e$ the deflective chord, and $a\,c$ the arch of the circumference deſcribed in a ſmall moment of time. This is the meaſure afforded immediately by obſervation. We have obſerved the arch AC that is deſcribed, and know the direction and the length of AE from ſome circumſtances of the caſe. The formula which comes to us, when treating this queſtion by the help of fluxions, is $f = \frac{2\,v^2}{c}$. This is perhaps a more proper expreſſion of the phyſical fact; for it expreſſes twice the line $b\,c$, or the meaſure of the velocity which the deflecting force would have generated in the body by acting on it during the time of its deſcribing the arch $a\,c$. But it is indifferent which meaſure we take, provided we always take the ſame meaſure. The firſt mathematicians, however, have committed miſtakes by mixing them.

The planets, however, do not deſcribe circles: but all the curves which can be deſcribed by the action of finite deflecting forces are of ſuch a nature, that we can deſcribe a circle through any point, having the ſame tangent, and the ſame curvature which the planetary curve has in that point, and which therefore ultimately coaleſces with it. This being the caſe, it is plain that the planet, while paſſing through a point of the curve, and deſcribing an indefinitely ſmall arch of it, is in the ſame condition as if deſcribing the coincident arch of the equicurve circle. Hence we obtain this moſt general propoſition, that *the tranſverſe force by which a planet is made to deſcribe any curve, is directly as the ſquare of its velocity, and inverſely as the deflective chord of the equicurve circle.*

Farther: The velocity of a body in any point A (fig.

(*fig.* 2.) of the curve, is equal to that which the deflective force in that point would generate in the body by acting uniformly on it along AF, one-fourth part of the deflective cord AE of the equicurve circle. It is the ſame which the body would acquire at F, after a uniformly accelerated motion along AF.

For it is certain that there is ſome length AF, ſuch that the velocity acquired at F is the ſame with the velocity in the point A of the curve. Draw FG parallel to the tangent, and join AG. Make the arch ACI = 2AF. Then, becauſe the ſpace deſcribed with a uniformly accelerated motion is one half of the ſpace which would be uniformly deſcribed with the final velocity, the arch ACI would be uniformly deſcribed with the velocity which the body has at A in the time that AF is deſcribed with the uniformly accelerated motion; and the arch AB will be to the arch AI as the time of deſcribing AB to that of deſcribing AI; that is, as the time of falling through AD to that of falling through AF. But the motion along AF being uniformly accelerated, the ſpaces are as the ſquares of the times. Therefore AD is to AF as the ſquare of the arch AC to the ſquare of the arch AI. But AD is to AF as the ſquare of the chord AC is to the ſquare of the chord AG. Therefore the arch AC is to the chord AC as the arch AI is to the chord AG. But the arch and chord AC are ultimately in the ratio of equality. Therefore the chord AG is equal to the arch AI. Therefore AG is double of AF. But becauſe the triangles FAG and GAE are ſimilar, AF is to AG as AG to AE; and therefore AE is double of AG and quadruple of AF. Therefore the velocity at A in the curve is that which would be produced by the uniform impulſe of the deflecting force along the fourth part of the deflective chord of the equicurve circle.

10
Two uſeful affections of curvilineal motions.

Theſe two affections or properties of curvilineal motions are of the moſt extenſive uſe, and give an eaſier ſolution of moſt queſtions than we obtain by the more uſual methods, and deſerve to be kept in remembrance by ſuch as engage much in the diſcuſſion of queſtions of this kind.

Thus the inveſtigation of the forces which regulate the planetary motions is reduced to the taſk of diſcovering the velocity of the planet in the different points of its orbit, and the curvature in thoſe points, and the poſition of the deflective chords.

11
Phyſical ſcience of aſtronomy

The phyſical ſcience of aſtronomy muſt conſiſt in the diſcovery of the general laws which can be affirmed with reſpect to the exertion of thoſe forces, whether with reſpect to their direction or the intenſity of their action. If the mechanician can do more than this, and ſhow that every motion that is obſerved is an immediate or remote conſequence of thoſe general laws, he will have completed the ſcience, and explained every appearance.

12
Completed by Newton and

13
His followers.

This has accordingly been done by Sir Iſaac Newton and his followers. Sir Iſaac Newton has diſcovered the general laws which regulate the exertions of thoſe forces which produce the planetary motions, by reaſoning from general phenomena which had been obſerved with a certain preciſion before his time; and has alſo ſhown that certain conſiderable deviations from the generality which he ſuppoſed to be perfect were neceſſary conſequences of the very univerſality of the phyſical law, although the phenomenon was not ſo general as was at firſt imagined. He has gone farther, and has pointed out ſome other minute deviations which muſt reſult from the phyſical law, but which the art of obſervation was not then ſufficiently advanced to diſcover in the phenomena. This excited the efforts of men of ſcience to improve the art of aſtronomical obſervation; and not only have the intimations of Newton been verified by modern obſervation, but other deviations have been diſcovered, and, in proceſs of time, have alſo been ſhown to be conſequences of the ſame general law of agency: And, at this preſent day, there is not a ſingle anomaly of the planetary motions which has not been ſhown to be a modification of one general law which regulates the action; and therefore characteriſes the nature of that ſingle force which actuates the whole ſyſtem of the ſun, and his attending planets and comets.

It was a moſt fortunate circumſtance that the conſtitution of the ſolar ſyſtem was ſuch that the deviations from the general law are not very conſiderable. The caſe might have been far otherwiſe, although the law, or nature of the planetary force, were the ſame, and the ſyſtem had been equally harmonious and beautiful. Had two or three of the planets been vaſtly larger than they are, it would have been extremely difficult to diſcover any laws of their motion ſufficiently general to have led to the ſuſpicion or the diſcovery of the univerſal law of action, or the ſpecific circumſtance in the planetary force which diſtinguiſhes it from all others, and characteriſes its nature. But the three laws of the planetary motions diſcovered by Kepler were ſo nearly true, at leaſt with reſpect to the primary planets, that the deviations could not be obſerved, and they were thought to be exact. It was on the ſuppoſition *that they were exact*, that Newton affirmed that they were only modifications of one law ſtill more general, nay univerſal.

We ſhall follow in order the ſteps of this inveſtigation.

14
The ſteps by which they proceeded.

Sir Iſaac Newton took it for granted, that the ſun and planets conſiſted of matter which reſembled thoſe bodies which we daily handle, at leaſt in reſpect of their mobility; and that the forces which agitate them, conſidered merely as moving forces, but without conſidering or attending to their mode of operation, were to be inferred, both as to their direction and as to their intenſity, from the changes of motion which were aſcribed to their agency. He firſt endeavoured to diſcover the *direction* of that tranſverſe force by which the planets are made to diſcover curve lines. Kepler's firſt law furniſhed him with ample means for this diſcovery. Kepler had diſcovered, that *the right line joining the ſun and any planet deſcribed areas proportional to the times.* Newton demonſtrated, that if a body was ſo carried round a fixed point ſituated in the plane of its motion, that the right line joining it with that point deſcribed areas proportional to the times, the force which deflected it from an uniform rectilineal motion was continually directed to that fixed point. This makes the 2d propoſition of his immortal work *The Mathematical Principles of Natural Philoſophy*, and it is given in the article ASTRONOMY of the Encyclopædia Britannica, § 260.

Hence Sir Iſaac Newton inferred, that the primary planets were retained in their orbits by a force continually directed to the ſun; and, becauſe Kepler's law of motion was alſo obſerved by the ſecondary planets in their revolutions round their reſpective primary planets, this inference was extended to them.

15 Centripetal forces.

From the circumſtance that the planetary deflecting forces in the different points of the orbit are always directed toward one point as to a centre, they have been called CENTRIPETAL FORCES.

16 Velocity of a planet in the different points of its orbit.

From this propoſition may be deduced a corollary which eſtabliſhes a general law of the motion of any planet in the different parts of its orbit, namely, that the velocity which a planet has in the different points of its path are inverſely proportional to the perpendiculars drawn from the ſun on the tangents to the orbit in thoſe points reſpectively. For, let AB, $a\,b$ (fig. 3.) be two arches (extremely ſmall), deſcribed in equal times, theſe arches muſt be ultimately proportional to the velocities with which they are deſcribed. Let SP, S p be perpendicular to the tangents AP, $a\,p$. The triangles ASB, a S b are equal, becauſe equal areas are deſcribed by the *radii vectores* SA, S a, in equal times: but in equal triangles, the haſes AB, $a\,b$, are reciprocally as their heights SP, S p, or $AB : a\,b = S\,p : SP$.

This corollary gives us another expreſſion of the ratio of the centripetal forces in different points A and a of a curve. We ſaw by a former propoſition, that the force at A (fig. 2.) is to the force at a as $AC^2 \times a\,e$ to $a\,c^2 \times AE$, which we may expreſs thus: $F : f = V^2 \times c : v^2 \times C$. If we expreſs the perpendiculars SP, S p (in fig. 3.) by the ſymbols P, p, we have $V^2 : v^2 = p^2 : P^2$, and therefore $F : f = p^2 \times c : P^2 \times C$. *The centripetal forces in different points of an orbit are in the ratio compounded of the inverſe duplicate ratio of the perpendiculars drawn to the tangents in thoſe points from the centre of forces, and the inverſe ratio of the deflective chords of the equicurve circles.*

17 Law of action of the centripetal force,

We are now in a condition to determine the law of action of the centripetal force by which a planet is retained in its orbit round the ſun, or the relation which ſubſiſts between the intenſity of its action and the diſtance of the planet from the ſun: for we know the elliptical figure of the orbit, and we can draw a tangent to it in any point, and a perpendicular from the ſun to that tangent.

Kepler's ſecond law or obſervation of the planetary motions was, that *each primary planet deſcribed an ellipſe, having the ſun in one focus.* It is eaſy to ſhow, even without any knowledge of the geometrical properties of the ellipſe, what is the proportion of the intenſities of the deflecting force at the aphelion and perihelion (ſee fig. 4.) At thoſe two points of the orbit, the motion of the planet is at right angles to the line joining it with the ſun. Therefore, ſince the areas deſcribed in equal times are equal, the arches deſcribed in equal times muſt be inverſely at the diſtances from the ſun; or the velocities muſt be inverſely as the diſtances from the ſun. But the curvature in the aphelion and perihelion is the ſame; and therefore the diameters of the equicurve circles in thoſe points are equal. But thoſe diameters are, in this particular caſe, what we called the deflective chords. Therefore, calling the aphelion and perihelion diſtances D and d, the velocities in the aphelion and perihelion V and v, let the common deflective chord be C. Then we have $F : f = V^2 \times C : v^2 \times C, = V^2 : v^2, = d^2 : D^2$. That is, the forces which deflect the planet in the aphelion and perihelion are inverſely as the ſquares of the diſtances from the ſun. A perſon almoſt ignorant of mathematics may ſee the truth of this by looking into a table of natural verſed ſines. He will obſerve, that the verſed ſine of one degree is quadruple the verſed ſine of half a degree, and ſixteen times the verſed ſine of a quarter of a degree; in ſhort, that the verſed ſines of ſmall arches are in the proportion of the ſquares of the arches. Now ſince the arches deſcribed in equal times are inverſely as the diſtances, their verſed ſines are inverſely as the ſquares of the diſtances. But theſe verſed ſines are the ſpaces through which the centripetal forces at the aphelion and perihelion deflect the planet from the tangent. Therefore, &c.

Thus we have found, that in the aphelion and perihelion the centripetal force acts with an intenſity that is proportional to the ſquares of the diſtances inverſely. As theſe are the extreme ſituations of a planet, and as the proportion of the aphelion and perihelion diſtances are conſiderably different in the different planets, and yet this law of action is obſerved in them all, it is reaſonable to imagine that it holds true, not in thoſe ſituations only, but in every intermediate ſituation. But a conjecture, however probable, is not ſufficient, when we aim at accurate ſcience, and it is neceſſary to examine whether this law of action is really obſerved in every point of the elliptical orbit.

18 Demonſtrated with reſpect to the earth,

For this purpoſe it is neceſſary to mention ſome geometrical properties of the ellipſe. Therefore let ADBE (fig. 4.) be the elliptical orbit of a planet or comet, having the ſun in the focus S. Let AB be the tranſverſe axis, and DE the conjugate axis, and C the centre. Let P be any point of the ellipſe. Draw PS through the focus. Draw the tangent PN, and SN from the focus, perpendicular to PN. Draw PQ perpendicular to PN, meeting the tranſverſe axis in Q. Draw QO parallel to PN, meeting PS in O. Alſo draw QR perpendicular to PS. Biſect PO in T.

It is demonſtrated in the treatiſes of conic ſections, that PO is one half of the chord of the equicurve or oſculating circle drawn through the point P. Therefore PO is one half of the deflective chord of the planetary orbit. It is alſo demonſtrated, that PR is one half of the parameter or *latus rectum* of the tranſverſe axis AB, or that it is the third proportional to AC and DC. Therefore PR or D r is of the ſame conſtant magnitude, in whatever part of the circumference the point P is taken.

It is evident that the triangles NSP, RPQ, and QPO, are all ſimilar, by reaſon of the parallels PN, QO, and the right angles SNP, PRQ, PQO. Therefore we have $PR : PQ = PQ : PO$. Therefore $PR : PO = PR^2 : PQ^2, = SN^2 : SP^2$. Therefore $PR \times SP^2 = PO \times SN^2$. But the *latus rectum* L is equal to twice PR, and the deflective chord C is equal to twice PO. Therefore $L \times SP^2 = C \times SN^2$. But we have ſeen, that when a curve is deſcribed by means of a centripetal force, ſo that areas are deſcribed proportional to the times, and therefore the velocities are reciprocally proportional to the perpendiculars drawn from the centre of forces to the tangents, the forces are inverſely proportional to $C \times SN^2$. Therefore, in the elliptical motion of the planets, the forces are inverſely proportional to $L \times SP^2$; and ſince L is a conſtant quantity, the centripetal forces are inverſely proportional to SP^2, or to the ſquares of the diſtances from the ſun.

Thus

19
Obſerved in the motion of the moon &c.

Thus it appears that, with reſpect to any individual planet, the centripetal force which continually deflects it from the tangent to its orbit diminiſhes in the inverſe duplicate ratio of the diſtance from the ſun. The ſame thing is obſerved to be very nearly true in the moon's motion round the earth, and in the motion of ſuch ſatellites of Jupiter and Saturn as deſcribe orbits which are ſenſibly elliptical. It is alſo obſerved in the motion of the comets, at leaſt in that which appeared in 1682 and in 1759.

It was therefore very natural for Sir Iſaac Newton to examine whether the like diminution of force obtained in the action of this force on different planets; that is, whether the deflection of the earth from the tangent of its orbit was to the ſimultaneous deflection of Jupiter as the ſquare of Jupiter's diſtance from the ſun to the ſquare of the earth's diſtance. This was very probable, but by no means certain. Its probability is very great indeed, when we know that a comet moves ſo in its orbit that its deflections in equal times are inverſely as the ſquares of its diſtances from the ſun, and that the comet paſſes through the orbits of all the planets; and when at the ſame diſtance from the ſun as any one of them, it ſuffers the ſame deflection with it. Newton therefore calculated the actual ſimultaneous deflections of the different planets, and found them agreeable to this law. But it was deſirable to obtain a demonſtration of this important propoſition in general terms. This was ſupplied by Kepler's third general obſervation of the motions, viz. that *the ſquares of the periodic times of the different planets were proportional to the cubes of their mean diſtances from the ſun.* The orbits of the planets are ſo nearly circular, that we may ſuppoſe them exactly ſo in the preſent queſtion, without any remarkable error. In this caſe, then, the deflective chords are the diameters of the orbits (for DS is equal to AC), and are proportional to the diſtances, which are their halves. The centripetal forces, being proportional to $\frac{v^2}{c}$, are proportional to $\frac{v^2}{d}$, when d is the radius of the orbit, or the mean diſtance from the ſun. But the velocity in a circular orbit is as the circumference directly, and as the time of a revolution inverſely. Therefore, inſtead of v^2, we may write $\frac{d^2}{t^2}$, and then the forces will be proportional to $\frac{d^2}{t^2 d}$, or to $\frac{d}{t^2}$; that is, directly as the diſtances, and inverſely as the ſquares of the times of revolution. But, by Kepler's obſervation, t^2 is proportional to d^3. Therefore the centripetal forces are proportional to $\frac{d}{d^3}$, or to $\frac{1}{d^2}$; that is, inverſely as the ſquares of the mean diſtances from the ſun.

20
And demonſtrated in general terms.

But ſince the orbits of the planets are not accurate circles, this determination is but an approximation to the truth, and therefore inſufficient for the foundation of ſo important a propoſition; at any rate, it will not apply to the comets, whoſe orbits are very far from being circular. We muſt obtain a more accurate demonſtration.

Therefore draw SD (fig. 4.) to the extremity of the conjugate axis, and biſect it in t. About S, with the radius SD, deſcribe the circle DFG. Let D d, D δ be equal ſmall arches of the ellipſe and the circle. Join d S, δ S. It is well known that DS is half of the chord of the equicurve circle at D, and therefore D t is one fourth part of it. It has been demonſtrated, that the velocity in any point D of a curve, deſcribed by means of a deflecting force, is that which the force in that point would communicate to it by uniformly impelling it along the fourth part of the deflective chord, that is, along D t. But if a body revolved round S in a circle DFG, its velocity in that circle would be that which the deflecting force would communicate to it by uniformly impelling it along one-fourth of the diameter, that is, along D t. Therefore the planet, if projected in the direction D δ, with the velocity which it has in the point D of the ellipſe, would deſcribe the circle DFG by the action of the centripetal force. Farther, it would deſcribe it in the ſame time that it deſcribes the ellipſe; for becauſe the velocities are equal, the areas DS d, DS δ are deſcibed in the ſame time. But the baſes D d, D δ being equal, theſe areas are as their heights S n (or CD), and SD (or CA). But becauſe the diameter of the circle is equal to AB, the area of the whole ellipſe is to the area of the circle as CD is to CA; that is, as the area DS d to the area DS δ deſcribed in the ſame time. Therefore the elliptical and circular areas are ſimilar portions of the ellipſe and circle; and therefore the times of deſcribing them are ſimilar portions of the whole revolutions in the ellipſe and in the circle. Therefore theſe revolutions are performed in equal times.

And thus it follows, that if all the planets and comets were projected, when at their mean diſtances from the ſun, perpendicularly to the *radii vectores*, they would deſcribe circles round the ſun, and the ſquares of their periodic times would be proportional to the cubes of their mean diſtances from the ſun, as Kepler has obſerved; and therefore the centripetal forces would be inverſely as the ſquares of their diſtances from the ſun.

21
All the planets retained in their reſpective orbits by one and the ſame force.

They are not different forces therefore which retain the different planets in their reſpective orbits, but one force, acting by the ſame law upon them all. We may either conceive it as an attractive force, exerted by the ſun, or as a tendency in each planet; nay, nothing hinders us from conceiving it as a force external, both to ſun and planets, impelling them towards the ſun. It may be the impulſe of a ſtream of fluid moving continually towards the ſun. Sir Iſaac Newton did not concern himſelf with this queſtion, but contented himſelf with the diſcovery of the law according to which its action was exerted. The ſteps of this inveſtigation ſhewed him, that a body, projected in any direction whatever, and with any velocity whatever, and ſubjected to the action of a force directed to the ſun, and inverſely proportional to the ſquare of the diſtance from the ſun, will neceſſarily deſcribe a conic ſection, having the ſun in the focus. This will be a parabola, if the velocity of projection be that which the centripetal force in that place would communicate to the body by acting on it uniformly along a line equal to half its diſtance from the ſun. If the velocity be greater than this, the path will be a hyperbola; if the velocity be leſs than this, the path will be an elliptical orbit, in which the body will revolve for ever round the ſun.

The 3d Keplerean law is alſo obſerved in the revolutions of the ſatellites of Jupiter, Saturn, and the lately diſcovered planet; and we muſt infer from it, that they are retained in their orbits round their reſpective primary planets, by forces whoſe intenſity decreaſes according to the ſame law of the diſtances. Alſo the elliptical motion of the moon round the earth, ſhews that the force by which ſhe is retained in her orbit varies in the ſame proportion of the diſtances. But when we compare the motion of a ſatellite of Jupiter with that of one of the ſatellites of the other two planets, we find that the proportion does not hold. We ſhall find that, at equal diſtances from Jupiter and Saturn, the force toward Jupiter is almoſt thrice as great as the force toward Saturn. We ſhall alſo find that the force toward Jupiter is three hundred times greater than the force which retains the moon in its elliptical orbit round the earth, when acting at the ſame diſtance.

Since a force directed to the ſun, and inverſely as the ſquare of the diſtance, is thus found to pervade all the planetary orbits, it is highly improbable that it will not affect the ſecondary planets alſo. The moon accompanies the earth in its motion round the ſun. It may appear ſufficient for this purpoſe, that the moon be retained in its orbit by a force directed to the earth. Were the moon connected with the earth by a rope or chain, this would be true; for the earth could get no motion without dragging the moon along with it: but it is quite otherwiſe with bodies moving in free ſpace, without any material connections. When a body that is moving uniformly in a ſtraight line is accompanied by another which deſcribes around it areas proportional to the times, the force which continually deflects this ſatellite is always directed to the moving central body. This is eaſily ſeen; for whatever be the mutual action of two bodies, and their relative motions in conſequence of this action, if the ſame velocity be impreſſed at once on both bodies in the ſame direction, their mutual actions and relative motions will be the ſame as they would have been without this common impulſe. Thus every thing is done in a ſhip that is ſailing ſteadily in the ſame manner as if ſhe were at reſt. If therefore the moon be obſerved to deſcribe areas round the earth, which are *preciſely* proportional to the times, while the earth moves in an orbit round the ſun, we muſt infer that the moon receives, in every inſtant, an impulſe the ſame in every reſpect with what the earth receives at the ſame inſtant; or that the moon is acted on by a force parallel to the earth's diſtance from the ſun, and proportional to the ſquare of that diſtance inverſely. Now this is very nearly true of the lunar motions; and we muſt infer that the moon is ſubjected to this ſolar action, or this tendency to the ſun. The ſame muſt be affirmed of the ſatellites of the other planets.

22
The ſatellites of all the planets ſubjected to this ſolar action.

But a force inverſely proportional to the ſquare of the earth's diſtance from the ſun is not what the univerſality of the law requires: It muſt be inverſely as the ſquare of the moon's diſtance from the ſun; and it muſt not be parallel to the earth's diſtance from the ſun, but muſt be directed toward the ſun; and therefore, in the quadratures, it muſt converge to the earth's *radius vector*. Therefore, ſince a force having the above mentioned conditions will allow the deſcription of areas round the earth exactly proportional to the times, a force acting on the moon, inverſely proportional to the ſquare of her diſtance from the ſun, and directed exactly to the ſun, is incompatible with the accurate elliptical motion round the earth. At new moon, her tendency to the ſun exceeds the earth's tendency to him, and this exceſs will diminiſh her tendency to the earth, and her motion will be leſs incurvated, ſo that ſhe will retire a little from the earth. At full moon, the earth's tendency to the ſun exceeds the moon's tendency to him, and the earth will ſeparate a little from the moon, ſo that the relative orbit will again be leſs incurvated. In the quadratures, the impulſe on the moon is indeed equal to that on the earth, but not parallel, and tends to make the moon approach the earth, and increaſe the curvature of her orbit. In other ſituations of the moon, this want of equality and paralleliſm of the forces acting on the earth and moon, muſt produce other diſturbances of the regular elliptical motion.

23
How the irregularity of the moon's motion

Newton ſaw this at once; and, to his great delight, he ſaw that the great deviations from regular motion, which had been diſcovered by Ptolemy and Tycho Brahé, called the *Annual Equation*, the *Variation*, and the *Evection*, were ſuch as moſt obviouſly reſulted from the regular influence of the ſun on the moon. The firſt deviation from the regular elliptical motion is occaſioned by the increaſe of the ſun's diſturbing force as the earth approaches the perihelion; and it enlarges the lunar orbit, by diminiſhing the tendency to the earth, and increaſes the periodic time. The ſecond ariſes from the *direction* of the diſturbing force, by which it accelerates the moon's angular motion in the ſecond and fourth quadrants of her orbit, and retards it in the firſt and third. The laſt affects the eccentricity of the orbit, by changing the ratio of the whole or compound tendency of the moon to the earth in her perigee and apogee. This ſucceſs incited him to an accurate examination of the conſequences of this influence. It is the boaſt of this diſcovery of the law of the planetary deflections, that all its effects may be calculated with the utmoſt preciſion. The part of the moon's deflection toward the ſun, which is neither equal nor parallel to the ſimultaneous deflection of the earth, may be ſeparated from the part which is equal and parallel to it, and it may be called the ſun's diſturbing force. Its proportion to the moon's deflection towards the earth may be accurately aſcertained, and its inclination to the line of the moon's motion in every point of her orbit may be pointed out. This being done, the accumulated effect of this diſturbing force after any given time, however variable, both in direction and intenſity during this time, may be determined by the 39th and other propoſitions of the firſt book of the Mathematical Principles of Natural Philoſophy. And thus may the moon's motion, when ſo diſturbed, be determined and compared with her motion really obſerved.

24
May be calculated with preciſion.

All this has been done by Sir Iſaac Newton with the moſt aſtoniſhing addreſs and ſagacity, *ſua matheſi facem preferente*, partly in the PRINCIPIA, and partly in his LUNÆ THEORIA. This inveſtigation, whether we conſider the complete originality of the whole proceſs, or the ingenuity of the method, or the ſagacity in ſeeing and clearly diſcriminating the different circumſtances of the queſtion, or the wonderful fertility of reſource, or the new and moſt refined mathematical principles and methods that he employed—muſt ever be conſidered as the moſt brilliant ſpecimen of human invention and reaſoning that ever was exhibited to the world.

In this inveſtigation Newton not only determined the quantity, the period, and the changes of thoſe inequalities, which had been ſo conſiderable and remarkable as to be obſerved by former aſtronomers, and this with an exactneſs far ſurpaſſing what could ever be attained by mere obſervation; but he alſo pointed out ſeveral other periodical inequalities, which were too ſmall, and too much implicated with the reſt, ever to be diſcovered or to be ſeparated from them. We do not ſay that he completed the theory of the lunar motions; but he pointed out the methods of inveſtigation, and he furniſhed all the means of proſecuting it, by giving the world the elements of a new ſpecies of mathematics, without which it would have been in vain to attempt it. Both this new mathematics, and the methods of applying it to ſuch queſtions, have been aſſiduouſly ſtudied and improved by the great mathematicians of this century; and the lunar theory has been carried to ſuch a degree of perfection, that we can compute her place in the heavens for any paſt age without deviating above one minute of a degree from the actual obſervation.

25 The ſecular equation of the moon's mean diſtance

There is one empirical equation of the moon's motion which the compariſon of ancient and modern eclipſes obliges the aſtronomers to employ, without being able to deduce it, like the reſt, *à priori*, from the theory of an univerſal force inverſely proportional to the ſquare of the diſtance. It has therefore been conſidered as a ſtumbling block in the Newtonian philoſophy. This is what is called *the ſecular equation of the moon's mean motion.* The mean motion is deduced from a compariſon of diſtant obſervations. The time between them, being divided by the number of intervening revolutions, gives the average time of one revolution, or the mean lunar period. When the ancient Chaldean obſervations are compared with thoſe of Hipparchus, we obtain a certain period; when thoſe of Hipparchus are compared with ſome in the 9th century, we obtain a period ſomewhat ſhorter; when the laſt are compared with thoſe of Tycho Brahé, we obtain one ſtill ſhorter; and when Brahé's are compared with thoſe of our day, we obtain the ſhorteſt period of all—and thus the moon's mean motion appears to accelerate continually; and the accelerations appear to be in the duplicate ratio of the times. The acceleration for the century which ended in 1700 is about 9 ſeconds of a degree; that is to ſay, the whole motion of the moon during the 17th century muſt be increaſed 9 ſeconds, in order to obtain its motion during the 18th; and as much muſt be taken from it, or added to the computed longitude, to obtain its motion during the 16th; and the double of this muſt be taken from the motion during the 16th, to obtain its motion during the 15th, &c. Or it will be ſufficient to calculate the moon's mean longitude for any time paſt or to come by the ſecular motion which obtains in the preſent century, and then to add to this longitude the product of 9 ſeconds, multiplied by the ſquare of the number of centuries which intervene. Thus having found the mean longitude for the year 1200, add 9 ſeconds, multiplied by 36, for ſix centuries. By this method we ſhall make our calculation agree with the moſt ancient and all intermediate obſervations. If we neglect this correction, we ſhall differ more than a degree from the Chaldean obſervations of the moon's place in the heavens.

The mathematicians having ſucceeded ſo completely in deducing all the obſerved inequalities of the planetary motions, from the ſingle principle, that the deflecting forces diminiſhed in the inverſe duplicate ratio of the diſtances, were fretted by this exception, the reality of which they could not conteſt. Many opinions were formed about its cauſe. Some have attempted to deduce it from the action of the planets on the moon: others have deduced it from the oblate form of the earth, and the tranſlation of the ocean by the tides; others have ſuppoſed it owing to the reſiſtance of the ether in the celeſtial ſpaces; and others have imagined that the action of the deflecting force requires time for its propagation to a diſtance: But their deductions have been proved unſatisfactory, and have by no means the preciſion and evidence that have been attained in the other queſtions of phyſical aſtronomy. At laſt M. de la Place, of the Royal Academy of Sciences at Paris, has happily ſucceeded, and deduced the ſecular equation of the moon from the Newtonian law of planetary deflection. It is produced in the following manner:

26 Deduced from the Newtonian law of planetary deflection.

Suppoſe the moon revolving round the earth undiſturbed by any deflection toward the ſun, and that the time of her revolution is exactly aſcertained. Now let the influence of the ſun be added. This diminiſhes her tendency to the earth in oppoſition and conjunction, and increaſes it in the quadratures: but the diminutions exceed the augmentations both in quantity and duration; and the exceſs is equivalent to $\frac{1}{179}$th of her tendency to the earth. Therefore this diminiſhed tendency cannot retain the moon in the ſame orbit; ſhe muſt retire farther from the earth, and deſcribe an orbit which is leſs incurvated by $\frac{1}{179}$th part; and ſhe muſt employ a longer time in a revolution. The period therefore which we obſerve, is not that which would have obtained had the moon been influenced by the earth alone. We ſhould not have known that her natural period was increaſed, had the diſturbing influence of the ſun remained unchanged; but this varies in the inverſe triplicate ratio of the earth's diſtance from the ſun, and is therefore greater in our winter, when the earth is nearer to the ſun. This is the ſource of the annual equation, by which the lunar period in January is made to exceed that in July nearly 24 minutes. The angular velocity of the moon is diminiſhed in general $\frac{1}{179}$, and this numerical coefficient varies in the inverſe ratio of the cube of the earth's diſtance from the ſun. If we expand this inverſe cube of the earth's diſtance into a ſeries arranged according to the ſines and coſines of the earth's mean motion, making the earth's mean diſtance unity, we ſhall find that the ſeries contains a term equal to $\frac{3}{2}$ of the ſquare of the eccentricity of the earth's orbit. Therefore the expreſſion of the diminution of the moon's angular velocity contains a term equal to $\frac{1}{179}$ of this velocity, multiplied by $\frac{3}{2}$ of the ſquare of the earth's eccentricity; or equal to the product of the ſquare of the eccentricity, multiplied by the moon's angular velocity, and divided by 119,33 ($\frac{2}{3}$ of 179). Did this eccentricity remain conſtant, this product would alſo be conſtant, and would ſtill be confounded with the general diminution, making a conſtant part of it: but the eccentricity of the earth's orbit is known to diminiſh, and its diminution is the reſult of the univerſality of the Newtonian law of the planetary deflections. Although this diminution is exceedingly ſmall, its effect on the lunar motion becomes ſenſible by accumulation in the courſe of ages. The eccentricity diminiſhing, the diminution of the moon's angular motion muſt alſo diminiſh, that is, the angular motion muſt increaſe.

During the 18th century, the ſquare of the earth's eccentricity has diminiſhed 0,0000015325, the mean diſtance from the ſun being = 1. This has increaſed the angular motion of the moon in that time 0,00000001285. As this augmentation is gradual, we muſt multiply the angular motion during the century by the half of this quantity, in order to obtain its accumulated effect. This will be found to be 9″ very nearly, which exceeds that deduced, from a moſt careful compariſon of the motion of the laſt two centuries, only by a fraction of a ſecond!

As long as the diminution of the ſquare of the eccentricity of the earth's orbit can be ſuppoſed proportional to the time, this effect will be as the ſquares of the times. When this theory is compared with obſervations, the coincidence is wonderful indeed. The effect on the moon's motion is periodical, as the change of the ſolar eccentricity is, and its period includes millions of years. Its effect on the moon's longitude will amount to ſeveral degrees before the ſecular acceleration change to a retardation.

Thoſe who are not familiar with the diſquiſitions of modern analyſis, may conceive this queſtion in the following manner.

Let the length of a lunar period be computed for the earth's diſtance from the ſun for every day of the year. Add them into one ſum, and divide this by their number, the quotient will be the mean lunar period. This will be found to be greater than the arithmetical medium between the greateſt and the leaſt. Then ſuppoſe the eccentricity of the earth's orbit to be greater, and make the ſame computation. The average period will be found ſtill greater, while the medium between the greateſt and leaſt periods will hardly differ from the former. Something very like this may be obſerved without any calculation, in a caſe very ſimilar. The angular velocity of the ſun is inverſely as the ſquare of his diſtance. Look into the ſolar tables, and the greateſt diurnal motion will be found 3673″, and the leaſt 3433″. The mean of theſe is 3553″, but the medium of the whole is 3548″. Now make a ſimilar obſervation in tables of the motion of the planet Mars, whoſe eccentricity is much greater. We ſhall find that the medium between the greateſt and leaſt exceeds the true medium of all in a much greater proportion.

27 Certainty and utility of this law.

Thus has the patient and aſſiduous cultivation of the Newtonian diſcoveries explained every phenomenon, and enabled us to foreſee changes in them which no examination of the paſt appearances, unaſſiſted by this theory, could have pointed out, and which muſt have exceedingly embarraſſed future aſtronomers This great but ſimple law of deflection repreſents every phenomenon of the ſyſtem in the moſt minute circumſtances. Far from fearing that future experience may overturn this law, we may reſt aſſured that it will only confirm it more and more; and we may confide in its moſt remote conſequences as if they were actually obſerved.

28 Reciprocal deflection of the earth and moon, and of the ſun and planets,

It is diſcovered by obſervation, that the deflection of the moon to the earth, and of the planets to the ſun, are accompanied by an equal and oppoſite deflection of the earth to the moon, and of the ſun to the planets.

The tendency of the earth to the moon is plainly indicated by the riſe of the waters of the ocean under the moon, and on the oppoſite ſide of the earth. Sir Iſaac Newton tried what ſhould be the reſult of a tendency of the water to the moon. His inveſtigation of this queſtion was very ſimilar to that in his lunar theory. We may conceive the moon to be one of many millions of particles of a fluid, occupying a globe as big as the lunar orbit. Each will feel a ſimilar diſturbing force, which will diminiſh its tendency to the earth in the neighbourhood of the place of conjunction and oppoſition, and will increaſe it in the neighbourhood of the quadratures. They cannot therefore remain in equilibrio in their ſpherical form; they muſt ſink in the quadratures, and riſe in the conjunction and oppoſition, till their greater height compenſates for the diminiſhed weight of each particle. In like manner, the waters of the ocean muſt ſink on thoſe parts of the earth where the moon is ſeen in the horizon, and muſt riſe in thoſe which have the moon in the zenith or nadir. All theſe effects are not only to be ſeen in general, but they may all be calculated, and the very form pointed out which the ſurface of the ocean muſt aſſume; and thus a tendency of every particle of the ocean to the moon, inverſely proportional to the ſquare of its diſtance from it, gives us a theory of the ebbing and flowing of the ſea. This is delivered in ſufficient detail in the article TIDE of the Encyclopædia Britannica, and therefore need not be inſiſted on in this place. The ſame inference muſt be drawn from the preceſſion of the equinoxes produced by the action of the moon on the protuberant matter of our equatorial regions. See PRECESSION in the *Encycl.*

29 Proved by the ebbing and flowing of the ſea,

30 And by di ferent con putations of the ſun place in th heavens.

But the mutual tendency of the earth and moon is clearly ſeen in a phenomenon that is much more ſimple. If we compute the ſun's place in the heavens, on the ſuppoſition that the earth deſcribes areas proportional to the times, we ſhall find it to agree with obſervation at every new and full moon: But at the firſt quarter the ſun will be obſerved about 9 ſeconds too much advanced to the eaſtward; and at the laſt quarter he will be as much to the weſtward of his calculated place. In all intermediate poſitions, the deviation of the obſerved from the computed place of the ſun will be 9 ſeconds, multiplied by the ſine of the moon's diſtance from conjunction or oppoſition. In ſhort, the appearances will be the ſame as if it were not the earth which deſcribed areas proportional to the times round the ſun, but that a point, lying between the earth and moon, and very near the earth's ſurface, were deſcribing the ellipſe round the ſun, while the earth and moon revolve round this point in the courſe of a lunation, having the point always in the line between them, in the ſame manner as if they were on the extremities of a rod which turns round this point, while the point itſelf revolves round the ſun.

This then is the fact with reſpect to the motions; and the earth in a month deſcribes an orbit round this common centre of the earth and moon. It cannot do this unleſs it be continually deflected from the tangent to this orbit; therefore it is continually deflected toward the moon: and the momentum of this deflection, that is, its quantity of motion, is the ſame with that of the moon's deflection, becauſe their diſtances from the common centre are as their quantities of matter inverſely.

Appearances perfectly ſimilar to theſe oblige us to affirm

xtenſion
f that law

affirm that the ſun is continually deflected toward the planets. Aſtronomical inſtruments, and the art of obſerving, have been prodigiouſly improved ſince Sir Iſaac Newton's time; and the moſt ſcrupulous attention has been paid to the ſun's motion, becauſe it is to his place in the univerſe that continual reference is made in computing the place of all the planets. He is ſuppoſed at reſt in the common focus of all their orbits; and the *obſerved* diſtance of a planet from the ſun is always conſidered as the *radius vector.* If this be not the caſe, the orbital motions contained in our tables are not the abſolute motions of the planets, nor the deflections from the tangents the real deflections from abſolute rectilineal motion; and therefore the forces are not ſuch as we infer from thoſe miſtaken deflections. Accordingly Sir Iſaac Newton, induced by certain metaphyſical conſiderations, aſſumed it as a law of motion, that every action of a body A on another body B, is accompanied by an equal and contrary action of B on A. We do not ſee the propriety of this aſſertion as a metaphyſical axiom. It is perfectly conceivable that a piece of iron will always approach a magnet when in its neighbourhood; but we do not ſee that this obliges us to aſſert, that *therefore* the magnet will alſo approach the iron. Thoſe who explain the phenomena of magnetiſm by the impulſe of a fluid, muſt certainly grant that there is no metaphyſical neceſſity for another ſtream of fluid impelling the magnet toward the iron. And accordingly this, and the ſimilar reciprocity in the phenomena of electricity, have *always* been conſidered as deductions of experimental philoſophy; yet we obſerve the ſame reciprocity in all the actions of ſublunary bodies; and Newton's third law of motion is received as true, and admitted as a principle of reaſoning. But we apprehend that it was haſty in this great philoſopher, and unlike his ſcrupulous caution, to extend it to the planetary motions. He did, however, extend it, and aſſerted, that as each planet was deflected toward the ſun, the ſun was equally (in reſpect of momentum) deflected toward each planet, and that his real motion was the compoſition of all thoſe ſimultaneous deflections. He aſſerted that there was a certain point round which the ſun and his attending planets revolved; and that the orbit of a planet, which our meaſurements determined by continual reference to the ſun as to a fixed body, was not the true orbit, but conſiſted of the contemporaneous orbits of that planet and of the ſun round this fixed point. Any little ſector of the apparent orbit was greater than the correſponding ſector of the planet's true orbit in abſolute ſpace, and the apparent motion was compounded of the true motion of the planet, and the oppoſite to the true motion of the ſun. After a moſt ingenious and refined inveſtigation, he ſhewed that, notwithſtanding this great difference of the Keplerean laws from the truth, the inference, with reſpect to the law of planetary deflection, is juſt, and that not only the apparent deflections are in the inverſe duplicate ratio of the diſtances from the ſun, but that the real deflections vary in the ſame ratio of the diſtances from the fixed point, and alſo from the ſun; for he ſhewed that the diſtances from the ſun were in a conſtant ratio to the diſtances from this point. He ſhewed alſo that the ſame forces which produced the contemporaneous revolution of a planet and the ſun round the centre of the ſyſtem, would produce a revolution of the planet in a ſimilar orbit round the ſun (ſuppoſed to be held faſt in his place) at the ſame diſtance which really obtains between them, with this ſole difference, that the periodic time will be longer, in the ſubduplicate ratio of the quantity of matter in the ſun to the quantity of matter of the ſun and planet together. Areas will be deſcribed proportional to the times, and the orbit will be elliptical; but the ratio of the ſquares of the periodic times will not be the ſame with the ratio of the cubes of the diſtances, unleſs all the planets are equal.

Thus was the attention of aſtronomers directed to a number of *apparent* irregularities in the motion of the earth, which muſt reſult from this derangement of the ſun, which they had imagined to remain ſtedfaſt in his place. They were told what to expect, and on what poſitions of the planets the kind and quantity of every irregularity depended. This was a moſt inviting field of obſervation to a curious ſpeculatiſt; but it required the niceſt and moſt expenſive inſtruments, and an uninterrupted ſeries of long continued obſervations, ſufficient to occupy the whole of a man's time. Fortunately the accurate determination of the ſolar and lunar motions were of the utmoſt importance, nay, indiſpenſably neceſſary for ſolving the famous problem of the longitude of a ſhip at ſea: and thus the demands of commercial Europe came in aid of philoſophical curioſity, and occaſioned the erection of obſervatories, firſt at Greenwich, and ſoon after at Paris and other places, with eſtabliſhments for aſtronomers, who ſhould carefully watch the motions of the ſun and moon, not neglecting the other planets.

33
Confirmed
by obſerva-
tion.

The fortunate reſult of all this ſolicitude has been the complete eſtabliſhment of the Newtonian conjecture (for ſo we muſt ſtill think it), and the verification of Newton's aſſertion, that action was accompanied, through the whole ſolar ſyſtem, by an equal and contrary reaction. All the inequalities of the ſolar motion predicted by Newton have been obſerved, although they are frequently ſo complicated that they could never have been detected, had not the Newtonian theory directed us when to find any of them pretty clear of complication, and how to aſcertain the accumulated reſult of them all in any ſtate of combination.

But in the courſe of this attention to the motions of the ſun and moon, the planets came in for a ſhare, and conſiderable deviations were found, from the ſuppoſition that all their deflections were directed to the ſun, and were in the inverſe duplicate ratio of their diſtances. The nice obſervation ſhewed, that the period of Jupiter was ſomewhat ſhorter than Kepler's law required.

A ſlight reflection ſhewed that this was no inconſiſtency; becauſe the common centre of the conjoined orbits of the ſun and Jupiter was ſenſibly diſtant from the centre of the ſun, namely, about the 1100th part of the *radius vector;* and therefore the real deflection was about a 2200th part leſs than was ſuppoſed. It was now plain that the diſtances to which the Keplerean law muſt be applied, are the diſtances, not from the ſun, but from the fixed point round which the ſun and planets revolve. This difference was too ſmall to be obſerved in Kepler's time; but the ſeeming error is only a confirmation of the Newtonian philoſophy.

But there are other irregularities which cannot be explained in this manner. The planetary orbits change their

their poſition; their aphelia advance, their nodes recede, their inclination to each other vary. The mean motions of Saturn and Jupiter are ſubject to conſiderable changes, which are periodical.

34
Deflection of the planets towards each other.

Sir Iſaac Newton had no ſooner diſcovered the univerſality and reciprocity of the deflections of the planets and the ſun, than he alſo ſuſpected that they were continually deflected towards each other. He immediately obtained a general notion of what ſhould be the more general reſults of ſuch a mutual action. They may be conceived in this way.

Plate VI.

Let S (fig. 5.) repreſent the ſun, E the earth, and I Jupiter, deſcribing concentric orbits round the centre of the ſyſtem. Make JS : EA $=$ $EI^2 : SI^2$. Then, if IS be taken to repreſent the deflection of the ſun toward Jupiter, EA will repreſent the deflection of the Earth to Jupiter. Draw EB equal and parallel to SI, and complete the parallelogram EBAD. ED will repreſent the diſturbing force of Jupiter. It may be reſolved into EF, perpendicular to ES, and EG in the direction of SE. By the firſt of theſe the earth's angular motion round the ſun is affected, and by the ſecond its deflection toward him is diminiſhed or increaſed.

35
General reſult of ſuch mutual action.

In conſequence of this firſt part of the diſturbing force, the angular motion is increaſed, while the earth approaches from quadrature to conjunction with Jupiter (which is the caſe repreſented in the figure), and is diminiſhed from the time that Jupiter is in oppoſition till the earth is again in quadrature, weſtward of his oppoſition. The earth is then accelerated till Jupiter is in conjunction with the ſun; after which it is retarded till the earth is again in quadrature.

The earth's tendency to the ſun is diminiſhed while Jupiter is in the neighbourhood of his oppoſition or conjunction, and increaſed while he is in the neighbourhood of his ſtationary poſitions. Jupiter being about 1000 times leſs than the ſun, and 5 times more remote, IS muſt be conſidered as repreſenting $\frac{1}{25000}$th of the earth's deflection to the ſun, and the forces ED and EG are to be meaſured on this ſcale.

In conſequence of this change in the earth's tendency to the ſun, the aphelion ſometimes advances by the diminution, and ſometimes retreats by the augmentation. It advances when Jupiter chances to be in oppoſition when the earth is in its aphelion; becauſe this diminution of its deflection towards the ſun makes it later before its path is brought from forming an obtuſe angle with the *radius vector*, to form a right angle with it. Becauſe the earth's tendency to the ſun is, on the whole, more diminiſhed by the diſturbing force of Jupiter than it is increaſed, the aphelion of the earth's orbit advances on the whole.

In like manner the aphelia of the inferior planets advance by the diſturbing forces of the ſuperior: but the aphelion of a ſuperior planet retreats; for theſe reaſons, and becauſe Jupiter and Saturn are larger and more powerful than the inferior planets, the aphelia of them all advance while that of Saturn retreats.

In conſequence of the ſame diſturbing forces, the node of the diſturbed planet retreats on the orbit of the diſturbing planet; therefore they all retreat on the ecliptic, except that of Jupiter, which advances by retreating on the orbit of Saturn, from which it ſuffers the greateſt diſturbance. This is owing to the particular poſition of the nodes and the inclinations of the orbits.

The inclination of a planetary orbit increaſes while the planet approaches the node, and diminiſhes while the planet retires from it.

36
A peculiarity explained in the motions of Jupiter and Saturn.

M. de la Place has completed this deduction of the planetary inequalities, by explaining a peculiarity in the motions of Jupiter and Saturn, which has long employed the attention of aſtronomers. The accelerations and retardations of the planetary motions depend, as has been ſhewn, on their configurations, or the relative quarters of the heavens in which they are. Thoſe of Mercury, Venus, the Earth, and Mars, ariſing from their mutual deflections; and their more remarkable deflections to the great planets Jupiter and Saturn, nearly compenſate each other, and no traces of them remain after a few revolutions: but the poſitions of the aphelia of Saturn and Jupiter are ſuch, that the retardations of Saturn ſenſibly exceed the accelerations, and the anomaliſtic period of Saturn increaſes almoſt a day every century: on the contrary, that of Jupiter diminiſhes. M. de la Place ſhews, that this proceeds from the poſition of the aphelia, and the almoſt perfect commenſurability of their revolutions; five revolutions of Jupiter making 21,675 days, while two revolutions of Saturn make 21,538, differing only 137 days.

Suppoſing this relation to be exact, the theory ſhews that the mutual action of theſe planets muſt produce mutual accelerations and retardations of their mean motions, and aſcertains the periods and limits of the ſecular equations thence ariſing. Theſe periods include ſeveral centuries. Again, becauſe this relation is not preciſe, but the odd days nearly divide the periods already found, there muſt ariſe an equation of this ſecular equation, of which the period is immenſely longer, and the maximum very minute. He ſhews that this retardation of Saturn is now at its maximum, and is diminiſhing again, and will, in the courſe of years, change to an acceleration.

This inveſtigation of the ſmall inequalities is the moſt intricate problem in mechanical philoſophy, and has been completed only by very ſlow degrees, by the arduous efforts of the greateſt mathematicians, of whom M. de la Grange is the moſt eminent. Some of his general reſults are very remarkable.

He demonſtrates, that ſince the planets move in one direction, in orbits nearly circular, no mutual diſturbances make any permanent change in the mean diſtances and mean periods of the planets, and that the periodic changes are confined within very narrow limits. The orbits can never deviate ſenſibly from circles. None of them ever has been or will be a comet moving in a very eccentric orbit. The ecliptic will never coincide with the equator, nor change its inclination above two degrees. In ſhort, the ſolar planetary ſyſtem oſcillates, as it were, round a medium ſtate, from which it never ſwerves very far.

37
Oſcillation of the planetary ſyſtem.

This theory of the planetary inequalities, founded on the univerſal law of mutual deflection, has given to our tables a preciſion, and a coincidence with obſervation, that ſurpaſſes all expectation, and inſures the legitimacy of the theory. The inequalities are moſt ſenſible in the motions of Jupiter and Saturn; and theſe preſent themſelves in ſuch a complicated ſtate, and their periods are ſo long, that ages were neceſſary for diſcovering them by mere obſervation. In this reſpect, therefore, the theory has outſtripped the obſervations on which it is founded.

38 Authenticity of the Indian aſtronomy.

founded. It is very remarkable, that the periods which the Indians aſſign to theſe two planets, and which appeared ſo inaccurate that they hurt the credit of the ſcience of thoſe ancient aſtronomers, are now found preciſely ſuch as muſt have obtained about three thouſand years before the Chriſtian era; and thus they give an authenticity to that ancient aſtronomy. The periods which any nation of aſtronomers aſſign to thoſe two planets would afford no contemptible mean for determining the age in which it was obſerved.

39 Origin of the aſtrological diviſion of the heavens.

The following circumſtance is remarkable: Suppoſe Jupiter and Saturn in conjunction in the firſt degree of Aries; twenty years after, it will happen in Sagittarius; and after another twenty years, it will happen in Leo. It will continue in theſe three ſigns for 200 years. In the next 200 it will happen in Taurus, Capricornus, and Virgo; in the next 200 years, it will happen in Gemini, Aquarius, and Libra; and in the next 200 years, it will happen in Cancer, Piſces, and Scorpio: then all begins again in Aries. It is highly probable that theſe remarkable periods of the oppoſitions of Jupiter and Saturn, progreſſive for 40 years, and oſcillating during 160 more, occaſioned the aſtrological diviſion of the heavens into the four *trigons*, of fire, air, earth, and water. Theſe relations of the ſigns, which compoſe a trigon, point out the repetitions of the chief irregularities of the ſolar ſyſtem.

M. de la Place obſerves (in 1796), that the laſt diſcovered planet gives evident marks of the action of the reſt; and that when theſe are computed and taken into the account of its bygone motions, they put it beyond doubt that it was ſeen by Flamſtead in 1690, by Mayer in 1756, and by Monnier in 1769.

40 Action of the comets.

We have hitherto overlooked the comets in our account of the mutual diſturbances of the ſolar ſyſtem. Their number is very great, and they go to all quarters of the univerſe: but we may conclude, from the wonderful regularity of the planetary motions, when all their own mutual actions are taken into account, that the quantity of matter in the comets is very inconſiderable. They remain but a ſhort time in the neighbourhood of the planets, and they paſs them with great rapidity. Some of them have come very near to Jupiter, but left no trace of their action in the motions of his ſatellites. They doubtleſs contribute, in general, to make the apſides of the planetary orbits advance.

41 They are affected by the planets

On the other hand, the comets may be conſiderably affected by the planets. The very important phenomenon of the return of the comet of 1682, which was to decide whether they were revolving planets deſcribing ellipſes, or bodies which came but once into the planetary regions, and then retired for ever, cauſed the aſtronomers to conſider this matter with great care. Halley had ſhewn, in a rough way, that this comet muſt have been conſiderably affected by Jupiter. Their motion near the aphelion muſt be ſo very ſlow, that a very ſmall change of velocity or direction, while in the planetary regions, muſt conſiderably affect their periods. Halley thought that the action of Jupiter might change it half a year. Mr Clairaut, by conſidering the diſturbing forces of Jupiter and Saturn through the whole revolution, ſhewed that the period then running would exceed the former nearly two years (618 days), and aſſigned the middle of April 1759 for the time of its perihelion. It really paſſed its perihelion on the 12th of March. This was a wonderful preciſion, when we reflect that the comet had been ſeen but a very few days in its former apparitions.

A comet obſerved by Mr Proſperin and others in 1771 has greatly puzzled the aſtronomers. Its motions appear to have been extremely irregular, and it certainly came ſo near Jupiter, that his momentary influence was at leaſt equal to the ſun's. It has not been recogniſed ſince that time, although there is a great probability that it is continually among the planets.

42 Conſequence of a comet and planet meeting.

It is by no means impoſſible, nor highly improbable, that in the courſe of ages, a comet may actually meet one of the planets. The effect of ſuch a concourſe muſt be dreadful; a change of the axis of diurnal rotation muſt reſult from it, and the ſea muſt deſert its former bed and overflow the new equatorial regions. The ſhock and the deluge muſt deſtroy all the works of man, and moſt of the race. The remainder, reduced to miſery, muſt long ſtruggle for exiſtence, and all remembrance of former arts and events muſt be loſt, and every thing muſt be invented anew. There are not wanting traces of ſuch devaſtations in this globe: ſtrata and things are now found on mountain tops which were certainly at the bottom of the ocean in former times; remains of tropical animals and plants are now dug up in the circumpolar regions. *Tempora mutantur, et nos mutamur in illis.*

43 Tendency of ſpherical bodies towards each other directly as the quantity of matter, and inverſely as the ſquare of the diſtance of their centres.

It is plain, that when we know the direction and the intenſity of the diſturbing force, we can tell what will be the accumulated effect of its action for any time. The direction is eaſily determined by means of the diſtance: but how ſhall we determine the intenſity? Since we ſee that the whole waters of the ocean are deflected toward the moon, and have ſuch probable evidence that planetary deflection is mutual; it follows that the moon is deflected towards *every* drop of water, and that *all* the matter in one body is deflected towards *all* the matter in another body; and therefore that the deflection towards the ſun or a planet is greater or leſs in proportion to its quantity of matter. Newton indeed thought it unreaſonable to ſuppoſe that a planet was deflected to the centre of the ſun, which had no diſtinguiſhing phyſical property; and thought it more probable that the deflection of a planet to the ſun was the accumulated deflection of every particle in the planet to every particle in the ſun. But he was too ſcrupulous to take this for granted. He therefore endeavoured to diſcover what would be the ſenſible deflection of one ſphere to another, when each conſiſted of matter, every particle of which was deflected to every particle of the other with an intenſity inverſely proportional to the ſquare of the diſtance from it. By help of a moſt beautiful and ſimple proceſs, he diſcovered, that the tendency of a particle of matter to a ſpherical ſurface, ſhell, or ſolid, of uniform denſity at equal diſtances from the centre, was the ſame as if all the particles in the ſurface, ſhell, or ſolid, were united in its centre: hence it legitimately followed, that the mutual tendency of ſpherical ſurfaces, ſhells, or ſolids, was proportional to the quantities of matter in the attracting body, and inverſely as the ſquare of the diſtance of their centres; and thus the law of attraction, competent to every particle of planetary matter, was the ſame with that which *was obſerved* among ſpherical bodies conſiſting of ſuch matter. And it is remarkable, that the inverſe duplicate ratio

tio of the diſtances is the only law that will hold, both with reſpect to ſingle particles and to globes compoſed of ſuch particles. He alſo demonſtrated, that a particle placed within a ſphere was not affected by all the ſhell, which was more diſtant than itſelf from the centre, being equally attracted on every ſide, and that it tended toward the centre of a homogenous ſphere, on the ſurface of which it was placed, with a force proportional to its diſtance from the centre.

Newton ſaw a caſe in which it was poſſible to diſcover whether the tendency of the matter of which the planets conſiſted was directed to a mathematical centre void of any phyſical properties, or whether it was the reſult of its united tendency to all the matter of the planet. He demonſtrated that if the earth conſiſted of matter which tended to the centre, it behoved it to aſſume the form of an elliptical ſpheroid, in conſequence of the centrifugal force ariſing from its diurnal motion, and that the polar axis muſt be to its equatorial diameter as 577 to 578; but if every particle tends to every other particle in the inverſe duplicate ratio of the diſtance from it, the form muſt ſtill be elliptical, but more protuberant, and the polar axis muſt be to the equatorial diameter as 230 to 231. Then only will a column of water from the pole to the centre balance a column from the equator to the centre. He alſo ſhewed what ſhould be the vibrations of pendulums in different latitudes, on both ſuppoſitions. Mathematicians were eager therefore to make thoſe experiments on pendulums, and to determine the figure of the earth by the meaſurement of degrees of the meridian in different latitudes. The reſult of their endeavours has been decidedly in favours of the mutual tendency of all matter. This has been farther confirmed by the obſervations of the mathematicians who meaſured the degrees of the meridian in Peru, and by Dr Maſkelyne in Britain, who found that a pendulum ſuſpended in the neigbourhood of a great and ſolid mountain, ſenſibly deviated from the true vertical, and was deflected toward the mountain.

44 Proportional quantities of matter in the ſun and planets determined.

From a collective view of all theſe circumſtances, Sir Iſaac Newton concluded, with great confidence, that the deflection toward any planet was the united deflection toward every particle of matter contained in it. This enabled him to determine the intenſity of the planetary diſturbing forces, by previouſly aſcertaining the proportions of their quantities of matter. This proportion, the diſcovery of which ſeems above our reach, is eaſily aſcertained in all thoſe bodies which have others revolving round them: for the deflection of the revolving body, being occaſioned by all the matter in the central body, will be proportional *(cæteris paribus)* to the quantity of matter in the central body, and therefore will give us a meaſure of that quantity. Would we compare the quantity of matter in Jupiter with the quantity of matter in the ſun, we have only to ſuppoſe that a planet revolves round the ſun at the diſtance of Jupiter's fourth ſatellite. Kepler's third law will tell us the time of its revolution. The diſtances, in this caſe, being the ſame, the centripetal forces, and conſequently the quantities of matter in the central bodies, will be inverſely as the ſquares of the periodic times of the revolutions around them. In this way have the quantities of matter been determined for the Sun, the Earth, Jupiter, Saturn, and the laſt diſcovered planet. If the quantity in the Earth be conſidered as the unit, we have,

The Earth - - - - -	1
The newly diſcovered planet -	17,75
Saturn - - - - - -	86,16
Jupiter - - - - - -	317,1
The Sun - - - -	338343.

Thus we ſee that the ſun is incomparably bigger than any planet, having more than a thouſand times as much matter as Jupiter, the moſt maſſy of them all. There is a conſiderable uncertainty, however, in the proportion to the ſun, becauſe we do not know his diſtance nearer than within $\frac{1}{500}$th part. The proportions of the reſt to each other are more accurate. The quantities of matter in Mercury and Mars can only be gueſſed at: the quantity in Mercury may be called 0,1, and Mars may be called 0,12. Venus is ſuppoſed nearly equal to the Earth. This is concluded from the effect which ſhe produces on the preceſſion of the equinoxes and the equation of the ſun's motion. The moon is ſuppoſed to be about $\frac{1}{60}$th of the earth, from the effect ſhe produces on the tides and the preceſſion of the equinoxes, compared with thoſe produced by the ſun.

45 Sun's place and the tranſit of a planet determined exactly.

When theſe quantities of matter are introduced into the computation of the planetary inequalities, and the intenſity of the diſturbing forces aſſumed accordingly, the reſults of the computations tally ſo exactly with obſervation, that we can now determine the ſun's place for any moment within two or three ſeconds of a degree, and are certain of the tranſit of a planet within one beat of the clock!

46 Progreſs of Newton's diſcovery of

Sir Iſaac Newton having already made the great diſcovery of an univerſal and mutual deflection of all the matter in the ſolar ſyſtem, was one day ſpeculating on this ſubject, and comparing it with other deflections which he obſerved among bodies, ſuch as magnets, &c. He conſidered terreſtrial gravity as a force of this kind. By the weight of terreſtrial bodies they kept united with the earth. By its weight was the water of the ocean formed into a ſphere. This force extended, without any remarkable diminution, to the tops of the higheſt mountains. Might it not reach much farther? May it not operate even at the diſtance of the moon? In the ſame manner that the planetary force deflects the moon from the tangent to her orbit, and cauſes her to deſcribe an ellipſe, the weight of a cannon ball deflects it from the line of its direction, and makes it deſcribe a parabola. What if the deflecting force which incurvates her path towards the earth be the ſimple weight of the moon? If the weight of a body be the ſame with the general planetary force, it will diminiſh as the ſquare of its diſtance from the earth increaſes. Therefore, ſaid he to himſelf, ſince the diſtance of the moon from the centre of the earth is about 50 times greater than the diſtance of the ſtone which I throw from my hand, and which is deflected 16 feet in one ſecond, the weight of this ſtone, if taken up to the height of the moon, ſhould be reduced to the 2500th part, and ſhould there deflect $\frac{1}{2500}$th of 16 feet in a ſecond; and the moon ſhould deflect

deflect as much from the tangent in a ſecond. Having the dimenſions, as he thought, of the moon's orbit, he immediately computed the moon's deflection in a ſecond; but he found it conſiderably different from what he wiſhed it to be. He therefore concluded that the planetary force was not the weight of the planet. For ſome years he thought no more of it: but one day, in the Royal Society, he heard an account read of meaſurements of a degree of the meridian, which ſhewed him that the radius of the earth and the diſtance of the moon were very different from what he had believed them to be. When he went home he repeated his computation, and found, that the deflection of a ſtone was to the ſimultaneous deflection of the moon as the ſquare of the moon's diſtance from the centre of the earth to the ſquare of the ſtone's diſtance. Therefore the moon is deflected by its weight; and the fall of a ſtone is juſt a particular inſtance of the exertion of the univerſal planetary force. This computation was but roughly made at firſt; but it was this coincidence that excited the philoſopher to a more attentive review of the whole ſubject. When every circumſtance which can affect the reſult is taken into account, the coincidence is found to be moſt accurate. The fall of the ſtone is not the full effect of its weight; for it is diminiſhed by the rotation of the earth round its axis: It is alſo diminiſhed by the weight of the air which it diſplaces: It is alſo diminiſhed by its tendency to the moon. On the other hand, the moon does not revolve round the earth, but round a common centre of the earth and moon, and its period is about $\frac{1}{170}$th ſhorter than if it revolved round the earth; and the moon's deflection is affected by the ſun's diſturbing force. But all theſe corrections can be accurately made, and the ratio of the full weight of the ſtone to the full deflection of the moon aſcertained. This has been done.

Terreſtrial gravity therefore, or that power by which bodies fall or preſs on their ſupports, is only a particular inſtance of that general tendency by which the planets are retained in their orbits. Bodies may be ſaid to *gravitate* when they give indications of their being *gravis* or heavy, that is, when they fall or preſs on their ſupports; therefore the planets may be ſaid to gravitate when they give ſimilar indications of the ſame tendency by their curvelineal motions. The general FACT, that the bodies of the ſolar ſyſtem are mutually deflected toward each other, may be expreſſed by the verbal noun GRAVITATION. Gravitation does not expreſs a quality, but an event, a deflection, or a preſſure.

The weight of a terreſtrial body, or its preſſure on its ſupport, is the effect of the accumulated gravitation of all its particles; for bodies of every kind of matter fall equally faſt. This has been aſcertained with the utmoſt accuracy by Sir Iſaac Newton, by comparing the vibrations of pendulums made of every kind of matter. Therefore their united gravitation is proportional to their quantity of matter; and we have concluded, that every atom of terreſtrial matter is heavy, and equally heavy. We extend this concluſion to the ſun and planets, and ſay, that the obſerved gravitation of a planet is the united gravitation of every particle. Therefore Sir Iſaac Newton inferred, from a collected view of all the phenomena, that *all matter gravitates to* all matter with a force in the inverſe duplicate ratio of the diſtance.

47 The univerſal law of gravitation,

But we do not think that this inference is abſolutely certain. We acknowledge that the experiments on pendulums, conſiſting of a vaſt variety of terreſtrial matter, all of which performed their oſcillations in equal times, demonſtrate that the acceleration of gravity on thoſe pendulums was proportional to their quantities of matter, and that equal gravitation may be affirmed of all terreſtrial matter.

The elliptical motion of a planet is full proof that the accelerating power of its gravity varies in the inverſe duplicate ratio of the diſtance; and the proportionality of the ſquares of the periods to the cubes of the diſtances, ſhews that the whole gravitations of the planets vary by the ſame law. But this third obſervation of Kepler might have been the ſame, although the gravitation of a particle of matter in Jupiter had been equal to that of a particle of terreſtrial matter, provided that all the matter in Jupiter did not gravitate. If $\frac{1}{25}$th of Jupiter had been ſuch gravitating matter, his deflection from the tangent of his orbit would have been the ſame as at preſent, and the time of his revolution would have been what we obſerve. In order that the third law of Kepler may hold true of the planetary motions, no more is required than that the accumulated gravitation of the planet be proportional to its quantity of matter, and thus the matter which does not gravitate will be compenſated by the ſuperior gravitation of the reſt.

But becauſe we have no authority for ſaying that there is matter which gravitates differently from the reſt, or which does not gravitate, we are intitled to ſuppoſe that gravity operates alike on all matter.

48 Which is the ultimatum of his philoſophy.

And this is the ultimatum of the Newtonian philoſophy, that the ſolar ſyſtem conſiſts of bodies compoſed of matter, every particle of which is, in fact, continually deflected by its weight toward every other particle in the ſyſtem; and that this deflection, or actual deviation, or actual preſſure, tending to deviation from uniform rectilineal motion, is in the inverſe duplicate ratio of the diſtance.

49 Objections to the law of gravitation ill-founded.

This doctrine has been called *the ſyſtem of univerſal gravitation;* and it has been blamed as introducing an unphiloſophical principle into ſcience. Gravitation is ſaid to be an occult quality; and therefore as unfit for the explanation of phenomena as any of the occult qualities of Ariſtotle. But this reproach is unfounded; gravitation does not expreſs any quality whatever, but a matter of fact, an event, an actual deflection, or an actual preſſure, producing an actual deflection of the body preſſed. Theſe are not occult, but matters of continual obſervation. True, indeed, Newton does not deny, although he does not poſitively ſay, that this deflection, preſſure, or gravitation, is an effect having a cauſe. *Gravity* is ſaid to be this cauſe. Gravity is the *being gravis or heavy*, and gravitation is the *giving indications of being heavy.* Heavineſs therefore is the word which expreſſes *gravitas*, and our notion of the cauſe of the planetary deflections is the ſame with our notion of heavineſs. This may be indiſtinct and unſatisfactory to a mind faſtidiouſly curious; but nothing can be more familiar. The planet is deflected, *becauſe it is heavy.* We are ſuppoſed to explain the fall of a ſtone through water very ſatisfactorily, and without having recourſe to any occult quality, when we ſay that it is heavier than the water; and we explain the riſe of a piece of cork, when we ſay that it is not ſo heavy as the water.

The

The explanations of the mutual actions of the planets are equally ſatisfactory, founded on the ſame principles, and equally free from all ſophiſtry or employment of occult cauſes. The weight of a body is not its heavineſs, but the effect of its heavineſs. It is a gravitation, an actual preſſure, indicated by its balancing the ſuppoſed heavineſs of another body, or by its balancing the known elaſticity of a ſpring, or by balancing any other natural power. It is ſimilar to the preſſure which a magnet exerts on a piece of iron. This may perhaps be produced by the impulſe of a ſtream of fluid; ſo may the weight of a heavy body. But we do not concern ourſelves with this queſtion. We gain a moſt extenſive and important knowledge by our knowledge of this univerſal law; for we can now explain every phenomenon, by pointing out how it is contained in this law; and we can predict the whole events of the ſolar ſyſtem with unerring exactneſs. This ſhould ſatisfy the moſt inquiſitive mind.

50 Our knowledge of that law ſatisfactory.

But, *nitimur in vetitum, ſemper cupimuſque negata.* There ſeems to be a fatal and ruinous diſpoſition in the human mind, a ſort of *priapiſm* of the underſtanding, that is irritated by every interdict of natural imperfection. We would take a microſcope to look at light; we would *know* what *knowing* is, and we would *weigh heavineſs*.

51 Vain attempts to account for it.

All who are acquainted with the writings of Ariſtotle have ſome notion of his whimſical opinions on this ſubject. He imagines that the planets are conducted in their orbits by a ſort of intelligences, ὁσκερ Ψυχαι, which animate the orbs that wheel them round. Although this crude conception met with no favour in later times, another, not more reaſonable, was maintained by Leibnitz, who called every particle of matter a *monad*, and gave it a perception of its ſituation in the univerſe, of its diſtance and direction from every other, and a power and will to move itſelf in conformity to this ſituation, by certain conſtant laws. This ὁσπερ Ψυχη in the Monad is nothing but an aukward ſubſtitute for the principle of gravitation, which the learned inſiſted that Newton placed in every particle of matter as an innate power, and which they reprobated as unphiloſophical. But in what reſpect this perception and active propenſity is better, we do not perceive. It is more complex, and involves every notion that is reprehenſible in the other; and it offers no better explanation of the phenomena.

But Newton is equally anxious with other philoſophers not to aſcribe gravity to matter as an innate inherent property. In a letter to Dr Bently, he earneſtly requeſts him not to charge him with ſuch an abſurd opinion. It is an avowed principle, that nothing can *act* on any thing that is at a diſtance; and this is conſidered as an intuitive axiom. But it is ſurely very obſcure; for we cannot obtain, or at leaſt convey, clear notions of the terms in which it is expreſſed. The word *act* is entirely figurative, borrowed from animal exertions; it is therefore unlike the expreſſion of any thing intitled to the appellation of *intuitive*. If we try to expreſs it without figure, we find our confidence in its certainty greatly diminiſhed. Should we ſay that the condition of a body A cannot depend on another body B that is at diſtance from it, we believe that no perſon will ſay that he makes this aſſertion from perceiving the abſurdity of the contrary propoſition. In the demonſtration, as it is called, of the perſeverance of a body in a ſtate of reſt, the only argument that is offered is, that no cauſe can be aſſigned why it ſhould move in one direction rather than in another: but ſhould any one ſay that another body is near it, to the right hand, and that this is a ſufficient reaſon for its moving that way, we know no method by which this aſſertion can be ſhewn to be falſe.

Such, however, has been the uniform opinion of philoſophers. *Nihil movetur* (ſays Leibnitz) *niſi a contigua et moto.* The celebrated mathematician Euler having diſcovered, as he thought, the production of a preſſure, like gravity, from motion, ſays, "as motion may ariſe from preſſing powers, ſo we have ſeen that preſſing powers may ariſe from motion. We ſee that both exiſt in the univerſe. It is the buſineſs of a philoſopher to diſcover, by reaſon and obſervation, which is the origin of the other. It is incompatible with reaſon that bodies ſhould be poſſeſſed of inherent tendencies; much more that powers ſhould exiſt independently. Farther, that philoſopher muſt be reckoned to have aſſigned the true cauſes of phenomena, who demonſtrates that they ariſe from motion; for motion, once exiſting, muſt be preſerved for ever. In the preſent inſtance (a certain whimſical fact of a ball running round the inſide of a hoop) we ſee how a preſſing power may be derived from motion; but we cannot ſee how powers can exert themſelves, or be preſerved, without motion. Wherefore we may conclude that gravity, and all other powers, are derived from motion; and it is our buſineſs to inveſtigate from what motions of what bodies each obſerved power derives its origin."

Accordingly many attempts have been made to trace the planetary deflections to their origin in the motion of ſome impelling matter; but theſe attempts could not be ſucceſsful, becauſe they are all built on hypotheſes. It has been aſſumed, that there is a matter diffuſed through the celeſtial ſpaces; that this matter is in motion, and by its impulſe moves the planets: but the only reaſon that can be given for the exiſtence of this matter is the difficulty we find in explaining the planetary deflections without it. Even if the legitimate conſequences of this hypotheſis were conſiſtent with the phenomena, we have not advanced in our knowledge, nor obtained any explanation. We have only learned, that the appearances are ſuch as would have obtained had ſuch a matter exiſted and acted in this manner. The obſerved laws of the phenomena are as extenſive as thoſe of the hypotheſis; therefore it teaches us nothing but what we knew without it.

52 Inconſiſten cy of ſome of theſe ac counts wit the phenomena.

But this is not all that can be ſaid againſt thoſe attempts; *their legitimate conſequences are inconſiſtent with the phenomena.* By legitimate conſequences we mean the laws of motion. Theſe muſt be admitted, and are admitted, by the philoſopher who attempts to explain the planetary motions by impulſe. It would be ridiculous to ſuppoſe a matter to fill the heavens, having laws of impulſe different from thoſe that are obſerved by common matter, and which laws muſt be *contrived* ſo as to anſwer the purpoſe. It would be more ſimple at once to aſſign thoſe *pro re nata* laws to the planets themſelves.

Yet ſuch was the explanation which the celebrated Deſcartes offered by his hypotheſis of vortices, in which the planets were immerſed and whirled round the ſun.

53 Vortices of Deſcartes. It is aſtoniſhing that ſo crude a conception ever obtained any partiſans; yet it long maintained its authority, and ſtill has zealous defenders. Till Sir Iſaac Newton ſaw the indiſpenſable neceſſity of mathematical inveſtigation in every queſtion of matter in motion, no perſon had taken the trouble of giving any thing like a diſtinct deſcription of thoſe vortices, the circumſtances of their motion, and the manner of their action; all determined with that preciſion that is required in the explanation: for this muſt always be kept in mind, that we want an explanation of the preciſe motions *which have been obſerved*, and which will enable us to predict thoſe which are yet to happen. Men were contented with ſome vague notion of a *ſort* of ſimilarity between the effects of ſuch vortices and the planetary motions in a few general circumſtances; and were neither at the trouble to conſider how theſe motions were produced, nor how far they tallied with the phenomena. Their account of things was only fit for careleſs chat, but unworthy of the attention of a naturaliſt. But ſince this explanation came from a perſon deſervedly very eminent, it was reſpected by Newton, and he honoured it with a ſerious examination.

54 Examined by Newton. It is to this examination alone that we are indebted for all the knowledge that we have of the conſtitution of a fluid vortex, of the motions of which it is ſuſceptible, of the manner in which it can be produced, the laws of its circulation, and the effects which it can produce. We have this account in Sir Iſaac Newton's Principles of Natural Philoſophy; and it contains many very curious and intereſting particulars, which have been found of great ſervice in other branches of mechanical philoſophy. But the reſult of the examination was fatal to the hypotheſis; ſhewing that the motions which were poſſible in the vortices, and the effects which they muſt produce, are quite incompatible with the appearances in the heavens. We do not know one perſon who has acquired any reputation as a mechanician that now attempts to defend it; nor do we know of any other perſon beſides Newton who has attempted to explain mathematically how the circulation of a fluid can produce the revolution of a planet, if we except Mr Leibnitz, the celebrated rival of the Britiſh philoſopher.

55 Hypotheſis of Leibnitz. This gentleman publiſhed in the Leipſic Review in 1689, three years after the publication of the *Principia*, an attempt to explain the elliptical motion of the planets, and the deſcription of areas proportional to the times, by the impulſe of a vortex. It muſt not be paſſed over in this place, becauſe it acquired great authority in Germany, and many of that country ſtill affirm that Leibnitz is the diſcoverer of the law of planetary gravitation, and of the mechanical conſtitution of the ſolar ſyſtem. We cannot help thinking this explanation the moſt faulty of any, and a moſt diſingenuous plagiariſm from the writings of Newton.

Mr Leibnitz ſuppoſes a fluid, circulating round the ſun in ſuch a manner that the velocity of circulation in every part is inverſely as its diſtance from the ſun. (*N. B.* Newton had ſhewn that ſuch a circulation was poſſible, and that it was the only one which could be generated in a fluid by an action proceeding from the centre). Leibnitz calls this *harmonical circulation*. He ſuppoſes that the planet adopts this circulation in every part of its elliptical orbit, obeying without any reſiſtance the motion of this fluid. He does not aſcribe this to the impulſe of the fluid, ſaying *expreſsly* that the planet follows its motion, *non abrepta tamen, ſed tranquilliter quaſi natante*. The planet therefore has no tendency to perſevere in its former ſtate of motion. Why therefore does it not follow this harmonic motion exactly, and deſcribe a circle *tranquilliter natans?* This is owing, ſays Leibnitz, to its centrifugal force, by which it perſeveres in a ſtate of rectilineal motion. It has no tendency to preſerve its former velocity, but it perſeveres in its former direction. The planet therefore is not like common matter, and has laws of motion peculiar to itſelf; it was needleſs therefore to employ any impulſe to explain its motions. But to proceed: This centrifugal force muſt be counteracted in every point of the orbit. Leibnitz therefore ſuppoſes that it is alſo urged toward the centre by a ſolicitation like gravity or attraction. He calls it the *paracentric force*. He computes what muſt be its intenſity in different parts of the orbit, in order to produce an elliptical motion, and he finds that it muſt be inverſely as the ſquare of the diſtance from the centre (for this reaſon he is frequently quoted by Bernoulli, Wolff, and others, as the diſcoverer of the law of gravitation). But Leibnitz arrives at this reſult by means of ſeveral mathematical blunders, either ariſing from his ignorance at that time of fluxionary geometry, or from his perceiving that an accurate procedure would lead him to a concluſion which he did not wiſh: for we have ſeen (and the demonſtration is adopted by Leibnitz in all his poſterior writings of this kind), that if the ordinary laws of motion are obſerved, a body, actuated by this paracentric force alone, will deſcribe an ellipſe, performing both its motion of harmonic circulation, and its motion of approach to and receſs from the centre, without farther help. Therefore, if the harmonic circulation is produced by a vortex, a force inverſely as the ſquare of the diſtance from the centre, combined with the harmonic circulation, will produce a motion entirely different from the elliptical. It is demonſtrated, that the force which is neceſſary for deſcribing circles at different diſtances, with the angular velocity of the different parts of the orbit, is not in the inverſe duplicate, but in the inverſe triplicate, ratio of the diſtances. This muſt have been the nature of his paracentric force, in order to counteract the centrifugal force ariſing from the harmonic circulation.

56 Diſingenuity of the author. Therefore Leibnitz has not arrived at his concluſion by juſt reaſoning, nor can be ſaid to have diſcovered it. He ſays, *Video hanc propoſitionem innotuiſſe viro celiberrimo Iſaaco Newtono, licet non poſſim judicare quomodo ad eam pervenerit*. This is really ſomewhat like impudence. The *Principia* were publiſhed in 1686. They were reviewed at Leipſic, and the Review publiſhed in 1687. Leibnitz was at that time the principal manager of that Review. When Newton publiſhed, Leibnitz was living at Hanover, and a copy was ſent him within two months of its publication, by Nicholas Facio, long before the Review. The language of the Review has ſeveral ſingularities, which are frequent in Leibnitz's own compoſition; and few doubt of its being his writing. Beſides, this propoſition in the *Principia* had been given to the Royal Society ſeveral years before, and was in the records before 1684. Theſe were all ſeen by Leibnitz when in England, being lent him by his friend Collins.

We think that the opinion which a candid perſon muſt form of the whole is, that Leibnitz knew the propoſition, and attempted to demonſtrate it in a way that would make it paſs for his own diſcovery; or that he only knew the enunciation, without underſtanding the principles. His harmonic circulation is a clumſy way of explaining the proportionality of areas to the times; and even this circulation is borrowed from Newton's diſſertation on the Carteſian vortices, which is alſo contained in the Leipſic Review above mentioned. Leibnitz was by this time a competitor with Newton for the honour of inventing the fluxionary mathematics, and was not guiltleſs of acts of diſingenuity in aſſerting his claim. He publiſhed at the ſame time, in the ſame Review, an almoſt unintelligible diſſertation on the reſiſtance of fluids, which, when examined by one who has learned the ſubject by reading the *Principia* of Newton, affords an enigmatical deſcription of the very theory publiſhed by Newton, as a neceſſary part of his great work.

But beſides all the above objections to Leibnitz's theory of elliptical motion, we may aſk, What is this paracentric force? He calls it like gravity. This is preciſely Newton's doctrine. But Leibnitz ſuppoſes this alſo to be the impulſe of a fluid. It would have been enough had he explained the action of this fluid, without the other circulating harmonically. He defers this explanation, however, to another opportunity. It muſt have very ſingular properties: it muſt impel the planet without diſturbing the other fluid, or being diſturbed by it. He alſo defers to another opportunity the explaining how the ſquares of the periodic times of different planets are proportional to the cubes of the mean diſtances; for this is quite incompatible with the harmonic circulation of his vortex. This would make the ſquares of the periods proportional to the diſtances. He has performed neither of theſe promiſes. Several years after this he made a correction of one of his mathematical blunders, by which he deſtroyed the whole of his demonſtration. In ſhort, the whole is ſuch a heap of obſcure, vague, inconſiſtent aſſumptions, and ſo replete with mathematical errors, that it is aſtoniſhing that he had the ignorance or the effrontery to publiſh it.

57
Hypotheſis of Le Sage.

There is another hypotheſis that has acquired ſome reputation. M. le Sage of Geneva ſuppoſes, that there paſſes through every point of the univerſe a ſtream of fluid, in every direction, with aſtoniſhing velocity. He ſuppoſes that, in the denſeſt bodies, the vacuity is incomparably more bulky than the ſolid matter; ſo that a ſolid body ſomewhat reſembles a piece of wire cage-work. The quantity of fluid which paſſes through will be incomparably greater than that of the intercepted fluid; but the impulſe of the intercepted fluid will be ſenſibly proportional to the quantity of ſolid matter of the body. A ſingle body will be equally impelled in every direction, and will not be moved; but another body will intercept ſome fluid. Each will intercept ſome from the other; and the impulſe on B, that is intercepted by A, will be nearly proportional to the matter in A, and inverſely proportional to the ſquare of its diſtance from B; and thus the two bodies will appear to tend toward each other by the law of gravitation.

M. le Sage publiſhed this in a work called *Chimie Mechanique*, and read lectures on this doctrine for many years in Geneva and Paris to crowded audiences. It is alſo publiſhed by Mr Prevoſt in the Berlin Memoirs, under the name of *Lucrece Newtonien*; and there are many who conſider it as a good explanation of gravitation: for our part, we think it inconceivable. The motions of the planets, with undiminiſhed velocity, for more than four thouſand years, appears incompatible with the impelling power of this fluid, be its velocity what it will. The abſolute preciſion of the law of gravitation, which does not ſhew the ſmalleſt error during that time, is incompatible with an impulſe which cannot be *exactly* proportional to the quantity of matter, nor to the reciprocal of the ſquare of the diſtance, nor the ſame on a body moving with the rapidity of the comet of 1680 in its perihelion, as on the planet Saturn, whoſe motion is almoſt incomparably ſlower. What is the origin of the motion of this fluid? Why does it not deſtroy itſelf by mutual impulſe, ſince it is continually paſſing through every point? &c.

58
Ether of Newton ſolves no difficulties.

We have already obſerved that Newton expreſſed the ſame anxiety to avoid the ſuppoſition of action among bodies at a diſtance. *He* alſo *ſeemed* to ſhow ſome diſpoſition to account for gravitation by the action of a contiguous fluid. This is the ſubterfuge ſo much recurred to by precipitate ſpeculatiſts, by the name of the *ether of Sir Iſaac Newton*. He ſuppoſes it highly elaſtic, and much rarer in the pores of bodies, and in their vicinity, than at a diſtance; therefore exceedingly rare in the ſun, and denſer as we recede from him. Being highly elaſtic, and repelled by all bodies, it muſt impel them to that ſide on which it is moſt rare; therefore it muſt impel them toward the ſun. This is enough of its general conſtitution to enable us to judge of its fitneſs for Newton's purpoſe. It is wholly unfit; for ſince it is fluid, unequally denſe and elaſtic, its particles are not in contact. Particles that are elaſtic, and in a ſtate of compreſſion, and in contact, cannot be fluid; they muſt be like ſo many blown bladders compreſſed in a box; therefore they are not in contact; therefore they are elaſtic by mutual repulſion; that is, by acting on each other at a diſtance. It is indifferent whether this diſtance is a million of miles, or the millionth part of a hair's breadth; therefore this fluid does not free Newton from the ſuppoſition which he wiſhes to avoid. Nay, it can be demonſtrated, that in order to form a fluid which ſhall vary in denſity from the ſun to the extremity of the ſolar ſyſtem, there muſt be a mutual repulſion *extending to that diſtance*. This is introducing millions of millions of the very difficulties which Newton wiſhed to avoid; for each particle preſents the ſame difficulty with a planet.

We would now aſk theſe atomical philoſophers, why they have, in all ages, been ſo anxious to trace the celeſtial motions to the effects of impulſe? They imagine that they have a clear perception of the communication of motion by impulſe, while their perception of the production of it in any other way is obſcure. Seeing, in a very numerous and familiar collection of facts, that motion *is* communicated by impulſe, they think that it is communicated in no other way, and that impulſe is the only moving power in nature.

59
Our notio
of impulſe
not cleare
than of gr
vitation.

But is it true that our notion of impulſe is more clear than that of gravitation? Its being more familiar is no argument. A cauſe may be real, though it has exerted itſelf but once ſince the beginning of time. In no caſe do we *perceive* the exertion of the cauſe; we only perceive the change of motion. The conſtitution of our mind

mind makes us conſider this as an effect, indicating a cauſe which is inherent in that body which we always ſee aſſociated with that change. Granting that our perception of the perſeverance of matter in its ſtate of motion is intuitive, it by no means follows that the body A in motion muſt move the body B by ſtriking it. The moment it ſtrikes B, all the metaphyſical arguments for A's continuance in motion are at an end, and they are not in the leaſt affected by the ſuppoſition that A and B ſhould continue at reſt after the ſtroke; and we may defy any perſon to give an argument which will prove that B will be moved; nay, the very exiſtence of B may, for any thing we know to the contrary, be a ſufficient reaſon for the ceſſation of the motion of A. The production of motion in B, by the impulſe of A, muſt therefore ſtand on the ſame foundation with every other production of motion. It indicates a moving power in A; but this inherent power ſeems to have no dependence on the motion of A: (See what is contained in n° 81. of the article PHYSICS, and n° 67. of OPTICS of the *Encycl.*) We ſee there a motion produced in B without impulſe, and taken from A, ſimilar in every reſpect to every caſe of impulſe; and we ſee that the motion of A is neceſſary for producing ſuch a motion in B as is obſerved in all caſes of impulſe, merely in order that the moving power, which is inherent in A, whether it be in reſt or in motion, may act during a ſufficient time. Our confidence in the communication of motion, in the caſe mentioned there, is derived entirely from experience, which informs us that A poſſeſſes a moving power totally different from impulſe. Our belief of the impelling power of matter therefore does not neceſſarily flow from our intuitive knowledge of the perſeverance of matter, although it gives us the knowledge of this perſeverance. It is like a mathematical demonſtration, a road to the diſcovery of the property of figure, but not the cauſe of that property. The impulſion of matter is merely a fact, like its gravitation, and we know no more of the one than of the other.

It is not a clearer perception, therefore, which has procured this preference of impulſion as the ultimate explanation of motion, and has given riſe to all the fooliſh hypotheſes of planetary vortices, ethers, animal ſpirits, nervous fluids, and many other crude contrivances for explaining the abſtruſe phenomena of nature.

60 mpulſe arely obſerved.

Nor does it deſerve any preference on account of its greater familiarity. Juſt the contrary; for one fact of undoubted impulſe, we ſee millions where no impulſe is obſerved. Conſider the motion produced by the exploſion of gunpowder. Where is the original impulſe? Suppoſe the impulſe of the firſt ſpark of fire to be immenſe, how comes it that a greater impulſe is produced by a greater quantity of gunpowder, a greater quantity of quieſcent matter? The ultimate impulſe on the bullet ſhould be leſs on this account. Here are plain exertions of moving powers, which are not reducible to impulſe. Conſider alſo the facts in animal motion. Reflect alſo, that there has been more motion, without any obſerved impulſe, produced in the waters of a river ſince the beginning of the world, than by all the impulſe that man has ever obſerved. Add to theſe, all the motions in magnetiſm, electricity, &c. Impulſe is therefore a phenomenon which is comparatively rare.

Have we ever obſerved motion communicated by pure impulſe, without the action of forces at a diſtance? This appears to us very doubtful. Every one acquainted with Newton's diſcoveries in optics will grant, that the colours which appear between two object-glaſſes of long teleſcopes, when they are preſſed together, demonſtrate that the glaſſes do not touch each other, except in the place where there is a black ſpot. It requires more than a thouſand pounds to produce a ſquare inch of this ſpot. Therefore every communication of motion between two pieces of glaſs, which can be produced by one of them ſtriking the other, is produced without impulſe, unleſs their mutual preſſure has exceeded 1000 pounds on the ſquare inch of the parts which act on each other. Nay, ſince we ſee that a black ſpot appears on the top of a ſoap bubble, in the middle of the coloured rings, we learn that there is a certain thickneſs at which light ceaſes to be viſibly reflected; therefore the black ſpot between the glaſſes does not prove that they touch in that part; therefore we cannot ſay that any force whatever can make them touch. The ultimate repulſion may be inſuperable. If this be the caſe, the production of motion by impulſe is, in every inſtance, like the production of motion between the magnets in n° 81. of the article PHYSICS in the *Encycl.* and is of the ſame kind with the production of motion by gravity.

61 Intervening fluids multiply difficulties.

Therefore no explanation of gravitation can be derived from any hypotheſis whatever of intervening fluids: They only ſubſtitute millions of bodies for one, and ſtill leave the action *e diſtanti* the ſame difficulty as before. It is not in the leaſt neceſſary that we ſhall be able to conceive how a particle of matter can be influenced by another at a diſtance; if we have diſcovered in every inſtance the preciſe degree and direction of the effect of this influence, we have made a moſt important addition to our knowledge of nature; and our ſucceſs in the caſe of the power of gravity ſhould make us aſſiduous in our endeavours to diſcover, from the phenomena, the laws which regulate the other actions *e diſtanti*, which obſervation is daily finding out. A knowledge equally accurate of the law of magnetic and electric action may enable us to give theories of magnetiſm and electricity equally exact with the Newtonian theory of gravitation.

Having, we hope, evinced the truth of this theory, by following out the inveſtigations to which Newton was gradually led, we might proceed to conſider, in order, the complicated and ſubordinate phenomena which depend on it. The lunar and planetary inequalities are the ſubjects that naturally come firſt in our way; but they have already been explained in all the detail that this conciſe account will admit, as they occurred to Newton as teſts of the truth of his conjecture. If the law be ſuch as he ſuſpected, its conſequences muſt be ſo and ſo; if the celeſtial motions do not agree with them, the law muſt be rejected. We ſhall not repeat any thing therefore on this head, but confine our obſervations to ſuch applications of the theory of univerſal gravitation, as newly diſcovered objects, or the improvement of aſtronomical obſervation and of fluxionary analyſis, have enabled us to make ſince the time of Newton.

The ſubſerviency of the eclipſes of Jupiter's ſatellites to geography and navigation had occaſioned their motions to be very carefully obſerved, ever ſince theſe uſes of them were firſt ſuggeſted by Galileo, and their theory is as far advanced as that of the primary planets. It has peculiar difficulties. Being very near to Jupiter, the great deviation of his figure from perfect ſphericity makes the relation between their diſtances from his centre and their gravitations toward it vaſtly complicated. But this only excited the mathematicians ſo much the more to improve their analyſis; and they ſaw, in this little ſyſtem of Jupiter and his attendants, an epitome of the ſolar ſyſtem, where the great rapidity of the motions muſt bring about in a ſhort time every variety of configuration or relative poſition, and thus give us an example of thoſe mutual diſturbances of the primary planets, which require thouſands of years for the diſcovery of their periods and limits. We have derived ſome very remarkable and uſeful pieces of information from this inveſtigation; and have been led to the diſcovery of the eternal durability of the ſolar ſyſtem, a thing which Newton greatly doubted of.

62
Eternal durability of the ſolar ſyſtem

Mr Pound had obſerved long ago, that the irregularities of the three interior ſatellites were repeated in a period of 437 days; and this obſervation is found to be juſt to this day.

247	revolutions of the firſt occupy	437d.	3h.	44′
123	ſecond	437	3	42
61	third	437	3	36
26	fourth	435	14	16

This naturally led mathematicians to examine their motions, and ſee in what manner their relative poſitions or configurations, as they are called, correſponded to this period: and it is found, that the mean longitude of the firſt ſatellite, *minus* thrice the mean longitude of the ſecond, *plus* twice the mean longitude of the third, always made 180 degrees. This requires that the mean motion of the firſt, added to twice that of the third, ſhall be equal to thrice the mean motion of the ſecond. This correſpondence of the mean motions is of itſelf a ſingular thing, and the odds againſt its probability ſeems infinitely great; and when we add to this the particular poſitions of the ſatellites in any one moment, which is neceſſary for the above conſtant relation of their longitudes, the improbability of the coincidence, as a thing quite fortuitous, becomes infinitely greater. Doubts were firſt entertained of the coincidence, becauſe it was not indeed accurate to a ſecond. The reſult of the inveſtigation is curious. When we follow out the conſequences of mutual gravitation, we find, that although neither the primitive motions of projection, nor the points of the orbit from which the ſatellites were projected, were *preciſely* ſuch as ſuited theſe obſerved relations of their revolutions and their contemporaneous longitudes; yet, if they differed from them only by very minute quantities, the mutual gravitations of the ſatellites would in time bring them into thoſe poſitions, and thoſe ſtates of mean motion, that would induce the obſerved relations; and when they are once induced, they will be continued for ever. There will indeed be a ſmall equation, depending on the degree of unſuitableneſs of the firſt motions and poſitions; and this cauſes the whole ſyſtem to oſcillate, as it were, a little, and but a very little way on each ſide of this exact and permanent ſtate. The permanency of theſe relations will not be deſtroyed by any ſecular equations ariſing from external cauſes; ſuch as the action of the fourth ſatellite, or of the ſun, or of a reſiſting medium; becauſe their mutual actions will diſtribute this equation as it did the original error.

This curious reſult came into view only by degrees, as analyſis improved and the mathematicians were enabled to manage more complicated formulas, including more terms of the infinite ſerieſes that were employed to expreſs the different quantities. It is to M. de la Grange that we are indebted for the completion of the diſcovery of the permanency of the ſyſtem in a ſtate very little different from what obtains in any period of its exiſtence. Although this required all the knowledge and addreſs of this great mathematician, in the management of the moſt complicated analyſis, the evidence of its truth may be perceived by any perſon acquainted with the mere elements of fluxionary geometry. The law of the compoſition of forces enables us to expreſs every action of the mutual forces of the ſun and planets by the ſines and coſines of circular arches, which increaſe with an uniform motion, like the perpetual lapſe of time. The nature of the circle ſhows, that the variations of the ſines and coſines are proportional to the coſines and ſines of the ſame arches. The variations of their ſquares, cubes, or other powers, are proportional to the ſines or coſines of the doubles or triples, or other multiples of the ſame arches. Therefore ſince the infinite ſerieſes which expreſs thoſe actions of forces, and their variations, include only ſines and coſines, with their powers and fluxions, it follows, that all accumulated forces, and variations of forces, and variations of variations, through infinite orders, are ſtill expreſſible by repeated ſums of ſines or coſines, correſponding to arches which are generated by going round and round the circle. The analyſt knows that theſe quantities become alternately poſitive and negative; and therefore, in whatever way they are compounded by addition of themſelves, or their multiples, or both, we muſt always arrive at a period after which they will be repeated with all their intermediate variations. It may be extremely difficult, it may be impoſſible, in our preſent ſtate of mathematical knowledge, to aſcertain all thoſe periods. It has required all the efforts of all the geniuſes of Europe to manage the formulas which include terms containing the fourth and fifth powers of the eccentricities of the planetary orbits. Therefore the periods which we have already determined, and the limits to which the inequalities expreſſed by ſecular equations arrive, are ſtill ſubjected to ſmaller corrections of incomparably longer periods, which ariſe from the terms neglected in our formulas. But the correction ariſing from any neglected term has a period and a limit; and thus it will happen that the ſyſtem works itſelf into a ſtate of permanency, containing many intervening apparent anomalies. The elliptical motion of the earth contains an anomaly or deviation from uniform circular motion; the action of Jupiter produces a deviation from this elliptical motion, which has a period depending on the configuration of the three bodies; Saturn introduces a deviation from this motion, which has alſo a period; and ſo on.

There is another accurate adjuſtment of motions which has attracted attention, as a thing in the higheſt degree improbable, in events wholly independent on each other. This is the exact coincidence of the period of the moon's revolution round the earth with that of her rotation round her own axis. The ellipticity or oval ſhape of the moon differs ſo inſenſibly from a ſphere, that

that if the original rotation had differed conſiderably from the period of revolution, the pendular tendency to the earth could never have operated a change: but if the difference between thoſe two motions was ſo ſmall that the pendular tendency to the line joining the centres of the earth and moon was able to overcome it after ſome time, the pole of the lunar ſpheroid would deviate a little from the line joining the earth and moon, and then be brought back to it with an accelerated motion; would paſs it as far on the other ſide, and then return again, vibrating perpetually to each ſide of the mean poſition of the *radius vector*. The extent of this vibration would depend on the original difference between the motion of rotation and the mean motion of revolution. This difference muſt have been very ſmall, becauſe this *pendular vibration* is not ſenſible from the earth. The obſerved LIBRATION of the moon is preciſely what ariſes from the inequality of her orbital motion. For the ſame reaſons, the effects of the ſecular equations of the moon (which would, in the courſe of ages, have brought her whole ſurface into our view, had her rotation been ſtrictly uniform) are counteracted by her pendular tendency, which has a force ſufficient to alter her rotation by nearly the ſame ſlow and inſenſible changes that obtain in her mean motions. The ſame cauſes alſo preſerve the nodes of her equator and of her orbit in the ſame points of the ecliptic. The complete demonſtration of this is perhaps the moſt delicate and elegant ſpecimen that has been given of the modern analyſis. We owe it to M. de la Grange: and he makes it appear that the figure of the moon is not that which a fluid ſphere would acquire by its gravitation to the earth; it muſt be the effect of a more conſiderable ellipticity, or internal inequality of denſity.

63
epends on
e law of
inetary
flection,

This permanency of the ſyſtem, within very narrow limits of deviation from its preſent ſtate, depends entirely on the law of planetary deflection. Had it been directly or inverſely as the diſtance, the deviations would have been ſuch as to have quickly rendered it wholly unfit for its preſent purpoſes. They would have been very great, had the planetary orbits differed much from circles; nay, had ſome of them moved in the oppoſite direction. The ſelection of this law, and this form of the orbits, ſtrikes the mind of a Newton, and indeed any heart poſſeſſed of ſenſibility to moral or intellectual excellence, as a mark of wiſdom prompted by benevolence. But De la Place and others, infected with the *Theophobia Gallica* engendered by our licentious deſires, are eager to point it out as a mark of fataliſm. They ſay that it is eſſential to all qualities that are diffuſed from a centre to diminiſh in the inverſe duplicate ratio of the diſtance. But this is falſe, and *very falſe*: it is a mere geometrical conception. We indeed ſay, that the denſity of illumination decreaſes in this proportion; but who ſays that this is a quality? Whether it be conſidered as the emiſſion of luminous corpuſcles, or an undulation of an elaſtic fluid, it is not a quality emanating from a centre: and even in this eſtimation, it ſeems gratuitous, whether we ſhall conſider the baſe of the luminous pyramid, or its whole contents, as the expreſſion of the quantity. Nay, if all qualities muſt diminiſh at this rate, all action *e diſtanti* muſt do the ſame; for when the diſtances bear any great proportion to the diameters of the particles, their action deviates inſenſibly from this law, and is perceived only by the accumulation of its effects after a long time. It is only thus that the effects of the oblate figure of Jupiter are perceived in the motion of his ſatellites. The boaſted ſound philoſophy, which ſees fatal neceſſity where the *moſt ſucceſsful ſtudents of nature* ſaw moral excellence, has derived very little credit or title to the name of *wiſdom*, by letting looſe all thoſe propenſities of the human heart which are eſſentially deſtructive of ſocial happineſs. Theſe propenſities were always known to lurk in the heart of man; and thoſe ſurely were the wiſeſt who laboured to keep them in check by the influence of moral principles, and particularly by cheriſhing that diſpoſition of the human heart which prompts us to ſee contrivance wherever we ſee nice and refined adjuſtment of means to ends; and, from the admirable beauty of the ſolar ſyſtem, to cry out,

> " Theſe are thy glorious works, Parent of good!
> " Almighty, thine this univerſal frame,
> " Thus wond'rous fair; thyſelf how wond'rous then!
> " Unſpeakable, who ſitt'ſt above theſe heavens,
> " To us inviſible, or dimly ſeen
> " In theſe thy loweſt works; yet theſe declare
> " Thy goodneſs beyond thought, and power divine."
> *Par. Loſt*, b. v.
>
> " But wandering oft, with brute unconſcious gaze,
> " Man marks not THEE, marks not the mighty hand
> " That, ever buſy, wheels the ſilent ſpheres."
> THOMSON.

64
And evince the wiſdom of the Creator.

65
Saturn's ring.

The moſt important addition (in a philoſophical view) that has been made to aſtronomical ſcience ſince the diſcovery of the aberration of light and the nutation of the earth's axis, is that of the rotation of Saturn's ring. The ring itſelf is an object quite ſingular; and when it was diſcovered that all the bodies which had any immediate connection with a planet were heavy, or gravitated toward that planet, it became an intereſting queſtion, what was the nature of this ring? what ſupported this immenſe arch of heavy matter without its reſting on the planet; what maintains it in perpetual concentricity with the body of Saturn, and maintains its ſurface in one invariable poſition?

The theory of univerſal gravitation tells us what things are poſſible in the ſolar ſyſtem; and our conjectures about the nature of this ring muſt always be regulated by the circumſtance of its gravitation to the planet. Philoſophers had at firſt ſuppoſed it to be a luminous atmoſphere, thrown out into that form by the great centrifugal force ariſing from a rotation; but its well defined edge, and, in particular, its being two very narrow rings, extremely near each other, yet perfectly ſeparate, rendered this opinion of its conſtitution more improbable.

66
Diſcovery of Dr Herſchel relating to it.

Dr Herſchel's diſcovery of brighter ſpots on its ſurface, and that thoſe ſpots were permanent during the whole time of his obſervation, ſeems to make it more probable that the parts of the ring have a ſolid connection. Mr Herſchel has diſcovered, by the help of thoſe ſpots, that the ring turns round its axis, and that this axis is alſo the axis of Saturn's rotation. The time of rotation is 10h. 32¼'. But the other circumſtances are not narrated with the preciſion ſufficient for an accurate compariſon with the theory of gravity. He informs us, that the radii of the four edges of the ring are 590, 751, 774, 830, of a certain ſcale, and that the angle

angle ſubtended by the ring at the mean diſtance from the earth is $46\frac{2}{3}''$. Therefore its elongation is $23\frac{1}{3}'$. The elongation of the ſecond Caſſinian ſatellite is 56′, and its revolution is 2d. 17h. 44′. This ſhould give, by the third law of Kepler, 17h. 10′ for the revolution of the outer edge of the ring, or rather of an atom of that edge, in order that it may maintain itſelf in equilibrio. The ſame calculation applied to the outer edge of the inner ring gives about 13h. 36′; and we obtain 11h. 16′ for the inner edge of this ring. Such varieties are inconſiſtent with the permanent appearance of a ſpot. We may ſuppoſe the ring to be a luminous fluid or vapour, each particle of which maintains its ſituation by the law of planetary revolution. In ſuch a ſtate, it would conſiſt of concentric ſtrata, revolving more ſlowly as they were more remote from the planet, like the concentric ſtrata of a vortex, and therefore having a relative motion incompatible with the permanency of any ſpot. Beſides, the rotation obſerved by Herſchel is too rapid even for the innermoſt part of the ring. We think therefore that it conſiſts of cohering matter, and of conſiderable tenacity, at leaſt equal to that of a very clammy fluid, ſuch as melted glaſs.

We can tell the figure which a fluid ring muſt have, ſo that it may maintain its form by the mutual gravitation of its particles to each other, and their gravitation to the planet. Suppoſe it cut by a meridian. It may be in equilibrio if the ſection is an ellipſe, of which the longer axis is directed to the centre of the planet, and very ſmall in compariſon with its diſtance from the centre of the planet, and having the revolution of its middle round Saturn, ſuch as agrees with the Keplerean law. Theſe circumſtances are not very conſiſtent with the dimenſions of Saturn's inner ring. The diſtance between the middle of its breadth and the centre of Saturn is 670, and its breadth is 161′, nearly one-fourth of the diſtance from the centre of Saturn. De la Place ſays, that the revolution of the inner ring obſerved by Herſchel is very nearly that required by Kepler's law: but we cannot ſee the grounds of this aſſertion. The above compariſons with the ſecond Caſſinian ſatellite ſhows the contrary. The elongation of that ſatellite is taken from Bradley's obſervations, as is alſo its periodic time. A ring of detached particles revolving in 10h. $32\frac{1}{2}'$ muſt be of much ſmaller diameter than even the inner edge of Saturn's ring. Indeed the quantity of matter in it might be ſuch as to increaſe the gravitation conſiderably; but this would be ſeen by its diſturbing the ſeventh and ſixth ſatellites, which are exceedingly near it. We cannot help thinking therefore that it conſiſts of matter which has very conſiderable tenacity. An equatorial zone of matter, tenacious like melted glaſs, and whirled briſkly round, might be thrown off, and, retaining its great velocity, would ſtretch out while whirling, enlarging in diameter and diminiſhing in thickneſs or breadth, or both, till the centrifugal force was balanced by the united force of gravity and tenacity. We find that the equilibrium will not be ſenſibly diſturbed by conſiderable deviations, ſuch as unequal breadth, or even want of flatneſs. Such inequalities appear on this ring at the time of its diſparition, when its edge is turned to the ſun or to us. The appearances of its different ſides are then conſiderably different.

67
Its probable conſiſtency

Such a ring or rings muſt have an oſcillatory motion round the centre of Saturn, in conſequence of their mutual action, and the action of the ſun, and their own irregularities: but there will be a certain poſition which they have a tendency to maintain, and to which they will be brought back, after deviating from it, by the ellipticity of Saturn, which is very great. The ſun will occaſion a nutation of Saturn's axis and a preceſſion of his equinoxes, and this will drag along with it both the rings and the neighbouring ſatellites.

The atmoſphere which ſurrounds a whirling planet cannot have all its parts circulating according to the third law of Kepler. The mutual attrition of the planet, and of the different ſtrata, ariſing from their different velocities, muſt accelerate the ſlowly moving ſtrata, and retard the rapid, till all acquire a velocity proportional to their diſtance from the axis of rotation; and this will be ſuch that the momentum of rotation of the planet and its atmoſphere remains always the ſame. It will ſwell out at the equator, and ſink at the poles, till the centrifugal force at the equator balances the weight of a ſuperficial particle. The greateſt ratio which the equatorial diameter can acquire to the polar axis is that of four to three, unleſs a coheſive force keeps the particles united, ſo that it conſtitutes a liquid, and not an elaſtic fluid like air; and an elaſtic fluid cannot form an atmoſphere bounded in its dimenſions, unleſs there be a certain rarity which takes away all elaſticity. If the equator ſwells beyond the dimenſion which makes the gravitation balance the centrifugal force, it muſt immediately diſſipate.

If we ſuppoſe that the atmoſphere has extended to this limit, and then condenſes by cold, or any chemical or other cauſe different from gravity, its rotation neceſſarily augments, preferring its former momentum, and the limit will approach the axis; becauſe a greater velocity produces a greater centrifugal force, and requires a greater gravitation to balance it. Such an atmoſphere may therefore deſert, in ſucceſſion, zones of its own matter in the plane of its equator, and *leave* them revolving in the form of rings. It is not unlikely that the rings of Saturn may have been furniſhed in this very way; and the zones having acquired a common velocity in their different ſtrata, will preſerve it; and they are ſuſceptible of irregularities ariſing from local cauſes at the time of their ſeparation, which may afford permanent ſpots.

68
And origi

We think that the rotation of Saturn's ring affords ſome hopes of deciding a very important queſtion about the nature of light. If light be the propagation of elaſtic undulations, its velocity depends entirely on the elaſticity and denſity of the fluid: but if it be the emiſſion of corpuſcles, their velocity may be affected by other cauſes. The velocity of Saturn's ring is $\frac{50}{63}$ of that of the earth in its orbit, and therefore about $\frac{1}{100000}$ of the velocity of light. The weſtern extremity (to us in the northern regions) is moving from us, and the eaſtern is moving toward us. If light, by which we ſee it, be reflected like an elaſtic ball from an elaſtic body, there will be an exceſs in the velocity of the light by which we ſee the eaſtern limb above the velocity of the light by which we ſee the weſtern limb. This exceſs will be $\frac{1}{2500}$ of the mean velocity of light. This ſhould be diſcovered by a difference in the refraction of the two lights. If an acromatic priſm could be made to refract fourteen degrees, and if Saturn be viewed through a teleſcope with this priſm placed before it, there ſhould be

69
It may f
niſh the

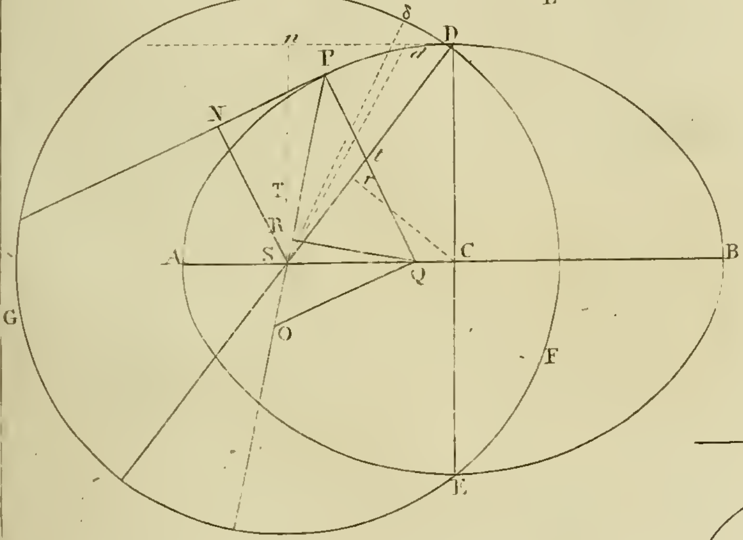

Fig. 3.

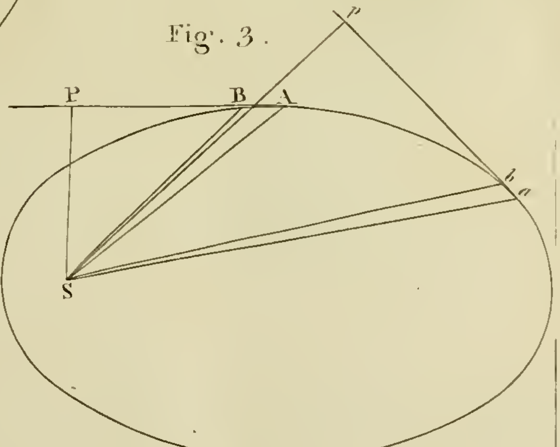

Fig. 6.

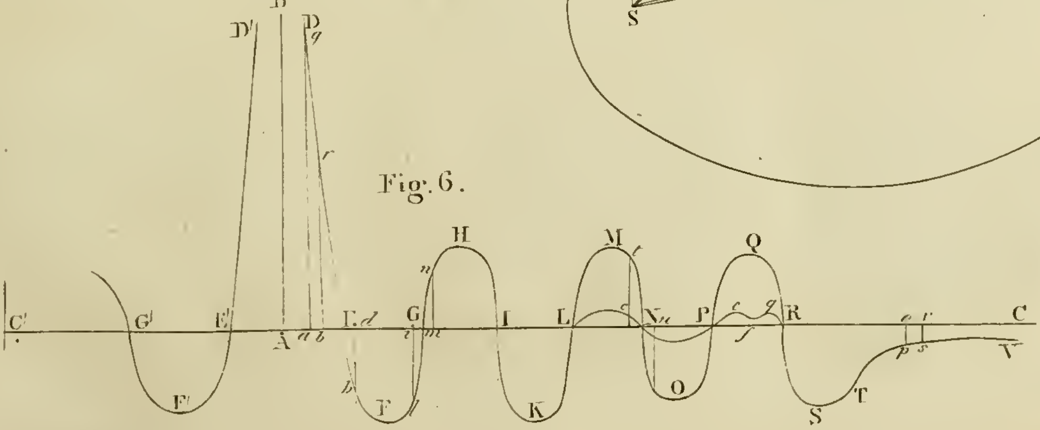

be a change of ſhape amounting to ſixteen ſeconds; if the axis of the priſm be parallel to the longer axis of the ring, it will diſtort it prodigiouſly, and give it an oblique poſition.

A ſimilar effect will be produced by placing the priſm between the eye-glaſs and the image in the focus of the object-glaſs.

Our expectation is founded on this unqueſtionable principle in dynamics, that when a particle of light paſſes through the active ſtratum of a tranſparent body which refracts light toward the perpendicular, the addition made to the ſquare of its velocity by the refracting forces is equal to the ſquare of the velocity which thoſe forces would communicate to a particle at reſt on the ſurface of this refracting ſtratum of the tranſparent body. Therefore if the velocity of the incident light be increaſed, the ratio of the ſine of incidence to the ſine of refraction will be diminiſhed. It is conſonant to common ſenſe, that when the incident light has a greater velocity, it paſſes more rapidly through the attracting ſtratum, and a ſmaller addition is made to the velocity. When the velocity of the incident light is 10000 times greater than that of the earth's annual motion, the ſine of incidence is to the ſine of refraction in glaſs as 20 to 31, or as 10000 to 15500. If this be increaſed $\frac{1}{2500}$, making it 10004, the ratio will be that of 10004 to 15502,62, or of 10000 to 15496,4. The difference between the refractions of the light from the eaſtern and weſtern extremities of the ring will be, to all ſenſe, the ſame, if the velocity of the one be diminiſhed to 9998, and the other increaſed to 10002.

70 bable ſon why ſee no noſphere out the on.

We may juſt add here, by the way, that the action of another body may conſiderably change the conſtitution of this atmoſphere. Thus, ſuppoſing that the moon had originally an atmoſphere, the limit will be that diſtance from the moon where the centrifugal force, ariſing from the moon's rotation, added to the gravitation to the earth, balances the gravitation to the moon. If the moon be $\frac{1}{59}$th of the earth, this limit will be about $\frac{1}{9}$th of the moon's diſtance from the earth. If at this diſtance the elaſticity of the atmoſphere is not annihilated by its rarefaction, it will be all taken off by the earth, and accumulate round it. This may be the reaſon why we ſee no atmoſphere about the moon.

What has been ſaid in the article Tide *(Encycl.)*, will explain the trade-winds on the earth and in Jupiter and Saturn. On the earth they are increaſed by the expanſion of the air by heat. This cauſes it to riſe in the parts warmed by the ſun, and flow off toward the poles, where it is again cooled and condenſed. The under ſtratum of colder and denſer air is continually flowing in from the poles. This having leſs velocity of circulation than the equatorial parts of the earth, muſt have a relative motion contrary to that of the earth, or from eaſt to weſt, and this muſt augment the current produced by gravitation.

71 All the mechanical phenomena of the ſolar ſyſtem flow from one ſimple principle.

Thus we ſee that all the mechanical phenomena of the ſolar ſyſtem, whether relating to the revolutions round the various centres of gravitation, or to the figure of the planets and the oſcillations of the fluids which cover them, or to the rotations round their reſpective axes—are neceſſary conſequences of one ſimple principle of a gravitation in every particle, decreaſing in the reciprocal duplicate ratio of the diſtance. We ſee that this, combined with a primitive projection, will produce every motion that we obſerve. It was not neceſſary, as Copernicus imagined, to impreſs three motions on the earth: one, by which it was made to revolve round the ſun; a ſecond, cauſing it to turn round an axis inclined to that of its orbit; and a third, by which this axis deſcribed that conic ſurface which forms the preceſſion of the equinoxes. One impulſe, not paſſing through the centre of the earth, nor in the plane of the ecliptic, will produce the two firſt motions, and the protuberant matter produced by the rotation will generate the third motion, by the tendency of its parts to the other heavenly bodies. Without this principle, the elliptic motion of the planets and comets, their various inequalities, ſecular or periodical, thoſe of the moon and of the ſatellites of Jupiter, the preceſſion of the equinoxes, the nutation of the earth's axis, the figure of the earth, the undulations of its ocean—all would have been imperfectly known, as matters of fact, wholly different from each other, and ſolitary and unconnected. It is truly deſerving admiration, that ſuch an immenſe variety of important phenomena flow ſo palpably from one principle, of ſuch ſimplicity, and ſuch univerſality, that no phenomenon is now left out unexplained, and predicted with a certainty almoſt equal to actual obſervation.

Quæ toties animos veterum torſêre ſophorum,
Quæque ſcholas hodie rauco certamine vexant,

ſtrothemata

ASTROTHEMATA, the places or poſitions of the ſtars, in an aſtrological ſcheme of the heavens.

ASTROTHESIA, is uſed by ſome for a conſtellation or collection of ſtars in the heavens.

ASTRUM, or Astron, a conſtellation or aſſemblage of ſtars: in which ſenſe it is diſtinguiſhed from *Aſter*, which denotes a ſingle ſtar. Some apply the term, in a more particular ſenſe, to the Great Dog, or rather to the large bright ſtar in his mouth.

ymmetry.

ASYMMETRY, the want of proportion, otherwiſe

called *incommenſurability*, or the relation of two quantities which have no common meaſure, as between 1 and $\sqrt{2}$, or the ſide and diagonal of a ſquare.

Aſymptotes.

ASYMPTOTES (ſee *Encycl.*) are, by ſome, diſtinguiſhed into various orders. The aſymptote is ſaid to be of the firſt order, when it coincides with the baſe of the curvilinear figure; of the ſecond order, when it is a right line parallel to the baſe; of the third order, when it is a right line oblique to the baſe; of the fourth order, when it is the common parabola, having its axis

axis perpendicular to the baſe; and, in general, of the $n + 2$ order, when it is a parabola whoſe ordinate is always as the n power of the baſe. The aſymptote is oblique to the baſe, when the ratio of the firſt fluxion of the ordinate to the fluxion of the baſe approaches to an aſſignable ratio, as its limit; but it is parallel to the baſe, or coincides with it, when this limit is not aſſignable.

ATTAR OF ROSES. See *Roses, Otter of*, both in the Encyclopædia and in this Supplement.

AVANT FOSS, or *Ditch of the Counterſcarp*, in fortification, is a wet ditch ſurrounding the counterſcarp on the outer ſide, next to the country, at the foot of the glacis. It would not be proper to have ſuch a ditch if it could be laid dry, as it would then ſerve as a lodgment for the enemy.

AUBIGNE. See STUART in this Supplement.

AUMIL, in Bengal, a native collector or manager of a diſtrict on the part of government.

AUTENIQUA, a large and beautiful country in Africa, lying to the eaſt of the Cape of Good Hope, and inhabited, part of it, by Dutch coloniſts. The word *Auteniqua* ſignifies, in the Hottentot language, "a man loaded with honey:" a name which is not improperly given to the country, ſince, as you enter it from the Cape, you cannot proceed a ſtep without ſeeing a thouſand ſwarms of bees. The flowers on which they feed ſpring up in myriads; and your attention is engaged, and your courſe ſuſpended, by the mixed odours which exhale from them, by their colours and variety, and by the pure cool air which you breathe. Nature has made theſe enchanting regions like fairy land. The calyxes of all the flowers abound with excellent juices, from which the bees extract the honey that they everywhere depoſite in hollow rocks and trees.

This country was viſited in 1782 by M. Vaillant, who calls it the moſt delightful region in the univerſe; and ſays, that, as he approached it, he beheld, from the top of a very high mountain, an immenſe valley, adorned with agreeable hills, variegated in an infinite number of ſhapes, and extending in an undulating manner as far as the ſea; whilſt enamelled meads, and the moſt beautiful paſtures, ſtill added to the magnificent ſcene. It abounds with ſmall rivulets, which, flowing down from the mountains, run into the ſea through an hundred different channels. The water of theſe rivulets has the colour of Madeira wine, and a ferruginous taſte; but our traveller did not examine whether this taſte and colour proceed from their flowing through ſome mine in their paſſage, or from the roots and leaves of trees which they carry along with them.

The whole of Auteniqua, from the chain of mountains which divides it from the country of that race of Hottentots called *Gonaquas* to the ſea, is inhabited by ſeveral planters, who rear a number of cattle, make butter, cut down timber, and collect honey; all of which they tranſport to the Cape: but it appears that they make not the moſt of their ſituation. "Can it be believed (ſays M. Vaillant), that the directors of the Company, for their own uſe, ſhould order ſhips to be ſent every year from Amſterdam, loaded with planks and boards of every kind, whilſt in this country there are immenſe foreſts, and the moſt beautiful trees in the world? This abſurdity, however, is not at all aſtoniſhing. The Company gratuitouſly furniſhes the governor and all the officers with whatever wood they have occaſion for; and it is delivered to them at their houſes without any expence. The governor therefore has no *perſonal* intereſt to extend his views to this part of the adminiſtration, and to aboliſh an abuſe ſo prejudicial to the colony."

But the coloniſts themſelves muſt be a very indolent and ſtupid kind of people; ſince, if our traveller deſerves credit, they neglect advantages with which the perſonal intereſt of the governor cannot poſſibly interfere. "I was filled with indignation (ſays M. Vaillant) to ſee people, who have wood within their reach, employ it in commerce, and not have the courage to build for themſelves habitable houſes. They live in wretched hovels, conſtructed of wicker-work, daubed over with clay; the ſkin of a buffalo, fixed at the four corners to as many ſtakes, ſerves them for a bed; and the door, which is at the ſame time a window, is ſhut by a mat; while two or three mutilated chairs, a few pieces of plank, a kind of table, and a pitiful box of two feet ſquare, form all the furniture of theſe colonial habitations. Thus is the picture of the moſt profound miſery contraſted with the charms of this terreſtrial paradiſe; for the beauties of theſe regions extend even beyond Auteniqua. The people, however, though their houſes be bad, live well. They have game and ſalt-water fiſh in abundance; and enjoy excluſively, over all the other cantons of theſe colonies, the advantage of having, for the whole year without interruption, vegetables of every kind in their gardens. For this they are indebted to the excellence of the ſoil, and to its being naturally watered by ſmall ſtreams, which croſs each other in a thouſand different directions, and, as one may ſay, lay the four ſeaſons under contribution to fertilize Auteniqua. Theſe ſtreams, which frequently overflow their banks, but never dry up, proceed from a cauſe well known; the high mountains towards the eaſt, which are covered with foreſts, ſtop the clouds and the fogs carried from the ſea, and this occaſions very abundant rains."

In theſe mountainous regions, which, as well as the plain, our author comprehends under the denomination of *Auteniqua*, there are multitudes of elephants, buffaloes, panthers, hyenas, and antelopes of every ſpecies; and all theſe animals are hunted and killed by the natives, as well for food as for the protection of their flocks and herds from ſuch of them as are beaſts of prey. Our author has eaten the fleſh of every one of them except the hyena; and declares, that the foot of an elephant, baked after the Hottentot manner, is one of the moſt delicious morſels that he ever taſted. He gives directions for hunting them all; but warns his readers from attacking elephants when he finds them in droves, for then, he ſays, they are invincible. He even thinks it exceedingly dangerous for one man, however well armed, to attack a ſingle elephant in the plain. The buffalo he deſcribes, contrary to moſt other travellers, as a timid animal, which never reſiſts till his ſituation becomes deſperate; and he thinks that there would be no difficulty in training him, if caught when a calf, to the yoke like the bullocks of Europe.

The kites and vultures of this country, our traveller repreſents as in the higheſt degree voracious and fierce, inſomuch that it is hardly poſſible to fright them from their prey. He had on one occaſion killed two buffaloes, which

which he ordered to be cut into very ſmall pieces, that they might be more eaſily ſalted, and expoſed afterwards to the air and the ſun. His wagons, as well as the buſhes and trees which ſurrounded him and his people, were loaded with the bloody fragments of theſe two animals, and they had begun their operation of ſalting; but on a ſudden, while they were not expecting it, they found themſelves attacked by flights of kites and vultures, which, without exhibiting the leaſt ſymptoms of fear, perched in the midſt of them. The kites were above all the moſt impudent. They ſeized upon the morſels of fleſh, and even contended furiouſly with his people. "When they had each carried away (ſays he) a pretty large piece, they retired to ſome branch, at the diſtance of ten paces from us, and devoured it before our eyes. Though we fired our fuſees they were not frightened, but returned inceſſantly to the charge; ſo that finding our powder waſted in vain, we reſolved to keep them off with large poles until our proviſions ſhould be quite dry. This manœuvre, which for a long time haraſſed my people, did not prevent us from being plundered without mercy; but had we not employed it, nothing would have remained to us of our two buffaloes."

This battle with the kites took place on the confines of the Dutch ſettlements; but when M. Vaillant had with difficulty paſſed over the mountains which bound them, the proſpects became more magnificent, the ſoil ſeemed to be more fruitful and rich, nature appeared to be more majeſtic and grand, and the lofty mountains preſented on all ſides more charming and delightful points of view than any that he had ever before met with. Theſe ſcenes, contraſted with the dry and parched fields of the Cape, made him exclaim, he ſays, in ecſtacy, "What! ſhall theſe ſuperb regions be eternally inhabited by tigers and lions? What ſpeculator, with the ſordid view only of eſtabliſhing a kind of centre for commerce, could have preferred the ſtormy Table Bay to the numberleſs roads and commodious harbours which are to be found on the eaſtern coaſts of Africa? Thus (continues he) was I reflecting within myſelf, whilſt I was climbing the mountain, and forming vain wiſhes for the conqueſt of this beautiful country, which the indolent policy of the European nations will perhaps never gratify."

If his deſcription of its beauties and fertility be not greatly exaggerated, it is indeed wonderful that either the Dutch or ſome other maritime power of Europe has not long ago taken poſſeſſion of it. After he had paſſed the mountain, one could not, he ſays, chooſe a more agreeable or advantageous ſpot than that upon which he then was for eſtabliſhing a thriving colony. The ſea advances through an opening of about a thouſand paces in breadth, and penetrates into the country to the diſtance of more than two leagues and a half. The baſon which it forms is more than a league in extent (he does not ſay whether in breadth or in circumference); and the whole coaſt, both on the right and the left, is bordered with rocks, which intercept all communication with it. The land is watered by limpid and refreſhing ſtreams, which flow down on all ſides from the eaſtern mountains; and theſe mountains, crowned with majeſtic woods, extending as far as the baſon, and winding round it with a number of ſinuoſities, exhibit a hundred groves, which are naturally variegated, and each more agreeable than another.

The author proceeding forwards about two days journey, arrived at a bay known to navigators by the name of the Bay of *Agoa*, but called by the coloniſts *Blettenberg's* Bay, from its having been viſited ſome time before by a Governor Blettenberg, who ordered his name, together with the year and day of his arrival, to be engraven on a ſtone column. This bay is a little beyond the limits of the country called Auteniqua; but it is not foreign from the purpoſe of this article to inſert in this place our traveller's account of it, and of the country around it.

The bay itſelf, he ſays, is very ſpacious, and has a ſufficient depth of water for the largeſt veſſels. The anchoring ground is ſure, and boats can ſail to a beautiful part of the ſhore, which is not confined by the rocks, as they are all there detached from one another. By advancing a league along the coaſt, the crews would arrive at the mouth of a conſiderable river called the *Queur-Boom*, where they would find water. Refreſhments might be procured from the inhabitants of the environs; and the bay would ſupply them with excellent fiſh, with which it abounds.

This bay is one of thoſe places where government might eſtabliſh warehouſes and repoſitories for timber; and it is for this reaſon that we have introduced it to notice in this article. The foreſts around it, ſays M. Vaillant, are everywhere magnificent, and the trees could be more eaſily cut down than anywhere elſe; for it is not to ſteep mountains that one muſt go for wood, as at Auteniqua; it is here ready at hand; and during the fine monſoon might be tranſported to the Cape with little trouble and no riſk. The inexhauſtible and fertile lands in the neighbourhood of the bay, if once cultivated, would produce abundant crops, and draw together a great number of intelligent planters, on account of the ready communication which they would have with the Cape. In a word, the Company, continues he, have nothing to do ſo much for their own intereſt as to form here a proper eſtabliſhment. To the general profits of ſuch an inſtitution, would be added thoſe of individuals, which could not fail to be of great importance. They might, for example, cut down a certain tree called *ſtinking wood*, and export it to Europe, where it would undoubtedly be ſoon preferred to mahogany and every other kind of wood employed by cabinet makers.

The Hottentots, who in ſcattered *kraals* inhabit this delightful country, our author deſcribes as a faithful, gentle, and rather timid race. He affirms that they have no religious impreſſions whatever, nor any notion of ſuperior powers who govern the world. But this, if not a wilful falſehood dictated by the philoſophy of France, is probably a miſtake ariſing from his ſcanty knowledge of their language, and total ignorance of the meaning of their religious ceremonies. His great maſter, as well as the maſter of his ſect, *Lucretius*, might have taught him, that fear, if not a better principle, will generate the notion of ſuperior beings in the minds of ſavages; and from fear, by his own account, the inhabitants of Auteniqua are far from being free. He likewiſe affirms, and ſeems to conſider it as much to their credit, that this race of gentle beings, ſo far from being

Automaton.

a prey to the paſſion of jealouſy (as other travellers have repreſented the Hottentots in general), are ſo obliging, as to lend their wives to travellers who viſit them, and that they actually accommodated his Hottentots in this way. Auteniqua, as laid down in M. Vaillant's map, lies between 33° 30′ and 34° 50′ of ſouth latitude, and between 20° and 23° 40′ of eaſt longitude; and his rout through the country was from ſouth-weſt to north-eaſt, or nearly ſo.

AUTOMATON. Under this title and that of Androides full credit was allowed in the *Encyclopædia Britannica* to the ſtory of M. de Kempel's mechanical *cheſs-player*, and a detail at ſome length was given of the feats of that figure, as well as of ſome other ſurpriſing *automata*. No man more readily admits the powers of the ſkilful mechanician than the writer of this ſhort article; but having many years ago detected the impoſition which was practiſed on the public in ſome parts of Scotland by a circumforaneous mountebank, who exhibited a figure apparently capable of writing a certain number of words, he has ever ſince ſuſpected impoſture in all automata which appear to have the power of varying their motions according to circumſtances. With reſpect to the *cheſs-player*, there is now ſufficient evidence that his ſuſpicions were well founded.

In the deſcription of this figure (*Encycl.* Vol. I. p. 787.), "it is ſaid that the automaton could not play unleſs M. de Kempel or his ſubſtitute was near it to direct its moves. A ſmall box during the game was frequently conſulted by the exhibiter; and herein conſiſted the ſecret, which he ſaid he could in a moment communicate." The ſecret was indeed ſimple: "A well taught boy, very thin and ſmall of his age, was concealed in this box almoſt immediately under the cheſs-board, and agitated the whole machine." This we learn from Thomas Collinſon, Eſq; who was let into the ſecret at Dreſden by a gentleman of rank and talents, named *Joſeph Freidrick Freyhere*, by whom the *vitality* and *ſoul* of the cheſs-playing figure had ſome time before been completely diſcovered. Mr Collinſon, finding that Dr Hutton had given the ſame credit with us to the reality of mechanical cheſs-playing, undeceived his friend, by communicating the diſcovery of Freyhere in a letter, which the Doctor has with great propriety publiſhed in the *Addenda* to his Mathematical Dictionary. Mr Collinſon adds, and we doubt not with truth, that, "even after this abatement of its being ſtrictly an automaton, much ingenuity remains to the contriver." This was in ſome degree true of the mechaniſm of the writing figure, of which the compiler of this article detected the bungling impoſture of the two exhibiters. The figure itſelf, with all the principles of its motion, were very ingeniouſly conſtructed; but the two men who exhibited it were ignorant and awkward, and could not conceal from a ſcrutinizing eye, that the automaton wrote ſometimes well and ſometimes ill, and never wrote at all when they were both preſent to the company. It was by inſiſting upon ſeeing them both together, and threatening to expoſe the cheat to the whole town, that the preſent writer prevailed upon him who appeared to be the principal exhibiter, to confeſs in private that his companion was concealed behind a ſcreen, and to ſhow how, from thence, he directed the movements of the figure.

Automaton, Axis.

Conjugate AXIS, or *Second Axis*, in the ellipſe and hyperbola, is the diameter paſſing through the centre, and perpendicular to the tranſverſe axis; and is the ſhorteſt of all the conjugate diameters.

Tranſverſe Axis, in the ellipſe and hyperbola, is the diameter paſſing through the two foci and the two principal vertices of the figure. In the hyperbola it is the ſhorteſt diameter, but in the ellipſe it is the longeſt.

B.

Bahrdt.

BAHRDT (Dr Carl Friedirich) was ſo deeply concerned in a combination of philoſophers formed, as they ſaid, for the advancement of ſcience and virtue, that an account of his life muſt be intereſting, if it were only to ſhow the effects of this philoſophic culture on his own morals. We truſt therefore that our readers will be pleaſed, perhaps improved, by the following narrative, taken from documents the moſt authentic, by a man* whoſe communications on other ſubjects do credit to this volume.

Carl Friedirich Bahrdt was, in 1741, born at Leipſig, where his father, then a pariſh miniſter, and afterwards profeſſor of theology, died in 1775. It is natural to ſuppoſe that ſuch a parent would be at due pains to inſtil into the mind of his ſon the principles of piety, virtue, and patriotiſm, which is indeed a branch of virtue; but if ſo, he lived to ſee that his labour had been in vain. While yet at college, where the courſe of his ſtudies was calculated to fit him for the important office of preaching the goſpel, the young man enliſted as a huſſar in the Pruſſian ſervice; but being bought off, he returned to the univerſity, where, in 1761, he was admitted to the degree of M. A. Soon afterwards he became catechiſt in his father's church, was a popular preacher, and in 1765 publiſhed ſermons, and ſome controverſial writings, which evinced that he poſſeſſed both learning and genius. Neither learning nor genius, however, nor both united, could attach him to the cauſe of virtue, or make him obſerve even the common rules of decorum; for immediately after this publication he began to indulge in conviviality, and to give ſcope to his reſentments in anonymous paſquinades, in the higheſt degree bitter and offenſive. From the ſhafts of his malice no perſon was ſafe. Profeſſors, magiſtrates,

Bahrdt.

* See Profeſſor Robiſon of Edinburgh's *Proofs of a Conſpiracy againſt all the Religions and Governments of Europe.*

and clergyman, had indeed his chief notice ; but he condeſcended occaſionally to attack ſtudents, and ſpared not even his own comrades or his friends.

Whilſt he was thus labouring to make enemies of all to whom he was known, unfortunately, for his own character, his temperament was what the atomical philoſophers (who can explain every thing by ethers and vibrations) call ſanguine ; and he was, as he himſelf acknowledged, a paſſionate admirer of the ladies. Coming home from his midnight revels, he frequently met in his way a young girl neatly dreſſed in a roſe-coloured ſilk jacket and train, and a coſtly ſable bonnet ; and one evening, after having, as he ſays, indulged freely in ſome old Rheniſh, he ſaw her home to her lodgings. Some time after this interview, the miſtreſs of the houſe (a Madam Godſchuſky) came into his room, and ſaid that the poor *maiden* whom he had debauched was pregnant. This was a misfortune *which he could not help ;* but as it would ruin his character if known, he gave to the old lady a bond for 200 dahlers (about L.40 ſterling), to be paid by inſtalments of twenty-five, to keep the matter ſecret. "The girl (he ſays) was *ſenſible* and *good ;* and as her converſation, for which he had already paid, was agreeable, he did not diſcontinue his acquaintance."

It could not be ſuppoſed that ſuch viſits, by a clergyman, would paſs unobſerved, however cautiouſly made, in the midſt of a town, of which the inhabitants had been the indiſcriminate objects of his ſatire ; and he could hardly be ſurpriſed when told by a friend, that one Bel, a magiſtrate whom he had lampooned, was accquainted with the whole affair, and would bring it into a court of juſtice, unleſs the bond was immediately retired.

This bond was the only evidence which could be produced againſt Bahrdt, but it was ſufficient to blaſt his character in Leipſig, and muſt therefore by any means be removed out of the way. To accompliſh this, however, was a matter of ſome difficulty ; for neither he nor his friend could raiſe the money. In this dilemma they fell upon a contrivance worthy of themſelves. They invited Madam Godſchuſky to meet them in another houſe to receive the 200 dahlers due to her by Bahrdt ; but when ſhe was uſhered into the room, and found no perſon waiting for her but Bahrdt's friend, ſhe could not be prevailed upon to produce the bond till the money ſhould be put into her hands, together with a preſent to herſelf. The *Gentleman* tried to intimidate her. He drew his ſword ; ſhowed her how men fence ; made puſhes at the wall and then at her : but finding that ſhe could not be frightened out of her ſenſes, he threw away his ſword, and endeavoured to take the bond from her by force. It was ſome time before he prevailed ; but at laſt getting the paper out of her pocket, he tore it in pieces, opened the door of a cloſet in which Bahrdt was concealed, and ſaid, "There, you b—— ; there is the honourable fellow whom you and your whore have bullied ; but it is with me you have now to do, and you know that I can bring you to the gallows."

Bahrdt, from whoſe memoirs of himſelf this ſtory is taken, admits that there was a great ſquabble on the occaſion ; but he went home, comforting himſelf with the belief that he ſhould now have no farther trouble from Madam Godſchuſky or her girl. He chanced, however, to be miſtaken. The magiſtrate Bel had ſome how been made acquainted with this nefarious tranſaction, and brought it into court on the day that our hero was to make ſome very reverend appearance at church. The caſe of Bahrdt was now hopeleſs ; for after ſome unſucceſsful attempts of his poor father to ſave him, he was obliged to give in his gown and band, and to quit Leipſig.

To a parent the public diſgrace of a child is one of the ſevereſt calamities to which human nature is liable ; but for this calamity the father of Bahrdt muſt have been long prepared, as his ſon appears to have been remarkably undutiful. Of this we have one memorable inſtance recorded by himſelf. His father, he ſays, was ſevere, and his own temperament haſty, ſo that he ſometimes forgot himſelf. "One day (continues he) I laid a loaded piſtol on the table, and told him that he ſhould meet with that if he went on ſo ; but I was then only SEVENTEEN !"

On his being obliged to leave the place of his nativity, the friends of Bahrdt, and in particular Semler, an eminent theological writer, who had formed a very favourable opinion of his talents, were aſſiduous in their endeavours to procure an eſtabliſhment for him elſewhere ; but his high opinion of himſelf, his impetuous and precipitant temper, and that ſatirical habit which he had ſo freely indulged in his outſet in life, made their endeavours long ineffectual. At laſt he got a profeſſorſhip at Erlangen, then at Erfurth, and in 1771 at Gieſſen. But in each of theſe places he was no ſooner ſettled than he got into diſputes with his colleagues and with the eſtabliſhed church ; for he was a ſtrenuous partizan of the innovations then attempted to be made in the doctrines of Chriſtianity. In his publications, which were generally anonymous, he did not truſt to rational diſcuſſion alone, but had recourſe to ridicule and perſonal anecdotes, and indulged in the moſt cutting ſarcaſms and groſs ſcurrility.

His love for convivial company continuing, his income was inſufficient for the craving demand. Finding therefore that anecdote and ſlander always procured readers, and poſſeſſing a wonderful activity and facility in writing, he never ceaſed from publiſhing lampoons and ſatires, in which he ſpared neither friends nor foes. But it was impoſſible to prevent theſe publications from being traced to their author; and his avowed theological writings being ſuch as could not be ſuffered in a profeſſor of divinity, the hoſt of enemies which he had been at ſo much pains to raiſe againſt himſelf, were furniſhed with ſufficient grounds for ſubjecting his conduct to legal cognizance ; even the very ſtudents at Gieſſen were ſhocked at ſome of his liberties.

The conſequence of all this was, that, after much wrangling in the church judicatories, he was juſt about to be diſmiſſed from his profeſſorſhip, when he got an invitation to Marſchlins in Switzerland to ſuperintend an academy.

To Marſchlins he went about the year 1776, and began his new career by forming the ſeminary after the model of an academy which had ſome time before been ſet up in the principality of Anhalt Deſſau by one Baſedow, a man of talents and learning, who gave to it the appellation of PHILANTHROPINE. The plan of this academy was very different from thoſe of the univerſities ; for its author profeſſed to conſider languages, ſciences, and the ornamental exerciſes, as mere acceſſories, his aim being to form the young mind to the love of mankind and of virtue, by a courſe of moral education certainly ſpecious, and apparently unexceptionable. To make this novel inſtitution the more extenſively uſeful, the rules by which the education was to be conducted were framed in ſuch a manner as, it was thought, would remove from the minds of Catholics, Lutherans, and Calviniſts, all uneaſineſs reſpecting the faith of their children, as it related to thoſe particular tenets which ſeparated them into different communions. It was even propoſed to baniſh from the philanthropine all *poſitive* religion whatever, and to inſtruct the youth educated there in the principles only of natural, or, as it was called, *philoſophical religion*.

This plan was peculiarly ſuited to Bahrdt's taſte, becauſe it left him at liberty to introduce into his academy any ſyſtem of religious or irreligious opinions that he pleaſed; a liberty of which he reſolved to avail himſelf, and, though now a doctor in theology, to outſtrip, in licentiouſneſs, even the founder of the philanthropine, who was not in orders. By meditating on the workings of his own mind, he had by this time formed his theory of human nature, which was indeed very ſimple. "The leading propenſities of the human mind (he ſays) are three; inſtinctive liberty, inſtinctive activity, and inſtinctive love." By theſe expreſſions we ſuppoſe he means, "innate *love* of liberty, inſtinct prompting to action, and the ſexual appetite:" and he immediately adds, that "if a man is obſtructed in the gratification of any of theſe propenſities, he ſuffers an injury. The buſineſs therefore of a good education is to teach us how they are to be gratified in the higheſt degree."

That ſuch an education would be approved of by the uncorrupted natives of Switzerland was hardly to be expected; and Bahrdt ſoon found his ſituation at Marſchlins as uncomfortable as it had been at Gieſſen. "The Griſons (he ſays) were a ſtrong inſtance of the immenſe importance of education. They knew nothing but their handicrafts; and their minds were as coarſe as their perſons." He quarrelled with them all, and was obliged to abſcond after lying ſome time in priſon.

From Marſchlins he went to Durkheim, a town in the Palatinate, where his father had been miniſter, and where his literary talents were well known. After ſome little time he got an aſſociation formed for erecting and ſupporting a *Philanthropine* or houſe of education. A large fund was collected; and he was enabled to travel into Holland and England to engage pupils, and was furniſhed with proper recommendations.

In London he gained the friendſhip of a clergyman, whom he repreſents as a perſon in the higheſt degree accompliſhed. "With ſound judgment (ſays Bahrdt), great genius, and correct taſte, he was perfectly a man of the world. He was my friend, and the only perſon who warmly intereſted himſelf for my inſtitution. To his earneſt and repeated recommendations I owe all the pupils that I got in England, and many moſt reſpectable connections; for he was univerſally eſteemed as a man of learning and of the moſt unblemiſhed character. He was my friend, my conductor, and I may ſay my preſerver; for when I had not bread for two days, he took me to his houſe, and ſupplied all my wants."

For ſo much kindneſs the reader doubtleſs ſuppoſes that the heart of Bahrdt overflowed with gratitude; but if ſuch be his opinion, he is a ſtranger to the principles of thoſe who have on the continent of Europe aſſociated for the purpoſe of enlightening the world. This amiable man, whoſe character is here ſo juſtly drawn, was afterwards depicted by the monſter whom he had ſaved from periſhing by hunger, as a wretch loſt to all ſenſe of ſhame and decency, as an apoſtate from the Chriſtian faith, and as a notorious frequenter of the London brothels! Fortunately he was able to vindicate his character completely from this ſlanderous abuſe, and to convict Bahrdt of having publiſhed what *could not poſſibly be true*.

This ungrateful liar returned from England, and carried into execution his plan of the Philanthropine. The caſtle of Count Leining Hartzburgh at Heideſheim, having gardens, park, and every handſome accommodation, had been fitted up for it; and in 1778 it was conſecrated by a ſolemn religious feſtival. But his old misfortunes purſued him. He had indeed no colleagues with whom he could quarrel; but his *avowed* publications became every day more obnoxious; and when any of his *anonymous* pieces had a great run, he could not ſo far ſtifle his vanity as to conceal that he was the author. Of theſe pieces ſome were ſhocking to decency, and others ſo horribly injurious to the characters of the moſt reſpectable men in the ſtate, that he was continually under the correction of the courts of juſtice. It was hardly poſſible for a man of letters to be in his company, and not ſuffer by it; for it was his conſtant practice to attribute every ſtep which he took towards atheiſm, to the force of the arguments urged by ſome of his friends.

To be his friend, or to obtain his applauſe, was indeed ſo great a misfortune, that when the reader ſees any perſon celebrated by Dr Bahrdt, in the beginning of a book, for ſound ſenſe, profound judgment, accurate reaſoning, or praiſed for acts of friendſhip to himſelf, he may be aſſured, that before the cloſe of the book this man ſhall be repreſented as having in private converſation convinced the author, that ſome doctrine, cheriſhed and venerated by all Chriſtians, is a piece of knaviſh ſuperſtition.

Dr Bahrdt had married, while at Gieſſen, a woman with a ſmall fortune: but ſuch a ſtranger was he to the delicacies of wedded love, ſo loſt indeed to all ſenſe of decency, that he contrived one day to entice his wife *naked* into the bath in the garden of his Philanthropine, where, in the water, he, being alſo *naked*, toyed with her in the ſight of all his pupils. It was his boaſt that he held his opinions independent of all mankind, and was indifferent whether they procured him praiſe or reproach; but it appears from this fact, that he was equally regardleſs of the praiſe or cenſure which might be attached to his actions; for ſurely the groſſeſt hog that ever before him battened in the Epicurean ſty would not have preſented ſuch an exhibition to boys.

The conſequence of all this was, that he was obliged to fly from Heideſheim, leaving his ſureties in the Philanthropine to pay about 14,000 dahlers, beſides debts without number to his friends. He was impriſoned at Dienheim; but being ſoon releaſed, he ſettled at Halle, where he ſunk to be the keeper of a tavern and billiard-table. His houſe became of courſe the reſort and the bane of the ſtudents in the univerſity, and he was obliged to leave the city. He had ſomehow got money ſufficient to purchaſe a little vineyard, pleaſantly ſituated

ted in the neighbourhood. This he fitted up with every accommodation that could invite the ſtudents, and called it *Bahrdt's Ruhe* (Bahrdt's repoſe); where he lived for two years, directing the operations of a ſecret ſociety called the GERMAN UNION, FOR ROOTING OUT SUPERSTITION AND PREJUDICES, AND FOR ADVANCING TRUE CHRISTIANITY.

With Bahrdt's qualifications for advancing the intereſts of genuine Chriſtianity, the Chriſtian reader is already ſufficiently accequainted; but he will not wonder at his appointment to this high office, when he is informed that the GERMAN UNION is nothing more than a ſpawn of the ſecret ſociety of *Illuminati* (ſee ILLUMINATI in this Supplement); and that its object is to aboliſh the religion of the goſpel, and to teach in its ſtead the fataliſm of the Stoics. With this view Chriſtianity is conſidered in the UNION as a myſtical ſociety, and its Divine Founder as the grand maſter of a lodge! The apoſtles Peter, James, John, and Andrew, were the ELECT, brethren of the *third* degree, and initiated into all the myſteries. The remaining apoſtles were only of the *ſecond* degree; and the ſeventy-two, of the *firſt*: a degree into which ordinary Chriſtians may be admitted, and prepared for farther advancement. The great myſtery is, that J—— C—— was a NATURALIST, and taught the doctrine of a ſupreme mind, the ſpectator but not the governor of the world.

To propagate theſe impious and abſurd notions, Bahrdt publiſhed many books of the moſt antichriſtian tendency, and ſome of them calculated to make their readers ſhake off all moral obligation. But the labours of the ſociety were not confined to religion: it inculcated on its members the moſt dangerous maxims of civil conduct: for, as we learn from Bahrdt himſelf, the objects at which the Union aimed were—*Advancement of ſcience—a general intereſt and concern for arts and learning—excitement of talents—check of ſcribbling—good education*—LIBERTY—EQUALITY—*hoſpitality*—DELIVERY OF MANY FROM MISFORTUNES—*union of the learned—and at laſt—perhaps—Amen.*

What the meaning of this enigmatical concluſion is we can only gueſs; and we agree with the real philoſopher from whom we have taken this account, that our conjectures cannot be favourable. Bahrdt was a villain, and could be aſſociated only with villains, whoſe affairs he managed with the help of an old man, who lived at bed and board in his houſe for about ſix ſhillings a-week, and diſcharged the office of ſecretary to the UNTON.

When he had toiled in this cauſe near two years, ſome of the ſecrets of the Union tranſpired; his former conduct and his conſtant imprudence made him ſuſpected; his aſſociated friends lodged informations againſt him; his papers were ſeized; and he himſelf was ſent to priſon, firſt at Halle and then at Magdeburgh. After ſomething more than a year's confinement, he was ſet at liberty, and returned to his *Ruhe*, not, alas! to live at eaſe, or to exhibit ſymptoms of repentance, but to lie down on a ſick-bed, where, after many months ſuffering of increaſing pain, he died on the 23d of April 1793, the moſt wretched and loathſome victim of unbridled ſenſuality.

Such were the fruits of the German Union, and of that illumination which was to refine the heart of man, and bring to maturity the ſeeds of native virtue, which are choaked in the heart by ſuperſtition and deſpotiſm. Dr Bahrdt affected to be the enlightener and reformer of the world; and affirmed that all the evils of life originated from deſpotiſm and ſuperſtition. "In vain (ſays he) do we complain of the inefficacy of religion. All poſitive religion is founded on injuſtice. No prince has a right to preſcribe or ſanction any ſuch ſyſtem; nor would he do it, were not the prieſts the firmeſt pillars of his tyranny, and ſuperſtition the ſtrongeſt fetters for his ſubjects. He dares not ſhow Religion as ſhe is, pure and undefiled—ſhe would charm the eyes and the hearts of mankind, would immediately produce true morality, would open the eyes of freeborn man, would teach him what are his rights and who are his oppreſſors, and princes would vaniſh from the face of the earth."

Therefore, without troubling ourſelves with the truth or falſehood of his religion of nature, and aſſuming it as an indiſputable point, that Dr Bahrdt has ſeen it in this natural and ſo effective purity, it is ſurely a very pertinent queſtion, "Whether has the ſight produced on his mind an effect ſo far ſuperior to the acknowledged faintneſs of the impreſſion of Chriſtianity on the bulk of mankind, that it will be prudent to adopt the plan of the German Union, and at once put an end to the diviſions which ſo unfortunately alienate the minds of profeſſing Chriſtians from each other?" The account here given of Dr Bahrdt's life ſeems to decide the queſtion.

But it will be ſaid that we have only related ſo many inſtances of the quarrels of prieſts and their ſlaviſh adherents with Dr Bahrdt. Let us view him in his ordinary conduct, not as the champion and martyr of illumination, but as an ordinary citizen, a huſband, a father, a friend, a teacher of youth, a clergyman.

When Dr Bahrdt was a pariſh-miniſter, and preſident of ſome inferior eccleſiaſtical diſtrict, he was empowered to take off the cenſures of the church from a young woman who had born a baſtard child. By violence he again reduced her to the ſame condition, and eſcaped cenſure by the poor girl's dying of a fever before her pregnancy was far advanced, or even legally documented. On the night of the ſolemn farce of conſecrating his Philanthropine, he debauched the maid-ſervant, who bore twins, and gave him up for the father. The thing was not judicially proved, but was afterwards made ſufficiently evident by letters found among his papers, and publiſhed by one of his friends in the UNION. Having ſupported theſe infants, in a pitiful manner, for little more than a year, he cauſed them to be taken away from their mother, during night, ſome time in the month of February 1780; and they were found expoſed, the one at Ufſtein, and the other at Worms, many miles diſtant from each other, and almoſt frozen to death.

So much for the purity of his morals and his religion, as he appears in the character of a father and of a clergyman. His *decency* as a huſband, and his gratitude to his friend, we have already ſeen; and we ſhall now ſee his kindneſs and fidelity. After waſting the greateſt part of his wife's little fortune, he was ſo provoked becauſe her brother would not give him up the remainder, amounting to about L. 110, that he ever afterwards treated her with the greateſt cruelty, and exhibited her to contempt and ridicule in two infamous novels. At Halle he brought a miſtreſs into the houſe, and committed to her the care of his family, confining his wife and daughter to their own apartment; and the laſt thing which he did was to ſend for a bookſeller, who had publiſhed ſome of his vileſt pieces, and, without a thought of his injured wife, recommend his ſtrumpet and her children to his protection.

"Think not, indignant reader (ſays Arbuthnot), that this man's life is uſeleſs to mortals." It ſhows in a ſtrong light the falſity of all his declamations in favour of his ſo much praiſed natural religion and univerſal kindneſs and humanity. No man of the party writes with more perſuaſive energy, and, though his petulance and precipitant ſelf-conceit lead him frequently aſtray, no man has occaſionally put all the arguments of theſe philoſophers in a clearer light; yet we ſee that all is falſe and hollow. He is a vile hypocrite, and the real aim of all his writings is to make money, by foſtering the ſenſual propenſities of human nature, although he ſees and feels that the completion of the plan of the German Union would be an event more deſtructive and lamentable than any that can be pointed out in the annals of ſuperſtition. We will not ſay that all the partiſans of illumination are hogs of the ſty of Epicurus like this wretch; and it would be extremely unjuſt to conſider his vices as the effects of his illumination. He was ſenſual, ungrateful, and profane, before he was admitted into the order of the *Illuminati*; but had the views of that order been ſuch as were held out to the world at large, its ſagacious founder would not have initiated a wretch ſo notoriouſly profligate as Dr Bahrdt. Their views, however, being to govern mankind thro' the medium of their ſenſual appetites, and to reign in hell, rather than ſerve in heaven, they could not have employed a better inſtrument. Dr Bahrdt was a true diſciple of illumination; and though his torch was made of the coarſeſt materials, and ſerved only to diſcover ſights of woe, the horrid glare darted into every corner, rouſing hundreds of filthy vermin, and directing their flight to the rotten carrion, where they could beſt depoſite their poiſon and their eggs. Whilſt the more decent members of the Union laboured to pervert the refined part of mankind by declamations on the rights of man and the bleſſings of liberty, Bahrdt addreſſed himſelf to readers of all deſcriptions, and aſſailed at once the imagination and the appetites. He taught them, that religion is an impoſture; that morality is convenience; and, with blaſphemy peculiar to himſelf, that he and his order, by their licentious doctrines, were to *complete the plan and aim of* J—— C——.

BAILLY (Jean-Sylvian), who made ſuch a figure during the firſt years of the French revolution, was born at Paris on the 15th of September 1736, of a family which had been diſtinguiſhed painters during four ſucceſſive generations. He was bred to the ſame profeſſion, but ſhowed an early taſte for poetry and the belles lettres. Chancing, however, to become acquainted with the geometer La Caille, this circumſtance decided his genius, and he thenceforth devoted himſelf to the cultivation of ſcience. He calculated the orbit of the comet of 1759; and on the 29th of January 1763 was received into the Academy of Sciences. In that year he publiſhed an uſeful and laborious compilation, being the reduction of the obſervations made by La Caille in 1760 and 1761, on the zodiacal ſtars. He likewiſe began to conſider the theory of Jupiter's ſatellites, and, in the competition for this prize queſtion of 1764, had a formidable rival in La Grange, who already promiſed to become the firſt mathematician in Europe. The reſults of his inveſtigations were collected into a treatiſe publiſhed in 1766, containing alſo the hiſtory of that part of aſtronomy. In 1771 he gave a moſt curious and important memoir on the light of the ſatellites, and introduced a degree of accuracy till then unknown in the obſervations of their eclipſes.

His ſtudies were not confined to the abſtract ſciences; for he cultivated letters with ſucceſs. His eloges of Charles V. of Corneille, of Leibnitz, of Moliere, and afterward thoſe of Cook, La Caille, and Greſſet, were much admired. His eloquence pointed him out as a proper perſon to fill the charge, vacant in 1771, of ſecretary to the Academy of Sciences; and, under the patronage of Buffon, he ſtood candidate for that enviable place. He failed: but it was the high birth and promiſing talents of the young Condorcet, joined to the active influence of D'Alembert, that carried the prize.

In 1775 appeared the firſt volume of the Hiſtory of Aſtronomy, which indeed ſtrews the path of ſcience with flowers, and in every reſpect is a moſt valuable work—full of animated deſcription, of luminous narrative, and intereſting detail. His very peculiar ideas concerning the early ſtate of Upper Aſia gave riſe to an ingenious correſpondence and diſcuſſion with the veteran philoſopher Voltaire, the ſubſtance of which ſoon appeared in two volumes, intitled, "Letters on the Origin of Sciences," and "Letters on the Atlantide of Plato." If imagination ſhone forth in theſe eſſays, erudition was no leſs conſpicuous in a great work compoſed in the years 1781 and 1782, on the fables and religious creeds of antiquity; which ſtill exiſts in manuſcript, and the publication of which would aſſuredly extend the fame of its author, and gratify the learned world. His opinions on ſome points happening to coincide with the theories of Buffon, he contracted with that celebrated naturaliſt a cloſe friendſhip, which was diſſolved by Bailly's uncourtly oppoſition to the election of the Abbé Maury into the *Academie Françaiſe*. Of that academy he had been choſen ſecretary in 1784; and he was admitted, in the following year, into the Academy of Inſcriptions and Belles Lettres; the only inſtance, ſince Fontenelle, of the ſame perſon being at once a member of all the three academies. In the meantime, the other volumes of the Hiſtory of Aſtronomy ſucceſſively appeared, and that capital work was completed in 1787 by the Hiſtory of the Indian and Oriental Aſtronomy; a production of ſingular acuteneſs, reſearch, and nice calculation.

In 1784 he made an elegant report to the Academy of Sciences on the animal magnetiſm of Meſmer; and in 1786 another report, which diſplays the judgment and humanity of its author, on a project for a new *hotel-dieu* or infirmary.

We now approach the eventful period which ſummoned Bailly from his retirement, to enter on a political career, that was full of difficulty and danger, and for which his habits and ſtudies appear not to have fitted him. He had ſeen, as others ſaw, the defects of the old government of France. His heart panted for civil and eccleſiaſtical liberty; but unfortunately, like many other philoſophers both in his own country and in this, he had formed notions of that bleſſing which experience ſhould have taught him can never be realiſed among beings ſo imperfect as the bulk of mankind. When the ſtates-general were ſummoned to meet, he was on the 26th of April 1789 nominated ſecretary by the electors of Paris, and then appointed one of the deputies. He was choſen preſident of the *Tiers Etat;* and when that chamber was conſtituted the National Aſſembly, he continued in the chair, and concurred in all the levelling decrees which laid the foundation of the preſent miſery of his country, as well of moſt other countries of Europe.

After the taking of the Baſtile, when the king was removed to Paris on the 15th of July, Bailly was called by public acclamation to the head of that city, with the title of *Mayor*. In his ſeveral functions he acted with integrity, courage, and moderation. He reached the ſummit of glory:—but how mutable, alas! is human grandeur! That middle courſe of conduct, the *aurea mediocritas*, at which virtue aims, is fitted to pleaſe neither of the contending parties in the midſt of revolutions; and ſuch proved the ruin of Bailly. His popularity began to decline, and was at length changed into inveterate enmity by an unfortunate accident. On the 17th of July 1791, the populace having collected tumultuouſly to demand the abolition of monarchy, Bailly was ordered by the National Aſſembly to diſperſe the mob. He was obliged to proceed to the Champ-de-Mars at the riſk of his life; and, in ſpite of all his exertions and forbearance, ſome ſhots were fired by the ſoldiery. It was no longer deſirable to hold his perilous charge, and on the 16th of November following he give way to the aſcending reputation of Petion. The impaired ſtate of his health, too, rendered it expedient to retire from the focus of turbulence. He ſpent the year 1792 and part of 1793 in travelling through different provinces of France. During this period he wrote memoirs of the events which he had witneſſed, and in which he had often been a principal actor. Theſe come down only to the 2d of October 1789, but would make a large quarto volume; and La Lande, from whoſe *Eloge de Bailly* this article is taken, gives us hopes that the manuſcript will be publiſhed. He was adviſed by his friends to withdraw from France, but he choſe rather, like Socrates, to ſubmit to the injuſtice and ingratitude of his country. At the nod of a vulgar tyrant he was arreſted, ſummarily condemned by a ſanguinary tribunal, and on the 15th of November 1793 was delivered over to appeaſe the vengeance of an incenſed and indiſcriminate populace. His ſufferings were ſtudiouſly protracted, but he bore them with the calmneſs and magnanimity of a ſage. Nature recoils at the recital of ſuch barbarities.

In 1787 M. Bailly married the widow of one who had been during 25 years his intimate friend; a woman more qualified by her age and condition to inſpire reſpect than the paſſion of love. He was tall in his perſon, of a ſerious deportment, and joined firmneſs to ſenſibility. Never did philoſopher diſtinguiſh himſelf in ſo many different lines, nor acquire ſuch deſerved reputation in them all. His diſintereſtedneſs was pure and unaffected; and during his magiſtracy he ſpent a part of his fortune in relieving the wants of the poor. His virtue remained as untainted in his various public ſtations as in the ſweet retirement of domeſtic life.

Such is the encomium paſſed upon this philoſopher and ſtateſman by no leſs a man than the celebrated aſtronomer M. DE LA LANDE; but to thoſe who are not infected with the *mania* of freedom, it will doubtleſs appear greatly exaggerated. That M. Bailly was a man of eminence in the republic of letters, is known to all the learned of Europe; that in his political conduct he meant to promote the good of his country, it would certainly be preſumptuous in us to deny; and that he ſuffered unjuſtly, is incontrovertible: But let it be remembered that he ſuffered in a ſtorm, which he exerted all his abilities to raiſe; and that he ſet an example of injuſtice, when he concurred in the degradation of the privileged orders, and in the violent confiſcation of the property of the church.

BALIOL (John), the competitor with Bruce for the crown of Scotland, was not (as he is ſaid to have been in the *Encyclopædia*) the brother of King ALEXANDER, but the great grandſon of David Earl of Huntington, third ſon of King David I.

BALLISTIC PENDULUM, an ingenious machine invented by Benjamin Robins, for aſcertaining the velocity of military projectiles, and conſequently the force of fired gunpowder. It conſiſts of a large block of wood, annexed to the end of a ſtrong iron ſtem, having a croſs ſteel axis at the other end, placed horizontally, about which the whole vibrates together like the pendulum of a clock. The machine being at reſt, a piece of ordnance is pointed ſtraight towards the wooden block or ball of this pendulum, and then diſcharged: the conſequence is this—the ball diſcharged from the gun ſtrikes and enters the block, and cauſes the pendulum to vibrate more or leſs according to the velocity of the projectile or the force of the blow; and by obſerving the extent of the vibration, the force of that blow becomes known, or the greateſt velocity with which the block is moved out of its place, and conſequently the velocity of the projectile itſelf which ſtruck the blow and urged the pendulum.

Hutton's Dictionary.

BANKA (ſee BANCA, *Encycl.*) is noted throughout Aſia for its tin mines. It lies oppoſite to the river Palambang, in the iſland of Sumatra, on which the ſovereign of Banka, poſſeſſor alſo of the territory of Palambang, keeps his conſtant reſidence. This prince maintains his authority over his own ſubjects, and his independence of the neighbouring ſovereigns, chiefly by the aſſiſtance of the Dutch, who have a ſettlement and troops at Palambang, and enjoy the benefit of a contract with the king of Banka for the tin which his ſubjects procure from that iſland. Such at leaſt was the caſe in 1793, when Lord Macartney touched at Banka on his way to China. At that period the ſovereign compelled his ſubjects, and probably does ſo at preſent, to deliver the tin to him at a low price, and ſold it to the Dutch at a ſmall advance, purſuant to his contract. Thoſe miners, from long practice, have arrived at great perfection in reducing the ore into metal, employing wood as fuel in their furnaces, and not foſſile coal, or *coak*, which is ſeldom ſo free from ſulphur as not to affect the malleability of the metal. It is ſometimes preferred therefore to European tin at the Canton market; and the profit upon it to the Dutch company was, at the period mentioned above, ſuppoſed to have long been not leſs than L. 150,000 a-year. Into whoſe hands this trade has now fallen we know not; probably it is in a great degree neglected.

BANTAM, the capital of a kingdom of the ſame name in the iſland of Java, is, in the *Encyclopædia*, ſaid to be a large town with a good harbour and fortified caſtle Sir George Staunton, however, who viſited Bantam ſince that article was publiſhed, gives a very different account both of the town and of its harbour. Once indeed it was a place of conſiderable conſequence, being the great mart for pepper and other ſpices, whence they were diſtributed to the reſt of the world The chief factory of the Engliſh as well as Dutch Eaſt India Company was ſettled there. The merchants of Arabia and Hindoſtan reſorted to it. Its ſovereigns were ſo deſirous of encouraging trade, by giving ſecurity to foreign merchants againſt the violent and revengeful diſpoſition of the natives, that the crime of murder was never pardoned when committed againſt a ſtranger, but might be commuted by a foreigner for a fine to the relations of the deceaſed. This place flouriſhed for a conſiderable time ; but the Dutch having conquered the neighbouring province of Jacatra, where they ſince have built Batavia, and transferred their principal buſineſs to it, and the Engliſh having removed to Hindoſtan and China, and trade in other reſpects having taken a new courſe, Bantam was reduced to a poor remnant of its former opulence and importance. Other circumſtances have accelerated its decline. The bay is ſo choaked up with daily acceſſions of new earth waſhed down from the mountains, as well as by coral ſhoals extending a conſiderable way to the eaſtward, that it is inacceſſible at preſent to veſſels of burden ; even the party who went there from the Lion, the ſhip which carried Lord Macartney to China, was obliged to remove from her pinnace into a canoe, in order to reach the town. With the trade of Bantam the power of its ſovereign declined. In his wars with other princes of Java he called in the aſſiſtance of the Dutch ; and from that period he became in fact their captive. He reſides in a palace built in the European ſtyle, with a fort garriſoned by a detachment from Batavia, of which the commander takes his orders not from the king of Bantam, but from a Dutch chief or governor, who lives in another fort adjoining the town, and nearer to the ſea-ſide. His Bantameſe majeſty is allowed, however, to maintain a body of native troops, and has ſeveral ſmall armed veſſels, by means of which he maintains authority over ſome parts of the ſouth of Sumatra. His ſubjects are obliged to ſell to him all the pepper they raiſe in either iſland, at a low price, which he is under contract with the Dutch to deliver to them at a ſmall advance, and much under the marketable value of that commodity. The preſent king joins the ſpiritual to the temporal power, and is high prieſt of the religion of Mahomet ; with which he mingles, indeed, ſome of the rites and ſuperſtitions of the aboriginal inhabitants of Java ; adoring, for inſtance, the great banyan, or Indian fig-tree, which is likewiſe held ſacred in Hindoſtan, and under which religious rites might be conveniently performed ; in like manner, as all affairs of ſtate are actually tranſacted by the Bantameſe under ſome ſhadowing tree by moon-light. To complete the ruin of Bantam, a fire ſome time ago deſtroyed moſt of the houſes, and few have been ſince rebuilt.

BANYAN-TREE. See FICUS, *Encycl.*

BRITISH BARILLA, is the name given by Mr James King of Newcaſtle upon Tyne, to a material invented by him to ſupply the place of Spaniſh barilla in the making of crown window-glaſs, broad window-glaſs, and glaſs-bottles, as alſo in the manufacturing of ſoap and alum. For theſe purpoſes he affirmed that it anſwered much better than any other material then in uſe ; and in conſequence of that affirmation he obtained a patent for his invention, dated March 4. 1787.

Though we can hardly allow to this invention all the merit claimed for it by its fond author, yet as it *may* be of uſe to different manufacturers, we ſhall lay before our readers his method of making the Britiſh barilla. It is as follows : "Take a certain quantity of aſhes obtained by burning the loppings or branches of aſh, oak, beech, elm, alder, or any other kind of green wood or bramble : Take an equal quantity of the aſhes obtained by burning the green vegetables known by the name of fern, brecon, bean and pea-ſtraw, whins, common field and high-way thiſtles, the ſtalks of rape or muſtard-ſeed, or the bent or ruſhes that grow by the ſea-ſhore." Though we know not in what qualities the aſhes obtained from the former ſubſtances differ from thoſe obtained from the latter, the author, as if the difference was very great, directs theſe equal quantities to be mixed together, ſifted through a fine ſieve, and laid upon a boarded floor, where a quantity of ſoapers waſte-aſhes, equal to the whole compound maſs, is to be added to it, and well mixed with it by means of a ſhovel or other inſtrument. To this mixture of vegetable aſhes and ſoapers waſte-aſhes is to be added a quantity of fine quick-lime, in the proportion of one hundred weight to twelve hundred of the blended aſhes, and the lime and aſhes are to be well mixed together. After this the whole is to be put into an iron pan, into which is to be poured a quantity of ſea-water ſufficient, ſays the author, to diſſolve the aſhes and lime ; and the whole is to be ſtirred with an iron rake till it incorporate. This being done, a coal fire is to be lighted up under the pan, and kept burning for two days and two nights without intermiſſion, additional quantities of ſea-water being conſtantly ſupplied to impregnate the materials with ſaline matter ſufficient for calcination in a reverberating furnace or calcar. In this calcar the ſaline maſs, which was boiled in the pan, is by intenſe heat to be diſſolved, and kept in a ſtate of fuſion for the ſpace of an hour ; during which time the volatile part flies off, and leaves remaining a fixed alkaline ſalt, which, cooled in iron pans, is the Britiſh barilla, and has the appearance of Spaniſh barilla. See BARILLA, *Encycl.*

BARTHELEMI (Jean Jacques), the Neſtor of French literature, was a man ſo eminent for his knowledge of antiquities, that every claſſical reader muſt be intereſted in his fate. He was born, we believe, at Paris about the latter end of the year 1715 ; and being educated for the ſervice of the church, he became prior of Courcay, keeper of the medals and antiques in the French king's cabinet, and in 1747 was elected a member of the Academy of Inſcriptions. From that period his life was wholly devoted to letters ; and in recording the principal events of it, we can only enumerate, in their order, his various publications.

A diſſertation of his on the river Pactolus was read 1748 (*Hiſt. de l'Acad.* X. 29.) ; Reflections on a Medal of Xerxes, King of Arſamata (*Mem. de l'Acad.* XXXVII. 171.), found, or ſaid to be found, by Fourmont in the temple of Apollo Anycleus (XXXIX. 129.) ; Eſſay on Numiſmatic Palæography, *ib.* 223 ; Diſſertation on two Samaritan Medals of Antigonus

King

King of Judea, *ib.* 257; Remarks on ſome Inſcriptions publiſhed by different authors, XLV. 99; Diſſertation on Arabic Coins, *ib.* 143; by which it appears that the Mohammedan princes copied the heads of Greek and Roman ones on their coins, and gave Arabic inſcriptions of their own names on the reverſe. On the Ancient Alphabet and Language of Palmyra, *ib.* 179; on the Ancient Monuments of Rome, the reſult of a tour in Italy to collect medals for the royal cabinet, to which he added 300, XLIX. 151; on ſome Phœnician Monuments, and the Alphabets formed from them, LIII. 23. The characters on the written mountains, which he here cites, have been proved of no value; and he illuſtrates the conformity between the Phœnician and the Egyptian characters from the latter on the bandages of the mummies. Explanation of the Moſaic Pavement of the Temple of Præneſte, *ib.* 149; of which there have been four engravings ſince its firſt diſcovery in 1650, and which Barthelemi refers to the voyage of Adrian into Egypt. It may be of that date, but there is no reaſon to ſuppoſe that it repreſents any thing more than an Egyptian landſcape. The form of letters determines the date in the judgment of the learned Abbé. On the Relations of the Egyptian, Phœnician, and Greek Languages, LVII. 383; on ſome Medals publiſhed by different authors, LIX. 270; Explanation of an Inſcription under a Bas-relief in the Biſhop of Carpentras's Library, 1767, *ib.* 365; on the Number of Pieces repreſented in one Day on the Theatre at Athens, LXXII. 286; three Comedies, as many Tragedies, a Satire, and a Petite Piece; Remarks on ſome medals of the Emperor Antoninus ſtruck in Egypt, LXXX. 484. 1775 (A).

His interpretation of the Phœnician inſcription at Malta, LIII. 23, was controverted by our learned linguiſt, Mr Swinton, in Philoſ. Tranſact. LIV. art. xxii. p. 119; in farther remarks, *ib.* art. lxx. p. 393.

In 1792 he publiſhed a diſſertation on an ancient Greek inſcription, containing an account of expences of the public feaſts under the archontate of Glaucippus, 410 years before Chriſt.

The intimate acquaintance which he had cultivated with claſſical antiquity, enabled him, in the cloſe of a long life, to compoſe that *chef-d'œuvre*, the "Travels of the Younger Anacharſis into Greece" in the middle of the fourth century before the vulgar era. In repreſenting the curioſity of a Scythian ſavage (for we cannot conſider in any other light the man who put muſic and the exceſſes of the table on the ſame level), he takes occaſion to interweave very curious and inſtructive details on the laws, religion, manners, cuſtoms, and general ſpirit, of a great nation, as well as its progreſs in arts and ſciences. The epoch which he has choſen is that of letters and arts, combining the age of Pericles with that of Alexander, the revolution which changed the appearance of Greece, and ſoon after overturned the empire of Perſia. The introduction comprehends the 1250 years elapſed from the age of Cecrops to the ſuppoſed era of Anacharſis, in two intervals; the firſt reaching to the commencement of the Olympiads, the ſecond to the capture of Athens by the Lacedemonians. The hiſtory of the Athenians commences about 150 years after the firſt Olympiad, including the age of Solon, or that of legiſlation; that of Themiſtocles and Ariſtides, or that of glory, of luxury, and arts. In the ſecond, ſpeaking of war, his obſervation, that "the example of one nation, that prefers death to ſlavery, is too important and too inſtructive to be paſſed in ſilence," ſhould have preſerved him from the horrors of a long confinement in an advanced age, from which he was delivered only to die. But arts, ſciences, and literature, are alike forgotten and overwhelmed in France. In the third interval, ſpeaking of the corruption of manners introduced by Pericles to ſupport his power, he has this obſervation, applicable to every ſtate: "Corrupted morals are not reſtored but by the loſs of liberty, which brings that poverty inconſiſtent with ſoftneſs, and inſeparable from abſtemiouſneſs, if not that rigid principle of a healthy mind, which is properly called *virtue*." In this period, though the arts were encouraged, philoſophy was neglected.

In this diverſified undertaking, where the picture of ancient Greece, in its minuteſt parts, both of public and private uſe, is brought before our eyes, the Abbé is frequently more brilliant than ſolid, and occaſionally loſes the ſubſtance of a reflection in purſuit of ſomething ingenious to add to it. The plans, views, and maps, are executed with great ſpirit and accuracy by Mr Barber, a young man of very promiſing talents; and to the charts many uſeful tables are added. The beauties of the claſſics are diffuſed in a very pleaſing manner, and interſperſed with anecdotes little known.

Such was the man whom the French government detained in priſon for months, and releaſed on the fall of Robeſpierre. As he concurred in the revolution, we know of no cauſe for his impriſonment but the mildneſs of his diſpoſition, and the jealouſy of that tyrant, which purſued, with relentleſs cruelty, every man ſuſpected of being a friend to peace. Of the perſecution of Barthelemi, in the extremity of old age, the convention itſelf ſeemed to be aſhamed; for it unanimouſly voted him a penſion as ſome recompence for his ſufferings. But, alas! the recompence came too late: the old man lived but a few months after his liberation, having died at Paris on the 4th of May 1795; and the day after the following tribute was paid to his memory by Duſſaulx, in the national convention:

"Legiſlators, your liberality conferred honour on the latter days of the life of our reſpectable fellow citizen, Barthelemi. Our ſucceſſors, I have no doubt, will conſecrate his memory ſo ſoon as the period fixed by the law ſhall permit them. May his old friend, however, be permitted, in a few words, to point out the rare qualities of that Neſtor of French literature? It might, perhaps, be ſufficient to tell you, as Xenophon ſaid with ſo much ſimplicity of one of his moſt illuſtrious contemporaries, that Barthelemi was an excellent man in all reſpects. In fact, thoſe who knew him were at a loſs which to admire moſt—his immortal Anacharſis, or his own life. His policy conſiſted in goodneſs; his ſcience was an immenſe treaſure of every thing that could purify the morals, perfect the taſte, render man

---

more dear to man, and contribute to the ſplendour of his country. A ſingle trait will convince you of the mildneſs of his philanthropic mind: 'Why is it not permitted (he often ſaid) to a mortal to bequeath proſperity to his fellow-creatures?' After having been overwhelmed with the favours of fortune, which came unexpectedly and unſought, he became poor; yet his character, far from ſinking under the preſſure, acquired new reſpect; and he proved that poverty, ſupported with dignity, is not leſs honourable than wealth accompanied with benevolence. Perſecuted, as all virtuous and enlightened citizens were, he carried with him to the dungeon of that tyranny which you have ſo gloriouſly deſtroyed, the conſtancy and ſerenity of Socrates. It was there that the venerable old man offered to his companions in misfortune the magnificent ſpectacle of a good man ſtruggling with adverſity. I have ſaid that he was rich; but let us not forget that he was not rich at the expence of the unfortunate, and that he adopted all the branches of his numerous family. The republic has gained by that family good citizens, who ſerve her in the moſt uſeful and brilliant manner. Barthelemi felt that the period of his diſſolution was approaching; yet though exhauſted by long fatigue, and bending beneath the weight of 80 years, his ſenſibility was ſtill vigorous, and your juſt decrees made the cloſing ſcene of his life happy. When he heard that you were endeavouring to repair the ills under which ſo many thouſand innocent men laboured, he lifted up his hands to heaven, and exclaimed, 'Glory to God—honour to the national convention—I have lived long enough!' In the preſent poſture of affairs, the country demands all your attention. I ſhall therefore confine myſelf to requeſt the favour due to the manes of the illuſtrious Barthelemi. One of his nephews, I do not mean your reſpectable ambaſſador at Baſle, but the citizen Courcey, has, for 25 years, diſcharged all the duties of a ſon to his uncle, and for a long time has performed the functions of keeper of the medals and antiquities of the national cabinet. I move, that the citizen Courcey be appointed to that office, which he has already proved himſelf ſo worthy to fill."

Whatever became of this motion, which was referred to the committee of public inſtruction, the cruelty of the government purſued the family; and the late baniſhment of his other nephew by the directory, of which he was a member, ſurpaſſes, if poſſible, the injuſtice of Robeſpierre to the uncle. But their crimes were the ſame: both Barthelemis were men of mild diſpoſitions and friends to peace.

BARYTES, one of the earths. See CHEMISTRY in this Supplement, Part I. Chap. iv.

BASTER, the name given by the Dutch at the Cape of Good Hope to the offspring of a white man and Hottentot woman.

BAT, an animal which has been deſcribed under its generic name VESPERTILIO in the *Encycl.* but ſince that article was written, we have met with an account of a new ſpecies, ſo very ſingular, that, if the veracity of our author can be depended on, it is well intitled to a place here. This ſpecies was diſcovered in the country of the Nimiquas, in the interior of Africa, by *M. Vaillant*, during the courſe of his ſecond travels, and is by him called the *oreillar* bat. To this title it has indeed a very good claim; for it has, he ſays, four ears, or at leaſt the external part of four ears, each ear being double; the outer fold, which ſerves as a covering to the inner, is very ample, being two inches eight lines high, and nearly as broad when ſtretched out. On the noſe alſo a membrane ſtands erect, one inch four lines in height, which might be taken for another ear, as it has exactly the ſhape of one. This membrane, as well as the ears and wings of the animal, are of a ruſty red, paler below than above. The body is only three inches long, and is covered with very fine greyiſh hair. Its width, from the tip of one wing to that of the other, is eight inches. The reader will pardon me, ſays our author, for inſerting theſe trifling details of meaſurement, of which I am not more fond than himſelf; but they appeared to me neceſſary here, to convey an accurate idea of the extraordinary length of the ears of this animal, which are certainly larger in proportion than thoſe of any other we are acquainted with, ſince they are only four lines, or the third part of an inch, ſhorter than the body itſelf.

BATAVIA, the capital of the Dutch ſettlements in the Eaſt Indies, has been already deſcribed under the article JAVA in the Encyclopædia. The following account of it, however, as well as of the country around it, and the manners and cuſtoms of its various inhabitants, as they preſented themſelves to Sir George Staunton in March 1793, will probably prove acceptable to many of our readers.

The city of Batavia, including the ſuburbs, conſiſts of near eight thouſand houſes, inhabited by Dutch, Chineſe, and natives of Java. The houſes of the Chineſe are low, and crammed with people. The Dutch houſes are well built, clean, and ſpacious, and their conſtruction for the moſt part well ſuited to the climate. The doors and windows are wide and lofty. The ground floors are covered with flags of marble, which being ſprinkled frequently with water, give a pleaſant coolneſs to the apartment; but a conſiderable proportion of thoſe was untenanted, which denoted a declining ſettlement. Among other circumſtances which announced the ſame, were thoſe of the Company's veſſels lying uſeleſs in the road, for want of cargoes to fill, or men to navigate them; no ſhips of war to protect their commerce, even againſt pirates who attacked their veſſels ſometimes in the ſight of Batavia road; an invaſion threatened from the Iſle of France; the place in no condition of defence, particularly againſt an enemy leſs affected by the climate than Europeans; ſometimes as many of the troops in hoſpitals as fit for duty; commiſſioners expected from Holland to reform abuſes. Such a commiſſion, implying a general ſuſpicion, could not be welcome; nor was it quite certain whether, in ſome minds, its arrival, or that of the enemy, was deprecated the moſt cordially.

The fortifications of Batavia, though a place of ſo much importance, were not, when Sir George ſaw them, ſuch as would be deemed formidable in Europe; but when the difficulties were conſidered of forcing the paſſage of the river, or of landing troops on other parts of the iſland, it might perhaps be thought of greater ſtrength than it would at the firſt view have credit for. The defences of the river were the water fort, ſituated at its entrance, having mounted or diſmounted fourteen guns and two howitzers. It conſiſted of a parapet, originally well conſtructed, retained by by a wall; but the parapet was much neglected, and the wall nearly deſtroyed by the conſtant working of the ſea. This fort was protected on the land ſide by a noxious ſwamp, and towards the ſea, on the north-weſt, by extenſive flats, over which even boats could not paſs. The only good approach was that by the channel, which it ſees and defends. The next work upon the river was on the weſt ſhore, about a quarter of a mile from the water fort. It is a battery mounting ſeven guns, bearing down the river. Oppoſite to this was a battery of ſix guns, facing the river, and two to the eaſtward. This formed one flank of a line that occupied the low land to the north-eaſt of the town. The line was a low breaſt-work of earth, that was ſcarcely diſcoverable. The canals which interſect the town joined the great canal or river, at the diſtance of half a mile from the entrance. Below the junction a boom was laid of wood, armed with iron ſpikes. A little above was the caſtle, a regular ſquare fort, but without ravelins or other outworks. It had two guns mounted on each flank, and two, or ſometimes three, on each face: they were not *en barbette*, nor properly *en embraſure*, but in a ſituation between both, having both their diſadvantages without the advantage of either. The wall was of maſonry, about 24 feet high. It had no ditch, but a canal ſurrounded it at ſome diſtance. It had no cordon. The length of the exterior ſide of the work was about 700 feet. The town is rectangular, three quarters of a mile long, and half a mile broad, incloſed by a wall of about 20 feet in height. Small projections were conſtructed, of various forms, at intervals of about 350 feet. Theſe generally mounted three guns each. It was alſo ſurrounded by a canal, having ſeveral ſluices. At ſhort diſtances from the town, three or four ſmall ſtar forts of earth were erected in particular paſſes, perhaps for defence againſt the inhabitants of the iſland.

The eſtabliſhment of regular troops was 1200 Europeans, of whom 300 were to be artillery, the reſt infantry. But as it was found impoſſible, on account of the climate, to keep the number complete, recourſe was had to the natives, of whom 500 were employed; ſo that the eſtabliſhment of European regulars was reduced to 700. There were alſo 300 volunteers of the town, who were formed into two companies, but they were not diſciplined. Their regulars were very numerous, conſiſting of enrolled natives of Java, who were never embodied, and of Chineſe, of whom the Dutch were ſo jealous as to arm them with lances only. Much dependence was not to be placed on the exertions of either of theſe bodies in favour of the Dutch; and as they loſe many of their European troops every year, their eſtabliſhment appeared too ſmall for any effectual reſiſtance. The chief protection of their ill-manned veſſels lying here, muſt be from the fortified iſland of Onruſt, well ſituated to command the channel that affords the principal paſſage into the road. The work upon that iſland was of a pentagonal form; its baſtions were ſmall and low, not more than 12 feet the higheſt, and not always connected by curtains. A few batteries were lately conſtructed on the outſide of this work, that bore towards the ſea. On theſe and on the baſtions about 40 guns were mounted in different directions. South of theſe was another iſland, at the diſtance of a few hundred yards, on which two batteries, mounting together 12 guns, had been lately erected.

The caſtle is built of coral rock, brought from ſome of the adjoining iſlands, compoſed of that material; and has the advantage of a fortification of brick, in which cannon ball is apt to bury itſelf without ſpreading ſplinters or ſhattering the wall. A part of the town wall is built of lava, which is of a dark blue colour, of a very hard denſe texture, emits a metallic ſound, and reſembles very much ſome of the lava of Veſuvius. It is brought from the mountains in the centre of Java, where a crater is ſtill ſmoking. No ſtone of any kind is to be found for many miles behind the city of Batavia. Marble and granite are brought thither from China, in veſſels belonging to that country, commonly called *junks*, which generally ſail for Batavia from the ports of the provinces of Canton and Fokien, on the ſouthern and ſouth-eaſt coaſts of that empire, laden chiefly with tea, porcelain, and ſilks.

The chief protection of Batavia againſt the attacks of a foreign enemy, ariſes from the havoc which it is well known the climate would make amongſt European troops. This was acknowledged to Lord Macartney by ſome of the Dutch officers themſelves, and even by one of the counſellors of the Indies. Such indeed is the climate, that there have been very few examples of ſtrangers remaining long in Batavia without being attacked by fever, which is the general denomination in that place for illneſs of every kind. Europeans ſoon after their arrival firſt become languid and feeble, and in a few weeks, or even in a few days, are taken ſeriouſly ill. The diſorder at firſt is commonly a tertian ague, which after two or three paroxyſms becomes a double tertian, and then a continued remittent, that frequently carries off the patient in a ſhort time. Many fall victims to the ſecond or third fit; but in theſe caſes a conſtant delirium, and a great determination of the blood to the brain, accompany the other ſymptoms. In ſome it begins in a quotidian form, with regular intermiſſions for a day or two; and then becomes a continued remittent, attended with the ſame fatal conſequences as the former. Of the Europeans of all claſſes who come to ſettle at Batavia, it is ſuppoſed that not half the number always ſurvives the year. The place reſembles in that reſpect a field of battle or a town beſieged. The frequency of deaths renders familiar the mention of them, and little ſigns are ſhewn of emotion or ſurpriſe on hearing that the companion of yeſterday is to-day no more. It is probable, female Europeans ſuffer leſs at Batavia than the men. The former ſeldom expoſe themſelves to the heat of the ſun, make frequent uſe of the cold bath, and live more temperately than the other ſex.

But it is not to thoſe who have lately arrived from Europe that this havoc is wholly confined. The greateſt number of the Dutch ſettlers, even thoſe who had reſided long in the country, appeared wan, weak, and languid, as if labouring with the "diſeaſe of death." Their place of reſidence, indeed, is ſituated in the midſt of ſwamps and ſtagnated pools, from whence they are every morning ſaluted with "a congregation of foul and peſtilential vapours," whenever the ſea breeze ſets in, and blows over this moraſs. The meridian ſun raiſes from the ſhallow and muddy canals, with which the town is interſected, deleterious miaſmata into the air; and the trees, with which the quays and ſtreets are crowded, emit noxious exhalations in the night.

The general reputation of the unhealthineſs of Batavia is indeed ſuch as to deter even Dutchmen, who can reſide at home with any comfort, from coming to it, notwithſtanding the temptation of fortunes to be quickly amaſſed in it. From this circumſtance it happens, that offices and profeſſions are often neceſſarily entruſted to perſons little qualified to fill them. One of the clergymen, and the principal phyſician of the place, were both ſaid to have originally been barbers. The United Provinces furniſh even few military recruits. The reſt are chiefly Germans, many of whom are ſaid to have been kidnapped into the ſervice. Though nominally permitted, after a certain length of time, to return home, they are in fact compelled to enliſt for a longer time, the pay being too ſcanty to allow them to ſave enough to defray the expence of their paſſage to Europe. The government is accuſed of the barbarous policy of intercepting all correſpondence between thoſe people and their mother country; by which means they are deprived of the conſolation of hearing from their friends, as well as of the chance of receiving ſuch aſſiſtance as might enable them to get home.

Difficult, however, as it is, on account of the climate, to recruit the army, ſuch is the deſire of accumulating wealth in a foreign land, that it draws annually great numbers of Chineſe as well as of Dutch to Batavia. Both indeed belong generally to the humbler claſſes of life, and are bred in ſimilar habits of induſtry in their own country; but the different circumſtances that attend them after their arrival in Batavia put an end to any further reſemblance between them. The Chineſe have there no way of getting forward but by the continuance of their former exertions in a place where they are more liberally rewarded, and by a ſtrict economy in the preſervation of their gains. They have no chance of advancing by favour, nor are public offices open to their ambition; but they apply to every induſtrious occupation, and obtain whatever either care or labour can accompliſh. They become in town retailers, clerks, and agents; in the country they are farmers, and are the principal cultivators of the ſugar-cane. They do at length acquire fortunes, which they value by the time and labour required to earn them. So gradual an acquiſition makes no change in their diſpoſition or mode of life. Their induſtry is not diminiſhed, nor their health impaired. The Dutch, on the contrary, who are ſent out by the Company to adminiſter their affairs in Aſia, become ſoon ſenſible that they have the power, wealth, and poſſeſſions of the country at their diſpoſal. They who ſurvive mount quickly into offices that are lucrative, and not to them laborious. They riſe to the dignity of governor-general and counſellors of the Indies, as the members of the Batavian government are called. Their influence likewiſe enables them to ſpeculate in trade with vaſt advantage. The drudgery and detail of buſineſs are readily undertaken by the Chineſe; while their principals find it difficult, under ſuch new circumſtances, to retain their former habits, or to reſiſt a propenſity to indolence and voluptuouſneſs, though often attended with the ſacrifice of health, if not of life. Convivial pleaſures, among others, are frequently carried to exceſs.

In ſeveral houſes of note throughout the ſettlement, the table is ſpread in the morning at an early hour: beſide tea, coffee, and chocolate, fiſh and fleſh are ſerved for breakfaſt; which is no ſooner over than Madeira, claret, gin, Dutch ſmall beer, and Engliſh porter, are laid out in the portico before the door of the great hall, and pipes and tobacco preſented to every gueſt, and a bright braſs jar placed before him to receive the phlegm which the tobacco frequently draws forth. This occupation continues ſometimes with little interruption till near dinner time, which is about one o'clock in the afternoon. It is not very uncommon for one man to drink a bottle of wine in this manner before dinner; and thoſe who have a predilection for the liquor of their own country ſwallow ſeveral bottles of Dutch ſmall beer, which they are told dilutes their blood, and affords plenty of fluids for a free perſpiration. Immediately before dinner, two men ſlaves go round with Madeira wine, of which each of the company takes a bumper as a tonic or whetter of the appetite. Then follow three females, one with a ſilver jar containing water, ſometimes roſe-water, to waſh; a ſecond with a ſilver baſon and low cover of the ſame metal, pierced with holes, to receive the water after being uſed; and the third with towels for wiping the hands. During dinner a band of muſic plays at a little diſtance: the muſicians are all ſlaves, and pains are taken to inſtruct them. A conſiderable number of female ſlaves attend at table, which is covered with a great variety of diſhes; but little is received, except liquors, into ſtomachs already cloyed. Coffee immediately follows dinner. The 24 hours are here divided, as to the manner of living, into two days and two nights; for each perſon retires, ſoon after drinking coffee, to a bed, which conſiſts of a mattraſs, bolſter, pillow, and chintz counterpane, but no ſheets; and puts on his night dreſs, or muſlin cap and looſe long cotton gown. If a bachelor, which is the caſe of much the greateſt number, a female ſlave attends to fan him while he ſleeps. About ſix they riſe, dreſs, drink tea, take an airing in their carriages, and form parties to ſpend the evening together to a late hour. The morning meetings conſiſt generally of men, the ladies ſeldom chooſing to appear till evening.

Few of theſe are natives of Europe, but many are deſcended from Dutch ſettlers here, and are educated with ſome care. The features and outlines of their faces are European; but the complexion, character, and mode of life, approach more to thoſe of the native inhabitants of Java. A pale languor overſpreads the countenance, and not the leaſt tint of roſe is ſeen in any cheek. While in their own houſes they dreſs like their ſlaves, with a long red checkered cotton gown deſcending to the ankles, with large wide ſleeves. They wear no head-dreſs, but plait their hair, and faſten it with a ſilver bodkin on the top of the head, like the country girls in ſeveral cantons of Switzerland. The colour of their hair is almoſt univerſally black; they anoint it with the oil of the cocoa nut, and adorn it with chaplets of flowers. When they go abroad to pay viſits, or to take an airing in their carriages, and particularly when they go to their evening parties, they dreſs magnificently, in gold and ſilver ſpangled muſlin robs, with a profuſion of jewels in their hair, which, however, is worn without powder. They never attempt to mould or regulate the ſhape by any fancied idea of elegance, or any ſtandard of faſhion; and conſequently formed a ſtriking contraſt with ſuch few ladies as were lately arrived from Holland, who had powdered hair and fair complexions, had contracted their waiſts with ſtays, wore large head-dreſſes and hoops, and perſevered in the early care of forcing back the elbows, chin, and ſhoulders. Every native lady is conſtantly attended by a female ſlave handſomely habited, who, as ſoon as her miſtreſs is ſeated, ſits at her feet before her, on the floor, holding in her hands her miſtreſs's gold or ſilver box, divided into compartments, to contain areca nut, cardamom ſeeds, pepper, tobacco, and ſlacked lime; all which, mixed together in due proportions, and rolled within a leaf of betel, conſtitute a maſticatory of a very pungent taſte, and in general uſe. When in the public aſſemblies the ladies find the heat diſagreeable, they retire to free themſelves from their coſtly but inconvenient habits, and return without ceremony in a more light and looſe attire, when they are ſcarcely recognizable by ſtrangers. The gentlemen follow the example; and throwing off their heavy and formal dreſſes, appear in white jackets, ſometimes indeed adorned with diamond buttons. The elderly gentlemen quit their periwigs for nightcaps. Except in theſe moments the members of this government have always combined their perſonal gratification with the eaſtern Policy of ſtriking awe into vulgar minds, by the aſſumption of exterior and excluſive diſtinctions. They alone, for inſtance, appear abroad in crimſon velvet. Their carriages are diſtinguiſhed by peculiar ornaments. When met by others, the latter muſt ſtop and pay homage to the former. One of the gates of the city is opened only to let them paſs. They certainly ſucceed in ſupporting abſolute ſway over a vaſt ſuperiority in number of the deſcendants of the original inhabitants of the country, as well as of the ſlaves imported into it, and of the Chineſe attracted to it by the hope of gain; thoſe claſſes, though healthy, active, and as if quite at home, readily obeying a few emaciated Europeans. Such is the conſequence of dominion once acquired; the prevalence of the mind over mere bodily exertions, and the effect of the combination of power againſt divided ſtrength.

The native Javaneſe are in general too remote from civilization to have any wants that are not eaſily ſatisfied in a warm and fertile climate. No attempt is made to enſlave their perſons; and they find the government of the Dutch leſs vexatious than that of others, who divide ſome ſhare of the ſovereignty of the iſland with them. The ſultan of Mataran rules to the eaſt, the emperor of Java in the centre, and the king of Bantam to the weſt; while the coaſt and effective power almoſt entirely belong to Holland. Thoſe other ſovereigns are deſcended from foreigners alſo; being Arabians, who imported the Mahometan religion into Java, and acquired the dominion of the country; a few inhabitants in the mountains excepted, who have preſerved their independence and their faith, and among other articles that of the tranſmigration of ſouls. According to the Dutch accounts, nothing can be more tyrannic than thoſe Mahometan rulers. The Emperor is ſaid to maintain his authority by an army of many thouſand men diſperſed throughout his territories, beſide a numerous female guard about his perſon. Theſe military ladies are trained, it ſeems, to arms, without neglecting thoſe accompliſhments which may occaſion a change in the occupation of ſome among them, rendering them the companions, inſtead of being the attendants, of his Imperial majeſty. This ſingular inſtitution may owe its origin to the facility of obtaining recruits, if it be true, as the ſame accounts pretend, that the number of female births exceeds very conſiderably that of males in Java.

Moſt of the ſlaves are imported into it from Celebes and other eaſtern iſlands. They do not form a corps, or have any bond of union: nor is the general conduct of their owners, towards them calculated to aggravate the misfortune of being the property of others. They are not forced to exceſſive labour. They have ſufficient ſuſtenance; but many of the males among them, who had formerly perhaps led an independent life till made captives in their wars, have been found to take offence againſt their maſters upon very ſlight occaſions, and to wreak their vengeance by aſſaſſination. The apprehenſion of ſuch an event is among the motives for preferring at Batavia female ſlaves for every uſe to which they can be applied; ſo that the number purchaſed of them much exceeds that of the other ſex. The ſlaves when determined on revenge often ſwallow, for the purpoſe of acquiring artificial courage, an extraordinary doſe of opium, and ſoon becoming frantic as well as deſperate, not only ſtab the objects of their hate, but ſally forth to attack in like manner every perſon they meet, till ſelf-preſervation renders it neceſſary to deſtroy them. They are ſaid in that ſtate to be *running a muck;* and inſtances of it are not more common among ſlaves than among free natives of the country, who, in the anguiſh for loſing their money, effects, and ſometimes their families, at gaming, to which they are violently addicted, or under the preſſure of ſome other paſſion or misfortune, have recourſe to the ſame remedy, with the ſame fatal effects.

In the country round Batavia the eye looks in vain for the common animals and vegetables which it had been daily accuſtomed to meet in Europe. The moſt familiar bird about the houſe of the ambaſſador's hoſt was the crown bird, as it was called at Batavia, which was not, however, the *ardea pavonina* of Linnæus, but the *columba criſtata*, having nothing except its creſt in common with the former. The ſame gentleman had alſo at his country-houſe ſome large caſſowary birds, which, though long in his poſſeſſion, and having the appearance of tameneſs, ſometimes betrayed the fierceneſs of their nature, attacking with their ſtrong bill thoſe who approached too near them. The vegetation of the country is likewiſe new. Even the parterres in the gardens are bordered, inſtead of boxwood, by the Arabian jeſſamine, of which the fragrant flowers adorn the pagodas of Hindoſtan. The Dutch, who are ſo fond of gardens in Holland, have transferred that taſte, where it can certainly be cultivated with more ſucceſs, and indulge it to a great extent at their houſes a little way from the city of Batavia; but ſtill within that fenny diſtrict, concerning which an intelligent gentleman upon the ſpot uſed the ſtrong expreſſion, that the air was peſtilential and the water poiſonous. Yet the country is everywhere ſo verdant, gay, and fertile; it is interſperſed with ſuch magnificent houſes, gardens, avenues, canals, and draw-bridges; and is ſo formed in every reſpect to pleaſe, could health be preſerved in it—that a youth coming juſt from ſea, and enraptured with the beauty of every object he ſaw around him, but mindful of the danger there to life, could not help exclaiming, "what an excellent habitation it would be for immortals!"

The moſt tolerable ſeaſon here is from March or April to November; when the rains begin, and laſt the reſt of the year. The ſea breeze ſets in about ten o'clock in the morning, and continues till four or five in the afternoon. It becomes then calm till ſeven or eight, when the land breeze commences, and continues at intervals till day-break, followed by a calm for the remaining hours of the 24. Fahrenheit's thermometer was, in Batavia road, during the Lion's remaining there, from 86° to 88°, and in the town from 88° to 92°; but its variations by no means correſponded to the ſenſations produced by the heat on the human frame; the latter being tempered by any motion of the air, which circumſtance has little effect upon the thermometer. Nor are the animal ſufferings here from heat to be meaſured by its intenſeneſs at any given moment of the day, but by its perſiſting through the night; when, inſtead of diminiſhing, as it does in colder countries, ſometimes 20 degrees, it keeps generally here within four or five of what it attains in the ſhade, when the ſun is at its higheſt elevation.

The native Javaneſe derive, however, one advantage at leaſt from an atmoſphere not ſubject to the viciſſitudes of temperature experienced in the northern parts of Europe, where diſeaſes of the teeth are chiefly prevalent; as they are here entirely exempt from ſuch complaints. Their habit of living chiefly on vegetable food, and of abſtaining from fermented liquors, no doubt contributes to this exemption; yet ſuch is the caprice of taſte, that jet black is the favourite colour and ſtandard of beauty for the teeth amongſt them, comparing to monkeys thoſe who keep them of the natural colour. They accordingly take care to paint, of the deepeſt black, all their teeth, except the two middle ones, which they cover with gold leaf. Whenever the paint or gilding is worn off, they are as attentive to replace it on the proper teeth, as the belles of Europe are to purify and whiten theirs.

We have mentioned the rich vegetation of the country and the gardens which the Dutch have planted. In theſe gardens or orchards they cultivate the nutmeg, the clove, the camphor, and the cinnamon trees, together with the pepper plant, which, creeping like a vine, is ſupported on a living tree. It is a ſpecies of the pepper plant that affords the leaf called *betel*, chewed ſo univerſally by the ſouthern Aſiatics, and ſerving for the incloſure of a few ſlices or bits of the areca, from thence erroneouſly called the *betel nut*. The areca nut tree is among the ſmalleſt of the tribe of palms, but comes next in beauty to the mountain cabbage tree of the Weſt Indies, the latter differing chiefly in its ſize and amazing height from the areca nut tree, the diameter of whoſe jointed trunk ſeldom exceeds four inches, or height 12 feet. But the ſymmetry of each is perfect; the columns of a temple cannot be more regular than the trunk, which riſes without a branch, while the broad and ſpreading leaves which crown the top form the ornamented capital. The areca nut, when dried, has ſome ſimilitude in form and taſte to the common nutmeg, but is of a leſs ſize.

It would have been very extraordinary, and very culpable, in Sir George Staunton, and Dr Gillan phyſician to the embaſſy, if they had not, when on the ſpot, inquired into the truth of Foerſch's account of the *upas* or poiſon tree of Java (ſee *Poison Tree of Java*, Encycl.) But the moſt minute inquiries were made reſpecting it; and the reſult of them was, that no ſuch tree is known at Batavia, and certainly does not exiſt where Foerſch has planted it. It is indeed a common opinion at Batavia, that there exiſts in that country a vegetable poiſon, which, rubbed on the daggers of the Javaneſe, renders the ſlighteſt wounds incurable; though ſome European practitioners have of late aſſerted that they had cured perſons ſtabbed by thoſe weapons, but not without having taken the precaution of keeping the wound long open, and procuring a ſuppuration. One of the keepers of the medical garden at Batavia aſſured Dr Gillan, that a tree diſtilling a poiſonous juice was in that collection, but that its qualities were kept ſecret from moſt people in the ſettlement, leſt the knowledge of them ſhould find its way to the ſlaves, who might be tempted to make an ill uſe of it. In the ſame medical garden, containing it ſeems hurtful as well as grateful ſubſtances, is found alſo the plant from whence is made the celebrated gout remedy, or moxa of Japan, mentioned in the works of Sir William Temple, and deſcribed in the Encyclopædia under the titles of Artemisia and Moxa.

The whole country abounds with eſculent fruits, and, amongſt others, with the mangoſteen, which is ripe in March, and is conſidered as the moſt delicious of all fruits (ſee Garcinia, *Encycl.)* Pine apples are in Java planted not in gardens, but in large fields; and are carried like turneps in heaps upon carts to market, and ſold for conſiderably leſs than a penny each, where money is cheaper than in England. It was a common practice to clean ſwords, or other inſtruments of ſteel or iron, by running them through pine apples, as containing the ſtrongeſt and cheapeſt acid for diſſolving the ruſt that covered them. Sugar ſold for about five-pence a pound. All ſorts of proviſions were cheap, and the ſhips crews fed on freſh meat every day.

The ſerpents and noxious reptiles in Java have been mentioned elſewhere; but Sir George Staunton aſſures us, that not many accidents happen from them. Among the pagan Javaneſe, the crocodile, he ſays, is an object not only of fear, but alſo of religious veneration, to which offerings are made as to a deity. When a Javaneſe feels himſelf diſeaſed, he will ſometimes build a kind of coop, and fill it with ſuch eatables as he thinks moſt agreeable to the crocodiles. He places the coop upon the bank of the river or canal, in the perfect confidence that, by the means of ſuch offerings, he will get rid of his complaints; and perſuaded, that if any perſon could prove ſo wicked as to take away thoſe viands, ſuch perſon would draw upon himſelf the malady for the cure of which the offering was made. According to Sir George Staunton, Batavia road lies in 6° 10′ ſouth lat. and 106° 51′ eaſt long. from Greenwich.

BEER is a liquor ſo palatable to the natives of Britain, and, when properly made, ſo wholeſome, eſpecially in long voyages at ſea, that Mr Thornton of Eaſt Smithfield obtained a patent, dated April 15. 1778, for inventing a method of reducing *malt* and *hops* to an eſſence or extract, from which beer may be made anywhere, either at ſea or in diſtant countries. Though we do not perceive any great degree of ingenuity diſplayed in this invention, yet as the account of it is ſhort, we ſhall lay it before our readers.

His method then of preparing an eſſence or extract of malt and hops is, by the tranſmitted heat of compreſſed

preſſed vapour of boiling water, and a proper apparatus for that purpoſe. This apparatus may be made of iron, tin, or copper: it conſiſts of a boiler of any dimenſions, a double veſſel, and conducting tubes. The double veſſel conſiſts of one veſſel placed within another, and fitted tight at their rims. The upper veſſel forms the upper part of the under veſſel, and contains the liquor to be evaporated. The under veſſel is everywhere incloſed except at an aperture communicating with the boiler, and at another aperture communicating with the conducting tubes; and is conſtructed ſo as not to allow any part of the vapour condenſed into drops within it to eſcape, except back again into the boiler: it is not ſo extenſive as to act as a common refrigeratory, and yet is capacious enough to prevent the liquor boiling over. The aperture communicating with the boiler is large enough to freely admit the vapour from the boiler into the under veſſel; and the aperture communicating with the conducting tubes is of a proper ſize to allow of the vapour in the under veſſel being compreſſed, to a degree capable of tranſmitting to the liquor to be evaporated a proper heat, and at the ſame time to ſerve as a paſſage for more heat than is neceſſary to keep up that degree of compreſſion. The conducting tubes are to convey this ſuperfluous heat or vapour, to be uſed for farther purpoſes, or immediately out of the building.

BEETLE, an inſect deſcribed in the Encyclopædia under the name given to it by naturaliſts, SCARABÆUS. Since that aticle was publiſhed, we have met with an account of a nondeſcript ſpecies, which is furniſhed with very ſingular armour for its own defence. It was brought to M. Vaillant in the interior parts of Africa by a Nimiqua woman, and is by him called a ſuperb beetle, not to be found in any cabinet of Europe. "While I was examining this beautiful inſect (ſays he) with attention, I felt my face ſuddenly wetted by a cauſtic liquor, of a very ſtrong alkaline ſmell. The ſprinkling was accompanied by a ſort of exploſion, loud enough to be heard at ſome diſtance. Unfortunately ſome of the liquor entered one of my eyes, and occaſioned ſuch inſupportable pain, that I thought I ſhould have loſt the ſight of it. I was obliged to keep it covered for ſeveral days, and bathe it from time to time with milk. In every part of my face that the alkaline liquor had touched, I felt the pain of a burn; and everywhere the ſkin changed to a deep brown, which wore out only by degrees and a long time after. This will not be ſurpriſing to many, who already are acquainted with the ſame property in ſeveral inſects of the ſame genus; for inſtance, in that beautiful golden green bupreſtis, which is ſo common in our kitchen gardens in Europe: but as the inſect of which I am here ſpeaking is much larger, and inhabits a very hot country, it is natural that the effect produced by it ſhould be more ſtriking; tho' the liquor which our golden bupreſtis ejects at its enemy occaſions a very ſenſible ſmart, and its ſmell is conſiderably pungent."

The naturaliſts Dorci and Olivier have given, in their Entomology, the figure of this African inſect, which our author communicated to them, but they have given it erroneouſly. The human face, obſervable on its anterior corcelet in their figure, does not exiſt in nature; but M. Vaillant having given no figure of it himſelf, we cannot gratify our readers with a correct repreſentation.

BEGAH, a land meaſure in Bengal, about one-third of an Engliſh acre.

BEHADER *(Valiant)*, a title of honour conferred by the Mogul emperors upon either Mahomedans or Hindoos, and placed after their name or other title.

BEHEM (Martin), though hitherto little talked of, was one of the moſt enterpriſing men that ever lived, and deſerves to have his name tranſmitted with reverence to the lateſt poſterity. Born at Nuremberg, an Imperial city in the circle of Franconia, of a noble family not yet extinct, he had the beſt education which the darkneſs of that age would permit him to have; and the ſtudies to which from his infancy he was moſt addicted, were thoſe of geography, aſtronomy, and navigation. As he advanced in life, he often thought of the exiſtence of the antipodes and of a weſtern continent, of which he was ambitious to make the diſcovery.

Filled with this great idea, in 1459 he paid a viſit to Iſabella, daughter of John I. king of Portugal, at that time regent of the duchy of Burgundy and Flanders; and having informed her of his deſigns, he procured a veſſel, in which, ſailing weſtward, he was the firſt European who is known to have landed on the iſland of Fayal. He there eſtabliſhed in 1460 a colony of Flemings, whoſe deſcendants yet exiſt in the Azores, which were for ſome time called the Flemiſh Iſlands. This circumſtance is proved, not only by the writings of contemporary authors, but alſo by the manuſcripts preſerved in the records of Nuremberg; from the Latin of which the following is tranſlated: "Martin Behem tendered his ſervices to the daughter of John king of Luſitania, who reigned after the death of Philip of Burgundy, ſurnamed the *Good;* and from her procured a ſhip, by means of which, having ſailed beyond all the then known limits of the Weſtern Ocean, he was the firſt who in the memory of man diſcovered the iſland of Fayal, abounding with beech trees, which the people of Luſitania call *faye;* whence it derived its name. After this he diſcovered the neighbouring iſlands, called by one general name the *Azores*, from the multitude of hawks which build their neſts there (for the Luſitanians uſe this term for hawks, and the French too uſe the word *eſſos* or *eſores* in their purſuit of this game); and left colonies of the Flemiſh on them, when they began to be called Flemiſh Iſlands (A)."

After

(A) Although this record is contrary to the generally received opinion, that the Azores were diſcovered by Gonſalva Velho, a Portugueſe, yet its authenticity ſeems unqueſtionable. It is confirmed not only by ſeveral contemporary writers, and by Wagenſeil, one of the moſt learned men of the laſt century, but likewiſe by a note written on parchment in the German language, and ſent from Nuremberg, a few years ago, to M. Otto, who was then inveſtigating the diſcovey of America. The note contained, with other things, the following facts: "Martin Beham, Eſq; ſon of Mr Martin Beham of Scoperin, lived in the reign of John II. king of Portugal, in an iſland which he diſcovered, and called the iſland of *Fayal*, one of the Azores, lying in the Weſtern Ocean.

After having obtained from the regent a grant of Fayal, and reſided there about twenty years, Behem applied in 1484 (eight years before Columbus's expedition) to John II. king of Portugal, to procure the means of undertaking a great expedition towards the ſouth-weſt. This prince gave him ſome ſhips, with which he diſcovered that part of America which is now called Brazil; and he even ſailed to the Straits of Magellan, or to the country of ſome ſavage tribes whom he called Patagonians, from the extremities of their bodies being covered with a ſkin more like a bear's paws than human hands and feet.

A fact ſo little known, and apparently ſo derogatory to the fame of Columbus, ought not to be admitted without ſufficient proof; but the proofs which have been urged in ſupport of its authenticity are ſuch as cannot be controverted. They are not only the letters of Behem himſelf, written in 1486, and preſerved in the archives of Nuremberg, but likewiſe the public records of that city; in which we read that "Martin Behem, traverſing the Atlantic Ocean for ſeveral years, examined the American iſlands, and diſcovered the ſtrait which bears the name of Magellan before either Chriſtopher Columbus or Magellan ſailed thoſe ſeas; whence he mathematically delineated, on a geographical chart, for the king of Luſitania, the ſituation of the coaſt around every part of that famous and renowned ſtrait long before Magellan thought of his expedition."

This wonderful diſcovery has not eſcaped the notice of contemporary writers. The following paſſage is tranſlated from the Latin chronicle of Hartman Schedl: "In the year 1485, John II. king of Portugal, a man of a magnanimous ſpirit, furniſhed ſome galleys with proviſions, and ſent them to the ſouthward, beyond the Straits of Gibraltar. He gave the command of this ſquadron to James Canus, a Portugueſe, and Martin Behem, a German of Nuremberg in Upper Germany, deſcended of the family of Bonna: a man very well acquainted with the ſituation of the globe; bleſſed with a conſtitution able to bear the fatigues of the ſea; and who, by actual experiments and long ſailing, had made himſelf perfectly maſter with regard to the longitudes and latitudes of Ptolemy in the weſt. Theſe two, by the bounty of Heaven, coaſting along the Southern Ocean, and having croſſed the equator, got into the other hemiſphere, where, facing to the eaſtward, their ſhadows projected towards the ſouth and right hand. Thus, by their induſtry, they have opened to us another world hitherto unknown, and for many years attempted by none but the Genoeſe, and by them in vain. Having finiſhed this cruize in the ſpace of 26 months, they returned to Portugal with the loſs of many of their ſeamen by the violence of the climate."

Beſides this evidence of the firſt diſcovery of America having been made by Behem, we find the following particulars in the remarks made by Petrus Mateus on the canon law, two years before the expedition of Columbus: "*Primæ navigationes*, &c. The firſt Chriſtian voyages to the newly diſcovered iſlands became frequent under the reign of Henry, ſon of John, king of Luſitania. After his death Alphonſus V. proſecuted the deſign; and John, who ſucceeded him, followed the plan of Alphonſus, by the aſſiſtance of Martin Behem, a very ſkilful navigator; ſo that in a ſhort time the name of Luſitania became famous over the whole world." Cellarius, one of the moſt learned men of his age, ſays expreſsly, "*Behaimeus non modo*, &c. Bœhm did not think it enough to ſurvey the iſland of Fayal, which he firſt diſcovered, or the other adjacent iſlands which the Luſitanians call *Azores*, and we, after the example of Bœhm's companions, call *Flemiſh* iſlands, but advanced ſtill farther and farther ſouth, until he arrived at the remoteſt ſtrait, through which Ferdinand Magellan, following his track, afterwards ſailed, and called it after his own name."

All theſe quotations, which cannot be thought tedious, ſince they ſerve to prove a fact almoſt unknown, ſeem to demonſtrate, that the firſt diſcovery of America is due to the Portugueſe and not to the Spaniards; and that the chief merit belongs to a German aſtronomer. The expedition of Ferdinand Magellan, which did not take place before the year 1519, aroſe from the following fortunate circumſtance: This perſon, being in the apartment of the king of Portugal, ſaw there a chart of the coaſt of America drawn by Behem, and at once conceived the bold project of following the ſteps of this great navigator. Jerome Benzon, who publiſhed a deſcription of America in 1550, ſpeaks of this chart; a copy of which, ſent by Behem himſelf, is preſerved in the archives of Nuremberg. The celebrated aſtronomer Riccioli, though an Italian, yet does not ſeem willing to give his countryman the honour of this important diſcovery. In his *Geographia Reformata*, book iii. p. 90. he ſays, "Chriſtopher Columbus never thought of an expedition to the Weſt Indies until his arrival in the iſland of Madeira, where, amuſing himſelf in forming and delineating geographical charts, he obtained information from Martin Bœhm, or, as the Spaniards ſay, from Alphonſus Sanches de Huelva, a pilot, who had chanced to fall in with the iſland afterwards called *Dominica*." And in another place: "Let Bœhm and Columbus have each their praiſe; they were both excellent navigators; but Columbus would never have thought of his expedition to America, had not Bœhm gone there before him. His name is not ſo much celebrated as that of Columbus, Americus, or Magellan, although he is ſuperior to them all."

That Behem rendered ſome very important ſervices to the crown of Portugal, is put beyond all controverſy by the recompence beſtowed on him by King John; of which the following account has been given to the public from the archives of Nuremberg. "In the year 1485, on the 18th of Feb. in Portugal, in the city of Allaſavas, and in the church of St Salvador, after the maſs, Martin Behem of Nuremberg was made a knight, by the hands of the moſt puiſſant Lord John II. king of Portugal, Algarve, Africa, and Guinea; and his chief ſquire was the king himſelf, who put the ſword in his belt; and the Duke of Begia was his ſecond ſquire, who put on his right ſpur; and his third ſquire was Count Chriſtopher de Mela, the king's couſin, who put on his left ſpur; and his fourth ſquire was Count Martini Marbarinis, who put on his iron helmet; and the king himſelf gave him the blow on the ſhoulder, which was done in the preſence of all the princes, lords, and knights of the kingdom; and he eſpouſed the daughter of a great lord, in conſideration of the important ſervices he had performed; and he was made governor of the iſland of Fayal."

Theſe marks of diſtinction, conferred on a ſtranger, could

Behem.

could not be meant as a recompence for the diſcovery of the Azores, which was made twenty years before, but as a reward for the diſcovery of Congo, from whence the Chevalier Behem had brought gold and different kinds of precious wares. This diſcovery made much greater impreſſion than that of a weſtern world made at the ſame time, but which neither increaſed the wealth of the royal treaſury, nor ſatisfied the avarice of the merchants.

In 1492 the Chevalier Behem, crowned with honours and riches, undertook a journey to Nuremberg, to viſit his native country and his family. He there made a terreſtrial globe, which is looked on as a maſterpiece for that time, and which is ſtill preſerved in the library of that city. The outline of his diſcoveries may there be ſeen, under the name of weſtern lands; and from their ſituation it cannot be doubted that they are the preſent coaſts of Brazil, and the environs of the Straits of Magellan. This globe was made in the ſame year that Columbus ſet out on his expedition; therefore it is impoſſible that Behem could have profited by the works of that navigator, who beſides went a much more northerly courſe.

After having performed ſeveral other intereſting voyages, the Chevalier Behem died at Liſbon in July 1506, regretted by every one, but leaving behind him no other work than the globe and chart which we have juſt been ſpeaking of. The globe is made from the writings of Ptolemy, Pliny, Strabo, and eſpecially from the account of Mark Paul the Venetian, a celebrated traveller of the 13th century; and of John Mandeville, an Engliſhman, who, about the middle of the 14th century, publiſhed an account of a journey of 33 years in Africa and Aſia. He has alſo added the important diſcoveries made by himſelf on the coaſts of Africa and America.

From theſe circumſtantial accounts, but very lately brought to light, there can be little doubt, we think, but that America was diſcovered by Martin Behem. Dr Robertſon is indeed of a different opinion: but great as we willingly acknowledge his authority to be, we may differ from him without preſumption, ſince he had it not in his power to conſult the German documents to which we have appealed, and has himſelf advanced facts not eaſily to be reconciled to his own opinion. He allows that Behem was very intimate with Chriſtopher Columbus; that he was the greateſt geographer of his time, and ſcholar of the celebrated John Müller, or Regiomontanus; that he had diſcovered, in 1483, the kingdom of Congo, upon the coaſt of Africa; that he made a globe which Magellan made uſe of; that he drew a map at Nuremberg, containing the particulars of his diſcoveries; and that he placed in this chart land which is found to be in the latitude of Guiana. He adds indeed, without proof, that this land was a fabulous iſland; but if authentic records are to give place to bare aſſertion, there is an end of all hiſtorical evidence. If Behem took for an iſland the firſt land which he diſcovered, it was a miſtake ſurely not ſo groſs as to furniſh grounds for queſtioning his veracity, or for withholding from him for ever that juſtice which has been ſo long delayed.

But this very delay will by ſome be thought a powerful objection to the truth of Behem's claim to the diſcovery of America; for if it was really diſcovered by him, why did not he leave behind him ſome writing to confirm the diſcovery to himſelf? and why did not the court of Portugal, ſo jealous of the diſcovery of the new world, proteſt againſt the excluſive claim of the Spaniards?

Behem.

To theſe objections we may reply, that, however plauſible they may at firſt appear, they do not in the ſmalleſt degree invalidate the poſitive evidence which we have urged for the Chevalier Behem's being the real diſcoverer of the new world; for it would ſurely be very abſurd to oppoſe the *difficulty of aſſigning motives* for *certain* actions performed at a remote period, to the *reality* of *other* actions for which we have the teſtimony of a cloud of contemporary witneſſes. Suppoſing it were true, therefore, that Behem had left behind him no writing claiming to himſelf the diſcovery of any part of the continent of America, the only inference which could be drawn from his ſilence would be, either that he was a man of great modeſty, or that his mind was intent only on the acquiſition of knowledge to himſelf, without feeling the uſual impulſe to communicate that knowledge to others. But it is not true that he has left behind him no claim of this diſcovery to himſelf. The letters to which we have appealed, and which are preſerved in the archives of Nuremberg, together with the globe and map, which he certainly made, furniſh as complete a confirmation of his claim as could have been furniſhed by the moſt elegant account of his voyages.

For the ſilence of the Portugueſe, many reaſons might be aſſigned. The diſcoveries of Columbus were made ſo much farther north than thoſe of Behem, that, in an age when geographical knowledge was ſo very limited, both Spaniards and Portugueſe might very naturally believe that the country diſcovered by the former of theſe navigators had no connection with that diſcovered by the latter. At any rate, the Portugueſe, whoſe diſcoveries proceeded from avarice, were ſatisfied with ſcraping together gold wherever they could find it; and finding it in Africa, they thought not of ſearching for it in a more diſtant region, till the ſucceſs of the Spaniards ſhewed them their miſtake.

One thing more is worthy of attention. The long ſtay of Columbus at Madeira makes his interview with Behem more than probable. It is impoſſible that he ſhould have neglected ſeeing a man ſo intereſting, and who could give him every kind of information for the execution of the plan which he had formed. The mariners who accompanied the Chevalier Behem might alſo have ſpread reports at Madeira and the Azores concerning the diſcovery of which they had been witneſſes. What ought to confirm us in this is, that Mariana ſays himſelf (book xxvi. chap. iii.), that a certain veſſel going to Africa, was thrown by a gale of wind upon certain unknown lands; and that the ſailors at their return to Madeira had communicated to Chriſtopher Columbus the circumſtances of their voyage. All authors agree that this learned man had ſome information reſpecting the weſtern ſhores; but they ſpeak in a very vague manner. The expedition of the Chevalier Behem explains the myſtery (B).

(B) For the greater part of this memoir we are indebted to M. Otto's paper on the diſcovery of America, publiſhed

BEREANS, in ancient church hiſtory, the inhabitants of Berea. They are highly commended in Scripture for their ready reception of the goſpel, upon a fair and impartial examination of its agreement with the Old Teſtament prophecies. Sopater, a Berean, attended the apoſtle Paul to Aſia. Acts xvii. 10—13. and xx. 4.

BEREANS, in modern church hiſtory, a ſect of Proteſtant diſſenters from the church of Scotland, who take their title from, and profeſs to follow, the example of the ancient Bereans, in building their ſyſtem of faith and practice upon the Scriptures alone, without regard to any human authority whatever.

Doctrines.

The Bereans agree with the great majority of Chriſtians, both Proteſtants and Catholics, reſpecting the doctrine of the Trinity, which they hold as a fundamental article of the Chriſtian faith; and they alſo agree in a great meaſure with the *profeſſed* principles of both our eſtabliſhed churches reſpecting predeſtination and election, though they allege that theſe doctrines are not conſiſtently taught in either church. But they differ from the majority of all ſects of Chriſtians in various other important particulars. Such as,

1. Reſpecting our knowledge of the Deity. Upon this ſubject, they ſay that the majority of profeſſed Chriſtians ſtumble at the very threſhold of revelation; and, by admitting the doctrine of natural religion, natural conſcience, natural notices, &c. not founded upon revelation, or derived from it by tradition, they give up the cauſe of Chriſtianity at once to the infidels; who may juſtly argue, as Mr Paine in fact does in his Age of Reaſon, that there is no occaſion for any revelation or word of God, if man can diſcover his nature and perfections from his works alone. But this, the Bereans argue, is beyond the natural powers of human reaſon; and therefore our knowledge of God is from revelation alone; and that without revelation man would never have entertained an idea of his exiſtence.

2. With regard to faith in Chriſt, and aſſurance of ſalvation through his merits, they differ from almoſt all other ſects whatſoever. Theſe they reckon *inſeparable*, or rather the *ſame;* becauſe, they argue, God hath expreſsly declared, "He that believeth ſhall be ſaved;" and therefore it is not only abſurd, but impious, and in a manner calling God a liar, for a man to ſay, "*I believe* the Goſpel, but *have doubts* nevertheleſs of my own ſalvation." With regard to the various diſtinctions and definitions that have been given of different kinds of faith, they argue, that "there is nothing incomprehenſible or obſcure in the meaning of this word as uſed in Scripture; but that as faith, when applied to human teſtimony, ſignifies neither more nor leſs than the mere ſimple belief of that teſtimony as true, upon the authority of the teſtifier: ſo, when applied to the teſtimony of God, it ſignifies preciſely the belief of his teſtimony, and reſting upon his veracity alone, without any kind of collateral ſupport from concurrence of any other evidence or teſtimony whatever." And they inſiſt, that as this faith is the gift of God alone, ſo the perſon to whom it is given is as conſcious of poſſeſſing it, as the being to whom God gives life is of being alive; and therefore he entertains no doubts either of his faith or his conſequent ſalvation through the merits of Chriſt, who died and roſe again for that purpoſe. In a word, they argue, that the Goſpel would not be what it is held forth to be, "glad tidings of great joy," if it did not bring full perſonal aſſurance of eternal ſalvation to the believer: which aſſurance, they inſiſt, "is the preſent infallible privilege and portion of every individual believer of the Goſpel." Theſe definitions of faith, and its inſeparable concomitant aſſurance, they prove by a variety of texts, which our room permits us not to quote.

3. Conſiſtently with the above definition of faith, they ſay, that the ſin againſt the Holy Ghoſt, which has alarmed and puzzled ſo many in all ages, is nothing elſe but *unbelief;* and that the expreſſion, that "it ſhall not be forgiven, neither in *this world* nor that which is to come," means only, that a perſon dying in infidelity would not be forgiven, neither under the former diſpenſation by Moſes (the then *preſent* diſpenſation, kingdom, or government of God), nor under the Goſpel diſpenſation, which, in reſpect of the Moſaic, was a kind of future world or kingdom to come.

4. The Bereans interpret a great part of the Old Teſtament prophecies, and in particular the whole of the Pſalms, excepting ſuch as are merely hiſtorical or laudatory, to be typical or prophetical of Jeſus Chriſt, his ſufferings, atonement, mediation, and kingdom: and they eſteem it a groſs perverſion of theſe Pſalms and prophecies to apply them to the experiences of private Chriſtians. In proof of this, they not only urge the words of the apoſtle, that "no prophecy is of any private interpretation," but they inſiſt that the whole of the quotations from the ancient prophecies in the New Teſtament, and particularly thoſe from the Pſalms, are expreſsly applied to Chriſt. In this opinion many other claſſes of Proteſtants agree with them.

5. Of the abſolute all-ſuperintending ſovereignty of the Almighty, the Bereans entertain the higheſt ideas, as well as of the uninterrupted exertion thereof over all works in heaven, earth, and hell, however unſearchable by his creatures. "A God without election (they argue), or choice in all his works, is a god without exiſtence—a mere idol—a non-entity. And to deny God's election, purpoſe, and expreſs will in all his works, is to make him inferior to ourſelves." For farther particulars reſpecting the Berean doctrines, we muſt refer the reader to the works of Meſſrs Barclay, Nicol, Brookſhank, &c.

Origin.

The Bereans firſt aſſembled as a ſeparate ſociety of Chriſtians in the city of Edinburgh in autumn 1773, and ſoon after in the pariſh of Fettercairn. The opponents of the Berean doctrines allege, that this new ſyſtem of faith would never have been heard of, had not Mr Barclay, the founder of it, been diſappointed of a ſettlement in the church of Scotland. A reſpectable clergyman of the eſtabliſhed church has even hinted ſomething to this purpoſe in Sir John Sinclair's Statiſtical Account, Vol. IX. p. 599. But the Bereans, in anſwer to this charge, appeal not only to Mr Barclay's doctrine,

---

publiſhed firſt in the ſecond volume of the American Tranſactions, and afterwards by Nicholſon in N° II. and III. of his Journal.

doctrine, uniformly preached in the church of Fettercairn, and many other places in that neighbourhood, for fourteen years before that benefice became vacant ; but likewiſe to two different treatiſes, containing the ſame doctrines, publiſhed by him about ten or twelve years before that period. They admit, indeed, that, previous to May 1773, when the general aſſembly, by ſuſtaining the king's preſentation in favour of Mr Foote, excluded Mr Barclay from ſucceeding to the church of Fettercairn (notwithſtanding the almoſt unanimous deſire of the pariſhioners), the Bereans had not left the eſtabliſhed church, or attempted to erect themſelves into a diſtinct ſociety ; but they add, that this was by no means neceſſary on their part, until by the aſſembly's deciſion they were in danger of being not only deprived of his inſtructions, but of being ſcattered as ſheep without a ſhepherd. And they add, that it was Mr Barclay's open and public avowal, both from the pulpit and the preſs, of thoſe peculiar ſentiments which now diſtinguiſh the Bereans, that was the firſt and principal, if not the only, cauſe of the oppoſition ſet on foot againſt his ſettlement in Fettercairn.

Practice.

Having thus given a conciſe view of the origin and diſtinguiſhing doctrines of Bereaniſm, it only remains to mention a few particulars relative to the practice of the Bereans as a Chriſtian ſociety. Infant baptiſm they conſider as a divine ordinance inſtituted in the room of circumciſion ; and they think it abſurd to ſuppoſe that infants, who all agree are admiſſible to the kingdom of God in heaven, ſhould nevertheleſs be incapable of being admitted into His viſible church on earth. They commemorate the Lord's ſupper in general once a-month ; but as the words of the inſtitution fix no particular period, they ſometimes celebrate it oftener, and ſometimes at more diſtant periods, as may ſuit their general convenience. In obſerving this ordinance, they follow the primitive apoſtolic plan, without any previous days of faſting or preparation ; as they apprehend that ſuch human inſtitutions only tend to make an idol of the ordinance, and to lead people to entertain erroneous ideas of its ſuperior ſolemnity and importance. Equal and univerſal holineſs in all manner of converſation, they recommend at all times, as well as at the table of the Lord. They meet every Lord's day for the purpoſe of preaching, praying, and exhortation to love and good works. With regard to the admiſſion and excluſion of members, their method is very ſimple. When any perſon, after hearing the Berean doctrines, profeſſes his belief and aſſurance of the truths of the Goſpel, and deſires to be admitted into their communion, he is cheerfully received upon his profeſſion, whatever may have been his former manner of life. But if ſuch an one ſhould afterwards draw back from his good profeſſion or practice, they firſt admoniſh him ; and if that has no effect, they leave him to himſelf. They do not think that they have any power to deliver up a backſliding brother to Satan. That text and other ſimilar paſſages, ſuch as, "Whatſoever ye ſhall bind on earth ſhall be bound in heaven," &c. they conſider as reſtricted to the apoſtles and to the inſpired teſtimony alone, and not to be extended to any church on earth, or any number of churches or of Chriſtians, whether deciding by a majority of votes or by unanimous voices. Neither do they think themſelves authoriſed, as a Chriſtian church, to enquire into each others political opinions, any more than to examine into each others notions of philoſophy. They both recommend and practiſe, as Chriſtian duties, ſubmiſſion to lawful authority ; but they do not think that a man, by becoming a Chriſtian, or joining their ſociety, is under any obligation, by the rules of the Goſpel, to renounce his rights of private judgment upon matters of public or private importance. Upon all ſuch ſubjects they allow each other to think and act as each may ſee it his duty. And they require nothing more of their members than a uniform and ſteady profeſſion of the apoſtolic faith, and a ſuitable walk and converſation. With regard to feet-waſhing and the like practices, which ſome other ſects of Chriſtians conſider as duties, the Bereans are of opinion that they are by no means obligatory. They argue, that the example given by our Saviour of waſhing the feet of his diſciples was not an inſtitution of an ordinance, but merely a familiar inſtance, taken from the cuſtom of the country, and adopted by our Lord on that occaſion, to teach his followers that they ought at all times to be ready to perform even the meaneſt offices of kindneſs to each other.

Preſent ſtate.

It may not be improper to add to the above delineation of the principles and practice of the Bereans, that their doctrine has found converts in various places of Scotland, England, and America ; and that they have congregations in Edinburgh, Glaſgow, Paiſley, Stirling, Crieff, Dundee, Arbroath, Montroſe, Fettercairn, Aberdeen, and other towns in Scotland ; as well as in London and various places in England ; not to add Pennſylvania, the Carolinas, and other States in America.

The above account of the doctrines, origin, practice, and preſent ſtate of this ſociety, has been given to us by the founder himſelf.

BERKENHOUT (Dr John), was about the year 1730 born at Leeds in Yorkſhire, and educated at the grammar-ſchool in that town, His father, who was a merchant, and a native of Holland, intended him for trade; and with that view ſent him at an early age to Germany, in order to learn foreign languages. After continuing a few years in that country, he made the tour of Europe in company with one or more Engliſh noblemen. On their return to Germany they viſited Berlin, where Mr Berkenhout met with a near relation of his father's, the Baron de Bielfeldt, a nobleman then in high eſtimation with Frederick the Great king of Pruſſia; diſtinguiſhed as one of the founders of the Royal Academy of Sciences at Berlin, and univerſally known as a politician and a man of letters. With this relation our young traveller fixed his abode for ſome time; and, regardleſs of his original deſtination, became a cadet in a Pruſſian regiment of foot. He ſoon obtained an enſign's commiſſion, and in the ſpace of a few years was advanced to the rank of captain. He quitted the Pruſſian ſervice on the declaration of war between England and France in 1756, and was honoured with the command of a company in the ſervice of his native country. When peace was concluded in 1760, not chooſing, we ſuppoſe, to lead a life of inactivity on half-pay, he went down to Edinburgh, and commenced ſtudent of phyſic. During his reſidence at that univerſity, he publiſhed his *Clavis Anglica Linguæ Botanicæ;* a book of great utility to all ſtudents of botany.

Having continued ſome years at Edinburgh, Mr Berkenhout went to the univerſity of Leyden, where he was admitted to the degree of M. D. in the year 1765. On this occaſion he publiſhed a theſis, intitled, *Diſſertatio medica inauguralis de Podagra*, which he dedicated to his relation Baron de Bielfeldt. Returning to England, Dr Berkenhout ſettled at Iſleworth in Middleſex, and ſoon after publiſhed his *Pharmacopœia Medici*, the third edition of which was printed in 1782. In 1778 he was ſent by government with the commiſſioners to America. Neither the commiſſioners nor their ſecretary were ſuffered by the congreſs to proceed further than New York. Dr Berkenhout, however, found means to penetrate as far as Philadelphia, where the congreſs was then aſſembled. He appears to have remained in that city for ſome time without moleſtation: but at laſt they began to ſuſpect that he was ſent by Lord North for the purpoſe of tampering with ſome of their leading members. The Doctor was immediately ſeized and committed to priſon.

How long he remained a ſtate priſoner, or by what means he obtained his liberty, we are not informed; but we find from the public prints, that he rejoined the commiſſioners at New York, and returned with them to England. For this temporary ſacrifice of the emoluments of his profeſſion, and in conſideration of his having, in the ſervice of his ſovereign, committed himſelf to the mercy of a congreſs of enraged republicans, he obtained a penſion.

Many years previous to this event, Dr Berkenhout had publiſhed his *Outlines of the Natural Hiſtory of Great Britain and Ireland*, in three volumes 12mo; a work which eſtabliſhed his reputation as a naturaliſt. In the year 1773 he wrote a pamphlet, intitled, *An Eſſay on the Bite of a Mad Dog, in which the Claim to Infallibility of the Principal Preſervative Remedies againſt the Hydrophobia is examined.* This pamphlet is inſcribed to Sir George Baker, and deſerves to be univerſally read.

In the year following Dr Berkenhout publiſhed his *Symptomatology*; a book which is too univerſally known to require any recommendation.

At the beginning of the year 1788 he publiſhed a work, intitled, *Firſt Lines of the Theory and Practice of Philoſophical Chemiſtry*, which he dedicated to Mr Eden, now Lord Auckland, who had been one of the commiſſioners whom he accompanied to America.

Theſe, we believe, are the Doctor's principal publications in the line of his profeſſion; but he wrote on many other ſubjects with equal ability. His tranſlation of *Count Teſſin's Letters*, which was his firſt publication, and dedicated to the preſent king when prince of Wales, evinces his knowledge of the Swediſh language, and ſhews him to have been a good poet. His *Eſſay on Ways and Means*, proves him to have been better acquainted with the ſyſtem of taxation than moſt other men who have written on the ſubject. His biographical powers appear in his *Biographia Literaria*; and in all his works are ſufficient proofs of his claſſical learning, and that the Italian, French, German, and Dutch languages, were familiar to him. He poſſeſſed likewiſe a very conſiderable degree of mathematical ſcience, which he acquired in the courſe of his military ſtudies; and to thoſe more ſolid attainments he is ſaid to have added no ſmall ſkill in the fine arts of painting and muſic. This eminent man, who, for the variety and promptitude of his knowledge, has been compared to the Admirable Crichton, died on the 3d of April 1791.

BERNOULLI (John), a celebrated mathematician, was born at Baſil the 7th of Auguſt 1667. His father intended him for trade; but his own inclination was at firſt for the belles lettres, which, however, like his brother James, whoſe life is given in the Encyclopædia, he left for mathematics. He laboured with his brother to diſcover the method uſed by Leibnitz, in his eſſays on the differential calculus, and gave the firſt principles of the integral calculus. Our author, with Meſſrs Huygens and Leibnitz, is ſaid to have been the firſt who gave the ſolution of the problem propoſed by James Bernoulli, concerning the catenary, or curve formed by a chain ſuſpended by its two extremities. But for more on this ſubject, ſee ARCH in this Supplement.

John Bernoulli had the degree of doctor of phyſic at Baſil, and two years afterward was named profeſſor of mathematics in the univerſity of Groningen. It was here that he diſcovered the mercurial phoſphorus, or luminous barometer; and where he reſolved the problem propoſed by his brother concerning iſoperimetricals.

On the death of his brother James, the profeſſor at Baſil, our author returned to his native country, againſt the preſſing invitations of the magiſtrates of Utrecht to come to that city, and of the univerſity of Groningen, who wiſhed to retain him. The Academic Senate of Baſil ſoon appointed him to ſucceed his brother, without aſſembling competitors, and contrary to the eſtabliſhed practice; an appointment which he held during his whole life.

In 1714 was publiſhed his treatiſe on the management of ſhips; and in 1730 his memoir on the elliptical figure of the planets gained the prize of the Academy of Sciences. The ſame Academy alſo divided the prize for their queſtion concerning the inclination of the planetary orbits, between our author and his ſon Daniel. See BERNOULLI (Daniel), *Encycl.*

John Bernoulli was a member of moſt of the academies of Europe, and received as a foreign aſſociate of that of Paris in 1699. After a long life ſpent in conſtant ſtudy and improvement of all the branches of the mathematics, he died full of honours, the 1ſt of January 1748, in the 81ſt year of his age. Of five ſons which he had, three purſued the ſame ſciences with himſelf. One of theſe died before him; the two others, Nicolas and Daniel, he lived to ſee become eminent, and much reſpected in the ſame ſciences.

The writings of this great man were diſperſed through the periodical memoirs of ſeveral academies, as well as in many ſeparate treatiſes. And the whole of them were carefully collected and publiſhed at Lauſanne and Geneva, 1742, in 4 vols 4to. He was of undoubted eminence; but even in ſcience he was a haſty man, and certainly envious of the fame of Newton.

BETELGUESE, a fixed ſtar of the firſt magnitude, in the right ſhoulder of Orion.

BEZOUT (Stephen), a celebrated French mathematician, member of the Academies of Sciences and the Marine, and examiner of the guards of the marine and of the eleves of artillery, was born at Nemours the 31ſt of March 1730. In the courſe of his ſtudies he met with ſome books of geometry, which gave him a taſte for that ſcience; and the Eloges of Fontenelle, ſhewed him the honours attendant on talents and the

love

love of the ſciences. His father in vain oppoſed the ſtrong attachment of young Bezout to the mathematical ſciences. April 8. 1758, he was named adjoint-mechanician in the French Academy of Sciences; having before that ſent them two ingenious memoirs on the integral calculus, and given other proofs of his proficiency in mathematics. In 1763, he was named to the new office of examiner to the marine, and appointed to compoſe a ſyſtem of mathematics for their uſe; and in 1768, on the death of M. Camus, he ſucceeded as examiner of the artillery eleves.

Bezout fixed his attention more particularly to the reſolution of algebraic equations; and he firſt found out the ſolution of a particular claſs of equations of all degrees. This method, different from all former ones, was general for the cubic and biquadratic equations, and juſt became particular only at thoſe of the 5th degree. Upon this work our author laboured from 1762 till 1779, when he publiſhed it. He compoſed two courſes of mathematics; the one for the marine, the other for the artillery. The foundation of theſe two works was the ſame; the applications only being different, according to the two different objects: theſe courſes have every where been held in great eſtimation. In his office of examiner he diſcharged the duties with great attention, care, and tenderneſs. A trait of his juſtice and zeal is remarkable in the following inſtance: During an examination which he held at Toulon, he was told that two of the pupils could not be preſent, being confined by the ſmall-pox: he himſelf had never had that diſeaſe, and he was greatly afraid of it; but as he knew that if he did not ſee theſe two young men, it would much impede their improvement, he ventured to their bed-ſides to examine them, and was happy to find them ſo deſerving of the hazard into which he put himſelf for their benefit.

Mr Bezout lived in this employment for ſeveral years, beloved of his family and friends, and reſpected by all, enjoying the fruits and the credit of his labours. But the trouble and fatigues of his offices, with ſome perſonal chagrines, had reduced his ſtrength and conſtitution; he was attacked by a malignant fever, of which he died Sept. 27. 1783, in the 54th year of his age, regretted by his family, his friends, the young ſtudents, and by all his acquaintance in general.

The books publiſhed by him were: 1. Courſe of Mathematics for the uſe of the Marine, with a Treatiſe on Navigation, 6 vols in 8vo, Paris, 1764. 2. Courſe of Mathematics for the Corps of Artillery, 4 vols in 8vo, 1770. 3. General Theory of Algebraic Equations, 1779.

His papers printed in the volumes of the Memoirs of the Academy of Sciences are: 1. On curves, whoſe rectification depends on a given quantity, in the volume for 1758. 2. On ſeveral claſſes of equations that admit of an algebraic ſolution, 1762. 3. Firſt volume of a courſe of mathematics, 1764. 4. On certain equations, &c. 1764. 5. General reſolution of all equations, 1765. 6. Second volume of a courſe of mathematics, 1765. 7. Third volume of the ſame, 1766. 8. Fourth volume of the ſame, 1767. 9. Intergration of differentials, &c. vol. 3. Sav. Etr. 10. Experiments on cold, 1777.

BINOMIAL, a quantity conſiſting of two terms or members, connected by either of the ſigns + and —. See ALGEBRA, def. 9. *Encycl.*

Impoſſible or *Imaginary Binomial*, is a binomial which has one of its terms an impoſſible or an imaginary quantity; as $a + \surd - b$.

Binomial Curve, is a curve whoſe ordinate is expreſſed by a binomial quantity, as the curve whoſe ordinate is $x^{a} \times \overline{b + dx^{c}}|^{c}$. Stirling, Method. Diff. p. 58.

Binomial Line, or *Surd*, is that in which at leaſt one of the parts is a ſurd. Euclid, in the tenth book of his Elements, enumerates ſix kinds of binomial lines or ſurds, viz.

First binomial $3 + \surd 5$,
2d binomial $\surd 18 + 4$,
3d binomial $\surd 24 + \surd 18$,
4th binomial $4 + \surd 3$,
5th binomial $\surd 6 + 2$,
6th binomial $\surd 6 + \surd 2$.

Binomial Theorem. See ALGEBRA, Chap. VII. Sect. iii. (*Encycl.* Vol. I.); and *Infinite Series*, (Vol. XVII.) The reader who wiſhes for a fuller account of this famous theorem, may find it in Dr Hutton's Mathematical Tracts, Vol. I.

BIRD-CATCHING, is an art which, as it is practiſed by means of bird-lime, nets, decoys, &c. has been ſufficiently explained in the Encyclopædia. But there is another method of catching birds alive, by means of a *fuſee* or *muſket*, which was invented by M. Vaillant during his travels in Africa, and is ſufficiently ingenious to deſerve a place here. It is as follows:

Put a ſmaller or larger quantity of powder into your fuſee according as circumſtances may require. Immediately above the powder place the end of a candle of ſufficient thickneſs, ramming it well down; and then fill the barrel with water up to the mouth. When at a proper diſtance you fire a muſket thus loaded at a bird, you will only *ſtun* it by watering and moiſtening its feathers; and if you be alert, you may eaſily lay hold of it before it have time to ſpoil its plumage by fluttering. Our author admits, that in his firſt attempts he often put too much powder, or too thick a piece of candle into his fuſee, or fired at too ſhort a diſtance; and when any one of theſe miſtakes was committed, he generally found the candle entire in the animal's belly; but after a ſhort apprenticeſhip he acquired ſufficient ſkill to adjuſt matters ſo as that the water impelled by the powder went directly to the mark, whilſt the tallow being lighter than the water fell ſhort of it. If this method be indeed practicable (for not being ſportſmen we have not made trial of it), it may on many occaſions aid the reſearches of the ornithologiſt.

Birds-Neſts, in cookery. See *Encycl.* and CAP and BUTTON in this *Suppl.*

BLACK (Joſeph, M. D.), who has been ſtyled the father of pneumatic chemiſtry, and who, in that department of ſcience, had certainly no ſuperior, was born at Bourdeaux in France, in the year 1728. His father was a native of Ireland, but went to Bourdeaux to carry on the buſineſs of a wine-merchant; though with what ſucceſs he carried it on we have not learned. Where young Black received his claſſical education we know not; but at an early period of life he was ſent to the Univerſity of Glaſgow, and ſtrongly recommended to Dr Cullen, who adviſed him to ſtudy phyſic, and undertook, with that ardour which characteriſed his mind, to render him every ſervice in his power.

At that period Cullen read lectures on chemiſtry in the College of Glaſgow with great and deſerved applauſe;

plauſe; and Black becoming one of his favourite pupils, was allowed the free uſe of his laboratory, and aſſiſted him in his experiments; by which means he acquired a decided taſte for this branch of natural philoſophy. In 1754 he took the degree of doctor of phyſic in the univerſity of Edinburgh. where he had ſtudied for ſome time; and the choice which he made in regard to the ſubject of his inaugural diſſertation gave a proof of his attachment to chemical purſuits. It was *De humore acido a cibis orto et magneſia alba.* The principles of the doctrine which he brought forward in this theſis he afterwards fully explained in a paper read the next year before a ſociety in Edinburgh, and publiſhed in the ſecond volume of *Eſſays Phyſical and Literary*, 1756; containing experiments on magneſia alba, quick-lime, and alkaline ſubſtances. In this paper, by an ingenious and philoſophical ſeries of reſearches, he evidently proved the exiſtence of an aerial fluid, which he called *fixed air*, the preſence of which gave mildneſs, and its abſence cauſticity, to alkalies and calcareous earths. This noble diſcovery certainly paved the way to all that important knowledge reſpecting aerial bodies which has done ſo much honour to the names of a Cavendiſh, a Prieſtley, and a Lavoiſier, and which have made chemical philoſophy aſſume an entirely new form.

In the year 1756, on the removal of Dr Cullen to Edinburgh, Dr Black became profeſſor of medicine and lecturer on chemiſtry in the univerſity of Glaſgow. Next year he enriched the ſcience of chemiſtry with the curious doctrine of *latent heat*, in which he explained, in what has been hitherto reckoned a clear and ſatisfactory manner, the connection of heat with fluidity, the phenomena of freezing and boiling, and the manner in which they affect the thermometer. Theſe diſcoveries, the reſult of great natural ſagacity and experimental ſkill, certainly laid the foundation of all thoſe important facts relating to this part of chemiſtry which were afterwards brought to light by ſeveral of the moſt eminent philoſophers of the preſent period, and would alone be ſufficient to give celebrity to the name of Black. His reputation indeed was now raiſed ſo high, that a vacancy having taken place in the chemical chair of Edinburgh, by the removal of Dr Cullen, in 1765, to another department, Dr Black was looked up to as the only man capable of ſuſtaining, in this branch of ſcience, the ſuperiority which that celebrated ſchool of medicine had acquired in all others. He was therefore elected to ſucceed Cullen, and for many years diſcharged the duties of the office with univerſal approbation, being much admired for the care, perſpicuity, and elegance, with which he communicated inſtruction in his lectures, and his neatneſs and accuracy in performing experiments. Very complete manuſcript copies of his lectures were taken by many of his ſtudents, particularly in the early part of his teaching, when they contained a great deal of matter then little known to the chemical world; and theſe copies, read with avidity by the lovers of this ſcience, have greatly contributed to ſecure to him the honour of thoſe diſcoveries, and that original mode of reaſoning, which he ſcarcely ever made public in any other form. His lectures have lately been reviſed by his friend Dr Robiſon of Edinburgh; and, enriched with many valuable notes by that genuine philoſopher, are now in the preſs, and will ſpeedily be publiſhed.

After his election to the chemical chair, Dr Black publiſhed nothing but a paper on the Effect of Boiling upon Water, in diſpoſing it to freeze more readily, printed in the ſixty-fifth volume of the Philoſophical Tranſactions for 1774; and an Analyſis of the Water of ſome Hot Springs in Iceland, in the Philoſophical Tranſactions of Edinburgh for 1791. The latter contains ſome obſervations, highly intereſting to the chemiſt, on the formation of the ſiliceous ſtone depoſited by theſe wonderful ſprings; and has long been conſidered as a model of neatneſs and accuracy in the analyſis of mineral waters. Two of his letters on chemical ſubjects have been publiſhed by Crell and Lavoiſier.

Dr Black was long a ſtrenuous oppoſer of the new theories in chemiſtry; but he at length became an avowed convert to the principles of the French chemiſts, and did not heſitate to make amends by his applauſe for his former oppoſition. He never diſtinguiſhed himſelf as a practical phyſician. His manners were ſimple, his temper cold and reſerved, and his habits of life adapted to his own convenience. He was never married; and died ſuddenly, in his ſixty-ſecond year, on the 6th of December 1799, his health having been in a declining ſtate for ſome time before. He was a member of the Royal Societies of London and Edinburgh, and of the Imperial Academy of Sciences at St Peterſburgh; and by the intereſt of Lavoiſier he was choſen one of the eight foreign members of the Academy of Sciences of Paris, when that academy was Royal, and when a philoſopher of Britain could be a member of it without incurring diſgrace.

By thoſe who knew Dr Black intimately, and are capable of forming an eſtimate of the powers of his mind, he is believed to have been capable of becoming in chemiſtry what Newton was in mechanical philoſophy; but an unconquerable indolence, though it could not prevent him from doing his duty as profeſſor, reſtrained him not only from employing, as he might have done, his admirable talents in enlarging the boundaries of ſcience, but even from aſſerting his claim to diſcoveries which were certainly his. Of theſe we hope to have ſome account from his friend the editor of his lectures.

BLACKLOCK (Dr Thomas) deſerves, on ſo many accounts, to have the principal incidents of his life recorded in this work, that to omit ſuch an article from our liſt of biographical ſketches would be unpardonable negligence. We cannot, however, propoſe to write of him any thing which has not been written before, by an author who has repeatedly appeared before the public, and on each appearance has gained poſſeſſion of the public heart. We ſhall therefore content ourſelves with inſerting in this place a ſhort abridgment of the elegant account of the life and writings of Dr Blacklock, which was prefixed to that edition of his works which was publiſhed in 1793; and if we thus leſſen our own labour, we are conſcious that we ſhall at the ſame time increaſe the pleaſure of our readers.

Thomas Blacklock was in 1721 born at Anan, in the county of Dumfries in Scotland, but his parents were natives of the bordering county of Cumberland; ſo that, though a native of Scotland, his deſcent was Engliſh His father was a bricklayer, and his mother the daughter of a conſiderable dealer in cattle. Both were reſpectable in their characters, and poſſeſſed, tho' moving in an humble ſphere, a conſiderable degree of knowledge and urbanity. Their ſon was not quite ſix months old when he loſt his eye-ſight in the ſmall-pox, which rendered him as complete a ſtranger to the viſible world as if he had been blind from the hour of his birth. It rendered him likewiſe incapable of learning any of the mechanical arts; and therefore his father kept him at home, and with the aſſiſtance of ſome friends foſtered that inclination which, at a very early period, he ſhewed for books. This was done by reading to him firſt the ſimple ſort of publications which are commonly put into the hands of children, and then ſeveral of our beſt authors, ſuch as Milton, Spencer, Prior, Pope, and Addiſon. His companions, whom his early gentleneſs and kindneſs of diſpoſition, as well as their compaſſion for his misfortune, ſtrongly attached to him, were very aſſiduous in their good offices, in reading to inſtruct and amuſe him. By their aſſiſtance he acquired ſome knowledge of the Latin tongue, but he never was at a grammar-ſchool till at a more advanced period of life. Poetry was even then his favourite reading; and he found an enthuſiaſtic delight in the works of the beſt Engliſh poets, and in thoſe of his countryman Allan Ramſay. Even at an age ſo early as twelve he began to write poems, one of which is preſerved in the collection that was publiſhed after his death, and is not perhaps inferior to any of the premature compoſitions of boys aſſiſted by the beſt education, which are only recalled into notice by the future fame of their authors.

He had attained the age of nineteen when his father was killed by the accidental fall of a malt-kiln belonging to his ſon-in-law. This loſs, heavy to any one at that early age, would have been, however, to a young man poſſeſſing the ordinary means of ſupport, and the ordinary advantages of education, comparatively light; but to him—thus ſuddenly deprived of that ſupport on which his youth had leaned—deſtitute almoſt of every reſource which induſtry affords to thoſe who have the bleſſings of ſight—with a body feeble and delicate from nature, and a mind congenially ſuſceptible—it was not ſurpriſing that this blow was doubly ſevere, and threw on his ſpirits that deſpondent gloom to which he then gave way in the following pathetic lines, and which ſometimes overclouded them in the ſubſequent period of his life:

" Dejecting proſpect! ſoon the hapleſs hour
" May come; perhaps this moment it impends,
" Which drives me forth to penury and cold,
" Naked, and beat by all the ſtorms of heav'n,
" Friendleſs and guideleſs to explore my way;
" Till on cold earth this poor unſhelter'd head
" Reclining, vainly from the ruthleſs blaſt
" Reſpite I beg, and in the ſhock expire."

He lived with his mother for about a year after his father's death, and began to be diſtinguiſhed as a young man of uncommon parts and genius. Theſe were at that time unaſſiſted by learning; the circumſtances of his family affording him no better education than the ſmattering of Latin which his companions had taught him, and the peruſal and recollection of the few Engliſh authors which they, or his father in the intervals of his profeſſional labours, had read to him. Poetry, however, though it attains its higheſt perfection in a cultivated ſoil, grows perhaps as luxuriantly in a wild one. To poetry, as we have before mentioned, he was devoted from his earlieſt days; and about this time ſeveral of his poetical productions began to be handed about, which conſiderably enlarged the circle of his friends and acquaintance. Some of his compoſitions being ſhewn to Dr Stevenſon, an eminent phyſician of Edinburgh, who was accidentally at Dumfries on a profeſſional viſit, that gentleman formed the benevolent deſign of carrying him to the Scotch metropolis, and giving to his natural endowments the aſſiſtance of a claſſical education. He came to Edinburgh in the year 1741, and was enrolled a ſtudent of divinity in the univerſity there, though at that time without any particular view of entering into the church. In that univerſity he continued his ſtudies under the patronage of Dr Stevenſon till the year 1745, when he retired to Dumfries, and reſided in the houſe of Mr M'Murdo, who had married his ſiſter, during the whole time of the civil war, which then raged in the country, and particularly diſturbed the tranquillity of the metropolis. When peace was reſtored to the nation, he returned to the univerſity, and purſued his ſtudies for ſix years longer. During this laſt reſidence in Edinburgh, he obtained, among other literary acquaintance, that of the celebrated David Hume, who attached himſelf warmly to Mr Blacklock's intereſts, and was afterwards particularly uſeful to him in the publication of the 4to edition of his Poems, which came out by ſubſcription in London in the year 1756. Previouſly to this, two editions in 8vo had been publiſhed at Edinburgh, the firſt in 1746, and the ſecond in 1754.

In the courſe of his education at Edinburgh, he acquired a proficiency in the learned languages, and became more a maſter of the French tongue than was then common in that city. For this laſt acquiſition he was chiefly indebted to the ſocial intercourſe to which he had the good fortune to be admitted in the houſe of Provoſt Alexander, who had married a native of France. At the univerſity he attained a knowledge of the various branches of philoſophy and theology, to which his courſe of ſtudy naturally led, and acquired at the ſame time a conſiderable fund of learning and information in thoſe various departments of ſcience and belles lettres, from which his want of ſight did not abſolutely preclude him.

In 1757, he began a courſe of ſtudy, with a view to give lectures in oratory to young gentlemen intended for the bar or the pulpit. On this occaſion he wrote to Mr Hume, informed him of his plan, and requeſted his aſſiſtance in the proſecution of it. But Mr Hume doubting the probability of its ſucceſs, he abandoned the project; and then, for the firſt time, adopted the decided intention of going into the church of Scotland. After applying cloſely for a conſiderable time to the ſtudy of theology, he paſſed the uſual trials in the preſbytery of Dumfries, and was by that preſbytery licenſed a preacher of the goſpel in the year 1759. As a preacher he obtained high reputation, and was fond of compoſing ſermons, of which he has left ſome volumes in manuſcript, as alſo a Treatiſe on Morals.

The tenor of his occupations, as well as the bent of his mind and diſpoſitions, during this period of his life, will appear in the following plain and unſtudied account, contained in a letter from a gentleman, who was then his moſt intimate and conſtant companion, the Rev. Mr Jameſon,

Jameſon, formerly miniſter of the Epiſcopal chapel at Dumfries, afterwards of the Engliſh congregation at Dantzic, and who lately reſided, and perhaps yet reſides, at Newcaſtle upon Tyne.

"His manner of life (ſays that gentleman) was ſo uniform, that the hiſtory of it during one day, or one week, is the hiſtory of it during the ſeven years that our perſonal intercourſe laſted. Reading, muſic, walking, converſing, and diſputing on various topics, in theology, ethics, &c. employed almoſt every hour of our time. It was pleaſant to hear him engaged in a diſpute, for no man could keep his temper better than he always did on ſuch occaſions. I have known him frequently very warmly engaged for hours together, but never could obſerve one angry word to fall from him. Whatever his antagoniſt might ſay, *he* always kept his temper. '*Semper paratus et refellere ſine pertinacia, et refelli ſine iracundia.*' He was, however, extremely ſenſible to what he thought ill uſage, and equally ſo whether it regarded himſelf or his friends. But his reſentment was always confined to a few ſatirical verſes, which were generally burnt ſoon after.

"I have frequently admired with what readineſs and rapidity he could ſometimes make verſes. I have known him dictate from thirty to forty verſes, and by no means bad ones, as faſt as I could write them; but the moment he was at a loſs for a rhime or a verſe to his liking, he ſtopt altogether, and could very ſeldom be induced to finiſh what he had begun with ſo much ardour."

This account ſufficiently marks that eager ſenſibility, chaſtened at the ſame time with uncommon gentleneſs of temper, which characteriſed Dr Blacklock, and which indeed it was impoſſible to be at all in his company without perceiving. In the ſcience of mind, this is that diviſion of it which perhaps one would peculiarly appropriate to poetry, at leaſt to all thoſe lighter ſpecies which rather depend on quickneſs of feeling, and the ready conception of pleaſing images, than on the happy arrangement of parts, or the ſkilful conſtruction of a whole, which are eſſential to the higher departments of the poetical art. The firſt kind of talent is like thoſe warm and light ſoils which produce their annual crops in ſuch abundance; the laſt, like that deeper and firmer mould on which the roots of eternal foreſts are fixed. Of the firſt we have ſeen many happy inſtances in that ſex which is ſuppoſed leſs capable of ſtudy or thought; from the laſt is drawn that maſculine ſublimity of genius which could build an Iliad or a Paradiſe Loſt.

Dr Blacklock could never dictate till he ſtood up; and as his blindneſs made walking about without aſſiſtance inconvenient or dangerous to him, he fell inſenſibly into a vibratory ſort of motion of his body, which increaſed as he warmed with his ſubject, and was pleaſed with the conceptions of his mind. This motion at laſt became habitual to him; and though he could ſometimes reſtrain it when on ceremony, or on any public appearance, ſuch as preaching, he felt a certain uneaſineſs from the effort, and always returned to it when he could without impropriety. This appearance he deſcribes in a ſhort poem, in which he gives a ludicrous picture of himſelf; a picture indeed, of which, though the outlines are true, the general effect is greatly overcharged. Though his features were hurt by the diſeaſe which deprived him of ſight, there was a certain placid expreſſion in his countenance, which marked the benevolence of his heart, and was calculated to procure to him individual attachments and general regard.

In 1762 he married Miſs Sarah Johnſton, daughter of Mr Joſeph Johnſton ſurgeon in Dumfries; a connection which formed the great ſolace and bleſſing of his future life, and gave him, with all the tenderneſs of a wife, all the zealous care of a guardian and a friend. This event took place a few days before his being ordained miniſter of the town and pariſh of Kircudbright, in conſequence of a preſentation from the crown, obtained for him by the earl of Selkirk, a benevolent nobleman, whom Mr Blacklock's ſituation and genius had intereſted in his behalf. But the inhabitants of the pariſh, whether from that violent averſion to patronage, which was then ſo univerſal in the ſouthern parts of Scotland, from ſome political diſputes which at that time ſubſiſted between them and his noble patron, or from thoſe prejudices which ſome of them might naturally enough entertain againſt a paſtor deprived of ſight, or perhaps from all theſe cauſes united, were ſo extremely diſinclined to receive him as their miniſter, that after a legal diſpute of nearly two years, it was thought expedient by his friends, as it had always been wiſhed by himſelf, to compromiſe the matter, by reſigning his right to the living, and accepting a moderate annuity in its ſtead. With this ſlender proviſion he removed in 1764 to Edinburgh; and to make up by his induſtry a more comfortable and decent ſubſiſtence, he adopted the plan of receiving a certain number of young gentlemen as boarders into his houſe, whoſe ſtudies in languages and philoſophy he might, if neceſſary, aſſiſt. In this ſituation he continued till the year 1787, when he found his time of life and ſtate of health required a degree of quiet and repoſe, which induced him to diſcontinue the receiving of boarders. In 1767 the degree of doctor in divinity was conferred on him by the univerſity and Mariſchal college of Aberdeen.

In the occupation which he thus exerciſed for ſo many years of his life, no teacher was perhaps ever more agreeable to his pupils, nor maſter of a family to its inmates, than Dr Blacklock. The gentleneſs of his manners, the benignity of his diſpoſition, and that warm intereſt in the happineſs of others which led him ſo conſtantly to promote it, were qualities that could not fail to procure him the love and regard of the young people committed to his charge; while the ſociety, which eſteem and reſpect for his character and his genius often aſſembled at his houſe, afforded them an advantage rarely to be found in eſtabliſhments of a ſimilar kind.

In this mixed ſociety he appeared to forget the privation of ſight, and the melancholy which it might at other times produce in his mind. He entered, with the cheerful playfulneſs of a young man, into all the ſprightly narrative, the ſportful fancy, and the humorous jeſt that roſe around him. Next to converſation, muſic was perhaps the ſource of his greateſt delight; for he not only reliſhed it highly, but was himſelf a tolerable performer on ſeveral inſtruments, particularly the flute. He generally carried in his pocket a ſmall *flageolet*, on which he played his favourite tunes; and was not diſpleaſed when aſked in company to play or to ſing them; a natural feeling for a blind man, who thus adds a ſcene to the drama of his ſociety.

Of the happineſs of others, however, we are incompetent judges. Companionſhip and ſympathy bring forth thoſe gay colours of mirth and cheerfulneſs which they put on for a while, to cover perhaps that ſadneſs which we have no opportunity of witneſſing. Of a blind man's condition we are particularly liable to form a miſtaken eſtimate; we give him credit for all thoſe gleams of delight which ſociety affords him, without placing to their full account thoſe dreary moments of darkſome ſolitude to which the ſuſpenſion of that ſociety condemns him. Dr Blacklock had from nature a conſtitution delicate and nervous, and his mind, as is almoſt always the caſe, was in a great degree ſubject to the indiſpoſition of his body. He frequently complained of a lowneſs and depreſſion of ſpirits, which neither the attentions of his friends, nor the unceaſing care of a moſt affectionate wife, were able entirely to remove. The imagination we are ſo apt to envy and admire ſerves but to irritate this diſorder of the mind; and that fancy in whoſe creation we ſo much delight, can draw, from ſources unknown to common men, ſubjects of diſguſt, diſquietude, and affliction. Some of his later poems expreſs a chagrin, though not of an ungentle ſort, at the ſuppoſed failure of his imaginative powers, or at the faſtidiouſneſs of modern times, which he deſpaired to pleaſe.

"Such were his efforts, ſuch his cold reward,
"Whom once thy partial tongue pronounc'd a bard;
"Excurſive, on the gentle gales of ſpring,
"He rov'd, whilſt favour imp'd his timid wing;
"Exhauſted genius now no more inſpires,
"But mourns abortive hopes, and faded fires;
"The ſhort-liv'd wreath, which once his temples grac'd,
"Fades at the ſickly breath of ſqueamiſh taſte;
"Whilſt darker days his fainting flames immure
"In cheerleſs gloom and winter premature."

Theſe lines are, however, no proof of "exhauſted genius," or "faded fires." "Abortive hopes," indeed, muſt be the lot of all who, like Dr Blacklock, reach the period of old age. In early youth the heart of every one is a poet; it creates a ſcene of imagined happineſs and deluſive hopes; it clothes the world in the bright colours of its own fancy; it refines what is coarſe, it exalts what is mean; it ſees nothing but diſintereſtedneſs in friendſhip; it promiſes eternal fidelity in love. Even on the diſtreſſes of its ſituation it can throw a certain romantic ſhade of melancholy that leaves a man ſad, but does not make him unhappy. But at a more advanced age, "the fairy viſions fade," and he ſuffers moſt deeply who has indulged them the moſt.

About the time that theſe verſes were written, Dr Blacklock was, for the firſt time, afflicted with what to him muſt have been peculiarly diſtreſsful. He became occaſionally ſubject to deafneſs, which, though he ſeldom felt it in any great degree, was ſufficient, in his ſituation, to whom the ſenſe of hearing was almoſt the only channel of communication with the external world, to cauſe very lively uneaſineſs. Amidſt theſe indiſpoſitions of body, however, and diſquietudes of mind, the gentleneſs of his temper never forſook him, and he felt all that reſignation and confidence in the Supreme Being which his earlieſt and his lateſt life equally acknowledged. In ſummer 1791 he was ſeized with a feveriſh diſorder, which at firſt ſeemed of a ſlight, and never roſe to a very violent kind; but a frame ſo little robuſt as his was not able to reſiſt it, and after about a week's illneſs it carried him off on the 7th day of July 1791. His wife ſurvives him, to feel, amidſt the heavy affliction of his loſs, that melancholy conſolation which is derived from the remembrance of his virtues.

The writings of Dr Blacklock conſiſted principally of poems, which were publiſhed in 4to in the year 1793; and to that edition was added, *An Eſſay on the Education of the Blind, tranſlated from the French of M. Hauy.* But beſides his avowed works, we have reaſon to believe that he was the author of many articles in the ſecond edition of the *Encyclopædia Britannica*, though we cannot ſay with certainty what thoſe articles were. If our memory does not deceive us, we have been informed that the preface to that edition was furniſhed by him; and we have elſewhere attributed to him, on the beſt authority, the article Blind, and the *Notes* to the article Music: but he undoubtedly contributed much more to the work, and was one of the principal guides of the proprietors.

BLAIR (Dr Hugh), was born in Edinburgh, on the 7th day of April 1718. His father, John Blair, a reſpectable merchant in that city, was a deſcendant of the ancient family of Blair in Airſhire, and grandſon of the famous Mr Robert Blair miniſter of St Andrew's, chaplain to Charles I. and one of the moſt zealous and diſtinguiſhed clergymen of the period in which he lived. This worthy man, though firmly attached to the cauſe of freedom, and to the Preſbyterian form of church government, and though actively engaged in all the meaſures adopted for their ſupport; yet, by his ſteady, temperate conduct, commanded the reſpect even of his opponents. In preference to all the other eccleſiaſtical leaders of the covenanting party, he was ſelected by the king himſelf to fill an office which, from the circumſtances of the time, gave frequent acceſs to the royal perſon; "becauſe (ſaid his majeſty) that man is pious, prudent, learned, and of a meek and moderate calm temper." His talents ſeem to have deſcended as an inheritance to his poſterity. For of the two ſons who ſurvived him, David, the eldeſt, was a clergyman of eminence in Edinburgh, father to Mr Robert Blair miniſter of Athelſtonford, the celebrated author of the poem intitled *The Grave*; and grandfather to his majeſty's ſolicitor general for Scotland, whoſe maſculine eloquence and profound knowledge of law have, in the public eſtimation, placed him indiſputably at the head of the Scottiſh bar. From his youngeſt ſon Hugh, who engaged in buſineſs as a merchant, and had the honour to fill a high ſtation in the magiſtracy of Edinburgh, ſprung the learned clergyman who is the ſubject of this narrative.

The views of Dr Blair, from his earlieſt youth, were turned towards the church; and his education received a ſuitable direction. After the uſual grammatical courſe at ſchool, he entered the humanity claſs in the univerſity of Edinburgh in October 1730, and ſpent eleven years at that celebrated ſeminary, aſſiduouſly employed in the literary and ſcientific ſtudies preſcribed by the church of Scotland to all who are to become candidates for her licence to preach the goſpel. During this important period, he was diſtinguiſhed among his companions both for diligence and proficiency; and obtained from the profeſſors under whom he ſtudied repeated teſtimonies of approbation. One of them deſerves to be mentioned particularly, becauſe, in his own opinion, it determined the bent of his genius towards polite literature. An eſſay Περι του καλου, or, *On the Beautiful*, written by him when a ſtudent of logic in the uſual courſe of academical exerciſes, had the good fortune to attract the notice of profeſſor Stevenſon, and, with circumſtances honourable to the author, was appointed to be read in public at the concluſion of the term or ſeſſion. This mark of diſtinction made a deep impreſſion on his mind; and the eſſay which merited it he ever after recollected with partial affection, and preſerved to the day of his death as the firſt earneſt of his fame.

At this time Dr Blair commenced a method of ſtudy which contributed much to the accuracy and extent of his knowledge, and which he continued to practiſe occaſionally even after his reputation was fully eſtabliſhed. It conſiſted in making abſtracts of the moſt important works which he read, and in digeſting them according to the train of his own thoughts. Hiſtory, in particular, he reſolved to ſtudy in this manner; and, in concert with ſome of his youthful aſſociates, he conſtructed a very comprehenſive ſcheme of chronological tables, for receiving into its proper place every important fact that ſhould occur. The ſcheme deviſed by this young ſtudent for his own private uſe was afterwards improved, filled up, and given to the public by his learned friend Dr John Blair, prebendary of Weſtminſter, in his valuable work, "The Chronology and Hiſtory of the World."

In the year 1739, Dr Blair took his degree of A. M. On that occaſion he printed and defended a theſis, *De Fundamentis et Obligatione Legis Naturæ*, which contains a ſhort but maſterly diſcuſſion of this important ſubject, and exhibits in elegant Latin an outline of the moral principles which have been ſince more fully unfolded and illuſtrated in his Sermons.

The univerſity of Edinburgh, about this period, numbered among her pupils many young men who were ſoon to make a diſtinguiſhed figure in the civil, the eccleſiaſtical, and the literary hiſtory of their country. With moſt of them Dr Blair entered into habits of intimate connection, which no future competition or jealouſy occurred to interrupt, which held them united through life in their views of public good, and which had the moſt beneficial influence on their own improvement, on the progreſs of elegance and taſte among their contemporaries, and on the general intereſts of the community to which they belonged.

On the completion of his academical courſe, he underwent the cuſtomary trials before the preſbytery of Edinburgh, and received from that venerable body a licence to preach the Goſpel on the 21ſt of October 1741. His public life now commenced with very favourable proſpects. The reputation which he brought from the univerſity was fully juſtified by his firſt appearances in the pulpit; and, in a few months, the fame of his eloquence procured for him a preſentation to the pariſh of Coleſſie in Fife, where he was ordained to the office of the holy miniſtry on the 23d of September 1742. But he was not permitted to remain long in this rural retreat. A vacancy in the ſecond charge of the Canongate, a ſuburb of Edinburgh, furniſhed to his friends an opportunity of recalling him to a ſtation more ſuited to his talents. And, though one of the moſt popular and eloquent clergymen in the church was placed in competition with him, a great majority of the electors decided in favour of this young orator, and reſtored him in July 1743 to the bounds of his native city.

In this ſtation Dr Blair continued eleven years, diſcharging with great fidelity and ſucceſs the various duties of the paſtoral office. His diſcourſes from the pulpit in particular attracted univerſal admiration. They were compoſed with uncommon care; and, occupying a middle place between the dry metaphyſical diſcuſſion of one claſs of preachers, and the looſe incoherent declamation of another, they blended together, in the happieſt manner, the light of argument with the warmth of exhortation, and exhibited captivating ſpecimens of what had hitherto been rarely heard in Scotland, the poliſhed, well-compacted, and regular didactic oration.

In conſequence of a call from the town-council and general-ſeſſion of Edinburgh, he was tranſlated from the Canongate to Lady Yeſter's, one of the city churches, on the 11th of October 1754: and on the 15th day of June 1758, he was promoted to the High Church of Edinburgh, the moſt important eccleſiaſtical charge in Scotland. To this charge he was raiſed at the requeſt of the Lords of Council and Seſſion, and of the other diſtinguiſhed official characters who have their ſeats in that church. And the uniform prudence, ability, and ſucceſs, which, for a period of more that forty years, accompanied all his miniſterial labours in that conſpicuous and difficult ſtation, ſufficiently evince the wiſdom of their choice.

Hitherto his attention ſeems to have been devoted almoſt excluſively to the attainment of profeſſional excellence, and to the regular diſcharge of his parochial duties. No production of his pen had yet been given to the world by himſelf, except two ſermons preached on particular occaſions; ſome tranſlations, in verſe, of paſſages of Scripture for the pſalmody of the church; and a few articles in the Edinburgh Review; a publication begun in 1755, and conducted for a ſhort time by ſome of the ableſt men in the kingdom. But ſtanding as he now did at the head of his profeſſion, and releaſed by the labour of former years from the drudgery of weekly preparation for the pulpit, he began to think ſeriouſly on a plan for teaching to others that art which had contributed ſo much to the eſtabliſhment of his own fame. With this view, he communicated to his friends a ſcheme of lectures on compoſition; and having obtained the approbation of the univerſity, he began to read them in the college on the 11th of December 1759. To this undertaking he brought all the qualifications requiſite for executing it well; and along with them a weight of reputation, which could not fail to give effect to the leſſons he ſhould deliver. For, beſides the teſtimony given to his talents by his ſucceſſive promotions in the church, the univerſity of St Andrew's, moved chiefly by the merit of his eloquence, had in June 1757 conferred on him the degree of D. D. a literary honour which at that time was very rare in Scotland. Accordingly his firſt courſe of lectures was well attended, and received with great applauſe. The patrons of the univerſity, convinced that they would form a valuable addition to the ſyſtem of education, agreed in the following ſummer to inſtitute a rhetorical claſs, under his direction, as a permanent part of their academical eſtabliſhment: and on the 7th of April 1762, his Majeſty was graciouſly pleaſed "to erect and endow a pro-

profeſſorſhip of rhetoric and belles lettres in the univerſity of Edinburgh ; and to appoint Dr Blair, in conſideration of his approved qualifications, regius profeſſor thereof, with a ſalary of L.70." The lectures which he read as profeſſor of rhetoric, he publiſhed in 1783, when he retired from the labours of the office ; and the general voice of the public has pronounced them to be a moſt judicious, elegant, and comprehenſive ſyſtem of rules for forming the ſtyle and cultivating the taſte of youth.

About the time in which he was occupied in laying the foundations of this uſeful inſtitution, he had an opportunity of conferring another important obligation on the literary world, by the part which he acted in reſcuing from oblivion the poems of Oſſian. It was by the ſolicitation of Dr Blair and Mr John Home, that Mr Macpherſon was induced to publiſh his *Fragments of Ancient Poetry* ; and their patronage was of eſſential ſervice in procuring the ſubſcription which enabled him to undertake his tour through the Highlands for collecting the materials of Fingal, and of thoſe other delightful productions which bear the name of Oſſian. To theſe productions Dr Blair applied the teſt of genuine criticiſm ; and ſoon after their publication gave an eſtimate of their merits in *a Diſſertation*, which, for beauty of language, delicacy of taſte, and acuteneſs of critical inveſtigation, has few parallels. It was printed in 1763, and ſpread the reputation of its author throughout Europe.

The great objects of his literary ambition being now attained, his talents were for many years conſecrated ſolely to the important and peculiar employments of his ſtation. It was not till the year 1777 that he could be induced to favour the world with a volume of the Sermons which had ſo long furniſhed inſtruction and delight to his own congregation. But this volume being well received, the public approbation encouraged him to proceed : four other volumes followed at different intervals, the laſt of which was publiſhed after his death ; and all of them experienced a degree of ſucceſs of which few publications can boaſt. They circulated rapidly and widely wherever the Engliſh tongue extends ; they were ſoon tranſlated into almoſt all the languages of Europe ; and his preſent Majeſty, with that wiſe attention to the intereſts of religion and literature which diſtinguiſhes his reign, was graciouſly pleaſed to judge them worthy of a public reward. By a royal mandate to the Exchequer in Scotland, dated July 25th 1780, a penſion of L.200 a-year was conferred on their author, which continued unaltered till his death.

In that department of his profeſſional duty which regarded the government of the church, Dr Blair was ſteadily attached to the cauſe of moderation. From diffidence, and perhaps from a certain degree of inaptitude for extemporary ſpeaking, he took a leſs public part in the conteſts of eccleſiaſtical politics than ſome of his contemporaries ; and, from the ſame cauſes, he never would conſent to become moderator of the General Aſſembly of the Church of Scotland. But his influence among his brethren was extenſive : his opinion, guided by that ſound uprightneſs of judgment, which formed the predominant feature of his intellectual character, had been always held in high reſpect by the friends with whom he acted ; and, for many of the laſt years of his life, it was received by them almoſt as a law. The great leading principle in which they cordially concurred with him, and which directed all their meaſures, was to preſerve the church, on the one ſide, from a ſlaviſh, corrupting dependance on the civil power ; and, on the other, from a greater infuſion of democratical influence than is compatible with good order, and the eſtabliſhed conſtitution of the country.

The reputation which he acquired in the diſcharge of his public duties, was well ſuſtained by the great reſpectability of his private character. Deriving from family aſſociations a ſtrong ſenſe of clerical decorum, feeling on his heart deep impreſſions of religious and moral obligation, and guided in his intercourſe with the world by the ſame correct and delicate taſte which appeared in his writings, he was eminently diſtinguiſhed through life by the prudence, purity, and dignified propriety of his conduct. His mind, by conſtitution and culture, was admirably formed for enjoying happineſs. Well balanced in itſelf by the nice proportion and adjuſtment of its faculties, it did not incline him to any of thoſe eccentricities, either of opinion or of action, which are too often the lot of genius :—free from all tincture of envy, it delighted cordially in the proſperity and fame of his companions : ſenſible to the eſtimation in which he himſelf was held, it diſpoſed him to dwell at times on the thought of his ſucceſs with a ſatiſfaction which he did not affect to conceal : inacceſſible alike to gloomy and to peeviſh impreſſions, it was always maſter of its own movements, and ready, in an uncommon degree, to take an active and pleaſing intereſt in every thing, whether important or trifling, that happened to become for the moment the object of his attention. This habit of mind, tempered with the moſt unſuſpecting ſimplicity, and united to eminent talents and inflexible integrity, while it ſecured to the laſt his own reliſh of life, was wonderfully calculated to endear him to his friends, and to render him an invaluable member of any ſociety to which he belonged. Accordingly there have been few men more univerſally reſpected by thoſe who knew him, more ſincerely eſteemed in the circle of his acquaintance, or more tenderly beloved by thoſe who enjoyed the bleſſing of his private and domeſtic connection.

In April 1748, he married his couſin Katharine Bannatine, daughter of the Rev. James Bannatine, one of the miniſters of Edinburgh. By her he had a ſon who died in infancy, and a daughter who lived to her twenty-firſt year, the pride of her parents, and adorned with all the accompliſhments that became her age and ſex. Mrs Blair herſelf, a woman of great good ſenſe and ſpirit, was alſo taken from him a few years before his death, after ſhe had ſhared with the tendereſt affection in all his fortunes, and contributed near half a century to his happineſs and comfort.

Dr Blair had been naturally of a feeble conſtitution of body ; but as he grew up his conſtitution acquired greater firmneſs and vigour. Though liable to occaſional attacks from ſome of the ſharpeſt and moſt painful diſeaſes that afflict the human frame, he enjoyed a general ſtate of good health ; and, through habitual cheerfulneſs, temperance, and care, ſurvived the uſual term of human life.—For ſome years he had felt himſelf unequal to the fatigue of inſtructing his very large congregation from the pulpit ; and, under the impreſſion which this feeling produced, he has been heard at times to ſay with a ſigh, "that he was left almoſt the laſt of his contemporaries." Yet he continued to the end in the regular diſcharge of all his other official duties, and particularly in giving advice to the afflicted, who, from different quarters of the kingdom, ſolicited his correſpondence. His laſt ſummer was devoted to the preparation of the laſt volume of his ſermons; and, in the courſe of it, he exhibited a vigour of underſtanding and capacity of exertion equal to that of his beſt days. He began the winter pleaſed with himſelf on account of the completion of this work; and his friends were flattered with the hope that he might live to enjoy the acceſſion of emolument and fame which he expected it would bring. But the ſeeds of a mortal diſeaſe were lurking unperceived within him. On the 24th of December 1800, he complained of a pain in his bowels, which, during that and the following day, gave him but little uneaſineſs; and he received as uſual the viſits of his friends. On the afternoon of the 26th, the ſymptoms became violent and alarming:—he felt that he was approaching the end of his appointed courſe: and retaining to the laſt moment the full poſſeſſion of his mental faculties, he expired on the morning of the 27th, with the compoſure and hope which become a Chriſtian paſtor.

The lamentation for his death was univerſal and deep through the city which he had ſo long inſtructed and adorned. Its magiſtrates, participating in the general grief, appointed his church to be put in mourning; and his colleague in it, Dr Finlayſon, from whom this account of his life is borrowed*, preached his funeral ſermon, in which his character is drawn in a maſterly manner, though with the almoſt unavoidable partiality of friendſhip.

If we, who know Dr Blair only in his writings, might preſume to eſtimate his intellectual character, we ſhould ſay that he poſſeſſed a ſound judgment rather than what could be called a vigorous mind; that he had more taſte than genius; and that he taught ſucceſsfully, as far as it can be taught, *the art of poetry*, though he could not himſelf have been a poet. His moral character was amiable and reſpectable, though he ſeems, even from a hint dropt by his biographer, to have been in a ſlight degree tinctured with vanity. But this was ſurely a venial weakneſs; for where is the head that would be wholly unaffected by the fumes of incenſe burnt before it for fifty years?

BLEACHING. Since the article *Bleaching* in the Encyclopædia was written, very great improvements have been introduced into the art. Of theſe improvements we ſhall proceed to give an account.

1
Diſcovery of the oxy-muriatic acid.

Mr Scheele of Sweden diſcovered the oxy-muriatic acid, or dephlogiſticated muriatic acid, as he called it, about the year 1774, and ſoon after obſerved its effects on vegetable colours. His method of procuring it was as follows: In a ſand-bath is to be placed a glaſs retort, in which muriatic acid has been poured upon manganeſe; to this ſmall receivers are to be adapted capable of containing about twelve ounces each, into which is to be poured about two drachms of water, without any other lute than a ſlip of blotting-paper about the neck of the retort. In about a quarter of an hour a yellow air is perceived in the receiver, which is to be taken off. If the paper has been properly applied, the air ruſhes out forcibly; the receiver muſt be quickly ſtopped, and another applied. Thus many receivers may be filled with the dephlogiſticated muriatic acid; but it is neceſſary to place the retort in ſuch a manner that the drops which riſe into its neck may be able to fall back. The water ſerves to retain the vapours of the acid. "I uſe (ſays he) many receivers, that I may not be obliged to repeat a ſimilar diſtillation for every experiment. It is not proper to employ large ones, becauſe every time they are opened a great part of the acid is diſſipated in the air. What I ſubmitted to examination with this dephlogiſticated muriatic acid was placed in the neck of the receiver, which I had ſtopped. The cork was turned yellow as by aquafortis. Paper tinged with turnſol became almoſt white; all red, blue, and yellow flowers, as alſo green plants, turned yellow in a ſhort time, and the water in the receiver was changed into pure but weak muriatic acid. Neither alkalis nor acids were able to reſtore the colours of the flowers, or of the plants."

2
Its application to bleaching.

M. Berthollet, in 1785, proved that this acid was compoſed of muriatic acid combined with oxygen; and that when it had deprived vegetable matters of their colour, it was reduced to the ſtate of common muriatic acid; that is, it had loſt the oxygen with which it was united. This oxygen had combined with the colouring particles of the vegetable matter, and had rendered them colourleſs. After making theſe obſervations, it occurred to him that the oxy-muriatic acid might produce the ſame effect upon thoſe particles which give colour to thread and cloth, and which it is the object of bleaching to deſtroy. "At firſt (ſays he) I made uſe of water highly impregnated with this acid; and I renewed it when it was exhauſted, until the thread or cloth appeared white; but I ſoon perceived that they were conſiderably weakened, and that they were entirely loſing their ſolidity. I then weakened the liquor a little, and I ſucceeded in bleaching cloth without damaging it. But it ſpeedily became yellow by keeping, eſpecially if it was warmed, or paſſed through an alkaline ley. I reflected upon the circumſtances of common bleaching, and I endeavoured to imitate its proceſs, becauſe I thought the oxygenated muriatic acid might act in the ſame manner as the expoſition of the cloth in the meadows, which alone does not ſuffice, but which appears only to diſpoſe the colouring parts of the cloth to be diſſolved by the alkali of the ley. I examined dew, not only that which falls from the atmoſphere, but alſo that which comes from the nocturnal tranſpiration of plants; and I obſerved that both of them were impregnated with oxygen, ſufficiently to deſtroy the colour of paper ſlightly tinged with turnſol.

Ann. de Chim. II. 158.

"I therefore employed leys, and the action of oxygenated muriatic acid, alternately, and I then obtained a permanent white; and as, at the finiſhing of the common bleaching, the cloth is paſſed through four milk, or through ſulphuric acid diluted with a very large quantity of water, I alſo tried paſſing the cloth through a very dilute ſolution of ſulphuric acid, and I obſerved that the white was thereby rendered more clear. As ſoon as I made uſe of the leys intermediately, I found that it was not neceſſary to employ a concentrated liquor, or to let the cloth, at every immerſion, remain long therein: by this I avoided two inconveniences, which would have rendered this proceſs impoſſible to be

---

* *Blair's Sermons*, vol. v.

be practiſed in the large way. The firſt is the ſuffocating odour of the liquor, which it would be very inconvenient, and even dangerous, to reſpire for any length of time, and which has diſcouraged many perſons who tried to uſe it; the ſecond is, the danger of weakening the cloth. I now alſo left off mixing any alkali with the oxygenated muriatic acid, as I had practiſed in the greateſt part of my firſt trials.

"This is nearly the ſtate in which my experiments were, when I made ſome trials in the preſence of the celebrated Mr Watt. A ſingle view ſufficed for a philoſopher whoſe genius has been exerciſed ſo long upon the arts. In a ſhort time Mr Watt wrote to me from England, that even in the firſt operation he had bleached five hundred pieces of cloth at Mr Grigor's, who has a large bleaching-ground at Glaſgow, and who continues to make uſe of the new proceſs. In the mean time M. Bonjour, who had hitherto aſſiſted me in my experiments, and who joins great ſagacity to a moſt extended knowledge of chemiſtry, aſſociated himſelf with Mr Conſtant, at Valenciennes, in order to form an eſtabliſhment in that city."

M. Caillau made a great number of experiments at Paris reſpecting this new mode of bleaching; but the greateſt part of theſe experiments was made upon cotton, which is more eaſy to bleach, and does not require leys ſo often or ſo ſtrong as flax or hemp. He alſo went to St Quentin, to perform the operation upon the cloth of that country; but he found that all the cloths, which he had bleached to the ſatisfaction of the manufacturers, became again of a reddiſh colour when they were expoſed to a common ley, or even when they were left for ſome time in a warehouſe. Several ſimilar complaints were made by other perſons; and M. Berthollet himſelf had obſerved the ſame thing in his own experiments. M. Bonjour, however, and M. Welter, affirmed that the cloth which they had bleached preſerved its colour perfectly. M. Berthollet ſoon found, that the imperfection in his bleaching was owing to the manner in which he had uſed the leys. "I had contented myſelf (ſays he), in thoſe trials on ſmall pieces which I made in my laboratory, to pour the hot alkaline ſolution into a veſſel where I placed the pieces: it there became cool very rapidly, and therefore did not act with ſufficient power; but when I let theſe pieces remain in the liquor, which I kept nearly in a boiling heat during the ſpace of two or three hours, they were then no longer ſubject to the above mentioned defects: it was therefore merely the weakneſs of the leys which had occaſioned the accidents which were experienced by Meſſrs Caillau, Décroiſille, and myſelf. It is neceſſary that the colour of the cloth ſhould not be changed by the laſt ley, and this is the ſureſt mark that the bleaching is finiſhed; nevertheleſs, after this laſt action of the ley, it is proper to put the cloth, for a few moments, in the bleaching liquor.

. de
v. II.

"After this laſt immerſion, it is neceſſary to plunge the cloth in ſour milk, or in water acidulated with ſulphuric acid. I do not know the moſt convenient proportion of ſulphuric acid; but it appeared to me that we might ſucceſsfully, and without danger, make uſe of one part, in weight, of this acid to fifty of water. We muſt keep the cloths during about half an hour in this liquor warmed; after which it is proper to ſqueeze them well, and plunge them directly into common water; for if the evaporation ſhould take place, the ſulphuric acid, becoming thereby concentrated, would corrode them. The cloths being then well waſhed, require only to be dried and dreſſed in the ordinary manner, according to their different ſorts.

"It is of the utmoſt importance to take care that the water is not too ſtrongly impregnated with the ſulphuric acid.

"The bleaching of cotton cloth is much eaſier and ſhorter; two leys, or at moſt three, and as many immerſions in the bleaching liquor, are ſufficient for them. As they are bleached ſo eaſily, it is advantageous, when there are flaxen, hempen, and cotton cloths, to be bleached, to reſerve for the cotton the liquors which have been previouſly weakened by the cloths of flax or hemp; for it is economical to exhauſt the liquors as much as poſſible, and thoſe which are conſiderably weakened ſtill ſuffice for the cotton, although they have ſcarcely any action upon hemp or flax.

"Thread, in the common way of bleaching, is attended with a far greater number of difficulties than cloth; becauſe of the immenſe number of ſurfaces which it is neceſſary to preſent ſucceſſively to the action of the atmoſphere. Some part of theſe difficulties occur in bleaching with the oxygenated muriatic acid; nevertheleſs, in the end, it is more advantageous with reſpect to thread than with reſpect to cloth. M. Welter has formed at Liſle, with two partners, an eſtabliſhment for bleaching thread, with great ſucceſs, and he has already begun ſome others. He has found that ten or twelve leys, and as many immerſions, are required for ſome ſorts of thread; and, that the thread may be ſurrounded with the liquor, it is neceſſary to place it, quite looſely, in a baſket, which permits the liquor to penetrate to all its ſurfaces; when the liquor is much weakened, it is ſtill fit to be uſed for the bleaching of cotton.

"I had, in the beginning of my experiments, tried whether the vapour would not be preferable to the oxygenated muriatic acid in a liquid ſtate, and I obſerved that it bleached with greater quickneſs; but, whatever precautions I employed, it appeared to me that a conſiderable loſs of it took place; that thoſe parts of the cloths which were the moſt expoſed to it were ſubject to be weakened; and that it was more difficult to obtain an equal whiteneſs throughout.

"To prevent all the accidents which may reſult from the liquor acting with too great power, it is important to have a means of meaſuring its force. M. Décroiſille thought of uſing, for that purpoſe, a ſolution of indigo in ſulphuric acid. He takes one part of indigo, reduced into fine powder, and eighteen parts of concentrated ſulphuric acid; this mixture is put into a matraſs, which is kept, during ſome hours, in a water-bath; when the ſolution is finiſhed, it is diluted with a thouſand parts of water. To try the power of the oxygenated muriatic acid, one meaſure of this ſolution is put into a graduated glaſs tube, and ſome of the liquor is gradually added to it, until the colour of the indigo is deſtroyed. We muſt firſt determine how many meaſures of a liquor, the goodneſs of which has been aſcertained by experiments made upon cloth, are neceſſary to deſtroy the colour of one meaſure of the ſolution of indigo, and this number will ſerve to eſtimate the reſpective ſtrength of all the liquors which it may be neceſſary

ceſſary to compare with it. Mr Watt employs, in the ſame manner, a ſolution of cochineal."

3
Method of procuring the acid for bleaching.

M. Berthollet recommended the following method of procuring the oxy-muriatic acid: "If we have good oxide of manganeſe, formed in ſmall cryſtals, and containing but little extraneous matter, the proportions of the ſubſtances to be ſubmitted to diſtillation are the following: Six ounces of calx of manganeſe reduced to powder; one pound of common ſalt, alſo reduced to powder; twelve ounces of concentrated ſulphuric acid, or oil of vitriol; from ten to twelve ounces of water.

"When theſe materials are prepared, we muſt carefully mix the oxide of manganeſe with the common ſalt, and introduce the mixture into the diſtilling veſſel placed upon a ſand bath: we muſt then pour upon it the ſulphuric acid, previouſly diluted (and of which the heat occaſioned by its mixture with water is diſſipated), and immediately apply to the mouth of the matraſs the tube which is to conduct the gas into the intermediate veſſel.—It muſt not be forgot, that in this operation the lutes require particular attention.

"The ſize of the veſſels ſhould be ſuch, that the diſtilling matraſs may be about one-third empty; and, for the quantity above mentioned, the tub ſhould hold 100 quarts of water; there ſhould alſo be an empty ſpace of about 10 quarts, in order that when the gas lodges itſelf in the cavities intended to receive it, the water may have a free ſpace to riſe in.

"Before the commencement of the operation, the pneumatic tub muſt be filled with water. The mixture being made, the gas, which very ſoon begins to diſengage itſelf, drives out the atmoſpherical air which is in the apparatus; when it is judged that the atmoſpheric air has paſſed into the cavities, it is to be drawn off by means of a bent tube, which is to be introduced ſucceſſively under each cavity: to drive out the water which has entered into the tube, this laſt is to be forcibly blown into. The operation is then ſuffered to go on without fire until it is perceived that the bubbles come over but ſlowly: then a little fire is to be applied, which is not to be haſtily increaſed at the beginning, but may be gradually augmented, ſo that at the end of the operation the matter may be brought to a boiling ſtate. It is known to be nearly finiſhed when the tube by which the gas is diſengaged, and the intermediate veſſel, become hot. When the gas is diſengaged only in a ſmall quantity, the fire may be withdrawn; and when the diſtilling veſſel retains but a gentle warmth, it is to be unluted, and warm water is to be poured upon the reſidue, that it may remain in ſolution, and thereby be more eaſily poured out.

"The operation is longer or ſhorter according to the quantity of materials: with that above mentioned, it ſhould laſt five or ſix hours; it is proper not to haſten it, that a larger quantity of gas may be drawn off. A ſingle perſon is able to manage ſeveral diſtillations at the ſame time; to each of which may be given much larger quantities of materials than thoſe which have been pointed out.

"The intermediate veſſel by degrees becomes filled with a liquor, which is pure, though weak, muriatic acid; nevertheleſs, we may perform the operation ſeveral times without extracting it: but when it is ſuppoſed that there is not ſufficient empty ſpace, this acid is to be drawn off by means of a ſyphon, and, when we have collected a ſufficient quantity of it, it may be ſubſtituted for the mixture of vitriolic acid and common ſalt in the operation we have deſcribed, if we have no other uſe to make of it. That there may paſs but a ſmall quantity of muriatic acid, not oxygenated, the firſt tube ought to form a right angle, or even an obtuſe one, with the body matraſs.

"During the operation, the agitator muſt be from time to time put in motion, to favour the abſorption of the gas by the water; when it is finiſhed, the liquor is of a proper ſtrength to uſe in bleaching; or we may put a leſs quantity of water in the tub, and then dilute the liquor according to the proportion already mentioned.

"In this ſtate of concentration, although the liquor has a pretty ſtrong odour, it nevertheleſs is not hurtful, nor even very unpleaſant, to thoſe who uſe it: it is, however, proper to conduct it into the troughs where the cloths are placed by means of wooden canals, which are to be connected with the fauſet or tube which is at the lower part of the tub."—The following is a deſcription of the apparatus:

Plate VII fig. 1.

ABCD is a reverberatory furnace, having, on a line with B, many ſmall openings in its circumference, to ſerve as chimneys; within which, upon a ſand-bath *a*, is placed a matraſs *b*, the neck of which ſtands out above the furnace, running through the opening D; which is to be cloſed with clay. The mouth F, of the neck of the matraſs, is cloſed by a cork G, through the middle of which paſſes a tube H, which forms a communication between the inſide of the matraſs *b*, and the intermediate veſſel K, where it alſo paſſes through a cork I, which cloſes one of the three openings of that veſſel. The corks G and I ought to be prepared before-hand, and well fitted to each end of the tube of communication H, which is to be ſo diſpoſed that it may be fitted in immediately after the mixture is made in the matraſs.

The intermediate veſſel K is about an eighth part full of water; into it is plunged the tube of ſafety L, to prevent danger from regurgitation. This tube ought to be ſo high, that the weight of the water which enters into it, by the preſſure of the gas, may be great enough to cauſe the gas to paſs into the pneumatic tub NOP, by the tube of communication M, which is plunged therein, and reaches to the bottom, where it is bent horizontally, ſo that the gas may be emitted under the firſt of the three wooden, or (if they can be procured) ſtoneware, cavities, or receivers, which are placed in the inſide of the tub, one above the other. O is a handle which ſerves to turn the agitator E, the movement of which facilitates the combination of the gas with the water. P is a ſpigot and fauſet to draw off the liquor.

4
Method o
bleaching

It is neceſſary to prepare the cloth by leaving it to ſoak for 24 hours in water, or, which is better, in ſome old ley. Afterwards it ſhould be ſubmitted to the action of one or two good leys; becauſe all the colouring part which may be extracted by the leys would elſe, without any advantage, conſume a part of that liquor, which it is important to be as ſparing of as poſſible. After this, the cloth is to be carefully waſhed; then it is to be placed in the troughs, without any part being preſſed or confined, in ſuch a manner that it may be thoroughly impregnated with the liquor which is to

run

run thereon. The troughs, as well as the tub, ought to be conſtructed without iron; for that metal, being ruſted by the oxygenated muriatic acid, would produce iron moulds, which could not be taken out but by means of ſalt of ſorrel.

The firſt immerſion ought to be longer than the others; it may be continued for three hours, after which the cloth is to be taken out; it is to be again ſubmitted to the action of ley, and then placed in a trough, that freſh liquor may be poured thereon: it is ſufficient that this immerſion, and the following ones, continue half an hour. When the cloth is taken from the trough, the liquor is to be wrung out, it is to be again ſubmitted to the ley, and afterwards to freſh immerſions. The ſame liquor may ſerve until its ſtrength is exhauſted: when it is much weakened, there may be ſome freſh liquor added to it. When the cloth appears white, except ſome black threads and the liſts, it is to be impregnated with black ſoap, and then ſtrongly rubbed; after which it is to be ſubmitted to the laſt ley and the laſt immerſion. We cannot determine what number of leys and immerſions may be neceſſary, becauſe it varies according to the nature of the cloth: neverthleſs, the limits of this number are between four and eight for linen or hempen cloths.

The manufacturers at Javelle, to whom M. Berthollet had communicated this proceſs, ſoon after publiſhed, in different journals, that they had diſcovered a particular liquor which had the property of bleaching cloth by an immerſion of ſome hours only. The change they had made in the proceſs, performed in their preſence, conſiſted in putting ſome alkali into the water which receives the gas; this enables the liquor to become much more concentrated, ſo that it may be diluted with ſeveral times its own quantity of water before it is uſed.

" Theſe are the proportions which yielded me (ſays Berthollet), a liquor ſimilar to the pretended Javelle ley: two ounces and a half of common ſalt, two ounces of ſulphuric acid, ſix drachms of calx of manganeſe, and, in the veſſel where the gas is to be concentrated, one pound of water, and five ounces of potaſh, which ſhould be diſſolved in the water. The Javelle liquor has a ſomewhat reddiſh appearance, occaſioned by a ſmall quantity of manganeſe, which either paſſes in the diſtillation, becauſe an intermediate veſſel is not uſed, or exiſts in the potaſh; moſt kinds of which contain it, as I have well convinced myſelf.

"This liquor may be diluted with from ten to twelve parts of water; and, after this, it bleaches more ſpeedily than the liquor itſelf; but without ſpeaking of the imperfections of the method which is deſcribed in the publications from Javelle, and which can only ſuffice for cotton, we are not able to bleach near the ſame quantity of cloth with the oxygenated muriatic acid combined in this manner with an alkali, as might be bleached with the ſame quantity of that acid mixed with water alone; becauſe there is formed a portion of that neutral ſalt which is known at preſent by the name of oxygenated muriat of potaſs, and in which the oxygen becomes concentrated. Now all the oxygen which enters into the compoſition of this ſalt is rendered uſeleſs for bleaching; becauſe the oxygenated muriat of potaſh does not deſtroy colours."

This method of bleaching was very ſoon adopted in Britain, and is now almoſt univerſal among bleachers. A great many changes have been made in the proceſs; one of the moſt important of which is ſubſtituting lead veſſels for wooden ones, which, beſides weakening its action exceedingly, were very ſoon deſtroyed by the acid. We believe, too, that the bleachers very generally add ſome alkali to the acid, notwithſtanding the ſtrong objections which Mr Bertholiet has made to that manner of bleaching.

This method of bleaching has been found to anſwer remarkably well: the only objection that has been made to it is, that the cloth is apt to be weakened. And this, no doubt, muſt be the caſe, if care be not taken to prevent the acid from being too much concentrated: but we have little doubt that, with a ſufficient degree of caution, it will prove as ſafe as any other whatever; and, in point of expedition, there cannot ſurely be any compariſon drawn between the old mode of bleaching and the new.

It remains for us now to conſider whether the new diſcoveries in chemiſtry do not throw ſome rays of light upon the theory of bleaching; for it is only by perfecting the theory that we can advance with certainty in our practical improvements. 5 Theory of bleaching.

It has been already obſerved, in the article BLEACHING (*Encycl.*), that cloth, after being bleached, was a good deal lighter than it had been before that operation: It follows, therefore, that it muſt have been deprived of ſomething during the bleaching. Cloth bleached by means of the oxy-muriatic acid likewiſe undergoes a loſs of weight; ſo that, in all probability, both modes act in preciſely the ſame manner.

If raw linen or thread be boiled in a ſolution of cauſtic alkali, properly diluted, it gives out ſomething which tinges the ley of a deep brown, and at the ſame time the alkali loſes its cauſticity. If the linen be boiled in another ſimilar ſolution, it communicates the ſame colour, and even a third may be ſlightly tinged; but after this, alkalies, unleſs ſo much concentrated as to injure the texture of the cloth, have no effect on it whatever. If the linen be now plunged into oxy-muriatic acid, properly prepared, and allowed to remain till it begins to become white, and then plunged into an alkaline ley, the alkali loſes its cauſticity, and aſſumes the ſame deep colour that the firſt ley did. Here, then, we have two alkaline ſolutions; the one ſaturated with colouring matter before the action of the oxy-muriatic acid on the linen, the other after it. When theſe ſolutions are ſaturated with an acid, a yellow-coloured precipitate is obtained, which when dried aſſumes the appearance of a black powder. Preciſely the ſame ſubſtance is obtained from both ſolutions. This colouring matter is almoſt inſoluble in water. Pure or cauſtic potaſs diſſolves about double its own weight of it; carbonat of potaſs not ſo much.

Hence we ſee the uſe of alkalies in bleaching. The colouring matter is not ſoluble in water, but part of it is ſoluble in alkali. However, after the alkali has exhauſted all its power, the linen is not white: colouring matter therefore exiſts in it, which alkalies cannot act upon. But after being plunged in oxy muriatic acid, it alſo becomes ſoluble in acids. Here, then, is the uſe of that acid in bleaching—it communicates ſomething to the colouring matter which renders it ſoluble in alkali. This ſomething, we have already ſeen, is oxygen. It

follows,

follows, therefore, that before the greater part of the colouring matter of linen can be extracted by alkalies, it muſt be combined with oxygen. It is in producing this combination that the uſe of the expoſure to the ſun and air conſiſts; and it is becauſe the oxy-muriatic acid produces it almoſt inſtantaneouſly, that the new mode of bleaching is ſo much more expeditious than the old.

If into the alkaline ſolution of the colouring matter lime-water be poured, there takes place a copious precipitate, which conſiſts of the lime and colouring matter combined. Lime, therefore, has a ſtronger affinity for the colouring matter than alkali has; and as the compound of lime and the colouring matter is not very ſoluble in water, lime-water might be uſed to deprive the alkaline ley of the colouring matter which it has imbibed; after which it might be uſed again. Care, however, muſt be taken, that no lime-water remains in the ley; otherwiſe it might precipitate and fix the colouring matter on the linen, after which it would be very difficult to remove it.

6
Nature of the colouring matter of linen.

From an alkaline ley, ſaturated with the colouring matter of linen yarn, Mr Kirwan, by means of muriatic acid, precipitated the colouring matter. He found it to poſſeſs the following properties: When ſuffered to dry for ſome time on a filter, it aſſumed a dark green colour, and felt ſomewhat clammy like moiſt clay. "I took (ſays he) a ſmall portion of it, and added it to 60 times its weight of boiling water, but not a particle of it was diſſolved. The remainder I dried in a ſand heat; it then aſſumed a ſhining black colour, became more brittle, but internally remained of a greeniſh yellow, and weighed one ounce and a half.

Iriſh Tranſ. 1789.

"By treating eight quarts more of the ſaturated ley in the ſame manner, I obtained a further quantity of the greeniſh depoſite; on which I made the following experiments:

"1ſt, Having digeſted a portion of it in rectified ſpirit of wine, it communicated to it a reddiſh hue, and was in a great meaſure diſſolved: but by the affuſion of diſtilled water the ſolution became milky, and a white depoſite was gradually formed; the black matter diſſolved in the ſame manner.

"2dly, Neither the green nor the black matter was ſoluble in oil of turpentine or linſeed oil by a long-continued digeſtion.

"3dly, The black matter being placed on a red hot iron, burned with a yellow flame and a black ſmoke, leaving a coaly reſiduum.

"4thly, The green matter being put into the vitriolic, marine, and nitrous acids, communicated a browniſh tinge to the two former, and a greeniſh to the latter, but did not ſeem in the leaſt diminiſhed.

"Hence it appears, that the matter extracted by alkalies from linen yarn is a peculiar ſort of reſin, different from pure reſins only by its inſolubility in eſſential oils, and in this reſpect reſembling lacs. I now proceed to examine the power of the different alkalies on this ſubſtance. Eight grains of it being digeſted in a ſolution of cryſtallized mineral alkali, ſaturated in the temperature of 60°, inſtantly communicated to the ſolution a dark brown colour; two meaſures (each of which would contain 11 pennyweights of water) did not entirely diſſolve this ſubſtance. Two meaſures of the mild vegetable alkali diſſolved the whole.

"One meaſure of cauſtic mineral alkali, whoſe ſpecific gravity was 1,053, diſſolved nearly the whole, leaving only a white reſiduum.

"One meaſure of cauſtic vegetable alkali, whoſe ſpecific gravity was 1,039, diſſolved the whole.

"One meaſure of liver of ſulphur, whoſe ſpecific gravity was 1,170, diſſolved the whole.

"One meaſure of cauſtic volatile alkali diſſolved alſo a portion of this matter."

The colouring matter of cotton is much more ſoluble in alkali than that of linen; hence the greater facility with which cotton is bleached.

From theſe obſervations, the great importance of alkalies in bleaching, and the neceſſity of regulating the ſtrength, and aſcertaining the purity, of the leys made uſe of, muſt be apparent. Manufacturers, therefore, lie under very great obligations to Mr Kirwan, who has lately examined the alkaline matters uſed in bleaching with his uſual accuracy and abilities. The reſult of his experiments was as follows:

Table of the quantity of mere alkali in 100 *Avoirdupois pounds of the following ſubſtances.*

Iriſh Tranſ. 1789.

One hundred lbs.	*Mineral Alkali.*
Cryſtallized ſoda	20 lbs.
Sweet barilla	24
Mealy's cunnamara kelp	3,437
Ditto deſulphurated by fixed air	4,457
Strangford kelp	1,25
One hundred lbs.	*Vegetable Alkali.*
Dantzic pearl aſh	63,33 lbs.
Clarke's refined aſh	26,875
Caſhup	19,376
Common raw Iriſh weed-aſh	1,666
Ditto ſlightly calcined	4,666

When linen is allowed to remain for ſome time in oxy-muriatic acid, it becomes white. It is evident, then, that when the colouring matter of linen is ſaturated with oxygen, it becomes colourleſs: But linen bleached in this manner very ſoon becomes yellow, eſpecially when expoſed to heat. Berthollet, to whoſe ingenious experiments and obſervations we are indebted for the greater part of the above remarks, has given the following explanation of the cauſe of this change: He diſtilled the colouring matter of linen, and obtained a thick oil, a little ammonia, and $\frac{24}{100}$ of carbon remained behind. The oil contained carbon; and he ſuppoſed that carbonic acid gas, and carbonated hydrogen gas, were diſengaged. He concluded in conſequence, that one-third of this colouring matter was carbon. The other ingredient in the oil was hydrogen; for Lavoiſier has proved that oil is compoſed of oxygen and hydrogen. The colouring matter of linen, then, is compoſed principally of carbon and hydrogen.

Oxygen combines with hydrogen at a lower temperature than it does with carbon; for if a conſiderable quantity of oxy-muriatic acid be mixed with a ſolution of ſugar (a ſubſtance which conſiſts chiefly of carbon and hydrogen), and the liquor be evaporated, there remains behind little elſe than carbon, the hydrogen having combined with oxygen and formed water, which had paſſed off in the form of vapour. Now, whenever a quantity of hydrogen is ſeparated from a body principally

cipally compoſed of hydrogen and carbon, that body aſſumes a brown or yellow colour, becauſe the carbon becomes predominant; and this colour becomes the deeper the greater the proportion of the carbon is, compared to that of the hydrogen; and at laſt, when nothing but carbon remains, it becomes quite black.

It is probable, then, that when the oxy-muriatic acid renders linen white, a quantity of oxygen has combined with the colouring particles; but that this oxygen gradually enters into a combination with the hydrogen, and forms water which paſſes off; that then the carbon becomes predominant, and the linen in conſequence aſſumes a yellow colour*.

7
Bleaching of wool and ſilk.

The ſame method does not ſucceed in bleaching wool and ſilk which anſwers for linen and cotton. One would be diſpoſed to think that theſe ſubſtances are bleached rather by loſing oxygen than by abſorbing it. Wool, for inſtance, is rendered white very quickly when expoſed to the fumes of ſulphurous acid, which we know has a ſtrong affinity for oxygen, and ſoon ſaturates itſelf with it. But what paſſes during the whitening of animal matters has never yet been properly inquired into, though it would not only greatly elucidate *bleaching*, but *dyeing* likewiſe, and throw much light upon ſome of the obſcureſt parts of chemiſtry. A great improvement, however, has lately been made by M. Baumé in the manner of bleaching ſilk. Of this improvement we ſhall proceed to give an account†.

8
New mode of whitening ſilk.

Before the ſilk is wound off the cocons in which the ſilk worms are encloſed, it is neceſſary to kill the inſects, otherwiſe they would in all probability eat thro' it and deſtroy it. This is commonly done by expoſing the cocons, properly wrapped up, for two hours to the heat of about 158 degrees of Fahrenheit in an oven; after which they are kept for a certain time in a maſs to preſerve their heat, and effectually deſtroy ſuch of the inſects as might have eſcaped the power of the oven. The effect of this proceſs is, that the ſilk is hardened, and is more difficult to wind off than before. Hence the product of ſilk is leſs by one ninth part in quantity, and inferior in quality to what might have been obtained by winding off without this previous baking. M. Baumé, not only from theſe views, but likewiſe becauſe the ſilk which has not been baked proves ſuſceptible of a greater luſtre, was induced to deſtroy the chryſalis by ſpirit of wine. For this purpoſe he diſpoſes them in a wooden box in a ſtratum ſix inches deep: upon each ſquare foot half a pint of ſpirit of wine is to be ſprinkled with a ſmall watering-pot made for that purpoſe. The liquid is to be equally diſtributed, but it is not neceſſary that all the cocons ſhould be wetted. They are then to be mixed by hand. In the next place another ſtratum is to be formed over the firſt, nearly of the ſame depth, which is to be ſprinkled and treated as before. By this method of proceeding, the box becomes filled, and muſt then be covered, and left for 24 hours; during which time they become ſpontaneouſly heated to about 100 degrees, and the vapour of the ſpirit of wine exerts itſelf with wonderful activity. After this treatment they muſt be ſpread out to dry, which happens in a ſhort time, and is abſolutely neceſſary previous to winding off.

The ſpirit of wine to be uſed in this operation ought to be of the ſpecific gravity .847, at the temperature of 55 degrees. It is of the greateſt importance to uſe that ſpirit only which has been kept in veſſels of glaſs, of tinned copper, or of pure tin. Leaden veſſels are abſolutely to be rejected; wooden veſſels tinge the ſpirit, which gives the ſilk a degree of colour of conſiderable permanency, and very inimical to the bleaching proceſs.

The ſilk is wound off upon a reel, while the cocons are kept immerſed in water almoſt boiling. Upon this part of the proceſs M. Baumé remarks, 1. That the dead cocons muſt be ſeparated. Theſe are known by the brown or black ſpots on their ſurface. 2. That well-water, which on account of its clearneſs is almoſt univerſally uſed in the ſilk manufactories, moſtly contains nitre, and is extremely prejudicial to the bleaching proceſs. The preſence of nitrous acid gives a yellow colour, which reſiſts bleaching and even ſcouring; he therefore recommends river-water. 3. In ſome countries a ſmall quantity of alum is uſed. Neither this nor any other ſaline ſubſtance is of the leaſt advantage to the colour, beauty, or quality of the ſilk.

At the four places of contact of the ſilk upon the reel, all the threads ſtick together. It is abſolutely neceſſary that this ſhould be remedied. The method conſiſts in ſoaking the ſilk in a ſufficient quantity of warm water, at about 90 degrees, for about two hours; after which the threads are to be ſeparated by opening the hanks upon a pin, and lightly rubbing the parts which cohere. When the ſilk is dry, it is to be looſely folded in its original form, and is ready for bleaching.

The ſilk while wet is ſoft, and part of its gummy matter is in ſuch a ſtate, that its threads would readily adhere, if wrung while warm for the purpoſe of clearing it of the water. After ſuch improper treatment there would be no other remedy than to ſoak it again in warm water.

The apparatus for bleaching the ſilk conſiſts of a ſtone-ware veſſel, nearly of a conical form, capable of holding about 12 gallons, having a large opening at the one end, and a ſmaller of about an inch diameter at the other end. Common pottery cannot be uſed in this operation, becauſe it is ſoon rendered unſerviceable by the action of the muriatic acid, and the ſtone-ware itſelf is not very durable. This veſſel muſt be carefully examined, to aſcertain that it does not leak in the ſlighteſt degree; after which the inſide is to be rubbed with a pumice-ſtone, to clear it of aſperities which might break the threads. A cover of the ſame material is to be fitted on by grinding; and the ſmaller aperture, which in the uſe is the loweſt, is to be cloſed with a good cork, in the middle of which is thruſt a ſmall glaſs tube about a quarter of an inch in diameter; this is likewiſe ſtopped with a cork, excepting at the time when it is required to draw off the liquid contents of the jar. A ſmall perforated falſe bottom is placed within the veſſel, to prevent this tube from being obſtructed.

Six pounds of yellow raw ſilk are to be diſpoſed in the earthen pot; upon this is to be poured a mixture, previouſly made, of 48 pounds of ſpirit of wine of the ſpecific gravity .867, with 12 ounces of very pure marine acid, abſolutely exempt from all preſence of nitrous acid, and of the ſpecific gravity 1.114. The pot is then to be covered, and the whole left in digeſtion till the following day, or until the liquor, which at firſt aſſumes a fine green colour, ſhall begin to aſſume that of a duſky brown.

The acidulated ſpirit is then to be drawn off, clean

---

* *Ann de. Chim.* VI. 210.

† See the memoir in the *Ann. de Chim.* xvii. 156. and abridged in *Nicholſon's Journal*, I. 32. from which laſt we have taken our account of it.

ſpirit of wine poured upon the ſilk, and drawn off repeatedly until it paſſes colourleſs. The ſilk is then ſuffered to drain without ſtirring it. In this ſtate it is ready for a ſecond infuſion.

Forty-eight pounds of ſpirit of wine, acidulated with 12 ounces of marine acid, are now to be poured on the ſilk, and the whole ſuffered to remain for 24 hours or longer, until the ſilk becomes perfectly white. The time required for this ſecond infuſion is commonly longer than for the firſt: it ſometimes amounts to two, three, or even ſix days, according to circumſtances, particularly the temperature and the nature of the ſilk. Silk which has been in the oven is in general more difficult to bleach.

When the ſilk has thus obtained its utmoſt degree of whiteneſs, the acidulated ſpirit is to be drawn off into a ſeparate veſſel. This fluid is but ſlightly coloured, and may be uſed again in the firſt infuſion of other yellow ſilk, with the addition of ſix ounces more of marine acid. The receiving veſſel is to be removed, and another clean veſſel ſubſtituted in its place. The ſilk is then ſprinkled with clean ſpirit, and occaſionally preſſed down with the hand. As ſoon as the ſpirit of wine comes off abſolutely colourleſs, a third infuſion is to be made by pouring upon the ſilk 48 pounds of the pure ſpirit without acid, which is to remain till the following day: it is then to be drawn off, and reſerved for waſhing other ſilk after the firſt infuſion.

After the ſilk has been left to drain, and affords no more ſpirit, it ſtill retains its own weight of that fluid. This is recovered by ſprinkling the ſilk with a ſmall quantity of very clear river-water at a time. While the water applies itſelf and ſubſides along the ſilk, it drives the ſpirit of wine before it, ſo that the firſt portions which flow from the tube are ſcarcely diminiſhed in ſtrength. The addition of water is to be continued until nothing but mere water comes off below.

In this ſituation the ſilk is found to be well bleached, but ſtill retains a portion of marine acid ſufficient to render it harſh to the touch, and after a time brittle. It muſt be waſhed off with water. The beſt method is to put the ſilk looſely into a coarſe woollen bag, which is to be ſecured looſely in another cloth like a ſmall bed or pillow, then placed in a baſket, and left in a running ſtream for five or ſix hours; but where the convenience of a ſtream is wanting, the earthen pot containing the ſilk is to be covered with a cloth, and water pumped through it for five or ſix hours, or until that which iſſues from the lower aperture gives no red colour to the tincture of turnſol. At this period the lower opening is to be cloſed, and the veſſel filled with water, which muſt be changed once or twice in 24 hours.

Though the mineral acids are the moſt powerful and deſtructive of all ſaline ſubſtances, yet they may be applied to ſilk when diluted with ſpirit of wine in very conſiderable doſes. In trials made to aſcertain the maximum, two ounces of marine acid were added to one pound of ſpirit of wine, without altering the ſilk. Two drams of marine acid cauſe a very perceptible alteration in one pound of ſilk.

Spirit of wine which has been mixed with nitrous acid cannot be uſed in bleaching, even though afterwards rectified upon an alkali, becauſe it ſtill retains a portion of nitrous gas. Pure ſpirit of wine without acid extracts a fine yellow colour from ſilk, which does not ſeparate for years, even though expoſed to the ſun's light. Yellow ſilk expoſed to the ſun, loſes its colour in a ſhort time. The acidulated ſpirit which has been uſed in the infuſion of ſilk, is changed by expoſure to the ſun, but not in ſuch a manner as to be rendered fit for uſe a ſecond time. In order to obtain a beautiful white colour, it is eſſential that the ſilk ſhould be immerſed in a large quantity of the fluid, eſpecially at the firſt infuſion. Without this management it would become neceſſary to make three infuſions in the acidulated ſpirit. When the firſt infuſion is well managed, the ſilk will have loſt all its yellow colour, and become conſiderably white, at the ſame time that the liquor will have begun to change colour a little. As long as it continues of a fine green, it is certain that it has not exhauſted its whole action upon the ſilk. The duration of this firſt infuſion may be longer or ſhorter, without inconvenience, according to the temperature. When the temperature is at 77° of Fahrenheit, the firſt infuſion is often made in 10 or 12 hours. In ſmall experiments the heat of the atmoſphere may be ſupplied by the water bath; in which caſe all the infuſions are eaſily made in the courſe of a day.

When the firſt infuſion is finiſhed, and the liquor drawn off, the ſilk appears greeniſh: the ſubſequent waſhings in ſpirit of wine clear it of the liquor it retained. This ſprinkling ſhould be made with the watering pot, otherwiſe the quantity poured will be greater, and the management more waſteful.

Pieces of gauze and entire garments of ſilk have been ſucceſsfully bleached in this way.

The fineſt natural white ſilks are rendered infinitely whiter by this proceſs. Spirit of wine alone has the property of depriving yellow ſilk of its colour, which it brings to the ſtate of the naturally white ſilk. In this ſtate the ſilk is diſpoſed to acquire a greater degree of brightneſs by a ſingle infuſion in the acidulated ſpirit. This proceſs has its advantages over the other, to which it is alſo inferior in certain reſpects; concerning neither of which the author has entered into any detail.

The colouring matter was found to be a reſin perfectly animalized, affording by diſtillation the ſame products as other animal matters, and the concrete volatile alkali.

Silk whitened by ſcouring may be dried freely in the air without affecting its luſtre. This is not the caſe with the ſilk bleached in the gum: if it be left at liberty to dry in the air, it reſembles white flax without any luſtre. The beauty of this ſilk conſiſts in its ſhining brilliancy; to ſecure which it muſt be dried in a ſtate of tenſion. Mr Baumé has contrived a ſimple machine for this purpoſe. It conſiſts of a ſtrong ſquare frame of wood ſtanding upright upon feet: the upper horizontal bar is ſix feet long, and has ſix iron pins driven through it at equal diſtances, ſo as to project on each ſide for the purpoſe of receiving twelve bobbins. The lower horizontal bar is moveable up and down in a mortice, by means of a ſcrew at each end: it is furniſhed with ſix holes adapted to receive as many pins to correſpond with thoſe above. The ſkains of ſilk are to be dreſſed and arranged upon wooden pins, as they are taken out of the ſack from waſhing. As ſoon as there are twelve together, they are to be wrung with a ſtaff; after which the ſkains are to be hung one by one upon as many bobbins put upon the upper pins of the ſquare frame.

frame. Another bobbin with tails is to be inſerted in the lower loop of the ſkain, and faſtened to the correſponding pin of the lower bar, by means of a ſtrap and hook, which need not be deſcribed to ſuch as are ſlightly acquainted with mechanical objects. When the machine is thus ſupplied with ſkains on both ſides, the lower bar of the frame is to be preſſed down by the ſcrews until the ſilk is moderately ſtretched. When it is dry, the ſcrews are to be equally ſlackened, the ſkains taken off and folded with a ſlight twiſt, that they may not become entangled.

To complete the deſcription of this proceſs, it only remains to ſhow how to recover the alcohol, and enſure the purity of the acids made uſe of.

9
Method of recovering the alcohol uſed,

The alcohol which has been uſed in bleaching ſilk is acid, and loaded with colouring matter. In this ſtate it cannot be again uſed. There are two methods of diſtilling it which have their reſpective advantages and inconveniences.

By the firſt the acid is loſt; which is ſaturated with potaſs, in order that the diſtillation may be afterwards performed in a copper alembic. A ſolution of potaſs is to be poured into the acid ſpirit, and ſtirred about to promote the ſaturation. Carbonic acid is diſengaged with ſtrong effervеſcence from the alkali; and the point of ſaturation is known by the uſual teſt, that the fluid does not redden the tincture of turnſol. The diſtillation is then to be made in the copper alembic, and the alcohol reſerved in proper veſſels.

In the ſecond proceſs for diſtilling without alkali, the acid ſpirit is diſtributed into a great number of glaſs retorts, placed in the ſand bath, on the gallery of a furnace. The firſt product is ſcarcely acid; but what follows is more and more ſo, and muſt be kept in veſſels of glaſs or ſtone-ware, which become embarraſſing on account of their number. The fluid which remains in the retorts has the colour of beer ſlightly turbid, and contains the greateſt part of the marine acid. It muſt be poured into one or more retorts, and concentrated by heat gradually applied. The firſt liquor which comes over is ſlightly red, turbid, and ſcarcely acid. This is to be thrown away, and the receivers changed. The ſucceeding product is the colourleſs marine acid, of an aromatic ſmell reſembling the buds of poplar. The reſin of the ſilk remains in the retort decompoſed by the acid. The marine acid thus obtained is weaker than it originally was; which is in fact of little conſequence, as it is pure, and may be ſafely uſed, either by increaſing the doſe proportional to its diminiſhed ſtrength, or by concentrating it if required in the uſual way. If this diſtillation be made in a ſilver alembic, inſtead of retorts of glaſs, and a capital and worm of pure tin be annexed, the alcohol will be obtained ſo ſlightly acid as ſcarcely to redden the tincture of turnſol; but it is ſufficiently acid to receive injury if preſerved in a copper veſſel.

10
And of preparing a pure muriatic acid.

As to the acid, Mr Baumé obſerves that the muriatic acid of commerce is unfit for the purpoſe. It was formerly prepared with the marine ſalt of the ſaltpetre manufacturers; and even when it is made with good ſalt, the decompoſition is effected with common vitriolic acid which contains nitrous acid. Marine acid mixed with a ſmall quantity of nitrous acid does not prevent the ſilk from being beautifully whitened: it even accelerates the proceſs conſiderably, and in the moſt ſatisfactory manner. But the alcohol, every time it is uſed and rectified, becomes charged with the acid and gas of nitre, which aſſume the characters of the nitrous anodyne liquor. In this ſtate neither diſtillations nor repeated rectifications from alkali are ſufficient to ſeparate the nitrous matter from the alcohol. Then it is that the ſucceſs of the operator vaniſhes, with a degree of rapidity equal to the advances which encouraged his hopes at the commencement.

To purify common ſulphuric acid, 100 pounds of it are to be mixed in a large baſon of copper with the ſame quantity of river-water, and ſtirred with a wooden ſpatula. The mixture inſtantly becomes heated to the boiling water point, and a great quantity of red vapour is diſengaged, which has the ſmell of aqua-regia, and ariſes from the nitric and muriatic acids. When this mixture is made, it is proper to immerſe the baſon to a ſuitable depth in a large veſſel of water, to haſten the cooling. As ſoon as it is ſufficiently cooled, it is to be drawn off into bottles, and left to become clear during ſeveral days. It is in the next place to be decanted, and conveyed into retorts by a ſyphon funnel, and the rectification proceeded upon until it becomes perfectly white. Towards the end of the operation a ſmall quantity of ſulphur ſublimes in the neck of the retort. Inſtead of receivers, a ſmall glaſs cup is placed beneath the aperture of each retort, in order to facilitate the diſſipation of the nitric and muriatic acids. When the acid in the retorts is ſufficiently cooled, it is poured a ſecond time into the copper baſon, and mixed with 100 pounds of river-water, as at firſt, and again concentrated in the retorts till it becomes perfectly clear. The muriatic acid is to be diſengaged from common ſalt by the application of this acid in the uſual manner.

11
Bleaching paper.

The oxy-muriatic acid is alſo uſed very generally for bleaching paper, or rather the ſtuff out of which paper is made. It has been alleged, and we believe with ſome truth, that ſince this mode of whitening paper was introduced into this country, the ſtrength of paper is much inferior to what it was formerly. If this be really the caſe, perhaps it is owing to the uſe of too concentrated an acid.

We ſhall finiſh this article with Mr Chaptal's account of this proceſs, who was the firſt perſon that introduced it. "Blotting paper (ſays he), by being put into oxygenated muriatic acid, is bleached without ſuffering any injury; and rags of coarſe bad cloth, ſuch as are uſed in the paper manufactories to make this kind of paper, may be bleached by this acid, and will then furniſh paper of a very ſuperior quality. I bleached by it an hundred weight of paſte, intended to be made into blotting paper, and the increaſe of value in the product was computed at 25 *per cent.* whereas the expence of the operation, when calculated in the ſtricteſt manner, amounted only to 7 *per cent.*

12
Mode of whitening old books,

"The property poſſeſſed by this acid, of bleaching paper without injuring its texture, renders it very valuable for reſtoring old books and ſmoked prints. The latter, when diſcoloured to ſuch a degree that the ſubject of them could hardly be diſtinguiſhed, were re-eſtabliſhed and revived, in ſo aſtoniſhing a manner that they appeared to be new; and old books, ſoiled by that yellow tinge which time always produces, may be ſo completely renewed, that one might ſuppoſe them to be juſt come out of the preſs. The ſimple immerſion of a print in oxygenated muriatic acid (leaving it therein a longer or a ſhorter time, according to the ſtrength of the liquor) is all that is required for bleaching it ; but when a book is to be bleached, ſome farther precautions are to be uſed. As it is neceſſary that the acid ſhould wet every one of the leaves, the book muſt be completely ſpread open, and then, by letting the boards of the binding reſt upon the ſides of the veſſel, the paper only will be immerſed in the liquor. If any of the leaves ſtick together they muſt be carefully ſeparated, that all of them may be equally impregnated. The liquor takes a yellow tinge, the paper grows white ; and after two or three hours the book may be taken out of the liquor, and ſoaked in clean water, which ſhould be changed from time to time, in order to waſh out the acid with which the book is impregnated, and alſo to deprive it of the diſagreeable ſmell it has contracted.

“ The above method, which is the firſt I made uſe of, has generally ſucceeded pretty well: too often, however, the leaves of my books have had a motley appearance, and ſometimes ſeveral pages were not at all bleached ; I was therefore obliged to have recourſe to the following more certain proceſs. I began by unſewing the books, and reducing them into ſheets ; theſe ſheets I placed in diviſions made in a leaden veſſel, by means of thin ſlips of wood, ſo that the leaves when laid flat were ſeparated from each other by very ſmall intervals. I then put the acid into the veſſel, pouring it againſt the ſide, that the leaves might not be diſturbed ; and when the operation was finiſhed, I drew off the acid by means of a cock fixed in the bottom of the veſſel. I then filled the veſſel with clean water, which waſhed the leaves, and took off the ſmell of the oxygenated acid. They may then be dried, ſmoothed, and new bound. In this manner I have reſtored many valuable books, which had become worthleſs from the bad ſtate they were in.

13 And prints. “ When I had to bleach prints ſo torn to pieces that they conſiſted only of fragments fitted together, and paſted upon paper, I was afraid I might loſe ſome of theſe fragments in the liquor, becauſe they ſeparate from the paper by the ſoftening of the paſte : in that caſe therefore I took the precaution of encloſing the print in a large cylindrical bottle, which I turned upſide-down, fixing its mouth to that of a veſſel in which I had put a mixture proper for diſengaging oxygenated muriatic gas. This gas fills the inſide of the bottle, and, acting upon the print, takes off the ſtains, ink-ſpots, &c. while the fragments remain paſted to the paper, and conſequently keep their reſpective places.”

BLOCKS (*Encycl.* Plate XCV. fig. 5.) *a* Repreſents a ſingle block, and *b*, *c*, two double ones of different kinds, without ſtraps ; *e*, *f*, two double tackle blocks, iron bound, the lower one, *f*, being fitted with a ſwivel ; *g*, a double iron block with a large hook ; *h*, a ſmall block ; *i*, a top block ; *k*, a voyal block ; *l*, a clew garnet block ; *m*, the cat block, employed to draw the anchor up to the cat-head. See *Cat-Heads*, Encycl.

CAPE OR LARGE SNOUTED BOAR, a ſpecies of the genus Sus, which, according to M. Vaillant, differs from every known ſpecies, and has not been accurately deſcribed by any writer of natural hiſtory. Buffon, indeed, in the Supplement to his Hiſtory of Quadrupeds, has given a figure of it ; but nothing like the head of the animal is diſcoverable, ſays our author, in that figure, all its characteriſtics having been omitted by the draughtſman. M. Vaillant, during his laſt travels in Africa, ſhot a monſtrous boar of this ſpecies on the banks of Fiſh river, and in the country of the *Greater Nimiquas*. He deſcribes it in the following terms : Its ſnout, inſtead of being taper and in the form of a proboſcis, is, on the contrary, very broad and ſquare at the end. It has ſmall eyes, at a very little diſtance from each other, level with the ſurface, and near the top of the forehead. On each cheek a very thick cartilaginous ſkin projects horizontally, being about three inches long and as many broad. At firſt ſight you would be tempted to take theſe excreſcences for the ears ; particularly as the real ears of the animal, ſticking as it were to the neck, which is very ſhort, are partly concealed by an enormous mane, the briſtles of which, in colour red, brown, and greyiſh, are 16 inches in length on the ſhoulders. Directly below theſe falſe ears is a bony protuberance on each ſide, projecting more than an inch, ſerving the animal to ſtrike with to the right and left. The boar has, beſides, four tuſks, of the nature of ivory, two in each jaw : the upper ones are ſeven or eight inches long ; very thick at the baſe, and terminating in an obtuſe point, grooved, and riſing perpendicularly as they iſſue from the lips : the lower ones are much ſmaller, and ſo cloſe to the upper ones when the mouth is ſhut, that they appear as one. The head is a truly hideous object. It is ſcarcely leſs ſo than that of the hippopotamus, to which at firſt view it appears to have a ſtriking reſemblance. Syſtematiſts, accuſtomed to view nature only according to rules eſtabliſhed by themſelves, will be far from acknowledging this animal to be a boar ; for not to mention its large ſnout, it wants inciſive teeth in both jaws. Notwithſtanding its wide muzzle, it ploughs up the earth to ſeek for roots, on which it feeds. It is very active, though large and bulky ; running with ſuch ſpeed, that the Hottentots give it the name of the *runner*.

Plate VII.

BONNET (Charles), was deſcended from a French family, who being compelled, on account of their religious principles, to emigrate from their native country, eſtabliſhed themſelves at Geneva in the year 1572. His grandfather was advanced to the magiſtracy in that city, and adorned by his integrity an eminent ſtation. His father, who preferred the ſtation of a private citizen, paid unremitted attention to the education of his ſon, who was born on the 13th of March 1720 ; and Charles, at a very early period, recompenſed his father's aſſiduity, by the amiableneſs of his diſpoſition, and the rapid progreſs he made in general literature. When he was about 16 years of age, he applied himſelf, with great eagerneſs, to the peruſal of *Le Spectacle de la Nature* ; and this work made ſuch a deep impreſſion on his mind, that it may be ſaid to have directed the taſte and the ſtudies of his future life. What that publication had commenced, was confirmed by the work of *La Pluche* ; but having accidentally ſeen the treatiſe of *Reaumur* upon inſects, he was in a tranſport of joy. He was very impatient to procure the book ; but as the only copy in Geneva belonged to a public library, and as the librarian was reluctant to intruſt it in the hands of a youth, it was with the utmoſt difficulty that he could obtain his end.

By the poſſeſſion of this treaſure, our aſſiduous youth was enabled to make ſeveral new and curious experiments, which he communicated to Reaumur himſelf; and the high applauſe he gained from ſo great a naturaliſt added freſh vigour to his aſſiduity.

In compliance with his father's deſires, he applied himſelf, though with much reluctance, to the ſtudy of the law. The works of *Burlamaqui* pleaſed him the moſt, on account of the perſpicuous and philoſophic manner in which the ſubject was treated: the inſtitutes of *Heineccius* gave him ſome courage alſo, as he perceived order and connection; but the Roman law terrified him as the *hydra of Lerna.* Notwithſtanding his application to theſe authors, he ſtill continued attached to natural hiſtory, and was very active in making experiments. The experiments which demonſtrate that tree-lice propagate without copulation, was communicated by Reaumur to the Academy of Sciences; and this circumſtance occaſioned an epiſtolary correſpondence between M. Bonnet and that great naturaliſt. This was doubtleſs very flattering to a youth of twenty years. The letter of Reaumur was accompanied with a preſent of that very book which he had borrowed with ſo much difficulty two years before.

Animated by ſuch diſtinguiſhed marks of approbation, he diligently employed every moment he could ſteal from the ſtudy of juriſprudence to the completion of his natural hiſtory of the tree-louſe; to experiments on the reſpiration of catterpillars and butterflies, which he diſcovered to be effected by ſtigmata, or lateral pores; to an examination of the conſtruction of the tænia or tape-worm; in frequent correſpondence with Reaumur; and in aſſiſting Trembley in his diſcoveries and publication concerning millepedes, &c. Having in the year 1743 obtained the degree of doctor of laws, he relinquiſhed a purſuit which he had commenced with ſo much reluctance. In the ſame year he was admitted a fellow of the Royal Society, to which he had communicated a treatiſe on inſects.

Bonnet being now liberated from his other purſuits, applied himſelf, without intermiſſion, to collecting together his experiments and obſervations concerning the tree-louſe and the worm, which he publiſhed in 1744 under the title of *Inſectology.* This work acquired deſerved approbation from the public, and was honoured by the commendation of the celebrated B. de Juſſieu. He was reproached, however, in a periodical publication, with having paid too little attention to the delicacy of his reader; though his patience and accuracy were acknowledged to be deſerving of praiſe. Such unremitted application and labour could not fail of becoming injurious to his health. Inflammations, nervous fever, ſore eyes, &c. compelled him to relinquiſh the uſe of the microſcope and the ſtudy of inſects. This prevention was ſo extremely mortifying to a man of his taſte and activity of mind, that he was thrown into a deep melancholy, which could only be ſubdued by the reſolution inſpired by philoſophy, and the conſolations of religion: theſe gradually rouſed him from a dejected ſtate of mind. About the end of the year 1746 our philoſopher was choſen member of the Literary Inſtitution at Bologna, which introduced him to a correſpondence with the famed Zanotti, who may be deemed the Fontenelle of Italy.

In the year 1747 he undertook a very difficult work on the leaves of plants; which, of all his publications in natural hiſtory, bore the ſtrongeſt marks of originality, both with reſpect to the manner in which his experiments were made, and the diſcoveries reſulting from them. His extreme attachment to natural hiſtory gradually led him to a ſtudy of a very different nature; ſpeculative philoſophy now engaged his whole attention. The firſt fruits of his meditations in this department was his *Eſſay on Pſychology.* In this work the principal facts obſervable in human nature, and the conſequences reſulting from them, are ſtated in a conciſe and conſpicuous manner. He contemplated man from the firſt moment of his exiſtence, and purſued the developement of his ſenſes and faculties from ſimple growth up to intelligence. The work, which was publiſhed without his name, met with great oppoſition, and was criticiſed with ſeverity; but the cenſures were directed more againſt his expreſſions than his principles; nor were they of ſufficient importance to impede the general acceptance of the publication.

His analyſis of the mental faculties was ſimply a developement of the ideas contained in the preceding work. It engaged his inceſſant attention for the ſpace of five years; nor was it completed before 1759. It is ſomewhat ſingular that both he and the Abbé de Condillac ſhould have illuſtrated their principles by the ſuppoſition of a ſtatue, organized like the human body, which they conceived to be gradually inſpired with a ſoul, and the progreſſive developement of whoſe powers they carefully traced. In the year 1760 this work was publiſhed at Copenhagen, by order and at the expence of Frederick V. and it was followed in 1762 by contemplations on organized bodies. In this the author had three principal objects before him: the firſt was to give a conciſe view of every thing which appears intereſting in natural hiſtory, reſpecting the origin, developement, and reproduction of organized bodies; the ſecond was to confute the two different ſyſtems founded upon the Epigeneſis; and the third was to explain the ſyſtem of Germs, indicate the ground upon which it was founded, its correſpondence with facts, and the conſequences reſulting from it. This work was received with much ſatisfaction by natural philoſophers. The Academy of Berlin, which had propoſed the ſame ſubject as a prize queſtion for 1761, declared that they conſidered the treatiſe as the offspring of cloſe obſervation and profound reaſoning; and that the author would have had an indubitable right to the prize, if he had confined his labours to the preciſe ſtatement of the queſtion. It muſt alſo be recorded, to the honour of the great *Maleſherbes,* that he reverſed the interdict which the public cenſor had laid upon this book, under the pretext that it contained dangerous principles.

The Contemplation of Nature appeared in 1764. In this work the author firſt enlarged upon the common conceptions entertained concerning the exiſtence and perfections of God; and of the order and uniformity obſervable in the univerſe. He next deſcends to man, examines the parts of his compoſition, and the various capacities with which he is endowed. He next proceeds to the plants; aſſembles and deſcribes the laws of their economy; and, finally, he examines the inſects, indicates the principal circumſtances in which they differ from larger animals, and points out the philoſophical inferences that may legitimately be deduced from theſe differences; and he concludes with obſervations reſpecting the induſtry of inſects. This work being of a popular nature, the author ſpared no pains in beſtowing upon it thoſe ornaments of which it was ſuſceptible. The principles which he thus diſcovered and explained, induced him to plan *a ſyſtem of moral philoſophy;* which, according to his ideas, conſiſted ſolely in the obſervance of that relation in which man is placed, reſpecting all the beings that ſurround him. The firſt branch would have comprehended, various means which philoſophy and the medical ſcience have diſcovered for the prevention of diſeaſe, the preſervation and augmentation of the corporeal powers, and the better exertion of their force: in the ſecond, he propoſed to ſhew, that natural philoſophy has a powerful tendency to embelliſh and improve our mind, and augment the number of our rational amuſements, while it is replete with beneficial effects reſpecting the ſociety at large. To manifeſt the invalidity of opinions, merely hypothetical, he undertook, in the third place, to examine, whether there were not truths within the compaſs of human knowledge, to which the moſt ſceptical philoſopher muſt be compelled to yield his conſent, and which might ſerve as the baſis of all our reaſonings concerning man and his various relations. He then would have directed his attention to a firſt cauſe, and have manifeſted how greatly the idea of a Deity and Supreme Lawgiver favoured the concluſions which reaſon had drawn from the nature and properties of things: but it is deeply to be regretted that his health, impaired by inceſſant labour, would not permit him to complete the deſign.

His laſt publication was the *Palingeneſis*, which treats of the prior exiſtence and future ſtate of living beings.

Of his publications in natural hiſtory, thoſe deemed the moſt excellent are, his Treatiſe on the beſt Means of Preſerving Inſects and Fiſh in Cabinets of Natural Hiſtory; a Diſſertation on the Loves of the Plants; ſundry pieces on the Experiments of *Spallanzani*, concerning the Reproduction of the Head of the Snail; a Diſſertation on the *Pipa*, or Surinam Tod; and different Treatiſes on Bees.

In the year 1783 he was elected honorary member of the Academy of Sciences at Paris; and of the Academy of Sciences and the Belles Lettres at Berlin.

Much of his time was employed in a very extenſive correſpondence with ſome of the moſt celebrated natural philoſophers and others. Of this number were *Reaumur*, *De Geer* the Reaumur of Sweden, *Du Hamel*, the learned *Haller*, the experimental philoſopher *Spallanzani*, *Van Swieten*, *Merian*, and that ornament of Switzerland the great *Lambert*. He entertained, however, the utmoſt averſion to controverſy. He thought that no advantage to be obtained by it could compenſate for the loſs of that repoſe which he valued, with Newton, as the *rem prorſus ſubſtantialem*. He never anſwered remarks that were made to the prejudice of his writings, but left the deciſion with the public; yet, ever ready to acknowledge his errors, he was ſincerely thankful to every one who contributed to the perfection of his works. He was uſed to ſay that one confeſſion, *I was in the wrong*, is of more value than a thouſand ingenious confutations.

His literary occupations, and the care he was obliged to take of his health, prevented him from travelling. He delighted in retirement, and every hour was occupied in the improvement of his mind. The laſt 25 years of his life were ſpent in the ſame rural ſituation where he had paſſed the greater part of his early days; yet notwithſtanding the purſuit of literature was his ſupreme delight, he never refuſed to ſuſpend his ſtudies, when the good of his country ſeemed to demand his ſervices.

He was choſen in 1752 member of the Grand Council in the republic of Geneva: and he aſſiſted regularly at their deliberations till the year 1768, where he diſtinguiſhed himſelf by his eloquence; his moderation, united with firmneſs; by his good ſenſe and penetration in caſes of difficulty; and by the zeal with which he endeavoured to reclaim his fellow-citizens to that ancient ſimplicity of manners which had been ſo conducive to the welfare of the ſtate, and to the love of virtue, ſo eſſential to the exiſtence of genuine liberty. His conduct, in every caſe, was conſiſtent with his principles. He took no pains to accumulate wealth, but remained ſatisfied with a fortune equal to his moderate wants, and to the exerciſe of his benevolence. The perfect correſpondence between his extenſive knowledge and virtuous deeds procured him univerſal eſteem.

In the year 1788 evident ſymptoms of an *hydrops pectoris* manifeſted themſelves; and from this time he gradually declined. He ſuſtained his indiſpoſition with unremitted cheerfulneſs and compoſure. After various fluctuations, uſual in that complaint, he died on the 20th of May 1793, in the 73d year of his age; retaining his preſence of mind to the laſt moment, adminiſtering comfort to ſurrounding friends and relatives, and attempting to alleviate the diſtreſs of his diſconſolate wife, in whoſe arms he expired.

As a demonſtration of the high value placed upon his labours and talents by the literati, we have only to remark, that he was member of moſt of the learned ſocieties of Europe.

BOOK-KEEPING, is an art of which the importance is univerſally known; and as commonly practiſed, it has been ſufficiently explained in the Encyclopædia Britannica. But ſince that ariticle was written, a great improvement has been introduced into the art, or rather a new method of book-keeping has been invented by Mr Edward Thomas Jones of the city of Briſtol, accountant, who calls it the *Engliſh ſyſtem of book-keeping;* and thinks that by it accounts may be more regularly kept, and errors in accounts more eaſily detected, than by any other method hitherto known. We are much inclined to be of his opinion; and ſhall therefore lay before our redears his deſcription of this method, as we find it in the ſpecification of the patent which was granted to him January 26. 1796.

The Engliſh Syſtem of Book-Keeping requires three books, called a *day-book* or *journal*, an *alphabet*, and a *ledger*, which muſt be ruled after the following method, *viz.* the day-book to have three columns on each page, for receiving the amount of the tranſactions; one column of which to receive the amount of debits and credits, one column to receive the debits only, and one column to receive the credits only; or it may be ruled with only two columns on each page, one column to receive the amount of the debits, and one column to receive the amount of the credits. There muſt alſo be on each page of the day-book four other columns ruled,

two

two on the left ſide next the amount of the debits, and two on the right ſide next the amount of the credits, for receiving the letter or mark of poſting, and the page of the ledger to which each amount is to be poſted.

The alphabet need not be ruled at all; but muſt contain the name of every account in the ledger, the letter that is annexed to it as a mark of poſting, and the page of the ledger.

The ledger muſt be ruled with three, four, five, or ſeven columns on each page, as may be moſt agreeable, for receiving the amounts of the different tranſactions entered in the day-book. And the proceſs for uſing theſe books, or making up books of accounts on this plan, is as follows:

When a perſon enters into trade, whether by himſelf or with copartners, he muſt have an account opened with himſelf in the ledger; entering firſt in the day-book, and then to the credit of his account in the ledger, the amount of the property he advances into trade: The account may be headed either with his name only, or elſe called his ſtock-account.

If you buy goods, give the perſon credit of whom you purchaſe; when you ſell goods, debit the perſon to whom ſaid goods are ſold. If you pay money, debit the perſon to whom paid, not only for what you pay, but alſo for any diſcount or abatement he may allow, and give the caſhier credit for the neat amount paid. If you receive money, credit the perſon of whom you receive it, not only for what he pays, but alſo for any diſcount or abatement you may allow, and debit the caſhier for the neat amount received; taking care in theſe entries to have nothing myſterious or obſcure, but merely a plain narrative of the fact, introducing not one uſeleſs word, and avoiding every technical term or phraſe except the words debit and credit, which are full and comprehenſive, and the only terms that are applicable to every tranſaction, and may be affixed to every entry.

But as a hurry of buſineſs will ſometimes take place in almoſt every counting-houſe, which may cauſe the entries to be made to the debit inſtead of the credit of an account in the day-book, and to the credit inſtead of the debit, Mr Jones has endeavoured as much as poſſible to counteract the evil, by having only one column for receiving the amount of every tranſaction, whether debits or credits, at the inſtant of making the entry; and, for the convenience of ſeparating the debits from the credits, previous to poſting, which is neceſſary to prevent confuſion and perplexity, he has two other columns on the ſame page; that on the left ſide into which the amount of every debit muſt be carefully entered, and that on the right for the amount of the credits, which columns muſt be caſt up once a month. The column of debits and credits of itſelf forming one amount; the column for the debits producing a ſecond amount; and the column of credits a third amount; which ſecond and third amounts added together, muſt exactly agree with the firſt amount, or the work is not done right.

By this means the man of buſineſs may obtain monthly ſuch a ſtatement of his affairs as will ſhow how much he owes for that month, and how much is owing to him; and the debits being added together for any given time, with the value of the ſtock of goods on hand, will, when the amount of the credit is ſubtracted therefrom, ſhew the profits of the trade.

Our author now proceeds to the proceſs of poſting: which begins with opening an account in the ledger with every perſon to whoſe debit or credit there has been an entry made in the day-book; affixing to each account a letter, which is to be uſed as a mark of poſting. The perſon's name, place of abode, and the folio of the ledger, muſt then be entered in the alphabet, with the ſame letter prefixed to each name as is affixed to the account in the ledger. Next, the page of the ledger on which each account is opened (and which will be ſeen in the alphabet) muſt be affixed to each amount in the day-book, in the column for that purpoſe. The date and amount of each debit muſt then be poſted in the columns for receiving it in the ledger, on the left or debit ſide of that account to which it relates; entering, as a mark of poſting in the day-book, againſt each amount, the ſame letter that is affixed to the account in the ledger, to which ſaid amount may be poſted. Obſerving that the debits of January, February, March, &c. muſt be poſted into the column for thoſe months in the ledger, and the credits muſt alſo be poſted in like manner, filling up each account in the centre, at the expiration of every month, with the whole amount of the month's tranſactions; thus having, in a ſmall ſpace, the whole ſtatement of each perſon's account for the year; in the columns to the right and left the amount ſeparately of each tranſaction; and in the centre a monthly ſtatement.

Having deſcribed the proceſs of this method of book-keeping, he thus ſhews how to examine books kept by this method, ſo as to aſcertain, to an abſolute certainty, if the ledger be a true repreſentation of the day-book; *i. e.* not only if each tranſaction be correctly poſted, as to the amount thereof, but alſo if it be rightly entered to the debit or credit of its proper account. This examination differs from the modes that have heretofore been practiſed, as well in expedition as in the certain accuracy which attends the proceſs; it being only neceſſary to caſt up the columns through the ledger debits and credits, according to the examples given; and the amount of thoſe columns, if right, muſt agree with the columns in the day-book for the ſame correſponding ſpace of time. Theſe caſtings ſhould take place once a month; and if the amounts do not agree, the poſting muſt then, but not elſe, be called over: and when the time, whether it be one, two, three, or four months, that is allotted to each column of the ledger is expired, the amount of each column ſhould be put at the bottom of the firſt page, and carried forward to the bottom of the next, and ſo on to the end of the accounts; taking care that the amount in the day-book, of each month's tranſactions, be brought into one groſs amount for the ſame time.

But although this proceſs muſt prove that the ledger contains the whole contents of the day-book, and neither more nor leſs, yet it is not complete without the mode of aſcertaining if each entry be poſted to its right account; which may be aſcertained by the following method: He has laid down a rule that a letter, which may be uſed alphabetically in any form or ſhape that is agreeable, ſhall be affixed to each account in the ledger, and the ſame letter prefixed to the names in the alphabet, theſe letters being uſed as marks of poſting, and affixed to each account in the day-book as it is poſted: it is only neceſſary therefore to compare and ſee that the letter affixed to each entry in the day-book is the ſame as is prefixed to the ſame name in the alphabet; a difference here ſhews of courſe an error, or elſe it muſt be right.

At the end of the year, or at any other time, when perſons balance their accounts, if there be no objections to the profits of the trade appearing in the books, the ſtock of goods on hand at prime coſt may be entered in the day book, either the value in one amount, or the particulars ſpecified, as may be moſt expedient, and an account opened for it in the ledger, to the debit of which it muſt be poſted. The caſting up of the ledger muſt then be completed: and when found to agree with the day-book, and the amount placed at the bottom of each column, ſubtract the credits from the debits, and it will ſhew the profit of the trade; unleſs the credits be the greater amount, which will ſhew a loſs. In taking off the balances of the ledger, one rule muſt be obſerved, and it cannot be done wrong: As you proceed, firſt ſee the difference between the whole amounts of the credits and debits on each page for the year, with which the difference of the outſtanding balances of the ſeveral accounts on each page muſt exactly agree, or the balances will not be taken right. By this means every page will be proved as you proceed, and the balances of ten thouſand ledgers, on this plan, could not unobſervedly be taken off wrong.

BOSCOVICH (Roger Joſeph), one of the moſt eminent mathematicians and philoſophers of the preſent age, was born of virtuous and pious parents, on the 11th of May 1711, in the city of Raguſa, the capital of a ſmall republic of the ſame name, lying on the eaſtern coaſt of the Adriatic Sea. At baptiſm, the name of Roger was given him, to which he added that of Joſeph when he received the ſacrament (A) of confirmation.

He ſtudied Latin grammar in the ſchools which were taught by the Jeſuits in his native city. Here it ſoon appeared that he was endued with ſuperior talents for the acquiſition of learning. He received knowledge with great facility, and retained it with equal firmneſs. None of his companions more readily perceived the meaning of any precept than he; none more juſtly applied general rules to the particular caſes contained under them. He enounced his thoughts with great perſpicuity, and came ſoon to compoſe with propriety and elegance. His application was equal to his capacity, and his progreſs was rapid. At the beginning of the 15th year of his age, he had already gone through the grammar claſſes with applauſe, and had ſtudied rhetoric for ſome months. His moral behaviour had likewiſe been very good: he was reſpectful and obedient to his parents and maſters, affable and obliging to his equals, and exemplary in all the duties of religion. It was now time for him to determine what courſe he would ſteer through life; nor did he heſitate long in coming to a reſolution.

The Jeſuit fathers, by teaching the ſciences to youth, were very uſeful, and at the ſame time had a fine opportunity of obſerving their ſcholars, and of drawing into their ſociety thoſe boys who ſeemed fit for their purpoſe. Such a ſubject as the young Boſcovich could not eſcape their attention. They ſhewed him particular kindneſs, to which he was not inſenſible. He had an ardent thirſt for learning; to advance in which he felt himſelf capable; and he thought he could nowhere have a better opportunity of gratifying this laudable inclination than in their order, in which ſo many perſons had ſhone in the republic of letters. Accordingly, with the conſent of his parents, he petitioned to be received among them; and his petition was immediately granted, becauſe it was deſired by thoſe to whom it was made.

It was a maxim with the Jeſuits to place their moſt eminent ſubjects at Rome, as it was of importance for them to make a good figure on that great theatre. Wherefore, as Roger's maſters had formed great expectations of him, they procured his being called to that city; whither he was ſent in the year 1725, and entered the noviceſhip with great alacrity. This noviceſhip was a ſpace of two years, in which the candidate made a trial of his new ſtate of life; and in the mean time his new ſuperiors obſerved him, and deliberated whether or not they would admit him into their body. During theſe two years, the novice was principally employed in exerciſes of piety, in ſtudying books of Chriſtian morality, and in becoming perfectly acquainted with the rules and conſtitutions of the order. After theſe two years were paſt, the Jeſuits were willing to retain Boſcovich, and he was no leſs deſirous of remaining with them. He therefore paſſed to the ſchool of rhetoric; in which, for two other years under the moſt expert maſters of the ſociety, young men perfected themſelves in the arts of writing and ſpeaking, which was of ſo great conſequence to perſons who were deſtined to treat ſo much with their neighbours. Here Boſcovich became perfectly well acquainted with all the claſſical authors, and applied with ſome predilection to Latin poetry.

After this he removed from the noviciate to the Roman College, in order to ſtudy philoſophy, which he did for three years. In order to underſtand the doctrine of phyſics, it was neceſſary to premiſe the knowledge of the elements of geometry, which is alſo otherwiſe proper for forming the mind, and for giving to it a true taſte for truth. Here it was that our young philoſopher came to be in his true element; and it now appeared how extremely fit his genius was for this kind of ſtudy. His maſter, though he was able and expert, inſtead of leading him on, was ſcarcely able to keep pace with him, and his condiſciples were left far behind. He likewiſe found the application of the mathematics to natural philoſophy pleaſant and eaſy. From all this, before the end of the three years, he had made a great advancement in phyſical and mathematical knowledge; and his great merit was generally acknowledged by his companions, and well known to his ſuperiors. He had already begun to give private leſſons on mathematics.

According to the ordinary courſe followed by the Jeſuits, their young men, after ſtudying philoſophy, were

---

(A) For this article we are indebted to a dignified clergyman of the church of Rome, who was one of Boſcovich's favourite pupils.

were wont to be employed in teaching Latin and the belles lettres for the ſpace of five years, that ſo they might become ſtill better acquainted with polite learning, and arrive at the ſtudy of theology and the prieſthood at a riper age. But as Roger had diſcovered extraordinary talents for geometrical ſtudies, it was thought by his ſuperiors that it would be a pity to detain him from his favourite purſuits in a drudgery for which ſo many others were fit enough. He was therefore diſpenſed with from teaching thoſe ſchools, and was commanded to commence the ſtudy of divinity.

During the four years that he applied to that ſublime ſcience, he ſtill found ſome leiſure for geometry and phyſics; and even before that ſpace was ended, he was named profeſſor of his beloved mathematics.

He was now placed in an office for which he was ſuperlatively fit, and for which he had a particular predilection. Beſides having ſeen all the beſt modern productions on mathematical ſubjects, he ſtudied diligently the ancient geometricians, and from them learned that exact manner of reaſoning which is to be obſerved in all his works. Although he himſelf perceived eaſily the concatenation of mathematical truths, and could follow them into their moſt abſtruſe receſſes, yet he accommodated himſelf with a fatherly condeſcenſion to the weaker capacities of his ſcholars, and made every demonſtration clearly intelligible to them. When he perceived that any of his diſciples were capable of advancing faſter than the reſt, he himſelf would propoſe his giving them private leſſons, that ſo they might not loſe their time; or he would propoſe to them proper books, with directions how to ſtudy them by themſelves, being always ready to ſolve difficulties that might occur to them.

To the end that he might be the more uſeful to his ſcholars, he took time from higher purſuits to compoſe new elements of arithmetic, algebra, plain and ſolid geometry, and of plain and ſpheric trigonometry; and although theſe ſubjects had been well treated by a great many authors, yet Boſcovich's work will always be eſteemed by good judges as a maſterly performance, well adapted to the purpoſe for which it was intended. To this he afterwards added a new expoſition of conic ſections; in which, from one general definition, he draws, with admirable perſpicuity, all the properties of thoſe three moſt uſeful curves. He had meditated a complete body of pure and mixed mathematics, in which were to be comprehended treatiſes on muſic, and on civil and military architecture; but from accompliſhing this he was prevented by other neceſſary occupations.

According to the cuſtom of ſchools, every claſs in the Roman College, towards the end of the ſcholaſtic year, gave to the public ſpecimens of their proficiency. With this view Boſcovich publiſhed yearly a diſſertation on ſome intereſting phyſico-mathematical ſubject. The doctrine of this diſſertation was defended publicly by ſome of his ſcholars, aſſiſted by their maſter. At theſe literary diſſertations there was always a numerous concourſe of the moſt learned men in Rome. His new opinions in philoſophy were here rigorouſly examined and warmly controverted by perſons well verſed in phyſical ſtudies: but he propoſed nothing without ſolid grounds; he had foreſeen all their objections, anſwered them victoriouſly, and always came off with great applauſe and increaſe of reputation. He publiſhed likewiſe diſſertations on other occaſions; and theſe works, though ſmall in ſize, are very valuable both for the matter they contain, and alſo for the manner in which it is treated. The principal ſubjects of theſe diſſertations are the following: The ſpots in the ſun; the tranſit of mercury under the ſun; the geometrical conſtruction of ſpheric trigonometry; the aurora borealis; a new uſe of the teleſcope for the determination of celeſtial objects; the figure of the earth; the arguments made uſe of by the ancients to prove the rotundity of the ſame; the circles which are called oſculators; the motion of bodies projected in a ſpace void of reſiſtance; the nature of infinities and of infinitely little quantities; the inequality of gravity in different parts of the earth; the annual aberration of the fixed ſtars; the limits of the certainty to which aſtronomical obſervations can arrive; a diſcuſſion on the whole of aſtronomy; the motion of a body attracted by certain forces towards an immoveable centre in ſpaces void of reſiſtance; a mechanical problem on the ſolid of greateſt attraction; a new method of uſing the obſervation of the phaſes in the lunar eclipſes; the cycloid; the logiſtic and certain other curve lines; the forces that are called *living;* the comets; the flux and reflux of the ſea; light; whirlwinds; a demonſtration and illuſtration of a paſſage in Newton concerning the rainbow; the demonſtration and illuſtration of a method given by Euler, regarding the calculation of fractions; the determination of the orbits of a planet by means of catoptrics, certain conditions of its motions being given; the centre of gravity and that of magnitude; the atmoſphere of the moon; the law of continuity, and the conſequences of it in the elements of matter and their forces; the law of the forces that exiſt in nature; lenſes and dioptrical teleſcopes; the perturbation which appears to be cauſed mutually by Jupiter and Saturn, and that chiefly about the time of their conjunction; the diviſibility of matter and the elements of bodies; the objective micrometer;—beſides other ſubjects of the like nature, of which he has treated in ſeparate pieces, or in communications inſerted in the tranſactions of literary ſocieties or academies, he being a member of thoſe that are moſt famous in Europe. It was in ſome of the above-mentioned diſſertations that Boſcovich made known firſt to the world his ſentiments concerning the nature of body, which he afterwards digeſted into a regular theory, which is juſtly become ſo famous among the learned.

Father Noceti, another Jeſuit, had compoſed two excellent poems on the rainbow and the aurora borealis. Theſe poems were publiſhed with learned annotations by Boſcovich; in which, among other things, he with great ſagacity diſcovers errors in optics into which De Dominis, Kepler, and others, had fallen.

His countryman, Benedict Stay, after having publiſhed the philoſophy of Deſcartes in Latin verſe, attempted the ſame with regard to the more modern and more true philoſophy, and has executed it with wonderful ſucceſs, to the admiration of all good judges. The two firſt volumes of this elegant and accurate work were publiſhed with annotations and ſupplements by Boſcovich. Theſe ſupplements are ſo many ſhort diſſertations on the moſt important parts of phyſics and mathematics. Here is to be found a ſolution of the problem of the centre of oſcillation, to which Huygens had come by a wrong method ; here he confutes Euler, who had imagined that the *vis inertiæ* was neceſſary in matter ; here he refutes the ingenious efforts of Riccati on the Leibnitzian opinion of the forces called *living*. He likewiſe ſhews the falſehood of the mathematical prejudice, according to which the right line is conſidered as eſſentially more ſimple than curves, and makes it appear that the notion of the ſaid right line is commonly accompanied with many paradoxes. He demonſtrates, by the doctrine of combinations, ſome beautiful theorems concerning the ſpace occupied by the ſmall maſſes of body, with many uſeful obſervations on ſpace and time.

Benedict XIV. who was a great encourager of learning, and a beneficent patron of learned men, was not ignorant how valuable a ſubject Rome poſſeſſed in Boſcovich ; and this pope gave him many proofs of the eſteem he had for him. Two fiſſures which had been perceived in the cupola of the church of St Peter's on the Vatican had occaſioned ſome alarm. The pope deſired Boſcovich and ſome other mathematicians to make their obſervations, and give their opinion on the ſame. They obeyed, and their opinion was printed. They ſhewed that there was no cauſe to apprehend danger ; but, for greater ſecurity, they propoſed certain precautions, which were adopted and put in execution.

The high opinion which the pope had formed of his talents, and the favour in which he was with Cardinal Valenti, miniſter of ſtate, proved hinderances to his going to America, for which a propoſal was made to him by the court of Liſbon. Some differences had long ſubſiſted between Spain and Portugal concerning the boundaries of their reſpective dominions in that great continent ; and John V. of Portugal wiſhed that Boſcovich would go over and make a topographical ſurvey of the country in diſpute. He was not unwilling to undertake ſuch a taſk, which was entirely to his taſte ; and he was reſolved at the ſame time to meaſure a degree of the meridian in Brazil, which might be compared with that meaſured at Quito by the French academicians Bouguer and Condamine, with the Spaniards Ulloa and Doy. But the pope hearing of this propoſal, ſignified to the Portugueſe miniſter at Rome, that his maſter muſt needs excuſe him for detaining Boſcovich in Italy, where he had occaſion for him, and could by no means conſent to part with him.

Accordingly a commiſſion was given to Boſcovich by Benedict to correct the maps of the papal eſtate, and to meaſure a degree of the meridian paſſing through the ſame. This he performed with great accuracy, aſſiſted by F. Chriſtopher Maire an Engliſh Jeſuit, and likewiſe a great mathematician. Their map was engraved at Rome, and is perhaps the moſt exact piece of the kind that ever was printed, as all the places are laid down from triangular obſervations made by the ableſt hands. Boſcovich alſo publiſhed, in a quarto volume in Latin, an account of the whole expedition, which appeared at Rome in the year 1755, and was afterwards printed at Paris in French in the year 1770. Here he gives a detail of their obſervations and of the methods they followed, and likewiſe of the difficulties they encountered, and how they were ſurmounted. One of theſe embarraſſed them a good deal at the time, but was afterwards matter of diverſion to them and others. Some of the inhabitants of the Apennines, ſeeing them paſs from hill to hill with poles and ſtrange machines, imagined that they were magicians come among their mountains in ſearch of hidden treaſures, of which they had ſome traditions : and as tempeſts of thunder and hail happened about the ſame time, they ſuppoſed that theſe calamities were cauſed by the ſorceries of their new viſitants. They therefore inſiſted that Boſcovich and Maire ſhould depart ; and it was not eaſy to convince them that their operations were harmleſs. In this work there is inſerted a deſcription of the inſtruments made uſe of in determining the extent of the degree of the meridian ; and the whole work may be extremely uſeful to practical geometricians and aſtronomers.

In the year 1757 the republic of Lucca intruſted Boſcovich with the management of an affair which was to them of conſiderable importance. Between that republic and the regency of Tuſcany there had ariſen a diſagreeable diſpute concerning the draining of a lake, and the direction to be given to ſome waters near the boundaries of the two ſtates. The Lucchese ſenate choſe our philoſopher to treat of this buſineſs on their part. He repaired to the ſpot, conſidered it attentively, and drew up a writing, accompanied with a map, to ſhew more clearly what appeared to him moſt equitable and moſt advantageous for both parties. In order to enforce his reaſons the more effectually, it was thought proper that he ſhould go to Vienna, where the Emperor Francis I. who was likewiſe grand duke of Tuſcany, reſided. He was ſo ſucceſsful in this negociation, that he obtained every thing that Lucca deſired, and at the ſame time acquired great eſteem at the Imperial court. In proof of this, the Empreſs Queen made his opinion be aſked concerning the ſtability of the Ceſarean library, and the repairs to be made in it ; which he gave in writing, and it was received with thanks, as being very well grounded.

When he had concluded the affair which had brought him to Vienna, he foreſaw that, for a month or two, the ſnows in the Alps would not allow him to return to Italy. He therefore reſolved to employ that time in completing his ſyſtem of natural philoſophy, on which he had been meditating for the ſpace of thirteen years. He publiſhed his work on that great ſubject in the beginning of the year 1758, in the above-mentioned city. We ſhall in the end give an account of that celebrated ſyſtem, and here go on with our narration.

On his return to Lucca, he not only met with the approbation of all he had done for the intereſt of the republic ; but alſo the ſenate, in teſtimony of their gratitude, made him preſents, and enrolled him in the number of their nobility, which was the greateſt honour they had in their power to confer on him.

He, who was thus uſeful to foreigners, could not refuſe to be ſerviceable to his own country when an occaſion of being ſo offered itſelf. The Britiſh miniſtry had been informed, that ſhips of war, for the French, had been built and fitted out in the ſea-ports of Raguſa, and had ſignified their diſpleaſure on that account. This occaſioned uneaſineſs to the ſenate of Raguſa, as their ſubjects are very ſea-faring, and much employed in the carrying-trade ; and therefore it would have been inconvenient for them to have cauſed any diſguſt againſt them in the principal maritime power. Their countryman Boſcovich was deſired to go to London, in order to ſatisfy that court on the above-mentioned head ;

and with this deſire he complied cheerfully on many accounts. His ſucceſs at London was equal to that at Vienna. He pleaded the cauſe of his countrymen effectually there, and that without giving any offence to the French, with whom Raguſa ſoon after entered into a treaty of commerce.

Boſcovich came to London the more willingly, as he was deſirous of converſing with the learned men of Britain. He was received by the preſident and principal members of the Royal Society with great reſpect; and to that great body he dedicated his poem on the eclipſes of the ſun and moon, which was printed on this occaſion at London, in the year 1760. This is one of his works on which he himſelf put the greateſt value, and it has been much eſteemed by the learned. An edition of it was publiſhed at Venice the year following, and a third at Paris, which is the moſt correct: a tranſlation of it into French has likewiſe been publiſhed at Paris. In this very elegant Latin poem he gives an exact compend of aſtronomy, which ſerves as an introduction to the ſubject; he then explains all that belongs to the doctrine of eclipſes, and their uſe in geography; he conſiders the phenomena that are obſerved in the eclipſes of the ſun, and likewiſe of the moon; he propoſes a theorem, which is his own, concerning the diſtribution of light refracted from the atmoſphere of the earth by the ſhadow of the moon, which happens in the lunar eclipſes; he explains the phenomenon of the reddiſh colour which often appears in the moon when ſhe is eclipſed, of which a ſufficient explication had not before been given: this the author draws from the fundamental doctrine of Newton's theory concerning light and colours; and hence takes occaſion to give a clear idea of the principal conſequences of the ſaid theory. All this is clothed with a beautiful poetical dreſs, and is adorned with pleaſant epiſodes, not to mention the learned annotations which are ſubjoined. This poem was compoſed, for the moſt part, whilſt the author was in journeys, or by way of amuſement, when he was obliged to wait for the opportunities of making aſtronomical obſervations.

The fellows of the Royal Society invited Boſcovich to accompany ſome of their number to America, to obſerve the tranſit of Venus, which was to happen in the year 1762; but being otherwiſe engaged, he could not accept of that invitation. He intended, however, by all means to obſerve that remarkable phenomenon, and had fixed on Conſtantinople as a proper place for doing ſo. He was conducted thither in a Venetian man of war, and much honoured by one of the baylos of that republic, who commanded the veſſel; but, to his great regret, they arrived too late. He returned, by land, in the company of the Engliſh ambaſſador; and a relation of that journey was publiſhed in French and afterwards in Italian.

During theſe journeys, Boſcovich's place in the Roman College was well filled by ſome of thoſe whom he himſelf had trained up in mathematical learning. He was now called by the ſenate of Milan to teach mathematics in the univerſity of Pavia, with the offer of a very conſiderable ſalary. He and his ſuperiors thought proper to accede to this propoſal, and he was received without being ſubjected to any previous examination; which was always obſerved, excepting in ſuch an extraordinary caſe, by the decrees of the univerſity. Here he taught, with great applauſe, for the ſpace of ſix years, having at the ſame time the care of the obſervatory of the Royal College of Brera. About the year 1770, the Empreſs Queen made him profeſſor of aſtronomy and optics in the Palatine ſchools of Milan; requiring of him, however, that he ſhould continue to improve the obſervatory of Brera; which, under his direction, became one of the moſt perfect in Europe.

Here he was extremely happy, teaching the ſciences, applying to his favourite ſtudies, and converſing and correſponding with men of learning and of poliſhed manners; when an event happened which cauſed to him the moſt ſenſible affliction. In the year 1773, the ſociety to which he belonged, and to which he had been from his youth warmly attached, was, to his great regret and diſappointment, aboliſhed. They who had been Jeſuits were allowed no longer to teach publicly; nor was there any exception made in favour of Boſcovich, neither (ſuch was his humour then) would he have accepted of it, though it had been offered him. Propoſals were made to him by ſeveral perſons of diſtinction: and, after ſome deliberation, he choſe Paris for his place of abode; to which he was induced by the circumſtance of his being intimately acquainted with the prime miniſter at that court. He had not been many months at Paris when the univerſity of Piſa ſent him an invitation to go thither, in order to profeſs aſtronomy. But the French miniſter, underſtanding this, declared to the miniſter of Tuſcany, that it was the intention of his moſt Chriſtian majeſty to make his dominions agreeable to Boſcovich, by giving him liberal appointments. In fact he was ſoon naturalized, and two large penſions were beſtowed on him: the one as an honourable ſupport, to the end that he might proſecute his ſublime ſtudies at his eaſe and in affluence; the other as a ſalary annexed to a new office, created in his favour, under the name of *Director of Optics for the Sea Service*, and with the ſole obligation of perfecting the lenſes which are uſed in achromatical teleſcopes.

At Paris he remained ten years, applying principally to optics, and much regarded, not only by the moſt reaſonable men of letters, but likewiſe by the princes and miniſters, both of France and of other nations. But the greateſt men are not exempt from being envied. Some of the French were diſpleaſed that a foreigner ſhould appear ſuperior to themſelves; others of them could not forget that Boſcovich had diſcovered and expoſed their miſtakes. The irreligion which prevailed too much among thoſe who bore the name of philoſophers, was diſagreeable to him. Theſe, and other ſuch circumſtances, made him wearied of Paris, and he deſired to reviſit his friends in Italy; for which purpoſe he obtained leave of abſence for two years.

The firſt place in Italy in which he made any ſtay was at Baſſano, a town in the territories of Venice. Here, mindful of his obligations, he printed what he had been preparing for the preſs during his ſtay in France; and this compoſes five volumes in large octavo, and is a treaſure of optical and aſtronomical knowledge. The ſubjects treated of in theſe volumes are as follow: A new inſtrument for determining the refracting and diverging forces of diaphanous bodies; a demonſtration of the falſehood of the Newtonian analogy between light and ſound; the algebraic formulæ regarding the focuſes of lenſes, and their applications for calculating the ſphericity of thoſe which are to be uſed in achromatical teleſcopes; the corrections to be made in ocular lenſes, and the errors of the ſphericity of certain glaſſes; the cauſes which hinder the exact union of the ſolar rays by means of the great burning glaſſes, and the determination of the loſs ariſing from it; the method of determining the different velocities of light paſſing through different mediums by means of two dioptrical teleſcopes, one common, the other of a new kind, containing water between the objective glaſs and the place of the image; a new kind of objective micrometers; the defects and inutility of a dioptrical teleſcope propoſed and made at Paris, which gives two images of the ſame object, the one direct, the other inverſe, with two contrary motions of moveable objects; maſſes floating in the atmoſphere, as hail of an extraordinary ſize, ſeen on the ſun with the teleſcope, and reſembling ſpots; the aſtronomical refractions, and various methods for determining them; various methods for determining the orbits of comets and of the new planet, with copious applications of theſe doctrines to other aſtronomical ſubjects, and ſtill more generally to geometry and to the ſcience of calculation; the errors, the rectifications, and the uſe of quadrants, of ſextants, of aſtronomical ſectors, of the meridian line, of teleſcopes called the inſtruments of tranſits, of the meridian, and of the parallactic machine; the trigonometrical differential formulæ, which are of ſo much uſe in aſtronomy; the uſe of the micrometical rhombus, extended to whatever oblique poſition; the error ariſing from refractions in uſing the aſtronomical ring for a ſundial, and the correction to be made; the appearing and the diſappearing of Saturn's ring; the methods of determining the rotation of the ſun by means of the ſpots, propoſed formerly by the author, and now perfected; the greateſt exactneſs poſſible in determining the length of a pendulum oſcillating every ſecond of middle time by the compariſon of terreſtrial and celeſtial gravity; a compend of aſtronomy for the uſe of the marine, containing the elements of the heavenly motions, and of the aſtronomical inſtruments to be explained to a prince in the courſe of one month; a method for determining the altitude of the poles with the greateſt exactneſs, by means of a gnomon alone, where other inſtruments are not to be had; the determination of the illuminated edge of the moon to be obſerved on the meridian; a method of uſing the retrograde return of Venus to the ſame longitude, for determining the leſs certain elements of her orbit; a method for correcting the elements of a comet, of which the longitude of the node is given, and the inclination of the orbit has been found nearly; another method for the ſame purpoſe, and for finding the elliptical orbit, when the parabolic one does not agree with the obſervations; a method for correcting the elements of a planet by three obſervations; the projection of an orbit inclined in the plane of the ecliptic; the projection of an orbit inclined in any other plane; the calculation of the aberration of the ſtars, ariſing from the ſucceſſive propagation of light; ſome beautiful theorems belonging to triangles, which are of great uſe in aſtronomy, reduced to moſt ſimple demonſtrations.

After having ſeen the impreſſion of theſe five volumes finiſhed, Boſcovich left Baſſano, made an excurſion to Rome, and viſited his old friends there and in other places of Italy. He then took up his abode at Milan, and applied to the reviſing of ſome of his old works, and to the compoſing of new ones. He ſet himſelf particularly to prepare annotations and ſupplements to the remaining two volumes of Stay's Modern Philoſophy, which he had not had time to publiſh ſooner, and which he lived not to publiſh.

He was happy at Milan in the neighbourhood of Brera, where was his favourite obſervatory; and in the company of many friends, who were become the more dear to him by his long abſence from them. But he began to conſider, with grief, that his two years of abſence were drawing to an end. He was very unwilling to leave Italy and return to France. He thought of applying for a prolongation of his abſence; he thought of making intereſt at the Imperial court for ſome honourable commiſſion, which might be a pretext to him for remaining at Milan: but he was afraid that the propoſal of never returning to France might appear indelicate and ungrateful to a nation from which he was receiving conſiderable penſions. He apprehended that thoſe perſons at Paris who had before oppoſed him, would take occaſion to tax him with ingratitude, and that hence his reputation would be tarniſhed. Theſe, and other ſuch thoughts, occaſioned a great perplexity of mind, which was followed by a deep melancholy; and this could not be alleviated by the advice and comfort of his friends, becauſe by degrees he became incapable of hearing reaſon, his ideas being quite confuſed, and his imagination diſordered. To this diſagreeable change the ſtate of his health perhaps contributed. A gout had been wandering for ſome time through his body, and he had caught a ſevere cold; nor would he admit of medical aſſiſtance, of which he had always been very diffident. It may alſo be that his long and intenſe application had hurt the organs of the brain, which in ſome manner are ſubſervient to the uſe of reaſon as long as the ſoul is united to the body. Be that as it will, during the laſt five months of his life, this great man, who had been ſo far ſuperior in reaſoning to his ordinary fellow-creatures, was much inferior to every one of them who is endued with the right uſe of the underſtanding. He had indeed ſome lucid intervals, and once there were hopes of a recovery; but he ſoon relapſed, and an impoſthume breaking in his breaſt, put an end to his mortal exiſtence. He died at Milan on the 13th of February 1787, in the 76th year of his age.

He was tall in ſtature, of a robuſt conſtitution, of a pale complexion. His countenance was rather long, and was expreſſive of cheerfulneſs and good humour. He was open, ſincere, communicative, and benevolent. His friends ſometimes regretted that he appeared to be too irritable, and too ſenſible of what might ſeem an affront or neglect, which gave himſelf unneceſſary uneaſineſs. He was always unſtained in his morals, obedient to his ſuperiors, and exact in the performance of all Chriſtian duties, as became a Catholic prieſt, and in the obſervance of the particular rules of his order. His great knowledge of the works of Nature made him entertain the higheſt admiration of the power and wiſdom of their Creator. He ſaw the neceſſity and advantages of a divine revelation, and was ſincerely attached to the Chriſtian religion; having a ſovereign contempt of the preſumption and fooliſh pride of unbelievers, and being fully perſuaded that we cannot make a more noble uſe of our underſtanding than by ſubjecting it humbly to the authority of the Supreme Being, who knows numberleſs truths far beyond the utmoſt limits of our narrow comprehenſion, and who may juſtly require our belief of any of them that he ſees fit to propoſe to us.

The death of our philoſopher, who truly deſerved that name, was heard with regret by the learned through Europe, and more than ordinary reſpect has been paid to his memory. At Raguſa funeral exequies were performed for him with great ſolemnity by order of the ſenate, who aſſiſted at them in a body; on which occaſion an eloquent oration in praiſe of him was pronounced. By a decree of the ſame ſenate, a Latin inſcription to his honour, engraved on marble, was placed in the principal church of their city. Of this inſcription the following is a copy:

This inſcription was compoſed by his friend and countryman the celebrated poet Benedict Stay. Zamagna, another of his countrymen, who had likewiſe been his fellow-jeſuit, publiſhed a panegyric on him in elegant Latin. A ſhort encomium of him is to be found in the *Eſtratto della Litteratura Europea*; and another, in form of a letter, was directed by M. de la Lande to the Pariſian journaliſts, and by them given to the public. A more full elogium has been written by M. Fabroni; and another is to be met with in the journal of Modena; a third was publiſhed at Milan by the Abbate Ricca; and a fourth at Naples by the Dr Julius Bajamonti, of which a ſecond edition was made in the year 1790. Of this laſt chiefly uſe has been made here.

But what muſt ſecure to Boſcovich the eſteem of poſterity are his works, of the greater part of which we have:

Boſcovich.

have already taken notice. We have mentioned, 1. His Elements of Mathematics, with his Treatiſe on Conic Sections; 2. His many diſſertations publiſhed during his profeſſorſhip in the Roman college; 3. His account of his Survey of the Pope's Eſtate; 4. His Theory of Natural Philoſophy; 5. His Poem on the Eclipſes; 6. His five volumes printed at Baſſano.

To theſe we may add his hydrodynamical pieces. He had made a particular ſtudy of the force of running water, and of its effects in rivers; and he was often conſulted concerning the beſt means to prevent rivers from corroding their banks, and from overflowing the neighbouring plains, which often happens in Italy, where the Alps and Apennines pour down ſo many impetuous ſtreams. He gave a writing on the damages done by the Tiber at Porto Felice; another on the project of turning the navigation to Rome from Fiumicino to Maccareſe; a third on two torrents in the territory of Perugia; a fourth on the bulwarks on the river Panaro; a fifth on the river Sidone, in the territory of Placentia; a ſixth on the entrance into the ſea of the Adige. He wrote other ſuch works on the bulwarks of the Po; on the harbours of Ancona, of Rimini, of Magna Vacca, and Savona, beſides others, almoſt all which were printed. He had likewiſe received a commiſſion from Clement XIII. to viſit the Pomptin lakes, on the draining of which he drew up his opinion in writing, to which he added further elucidations at the deſire of Pius VI. On theſe occaſions he ſhewed how uſeful philoſophy may be to the public; and of this he gave another proof when it was referred entirely to his judgement to determine whether or not the cupola of the cathedral of Milan could bear the weight of a very high ſpire, which it was propoſed to raiſe on it, and which was actually erected according to his directions.

His application to abſtruſe ſtudies did not hinder him from paying ſome attention to what is more pleaſant. We have ſeen that he was a poet: he was alſo well acquainted with hiſtory, and particularly with that of the Greeks and Romans, and with their antiquities. He wrote a diſſertation on an ancient villa diſcovered in his time upon the Tuſculan Hill, and on an ancient dial found there; which diſſertation was publiſhed at Rome in a literary journal. He wrote likewiſe three letters on the obeliſk of Cæſar Auguſtus, two of which were printed with his own name, and the third under the name of another.

Beſides all theſe works that were given to the public in his lifetime, many writings of his remained in manuſcript in the hands of different perſons, and particularly with his friend M. Gaetani, and many more with Count Michael de Sorgo, a Raguſan ſenator, who inherited all his papers that were in his own hands at his death. Theſe, it is hoped, have either been already ſent to the preſs or will be ſo; as nothing came from the pen of Boſcovich which was not uſeful and deſerving to ſee the light.

Boſcovich's Syſtem of Natural Philoſophy.

IT now remains that we give an account of his THEORY OF NATURAL PHILOSOPHY; and in doing this we ſhall, in the *firſt* place, lay before our readers a view of this ſyſtem. We ſhall, in the *ſecond* place, relate, from what principles and by what ſteps it was deduced. We ſhall, *thirdly*, take notice of the principal objections made to it, and ſubjoin the author's anſwers to the ſame. We ſhall, *finally*, ſhew how happily it may be applied to explain the general properties of matter, as well as the particular qualities of all the claſſes of bodies, which have been examined according to what it teaches.

1
View of Boſcovich's ſyſtem of natural philoſophy.

1. In this ſyſtem, therefore, the whole maſs of matter, of which all the bodies of the univerſe are compoſed, conſiſts of an exceeding great, yet ſtill finite number of ſimple, indiviſible, inextended, atoms. Theſe atoms are endued with *repulſive* and *attractive* forces, which vary and change from the one to the other, according to the diſtance between them, in the following manner: In the leaſt and innermoſt diſtances they repel one another; and this repulſive force increaſes beyond all limits as the diſtances are diminiſhed, and is conſequently ſufficient for extinguiſhing the greateſt velocity, and for preventing the contact of the atoms. In the ſenſible diſtances, this force is *attractive* and decreaſes, at leaſt ſenſibly, as the ſquares of the diſtances increaſe, conſtituting univerſal gravity, and extending beyond the ſphere of the moſt diſtant comets. Between this innermoſt repulſive force and the outermoſt attractive one, in the inſenſible diſtances, many varieties and changes of the force, or determination to motion, take place: for the repulſive force decreaſes as the diſtance increaſes. At a certain diſtance it comes to vaniſh entirely; and, when that diſtance is increaſed, attraction begins, increaſes, becomes leſs, vaniſhes; and the diſtance becoming greater, the force becomes repulſive, increaſes, leſſens, and vaniſhes as before. Many varieties and changes of this kind happen in the inſenſible diſtances, ſometimes more rapidly, ſometimes more ſlowly, and ſometimes one of the forces may come to nothing, and then return back to the ſame without paſſing to the other. For all this there is full room in the diſtances that are inſenſible to us, ſeeing the leaſt part of ſpace is diviſible *in infinitum*. Beſides theſe repulſive and attractive forces, our atoms have that *vis inertiæ* which is admitted by almoſt all modern philoſophers. Theſe atoms, endued with theſe forces, conſtitute the whole ſubſtance of Boſcovich's ſyſtem; which, however ſimple and ſhort it may appear to be, has numberleſs and very wonderful conſequences, as we ſhall ſee afterwards. But, that a more clear idea of the whole theory may be eaſily formed, we ſhall make uſe of a geometrical figure well accommodated to that purpoſe. The right line C'AC is an axis, from which, in the point A, is drawn the right line AB at right angles. AB is conſidered as an *aſymptote*; on each ſide of which the two curves, quite ſimilar and equal, DEFGHIKLMNOPQRSTVU on the one ſide, and D'E'F'G' on the other, are placed. Now, if ED be ſuppoſed to be *aſymptotical*, and be extended, it will ſtill approach to BA, but will never come to touch it. This curve ED approaches to the axis C'C, comes to it in E, cuts it and departs to a certain diſtance in F, after which it again approaches the ſame axis and cuts it in G. In like manner it forms the arches GHI, IKL, LMN, NOP, PQL. At laſt it goes on in T *p s* V, which is aſymptotical, and approaches to the axis; ſo that the diſtances from it are in a duplicate reciprocal proportion of the diſtances from the right line BA. If from any points of the axis, as from *a*, *b*, *d*, we raiſe the per-

2
The whole theory expreſſed by a geometrical curve.
Plate VI. fig. 6.

ſcovich's
yſtem of
Natural
ilofophy.

perpendiculars *a g*, *b r*, *d h*, the ſegments of the axis A *a*, A *b*, A *d*, are called *abſciſſes*, and repreſent the diſtances of any two points of matter from one another; and the perpendiculars *a g*, *b r*, *d h*, are called *ordinates*, and exhibit the repulſive or attractive force, according as it lies on the ſame ſide with D, or on the other ſide of the axis.

Now it is evident that, in this form of the curve line, the *ordinate a g* will be increaſed beyond whatever limits, if the abſciſs A *a* be leſſened likewiſe beyond whatever limits; that if this abſciſs be increaſed to A *b*, the *ordinate* will be leſſened, and will paſs into *b r*, which will ſtill be leſſened as it approaches from *b* to E, where it will come to nothing; that then, the axis being increaſed to A *d*, the *ordinate* will change its direction into *b h*, and, on the oppoſite ſide, will increaſe at firſt to F, then it will decreaſe through *i l* as far as G, where it will again vaniſh, and again change its direction in *m n* to the former; and that, in the ſame manner, it will vaniſh and change its directions in all the ſections I, L, N, P, R, until the *ordinates o p*, *v s*, become of a conſtant direction, and decreaſe, at leaſt ſenſibly, in a reciprocal duplicate proportion of the abſciſſes A *o*, A *v*. Wherefore, it is manifeſt, that by ſuch a curve are expreſſed our forces; at firſt *repulſive* and increaſing beyond all limits, the diſtances being leſſened in like manner, and which decreaſe, the ſame diſtances being augmented; then vaniſh, change their direction, and become *attractive;* vaniſh again, and become *repulſive;* till at laſt, at ſenſible diſtances, they remain on the ſide oppoſite to D, and are *attractive* in a duplicate reciprocal proportion of the diſtances.

We may alſo obſerve that the *ordinates* may increaſe or decreaſe rapidly, as in *y v*, *z t*, or ſlowly, as in *v x*, *z c*; and, conſequently, that the forces may increaſe or decreaſe in like manner. We may add, that the curve may return back without interſecting, or even touching, the axis, as in *f*, and may return after having touched the ſame axis.

Although this curve expreſſes very clearly the *repulſive* and *attractive* forces of our ſyſtem, yet, at firſt ſight, it may appear to be a complicated irregular line. But the author ſhews that his curve is uniform and regular, and may be expreſſed by one uniform algebraical equation; which it will be neceſſary for us to conſider, in order to give ſatisfaction to our readers, and to do juſtice to the theory.

3
e ſimpli-
of this
ve pro-

Wherefore, from what we have ſeen, the curve muſt have the following ſix conditions: *1ſt*, It muſt be regular and ſimple, and not compoſed of an aggregate of arches of different curves. *2dly*, It is neceſſary that it cut the axis C′AC in certain given points only, at two equal diſtances on each ſide AE′, AE, AG , AG, and ſo on. *3dly*, That to every *abſciſs* an *ordinate* correſpond. *4thly*, That if we take equal *abſciſſes* on each ſide of A, they have equal *ordinates*. *5thly*, That the right line AB be an *aſymptote*, the area BAED being aſymptotical, and conſequently infinite. *6thly*, That the arches terminated by any two interſections may be varied at pleaſure, and recede to any diſtance from the axis C′AC, and approach at pleaſure to whatever arches of whatever curves, cutting them, touching them, or oſculating them, in any place and manner.

In order to find an algebraical formula expreſſing the nature of a curve line that would anſwer all theſe ſix conditions, let us call the ordinate *y*, the abſciſs *x*, and let it be made $xx = z$. Then let us take the values of all the abſciſſes AE, AG, AI, &c. with the negative ſign, and let the ſum of the ſquares of all theſe values be called *a*, the ſum of the products of every two ſquares *b*, the ſum of the products of every three, *c*, and ſo on; and let the product of all of them be called *f*, and the number of the ſame values *m*. All this being ſuppoſed, let it be made $z^m + a z^{m-1} + b z^{m-2} + c z^{m-3}$ &c. $+ f = P$. If we ſuppoſe P equal to nothing, it is clear that all the roots of that equation will be real and poſitive; that is, the ſquares only of the quantities AE, AG, AI, &c. which will be the values of *z*; and therefore, as it is $x = \pm \sqrt{z}$, becauſe it is $xx = z$, it is likewiſe clear that the values of *x* will be both AE, AG, AI, poſitive, and $A'E'$, $A'G'$, &c. negative.

Boſcovich's
Syſtem of
Natural
Philoſophy.

This being done, let any quantity be multiplied by *z*, providing it hath no common diviſor with P, leſt *z* vaniſhing, it likewiſe might vaniſh; and having made *x* an infiniteſim of the firſt order, it may become an infiniteſim of the ſame, or of a lower order, as will be whatever formula $z^r + g z^{r-1} + h z^{r-2}$ &c. $+ l$; which, being ſuppoſed equal to *o*, may have as many imaginary, and as many and whatever real roots, providing none of them be thoſe of AG, AE, AI, &c. either poſitive or negative. If then the whole formula be multiplied by *z*, let this product be called Q.

If we make $P - Q f = o$, this equation will ſatisfy the five firſt conditions above mentioned; and the value of Q being properly determined, the ſixth condition alſo may be complied with.

For, in the firſt place, ſeeing the value P and Q are made equal to *o*, they have no common root, and therefore no common diviſor. Hence this equation cannot be reduced to two by diviſion; and therefore it is not compoſed of two equations, but is ſimple, and therefore exhibits one ſimple continued curve, which is not compoſed of any others; which is the firſt condition.

Secondly, The curve thus expreſſed will cut the axis C′AC in all the points E′, G, I, &c. and G′, &c. and in them only: for it will cut that axis only in thoſe points in which $y = o$, and in all of them. Moreover, where it will be $y = o$, it will alſo be $Q y = o$; and therefore, becauſe of $P - Q y = o$, it will be $P = o$. But this will happen only in thoſe points in which *z* will be one of the roots of the equation $P = o$; that is, as we have ſeen above, in the points E, G, I, or E′, G′, &c.: wherefore, only in thoſe points will *y* vaniſh, and the curve cut the axis. Again, that the ſame curve will cut it in all theſe points, is clear from this, that in them all it will be $P = o$. Wherefore it will likewiſe be $Q y = o$; but it will not be $Q = o$, ſeeing there is no common root of the equations $P = o$ and $Q = o$: it muſt therefore be $y = o$, and the curve will cut the axis: and thus the ſecond condition is ſatisfied.

Beſides, whereas it is $P - Q x = o$, it will be $y = \frac{P}{Q}$. the abſciſs *x* being, however, determined, we will have a certain determinate quantity for *z*; and thus P, Q, will be determined, and the only two of the kind. Wherefore *y* alſo will be ſole and determined; and therefore to every abſciſs *z*, one only ordinate *y* will correſpond. This is the third condition.

Again, whether *x* be aſſumed poſitive or negative,

pro-

providing it be of the ſame length, ſtill the value $z = xx$ will be the ſame, and therefore the values of both P and Q will be the ſame: wherefore y will ſtill be the ſame. Taking, therefore, equal abſciſſes z on both ſides of A, the one poſitive, the other negative, they will have equal correſponding ordinates. This is the fourth condition.

If x be leſſened beyond all limits, whether it be poſitive or negative, z likewiſe will be leſſened beyond all limits, and will become an infiniteſim of the ſecond order: wherefore, in the value P, all the terms will decreaſe *in infinitum*, except in y, becauſe all the reſt beſides it are multiplied by z; and thus the value P will be as yet finite. But the value Q, which has the formula multiplied by z, will be leſſened *in infinitum*, and will be an infiniteſim of the ſecond order: therefore $\frac{P}{Q} = y$ will be augmented *in infinitum*, ſo as to become an infinite of the ſecond order. Wherefore the curve will have the right line AB for an *aſymptote*, and the area BAED will increaſe *in infinitum*: and if the ordinate y be aſſumed poſitive on the ſide AB, and expreſs repulſive forces, the aſymptotic arch ED will lie on the ſame ſide AB. This is the fifth condition.

Now the value Q can be varied in infinite manners; ſo that ſtill the conditions for which it was aſſumed may be fulfilled; and therefore the arches of the curve intercepted by the interſections may be varied in infinite manners; ſo that the firſt five conditions of the curve may be implemented: whence it follows that they may be ſo varied that the ſixth condition may alſo be anſwered.

For if there be given, however many, and whatever arches of whatever curve, providing they be ſuch that they recede always from the aſymptote AB, and thus no right line parallel to that aſymptote cut theſe arches in more than one point, and in them let there be taken as many points as you pleaſe, and as near one another; it will be eaſy to aſſume ſuch a value of P, that the curve ſhall paſs through all theſe points, and the ſame may be varied infinitely; ſo that ſtill the curve will paſs through all the ſame points.

Let the number of points aſſumed be what you pleaſe $= r$, and, from every one of ſuch points, let right lines be drawn parallel to AB, as far as the axis C′AC, which muſt be the ordinates of the curve that is ſought; and let the abſciſſes from A to the ſaid ordinates be called M^1, M^2, M^3, &c. and the ordinates $'N^1, 'N^2, 'N^3$, &c. Let there now be taken a certain quantity $Az^r + Bz^{r-1} + Cz^{r-2} + Gz$, and let this quantity be ſuppoſed equal to R. Then let another ſuch quantity T be aſſumed, ſo that z vaniſhing, whatſoever term of it may vaniſh, and ſo that there be no common diviſor of the value of P, and of the value of $R + T$: which may be eaſily done, ſeeing all the diviſors of the quantity P are known. Let it now be made $Q = R + T$, and then the equation of the curve will be $P - Ry - Ty = o$. After this, let there be put in the equation M1, M2, M3, ſucceſſively for x, and N1, N2, N3, &c. for y; we will have a number of equations equal to r, which will contain the values of A, B, C, ... G, each of them of one dimenſion, in number likewiſe equal to r; and, beſides, we will have the given values of M1, M2, &c. N1, N2, N3, &c. and the arbitrary values which in T are the coefficients of z.

By theſe equations, which are in number r, it will be eaſy to determine the values A, B, C, ... G, which are likewiſe in number r, aſſuming in the firſt equation, according to the uſual method, the value A, and ſubſtituting it in all the following equations; by which means the equations will become $r-1$. Theſe, again, by throwing out the value B, will be reduced to $r-2$, and ſo on until we come to one only; in which the value Q being determined by means of it, going back, all the preceding values will be determined, one by each equation.

The values A, B, C, ... G, being in this manner determined, in the equation $P - Ry - Ty = o$, or $P - Qy = o$, it is clear that the values M1, M2, M3, &c. being ſucceſſively put for x, the values of the ordinate y muſt ſucceſſively be N1, N2, N3, &c.; and, therefore, that the curve muſt paſs through theſe given points in thoſe given curves; and ſtill the value Q will have all the preceding conditions. For z being leſſened beyond whatever limits, every one of its terms will be leſſened beyond whatever limits, ſeeing all the terms of the value of T are leſſened which were thus aſſumed, and likewiſe the terms of the value R are leſſened, which are all multiplied by z; and, beſides this, there will be no common diviſor of the quantities P and Q, ſeeing there is none of the quantity P and $R + T$.

But if two of the neareſt of the points aſſumed in the arches of the curves, on the ſame ſide of the axis, be ſuppoſed to accede to one another beyond whatever limits, and at laſt to coincide, which will be done by making two M equal, and likewiſe two N equal; then the curve ſought will touch the arch of the given curve; and if three ſuch points coincide, they will *oſculate* it: nay, as many points as we pleaſe may be made to meet together where we pleaſe; and thus we may have *oſculations* of what order we pleaſe, and as near one another as we pleaſe, the arch of the given curve approaching as we pleaſe, and at whatever diſtances we pleaſe, to whatever arches of whatever curves, and yet ſtill preſerving all the ſix conditions required for expreſſing the law of the repulſive and attractive forces. And whereas the value of T can be varied in infinite manners, the ſame may be done in an infinite number of ways; and therefore a ſimple curve, anſwering the given conditions, may be found out in an infinite number of ways. *Q. E. F.*

What we have ſaid will, we hope, ſatiſfy our readers, and eſpecially thoſe of them who are in the leaſt acquainted with high geometry, that Boſcovich's curve is ſimple, regular, and uniform; and that therefore the law of repulſive and attractive forces, expreſſed by it, is ſimple and regular.

II. If this ſyſtem were a mere hypotheſis, it would ſtill be very ingenious, and, from what we ſhall ſay afterwards, would ſtill be well adapted for explaining the phenomena of nature. But its author is far from looking upon it as an arbitrary ſuppoſition; he aſſures us that he was led to it by a chain of ſtrict reaſoning, from evident principles. We ſhall now give an abridgement of that reaſoning from his Diſſertations on the Law of *Continuity*, and from his Theory of Natural Philoſophy.

4
Proofs of the theory.

He tells us, then, that in the examination of Leibnitz's opinion of the *vires vivæ*, he came to conſider the colliſion of bodies, and took for example two equal bodies. A proceeding with ſix degrees of velocity, and B following with the velocity of 12: after the colliſion,

ſion, they proceed jointly with the common velocity 9. Now, in the moment of colliſion, it either happens that A paſſes abrubtly from the velocity 6 to the velocity 9, without paſſing through the velocity 7 and 8, and B paſſes from 12 of velocity to 9, without paſſing through 11 and 10; or elſe there muſt be ſome cauſe which accelerates the one and retards the other before they come to contact. In the firſt caſe, the law of continuity is broken; in the ſecond, immediate contact of bodies would be rejected. Maclaurin ſaw this difficulty, and mentioned it in his work on *Newton's Diſcoveries*, l. 1. c. 4. He, not having courage to recede from the common opinion, allowed a breach, in ſuch caſes, of the law of continuity; but Boſcovich maintains the univerſality of the law of continuity; and holds that no bodies touch one another really and mathematically, but only phyſically and ſenſibly to us.

5
The law of continuity proved

The law of continuity is that by which variable quantities, paſſing from one magnitude to another, paſs through all the intermediate magnitudes, without ever abruptly paſſing over any of them. This law Boſcovich proves to be univerſal, in the firſt place, from induction. Thus we ſee that the diſtances of two bodies can never be changed without their paſſing through all the intermediate diſtances. We ſee the planets move with different velocities and directions; but in this they ſtill obſerve the law of continuity. In heavy bodies projected, the velocity decreaſes and increaſes through all the intermediate velocities: the ſame happens with regard to elaſticity and magnetiſm. No body becomes more or leſs denſe without paſſing through the intermediate denſities. The light of the day increaſes in the morning and decreaſes at night through all the intermediate poſſible degrees. In a word, if we go through all nature, we ſhall ſee the law of continuity ſtrictly take place, if all things be rightly conſidered. It is true, we ſometimes make abrupt paſſages in our minds; as when we compare the length of one day with that of another immediately following, and ſay that the ſecond is two or three minutes longer or ſhorter than the former, paſſing all at once, in our way of ſpeaking, round the globe; but if we take all the longitudes, we ſhall find days of all the intermediate lengths. We likewiſe ſometimes confound a quick motion with an inſtantaneous one: thus, we are apt to imagine that the ball is thrown abruptly out of the gun; but, in truth, ſome ſpace of time is required for the gradual inflammation of the powder, for the rarefaction of the air, and for the communication of motion to the ball. In like manner, all the objections made againſt the law of continuity may be ſolved to ſatisfaction.

6
A breach of this law impoſſible.

But however ſtrong this argument from judgment may appear to be, yet Boſcovich goes farther, and maintains, that a breach of this law, in the proper caſes, is metaphyſically impoſſible. This argument he draws from the very nature of continuity. It is eſſential to continuity that, where one part of the thing *continued* ends and another part begins, the limit be common to both. Thus, when a geometrical line is divided into two, an indiviſible point is the common limit to both; thus time is *continued;* and therefore where one hour ends, another immediately begins, and the common limit is an indiviſible inſtant. Now, as all variations in variable quantities are made in time, they all partake of its continuity; and hence none of them can haſten by an abrupt paſſage from one magnitude to another, without paſſing through the intermediate magnitudes. As we cannot paſs from the ſixth hour to the ninth without paſſing through the ſeventh and eighth; becauſe, if we did, there would be a common limit between the ſixth hour and the ninth, which is impoſſible: ſo likewiſe you cannot go from the diſtance 6 to the diſtance 9 without paſſing through the diſtances 7 and 8; becauſe, if you did, in the inſtant of paſſage you would be both at the diſtance 6 and at the diſtance 9, which is impoſſible. In like manner, a body that is condenſed or rarefied cannot paſs from the denſity 6 to the denſity 9, or *vice verſa*, without paſſing through the denſities 7 and 8; becauſe, in the abrupt paſſage, there would be two denſities, 6 and 9, in the ſame inſtant. The body muſt paſs through all the intermediate denſities. This it may do quickly or ſlowly, but ſtill it muſt evidently paſs through them all. The like may be ſaid of all variable quantities; and thence we may conclude, that the law of continuity is univerſal.

7
Objections to this law anſwered.

But, in creation, is there not an inſtance of an abrupt paſſage from *non-exiſtence* to *exiſtence?* No, there is not; becauſe before exiſtence a *being* is nothing, and therefore incapable of any ſtate. In creation, a *being* does not paſs from one ſtate to another abruptly; it paſſes over no intermediate ſtate: it begins to exiſt and to have a ſtate, and exiſtence is not diviſible. Do we not, at leaſt, allow of an abrupt paſſage from repulſive to attractive forces in our very theory itſelf? We do not. Our repulſive forces diminiſh, through all the intermediate magnitudes, down to nothing; through which, as a limit, they paſs to attraction. In the building of a houſe or ſhip, neither of them is augmented abruptly; becauſe the additions made to them are effected ſolely by a change of diſtances between the parts of which they are compoſed: and all the intermediate diſtances are gone through. The like may be ſaid of many other ſuch caſes; and ſtill the law of continuity remains firm and conſtant.

8
Impoſſibility of contact between bodies.

Let us now apply this doctrine to the caſe above mentioned of the colliſion of two bodies. We ſay that the body B cannot paſs from the velocity 6 to the velocity 9 without paſſing through the velocities 6 and 7; becauſe if it did, in the moment of contact of the two ſuperficies it would have the velocities 6 and 9. Now a body cannot have two velocities at the ſame inſtant. For if it had two *actual* velocities at the ſame time, it would be in two different places at the ſame time: if it had two different *potential* velocities or determinations to a certain velocity, it would be capable of being, after a given time, in two places at once—both which are impoſſible. It is therefore neceſſary that it go through the velocities 7 and 8, and through all the parts of them. What we have ſaid of the bodies A and B may be ſaid univerſally of all bodies. Therefore no two bodies in motion can come to immediate contact; but their velocities muſt undergo the ſucceſſive neceſſary change before contact. And as the velocity to be extinguiſhed may be increaſed beyond all limits, an adequate cauſe to effect this extinction muſt be admitted.

9
Repulſive forces

This naturally leads us to the interior repulſive forces of our ſyſtem; for the cauſe retarding the one body and accelerating the other muſt be a *force*, becauſe by this we mean a determination to motion; and it muſt be repulſive, becauſe it acts *from* the body; and it muſt increaſe

increaſe beyond all limits, ſeeing the velocity of the incurring bodies may be increaſed beyond all limits. It muſt likewiſe be mutual, becauſe action and reaction are always equal, as may be proved by induction.

10
Inextended atoms.

From theſe repulſive forces Boſcovich deduces the inextenſion of his atoms: for this repulſion being common to all matter, muſt cauſe a perfect ſimplicity in the firſt elements of body. If theſe elements were extended, and conſequently compounded of particles of an inferior order, theſe particles might poſſibly be ſeparated, and then they might meet, and an abrupt paſſage from one velocity to another might take place, which we have excluded from nature by induction, and by a poſitive argument.

Beſides this, by rejecting the extenſion of the firſt elements of matter, we get rid at once of all the difficulties ariſing from continued extenſion in body, which have always perplexed the philoſophers, and have never been ſatisfactorily explained. If the elements of matter are extended, each of them may be divided *in infinitum*, and each part may ſtill be divided *in infinitum*. Can this diviſion be actually made by the power of God or not? Can there be one *infinite* in number greater than another? Can there be a *compound* without a *ſimple* of the ſame kind? Theſe difficulties regard not ſpace, which is no real being; but they would regard matter if it had continued extenſion. All theſe perplexities are removed by maintaining, as Boſcovich does, that the firſt elements of bodies are perfectly ſimple, and therefore inextended (A).

11
Attractive forces.

With regard to the exterior attractive forces of our ſyſtem, there can be no queſtion; ſeeing they conſtitute univerſal gravity, the effects of which we ſee and feel every day. But between the interior repulſive and exterior attractive forces we muſt admit many tranſitions from repulſion to attraction, and from attraction back to repulſion, in inſenſible diſtances, which are indicated to us by coheſion, fermentation, evaporation, and other phenomena of nature. And thus we have given, in ſhort, Boſcovich's proofs of his whole ſyſtem.

12
Objections to the ſyſtem anſwered.

III. This ſyſtem has been well received by the learned in Europe, and has contributed much to render its author famous; yet many objections againſt it have been propoſed. Some are ſtartled at the rejection of all immediate contact between bodies: and indeed Boſcovich is perhaps the firſt of mankind who advanced that opinion; but he allows that bodies approach ſo near to one another, as to leave no ſenſible diſtance between them; and his repulſive forces make the ſame impreſſion on the nerves of our ſenſes as the ſolid bodies could do. And therefore this opinion of his, however new, is nowiſe contrary to the teſtimony of our ſenſes. He only removes a prejudice which was before univerſal.

Some ſay, that they cannot even form an idea of an inextended atom, and that Boſcovich reduces all matter to nothing: but certainly extenſion is not neceſſary for the eſſence of a *being*, as muſt be allowed by all thoſe who hold that ſpirits are inextended. Becauſe all the bodies that fall under our ſenſes are extended, we are apt to look upon extenſion as eſſential to matter: but this error may be corrected by reflection, and an idea of an inextended atom may be formed, by conſidering the nature of a mathematical point, which is the limit of any two contiguous parts of a line.

Others again have ſaid, that if the elements of matter were void of extenſion, there would be no difference between body and ſpirit. But the difference between body and ſpirit does not conſiſt in the having or not having extenſion; but in this, that the atoms of matter are endued with repulſive and attractive forces, which ſpirit has not; and ſpirit has a capacity of thought and volition which bodies have not.

We may here obſerve, that among the ancients Zeno, and among the moderns Leibnitz, held, that the firſt principles of matter are inextended points. But both held this opinion with the inconſiſtency, that they maintained the continued extenſion of bodies, without ever being able to ſhew how continued extenſion could ariſe from inextended elements.

It has been objected likewiſe, that our repulſive and attractive forces are no better than the occult qualities of the Peripatetics. The like objection has been made to Newton's attraction: but the anſwer is eaſy. We obſerve the effects, and take notice of them: for them we muſt admit an adequate cauſe, without being able to determine, whether that cauſe is an immediate law of the Creator, or ſome mediate inſtrument that he makes uſe of for that purpoſe.

Some are unwilling to give up the idea of motion occaſioned by immediate impulſe: but can they ſhow a good reaſon why *ſome diſtance* may not occaſion motion as well as *no diſtance?* Theſe are the principal objections that have been made againſt the Boſcovichian ſyſtem.

13
Obſervations with regard to the curve.

IV. Before we proceed to the explication of phenomena by means of our theory, we muſt advert, that in the curve expreſſing this theory, the abſciſſes denote the diſtances between the atoms that are under conſideration; the ordinates give the preſent *force*, and the area between any two of theſe ordinates gives the ſquare of the velocity generated between them; the arches are either repulſive or attractive, according as they fall upon the ſame ſide with the aſymptotic curve EG, or on the oppoſite ſide.

14
Limits of coheſion, &c.

We muſt, in the next place, conſider the paſſages from one ſide of the axis to the other. Sometimes the paſſage is from repulſion to attraction, at other times from attraction to repulſion. The firſt are called *limits of coheſion*, becauſe a particle removed from that limit returns back to it; becauſe if it is removed to a greater diſtance it is attracted back, and if it is removed nearer it is repelled back. The ſecond are called *limits of non-coheſion;*

(A) If a particle of matter is not extended, in what reſpect does it differ from a point of ſpace? Says Boſcovich, it is endowed with attractive and repulſive forces. What is this *it* before it is thus endowed? Does it *then* differ from a point of ſpace? We can form no notion of any ſuch difference. But a point of ſpace, conſidered as an individual, is diſtinguiſhed from another individual only by its ſituation; it is therefore immoveable, but matter is moveable. Have theſe forces, then, which make matter an object of ſenſe, any ſubſtratum, any thing in which they are inherent as qualities? What are the things which theſe qualities diſtinguiſh from each other as individuals?

coheſion; becauſe a particle removed thence to a greater diſtance is repelled ſtill further, and if removed nearer it is attracted ſtill nearer. Of the firſt kind are E, I, N; of the ſecond are G, L. Likewiſe, when the curve touches the axis, it may either be an attractive part of the curve, or a repulſive part. Theſe limits may be nearer one another, or farther away; and the limits of coheſion may be ſtronger or weaker, according as the forces near them are greater or leſs.

15 ompoſi- on of bo- es.

Boſcovich conſiders minutely the effects of theſe varieties of limits and forces; firſt with regard to two points, then with regard to three and four, demonſtrating the great variety of forces that may ariſe from theſe various combinations, and ſhewing how from ſimple atoms a great variety of bodies may be formed. He particularly proves, that, from the various poſition of the atoms, they may either always repel or always attract other atoms, or do neither. Four atoms may form a pyramid, eight may form a cube, and ſo on, in regular or irregular figures. Particles of the loweſt order may compoſe particles of a ſecond order, theſe of a third, and ſo on. This he exemplifies by a library, in which the letters of the books ſhould be compoſed of ſmall points, placed ſo near one another as that their diſtance could not be perceived without the help of a microſcope. Here the letters will be compoſed of points, the words of letters, and all the variety of books on different ſubjects, and in different languages, would be compoſed of words. In like manner, he ſays, his atoms may compoſe particles, theſe may compoſe others of different orders, of which may be formed various bodies, animal, vegetable, air, fire, water, earth, whole planets, central bodies, the whole univerſe.

16 e ſyſtem plied to count for

But to be more particular, our author proceeds to apply his ſyſtem to mechanics, and demonſtrates, with his uſual accuracy and originality, what regards the centre of gravity, action and reaction, the colliſion of bodies, the centre of equilibrium, and of oſcillation. Of theſe ſubjects he treats in the ſecond part of his *Theoria;* to which we muſt refer our learned readers, as it cannot be eaſily abridged.

17 penetra- ity,

In the third part of the ſame work he proceeds to account for the general properties of matter, beginning with *impenetrability*. This naturally flows from the interior repulſive forces, which prevent the compenetration of any two points. Beſides, as the leaſt part of ſpace is diviſible *in infinitum*, it is infinitely improbable that any two points ſhould ever meet, ſeeing they have an infinite number of other lines in which they can move, beſides the one that would join them. But an apparent compenetration might take place, if one body ſhould meet another with ſo great a velocity as not to give time to the repulſive forces to exert their action. Thus an iron ball may paſs ſwiftly near a ſtrong magnet, without being ſenſibly attracted by it, which it would be if it moved more ſlowly. Thus a ball from a gun paſſes through a piece of wood ſo quickly as to make only a paſſage for itſelf, without breaking the neighbouring parts, which it would do were its motion more ſlow. Of this kind of compenetration we have a reſemblance in *light* paſſing through pellucid bodies.

18 eſion,

Coheſion has never been well accounted for by any philoſopher before Boſcovich. From his ſyſtem it follows naturally, as we have ſeen in ſpeaking of the limits of coheſion; for when two atoms are placed in a limit of that kind, they neceſſarily cohere more or leſs ſtrongly, according as that limit is ſtronger or weaker. From the coheſion of the atoms ariſes the coheſion of compounded particles, and conſequently of ſenſible bodies.

19 Extenſion,

From the coheſion of particles ariſes the extenſion of bodies; becauſe there muſt always be ſpace between the particles. However, it is evident that this extenſion is not formed of a continuity of matter; though it may appear to be ſo to our ſenſes, which cannot perceive the ſmall intermediate diſtance between the parts of ſome bodies, and much leſs the diſtances between the ſimple elements of which they are compoſed.

20 Figure,

Extenſion of bodies involves *figurability;* becauſe every extended body muſt be ſurrounded by ſome ſuperficies of a certain figure; but the ſuperficies of bodies can never be accurately determined, upon account of the inequalities in all ſurfaces. We take, however, that figure for the true one which the body appears to come neareſt. Thus we call the earth a globe, notwithſtanding the hills and valleys that are on it.

Under the ſame figure, and of the ſame magnitude, there may be contained very different quantities of matter. Hence we come to the conſideration of *denſity*. That body is moſt denſe which contains in the ſame ſpace the greateſt number of atoms, and *vice verſa*.

21 Denſity,

This denſity may be increaſed beyond any given limits by the nearer approach of the atoms to one another. Hence a body of any given magnitude, however ſmall, may come to be diviſible beyond any given limits.

22 Mobility,

Mobility, which is likewiſe reckoned among the general properties of body, is eſſential to our ſyſtem, ſeeing an eſſential part of it conſiſts in *forces*, which are determinations to motion, at leaſt in certain diſtances.

23 Gravity,

Univerſal gravity in ſenſible diſtances is likewiſe a branch of our theory. On which ſubject it may be obſerved, that perhaps our curve, after it has extended beyond the ſphere of the comets moſt diſtant from the ſun, may depart from its aſymptotical nature, and approach to the axis, interſect it, and paſs to repulſion. This would effectually anſwer the objection made by ſome againſt Newton's attraction, when they allege, that, from his opinion, it would follow, that the fixed ſtars, and all matter, would be drawn together into one maſs. If ſuch a repulſion takes place, it may ſoon paſs again into attraction, and form limits of coheſion; ſo that our ſun may be in ſuch a limit with regard to the fixed ſtars, and our planetary ſyſtem make only a ſmall part of the whole univerſe. And this may ſuffice concerning the general properties of matter.

24 Fluidity,

Let us now deſcend to ſome particular claſſes of bodies, of which ſome are fluid, others ſolid. The parts of fluid bodies are eaſily ſeparated, and eaſily moved round one another, becauſe they are ſpherical and very homogeneous; and hence their forces are directed more to their centres than to one another, and their motions through one another are leſs obſtructed. Between the particles of ſome of them there is very little attraction, as in fine ſand or ſmall grains of ſeed, which approach much to fluidity. The particles of ſome others of them attract one another ſenſibly, as do thoſe of water, and ſtill more thoſe of mercury. This variety ariſes from the various combinations of the particles themſelves, of which we have already taken notice. But in air the particles repel one another very ſtrongly; and hence comes that great rarefaction, when it is not compreſſed by an external force. Its particles muſt be placed in ample limits of repulſion.

25 Solidity, Solid bodies are formed of parallelopipeds, fibres, and of irregular figures. This occaſions a greater coheſion than in fluids, and prevents the motion of the parts round one another; ſo that when one part is moved all the reſt follow. Of theſe bodies ſome are harder, whoſe particles are placed in limits which have ſtrong repulſive arches within them; others are ſofter, whoſe particles have thoſe arches of repulſion weaker. **26 Softneſs, flexibility, and elaſticity.** Some are flexible, the particles of which are placed in limits that have weak arches of repulſion and attraction on each ſide; and if thoſe arches are ſhort, the particles may come to new limits of coheſion, and remain bent: but if the arches are longer, the former repulſion and attraction will continue to act, and bring back the body to its former poſition; nay, in doing this with an accelerated velocity, the parts will paſs their former limits, and vibrate backwards and forwards, as may be ſeen in a bended ſpring. Thus elaſticity is accounted for.

27 Viſcoſity. Viſcous bodies ſtand in the middle between ſolid and fluid. Their particles have leſs coheſion than the firſt, and more than the ſecond: they ſtick to other bodies by an attraction which their particles have from their compoſition. In like manner water itſelf ſticks to ſome bodies, and is repelled by others. All which ariſes from the different compoſition of the particles, which gives a variety of reſpective forces.

28 Organization. What appears very wonderful in nature, is the compoſition of organic bodies. But if we conſider that particles may be ſo formed, that they may repel ſome and attract others, the whole of vegetation, nutrition, and ſecretion, may be underſtood, and follows from our ſyſtem. And as one particle may attract another in one part only, and repel it in every other ſituation, hence may be gathered the orderly ſituation of the particles in many cryſtallizations. The great variety of repulſive and attractive forces, or limits of coheſion, of the poſition of atoms, and of combinations of particles, will account for all theſe phenomena.

29 Chemical operations. The chemical operations, which are ſo curious in themſelves, and ſo uſeful to ſociety, are well explained by Boſcovich's ſyſtem, and ſerve as a confirmation of its truth. Of this we ſhall give ſome inſtances. When ſome ſolids are thrown into ſome liquids, there happens to be a greater attraction between the particles of the ſolid and of the liquid than there is between the particles of the ſolid itſelf. Hence the particles of the ſolid are detached and ſurrounded by the fluid; this mixture retaining the form of globules, and therefore continuing to be fluid. This is called *ſolution*. But when the ſolid particles are covered to a certain depth, the attractive forces ceaſe on account of the different diſtances, and no more of the ſolid is detached. Then the fluid is ſaid to be *ſaturated*. If into this mixture another ſolid be put, the particles of which attract the fluid more ſtrongly, and perhaps at greater diſtances than the particles of the former; then the fluid will abandon the former and cleave to the latter, diſſolving them, and the particles of the former will fall to the bottom in the form of powder, into which they had been reduced by the ſolution. This ſeparation is called *precipitation*. Perhaps rain ariſes from a precipitation of this kind, when the aqueous particles are left by the air, which is more ſtrongly attracted by ſome other particles floating in the atmoſphere.

Fluids of the ſame ſpecific gravity are eaſily mixed; and even though the ſpecific gravity be different, the particles of the one attract thoſe of the other, in ſuch a manner that they ſeem to form one fluid by a kind of ſolution. Nay, it happens that two fluids mixed together form a ſolid, becauſe their particles come to be in the limits of coheſion. They may even occupy leſs ſpace than they did before, by being attracted into leſs diſtances between their parts.

Fermentation is a neceſſary conſequence of our ſyſtem. For when bodies, whoſe particles, by the variety of their compoſition, are endued with different forces, come to be mixed, there muſt ariſe an agitation of the parts, and an oſcillation among them; ſometimes greater, ſometimes leſs, according to the nature of the particles. This agitation is ſtopped by the expulſion of ſome particles, by the intruſion of others into vacant ſpaces, and by the impreſſion of external bodies; but always there is a change in what remains, becauſe there is a new diſpoſition of particles.

30 Fire and fuſion, &c. Fire conſiſts in a violent fermentation of ſulphureous matter, eſpecially when it meets with the matter of light in any quantity. This fermentation agitates ſtrongly the parts of other bodies, ſeparates them from one another, and often throws them into a ſtate of fuſion; the coheſion between their parts being broken, and they being thrown into a circular motion. In this ſtate they may be often mixed together, ſo as to form one body; they may be again ſeparated by the action of the ſame fire, which evaporates ſome of them ſooner, ſome later. Hence the art of ſmelting metals.

When, in the agitation occaſioned by fire, ſome of the particles are thrown out into an arch of repulſion, they may fly off and evaporate. Sometimes the whole body may be thrown into a ſtrong repulſion and volatilization, or a ſudden exploſion take place; when, before the particles are near an equilibrium, a ſmall force may occaſion a great change; as the foot of a bird may occaſion the fall of a great rock, which was before almoſt detached from a mountain. In evaporation, the bodies that remain aſſume a particular figure, as all ſalts do; and this upon account of their particles having certain parts only that attract one another, and conſequently occaſion a particular diſpoſition. All theſe chemical operations evidently prove that there are in nature repulſive and attractive forces between the particles of bodies at ſmall diſtances: which greatly confirms our whole ſyſtem.

31 Light. Boſcovich holds, that light is an *effluvium*, emitted with great velocity from the luminous bodies by a ſtrong repulſion. He explains all the moſt remarkable properties of this extroardinary matter according to his own principles, and that with great acuteneſs. On this ſubject it is obſervable, that Newton ſaw the neceſſity of admitting repulſive forces for the reflexion of light, which extend at ſome diſtance from the reflecting ſurface, and therefore reſemble the repulſive forces of our theory.

32 Electrici and mag netiſm. Our author gives likewiſe a probable explication of electricity, according to Franklin's ingenious hypotheſis, and likewiſe of magnetiſm, deducing the whole of the appearances from various attractions and repulſions.

He ſuppoſes that fire and the electrical fluid differ only in this, that fire is in actual fermentation, and not ſo the electrical fluid.

33 enſation.

Finally, he explains our bodily ſenſations, in which he agrees pretty much with other philoſophers; excepting in this, that what they attribute to the immediate contact of bodies, or of certain particles emitted from them, he aſcribes to attractions and repulſions; which indeed are particularly fit for cauſing that motion in our nerves, which is ſuppoſed to take place in the organs of ſenſation, and to be thence communicated to the brain.

It is to be obſerved, that although Boſcovich maintains that the very firſt elements of matter are void of extenſion; yet he allows, that of theſe elements, combined in a certain manner, may be formed extended particles of various figures, the parts of which may be ſo coherent as to be inſeparable by any power in nature. By theſe means the opinion of thoſe philoſophers, who are ſo fond of extended particles, may be in ſo far gratified. Nay, the Peripatetics may, if they pleaſe, adopt Boſcovich's inextended atoms for their *Materia Prima* without any inconſiſtency; and his repulſive and attractive forces may ſerve for their *ſubſtantial forms*. And as God can make impreſſions on our ſenſes independently of the atoms, their abſolute accidents may in ſome ſenſe be admitted. Nor would ſome ſuch extraordinary exertions of Divine Power favour idealiſm in the ordinary courſe of nature.

34 econciliaon of this ith other ſtems,

But what is of more conſequence, it is more than probable, that had Newton lived to be acquainted with the Boſcovichian theory, he would have paid to it a very great regard. This we may conjecture from what he ſays in his laſt queſtion of optics; where, after having mentioned thoſe things which might be explained by an attractive force, ſucceeded by a repulſive one on a change of the diſtances, he adds, "And if all theſe things are ſo, then all nature will be very ſimple, and conſiſtent with itſelf, effecting all the great motions of the heavenly bodies by the attraction of gravity, which is mutual between all thoſe bodies, and almoſt all the leſs motions of its particles by another certain attractive and repulſive force, which is mutual between thoſe particles." And a little after, treating of the elementary particles, he ſays: "Now it ſeems that theſe elementary particles not only have in themſelves the *vis inertiæ*, and thoſe paſſive laws of motion which neceſſarily ariſe from that force, but that they likewiſe perpetually receive a motion from certain active principles; ſuch as gravity, and the cauſe of fermentation, and of the coheſion of bodies. And I conſider theſe principles, not as occult qualities, which are feigned to flow from the ſpecific forms of things, but as univerſal laws of nature, by which the things themſelves were formed. For that truly ſuch principles exiſt, the phenomena of nature ſhew, although what may be their cauſes has not as yet been explained. To affirm that every ſpecies of things is endued with ſpecific occult qualities, by which they have a certain power, is indeed to ſay nothing; but to deduce two or three general principles of motion from the phenomena of nature, and then to explain how the properties and action of all corporeal things follow from thoſe principles, this truly would be to have made a great advancement in philoſophy, although the cauſes of thoſe principles were not as yet known. Wherefore I do not heſitate to maintain the above ſaid principles of motion, ſeeing they extend widely through all nature." From this paſſage we may ſafely conclude, that the great Britiſh philoſopher would have been highly pleaſed, had he ſeen all nature ſo well explained by the one ſimple law of forces propoſed by the Raguſan.

35 ſpecially hat of ewton.

36 Compariſon of this ſyſtem to the key of a cypher.

Boſcovich himſelf was ſo fully convinced of the truth of his ſyſtem, that he was wont to make uſe of the following compariſon: When a letter has been written in occult characters, and we are endeavouring to decypher it, we make various ſuppoſitions of alphabets; and when we have found one according to which the whole letter comes to have a reaſonable meaning, agreeable to all the circumſtances of time, place, perſons, and things, we can entertain no doubt of our having diſcovered the true key of the cypher—ſo, ſaid he, my ſyſtem explains ſo well all the phenomena to which it has been properly applied, that I muſt flatter myſelf that I have diſcovered the true key of nature.

37 Exiſtence of God.

The being accuſtomed to contemplate ſo deeply the univerſe and the materials of which it is compoſed, made Boſcovich ſee moſt clearly the evident neceſſity of admitting an all-powerful, intelligent, ſelf-exiſtent Being, for the creation of thoſe materials, and for the arrangement of them into their preſent beautiful form. He was at a loſs to find words ſtrong enough to expreſs his ſurpriſe, that there ſhould be any man, not to ſay any one pretending to the name of philoſopher, who could be ſo deaf as not to hear the voice of nature loudly proclaiming its Author from all, even the leaſt of its parts. He gives us his ſentiments on this, the moſt important of all ſubjects, in the appendix to his *Theoria*, in which he treats of God and of the ſoul of man.

38 The world cannot be the effect of chance;

There, in the firſt place, he ſhows the abſurdity of their opinion, who maintain that this world may have been the work of *chance*, the effect of a jumble of ſelf-exiſtent, ſelf-moving atoms; becauſe chance is an empty word without a real meaning. Whatever exiſts has its determinate cauſe, and can only be called *fortuitous* by us on account of our ignorance of that cauſe. Beſides this, though the number of atoms compoſing this world is finite, yet their poſſible combinations are many times *infinitely infinite*: for they may be placed in infinite places of an infinite line; of theſe lines there is an infinite number in every *plane*, and of theſe planes there is an infinite number in ſpace. Again, theſe points may have an infinite number of velocities in an infinite number of directions. From all this it is evident, that the combinations in which the points of matter may be, is infinite in a high degree, whereas *duration* can be infinite in only one dimenſion. Hence it is infinitely improbable that ever the preſent combination of things could come out by chance. And this is ſo much the more infinitely improbable, becanſe the diſorderly, chaotic combinations are infinitely more than the regular ones. The whole of matter might roll about in a blind motion for a boundleſs eternity, without ever being capable to produce one ſingle muſhroom.

Moreover, had matter been in motion from all eternity, every atom would have deſcribed an infinite line, and then a part of that line would be aſſignable at an infinite diſtance from the point of ſpace in which the atom is at preſent; but an infinite line can never be run over; therefore the atom could never have come to its preſent place; and therefore the ſuppoſition is abſurd. Nothing ſucceſſive can be eternal with a *paſt* eternity, though it can continue without end. God alone can be eternal and actually infinite; but his eternity and infinity are beyond our comprehenſion.

39 Nor have exiſted from eternity.

Neither can the world have exiſted of itſelf in any thing like to its preſent form from all eternity; for matter is perfectly indifferent to numberleſs ſtates, and to its preſent ſtate it muſt be determined. This preſent ſtate is perfectly incapable of determining itſelf, becauſe this determination muſt be previous to its exiſtence. It muſt be determined by the preceding ſtate, which is alſo incapable of determining itſelf, and for its determination we muſt have recourſe to the ſtate before. Thus, though we go back to eternity, we ſhall ſtill find a nullity of determination; now an infinite ſum of *nothing* is *nothing:* and therefore as the preſent ſtate of things could have no determination, it could not poſſibly exiſt.

It is therefore evident that there muſt be a Determiner extrinſic to the material word. This Determiner muſt have an infinite knowledge of all the poſſible combinations, and an infinite elective creative power to chuſe and create freely the combination he pleaſed, in that point of eternity that he choſe, with all the numberleſs circumſtances that are agreeable to him.

40 Attributes of God which appear in the creation.

And here what a vaſt field of contemplation is laid open to a philoſophic mind! What a truly infinite knowledge was requiſite to foreſee ſo many ends, and ſo many means requiſite for obtaining thoſe ends, as are contained in the creation! Let us conſider light, for example, which was to be emitted for ſo many ages from ſo many luminous bodies, with ſo great velocity, ſo as to penetrate ſo many mediums with different degrees of reflectibility and refrangibility, with ſo many other wonderful qualities; at the ſame time, ſo many bodies were to be perfectly fitted for reflecting this light in a certain manner, and the animal eye was to be ſo formed as to have a picture of viſible objects painted on the bottom of it. – How many particular combinations were neceſſary for all this? What ſhall we ſay of the ſo many herbs, flowers, trees, and animal bodies, as there are on this our earth? All their kinds and ſpecies, all the ſeries of their individuals, all their parts and particles, were foreſeen, intended, and contrived, by one act of the Divine Mind. Again, how wonderful are the heavenly bodies, of what ſurpriſing magnitude, moving in the moſt beautiful order, at an immenſe diſtance from one another? To ſay nothing of the numberleſs creatures that are beyond the reach of the beſt teleſcope, or below that of the microſcope. He who reflects ever ſo little on theſe things, muſt neceſſarily ſee the moſt evident proofs of an infinite power, wiſdom, and providence; and he muſt be filled with admiration and awful reſpect for the Creator and Ruler of the univerſe.

41 Natural religion.

Nor are we unconcerned ſpectators of this grand ſcene. God has been pleaſed to make us enter deeply into his great plan of creation. He ſingled us out among an infinite number of poſſible human beings, in order to call us into exiſtence at a fixed period; and he has made a vaſt number of his creatures contribute to the formation of theſe wonderful machines, our bodies, as likewiſe to our nouriſhment, to our preſervation, to our neceſſities, conveniences, and gratifications. Every moment that we exiſt, we are enjoying a great number of benefits, expreſsly deſigned for us by that Supreme Being. This evidently demands from us the higheſt degree of gratitude, love, and obedience.

42 Revelation.

Let us go a ſtep ſtill farther: Is it not very reaſonable to ſuppoſe, that our God, who affords us ſo many inſtances of his beneficence towards us in the natural order, will alſo, out of compaſſion to our weakneſs and ignorance, have favoured us with a more full and explicit manifeſtation of himſelf, of our duties towards him, and of his intentions concerning us? According to Boſcovich and all true philoſophers, reaſon itſelf alone, and true philoſophy, point out to us the probability at leaſt of God's having given us a ſtill better and ſurer guide, by whoſe direction we may attain to that perfect happineſs which we naturally thirſt after, and to which we muſt have been deſigned by our Maker. This is probable from reaſon alone; and of this great fact we are aſcertained by unqueſtionable authority.

BOSHMEN have been generally deſcribed as a diſtinct race of Hottentots, who are enemies to the paſtoral life (ſee *Boshies-Men*, Encycl.) This M. Vaillant affirms to be a miſtake; and we think he has completely proved that it is ſo. "Theſe infamous wretches (ſays he) do not form a particular nation, nor are they a people who have had their origin in the places where they are now found. *Boſhmen* is a name compoſed of two Dutch words, which ſignify *buſh-men*, or *men of the woods*; and it is under this appellation that the inhabitants of the Cape, and all the Dutch in general, whether in Africa or America, diſtinguiſh thoſe malefactors or aſſaſſins who deſert from the colonies, in order to eſcape puniſhment. In a word, they are what in the Britiſh and French Weſt India iſlands are called *Maroon Negroes*. Theſe Boſhmen, therefore, far from being a diſtinct ſpecies, are only a promiſcuous aſſemblage of mulattoes, negroes, and maſtizos, of every ſpecies, and ſometimes of Hottentots and baſters (ſee BASTER, *Supplement*), who all differing in colour, reſemble each other in nothing but in villany. They are land pirates, who live without laws and without diſcipline, abandoned to the utmoſt miſery and deſpair; baſe deſerters, who have no other reſources but plundering and crimes. They retire to the ſteepeſt rocks and the moſt inacceſſible caverns, and there they paſs their lives. From theſe elevated places they command an extenſive proſpect over the ſurrounding plains, lie in wait for the unwary traveller and the ſcattered flocks, pour down upon them with the velocity of an arrow, and ſuddenly falling upon the inhabitants and their cattle, ſlaughter them without diſtinction. Loaded with booty, and whatever they can carry with them, they then repair to their gloomy caves, which they never quit till, like the lions, hunger again impels them to freſh maſſacres. But as treachery always marches with a trembling ſtep, and as the preſence of one reſolute perſon is ſufficient to overawe whole troops of theſe banditti, they carefully ſhun thoſe plantations where they are certain that the owners themſelves reſide. Artifice and cunning, the uſual reſources of timid ſouls, are the only means which they employ, and the only guides that accompany them in their expeditions."—*Vaillant's Travels into the Interior Parts of Africa* (A).

(A) Since this article was firſt publiſhed, a different account has been given of the *Boſhmen* or BOJESMANS by Mr

Boſwell.

BOSWELL (James), known to the learned world as the author of a life of Dr Johnſon and of ſeveral other valuable works, was born, we believe, at Auchinleck in Airſhire, in 1740. The family from which he ſprung was ancient and honourable. At the time of his birth his father was a well employed lawyer at the Scotch bar; but was afterwards raiſed to the dignity of Judge, and filled that important ſtation with acknowledged learning, probity, and honour. His title was Lord Auchinleck, taken from his family inheritance; and he died in 1782: on which occaſion Dr Johnſon wrote an elegant and inſtructive letter to the ſubject of this brief memorial; of which we ſhall tranſcribe a paſſage that alludes to ſome ſlight domeſtic differences, which did not happen in vain, ſince they gave riſe to ſuch ſalutary advice:

"Your father's death had every circumſtance that could enable you to bear it. It was at a mature age, and it was expected; and as his general life had been pious, his thoughts had, doubtleſs, for many years paſt, been turned upon eternity. That you did not find him ſenſible muſt doubtleſs grieve you; his diſpoſition towards you was undoubtedly that of a kind, though not of a fond father. Kindneſs, at leaſt actual, is in our own power, but fondneſs is not; and if, by negligence or imprudence, you had extinguiſhed his fondneſs, he could not at will rekindle it. Nothing then remained between you but mutual forgiveneſs of each other's faults, and mutual deſire of each other's happineſs."

The occaſion of this family diſſention is unknown to us. It might originate in the difference of their political principles, Mr Boſwell being a zealous Tory, and his father, as he repreſents him, a rancorous Whig; or it may have ariſen from the celebrated Douglas cauſe, which ſet many friends at variance in Scotland, and in which, though Lord Auchinleck and his ſon took the ſame ſide, they took it with very different degrees of ardour. The Judge ſaw not the propriety of illuminating his windows when the cauſe was finally decided by the Houſe of Peers; and to compel him to illuminate, the advocate got poſſeſſion of a Chineſe *gong*, and at the head of a number of young men and boys patrolled the ſtreets of Edinburgh, and made a loud and exulting noiſe at the windows of his father's houſe, where there was no ſymptom diſplayed of the general joy.

In 1762 Mr Boſwell made his firſt journey to London; where, under the auſpices of Dodſley the bookſeller, he publiſhed, "The Cub at Newmarket, a Tale." By the title of *Cub* he meant to characteriſe himſelf, as the reader will perceive in the following lines, which we ſhall give as a ſpecimen of the poem:

Lord Eglintoune, who loves, you know,
A little daſh of whim, or ſo,
By chance a curious Cub had got,
On Scotia's mountains newly caught.

During his ſtay in London Mr Boſwell was introduced to Dr Johnſon, with whom it is well known he continued to live in intimacy from that time till Johnſon's death in 1784; and this intimacy procured him the friendſhip of Burke, Goldſmith, Sir Joſhua Reynolds, and many other men of eminence, who compoſed what was called *The Literary Club*. In the latter end of 1765 he became acquainted with General Paoli when on his travels; and after his return he publiſhed, in 1768 or 1769, his account of Corſica, with the "Journal of a Tour to that Iſland."

Of this work, which gained him ſome diſtinction in the world, his great friend Johnſon writes thus: "Your hiſtory is like all other hiſtories, but your journal is in a very high degree curious and delightful. There is between the hiſtory and the journal that difference which there will always be found between notions borrowed from without and notions generated within. Your hiſtory was copied from books; your journal roſe out of your own experience and obſervation. You expreſs images which operated ſtrongly upon yourſelf, and you have impreſſed them with great force upon your readers. I know not whether I could name any narrative by which curioſity is better excited or better gratified."

In 1770 Mr Boſwell, who was then in good practice at the Scotch bar, married an amiable woman, by whom he had two ſons and three daughters, who ſurvived him. In 1773 he was choſen a member of the LITERARY CLUB; and in the autumn of the ſame year he viſited the Hebrides in company with his illuſtrious friend Johnſon; after whoſe death he publiſhed a very entertaining account of their tour, the places they ſaw, the characters with whom they converſed, and their own remarks on the different converſations. To many perſons, both in England and Scotland, this book gave great offence, as it brought before the public the unguarded talk of private ſocial circles; but it ſurely furniſhed much entertainment, as it exhibited a more faithful picture of Hebridian manners than the Britiſh public had ever before ſeen.

In 1784, when Mr Fox's famous India bill was before Parliament, Mr Boſwell publiſhed a "Letter to the People of Scotland on the Preſent State of the Nation;" in which he contends, that no charter would be ſafe if that bill ſhould paſs into a law; and more than inſinuates, that the principle of it was equally inimical to the liberties of the ſubject and to the prerogative of the king. Dr Johnſon ſeems to have thought of that bill as he did; for having read the letter, he writes to the author his approbation of it in the following words: "I am very much of your opinion; and, like you, feel great indignation at the indecency with which the king is every day treated. Your paper contains very conſiderable knowledge of the hiſtory and of the conſtitution, very properly produced and applied."

In 1785, Mr Boſwell quitted the Scotch bar, and went to reſide in London, where he continued till the day of his death. Having entered himſelf in one of the inns of court, and ſtudied the Engliſh law, he became a barriſter in England: but we have reaſon to believe that

---

Mr Barrow, who travelled into the interior of Southern Africa in 1797 and 1798. According to him, they are a diſtinct race, extremely ſavage, who neither cultivate the ground nor breed cattle, but ſubſiſt in part on the natural produce of their country, and ſupply its deficiency by depredations on the coloniſts on one ſide, and the neighbouring tribes of people that are more civilized than themſelves, on the other.

that his practice there was not ſo ſucceſsful as it had been in his own country. He enjoyed, however, more completely than he could do in Edinburgh, the converſation of the great, the wiſe, the witty, and the good; and ſuch converſation he always valued above wealth. He frequently viſited his native country, and eſpecially Auchinleck, the ſeat of his anceſtors; and ſoon after his return from one of thoſe viſits he was ſeized with a diſorder which proved fatal, on Tueſday the 19th of May 1795.

Such were the principal events in the life of Mr Boſwell. Of his character, it would be difficult to ſay *much more* than he has ſaid himſelf in his "Journal of a Tour to the Hebrides;" and which may, with ſome propriety, be copied here:

"I have given a ſketch of Dr Johnſon. My readers may wiſh to know a little of his fellow-traveller. Think, then, of a gentleman of ancient blood; the pride of which was his predominant paſſion. He was then in his 33d year, and had been about four years happily married. His inclination was to be a ſoldier; but his father, a reſpectable Judge, had preſſed him into the profeſſion of the law. He had travelled a good deal, and ſeen many varieties of human life. He had thought more than any body ſuppoſed, and had a pretty good ſtock of general learning and knowledge. He had all Dr Johnſon's principles, with ſome degree of relaxation. He had rather too little than too much prudence; and his imagination being lively, he often ſaid things of which the effect was very different from the intention. He reſembled ſometimes

'The beſt good man, with the worſt-natur'd muſe.'

"He cannot deny himſelf the vanity of finiſhing with the encomium of Dr Johnſon, whoſe friendly partiality to the companion of this tour, repreſents him as one 'whoſe acuteneſs would help my inquiry, and whoſe gaiety of converſation, and civility of manners, are ſufficient to counteract the inconveniences of travel, in countries leſs hoſpitable than we have paſſed.'

Few of Mr Boſwell's friends, we believe, could add much to this candid confeſſion. His enemies, if he had any, might dwell upon his failings; but his failings were few, and injurious to no perſon. In his character good nature was predominant. He appeared to entertain ſentiments of benevolence to all mankind, and to be incapable of *intentionally* injuring a human being. His converſation talents were always pleaſing, and often faſcinating. But can we wonder at this in him who, with a capacity to learn, had been the companion of Johnſon for more than 20 years? His attachment to the Doctor for ſo long a period, was a meritorious perſeverance in the deſire of knowledge. To it the world is indebted for the moſt finiſhed picture of an eminent man that ever was executed. We know there are objections to the *mode* of giving the life of Johnſon. It has been thought that ignorance has been wantonly expoſed, and the privacy of ſocial life endangered. We ſhall not enter deeply into this queſtion. All that we can certainly affirm is, that the work has been read with avidity and pleaſure; and that he who does not wiſh to read it again may be ſuſpected to be deficient in taſte and in temper.

Mr Boſwell has been accuſed of vanity; but when this accuſation is brought againſt him, it ſhould not be forgotten that he enjoyed advantages which rendered that conſpicuous in him from which no man can claim an exemption. We know not the man who would not have been vain to poſſeſs ſo much of Dr Johnſon's converſation, and proud to give it to the world, in hopes that he who venerated Johnſon would not be unthankful to his biographer. From the Doctor, however, he appeared to his friends to have imbibed a portion of melancholy, of which indeed he complained himſelf during the laſt two or three years of his life; and he flew for relief where perhaps it is beſt to be found, to the ſociety of the learned and the gay. Here, as he confeſſes, he "had rather *too little* than too much *prudence*;" and, with more attachment to the activity of rural life, he might, probably, have lengthened his days. But as his "belief in revelation was unſhaken," and his religious impreſſions deep, and recurring frequently, let us hope that he has now attained that ſtate from which imperfection and calamity are alike excluded.

BOTANY-BAY. See *New Holland*, Encycl.; and *New South Wales* in this Supplement.

BOUGUER (Peter), an eminent mathematician and mechanical philoſopher, was born at Croiſic, in Lower Bretagne, on the 10th of February 1698. His father John Bouguer, who was likewiſe a conſiderable mathematician, was then profeſſor royal of hydrography at that port; and under him young Bouguer ſtudied mathematics, and the application of them to ſhip-building, almoſt from the period when he began to ſpeak; ſo that he was a proficient in theſe ſciences before he had reached beyond the years of childhood. He was, however, removed from Croiſic to the Jeſuits college at Vannes, where, at 13 years of age, he triumphed, in a public conteſt, over a profeſſor of mathematics, who had advanced a mathematical propoſition erroneouſly. Two years after this he loſt his father, whom he was appointed to ſucceed in the office of hydrographer, after being publicly examined, and giving the moſt complete proof of his being duly qualified to fill the vacant chair. He was indeed qualified by prudence as well as by ſcience; for however ſurpriſing it may be, he filled it both with dignity and with abilities, though then not more than 15 years of age.

In the years 1727, 1729, and 1731, he gained the prizes ſucceſſively propoſed by the Academy of Sciences for eſſays on the beſt way of equipping ſhips with maſts, on the beſt method of obſerving at ſea the height of the ſtars, and on the moſt advantageous way of obſerving the declination of the magnetic needle or the variation of the compaſs. In 1729 he publiſhed an *Optical Eſſay upon the Gradation of Light*, in which he examined the intenſity of light, and determined its degrees of diminution in paſſing through different pellucid mediums, and particularly in traverſing the earth's atmoſphere. Of this eſſay, which was written upon a ſubject that till then had not attracted the attention of philoſophers, the reader will find ſome account in the *Encyclopædia Britannica*, under the title OPTICS, n° 32, &c.

In 1730 Bouguer was removed from the port of Croiſic to that of Havre. In 1731 he obtained, in the Academy of Sciences, the place of aſſociate geometrician, vacant by the promotion of Maupertuis to that of penſioner; and in 1735 he was promoted to the office of penſioner-aſtronomer. The ſame year he was ſent on the commiſſion to South America, along with Meſſrs Godin,

Godin, Condamine, and Jeuſſieu, to determine the meaſure of the degrees of the meridian, and the figure of the earth. In this painful and troubleſome buſineſs of ten years duration, chiefly among the lofty Cordelier mountains, our author, beſides attending to the object of the voyage, made many ſcientific obſervations; viz. on the effect of the Cordeliers on the polarity of the magnetic needle; on the expanſion and contraction of metals and other ſubſtances, by the ſudden and alternate changes of heat and cold among thoſe mountains; and on the refraction of the atmoſphere from the tops of the ſame, with the ſingular phenomenon of the ſudden increaſe of the refraction, when the ſtar can be obſerved below the line of the level. He likewiſe aſcertained the laws of the denſity of the air at different heights, from obſervations made at different points of thoſe enormous mountains; he diſcovered that the mountains have an effect upon a plummet, though he did not aſſign the quantity of that effect; he found out a method of eſtimating the errors committed by navigators in determining their route; gave a new conſtruction of the log for meaſuring a ſhip's way; and made ſeveral other uſeful improvements. M. Bouguer made at different times ſome important experiments on the famous reciprocation of the pendulum; he invented in 1747 the HELIOMETER (ſee that article *Encycl.*); and made many diſcoveries relating to the intenſity of light (for which ſee OPTICS-*Index*, Encycl.) His unremitting application to ſtudy undermined his health, and he died on the 15th of Auguſt 1758, in the 61ſt year of his age.

Of his works which have been publiſhed, the chief are, 1. The Figure of the Earth, determined by the Obſervations made in South America, 1749, in 4to. 2. Treatiſe on Navigation and Pilotage, Paris, 1752, in 4to. This work has been abridged by M. La Caille, in one volume 8vo, 1768. 3. Treatiſe on Ships, their Conſtruction and Motions, in 4to, 1756. 4. Optical Treatiſe on the Gradation of Light, firſt in 1729, then a new edition in 1760, in 4to.

His papers that were inſerted in the Memoirs of the Academy are very numerous and important: as, in the Memoirs for 1726, compariſon of the force of the ſolar and lunar light with that of candles; 1731, obſervations on the curvilinear motion of bodies in mediums; 1732, upon the new curves called the *lines of purſuit*; 1733, to determine the ſpecies of conoid, to be conſtructed upon a given baſe which is expoſed to the ſhock of a fluid, ſo that the impulſe may be the leaſt poſſible; determination of the orbit of comets; 1734, compariſon of the two laws which the earth and the other planets muſt obſerve in the figure which gravity cauſes them to take; on the curve lines proper to form the arches in domes; 1735, obſervations on the equinoxes; on the length of the pendulum; 1736, on the length of the pendulum in the torrid zone; on the manner of determining the figure of the earth by the meaſure of the degrees of latitude and longitude; 1739, on the aſtronomical refractions in the torrid zone; obſervations on the lunar eclipſe of the 8th September 1737, made at Quito; 1744, ſhort account of the voyage to Peru by the members of the Royal Academy of Sciences, to meaſure the degrees of the meridian near the equator, and from thence to determine the figure of the earth; 1745, experiments made at Quito and divers other places in the torrid zone, on the expanſion and contraction of metals by heat and cold; on the problem of the maſting of ſhips; 1746, treatiſe on ſhips, their ſtructure and motions; on the impulſe of fluids upon the fore parts of pyramidoids, having their baſe a trapezium; continuation of the ſhort account given in 1744 of the voyage to Peru for meaſuring the earth; 1747, on a new conſtruction of the log, and other inſtruments for meaſuring the run of a ſhip; 1748, of the diameters of the larger planets; the new inſtrument called a *heliometer*, proper for determining them, with obſervations of the ſun; obſervation of the eclipſe of the moon the 8th of Auguſt 1748; 1749, ſecond memoir on aſtronomical refractions, obſeved in the torrid zone, with remarks on the manner of conſtructing the tables of them; figure of the earth determined by MM. Bouguer and Condamine, with an abridgment of the expedition to Peru; 1750, obſervation of the lunar eclipſe of the 13th December 1750; 1751, on the form of bodies moſt proper to turn about themſelves, when they are puſhed by one of their extremities, or any other point; on the moon's parallax, with the eſtimation of the changes cauſed in the parallaxes by the figure of the earth; obſervation of the lunar eclipſe the 2d of December 1751; 1752, on the operations made by ſeamen, called *corrections*; 1753, obſervation of the paſſage of Mercury over the ſun the 6th of May 1753; on the dilatations of the air in the atmoſphere; new treatiſe of navigation, containing the theory and practice of pilotage, or working of ſhips; 1754, operations, &c. for diſtinguiſhing, among the different determinations of the degree of the meridian near Paris, that which ought to be preferred; on the direction which the ſtring of a plummet takes; ſolution of the chief problems in the working of ſhips; 1755, on the apparent magnitude of objects; ſecond memoir on the chief problems in the working of ſhips; 1757, account of the treatiſe on the working of ſhips; on the means of meaſuring the light.

BREAD is ſo eſſential an article of food that every uſeful method of making it ſhould be generally known. Much has accordingly been ſaid on that ſubject (*Encycl.*) under the titles BAKING, BARM, BREAD, and YEAST: but, ſince the laſt of theſe articles was publiſhed, we have ſeen, in Dr Townſon's *Travels in Hungary*, a method of making bread at Debretzen; of which, as it may ſometimes be adopted with advantage in this country, an account may, with propriety, be inſerted here.

In the baking of this bread, a ſubſtitute is uſed for yeaſt, which is thus made: Two good handfuls of hops are boiled in four quarts of water: this is poured upon as much wheaten bran as can be well moiſtened by it: to this are added four or five pounds of leaven; when this is only warm, the maſs is well worked together to mix the different parts. This maſs is then put in a warm place for 24 hours; and after that, it is divided into ſmall pieces about the ſize of a hen's egg, or a ſmall orange, which are dried by being placed upon a board, and expoſed to a dry air, but not to the ſun; when dry, they are laid by for uſe, and may be kept half a year. This is the ferment; and it may be uſed in the following manner: For a baking of ſix large loaves, ſix good handfuls of theſe balls, broken into fragments, are taken and diſſolved in ſeven or eight quarts of warm water. This is poured through a ſieve into one end of the bread trough, and three quarts more of warm water are poured through the ſieve after it, and what remains in the ſieve is well preſſed out. This liquor is mixed up with ſo much flour as to form a maſs of the ſize of a large loaf: this is ſtrewed over with flour; the ſieve, with its contents, is put upon it, and then the whole is covered up warm, and left till it has riſen enough, and its ſurface has begun to crack: this forms the leaven. Then 15 quarts of warm water, in which ſix handfuls of ſalt have been diſſolved, are poured through the ſieve upon it, and the neceſſary quantity of flour is added, and mixed and kneaded with the leaven: this is covered up warm, and left for about an hour. It is then formed into loaves, which are kept in a warm room half an hour; and after that, they are put in the oven, where they remain two or three hours, according to the ſize. The great advantage of this ferment is, that it may be made in great quantities at a time, and kept for uſe. Might it not on this account be uſeful on board of ſhips, and likewiſe for armies when in the field?

Bread, in whatever way it is made, is a dear article; and it may be a deſirable object to many of our readers to know at what price the baker can afford to ſell it. This depends upon the price of wheat, the quantity of flour which the wheat may give, the loſs at the mill, the expence of grinding, and the expence of baking.

Of the price of wheat we can ſay nothing with preciſion, becauſe it varies according to the goodneſs or badneſs of the crop, and other circumſtances; but a buſhel of Eſſex wheat, Wincheſter meaſure, may be taken, on an average, as weighing 60 lb. Sixty pounds of wheat will yield, excluſive of the loſs in grinding and dreſſing, $45\frac{1}{2}$ lb. of that kind of flour which is called *ſeconds;* which alone is uſed, through the greateſt part of England, for bread, and which makes, indeed, the beſt of all bread, though not the whiteſt. A peck of this flour, weighing 14 lb. will take up between ſix and ſeven pints of water, and give 18 lb. of excellent bread; or a buſhel of flour, weighing 56 lb. will yield 72 lb. of bread. The expence of baking a buſhel of ſuch flour is, in Eſſex and ſome other Engliſh counties, about ninepence; viz. yeaſt, on an average, twopence; ſalt, before the late tax, one halfpenny; and baking, ſixpence.

But *ſeconds* is not all that is got from wheat. A buſhel of 60 lb. of wheat gives, beſides $45\frac{1}{2}$ lb. of ſeconds, 13 lb. of offal, i. e. of *pollards* and *bran;* for the utmoſt loſs in grinding and dreſſing a buſhel of wheat ſhould not exceed 1 pound 8 ounces. The millers, indeed, uſually reckon on two pounds of loſs; but we can ſay, with the utmoſt confidence, that the actual loſs is rather leſs than we have ſtated it. A correſpondent of ours, on whoſe accuracy we can depend, weighed, in 1795, two buſhels, Wincheſter meaſure, the one of white and the other of red wheat, and found the weight of them both to be 122 lb. This wheat was ground by his own ſervants, and it yielded $121\frac{1}{2}$ lb. of meal, ſo that there was here but $\frac{1}{2}$ lb. loſt of two buſhels, or of 122 lb. in grinding. He admits that he ſuffered the ſtones to turn too cloſe, and that the loſs ſhould therefore have been ſomewhat greater. The meal was dreſſed, as the wheat had been ground, under his own eye; and every poſſible precaution being taken to prevent his being deceived in the reſult, he had of flour, or *ſeconds*, $93\frac{1}{2}$ lb. and of bran and pollard $25\frac{1}{2}$ lb.; ſo that he loſt, of two buſhels, but $2\frac{1}{2}$ lb. both in grinding and dreſſing. The offal, or bran and pollard, being dreſſed in a bolting mill, yielded as follows:

Sharps -	6 lb.	0 oz.
Fine pollard	5	8
Coarſe pollard	7	8
Broad bran	5	8
Altogether	24	8

There was loſt, therefore, in bolting, only one pound; and of the ſharps, about three pounds, if ſifted, would have been good flour. Indeed were the ſharps and fine pollard to be added to the flour, the bread would, perhaps, be better, and more wholeſome, than without ſuch addition. From theſe data, which we believe to be very accurate, it will be eaſy to calculate, if the price of wheat be given, what ſhould be the price of flour per buſhel and peck, the price of bread per pound, and the quantity of bread that ſhould be ſold for a ſhilling.

It is a fact, however, which ſhould be attended to, that loaves are not always of the ſame weight, though made of equal quantities of the very ſame dough. This was fully aſcertained ſome years ago at Paris. On a violent complaint that the bread was not always of the ſame ſtandard weight, the bakers of the city were called before the police officers. They admitted the fact, that loaves, baked at the ſame time, and in the ſame oven, were ſeldom, if ever, of the ſame weight; but they inſiſted that they contained, each, the ſtandard quantity of dough, and that the variety of weight among them muſt proceed from ſome cauſe, which they did not pretend to aſcertain. The matter was referred to the Royal Academy of Sciences, which appointed one of its members to ſuperintend, for ſome days, the whole proceſs of baking. This being done, it was found that, of loaves baked in a large oven, thoſe were always heavieſt which occupied the centre of the oven, and that the bakers were innocent of the crime with which they were charged. The fact, we think, may eaſily be accounted for. Even in an oven there muſt be ſome condenſation of ſteam; and, from the very ſhape of the oven, the greateſt quantity muſt be condenſed towards the centre. Hence the loaves in the centre are neceſſarily wetter and heavier than thoſe round the circumference, if the plain of the oven has been equally heated.

BREAD of Rice might occaſionally be of great uſe in many countries during a ſcarcity of wheat; but the method of making it is not generally known. It is indeed impoſſible to make bread of the flour of rice, which is harſh and dry like ſand or aſhes, by treating it in the manner in which wheat-flour is commonly treated; and therefore it has been propoſed to mix it with an equal quantity of the flour of rye. But this method of uſing the flour of rice is a very uncertain remedy in caſe of want; ſince we can have no rice-bread if we have not rye. We are taught, however, in the *Journal des Sciences*, *des Lettres*, *et des Arts*, how to make excellent bread from rice alone, by a method which the author of the memoir ſays he learned from the natives of America.

According to this method of making the wiſhed-for bread, the firſt thing to be done to the rice is, to reduce it to flour, by grinding it in a mill, or, if we have not a mill, it may be done in the following manner:

Let a certain quantity of water be heated in a ſauce-pan or caldron ; when the water is near boiling, let the rice we mean to reduce into flour be thrown into it : the veſſel is then to be taken off the fire, and the rice left to ſoak till the next morning. It will then be found at the bottom of the water, which is to be poured off, and the rice put to drain upon a table placed in an inclined poſition. When it is dry, it muſt be beat to powder, and paſſed through the fineſt ſieve that can be procured.

When we have brought the rice into flour, we muſt take as much of it as may be thought neceſſary, and put it into the kneading trough in which bread is generally made. At the ſame time we muſt heat ſome water in a ſaucepan or other veſſel, and, having thrown into it ſome handfuls of rice, we muſt let them boil together for ſome time : the quantity of rice muſt be ſuch as to render the water very thick and glutinous. When this glutinous matter is a little cooled, it muſt be poured upon the rice-flour, and the whole muſt be well kneaded together, adding thereto a little ſalt, and a proper quantity of leaven. We are then to cover the dough with warm cloths, and to let it ſtand that it may riſe. During the fermentation, this paſte (which, when kneaded, muſt have ſuch a proportion of flour as to render it pretty firm) becomes ſo ſoft and liquid that it ſeems impoſſible it ſhould be formed into bread. It is now to be treated as follows :

While the dough is riſing, the oven muſt be heated ; and, when it is of a proper degree of heat, we muſt take a ſtewpan of tin, or copper tinned, to which is fixed a handle of ſufficient length to reach to the end of the oven. A little water muſt be put into this ſtewpan, which muſt then be filled with the fermented paſte, and covered with cabbage or any other large leaves, or with a ſheet of paper. When this is done, the ſtewpan is to be put into the oven, and puſhed forward to the part where it is intended the bread ſhall be baked; it muſt then be quickly turned upſide down. The heat of the oven acts upon the paſte in ſuch a way as to prevent its ſpreading, and keeps it in the form the ſtewpan has given it.

In this manner pure rice-bread may be made ; it comes out of the oven of a fine yellow colour, like paſtry which has yolk of eggs over it. It is as agreeable to the taſte as to the ſight ; and may be made uſe of, like wheat-bread, to put into broth, &c. It muſt, however, be obſerved, that it loſes its goodneſs very much as it becomes ſtale.

It may be here remarked, that the manner in which Indian corn is uſed in ſome countries, for making bread, can only produce (and does in fact produce) very bad dough, and of courſe very bad bread. To employ it advantageouſly, it ſhould be treated like rice ; and it may then be uſed, not only for making bread, but alſo for paſtry.

BREWING is an art of vaſt importance, and has accordingly been explained in the Encyclopædia Britannica. A few improvements, however, have been made in the art, which, though not noticed in that Work, ſeem to be worthy of general attention, and, therefore, to deſerve a place in this Supplement. The firſt, of which we ſhall give an account, is an invention of Mr William Ker of *Kerfield*, in the county of Tweedale, for the ſaving of hops, and, at the ſame time, giving to the liquor, whether ale, beer, or porter, a ſuperior flavour and quality.

The ſteam which ariſes from the boiling copper is known to be ſtrongly impregnated with the eſſential oil of the hops, in which their flavour conſiſts. Inſtead, therefore, of allowing it to eſcape and evaporate, as it does in the common mode of brewing, Mr Ker contrives to preſerve and condenſe it, by means of a winding-pipe fixed to the copper, ſimilar to the worm of a ſtill, or by a ſtraight pipe paſſing through cold water, or any other cooling medium. The oil and water, thus obtained, are returned into the worts when boiled, or the oil, after being ſeparated from the water, along with which it had been exhaled, is returned into the worts after they are boiled ; and the watery part, which, after the oil is ſeparated, ſtill continues impregnated with the aromatic taſte and bitter of the hop, is returned into the next copper or boiling-veſſel ; and ſo on from one copper or boiling-veſſel into another. By this proceſs a conſiderable part of the hop and flavour, which is loſt in the ordinary mode of brewing, is preſerved : the flavour of the liquor is improved by the preſervation of the finer parts of the aromatic oil : and the ale and beer are better ſecured from any tendency to acidity or putrefaction, and therefore muſt be fitter for home conſumption and exportation. For this invention, which is certainly ſimple, and we think rational, Mr Ker obtained a patent, dated March 4 1788.

On the 4th of June 1790, Mr John Long of *Longville*, in the county of *Dublin*, Ireland, obtained a patent for an improvement in brewing, reſembling, in one particular, this invention of Mr Ker's. To his invention, however, he gives the name of *an entire new method*, in *all the eſſential parts*, of brewing good malt liquor ; and therefore, as it comprehends the whole proceſs of brewing, we ſhall lay it before our readers in the words of its author.

" 1. For the better extracting from malt, place near a maſh-tun a ſhallow copper or other veſſel that will readily heat ; the curb of which to be on a level with the tun, and to contain from two to ſix hogſheads, according to the dimenſion of the tun, more or leſs; and, at the lower end of the copper, have a cock from two to five inches diameter, more or leſs, to conduct the heated liquor from the copper into a tube which paſſes down the external part of the tun, and enters it through an aperture about ſix inches from the bottom; then forming two revolutions, more or leſs, through the body of the tun, and communicating its heat to the wort as it paſſes through the tube; and then, at a convenient diſtance from the place it firſt entered, it runs from the tun into a ciſtern or tub, ſituate as near as convenient to the copper or heating-veſſel. In the tub or ciſtern is to be placed a pump, for the purpoſe of conveying the cooler liquor back to the copper or heating-veſſel again ; there to receive the heat of 208 degrees, more or leſs (which it will require after the firſt half-hour), and then convey it through the maſhing-tun as before, and in the ſame manner, as long as the working brewer or diſtiller may think neceſſary, to raiſe the maſhing-tun to any degree of heat required. By adhering to the foregoing proceſs, the firſt liquor may, with the greateſt ſafety, be let upon the malt from 20 to 30 degrees lower than the preſent practice ; by which means it operates with gentleneſs, opens and expands the malt and raw corn, and prepares it for the reception of ſharper or warmer liquor, ſo as to extract the whole of the ſaccharine quality from the malt and raw corn. By the foregoing method, the maſhing-tun, inſtead of loſing its firſt heat (which it does by the preſent practice), continues to increaſe in heat every moment, by conveying the heated liquor through the tube into the tun; by which means, at the end of two hours, the working brewer or diſtiller can have the tun brought to any degree of heat he ſhall think beſt ſuited to the different qualities of the malt or raw corn. Perſons who would wiſh to ſave expence, may heat their maſhing-tun at the ſide or bottom by a large piece of metallic ſubſtance made fire proof, and fixed therein; which, in ſome degree, will anſwer the end propoſed, but with great trouble and delay.

"2. To prevent the wort from receiving a diſagreeable flavour while in the under-back, a tube muſt be placed at the cock of the maſhing-tun, to receive the wort as it comes off, and convey it to a great ciſtern or refrigeratory, which is ſupplied with a ſtream of water. The wort, paſſing through that medium in a ſpiral tube, ſoon loſes that heat which ſo often proves prejudicial to the brewer and diſtiller in warm weather: then paſs it from the tube into a veſſel in which pumps are placed, to return the worts into the copper for the purpoſe of boiling off. All veſſels for receiving the cold wort muſt be placed lower than the ſource whence the wort comes.

"3. As the great object of long boiling the wort is remedied, by my invention of taking the extract from the hops in a ſeparate manner from the worts, I boil my worts no longer than from 15 to 20 minutes; and, by purſuing that method, I ſave much time and fuel, and regulate my lengths accordingly.

"4. I ſteep my hops, the preceding day to which they are to be uſed, in a copper or other veſſel, with as much fluid, blood-warm, as will cover the hops, where it is to remain over a ſlow fire at leaſt 14 hours, cloſe covered; the copper at the tenth hour not to be of a greater heat than 175 degrees, continuing ſlow until the laſt hour. Then I bring the copper gradually to a ſimmer or ſlow boil; in which ſtate I let it remain about 10 minutes, and then run off the fluid; and this I do at the ſame time the firſt wort is boiled off, that they may both paſs together through the refrigeratory into the fermentation or working tun. After the foregoing operation, I cover the hops again with other liquor, and bring the copper to boil as ſoon as convenient, and let it remain in that ſtate a conſiderable time, until the ſecond worts are boiled off. Then I paſs the hop-fluid with the wort, the ſame as in the firſt inſtance; and, if there is a third wort, I boil my hops a third time with ſmall worts, and paſs it off as before; by which means I gradually obtain the whole of the eſſential oil and pleaſing bitter from the hops, which is effectually preſerved in the beer.

"5. To cool worts. When the wort is boiled off, it is conducted from the cock of the copper or boiler into a tube of a proper dimenſion, which paſſes the wort from the cock to the large ciſtern or refrigeratory, and there performs ſeveral revolutions, in a ſpiral manner, through the ſame tube; which is immerſed in conſtant ſupply of cold water, where it loſes the greateſt part of its heat in a ſhort time, and thence continues a ſtraight courſe through the tube, a little elevated and of a ſuitable length, placed in brick-work, until it meets a ſmall refrigeratory, ſupplied with colder water from a reſervoir made for that purpoſe at the head of the works; whence a continual ſtream runs on the ſurface of the tube down to the great refrigeratory, cooling the wort as it paſſes, in order to enable the working brewer or diſtiller to ſend it into the backs or working-tuns at whatever degree of heat he ſhall think proper. There is no other difference between brewer and diſtiller in this proceſs, but that the diſtiller immediately paſſes the ſtrong wort from the maſhing-tun to the back, thro' the ſame machinery above inſerted, and the tubes may be made of lead, or any other metallic ſubſtance.

"6. To enable me to brew in the warm ſummer months, I ſink my backs or working-tuns at leaſt to a level with the ground, but if deeper the better, and cover them cloſely by an arch made of bricks, or other materials, that will totally exclude the atmoſpheric air from them. I place them as near as poſſible to a ſpring or ſand-drain, as their depth will naturally draw the water thence, which muſt be ſo contrived as to paſs or flow round the backs or tuns. I then introduce a large tube, which paſſes through the tuns, and keeps the wort ſeveral degrees lower than can poſſibly be done by the preſent practice; by which means I can produce a complete fermentation even in the dog-days.

"7. In cold or froſty weather, if the tun and backs ſhould loſe the firſt heat, intended to carry it through the proceſs by the foregoing method, you may convey a ſupply of warm or boiling water by the tube, which paſſes through the body of the backs or tun, communicating its heat, which riſes to any degree the working brewer ſhall think proper: by purſuing this method, in the coldeſt ſeaſon, I never want a fermentation."

We regret that we cannot with propriety ſtate to our readers, under this article, a ſummary of Mr Richardſon of Hull's *Philoſophical Principles of Brewing*; for as the author has a new edition of his work in the preſs, it is our duty rather to refer to it, than to quote from a former edition, which contains not his laſt improvements. See FERMENTATION and MALT, in this Supplement.

BRIDEALE. See SCOTALE in this Supplement.

BRIDGE. See that article *(Encycl.)*, and ARCH in this Supplement. A *wooden*-bridge, of large ſpan, ſhould be conſtructed on the principles explained under the title ROOF (*Encycl.*) See alſo CENTRE (*Suppl.*)

BRINDLEY (James), was born at Tunſted, in the pariſh of Wormhill, Derbyſhire, in 1716. His father was a ſmall freeholder, who diſſipated his property in company and field amuſements, and neglected his family. In conſequence, young Brindley was left deſtitute of even the common rudiments of education, and till the age of 17 was caſually employed in ruſtic labours. At that period he bound himſelf apprentice to one Bennet, a mill-wright at Macclesfield, in Cheſhire, where his mechanical genius preſently developed itſelf. The maſter being frequently abſent, the apprentice was often left for weeks together to finiſh pieces of works concerning which he had received no inſtruction; and Bennet, on his return, was often greatly aſtoniſhed to ſee improvements in various parts of mechaniſm, of which he had no previous conception. It was not long before the millers diſcovered Brindley's merits, and preferred

ferred him in the execution of their orders to the maſter or any other workman. At the expiration of his ſervitude, Bennet being grown into years, he took the management of the buſineſs upon himſelf, and by his ſkill and induſtry contributed to ſupport his old maſter and his family in a comfortable manner.

In proceſs of time Brindley ſet up as a mill-wright on his own account; and by a number of new and ingenious contrivances greatly improved that branch of mechanics, and acquired a high reputation in the neighbourhood. His fame extending to a wider circle, he was employed, in 1752, to erect a water-engine at Clifton, in Lancaſhire, for the purpoſe of draining ſome coal mines. Here he gave an eſſay of his abilities in a kind of work for which he was afterwards ſo much diſtinguiſhed, driving a tunnel under ground through a rock nearly 600 yards in length, by which water was brought out of the Irwell for the purpoſe of turning a wheel fixed 30 feet below the ſurface of the earth. In 1755 he was employed to execute the larger wheels for a ſilk mill at Congleton: and another perſon, who was engaged to make other parts of the machinery, and to ſuperintend the whole, proving incapable of completing the work, the buſineſs was entirely committed to Brindley; who not only executed the original plan in a maſterly manner, but made the addition of many curious and valuable improvements, as well in the conſtruction of the engine itſelf, as in the method of making the wheels and pinions belonging to it. About this time, too, the mills for grinding flints in the Staffordſhire potteries received various uſeful improvements from his ingenuity.

In the year 1756 he undertook to erect a ſteam engine, upon a new plan, at Newcaſtle-under-Line; and he was, for a time, very intent upon a variety of contrivances for improving this uſeful piece of mechaniſm. But from theſe deſigns he was, happily for the public, called away to take the lead in what the event has proved to be a national concern of capital importance—the projecting the ſyſtem of canal navigation. The Duke of Bridgewater, who had formed his deſign of carrying a canal from his coal-works at Worſley to Mancheſter, was induced by the reputation of Mr Brindley to conſult him on the execution of it; and having the ſagacity to perceive, and ſtrength of mind to confide in, the original and commanding abilities of this ſelf-taught genius, he committed to him the management of the arduous undertaking. The nature of this enterpriſe has already been deſcribed (*Encycl.* vol. IV. p. 8c.); it is enough here to mention, that Mr Brindley, from the very firſt, adopted thoſe leading principles, in the projecting of theſe works, which he ever after adhered to, and in which he has been imitated by all ſucceeding artiſts. To preſerve as much as poſſible the level of his canals, and to avoid the mixture and interference of all natural ſtreams, were objects at which he conſtantly aimed. To accompliſh theſe, no labour or expence was ſpared; and his genius ſeemed to delight in overcoming all obſtacles by the diſcovery of new and extraordinary contrivances.

The moſt experienced engineers upon former ſyſtems were amazed and confounded at his projects of aqueduct bridges over navigable rivers, mounds acroſs deep valleys, and ſubterraneous tunnels; nor could they believe in the practicability of ſome of theſe ſchemes till they ſaw them effected. In the execution, the ideas he followed were all his own; and the minuteſt, as well as the greateſt, of the expedients he employed, bore the ſtamp of originality. Every man of genius is an enthuſiaſt. Mr Brindley was an enthuſiaſt in favour of the ſuperiority of canal navigations above thoſe of rivers; and this triumph of art over nature led him to view with a ſort of contempt the winding ſtream, in which the lover of rural beauty ſo much delights. This ſentiment he is ſaid to have expreſſed in a ſtriking manner at an examination before a committee of the Houſe of Commons, when, on being aſked, after having made ſome contemptuous remarks relative to rivers, what he conceived they were created for? he anſwered, "to feed navigable canals." A direct rivalry with the navigation of the Irwell and Merſey was the bold enterprize of his firſt great canal; and ſince the ſucceſs of that deſign, it has become common, all over the kingdom, to ſee canals accompanying, with inſulting parallel, the courſe of navigable rivers.

After the ſucceſsful execution of the Duke of Bridgewater's canal to the Merſey, Mr Brindley was employed in the revived deſign of carrying a canal from that river to the Trent, through the counties of Cheſter and Stafford. This undertaking commenced in the year 1766; and from the great ideas it opened to the mind of its conductor, of a ſcheme of inland navigation which ſhould connect all the internal parts of England with each other, and with the principal ſea-ports, by means of branches from this main ſtem, he gave it the emphatical name of the *grand trunk*. In executing this, he was called upon to employ all the reſources of his invention, on account of the inequality and various nature of the ground to be cut through: in particular, the hill of Harecaſtle, which was only to be paſſed by a tunnel of great length, bored through ſtrata of different conſiſtency, and ſome of them mere quickſand, proved to be a moſt difficult, as well as expenſive, obſtacle, which, however, he completely ſurmounted. While this was carrying on, a branch from the grand trunk, to join the Severn near Bewdly, was committed to his management, and was finiſhed in 1772. He alſo executed a canal from Droitwich to the Severn; and he planned the Coventry canal, and for ſome time ſuperintended its execution; but on account of ſome difference in opinion, he reſigned that office. The Cheſterfield canal was the laſt undertaking of the kind which he conducted, but he only lived to finiſh ſome miles of it. There was, however, ſcarcely any deſign of canal-navigation ſet on foot in the kingdom, during the latter years of his life, in which he was not conſulted, and the plan of which he did not either entirely form, or reviſe and improve. All theſe it is needleſs to enumerate; but, as an inſtance of the vaſtneſs of his ideas, it may be mentioned, that on planning a canal from Liverpool to join that of the Duke of Bridgewater at Runcorn, it was part of his intention to carry it, by an aqueduct bridge, acroſs the Merſey, at Runcorn Gap, a place where a tide, ſometimes riſing fourteen feet, ruſhes with great rapidity through a ſudden contraction of the channel. As a mechanic and engineer, he was likewiſe conſulted on other occaſions; as with reſpect to the draining of the low lands in different parts of Lincolnſhire and the Iſle of Ely, and to the cleanſing of the docks of Liverpool from mud. He pointed out a method, which has been ſucceſsfully practiſed, of building ſea-walls without mortar; and he was the author of a very ingenious improvement of the machine for drawing water out of mines by the contrivance of a loſing and a gaining bucket.

The intenſity of application which all his various and complicated employments required, probably ſhortened his days; as the number of his undertakings, in ſome degree, impaired his uſefulneſs. He fell into a kind of chronic fever, which, after continuing ſome years, with little intermiſſion, at length wore out his frame. and put a period to his life on September 27. 1772, in the 56th year of his age. He died at Tunhurſt, in Staffordſhire, and was buried at New Chapel in the ſame county.

In appearance and manners, as well as in acquirement, Mr Brindley was a mere peaſant. Unlettered, and rude of ſpeech, it was eaſier for him to deviſe means for executing a deſign than to communicate his ideas concerning it to others. Formed by nature for the profeſſion he aſſumed, it was there alone that he was in his proper element; and ſo occupied was his mind with his buſineſs, that he was incapable of relaxing in any of the common amuſements of life. As he had not the ideas of other men to aſſiſt him, whenever a point of difficulty in contrivance occurred, it was his cuſtom to retire to his bed, where, in perfect ſolitude, he would lie for one, two, or three days, pondering the matter in his mind till the requiſite expedient had preſented itſelf. This is that true inſpiration which poets have almoſt excluſively arrogated to themſelves, but which men of original genius in every walk are actuated by, when, from the operation of the mind acting upon itſelf, without the intruſion of foreign notions, they create and invent.

A remarkably retentive memory was one of the eſſential qualities which Mr Brindley brought to his mental operations. This enabled him to execute all the parts of the moſt complex machine in due order, without any help of models or drawings, provided he had once accurately ſettled the whole plan in his mind. In his calculations of the powers of machines, he followed a plan peculiar to himſelf; but, indeed, the only one he could follow without inſtruction in the rules of art. He would work the queſtion ſome time in his head, and then ſet down the reſult in figures. Then taking it up in this ſtage, he would again proceed by a mental operation to another reſult; and thus he would go on by ſtages till the whole was finiſhed, only making uſe of figures to mark the ſeveral reſults of his operations. But though, by the wonderful powers of native genius, he was thus enabled to get over his want of artificial method to a certain degree; yet there is no doubt that when his concerns became extremely complicated, with accounts of various kinds to keep, and calculations of all ſorts to form, he could not avoid that perplexity and embarraſſment which a readineſs in the proceſſes carried on by pen and paper can alone obviate. His eſtimates of expence have generally proved wide of reality; and he ſeems to have been better qualified to be the contriver, than the manager of a great deſign. His moral qualities were, however, highly reſpectable. He was far above envy and jealouſy, and freely communicated his improvements to perſons capable of receiving and executing them; taking a liberal ſatisfaction in forming a new generation of engineers able to proceed with the great plans in the ſucceſs of which he was ſo deeply intereſted. His integrity and regard to the advantage of his employers were unimpeachable. In fine, the name of Brindley will ever keep a place among that ſmall number of mankind who form eras in the art or ſcience to which they devote themſelves, by a large and durable extenſion of its limits.

BRISSOT (J. P.), acted ſo conſpicuous a part in the French revolution, that a fair detail of the principal events of his life would undoubtedly be acceptable to all our readers. A fair detail, however, of ſuch a life, we believe it impoſſible at preſent to give; for characters like Briſſot's are almoſt always miſrepreſented both by their friends and by their enemies; and till the troubles which they have excited, or in which they have been engaged, have long ſubſided, the impartial truth is nowhere to be found.

In a fulſome panegyric, under the denomination of *The Life of J. P. Briſſot*, ſaid to be written by himſelf, we are told, that he was born January 14. 1754; and that his father was a *traiteur*, or "the keeper of an eating-houſe," but in what place we are not informed. Our author, however, aſſures us that the old man was in eaſy circumſtances, and that he employed all the means reſulting from them to give to his numerous family a good education. The ſubject of this memoir was intended for the bar; but not reliſhing the ſtudies neceſſary to fit him for the profeſſion of the law, or, if we chooſe to believe him, having a mind too *pure* and *upright* for the ſtudy of *chicane*, he relinquiſhed the purſuit after five years of drudgery!

To relieve his wearineſs and diſguſt, he applied himſelf, he ſays, to literature and the ſciences. The ſtudy of the languages was above all others his favourite purſuit. Chance brought him acquainted with two Engliſhmen on their travels through France: he learned their language; and this circumſtance, he tells us, decided his fate.

"It was at the commencement of my paſſion for that language (continues he) that I made the metamorphoſis of a diphthong in my name which has ſince been imputed to me as ſo heinous a crime. Born the thirteenth child of my family, and the ſecond of my brothers in it, I bore, for the ſake of diſtinction, according to the cuſtom of Beauce, the name of a village in which my father poſſeſſed ſome landed property. This village was called *Ouarville*, and Ouarville became the name by which I was known in my own country. A fancy ſtruck me that I would caſt an Engliſh air upon my name; and accordingly I ſubſtituted, in the place of the French diphthong *ou*, the *w* of the Engliſh, which has preciſely the ſame ſound." For this puerile affectation, which was certainly not criminal, he juſtifies himſelf by the example of the literati of the 16th and 17th centuries, who made no ſcruple of Greciſing and Latiniſing their appellatives.

Having proſecuted his ſtudies for two years, he had an application from the Engliſh proprietor of a paper then much in circulation, and intitled *Le Courier de l' Europe*. This man having drawn upon himſelf an attack from government, felt and yielded to the neceſſity of printing his paper at Boulogne-ſur-mer. It was his wiſh to render it intereſting to the French in the department of miſcellaneous intelligence; which he therefore wiſhed to ſubmit to the ſuperintendency and arrangement of Briſſot, who repreſents himſelf as for ſome moments heſitating. The profeſſion of a journaliſt, ſubject to a licenſer, was repugnant to his principles; yet it ſecured his independence, and put into his power the means of proſecuting an inveſtigation of conſtitutions and of the ſciences. After ſome ridiculous reaſoning from the original ſtations of *Bayle*, *Poſtel*, and *Rouſſeau*, he at laſt accepted of the employment, and became enamoured of it, "becauſe (ſays he) it enabled me to ſerve talents and virtue, and, as it were, to inoculate the French with the principles of the Engliſh conſtitution.

This employment, however, did not laſt for any length of time. The plan of the proprietor of the *Courier* was overthrown by adminiſtration, and Briſſot quitted Boulogne to return to his firſt ſtudies. Having informed us of this fact, he makes an extravagant pretence to unſullied virtue, and calls upon the inhabitants of the city which he had left to bear witneſs, not only that he had *no vices*, but that he had not even the *ſeeds* of any one of the vices which his adverſaries, it ſeems, had laid to his charge.

"Doubtleſs (ſays he), too eager to publiſh my ideas, I conceived that the proper moment had arrived, and I felt an inclination to commence with an important work. Revolting, from the very inſtant of my beginning to reflect, againſt religious and political tyranny, I ſolemnly proteſted, that thenceforward I would conſecrate my whole life to their extirpation. Religious tyranny had fallen under the redoubled ſtrokes of Rouſſeau, of Voltaire, of Diderot, and of D'Alembert. It became neceſſary to attack the ſecond;" and this was a taſk which the vanity of Briſſot led him to conſider as reſerved for him.

What Voltaire and his friends meant by religious tyranny, and how they conducted their attacks againſt it, are matters, alas! too well known to all Europe; and as our author choſe theſe philoſophers for his guides, we might infer, without much degree of miſtake, what he underſtood by political tyranny, and by what means he meditated its extirpation. But he has not left us to make this diſcovery by inference.

"It became neceſſary (ſays he) to break in pieces the political idol, which, under the name of *monarchy*, practiſed the moſt violent deſpotiſm; but to attack it openly, was to expoſe the aſſailant without the poſſibility of ſerving mankind. It was by a ſide blow that it was to be wounded moſt effectually;" and therefore he reſolved to begin his operations by attacking ſome of thoſe abuſes which might be reformed without apparently ſhaking the authority of the prince.

Our readers, at leaſt the ſober part of them, will probably think that this mode of attack is not peculiar to Briſſot, but that it has been practiſed, or attempted to be put in practice, by aſpiring demagogues in all ages and countries, who have uniformly begun their career of innovation by exciting the public mind againſt thoſe abuſes in government, of which the exiſtence cannot wholly be denied. The ſubject to which our author thought fit to call the attention of his countrymen, was the criminal juriſprudence: a ſubject, ſays he, which, with the exception of ſome particulars that had been ſucceſsfully inveſtigated by Beccaria and Servan, no writer had thoroughly conſidered in a philoſophical point of view. Thinking himſelf fully equal to this taſk, he drew up a general plan; and in the year 1780 publiſhed his Theory of Criminal Laws, in two vols 8vo. This work, favourably received by foreigners, applauded by ſome journaliſts, and pulled to pieces by others, procured him the friendſhip of the warmeſt advocates for human liberty, in whoſe opinion the defects of his plan were highly pardonable, on account of the energy conſpicuous in his remarks. This publication was ſoon followed by two diſcourſes which gained the prize in 1782 at the academy of Chalons-ſur-Marne; the one upon the reform of the criminal laws, and the other on the reparation due to innocent perſons unjuſtly accuſed.

It is natural to ſuppoſe that the government beheld with an evil eye theſe writings, which, under pretext of dragging into light the abuſes of the criminal laws, inſinuated dangerous principles on the nature of government in general.

His next work was intitled, *A Philoſophical Library of the Criminal Laws*, in 10 vols; the true object of which was to diſſeminate in France thoſe principles of liberty which guided the Engliſh and the Americans in framing and expounding their laws.

But the ſtudy of legiſlation and politics had not entirely drawn him off from that of other ſciences; ſuch as chemiſtry, phyſics, anatomy, theology, &c. Theſe he conſtantly cultivated with ardour; but acknowledges that in each he met with obſcurities, and that in every quarter truth eſcaped from his reſearches. He therefore ſat down to inveſtigate the nature of truth, and the proper method of attaining to it in every department of reſearch; and the reſult of his labours was a kind of *novum organum*, by which he ſeems to have expected that Bacon's work would be buried in oblivion; and to this important volume he gave the title of *Concerning Truth; or, Thoughts on the Means of attaining Truth in all the Branches of Human Knowledge.* This volume was meant as nothing more than the introduction to a greater work, in which he propoſed to inveſtigate what is *certain* in knowledge and what *doultful*, and then to ſtrike the balance of the account.

He was prevented, however, from completing his plan, which he regrets exceedingly; for, as he affirms, with *becoming modeſty*, his work would certainly have amended its readers! But the French government happened to think otherwiſe; his aim, which, he ſays, was to lead mankind to reflect on their rights, was perceived, and he was accuſed to the miniſter as a ſeditious writer. The career of genius was ſtopped by the dread of the Baſtile; and he was obliged to take refuge in London. There it was his wiſh to create *a univerſal confederation of the friends of liberty and truth*, and to eſtabliſh a *centre of correſpondence and union* with the learned and the politicians of Europe. This dark deſign, however, was fruſtrated by the treachery, as it would appear, of his aſſociates, who had bound themſelves, he ſays, by the moſt *ſacred oaths*, to aſſiſt him, and had offered to ſign articles *even with their own blood*.

Finding himſelf unable to proceed directly to the object which he had in view, he reſolved to *enlighten his* countrymen gradually, and to begin with exciting their love and admiration of the Engliſh conſtitution. That conſtitution, which he had inveſtigated on the ſpot, appeared to him a model for thoſe ſocieties which were deſirous of changing their form of government. It was but little known, he ſays, in France (the work of *De Lolme* being at that time only in the hands of the learned);

ed); and to make it known was to make it beloved, was to render it deſired. But the French miniſters ſtood upon their guard, and it became neceſſary to *deceive* them. He reſolved therefore to bring forward a journal written actually in London, and profeſſing to contain only a *deſcription of the ſciences and arts of England*, whilſt the greater part of it was to be occupied in reality by an inveſtigation of the *Engliſh conſtitution*.

After many difficulties, the miniſtry granted a privilege for this journal, being publiſhed in London, to be reprinted in Paris; and it firſt appeared in 1784. "In the twelve numbers which have been publiſhed (ſays the author), the friends of liberty muſt have perceived, that if, on the one ſide, I endeavoured to inculcate more juſt ideas than had hitherto been entertained concerning this celebrated iſland; ſo, on the other, I reſolutely made my advances toward that important end which has perpetually preſided over all my labours, *the univerſal emancipation of men*."

His affairs calling him at this time to Paris, he was arreſted and conveyed to the Baſtile on the 12th of July 1784. In this conduct of the government we cannot perceive any thing very tyrannical or arbitrary, ſince he confeſſes, that, in the 16th page of the firſt number of his Journal, he had ſuffered the *ſecret and favourite aim*, which always guided his pen, to become diſcernible. He was, however, diſcharged from priſon on the 5th of September, and returned with increaſed zeal to his former employments.

"This perſecution (ſays he), far from extinguiſhing the ardour of my wiſhes to inculcate the principles of freedom, ſerved only to inflame it the more." Accordingly, in 1785, he publiſhed two letters to the Emperor Joſeph II. *concerning the right of emigration, and the right of people to revolt*. The firſt of theſe letters, which, though well known in Germany, were in France ſuppreſſed by the *police*, was occaſioned by what the author calls the ridiculous and barbarous edict againſt emigration; and the ſecond by the puniſhment of *Horiah* the chief of the *Walachian* inſurgents. In this laſt letter he lays it down as a maxim, that all people under ſuch a government as that of the *Walachians*, have from nature a ſacred *right* to revolt, a right which they can and ought to exerciſe. In the ſame ſpirit he brought out, in 1786, his Philoſophical Letters on the Hiſtory of England, in 2 vols, and A Critical Examination of the Travels of the Marquis de Chatelleux in North America.

The French revolution appearing to him extremely diſtant, notwithſtanding all his efforts to haſten it, he reſolved to leave France for the purpoſe of ſettling in America. His project received the approbation of ſeveral, whoſe ſentiments were congenial with his own. But as it was thought imprudent to tranſport numerous families to a country ſo far off, without thoroughly knowing it, Briſſot was engaged to proceed thither, to examine the different places, to obſerve the inhabitants, and to diſcover where and in what manner the eſtabliſhment they had propoſed might be moſt advantageouſly fixed. He had ſome time before inſtituted a ſociety at Paris for accompliſhing the abolition of the negro trade, and for ſoftening the condition of the ſlaves. At the period of his departure, this ſociety conſiſted of a conſiderable number of diſtinguiſhed members, and he was commiſſioned to carry the firſt fruits of their labours to America. His ſtay there, however, was not ſo long as he was deſirous of making it. In the beginning of 1789 he was recalled by the news of the French revolution, which he conceived might probably produce a change in his own meaſures and in thoſe of his friends. This idea, added to other circumſtances, accelerated his return. The fire had blazed forth in his native country. "Hope (ſays he) animated every heart; the moſt diſtinguiſhed champions had engaged in the conteſt; I too became deſirous to break a lance, and I publiſhed my *Plan of Conduct for the Deputies of the People*."

This, and other works of a ſimilar kind, of which he loudly boaſts the merits, raiſed him high in the favour of the republican part of the nation, and he became preſident of his diſtrict; where he acted, according to his own account, with great uprightneſs in the municipality, in the firſt committee of inquiries, and as an elector. At laſt he became a member, firſt of the *National Aſſembly*, and, after its diſſolution, of the *Sanguinary Convention*; and by ſome means or other got to be the leader of a party called ſometimes the *Girondiſts*, and ſometimes the *Briſſotines*. From that period the principal events of his life were involved with the public tranſactions of the nation, of which we have given an account in the *Encyclopædia* under the title REVOLUTION (ſee that article, n° 101—182.) The Girondiſt faction was denounced by the Mountain, and Briſſot ſuffered by the guillotine on the 30th of November 1793. He fell indeed by a very unjuſt ſentence; but his fall was the natural conſequence of that anarchical tyranny under which no man had contributed more than he to ſubject his native country.

BROWN (Dr John), author of the *Elementa Medicinæ*, &c. was born in the village of Dunſe, or, as ſome ſay, Lintlaws, in the county of Berwick, in the year 1735-6. His parents were of mean condition, but much reſpected in the neighbourhood for the integrity of their lives. His father gained his livelihood in the humble capacity of a day-labourer; while his mother contributed her ſhare towards the ſupport of the family by the profits ariſing from a milch cow.

Such were the perſons who, in an obſcure part of the country, gave birth to a ſon deſtined, at a future period, to make a diſtinguiſhed figure in the republic of letters; and from whom originated a ſyſtem of the animal economy, which, whatever be its real merits, has undoubtedly produced a conſiderable revolution in the practice of medicine.

At the age of three or four years, young Brown was put to a reading ſchool in Dunſe, which he himſelf commemorates as the place rather of his education than of his nativity. Here, under the tuition of an old woman, he very early began to exhibit marks of that ſtrength of mind for which he was afterwards ſo eminently diſtinguiſhed. In the ſhort period of a year he became able to read with facility any part of the Bible, and acquired over his claſs-fellows that ſuperiority which he ever after maintained both at ſchool and college.

It was almoſt immediately after his entrance into this ſchool, that his inſatiable deſire of reading commenced; and ſo unremitting was his application, that he is ſaid never to have been found, even at thoſe hours which children much more advanced in life devote to amuſement, without a book in his hand.

While he was making this rapid progreſs in the rudiments

diments of literature, he ſuffered what muſt have appeared to be a very heavy loſs in the death of his father; but his mother ſoon afterwards married a worthy man of the ſame name, whoſe care and attention ſupplied the place of a father to her ſon. This man being a weaver, deſigned to educate his ſon-in-law to the ſame buſineſs, and began to inſtruct him in his art when he was about nine years of age: but the taſte which young Brown had already acquired for letters, made him look with diſguſt on the inſipid employment of a weaver. His ſtep-father was no tyrant, and his mother was affectionate. They were both proud of the talents which at ſo early a period of life had appeared in their ſon, and they felt no inclination to ſtruggle with the invincible averſion which he expreſſed to the buſineſs for which they intended him.

Another circumſtance, however, contributed in no ſmall degree to make them recal their original reſolution. They were both of that ſect of religioniſts which in Scotland are called Seceders (ſee SECEDERS, *Encycl.*); and it was ſuggeſted to them by ſome perſons of their own perſuaſion, who had remarked the uncommon abilities of the boy, that he might one day prove an able ſupport and promoter of their tenets as a preacher. He was accordingly, much to his ſatisfaction, taken away from the buſineſs to which he had conceived ſuch a diſtaſte, and ſent to the grammar-ſchool of Dunſe, which was taught at that time by a gentleman of the name of Cruickſhank, eminent for his grammatical knowledge. Here he appears to have ſpent ſome years with uncommon advantage and happineſs; during which he was eſteemed by all the country round as a kind of prodigy. Like Johnſon, and many other men of the higheſt celebrity, he united in the ſame perſon uncommon powers of mind, with no leſs ſtrength of body, as indeed his appearance indicated; and in his youth he enſured his own perſonal importance among his ſchool-fellows, by excelling them not leſs in athletic exerciſes than in the taſks preſcribed by their maſter. He was particularly fond, when a boy, of practiſing the pugiliſtic art; and indeed until the laſt period of his life he was obſerved by his friends always to view an exhibition of that kind with peculiar reliſh. He alſo prided himſelf much in being a ſtout walker; and mentions his having in one day accompliſhed, when but fifteen years of age, a journey of fifty miles between Berwick-upon-Tweed and Morpeth in Northumberland. When farther advanced in life, he travelled on foot from four in the afternoon of one day to two in the afternoon of next day, with the ſhort interval of one hour's reſt! But as one of his biographers very juſtly obſerves, "we have ſeen that he could make a more rational uſe of his ſtrength than merely to ſtake it againſt time and ſpace *."

* Dr Bed- s.

His early years while at ſchool were marked by the moſt rigid attachment to his ſect. So ſtrict indeed were his religious ſentiments, if a boy of ten or eleven can be ſaid to have any ſentiments deſerving to be called religious, that he would have conceived the holding of any communion with the eſtabliſhed church as a kind of profanation. An event, however, happened, ſome time between the eleventh and thirteenth years of his age, which produced a total and unexpected revolution in his religious opinions. At a meeting of the provincial ſynod of Merſe and Tiviotdale, he was prevailed upon, though not without manifeſting much reluctance, to accompany a party of his ſchool-fellows to the pariſh church of Dunſe. The conſequence of this tranſgreſſion, as he had dreaded, was an immediate ſummons to appear before the ſeſſion of the Seceding congregation; to which, through pride, not chooſing to attend, in order to preclude a formal expulſion, he voluntarily abjured their tenets, and openly avowed his apoſtacy to the eſtabliſhment.

All changes in religion which are not the conſequence of candid inveſtigation are dangerous. He who leaves one ſect he knows not why, will quickly abandon, with as little reaſon, that to which in a fit of paſſion he had haſtily joined himſelf. From the moment of his quitting the communion of the Seceders, Brown's religious ardour ſuffered a gradual abatement; and though, to pleaſe his mother, he continued to proſecute his ſtudies with a view to the office of a clergyman in the church of Scotland, his opinions became daily more and more lax, and his life of courſe leſs and leſs regular. It was, however, a conſiderable time before he admitted, in their full extent, thoſe principles of irreligion which he afterwards avowed; for upon his firſt peruſing the Eſſays of Mr Hume, though his own zeal was then much cooled, he expreſſed great indignation at their dangerous tendency.

At the age of twelve years he had been employed by Mr Cruickſhank as a kind of uſher in the ſchool of Dunſe; and that gentleman having declared that his knowledge of the Latin language was equal to his own, his fame as a ſcholar was ſo ſpread over the country, that at the age of thirteen he was intruſted with the education of a gentleman's ſon in the neighbourhood, when he quitted the ſchool and his beloved maſter. In his new ſituation, however, he remained not long. Dr Beddoes conjectures, that to the ſtiffneſs of pedantry he added the ſourneſs of a bigot, and was therefore a diſagreeable inmate of the family. That a boy of thirteen, proud of his talents, and prouder of his learning, ſhould have the ſtiffneſs of a pedant, is indeed extremely probable; it was the natural conſequence of the praiſe with which he had been honoured by Mr Cruickſhank: but there is reaſon to believe that of his original bigotry few traces now remained. The real cauſe of his diſmiſſion from the family, we are aſſured, was his pride; and as it muſt have been the pride of parts, it confirms the firſt part of Dr Beddoes's conjecture.

It ſeems he was much diſpleaſed that, when company were at dinner, he was not deſired to remain after the cloth was removed; and yet if he was then only thirteen years of age, it is not eaſy to conceive for what purpoſe he ſhould have ſtaid. He could not poſſibly know much of the world, or of any thing likely to employ the converſation of country gentlemen; and we cannot help thinking, that the maſter of the houſe would have treated his gueſts with rudeneſs, had he detained among them a raw boy to liſten to every unguarded expreſſion which might eſcape them over their wine. It would appear, however, that he was not unwilling to give the tutor of his ſon an opportunity of diſplaying his abilities, when ſuch ſubjects were introduced as he knew him to have ſtudied; for a diſpute having ariſen, one day after Brown had retired to his own room, concerning the decrees of Providence, he ſent to requeſt his opinions on that abſtruſe ſubject. By the meſſenger Brown returned a verbal anſwer, that "the decrees of Providence are very unjuſt, for having made blockheads lairds."

Mr Cruickſhank had ſome time before requeſted him to return to the ſituation which he had formerly held in the ſchool of Dunſe; and we cannot wonder that, immediately after making this inſolent anſwer, he found it convenient to comply with his requeſt. He was now about fifteen, and he continued in the ſchool till the 20th year of his age; during which time, from the conſtant habit of teaching the Latin and Greek languages, he acquired a wonderful facility in reading both theſe languages, and in writing the former, though he wrote not with taſte.

About this time it occurred to him that he might turn his claſſical acquirements to more account, by becoming a private teacher of languages in Edinburgh. To that city he accordingly repaired, where, while he obtained a livelihood as a teacher, he propoſed at the ſame time to purſue his theological ſtudies at the univerſity. But an accident happened to him here which made him altogether change the plan he had come upon; and the death of his mother, after a reſidence of ſome time in Edinburgh, abſolved him, as he thought, from the promiſe which he had made to her of appearing one day in the pulpit. Shortly after an unſucceſsful competition for one of the chairs then vacant in the high-ſchool, an application was made to a friend of his for a proper perſon to turn a medical theſis into Latin. Brown was recommended. He was limited to a certain time; within which it appeared ſcarce practicable to perform the taſk. He accompliſhed it, however, and in ſuch a ſtyle of grammatical correctneſs and purity as far exceeded the general run of ſuch productions. On this being remarked to him by his friends, he obſerved, "that he now knew his ſtrength, and was ambitious of riding in his carriage as a phyſician." He therefore determined to apply himſelf with ardour to the ſtudy of medicine, to which this accidental circumſtance alone directed his attention. Accordingly, at the commencement of the next winter ſeſſion, he addreſſed a Latin letter to each of the medical profeſſors, and by them was preſented with tickets of admittance to their ſeveral claſſes.

From ſuch a favourable beginning, being of a very ſanguine diſpoſition, he conceived the moſt flattering expectations of his future ſucceſs; and indeed for ſome time he ſeems to have lived in affluent circumſtances. His attainments were ſo various, and in ſuch requeſt in Edinburgh, that as a ſingle man he could ſcarcely fail to gain a competent living; for during the laſt five years of his reſidence under Mr Cruickſhank, to a thorough acquaintance with ancient hiſtory, he had added a very conſiderable knowledge of mathematics; in which, among other branches of ſcience, he never had any objection to give inſtructions. In the acquiſition of that variety of knowledge which he poſſeſſed, he was greatly aſſiſted by a moſt tenacious memory; to the retentiveneſs of which an old ſchool-fellow bears teſtimony, by affirming, that "after once reading over the leſſon, conſiſting of two octavo pages in Latin, he would lay aſide the book, and prelect the whole over without miſtaking a ſingle word."

Brown, already in eaſy circumſtances for an individual, ſaw, or thought he ſaw, in the eſtabliſhment of a boarding-houſe for ſtudents a reſource which would enable him to maintain a family; and in expectation of realiſing this proſpect, he married, in 1765, the daughter of a reſpectable tradeſman in Edinburgh. The diſtinguiſhed attention at that time paid him by Dr Cullen, in whoſe family he had become a neceſſary perſon, contributed in all probability to ſtrengthen his hopes that his houſe would be filled with proper boarders through the Doctor's recommendation. His ſucceſs in this way for ſome time anſwered his moſt ſanguine expectations; and his circumſtances at one period were ſo flouriſhing, that he is ſaid to have kept a one-horſe chaiſe.

It was, perhaps, the greateſt misfortune that could have befallen Brown, that he poſſeſſed, in a high degree, thoſe talents which make a man's company ſought after by the gay and the diſſipated: He was capable of "ſetting the table in a roar." We need not therefore wonder at his frequently neglecting more neceſſary purſuits to enjoy the conviviality of the numerous friends who courted his company; or that drinking and diſſipation became habitual to him. He was as deficient in point of prudence as he excelled in genius. His houſe was filled with reſpectable boarders; but as he lived too ſplendidly for an income at beſt but precarious, he became gradually involved in debt, and his affairs were ſtill more embarraſſed by the burden of a numerous family. Soon after he began to be involved in theſe difficulties, he ſuffered an additional loſs in being deprived of the patronage of Dr Cullen, in conſequence of a diſagreement that had taken place between them. This enmity, which had for ſome time before ſecretly ſubſiſted, probably from mutual jealouſy, was at length excited into an open rupture; firſt, by Dr Cullen's not exerting his intereſt in procuring for Brown the theoretical chair of medicine, then vacant in conſequence either of the death or reſignation of Dr Alexander Monro Drummond; and, ſecondly, by his rejecting, ſome time after, Brown's petition for admittance into the Edinburgh Philoſophical Society.

In 1776 Brown was elected preſident of the Medical Society; and the ſame honour was again conferred on him in 1780. He was led on, in the gradual manner he himſelf deſcribes in his maſterly preface to the *Elementa Medicinæ*, to the diſcovery of his new doctrine; which, on dropping all correſpondence with his former friend and benefactor, he now, for the firſt time, began to illuſtrate in a courſe of public lectures; and in theſe he diſplayed equal ingenuity and philoſophical profundity. Much about the time of which we now ſpeak, he publiſhed the firſt edition of the *Elementa Medicinæ*; a work which certainly proves its author to have been a man of uncommon genius and originality of thought. The circumſtances in which this work was compoſed reflect great honour on his abilities. He never retired to his ſtudy; but, totally abſorbed in his own ideas, wrote with the greateſt tranquillity amidſt the noiſe of ten children, occaſionally ſettling their childiſh differences.

In the year 1779, though he had ſtudied medicine ten or twelve years at the univerſity of Edinburgh, he was prevailed upon by his friends to take a degree at St Andrews, where he gave a conſpicuous proof of his facility in Latin compoſition. He wrote a theſis, or inaugural diſſertation, in the tavern while the cloth was laying for dinner; and one of his companions, who was ſinging beſide him, having uttered a falſe note, or ſung out of time, Mr Brown, in the middle of his writing, ſtopped to ſhew him how the ſong ought to be ſung, and then inſtantly proceeded in his theſis.

His family having now become ſo numerous as to render keeping a boarding-houſe inconvenient, he had already for ſome time given it up, and depended for ſupport entirely on his practice as a phyſician and his public lectures. At this time the diſputes between the Cullenians and the Brunonians (as the young men now ſtyled themſelves) were carried on with ſuch acrimony on both ſides, in the different ſocieties, that it was not unuſual for them to terminate in duels; and there exiſts at this day, on the records of the Medical Society, a law which it was thought expedient to enact, by which a member who challenges another for any thing ſaid in public debate incurs the penalty of expulſion.

Obſerving the ſtudents of medicine frequently to ſeek initiation into the myſteries of free-maſonry, Dr Brown thought their youthful curioſity afforded him a chance of proſelytes. In 1784, he inſtituted a meeting of that fraternity, and intitled it *the Lodge of the Roman Eagle.* The buſineſs was conducted in the Latin language, which he ſpoke with the ſame fluency as Scotch; and he diſplayed much ingenuity in turning into Latin all the terms uſed in maſonry.

As the terms on which he lived with his brethren of the faculty were ſuch that he obſtinately avoided meeting them even in conſultation, we may conclude that his own private practice was but limited. His friends affirmed, perhaps without ſufficient proof, that cabals were formed againſt him, and every advantage taken of the errors he was led to commit by his own imprudence. After a long ſeries of ſtruggles, therefore, hoping to meet with that encouragement among the Engliſh of which he had been diſappointed in his own country, he put in practice a plan upon which he had long meditated, and removed in 1786 with part of his family to London. Immediately on his arrival, an incident befel him, which Dr Beddoes ſays he has heard the late Mr Murray, bookſeller in Fleet-ſtreet, relate as a proof of his ſimplicity. The peculiarity of his appearance as he moved along (a ſhort ſquare figure, with an air of dignity, in a black ſuit, which heightened the ſcarlet of his cheeks and noſe) fixed the attention of ſome *gentlemen* in the ſtreet. They addreſſed him in the dialect of his country. His heart, heavy as it muſt have been, from the precariouſneſs of his ſituation, and diſtance from his accuſtomed haunts, expanded at theſe agreeable ſounds. A converſation enſued; and the parties, by common conſent, adjourned to a tavern. Here the ſtranger was kindly welcomed to town; and, after the glaſs had circulated for a time, ſomething was propoſed by way of ſober amuſement—a game at cards, or whatever the Doctor might prefer. The Doctor had been too civilly treated to demur; but his purſe was ſcantily furniſhed, and it was neceſſary to quit his new friends in ſearch of a ſupply. Mr Murray was the perſon to whom he had recourſe: the reader will not wonder that his interference ſhould have ſpoiled the adventure.

A London ſharper, of another denomination, afterwards tried to make advantage by the Doctor. This was an ingenious ſpeculator in public medicines. He thought a compoſition of the moſt powerful ſtimulants might have a run, under the title of *Dr Brown's exciting pill*; and, for the privilege of his name, offered him a ſum in hand by no means contemptible, as well as a ſhare of the contingent profits. Poor Brown, needy as he was, ſpurned at the propoſal.

After this period, his life affords little variety of incident. Like Avicenna, his time ſeems to have been ſpent between his literary purſuits and his pleaſures. A ſplendid manner of living, without an income to ſupport it, had become habitual to him: The conſequence was, that, from inability to diſcharge certain debts he had contracted, he was thrown into the king's bench priſon; from which, however, he was, not long afterwards, releaſed by the exertions of a few firm friends, particularly Mr Maddiſon of Charing-croſs, a gentleman univerſally reſpected for his well-known benevolence. As a proof of the activity he was ſtill capable of exerting, it will be ſufficient to mention, that he accompliſhed the tranſlation of his *Elementa*, with the addition of the ſupplementary notes, within 23 days, having been informed that a tranſlation of the ſame was about to be publiſhed by another perſon.

Shortly before his death, the ambaſſador of the king of Pruſſia, in the name of his maſter, made Dr Brown an offer of a ſettlement in the court of Berlin; during the negociation of which he was unexpectedly cut off by an apoplexy early in the morning of the 7th of October 1788, the day ſucceeding that on which he had delivered to a company of thirteen gentlemen the greater part of the introductory lecture to his ſecond courſe. At his death, he was between 52 and 53 years of age. His remains were interred in the church-yard of St James's Picadilly; and the only monument left behind him to tranſmit his name to poſterity is his own works; which, when perſonal prejudice no longer ſhall prevail againſt their ingenious author, cannot fail to procure him all that deſerved celebrity which they have already, in part, obtained in the different countries of Europe.

In 1787, he publiſhed his "Obſervations," without his name, which he afterwards, however, refers to in the Elements as his own. The "Enquiry," ſaid to be written by Dr Jones, and which was compoſed in as ſhort a time as the generality of men would tranſcribe a work of its extent, we can affirm, from undoubted authority, to be his production.

This ſketch of the life of the unfortunate Dr Brown would be of very little value if not followed by a view of his ſyſtem; but to give a complete view of that ſyſtem would far exceed the limits within which, in a work like this, ſuch articles muſt be confined. We truſt, therefore, that our readers will be ſatisfied with an abſtract; and as we are neither the partiſans nor opponents of the Doctor, and not very partial to any medical *ſyſtem* whatever, we ſhall content ourſelves with inſerting, in this place, the view which Dr Beddoes has given of Dr Brown's fundamental propoſitions in the valuable obſervations which he has prefixed to his edition of the Elements of Medicine.

"The varied ſtructure of organized beings (ſays Dr Beddoes), it is the buſineſs of anatomy to explain. Conſciouſneſs, aſſiſted by common obſervation, will diſtinguiſh animated from inanimate bodies with preciſion more than ſufficient for all the ends of medicine. The cauſe of gravitation has been left unexplored by all prudent philoſophers; and Brown, avoiding all uſeleſs diſquiſition concerning the cauſe of vitality, confines himſelf to the phenomena which this great moving principle in nature may be obſerved to produce. His moſt general propoſitions are eaſy of comprehenſion.

" 1. To every animated being is allotted a certain portion only of the quality or principle on which the phenomena of life depend. This principle is denominated *excitability*.

" 2. The excitability varies in different animals, and in the ſame animal at different times. As it is more intenſe, the animal is more vivacious or more ſuſceptible of the action of exciting powers.

" 3. Exciting powers may be referred to two claſſes. 1. External; as heat, food, wine, poiſons, contagions, the blood, ſecreted fluids, and air. 2. Internal; as the functions of the body itſelf, muſcular exertion, thinking, emotion, and paſſion.

" 4. Life is a forced ſtate; if the exciting powers are withdrawn, death enſues as certainly as when the excitability is gone.

" 5. The excitement may be too great, too ſmall, or in juſt meaſure.

" 6. By too great excitement, weakneſs is induced, becauſe the excitability becomes defective; this is *indirect debility*: when the exciting powers and ſtimulants are withheld, weakneſs is induced; and this is *direct debility*. Here the excitability is in exceſs.

" 7. Every power that acts on the living frame is ſtimulant, or produces excitement by expending excitability. Thus, although a perſon accuſtomed to animal food may grow weak if he lives upon vegetables, ſtill the vegetable diet can only be conſidered as producing an effect, the ſame in kind with animals, though inferior in degree. Whatever powers, therefore, we imagine, and however they vary from ſuch as are habitually applied to produce due excitement, they can only weaken the ſyſtem by urging it into too much motion, or ſuffering it to ſink into langour.

" 8. Excitability is ſeated in the medullary portion of the nerves, and in the muſcles. As ſoon as it is anywhere affected, it is immediately affected everywhere; nor is the excitement ever increaſed in a part, while it is generally diminiſhed in the ſyſtem; in other words, different parts can never be in oppoſite ſtates of excitement.

" I have already ſpoken of an illuſtration, drawn up by Mr Chriſtie from a familiar operation, to facilitate the conception of Brown's fundamental poſitions. I introduce it here as more likely to anſwer its purpoſe than if ſeparately placed at the end of my preliminary obſervations. ' Suppoſe a fire to be made in a grate, filled with a kind of fuel not very combuſtible, and which could only be kept burning by means of a machine containing ſeveral tubes, placed before it, and conſtantly pouring ſtreams of air into it. Suppoſe alſo a pipe to be fixed in the back of the chimney, through which a conſtant ſupply of freſh fuel was gradually let down into the grate, to repair the waſte occaſioned by the flame, kept up by the air machine.

' The grate will repreſent the human frame; the fuel in it, the matter of life—the excitability of Dr Brown, and the ſenſorial power of Dr Darwin; the tube behind, ſupplying freſh fuel, will denote the power of all living ſyſtems, conſtantly to regenerate or reproduce excitability; while the air machine, of ſeveral tubes, denotes the various ſtimuli applied to the excitability of the body; and the flame drawn forth in conſequence of that application repreſents life, the product of the exciting powers acting upon the excitability.

' As Dr Brown has defined life to be *a forced ſtate*, it is fitly repreſented by a flame forcibly drawn forth from fuel little diſpoſed to combuſtion, by the conſtant application of ſtreams of air poured into it from the different tubes of a machine. If ſome of theſe tubes are ſuppoſed to convey pure or dephlogiſticated air, they will denote the higheſt claſs of exciting powers, opium, muſk, camphor, ſpirits, wine, tobacco, &c. the diffuſible ſtimuli of Dr Brown, which bring forth for a time a greater quantity of life than uſual, as the blowing in of pure air into a fire will temporarily draw forth an uncommon quantity of flame. If others of the tubes be ſuppoſed to convey common or atmoſpheric air, they will repreſent the ordinary exciting powers, or ſtimuli, applied to the human frame, ſuch as heat, light, air, food, drink, &c. while ſuch as convey impure and inflammable air may be uſed to denote what have formerly been termed ſedative powers, ſuch as poiſons, contagious miaſmata, foul air, &c.

' The reader will now probably be at no loſs to underſtand the ſeeming paradox of the Brunonian ſyſtem; that food, drink, and all the powers applied to the body, though they ſupport life, yet conſume it; for he will ſee that the application of theſe powers, though it brings forth life, yet at the ſame time it waſtes the excitability or matter of life, juſt as the air blown into the fire brings forth more flame, but waſtes the fuel or matter of fire. This is conformable to the common ſaying, " the more a ſpark is blown, the brighter it burns, and the ſooner it is ſpent." A Roman poet has given us, without intending it, an excellent illuſtration of the Brunonian ſyſtem, when he ſays,

" *Balnea, vina, Venus, conſumunt corpora noſtra;*
" *Sed vitam faciunt balnea, vina, Venus.*

" Wine, warmth, and love, our vigour drain;
" Yet wine, warmth, love, our life ſuſtain."

Or to tranſlate it more literally,

" Baths, women, wine, exhauſt our frame;
" But life itſelf is drawn from them."

' Equally eaſy will it be to illuſtrate the two kinds of debility, termed *direct* and *indirect*, which, according to Brown, are the cauſe of all diſeaſes. If the quantity of ſtimulus or exciting power is proportioned to the quantity of excitability, that is, if no more excitement is drawn forth than is equal to the quantity of excitability produced, the human frame will be in a ſtate of health, juſt as the fire will be in a vigorous ſtate when no more air is blown in than is ſufficient to conſume the freſh ſupply of fuel conſtantly poured down by the tube behind. If a ſufficient quantity of ſtimulus is not applied, or air not blown in, the excitability in the man, and the fuel in the fire, will accumulate, producing direct debility; for the man will become weak, and the fire low. Carried to a certain degree, they will occaſion death to the firſt, and extinction to the laſt. If, again, an over proportion of ſtimulus be applied, or too much air blown in, the excitability will ſoon be waſted, and the matter of fuel almoſt ſpent. Hence will ariſe indirect debility, producing the ſame weakneſs in the man, and lowneſs in the fire, as before, and equally terminating, when carried to a certain degree, in death and extinction.

‘ As all the diſeaſes of the body, according to Dr Brown, are occaſioned by direct or indirect debility, in conſequence of too much or too little ſtimuli, ſo all the defects of the fire muſt ariſe from direct or indirect lowneſs, in conſequence of too much or too little air blown into it. As Brown taught that one debility was never to be cured by another, but both by the more judicious application of ſtimuli, ſo will be found the caſe in treating the defects of the fire. If the fire has become low, or the man weak, by the want of the needful quantity of ſtimulus, more muſt be applied, but very gently at firſt, and increaſed by degrees, leſt a ſtrong ſtimulus applied to the accumulated excitability ſhould produce death ; as in the caſe of a limb benumbed with cold (that is, weakened by the accumulation of its excitability in conſequence of the abſtraction of the uſual ſtimulus of heat), and ſuddenly held to the fire, which we know from experience is in danger of mortification ; or as in the caſe of the fire becoming very low by the accumulation of the matter of fuel, when the feeble flame, aſſailed by a ſudden and ſtrong blaſt of air, would be overpowered and put out, inſtead of being nouriſhed and increaſed. Again, if the man or the fire have been rendered indirectly weak, by the application of too much ſtimulus, we are not ſuddenly to withdraw the whole, or even a great quantity of the exciting powers or air, for then the weakened life and diminiſhed flame might ſink entirely ; but we are by little and little to diminiſh the overplus of ſtimulus, ſo as to enable the excitability, or matter of fuel, gradually to recover its proper proportion. Thus a man who has injured his conſtitution by the abuſe of ſpirituous liquors is not ſuddenly to be reduced to water alone, as is the practice of ſome phyſicians, but he is to be treated as the judicious Dr Pitcairn of Edinburgh is ſaid to have treated a Highland chieftian, who applied to him for advice in this ſituation. The Doctor gave him no medicines, and only exacted a promiſe of him, that he would every day put in as much wax into the wooden *queich*, out of which he drank his whiſky, as would receive the impreſſion of his arms. The wax thus gradually accumulating, diminiſhed daily the quantity of the whiſky, till the whole *queich* was filled with wax ; and the chieftain was thus gradually, and without injury to his conſtitution, cured of the habit of drinking ſpirits.

‘ Theſe analogies might be purſued farther ; but my object is ſolely to furniſh ſome general ideas, to prepare the reader for entering more eaſily into the Brunonian theory, which I think he will be enabled to do after peruſing what I have ſaid. The great excellence of that theory, as applied, not only to the practice of phyſic, but to the general conduct of the health, is, that it impreſſes on the mind a ſenſe of the impropriety and danger of going from one extreme to another. The human frame is capable of enduring great varieties, if time be given it to accommodate itſelf to different ſtates. All the miſchief is done in the tranſition from one ſtate to another. In a ſtate of low excitement, we are not raſhly to induce a ſtate of high excitement ; nor when elevated to the latter, are we ſuddenly to deſcend to the former, but ſtep by ſtep, and as one who from the top of a high tower deſcends to the ground. From haſty and violent changes the human frame always ſuffers ; its particles are torn aſunder, its organs injured, the vital principle impaired, and diſeaſe, often death, is the inevitable conſequence.

‘ I have only to add, that though in this illuſtration of the Brunonian ſyſtem (written ſeveral years ago), I have ſpoken of a tube conſtantly pouring in freſh fuel, becauſe I could not otherwiſe convey to the reader a familiar idea of the power poſſeſſed by all living ſyſtems, to renew their excitability when exhauſted ; yet it may be proper to inform the ſtudent, that Dr Brown ſuppoſed every living ſyſtem to have received at the beginning its determinate portion of excitability ; and, therefore, although he ſpoke of the exhauſtion, augmentation, and even renewal of excitability, I do not think it was his intention to induce his pupils to think of it as a kind of fluid ſubſtance exiſting in the animal, and ſubject to the law by which ſuch ſubſtances are governed. According to him, excitability was an unknown *ſomewhat*, ſubject to peculiar laws of its own, and whoſe different ſtates we were obliged to deſcribe (though inaccurately) by terms borrowed from the qualities of material ſubſtances.’

“ The Brunonian ſyſtem has frequently been charged with promoting intemperance. The objection is ſerious ; but the view already given of its principles ſhews it to be groundleſs. No writer had inſiſted ſo much upon the dependence of life on external cauſes, or ſo ſtrongly ſtated the inevitable conſequences of exceſs. And there are no means of promoting morality upon which we can rely, except the knowledge of the true relations between man and other beings or bodies. For by this knowledge we are directly led to ſhun what is hurtful, and purſue what is ſalutary. And in what elſe does moral conduct, as far it regards the individual, conſiſt ? It may be ſaid that the author's life diſproves the juſtneſs of this repreſentation : his life, however, only ſhews the ſuperior power of other cauſes, and of bad habits in particular ; and I am ready to acknowledge the little efficacy of inſtruction when bad habits are formed. Its great uſe conſiſts in preventing their formation ; for which reaſon popular inſtruction in medicine would contribute more to the happineſs of the human ſpecies, than the complete knowledge of every thing which is attempted to be taught in education, as it is conducted at preſent. But though the principles of the ſyſtem in queſtion did not correct the propenſities of its inventor, it does not follow that they tend to produce the ſame propenſities in others.”

BRUCE (James, Eſq; F. R. S.), the celebrated Abyſſinian traveller, was born, 1730, at Kinnaird houſe, in the pariſh of Larbert and county of Stirling. His deſcent by both parents was ancient and honourable ; and of that deſcent he was, perhaps, too proud. His grandfather was —— Hay, Eſq; of Woodcockdale, in the county of Linlithgow, who, marrying Miſs Bruce, the heireſs of Kinnaird, gave the name of *Bruce* to all his deſcendants.

Perhaps this change of name may have taken place in obedience to the deed by which the eſtate of Kinnaird was ſettled on Mrs Hay's children ; but it is a change which, in a country like Scotland, where antiquity of deſcent is highly valued, any man would voluntarily have adopted, who had married the heireſs of ſuch

ſuch a family. The Bruces of Kinnaird had been in poſſeſſion of that eſtate for three centuries: they were deſcended from a younger ſon of Robert de Bruce, the competitor with Baliol for the crown of Scotland. It would readily occur, that the knowledge of ſuch a deſcent would be beſt preſerved by continuing the name of their great anceſtor; and we have reaſon to believe, that the ſubject of this memoir was not much delighted when put in mind, as he frequently was, that, though the heir of the line, he was not the *male* heir of that branch of the illuſtrious family.

As he was allied to royalty by his father and grandmother, through his mother he was related to ſome of the moſt reſpectable families in the kingdom. She was the daughter of James Graham, Eſq; of Airth, dean of the faculty of advocates, and judge of the high court of admiralty in Scotland, by Marion, daughter of James Hamilton Eſq; of Pencaitland; and to a man of our traveller's turn of mind, there can be no doubt but that it muſt have afforded much ſatisfaction to think, that no family ranks higher in Scotland than thoſe of Bruce, Graham, and Hamilton. In him, however, it was weakneſs to be proud, if indeed he was proud, of family; for the talents beſtowed upon him by nature, or, to ſpeak more properly, by nature's God, would have made him great though he had been born on a dunghill. He would indeed have been, in all probability, much greater than he was, had he not been in poſſeſſion of the phantom of birth to gratify much of his ambition; for the facility with which he maſtered every ſtudy in which he engaged, would have carried him quickly to the top of the moſt honourable profeſſion.

Mr Bruce was inſtructed in grammatical learning at the ſchool of Harrow on the Hill, in the county of Middleſex, where he gave the moſt unequivocal proofs of genius, and acquired a very conſiderable knowledge of the Greek and Latin languages. It was cuſtomary with him to perform, not only his own exerciſes, but alſo the exerciſes of ſuch of his companions as were not equal to the taſk themſelves. Among theſe was his maternal uncle, who was frequently indebted to his aſſiſtance, and, on one occaſion, produced a copy of verſes of his compoſition, which excited, not only the applauſe, but the admiration of their maſter. Mr Graham, who was but a few months older than Mr Bruce, had, for ſome tranſgreſſion (we know not what), been puniſhed, as boys in the great ſchools in England are often puniſhed, by having a taſk ſet him, which he ſoon found himſelf unable to perform. His nephew deſired him to be under no uneaſineſs, promiſing to furniſh him with the verſes before the time at which they were to be given in. He was as good as his word; but the maſter of the ſchool ſoon diſcovering that they were not the performance of Mr Graham, exclaimed, that the author of theſe verſes, whoever he was, might apply to himſelf the words of Horace,

—— *Sublimi feriam ſidera vertice.*

While Mr Bruce was at Harrow, and for a year or two after he had left it, he was of a very delicate frame, and appeared to his friends to be threatened with a conſumption. The truth is, that he was uncommonly tall for his age, and felt all the feebleneſs of joints and other bodily weakneſſes to which overgrown boys are generally ſubject. His father intended him for the profeſſion of the law; and, upon his return from Harrow, he was entered into the univerſity of Edinburgh, where he went through a regular courſe of ſtudy to fit him for being enrolled in the body of advocates: but for ſome reaſon, which we do not perfectly know, he relinquiſhed the ſtudy of law for the purſuits of trade; and, going to London, entered into partnerſhip with a wine merchant of the name of Allen, whoſe daughter he married.

That lady falling into a bad ſtate of health, Mr Bruce took her abroad, in hopes that travelling would be attended with beneficial effects; but in theſe he was diſappointed, as ſhe died within a year after her marriage. He was induced, in order to diſpel his grief, to continue his travels; during which his father dying (at Edinburgh, 4th May 1758), the inheritance of his anceſtors devolved upon him, and he returned to Britain. Some of his ſubſequent tranſactions ſhall now be related in his own words.

" Every one will remember that period, ſo glorious to Britain, the latter end of the miniſtry of the late earl of Chatham. I was then returned from a tour through the greateſt part of Europe, particularly through the whole of Spain and Portugal, between whom there was then the appearance of an approaching war.

" I was about to retire to a ſmall patrimony I had received from my anceſtors, in order to embrace a life of ſtudy and reflection, nothing more active appearing within my power, when chance threw me unexpectedly into a very ſhort and very deſultory converſation with Lord Chatham.

" It was a few days after this that Mr Wood, then under-ſecretary of ſtate, my zealous and ſincere friend, informed me that Lord Chatham intended to employ me upon a particular ſervice; that, however, I might go down for a few weeks to my own country to ſettle my affairs, but, by all means, to be ready upon a call. Nothing could be more flattering to me than ſuch an offer, when ſo young; to be thought worthy by Lord Chatham of any employment, was doubly a preference. No time was loſt on my ſide; but juſt after receiving orders to return to London, his lordſhip had gone to Bath, and reſigned his office.

" This diſappointment, which was the more ſenſible to me that it was the firſt I had met with in public life, was promiſed to be made up to me by Lord Egremont and Mr George Grenville. The former had been long my friend; but unhappily he was then far gone in a lethargic indiſpoſition, which threatened, and did very ſoon put a period to his exiſtence. With Lord Egremont's death my expectations vaniſhed. Further particulars are unneceſſary; but I hope that, at leaſt in part, they remain in that breaſt where they naturally ought to be, and where I ſhall ever think, not to be long forgotten, is to be rewarded.

" Seven or eight months were paſſed in an expenſive and fruitleſs attendance in London, when Lord Halifax was pleaſed, not only to propoſe, but to plan for me a journey of conſiderable importance, and which was to take up ſeveral years. His lordſhip ſaid, that nothing could be more ignoble than, at ſuch a time of life, at the height of my reading, health, and activity, I ſhould, as it were, turn peaſant, and voluntarily bury myſelf in obſcurity and idleneſs; that though war was now drawing faſt to an end, full as honourable a competition remained

mained among men of ſpirit, which ſhould acquit themſelves beſt in the dangerous line of uſeful adventure and diſcovery.

"He obſerved, that the coaſt of Barbary, which might be ſaid to be juſt at our door, was yet but partially explored by Dr Shaw, who had only illuſtrated (very judiciouſly indeed) the geographical labours of Sanſon; that neither Dr Shaw nor Sanſon had been, or pretended to be, capable of giving the public any detail of the large and magnificent remains of ruined architecture, which they both vouch to have ſeen in great quantities, and of exquiſite elegance and perfection, all over the country. Such had not been their ſtudy, yet ſuch was really the taſte that was required in the preſent times. He wiſhed, therefore, that I ſhould be the firſt, in the reign juſt now beginning, to ſet an example of making large additions to the royal collection; and he pledged himſelf to be my ſupport and patron, and to make good to me, upon this additional merit, the promiſes which had been held forth to me by former miniſters for other ſervices.

"The diſcovery of the ſource of the Nile was alſo a ſubject of theſe converſations, but it was always mentioned to me with a kind of diffidence, as if to be expected from a more experienced traveller. Whether this was but another way of exciting me to the attempt I ſhall not ſay; but my heart, in that inſtant, did me juſtice to ſuggeſt, that this too was either to be atchieved by me, or to remain as it had done for theſe laſt 2000 years, a defiance to all travellers, and an opprobrium to geography.

"Fortune ſeemed to enter into this ſcheme. At the very inſtant, Mr Aſpinwall, very cruelly and ignominiouſly treated by the dey of Algiers, had reſigned his conſulſhip, and Mr Ford a merchant, formerly the dey's acquaintance, was named in his place. Mr Ford was appointed, and, dying a few days after, the conſulſhip became vacant. Lord Halifax preſſed me to accept of this as containing all ſorts of conveniences for making the propoſed expedition.

"This favourable event finally determined me. I had all my life applied unweariedly, perhaps with more love than talent, to drawing, the practice of mathematics, and eſpecially that part neceſſary to aſtronomy. The tranſit of Venus was at hand. It was certainly known that it would be viſible once at Algiers, and there was great reaſon to expect it might be twice. I had furniſhed myſelf with a large apparatus of inſtruments, the completeſt of their kind, for the obſervation. In the choice of theſe, I had been aſſiſted by my friend Admiral Campbell, and Mr Ruſſel ſecretary to the Turkey Company: every other neceſſary had been provided in proportion. It was a pleaſure now to know that it was not from a rock or a wood, but from my own houſe at Algiers, I could deliberately take meaſures to place myſelf in the liſt of men of ſcience of all nations, who were then preparing for the ſame ſcientific purpoſe.

"Thus prepared, I ſet out for Italy, through France; and though it was in time of war, and ſome ſtrong objections had been made to particular paſſports, ſolicited by our government from the French ſecretary of ſtate, Monſieur de Choiſeul moſt obligingly waved all ſuch exceptions with regard to me, and moſt politely aſſured me, in a letter accompanying my paſſport, that thoſe difficulties did not in any ſhape regard me, but that I was perfectly at liberty to paſs through, or remain in, France with thoſe that accompanied me, without limiting their number, as ſhort or as long a time as ſhould be agreeable to me.

"On my arrival at Rome, I received orders to proceed to Naples, there to await his majeſty's further commands. Sir Charles Saunders, then with a fleet before Cadiz, had orders to viſit Malta before he returned to England. It was ſaid that the grand-maſter of that order had behaved ſo improperly to Mr Harvey (afterwards Lord Briſtol) in the beginning of the war, and ſo partially and unjuſtly between the two nations in the courſe of it, that an explanation on our part was become neceſſary. The grand-maſter no ſooner heard of my arrival at Naples, than, gueſſing the errand, he ſent off Chevalier Mazzini to London, where he at once made his peace and his compliments to his majeſty upon his acceſſion to the throne.

"Nothing remained now but to take poſſeſſion of my conſulſhip. I returned, without loſs of time, to Rome, and from thence to Leghorn, where, having embarked on board the Montreal man of war, I proceeded to Algiers.

"While at Naples, I received from ſlaves, redeemed from the province of Conſtantine, accounts of magnificent ruins they had ſeen while traverſing that country with their maſter the Bey. I ſaw the abſolute neceſſity there was for aſſiſtance, without which it was impoſſible for any one man, however diligent and qualified, to do any thing but bewilder himſelf. All my endeavours, however, had hitherto been unſucceſsful to perſuade any Italian to put himſelf wilfully into the hands of a people conſtantly looked upon by them in no better light than pirates. At laſt Mr Lumiſden, by accident, heard of a young man who was then ſtudying architecture at Rome, a native of Bologna, whoſe name was Luigi Balugani. I can appeal to Mr Lumiſden as to the extent of this perſon's practice and knowledge, and that he knew very little when firſt ſent to me. In the twenty months which he ſtaid with me at Algiers, by aſſiduous application to proper ſubjects under my inſtruction, he became a very conſiderable help to me, and was the only one that ever I made uſe of, or that attended me for a moment, or ever touched one repreſentation of architecture in any part of my journey."

Our traveller, when in Spain, had endeavoured to find acceſs to that immenſe collection of Arabic manuſcripts which were periſhing in the duſt of the eſcurial; but in vain. "All my ſucceſs (ſays he) in Europe terminated in the acquiſition of thoſe few printed Arabic books that I had found in Holland; and theſe were rather biographers than general hiſtorians, and contained little in point of general information. The ſtudy of theſe, however, and of Maracci's Koran, had made me a very tolerable Arab; a great field was opening before me in Africa to complete a collection of manuſcripts, an opportunity which I did not neglect.

"After a year ſpent at Algiers, conſtant converſation with the natives while abroad, and with my manuſcripts within doors, had qualified me to appear in any part of the continent without the help of an interpreter. Ludolf had aſſured his readers, that the knowledge of any oriental language would ſoon enable them to acquire the Ethiopic; and I needed only the ſame number of books to have made my knowledge of that language

guage go hand in hand with my attainments in the Arabic. My immediate proſpect of ſetting out on my journey to the inland parts of Africa had made me double my diligence; night and day there was no relaxation from theſe ſtudies, although the acquiring any ſingle language had never been with me either an object of time or difficulty."

At Algiers Mr Bruce was detained longer than he expected, in conſequence of a diſpute with the Dey concerning Mediterranean paſſes. This being adjuſted, he proceeded to Mahon, and from Mahon to Carthage. He next viſited Tunis and Tripoli, and travelled over the interior parts of theſe ſtates. At Bengazi, a ſmall town on the Mediterranean, he ſuffered ſhipwreck, and with extreme difficulty ſaved his life, though with the loſs of all his baggage. He afterwards ſailed to the iſles of Rhodes and Cyprus, and proceeding to Aſia Minor, travelled through a conſiderable part of Syria and Paleſtine, viſiting Haſſia, Latikea, Aleppo, and Tripoli; near which laſt city he was again in imminent danger of periſhing in a river. The ruins of Palmyra and Baalbec were next carefully ſurveyed and ſketched by him; and his drawings of theſe places are depoſited in the king's library at Kew; " the moſt magnificent preſent in that line," to uſe his own words, " ever made by a ſubject to his ſovereign."

It is much to be regretted that Mr Bruce publiſhed no particular account of theſe various journeys; from the nature of the places viſited, and the abilities of the man, much curious and uſeful information might have been expected. Some manuſcript accounts of different parts of them are ſaid to have been left by him, but whether in ſuch a ſtate as to be fit for publication, we have not learned.

In theſe various travels ſome years were paſſed; and Mr Bruce now prepared for the grand expedition, the accompliſhment of which had ever been neareſt his heart, the diſcovery of the ſources of the Nile. In the proſecution of that dangerous object, he left Sidon on the 15th of June 1768, and arrived at Alexandria on the 20th of that month. He proceeded from thence to Cairo, where he continued to the 12th of December following, when he embarked on the Nile; and in a very extraordinary boat, called a *canja*, of which he ſays the main-ſail yard was about 200 feet in length, he ſailed up that river as far as Syene, viſiting in the courſe of his voyage the ruins of Thebes, and the place where Memphis once ſtood, now known by the name of *Metrahenny*. Leaving Kenne on the Nile, 16th February 1769, he croſſed the deſert of the Thebaid to Coſſeir on the Red Sea, and arrived at Jidda on the 3d of May. In Arabia Felix he remained, not without making ſeveral excurſions, till the 3d of September, when he ſailed from Loheia, and arrived on the 19th at Maſuah, where he was detained near two months by the treachery and avarice of the Naybe of that place. It was not till the 15th of November that he was allowed to quit Arkeeko, near Maſua; and he arrived on the 15th of February 1770 at Gondar, the capital of Abyſſinia, where he ingratiated himſelf with the moſt conſiderable perſons of both ſexes belonging to the court. This he accompliſhed by being a phyſician in the city, a ſoldier in the field, a courtier every where, demeaning himſelf as conſcious that he was not unworthy of being a companion to the firſt of their nobility, and the king's gueſt, which is there a character, as it was with eaſtern nations of old, to which a certain ſort of conſideration is due. " To this I may add (ſays he), that, being in the prime of life, of no ungracious figure, having an accidental knack, which is not a trifle, of putting on the dreſs, and ſpeaking the language eaſily and gracefully, I cultivated, with the utmoſt aſſiduity, the friendſhip of the fair ſex, by the moſt modeſt and reſpectful diſtant attendance and obſequiouſneſs in public, abating juſt as much of that in private as ſuited their humours and inclination;" and jealouſy being a paſſion unknown in Abyſſinia, he thus acquired from the ladies great ſupport at court.

Several months were employed in attendance on the king, and in an unſucceſsful expedition round the lake of Dambea. Towards the end of October Mr Bruce ſet out for the ſources of the Nile; at which long deſired ſpot he arrived on the 14th of November; and his feelings on the accompliſhment of his wiſhes cannot better be expreſſed than in his own words:

" It is eaſier to gueſs than to deſcribe the ſituation of my mind at that moment; ſtanding in that ſpot which had baffled the genius, induſtry, and inquiry, of ancients and moderns for the courſe of near 3000 years. Kings had attempted this diſcovery at the head of armies, and each expedition was diſtinguiſhed from the laſt only by the difference of the numbers which had periſhed, and agreed alone in the diſappointment which had uniformly, and without exception, followed them all. Fame, riches, and honour, had been held out for a ſeries of ages to every individual of thoſe myriads thoſe princes commanded, without having produced one man capable of gratifying the curioſity of his ſovereign, or wiping off this ſtain upon the enterpriſe and abilities of mankind, or adding this deſideratum for the encouragement of geography. Though a mere private Briton, I triumphed here in my own mind over kings and their armies; and every compariſon was leading nearer and nearer to the preſumption, when the place itſelf where I ſtood, the object of my vain glory, ſuggeſted what depreſſed my ſhort-lived triumphs."

If theſe triumphs were ſhort-lived, they were equally ill-founded: for if the ſource of the Nile was ſeen by Mr Bruce, there can be no doubt of its having been likewiſe ſeen by the Portugueſe jeſuits. Of this we have elſewhere brought forward ſufficient proof; and the candid reader, who ſhall take the trouble to compare the extract printed at the bottom of this page (A), with our traveller's account of theſe coy fountains, as it ſtands

---

(A) " In the eaſtern part of this kingdom, on the declivity of a mountain, whoſe deſcent is ſo eaſy that it ſeems a beautiful plain, is that ſource of the Nile which has been ſought after at ſo much expence of labour, and about which ſuch a variety of conjectures hath been formed without ſucceſs. This ſpring, or rather theſe two ſprings, are two holes, each about two feet diameter, a ſtone's caſt diſtant from each other. The one is about five feet and an half in depth, at leaſt we could not get our plummet farther, perhaps becauſe it was ſtopped by roots, ſtands in his own book or in our article Nile (*Encycl.*), will be convinced that it was ridiculous in Mr Bruce, and is equally ridiculous in his friends, to pretend that he *diſcovered* what had baffled the genius of inquiry for the courſe of near 3000 years.

It was not, however, the conſciouſneſs of having been anticipated by the jeſuits (for theſe he without ceremony calls a ſet of liars), but the proſpect of danger to be encountered on his return to Europe, that caſt ſuch a damp on his preſent enjoyment. "I was but a few minutes (ſays he) arrived at the ſource of the Nile, through numberleſs dangers and ſufferings, the leaſt of which would have overwhelmed me, but for the continual goodneſs and protection of Providence; I was, however, but then half through my journey, and all thoſe dangers which I had already paſſed awaited me again on my return. I found a deſpondency gaining ground faſt upon me, which blaſted the crown of laurels I had too raſhly woven for myſelf."

When he returned to reſt the night of that diſcovery, repoſe was ſought for in vain. "Melancholy reflections upon my preſent ſtate, the doubtfulneſs of my return in ſafety, were I permitted to make the attempt, and the fears that even this would be refuſed, according to the rule obſerved in Abyſſinia with all travellers who have once entered the kingdom; the conſciouſneſs of the pain that I was then occaſioning to many worthy individuals, expecting daily that information concerning my ſituation which it was not in my power to give them: ſome other thoughts, perhaps ſtill nearer the heart than thoſe, crowded upon my mind, and forbade all approach of ſleep.

"I was, at that very moment, in poſſeſſion of what had for many years been the principal object of my ambition and wiſhes; indifference which, from the uſual infirmity of human nature, follows, at leaſt for a time, complete enjoyment, had taken place of it. The marſh, and the fountains, upon compariſon with the riſe of many of our rivers, became now a trifling object in my ſight. I remembered that magnificent ſcene in my own native country, where the Tweed, Clyde, and Annan, riſe in one hill; three rivers I now thought not inferior to the Nile in beauty, preferable to it in the cultivation of thoſe countries through which they flow; ſuperior, vaſtly ſuperior, to it in the virtues and qualities of the inhabitants, and in the beauty of its flocks, crowding its paſtures in peace, without fear or violence from man or beaſt. I had ſeen the riſe of the Rhine and Rhone, and the more magnificent ſources of the Soane; I began, in my ſorrow, to treat the inquiry about the ſource of the Nile as a violent effort of a diſtempered fancy.

'What's Hecuba to him, or he to Hecuba,
'That he ſhould weep for her?'

Grief and deſpondency now rolling upon me like a torrent, relaxed, not refreſhed, by unquiet and imperfect ſleep, I ſtarted from my bed in the utmoſt agony; I went to the door of my tent, every thing was ſtill; the Nile, at whoſe head I ſtood, was not capable either to promote or to interrupt my ſlumbers, but the coolneſs and ſerenity of the night braced my nerves, and chaſed away thoſe phantoms that while in bed had oppreſſed and tormented me.

"It was true that numerous dangers, hardſhips, and ſorrows, had beſet me through this half of my excurſion; but it was ſtill as true, that another Guide, more powerful than my own courage, health, or underſtanding, if any of them can be called man's own, had uniformly protected me in all that tedious half. I found my confidence not abated, that ſtill the ſame Guide was able to conduct me to my wiſhed-for-home. I immediately reſumed my former fortitude, conſidered the Nile as indeed no more than riſing from ſprings as all other rivers do, but widely differing in this, that it was the palm for 3000 years held out to all the nations of the world as a *detur digniſſimo*, which in my cool hours I had thought was worth the attempting at the riſk of my life, which I had long either reſolved to loſe, or lay this diſcovery a trophy in which I could have no competitor, for the honour of my country, at the feet of my ſovereign, whoſe ſervant I was."

How unworthy is this ranting reflection of the greatneſs of mind which Mr Bruce on other occaſions unqueſtionably diſplayed! Had he indeed been the firſt European who diſcovered thoſe pitiful holes from which the Nile is ſaid to flow, his merit would not have conſiſted in travelling from Gondar to the village Geeſh, and viewing the fountains which are at that village the objects of idolatrous adoration, but in the addreſs with which he contrived to make himſelf the favourite of all the factions which agitated a barbarous and almoſt inhuman nation. In managing thoſe factions, he was indeed great; but he ſeems to have valued himſelf more upon looking at three ſprings, of which it is far from being certain that they are the ſources of the Nile (ſee Nile in this *Suppl.*), and of which two had certainly been examined more than a century before he was born, by different miſſionaries from the kingdom of Portugal! This, however, he calls the object of his wiſhes; and

---

roots, for the whole place is full of trees: of the other, which is ſomewhat leſs, with a line of ten feet, we could find no bottom, and were aſſured by the inhabitants that none ever had been found. It is believed here that theſe ſprings are the vents of a great ſubterraneous lake; and they have this circumſtance to favour their opinion, that the ground is always moiſt, and ſo ſoft that the water boils up under foot as one walks upon it. Such is the ground round about theſe fountains. At a little diſtance to the ſouth is a village named *Guix* (the *Geeſh* of Mr Bruce), through which the way lies to the top of the mountain, whence the traveller diſcovers a vaſt extent of land, which appears like a deep valley, though the mountain riſes ſo imperceptibly, that thoſe who go up or down it are ſcarce ſenſible of any declivity."—*Johnſon's Tranſlation of Father Lobo's Voyage to Abyſſinia*, Chap. X.

The only difference between Lobo's and Bruce's account of theſe fountains worthy of notice is, that the former found but *two*, while the latter found *three* holes; but Bruce ſays expreſsly, that the holes are partly artificial; and Lobo's deſcription of them indicates the ſame thing. It is therefore not improbable that there may now be four or five holes.

and having now accompliſhed it, he bent his thoughts on his return to his native country.

He arrived at Gondar on the 19th November 1770; but found, after repeated ſolicitations, that it was by no means an eaſy taſk to obtain permiſſion to quit Abyſſinia. A civil war in the mean time breaking out (no uncommon occurrence in that barbarous country), ſeveral engagements took place between the king's forces and the troops of the rebels, particularly three actions at a place called Serbraxos on the 19th, 20th, and 23d of May 1771. In each of them Mr Bruce acted a conſiderable part; and for his valiant conduct in the ſecond received, as a reward from the king, a chain of gold, of 184 links, each link weighing $3\frac{1}{11}$ dwts. or ſomewhat more than $2\frac{1}{4}$ lbs. troy in all. At Gondar, after theſe engagements, he again preferred the moſt earneſt entreaties to be allowed to return home, entreaties which were long reſiſted; but his health at laſt giving way, from the anxiety of his mind, the king conſented to his departure, on condition of his engaging by oath (B) to return to him in the event of his recovery, with as many of his kindred as he could engage to accompany him.

After a reſidence of nearly two years in that wretched country, Mr Bruce left Gondar on the 16th of December 1771, taking the dangerous way of the deſert of Nubia, in place of the more eaſy road of Maſuah, by which he entered Abyſſinia. He was induced to take this route from his knowledge and former experience of the cruel and ſavage temper of the Naybe of Maſuah. Arriving at Teawa the 21ſt March 1772, he had the misfortune to find the Shekh Fidele of Atbara, the counterpart of the Naybe of Maſuah in every bad quality: by his intrepidity and prudence, however, and by making good uſe of his foreknowledge of an eclipſe of the moon, which happened on the 17th of April, he was permitted to depart next day, and he arrived at Sennaar on the 29th of the ſame month.

Mr Bruce was detained upwards of four months at that miſerable and inhoſpitable place; the inhabitants of which he deſcribes in theſe expreſſive words: "War and treaſon ſeem to be the only employment of theſe horrid people, whom heaven has ſeparated by almoſt impaſſable deſerts from the reſt of mankind, confining them to an accurſed ſpot, ſeemingly to give them an earneſt in time of the only other worſe which he has reſerved to them for an eternal hereafter." This delay was occaſioned by the villany of thoſe who had undertaken to ſupply him with money; but at laſt, by diſpoſing of 178 links of his gold chain, the well-earned trophy of Serbraxos, he was enabled to make preparation for his dangerous journey through the deſerts of Nubia.

He left Sennaar on the 5th of September, and arrived on the 3d of October at Chendi, which he quitted on the 20th, and travelled through the deſert of Gooz, to which village he came on the 26th of October. On the 9th of November he left Gooz, and entered upon the moſt dreadful and dangerous part of his journey; the perils attending which he has related with a power of pencil not unworthy of the greateſt maſters. All his camels having periſhed, Mr Bruce was under the neceſſity of abandoning his baggage in the deſert, and with the greateſt difficulty reached Aſſouan upon the Nile on the 29th of November.

After ſome days reſt, having procured freſh camels, he returned into the deſert, and recovered his baggage, among which is particularly to be remarked a quadrant (of three feet radius) ſupplied by Louis XV. from the Military Academy at Marſeilles; by means of which noble inſtrument, now depoſited in the Muſeum at Kinnaird, Mr Bruce was enabled with preciſion and accuracy to fix the relative ſituations of the ſeveral remote places he viſited.

On the 10th of January 1773, after more than four years abſence, he arrived at Cairo, where, by his manly and generous behaviour, he ſo won the heart of Mahomet Bey, that he obtained a firman, permitting the commanders of Engliſh veſſels belonging to Bombay and Bengal to bring their ſhips and merchandiſe to Suez, a place far preferable in all reſpects to Jidda, to which they were formerly confined. Of this permiſſion, which no European nation could ever before acquire, many Engliſh veſſels have ſince availed themſelves; and it has proved peculiarly uſeful both in public and private diſpatches. Such was the worthy concluſion of his memorable journey through the deſert; a journey which, after many hardſhips and dangers, terminated in obtaining this great national benefit.

At Cairo Mr Bruce's earthly career had nearly been concluded by a diſorder in his leg, occaſioned by a worm in the fleſh. This accident kept him five weeks in extreme agony; and his health was not re-eſtabliſhed till a twelvemonth afterwards, at the baths of Porretta in Italy. On his return to Europe, Mr Bruce was received with all the admiration due to ſo exalted a character. After paſſing ſome conſiderable time in France, particularly at Montbard, with his friend the Comte de Buffon, by whom he was received with much hoſpitality, and is mentioned with great applauſe, he at laſt reviſited his native country, from which he had been upwards of twelve years abſent.

It was now expected that he would take the earlieſt opportunity of giving to the world a narrative of his travels, in which the public curioſity could not but be deeply intereſted. But ſeveral circumſtances contributed to delay the publication; and what theſe were will be beſt related in his own words:

"My friends at home gave me up for dead; and as my death muſt have happened in circumſtances difficult to have been proved, my property became as it were a *hæreditas jacens*, without an owner, abandoned in common to thoſe whoſe original title extended no further than temporary poſſeſſion.

"A number of law-ſuits were the inevitable conſequences of this upon my return. To theſe diſagreeable avocations, which took up much time, were added others ſtill more unfortunate. The relentleſs ague, caught at Bengazi,

---

(B) With regard to this oath, Mr Bruce ſays, that he hopes the difficulty of performing it extinguiſhed the ſin of breaking it; and that, at any rate, it being merely perſonal, his engagement to return ceaſed with the death of the king, of which he received intelligence during his ſtay at Sennaar.

Bengazi, maintained its ground, at times, for a ſpace of more than 16 years, though every remedy had been uſed, but in vain; and what was worſt of all, a lingering diſtemper had ſeriouſly threatened the life of a moſt near relation (his ſecond wife), which, after nine years conſtant alarm, where every duty bound me to attention and attendance, conducted her at laſt, in very early life, to her grave."

Amidſt the anxiety and the diſtreſs thus occaſioned, Mr Bruce was by no means neglectful of his private affairs. He conſiderably improved his landed property, encloſing and cultivating the waſte grounds, and he highly embelliſhed his paternal ſeat, making many additions to the houſe, one in particular of a noble muſeum, filled with the moſt precious ſtores of oriental literature, large collections of drawings made, and curious articles obtained, during his far extended peregrinations. An excellent ſtratum of coal at Kinnaird drew much of his attention: he erected ſteam engines of the moſt approved conſtruction, and placed his coalery on ſuch a footing that, at the period of his deceaſe, it produced about 2000l. a-year.

The termination of ſome law-ſuits, and of other buſineſs, which had occupied much of his time, having at length afforded leiſure to Mr Bruce to put his materials in order, his greatly deſired and long expected work made its appearance in 1790, in five large quarto volumes, embelliſhed with plates and charts. It is unneceſſary, and might be tedious, to enter at preſent into any critic or analyſis of this celebrated work. It is univerſally allowed to be replete with much curious and uſeful information; and to abound in narratives which at once excite our admiration and intereſt our feelings. The very ſingular and extraordinary picture which it gives of Abyſſinian manners, ſtartled the belief of ſome; but theſe manners, though ſtrange in the ſight of an European, are little more than might be expected in ſuch a barbarous country; and had an enlightened philoſopher viſited Scotland in the times of our earlieſt monarchs, he might perhaps have witneſſed and related ſcenes, different indeed from what Mr Bruce ſaw in Abyſſinia, but which to us would have ſeemed equally ſtrange.

A more ſerious objection to the truth of Mr Bruce's narrative was ſtarted by an anonymous, but able, critic *, in an Edinburgh newſpaper, ſoon after the publication, from the account of two aſtronomical phenomena, which *could not poſſibly have happened*, as Mr Bruce aſſerts. The firſt of theſe is the appearance of the new moon at Furſhout, during Mr Bruce's ſtay in that place, which he mentions to have been from 25th December 1768 to the 7th of January 1769; and on a particular day in that interval aſſerts, that the new moon was ſeen by a fakir, and was found by the ephemerides to be three days old; whereas it is certain that the moon changed on the 8th of January 1769. The other phenomenon appears equally impoſſible. At Teawa Mr Bruce ſays he terrified the Shekh by foretelling that an eclipſe of the moon was to take place at four afternoon of the 17th of April 1772; that accordingly, ſoon after that hour, he ſaw the eclipſe was begun; and when the ſhadow was half over, told the Shekh that in a little time the moon would be totally darkened. Now, by calculation, it is certain that at Teawa this eclipſe muſt have begun at 36 minutes paſt four, and the moon have been totally covered at 33 minutes paſt five; while the ſun ſet there a few minutes paſt ſix, before which time the moon, then in oppoſition, could not have riſen: ſo that as the moon roſe totally eclipſed, Mr Bruce could not ſee the ſhadow half over the diſk, nor point it out to the Shekh. To theſe objections, which appear unſurmountable, Mr Bruce made no reply, though in converſation he ſaid he would do it in the ſecond edition of his book.

Theſe are miſtakes which can hardly be accounted for by attributing them to the inaccuracy of his notes, or indeed to any cauſe which we are inclined to name; and perhaps he has fallen into a miſtake of the ſame kind in his account of the enormous main-ſail yard of the *canja*, in which he ſailed up the river Nile. To every man who has but dipped into the ſcience of mechanics, it is known that a beam of wood 100 feet in length, muſt be of proportional thickneſs, or it would fall in pieces by its own weight. This thickneſs muſt be greatly increaſed, to enable it to bear the ſtrain occaſioned by a prodigious ſail filled with wind; and thoſe only who have been at the Nile, and have ſeen the canjas, can ſay, whether theſe veſſels, or indeed any veſſels which can be employed on that river, would not be overſet by yards,

——To equal which, the talleſt pine
Hewn on Norwegian hills, to be the maſt
Of ſome great admiral, were but a wand.

The language of the work is in general harſh and unpoliſhed, though ſometimes animated. Too great a diſplay of vanity runs through the whole, and the apparent facility with which the traveller gained the moſt familiar acceſs to the courts, and even to the harams of the ſovereigns of the countries through which he paſſed, is apt to create in readers ſome doubts of the accuracy of the narration. Yet there appears upon the whole ſuch an air of manly veracity, and circumſtances are mentioned with a minuteneſs ſo unlike deceit, that theſe doubts are overcome by the general impreſſion of truth, which the whole detail irreſiſtibly faſtens upon the mind. The character of Ras Michael has often ſtruck us, as containing very ſtrong internal evidence of its having been taken from nature; for it is ſuch a character, at once extraordinary and conſiſtent, as neither Mr Bruce, nor perhaps any writer ſince Shakeſpeare, had genius to feign.

The firſt impreſſion of the book being almoſt diſpoſed of, Mr Bruce had ſtipulated with an eminent bookſeller in London for a ſecond edition to be publiſhed, we think in octavo; and he was buſy in preparing that edition for the preſs when death removed him from this tranſitory ſtage. On the 26th of April 1794 he entertained ſome company at Kinnaird-houſe with his uſual hoſpitality and elegance. About eight o'clock in the evening, when his gueſts were ready to depart, he was handing one of the ladies down ſtairs, when, having reached the ſeventh or eighth ſtep from the bottom, his foot ſlipped, and he fell down headlong. He was taken up ſpeechleſs; his face, particularly the forehead and temples, being ſeverely cut and bruiſed, and the bones of his hands broken. He continued in a ſtate of apparent inſenſibility for eight or nine hours, and expired on Sunday the 27th, in the 64th year of his age.

Mr Bruce's ſecond wife, whom he married on the 20th

---

* Suppoſed o be Dr Rotheram. rofeſſor of naturalphi-oſophy in he univerity of St Andrew's.

20th May 1776, was Mary, eldeſt daughter of Thomas Dundas, Eſq; of Carron-hall, by Lady Janet Maitland, daughter of Charles ſixth Earl of Lauderdale. By that lady, who, after a ſevere and lingering indiſpoſition, died in 1784, he had three children, of whom one ſon and one daughter ſurvive him.

Mr Bruce's perſon was large, his height exceeding ſix feet, his bulk being in proportion to his height; and at the period when he entered on his dangerous expedition, he was equally remarkable for ſtrength and for agility. To thoſe who never beheld him, the engraved medallion in the title pages of the firſt and third volumes of his Travels will convey ſome idea of his features. He excelled in all manly accompliſhments, being trained to exerciſe and fatigue of every kind. He was a hardy, practiſed, and indefatigable ſwimmer; and his long reſidence among the Arabs had given him a more than ordinary facility in managing the horſe. In the uſe of fire-arms he was ſo unerring, that in innumerable inſtances he never failed to hit the mark; and his dexterity in handling the ſpear and lance on horſeback was alſo uncommonly great. He was maſter of moſt languages; and was ſo well ſkilled in oriental literature, that he reviſed the New Teſtament in the Ethiopic, Samaritan, Hebrew, and Syriac, making many uſeful notes and remarks on difficult paſſages. He had applied from early youth to mathematics, drawing, and aſtronomy, and had acquired ſome knowledge of phyſic and ſurgery. His memory was aſtoniſhingly retentive, and his mind vigorous. He was dexterous in negociation, a maſter of public buſineſs, and animated with the warmeſt zeal for the glory of his king and country. Such, at leaſt, is *his own* repreſentation of his character; and though an impartial judge would probably make conſiderable abatement for the natural bias of a man drawing his own portrait, yet it cannot be denied, that in perſonal accompliſhments Mr Bruce equalled, if not exceeded, moſt of his contemporaries.

Thus accompliſhed, he could not but be eminently fitted for an attempt ſo full of difficulty and danger as what he called the diſcovery of the ſources of the Nile: no one who peruſes his account of the expedition, can fail to pay an unfeigned tribute of admiration to his intrepidity, manlineſs, and uncommon dexterity, in extricating himſelf out of ſituations the moſt dangerous and alarming, in the courſe of his long and hazardous journey; not to mention his conduct during his reſidence in Abyſſinia, his behaviour at Maſuah, Teawa, and Sennaar, evinces the uncommon vigour of his mind: but it was chiefly during his paſſage through the Nubian deſert, that his fortitude, courage, and prudence, appeared to the greateſt advantage. Of his learning and ſagacity, his delineation of the courſe of Solomon's fleet from Tarſhiſh to Ophir, his account of the cauſe of the inundations of the Nile, and his comprehenſive view of the Abyſſinian hiſtory, afford ample proofs. It muſt indeed be confeſſed, that in his account of the inundations of the Nile, as well as in his delineation of the courſe of Solomon's fleet, he has not the merit of originality; but on both theſe occaſions he has ſtated the hypotheſis which he maintains with greater clearneſs, and ſupported it with more plauſible arguments, than any other author whoſe writings have fallen into our hands; and it was ſurely to his honour, that as ſoon as he learned that his hypotheſis reſpecting Ophir and Tarſhiſh had been controverted by Dr Doig of Stirling, he earneſtly courted the acquaintance of that eminent ſcholar.

After his return to his own country, he reſided moſtly at Kinnaird; and till he became corpulent, ſpent much of his time in the various ſports of the field, in which he engaged with great ardour. Though ſtudious in youth, and at all times a ſtranger to intemperance and diſſipation, he read but little in his later years; and ſeemed to find his chief pleaſure in converſation, eſpecially the converſation of well-informed ladies. In his friendſhips he ſometimes appeared to be capricious, attaching himſelf to men in whoſe heads and hearts no other perſon could perceive a charm for a mind like his. Though in his own dealings he was always juſt and honourable, he was too ready to apprehend unfairneſs in others, and to expreſs ſuch apprehenſions with undue warmth. To ſtrangers he was often arrogant, and ſometimes inſolent; but in his own family he was an affectionate huſband, a kind father, an agreeable entertainer, and to his ſervants a maſter perhaps too indulgent. In converſation, as well as in his writings, he embraced every opportunity of expreſſing a deep and lively ſenſe of the care of a ſuperintending Providence, without which he was convinced that there could be no ſafety in human ſtrength or human foreſight. His belief of the Chriſtian religion reſted on the ſureſt grounds; and ſuch was his veneration for the ſacred writings, that for ſome years before his death they ſeemed to occupy all the time which he gave to ſtudy. He read no ſermons, however elegant; and diſſuaded others from ſuch reading. "Read the Bible (ſaid he), and you will ſoon perceive the emptineſs of the moſt applauded ſermons."

BUCK-WHEAT, a ſpecies of POLYGANUM (ſee that article *Encycl.*), was firſt introduced into Europe about the end of the 15th or the beginning of the 16th century. According to ſome botaniſts, who lived at that period, its native country is the northern parts of Aſia, whence it was brought to Germany and France, where, about the year 1587, it was the common food of the poor.

A new ſpecies of this grain, or, to ſpeak perhaps more properly, a variety of this ſpecies, has been for ſome time known under the name of *Siberian* buck-wheat, which appears to have conſiderable advantages over the former. It was ſent from Tartary to St Peterſburgh by the German botaniſts, who travelled thro' that country in the beginning of the preſent century; and it has thence been diſperſed over all Europe. Linnæus received the firſt ſeeds of it in 1737 from Garber the botaniſt, and deſcribed the plant in his *Hortus Cliffertionus*. After this it was mentioned by Ammann in 1739: but it muſt have been earlier known in Germany; for in 1733 it was growing in the garden of Dr Ehrhart at Memmingen. In Siberia this plant ſows itſelf for four or five years by the grains that drop; but at the end of that period the land becomes ſo full of tares that it is choked, and muſt be ſown afreſh. Even in the economical gardens of Germany, it is propagated in the ſame manner; and in that country it is in ſome places found growing wild, though it is nowhere cultivated in the neighbourhood. It is not, however, indigenous, otherwiſe Ehrhart might have raiſed it from German ſeed, which it ſeems he could not find in 1733.

See much curious information concerning this plant in Profeſſor Beckmann's *Hiſtory of Inventions and Diſcoveries*.

BULAM, or BULAMA, as it is more uſually called, forms part of the Archipelago, or cluſter of iſlands, lying on the weſtern or windward coaſt of Africa, and known by the name of the *Biſſaos* or *Biſſagos*, which are ſuppoſed to have been celebrated by the ancients under the appellation of the *Heſperides*. It is ſituated at the mouth of the Rio Grande, in 11° N. Lat. and 15° W. Long. from the meridian of London; and is between ſeventeen and eighteen leagues long, and from four to five broad.

This iſland has become an intereſting object to the inhabitants of Great Britain, in conſequence of its having been purchaſed in the year 1792 by a ſociety inſtituted for the ſame humane purpoſes with thoſe which gave riſe to the Sierra-Leona company (ſee SIERRA-*Leona*, Encycl.) The Bulam aſſociation was formed towards the latter end of the year 1791; and they were induced to pitch upon that iſland as the moſt eligible tract for their intended colony, in conſequence of the flattering deſcription given of its climate, ſoil, and harbours, by M. Brue, formerly director-general of the French African companies.

The gentlemen originally appointed as truſtees for managing the concerns of the aſſociation at home were, *Paul Le Meſurier*, M. P.; *James Kirkpatrick*, Eſq; *George Hartwell*, Eſq; *Moſes Ximenes*, Eſq; *Sir John Riggs Miller*, Bart. and *David Scott*, Eſq. M. P.; and for eſtabliſhing the colony, and conducting the affairs of the ſociety abroad, the following gentlemen were nominated, viz. *Meſſrs H. H. Dalrymple*, *John Young*, *Sir William Halton*, Bart. *John King*, *Philip Beaver*, *Peter Clutterbuck*, *Nicholas Bayly*, *Francis Brodie*, *Charles Drake*, *John Paiba*, *Richard Hancorne*, *Robert Dobbins*, and *Iſaac Ximenes*.

A ſum of L. 9000 being quickly ſubſcribed for the eſtabliſhment of the intended colony, this committee ſailed from Spithead in three ſhips on the 11th of April 1792; and landing in due time at Bulama, they purchaſed that iſland from the kings of Canabac, who claimed it as their property. They purchaſed likewiſe from the kings of Ghinala the neighbouring iſland Arcas, and the adjacent land on the continent; and theſe ſeveral purchaſes being taken poſſeſſion of in the uſual form, a body of ſettlers, conſiſting of 49 men, 13 women, and 25 children, were left at Bulama under the ſuperintendence of Mr Beaver, with a temporary ſupply of proviſions, ſtores, plantation-tools, and merchandiſe, for trading with the neighbouring natives. It is from the diſpatches of theſe ſettlers, after having lived ſome time in Bulama, that the following account of the iſland was drawn up by Mr Johanſen.

"The climate, on the whole, may be deemed ſalubrious, and will become more ſo in proportion to the increaſe of cultivation. The mornings and evenings are temperate and pleaſant; the middle of the day is hot, but the fine ſea breeze which then ſets in tends greatly to cool and refreſh the air. The heat of the ſun is not either ſo exceſſive or intolerable as has been generally ſuppoſed: indeed nature has moſt admirably adapted our mechanical and phyſical qualities to the exigencies of different regions; and man, who is the inhabitant of every climate, may, in ſome meaſure, render himſelf indigenous to every ſoil. Here the only danger ariſes from too ſudden an expoſure to the operation of the vertical rays of the ſun, or an exceſs of labour; both of which the firſt ſettlers ought moſt ſtudiouſly to avoid.

"It appears from Mr Beaver's obſervations at noon, between the 20th of July 1792, and the 28th of April 1793, that the thermometer, when loweſt, was at 74; the medium heat 85; and that it never exceeded 96, except at one time when it roſe to 100, during a calm that occurred in the interval between the north-eaſt breeze in the morning and the ſouth-weſt in the evening of the 19th of February 1793. The difference between the heat of noon and that of the morning and evening is from 20 to 30 degrees. On the 23d of October 1792, hail of the ſize of a pin's head fell during two minutes, although not a cloud was to be ſeen during this phenomenon. The mercury in the thermometer then ſtood at 85; the wind was at north-eaſt in the morning and ſouth-weſt in the evening.

"Immediately after ſun-ſet a dew conſtantly begins to fall, which induces ſome to light a fire in their houſes; they at the ſame time put on warmer clothing. There is little or no twilight; and night and day are nearly equal: the earth has therefore time to cool during twelve hours abſence of the ſun.

"None of thoſe terrible and deſtructive hurricanes ſo frequently experienced in the Weſt Indies are to be met with here. The *tornadoes*, which ariſe chiefly from the eaſtern point of the compaſs, are but of ſhort duration, ſeldom laſting above an hour, and may be readily foreſeen ſome time previouſly to their commencement. They occur at the beginning and cloſe of the wet ſeaſon, and are highly beneficial, as they purify the air, and diſpel the noxious vapours with which it would otherwiſe abound.

"The rains ſet in about the latter end of May or the beginning of June, and diſcontinue in October or November. They do not fall every day, for there is often a conſiderable interval of clear weather, during which the atmoſphere is beautifully ſerene; the ſhowers in the firſt and laſt month occur but ſeldom, and are far from being violent; while, on the other hand, they ſometimes reſemble torrents, more eſpecially towards the middle of the ſeaſon. During the whole of this period, Europeans ſhould, if poſſible, confine themſelves to their habitations, as the rains prove injurious to health, more eſpecially if thoſe expoſed to them neglect to wipe their bodies dry, and to change their clothes immediately on their return home. It is deemed prudent alſo not to dig the earth until the expiration of a month after the return of fair weather, as this is conſidered to be unhealthy.

"During the continuance of the dry ſeaſon, a dew falls during the night, in ſufficient quantity to anſwer all the purpoſes of vegetation.

"Every ſtranger is generally here, as well as in the Weſt Indies, ſubject to a fever or *ſeaſoning* on his arrival. This is not infectious; it proceeds perhaps from an increaſed perſpiration and a ſudden extenſion of the pores of the human body, in conſequence of the heat, by which means it is rendered more liable to imbibe the abundant exhalations that ariſe from the animal, vegetable, and mineral kingdoms; but even this, ſlight as it is, might doubtleſs be avoided by means of a proper regimen, and a ſhort ſeclusion from the full action of the open air, more eſpecially at noon, and during the evening, until the climate has been rendered familiar.

“ Bulama is admirably adapted for all the purpoſes of an extenſive commerce, being not only happily ſituated at the mouth of the Rio Grande, but in the vicinity of ſeveral other navigable rivers ; ſo that a trade with the internal parts of Africa is thereby greatly facilitated. The landing is remarkably eaſy and ſafe, there being no ſurge ; the ebb and flow is regular, and there is an increaſe of 16 feet of water at ſpring tide. The bay oppoſite the Great Bulama is adorned with a number of iſlands, covered with trees, and forms a moſt excellent harbour, ſufficiently capacious to contain the whole navy of Great Britain, which might ride there in ſafety. The ſettlement in general is well ſupplied with water. A number of ſprings have been lately diſcovered in different places ; and beſides a draw-well in the fort, which was erected for the defence of the colony, there is a ſmall ſtream, which runs into Elewſis Bay, near the new ſettlement called Heſper Elewſis : this is admirably ſituated for the ſupply of ſhipping.

“ The iſland is beautifully ſurrounded, and interſperſed with woods : lofty fruit and foreſt trees, moſtly free from underwood and brambles, form a verdant belt, in ſome places two or three miles broad, which entirely encircles it, in ſuch a manner as to repreſent a plantation artificially formed around a park. Within this the fields are regularly divided by trees, ſo as to reſemble the hedge-rows in England. The beach has in ſome places the appearance of gravel walks ; it is fringed with mangrove trees, which forming a line with the high-water mark, dip their branches into the ſea, and thus afford nouriſhment to the oyſters that often adhere to their extremities.

“ Several parts of Bulama have been occaſionally cultivated by the neighbouring blacks, though they did not conſtantly reſide on it.

“ The land in general riſes gradually towards the middle of the iſland, where the higheſt ſpot is from 60 to 100 feet above the level of the ſea. The ſmall hill on which the fort is ſituated is nearly of the ſame altitude.

“ The ſoil is abundantly rich and deep ; ſtones do not here impede the labours of the farmer ; and indeed none have hitherto been diſcovered, but a ſmall ſort, reſembling pieces of ore, which are to be met with on the ſhore. There are many *ſavannahs* or natural meadows, ſo extenſive that the eye can ſcarcely deſcry their boundaries. Theſe are admirably adapted for the rearing of ſtock and feeding of cattle of every kind.

“ Cotton, indigo, rice, and coffee, grow ſpontaneouſly on this coaſt ; the ſugar-cane is indigenous to many parts of Africa, and might be cultivated here by the labour of freemen, in equal perfection, and to much greater advantage, than in the exhauſted iſlands of the Weſt Indies. All kinds of tropical productions, ſuch as pine-apples, limes, oranges, grapes, plums, caſſada, guava, Indian wheat, the papaw, water-melon, muſk-melon, the pumpkin, tamarind, banana, and numbers of other delicious fruits, alſo flouriſh here. The adjoining territories produce many valuable ſorts of ſpices, gums, and materials for dyeing : all of which it is but fair to ſuppoſe, might be readily cultivated in a kindred climate and a congenial ſoil.

“ The neighbouring ſeas abound with a variety of fiſh, highly agreeable to the palate. The lion, tyger, jackall, &c. are natives of the continent ; but in Bulama no animals have been diſcovered, the wolf, ſome buffaloes, a few elephants, and a ſpecies of the deer, excepted.

“ The woods abound with doves, guinea-fowls, and a variety of birds, celebrated for the beauty of their plumage.

“ The natives of this part of Africa, like all ſavages, are entirely under the dominion of their paſſions : hence the violence of their attachment to their friends, and the exceſs of their reſentment againſt their enemies. Their notions of property are very obſcure and confuſed : they have no idea of any right ariſing from occupancy or improvement. What they want, they either receive or take wherever they may happen to meet with it, and they permit others to do the ſame. They have been taught by experience that the Europeans will not agree to this : againſt them therefore they employ every artifice that it is in the power of cunning to ſuggeſt.

“ The coloniſts need not fear any attack on the part of the negroes, provided their own conduct be juſt and peaceable : for Mr Beaver, who was indeed admirably calculated by nature and habit for the ſtation he occupied, could enſure both ſafety and reſpect when the ſettlers under him were reduced to four white men, although the neighbouring nations knew that he was in poſſeſſion of commodities, for the acquiſition of which many of them had become day-labourers. He often kept from twenty to forty gromittos, or black cultivators in pay, at that very period, at about four or five bars (A) each per month. Theſe are eaſy to be procured, to almoſt any number that can poſſibly be wanted.

“ Until a ſufficient quantity of ſtock and proviſions can be raiſed in the company's ſettlements, the adjacent iſlands will furniſh abundance of cattle, hogs, fowls, &c. at a very cheap rate. A horſe may be purchaſed at Goree for 1l. 10s. a bullock may be had from 12s. to 18s. ſterling : proviſions of all kinds are equally reaſonable. Honey is alſo to be procured in great plenty, and bees-wax may be rendered an advantageous object of commercial ſpeculation.

“ In ſhort, the acquiſition of Bulama, Arcas, and the adjacent territories, preſents the faireſt opportunity of furniſhing Europe with many valuable articles that have hitherto been brought from more remote countries, with much greater hazard, and at an increaſed expence. The intercourſe with England is eaſy, ſafe, and expeditious ; for the voyage may be performed in the ſpace of three or four weeks : and by the terms of the firſt ſubſcription, a ſettler on Bulama might purchaſe 500 acres of land for L. 30 Sterling ; by the terms of the ſecond, which we ſuppoſe are the terms at preſent, he might purchaſe on the iſlands of Bulama and Arcas, or on that part of the adjacent coaſt which was ceded to the ſociety by the kings of Ghinala, 200 acres for L. 50 ſterling.

(A) A bar is about the value of three ſhillings and ſixpence.

“ The colonization of Africa opens a noble and extenſive field to nations and to individuals. To people thoſe fertile territories, deſpoiled of their inhabitants by the ſlave-trade; to rear the productions of the climes between the tropics, by the aſſiſtance of free men; to give ample ſcope to the induſtry and exertions of thoſe who may be inclined to remove from Great Britain; and to extend the commerce and the manufactures of our native country—theſe are ſubjects which have excited the attention of the Bulama aſſociation, and now claim the aſſiſtance of the ingenious, the ſupport of the rich, and the concurrence and good wiſhes of all.”

BUNTING, is a bird which has been deſcribed under its generic name EMBERIZA (*Encycl.*); but there is one ſpecies, the *orange ſhouldered bunting* of Latham, of which M. Vaillant relates ſome particulars certainly not unworthy of notice in this place.

“ The female of this beautiful bird (ſays he) has the ſimple colours of the ſky-lark, and a ſhort horizontal tail, like that of almoſt all other birds: the male, on the contrary, is wholly black except at the ſhoulder of the wing, where there is a large red patch; and his tail is long, ample, and vertical, like that of the common cock. But this brilliant plumage and fine vertical tail ſubſiſt only during the ſeaſon of love, which continues ſix months. This period over, he lays aſide his ſplendid habiliments, and aſſumes the more modeſt dreſs of his mate. The moſt extraordinary circumſtance is, that the vertical tail alſo changes to a horizontal one, and the male ſo exactly reſembles the female, that it is not poſſible to diſtinguiſh them from each other.

“ The female has her turn. When ſhe reaches a certain age, and has loſt the faculty of propagating the ſpecies, ſhe clothes herſelf for the remainder of her days in the garb which the male had temporarily aſſumed; her tail, like his at that period, grows long, and, like his alſo, from horizontal becomes vertical.

“ The birds of this ſpecies aſſociate together, live in a ſort of republic, and build their neſts near to each other. The ſociety uſually conſiſts of about fourſcore females; but, whether by a particular law of nature, more females are produced than males, or for any other reaſon of which I am ignorant, there are never more than twelve or fifteen males to this number of females, who have them in common.”

According to our author, this tranſmutation is by no means confined to this particular ſpecies of bunting. Many females of the feathered creation, when they grow ſo old as to ceaſe laying eggs, aſſume the more ſplendid colours of the male, which they retain during the remainder of their lives. This fact is ſtrikingly perceptible in thoſe ſpecies in which the male and female very much differ in colour, as the golden pheaſant of China, for inſtance. In ſome ſpecies, and thoſe not a few, the male alone regularly changes his colour, and aſſumes once in a year the plumage of the female; ſo that at a certain period all the birds of that ſpecies appear females. “ I have in my poſſeſſion (ſays our author) ſpecimens of more than fifty of thoſe changing ſpecies, in all their tranſitions from one hue to another; and the change is ſometimes ſo great, that a perſon would ſuppoſe himſelf to ſee individuals totally different. A cloſet-naturaliſt, for inſtance, ſhewed me four birds as ſo many different ſpecies, and even as not belonging to the ſame genus, with which I was well acquainted, and which I knew to be the ſame bird, only of different ages.”

Such changes as theſe, could they be proved to take place occaſionally among domeſtic fowls, would in ſome meaſure account for ſtrange ſtories of cocks laying eggs, which we have heard related by perſons whoſe general veracity was never queſtioned.

BURKE (Edmund), was born in the city of Dublin on the 1ſt of January 1730. His father was an attorney of conſiderable knowledge in his profeſſion, and of extenſive practice; and the family from which he ſprung was ancient and honourable. He received the rudiments of his claſſical education under Abraham Shackleton, a Quaker, who kept a private ſchool or academy, as it has been called, at Bellytore, near Carlow, and is ſaid to have been a very ſkilful and ſucceſsful teacher.

Under the tuition of this maſter, Burke devoted himſelf with great ardour, induſtry, and perſeverance, to his ſtudies; and manifeſted, even from his boyiſh days, a diſtinguiſhed ſuperiority over his contemporaries. He was the pride of his preceptor, who prognoſticated every thing great from his genius, and who was, in return, treated by his illuſtrious pupil, for forty years, with reſpect and gratitude.

From ſchool Burke was ſent to Trinity-college, Dublin, where it was aſſerted by Goldſmith and others his contemporaries, that he diſplayed no particular eminence in the performance of his exerciſes. Like Swift, he deſpiſed the logic of the ſchools; and like him too, he devoted his time and his talents to more uſeful purſuits. Johnſon, though proud of being an Oxonian, did not much employ himſelf in academical exerciſes; and Dryden and Milton, who ſtudied at Cambridge, were neither of them ambitious of college diſtinctions. Let not, however, the example of a Burke, a Johnſon, a Dryden, or a Milton, ſeduce into by-paths the ordinary ſtudent; for though great genius either finds or makes its own way, common minds muſt be content to purſue the beaten track. Shakeſpeare, with very little learning, was the greateſt dramatic poet that ever wrote; but how abſurd would it be to infer from this fact, that every illiterate man may excel in dramatic poetry?

Whilſt at college Burke applied himſelf with ſufficient diligence to thoſe branches of mathematical and phyſical ſcience which are moſt ſubſervient to the purpoſes of life; and though he neglected the ſyllogiſtic logic of Ariſtotle, he cultivated the method of induction pointed out by Bacon. Pneumatology, likewiſe, and ethics, occupied a conſiderable portion of his attention; and whilſt attending to the acquiſition of knowledge, he did not neglect the means of communicating it. He ſtudied rhetoric and the art of compoſition, as well as logic, phyſics, hiſtory, and moral philoſophy; and had at an early period of his life, ſays Dr Biſſet, planned a confutation of the metaphyſical theories of Berkeley and Hume.

For ſuch a taſk as this, we do not think that nature intended him. Through the ever-active mind of Burke ideas ſeem to have flowed with too great rapidity to permit him to give that patient attention to minute diſtinctions, without which it is vain to attempt a confutation of the ſubtleties of Berkeley and Hume. The ableſt antagoniſt of theſe two philoſophers was remarkable for patient thinking, and even *apparent* ſlowneſs of apprehenſion;

apprehenſion ; and we have not a doubt, but that if he had poſſeſſed the rapidity of thought which characteriſed Burke, his confutation of Hume and Berkeley would have been far from concluſive. It might have been equal to the *Eſſay on the Nature and Immutability of Truth*, but would not have been what we find it in *The Inquiry into the Human Mind on the Principles of Common Senſe*, and in *The Eſſays on the Intellectual and Active Powers of Man.*

A taſk much better ſuited to Burke's talents than the writing of metaphyſical diſquiſitions on the ſubſtratum of body, preſented itſelf to him in the year 1749, and a taſk which was likewiſe more immediately uſeful. At that period one Lucas, a democratic apothecary, wrote a number of very daring papers againſt government, and acquired by them as great popularity at Dublin as Mr Wilkes afterwards obtained by his North Briton in London. Burke, though a boy, perceived, almoſt intuitively, the pernicious tendency of ſuch levelling doctrines, and reſolved to counteract it. He wrote ſeveral eſſays in the ſtyle of Lucas, imitating it ſo exactly as to deceive the public ; purſuing his principles to conſequences neceſſarily reſulting from them, and ſhewing at the ſame time their abſurdity and their danger. Thus was his firſt literary effort, like his laſt, calculated to guard his country againſt anarchical innovations.

Whilſt employed in treaſuring up knowledge, which at a future period was to command the admiration of liſtening ſenates, he did not neglect the means neceſſary to render himſelf agreeable in the varied intercourſe of private life. To the learning of a ſcholar he added the manners of a gentleman. His company was ſought among the gay and the faſhionable, for his pleaſing converſation and eaſy deportment ; as much as among the learned, for the force and brilliancy of his genius, and the extent and depth of his knowledge. But though the object of very general regard in his native country, he had hardly any proſpect of obtaining in it an independent ſettlement. He therefore applied, ſome time after the publication of his letters expoſing the doctrines of Lucas, for the profeſſorſhip of logic, which had then become vacant in the univerſity of Glaſgow : but whether that application was made too late, or that the univerſity was unwilling to receive a ſtranger, certain it is that the vacant chair was filled by another, and that Burke was diſappointed of an office in which he was eminently qualified to excel. For many years very little attention has been paid in the univerſities of Scotland, perhaps even too little, to the Ariſtotelian logic ; and the profeſſors, inſtead of employing their time in the analyſing of ſyllogiſms, deliver lectures on rhetoric and the principles of compoſition—lectures which no man was more capable of giving than the unſucceſsful candidate for the profeſſorſhip in Glaſgow.

Diſappointment of early views has frequently been the means of future advancement. Had Johnſon become maſter of the Staffordſhire ſchool, talents might have been conſumed in the tuition of boys which Providence formed for the inſtruction of men ; and had Burke obtained the profeſſorſhip of logic in Glaſgow, he would have been the moſt eloquent lecturer in that univerſity, inſtead of the moſt brilliant ſpeaker in the Britiſh ſenate : but whether his talents might not have been as uſefully employed in the univerſity as in the ſenate, may perhaps be a queſtion, though there can be no queſtion whether they would have inveſted himſelf with an equal blaze of ſplendour.

Diſappointed in Glaſgow, he went to London, where he immediately entered himſelf of the Temple ; and as there is reaſon to believe that he was in ſtraitened circumſtances, he ſubmitted to the drudgery of regularly writing for daily, weekly, and monthly publications, eſſays on general literature and particular politics. The profits ariſing from ſuch writings were at firſt ſmall ; but they were ſo neceſſary to their author, that the intenſe application which they required gradually impaired his health, till at laſt a dangerous illneſs enſued, when he reſorted for medical advice to Dr Nugent, a phyſician whoſe ſkill in his profeſſion was equalled only by the benevolence of his heart. The Doctor, conſidering that the noiſe, and various diſturbances incidental to chambers, muſt retard the recovery of his patient, furniſhed him with apartments in his own houſe, where the attention of every member of the family contributed more than medicines to the reſtoration of his health. It was during this period that the amiable manners of Miſs Nugent, the Doctor's daughter, made a deep impreſſion on the heart of Burke ; and as ſhe could not be inſenſible to ſuch merit as his, they felt for each other a mutual attachment, and were married ſoon after his recovery.

Hitherto his mental powers and acquirements were known in their full extent only to his friends and more intimate companions ; but they were now made public in his firſt acknowledged work, intitled, *A Vindication of Natural Society.* The object of this performance was to expoſe the dangerous tendency of Lord Bolingbroke's philoſophy. By the admirers of that nobleman, his principles were deemed inimical only to revealed religion and national churches, which they would have been glad to ſee overturned, provided our civil eſtabliſhment had been preſerved; and to the civil eſtabliſhment they perceived no danger in the writings of the author of *The Patriot King.* Mr Burke thought very differently ; and endeavoured to convince them, that if his Lordſhip's philoſophy ſhould become general, it would ultimately deſtroy their rank, their conſequence, and their property, and involve the church and ſtate in one common ruin. In his ironical attack upon artificial ſociety, he makes uſe of the ſame common place mode of unfair reaſoning which his noble antagoniſt had employed againſt religion and religious eſtabliſhments. He argues, from the incidental abuſes of political ſociety, that political ſociety muſt itſelf be evil ; he goes over every form of civil polity, pointing out its defects in the moſt forcible language; and, in perfect imitation of the ſceptical philoſophy, he pulls them all down, one after another, without propoſing any thing in their ſtead. So complete is the irony, that to many not acquainted with ſuch diſquiſitions, he would appear to be ſeriouſly inveighing againſt civil government ; and we have actually heard ſome of the advocates for modern innovation mention this work as a proof how different Mr Burke's opinions in politics once were from what they appear to have been when he wrote his *Reflections on the French Revolution.*

The truth, however, is, that there is no inconſiſtency between *The Vindication of Natural Society* and the lateſt publications of its illuſtrious author. At the period

riod when that work was publiſhed, infidelity had infected only the higher orders of men, and ſuch of the lower as had got the rudiments of a liberal education. Of theſe we believe a ſingle individual was not then to be found, who ſuppoſed that ſociety could ſubſiſt both without government and without religion; and therefore while they laboured to overturn the church, and to prove that Chriſtianity itſelf is an impoſture, they all pretended to be zealouſly attached to our civil government as eſtabliſhed in king, lords, and commons. Except the clergy of the eſtabliſhed church, there was no order of men whom they indiſcriminately reviled. Hence it was that not Burke only, but Warburton, and almoſt every other opponent of Lord Bolingbroke, began their defences of revelation, by ſhewing the indiſſoluble connection between our civil and eccleſiaſtical eſtabliſhments; and all the difference was, that he did, through the medium of the moſt refined irony, the very ſame thing which they had done by ſerious reaſoning.

Soon after his *Vindication of Natural Society*, Burke publiſhed *A Philoſophical Enquiry into the Origin of our Ideas of the Sublime and Beautiful;* a work which ſoon made its author univerſally known and admired, and which has been ſtudied by every Engliſh reader of taſte. It is therefore needleſs for us to hazard any opinion either of its general merit or its particular defects. In one of the literary journals of that day, Mr Murphy urged objections againſt ſome of its fundamental principles, which, in our opinion, it would be very difficult to anſwer; whilſt Johnſon, who was certainly a ſevere judge, conſidered it as a model of philoſophical criticiſm. "We have (ſaid he) an example of true criticiſm in Burke's Eſſay on the Sublime and Beautiful. There is no great merit in ſhewing how many plays have ghoſts in them, or how this ghoſt is better than that; you muſt ſhew how terror is impreſſed on the mind."

In conſequence of this manifeſtation of Burke's intellectual powers, his acquaintance was courted by men of diſtinguiſhed talents, and, among others, by Johnſon and Sir Joſhua Reynolds. The literary club which has been mentioned (*Encycl.*) in the life of JOHNSON, was inſtituted for their entertainment and inſtruction, and conſiſted at firſt of Johnſon, Burke, Reynolds, Goldſmith, Dr Nugent, Mr Topham, Beauclerk, Sir John Hawkins, Mr Chamier, and Mr Bennet Langton, who were all men of letters and general information, though far above the reſt ſtood Burke and Johnſon. Of Burke indeed Johnſon declared, upon all occaſions, that he was the greateſt man living; whilſt Burke, on a very ſolemn occaſion, ſaid of Johnſon, "He has made a chaſm, which not only nothing can fill up, but which nothing has a tendency to fill up. Johnſon is dead. Let us go to the next beſt—There is nobody—No man can be ſaid to put you in mind of Johnſon." Nor was the opinion which theſe two illuſtrious men held of each other's powers peculiar to themſelves alone: all the members of the club obſerved, that in colloquial talents they were nearly matched, and that Johnſon never diſcourſed with ſuch animation and energy as when his powers were called forth by thoſe of Burke.

Some years before the inſtitution of this club, Burke, who had devoted much of his time to the ſtudy of hiſtory and politics, propoſed to Mr Dodſley, an eminent bookſeller, a plan of an ANNUAL REGISTER of the civil, political, and literary tranſactions of the times; and the propoſal being acceded to, the work was begun and carried on for many years, either by Burke himſelf, or under his immediate inſpection. It bears indeed internal marks of his genius, his learning, and his candour, being by much the moſt elegant and impartial periodical hiſtory which has perhaps appeared in any age or nation. Even when the heat of oppoſition made him, in his ſpeeches, ſometimes miſrepreſent the conduct of adminiſtration, the Annual Regiſter, under his management, continued to render juſtice to all parties.

He ſtill continued to write occaſionally political eſſays for other publications than the Annual Regiſter; and ſome of theſe eſſays in the *Public Advertiſer* having attracted the notice of the Marquis of Rockingham, that nobleman ſought the acquaintance of their author. It was in the year 1765 that the firſt interview took place between them; and the Marquis, who was then at the head of the treaſury, offering to make Burke his own ſecretary, the offer was readily accepted. On this occaſion he gave a remarkable proof of diſintereſtedneſs and delicate integrity. Through the influence of Mr Hamilton, known by the appellation of *Single Speech* Hamilton, and long ſuſpected to be the author of *Junius's Letters*, he had ſome time before obtained a penſion of L.300 a-year on the Iriſh eſtabliſhment; but this penſion he now thought it incumbent upon him to reſign, becauſe he had connected himſelf with a party oppoſite in many things to the party whoſe meaſures were ſupported by his friend.

During the Rockingham adminiſtration he was choſen member of Parliament for the borough of Wendover in the county of Bucks; and he prepared himſelf for becoming a public ſpeaker, by ſtudying, ſtill more cloſely than he had yet done, hiſtory, poetry, and philoſophy; and by ſtoring his mind with facts, images, reaſonings, and ſentiments. He paid great attention likewiſe to parliamentary uſage; and was at much pains to become acquainted with old records, patents, and precedents, ſo as to render himſelf complete maſter of the buſineſs of office. That he might communicate without embarraſſment the knowledge which he had thus laboriouſly acquired, he frequented, with many other men of eminence, the Robin Hood Society, where he practiſed the replies and contentions of eloquence; and to acquire a graceful action, with the proper management of his voice, he was a very diligent obſerver of Garrick in Drury-Lane theatre. He procured his ſeat in 1765, and in the enſuing ſeſſion delivered his maiden ſpeech; which was ſuch a diſplay of eloquence as excited the admiration of the Houſe, and drew very high praiſe from its moſt diſtinguiſhed member Mr Pitt, afterwards Earl of Chatham.

The principal objects which engaged the attention of the Rockingham adminiſtration were the ferments in America, which was then in a ſtate little ſhort of rebellion, on account of the famous ſtamp-act. Parliament was divided in opinion reſpecting that meaſure. Whilſt Mr Grenville and his party (under whoſe auſpices the ſtamp-act had paſſed into a law) were for enforcing obedience to it by coercive meaſures, Mr Pitt and his followers denied that the parliament of Great Britain had a right to tax the Americans; and the marquis of Rockingham, who was hardly able to carry any meaſure in oppoſition to both theſe parties, had to conſider,

ſider, on this occaſion, whoſe ſentiments he would adopt. By the advice, it is ſaid, of Mr Burke, he choſe a middle courſe between the two oppoſite extremes. To gratify the Americans, he repealed the ſtamp-act; and to vindicate the honour of Britain, he got a law paſſed declaratory of her right to legiſlate for America in taxation as in every other caſe.

This meaſure, whoever was its author, was certainly not the offspring either of wiſdom or vigour. If the mother-country had a right to legiſlate in all caſes for America, obedience to the ſtamp-act ſhould certainly have been enforced; and the miniſtry which relinquiſhed an acknowledged right, to gratify the factious diſpoſition of diſtant colonies, was obviouſly unfit to guide the helm of a great empire. Lord Rockingham and his friends were accordingly diſmiſſed from office; and a new adminiſtration was formed under the auſpices of Mr Pitt, now created earl of Chatham.

Burke, in the mean time, wrote in defence of the party with which he was connected; and aſſumed great credit to it for compoſing the diſtractions of the Britiſh empire by the repeal of the American ſtamp-act, whilſt the conſtitutional ſuperiority of Great Britain was preſerved by the act for ſecuring the dependence of the colonies. After defending his friends, he proceeds to attack thoſe who had ſucceeded them in office. Of Lord Chatham he ſays—" He has once more deigned to take the reins of government into his own hand, and will, no doubt, drive with his wonted ſpeed, and raiſe a deal of duſt around him. His horſes are all matched to his mind; but as ſome of them are young and ſkittiſh, it is ſaid he has adopted the new contrivance lately exhibited by Sir Francis Delaval on Weſtminſter bridge: whenever they begin to ſnort and toſs up their heads, he touches the ſpring, throws them looſe, and away they go, leaving his lordſhip ſafe and ſnug, and as much at his eaſe as if he ſat on a woolpack."

The letter, of which this is an extract, was printed in the Public Advertiſer; and is ſaid to have contributed, in no ſmall degree, to leſſen the popularity of the illuſtrious ſtateſman againſt whom it was written. The miniſtry, indeed, which he had formed, conſiſted of very heterogeneous materials, and was not heartily approved of by the nation. It therefore ſoon fell in pieces by its own diſcord, and Lord Chatham retired in diſguſt.

The parliament being diſſolved in 1768, Burke was re-elected for Wendover, and took his ſeat, when the houſe met, in November. The duke of Grafton was now prime miniſter, and was oppoſed by two powerful parties in parliament; that of the marquis of Rockingham, and that of which Mr Grenville was conſidered as the leader. Theſe two parties, however, differed widely between themſelves. Mr Grenville had publiſhed a pamphlet, intitled, *The Preſent State of the Nation;* in which he very ably vindicated his own meaſures, and of courſe condemned the meaſures of thoſe who had ſucceeded him; and Burke replied to him, with greater eloquence, but perhaps with leſs of argument, in a tract, intitled, *Obſervations on the Preſent State of the Nation*, in which he makes a very high panegyric on his own patron, and the connections of the party, and animadverts with cutting ſeverity on their ſucceſſors in office.

About this period commenced the national frenzy which was excited by the expulſion of Wilkes from the houſe of commons, *for having printed and publiſhed a ſeditious libel, and three obſcene and impious libels.* In the controverſy to which this tranſaction gave riſe, Burke and Johnſon took oppoſite ſides. Johnſon, in his *Falſe Alarm*, contends, with great ability, that the expulſion of a member from the houſe of commons for the commiſſion of a crime, amounts to a diſqualification of that member from ſitting in the parliament from which he is expelled; whilſt Burke, though he diſapproved of the conduct of Wilkes as much as his friend, laboured to prove, that nothing but an act of the legiſlature can diſqualify any perſon from ſitting in parliament who is regularly choſen, by a majority of electors, to fill a vacant ſeat. It does not appear that this difference of opinion produced the ſmalleſt abatement of mutual regard between him and Johnſon. They both attended the weekly club, and were as much pleaſed with each other as formerly.

The proceedings of the Grafton adminiſtration, reſpecting Wilkes and other ſubjects, gave riſe to the celebrated *Letters of Junius.* That thoſe compoſitions were, in clearneſs, neatneſs, and preciſion of ſtyle, infinitely ſuperior to perhaps every other ſeries of newſpaper invectives, has never been controverted; and that they diſplay a vaſt extent of hiſtorical and political information, is known to all who are not themſelves ſtrangers to the hiſtory of this kingdom. Unclaimed by any author, and ſuperior to the productions of moſt authors, they have been given to Burke, to his brother Richard, a man likewiſe of very bright talents, to Mr Hamilton, and to Lord George Germaine. We ſhould hardly heſitate to adopt the opinion of thoſe who aſcribe them to Burke, had he not diſavowed them to his friend Johnſon. " I ſhould have believed Burke to be Junius (ſaid Johnſon), becauſe I know no man but Burke who is capable of writing theſe letters; but Burke *ſpontaneouſly* denied it to me. The caſe would have been different had I *aſked* him if he was the author. A man may think he has a right to deny when ſo queſtioned as to an anonymous publication." The difference between the ſtyle of theſe letters and that of Burke's acknowledged writings, would have had no weight with us; becauſe ſuch was his command of language, that he could aſſume, and occaſionally did aſſume, any ſtyle which he choſe to imitate. He had already ſo cloſely imitated the very different ſtyles of Lucas and Bolingbroke as to deceive the public; and what was to hinder him from imitating the ſtyle of Lord George Germaine, which certainly has a ſtrong reſemblance to that of Junius? We think, however, with Johnſon, that his *ſpontaneous diſavowal* of theſe letters ought to be held as ſufficient proof that he was not their author.

Burke had now gotten a very pleaſant villa near Beaconsfield in Buckinghamſhire; and being one of the freeholders of the county, he drew up a petition to the king, complaining of the conduct of the houſe of commons reſpecting the Middleſex election, and praying for a diſſolution of the parliament. The petition, though explicit and firm, was temperate and decorous, and as unlike to one on the ſame ſubject from the livery of London, as the principles of a moderate Whig are to thoſe of a turbulent democrate.

About

About this period he ſtated very clearly his own political principles in a pamphlet intitled, "Thoughts on the Cauſes of the Preſent Diſcontents;" and his plan for removing theſe diſcontents had not a grain of democracy in its compoſition. He propoſed to place the government in the hands of an open ariſtocracy of talents, virtue, property, and rank, combined together on avowed principles, and ſupported by the approbation and confidence of the people; and the ariſtocracy which he thought fitteſt for this great truſt, was a combination of thoſe Whig families which had moſt powerfully ſupported the revolution and conſequent eſtabliſhments. He expreſſed, in ſtrong terms, his diſapprobation of any change in the conſtitution and duration of parliament; and declared himſelf as averſe from an adminiſtration which ſhould have no other ſupport than popular favour, as from one brought forward merely by the influence of the court.

In this plan there is not that wiſdom or liberality which might have been expected from a man of Burke's cultivated mind and extenſive reading. The Whigs, when in power, had been as venal as the Tories; and the impriſonment of Lord Oxford, the baniſhment of Atterbury biſhop of Rocheſter, and the reſolution of the houſe of commons to ſit for ſeven years, when it had been choſen by its conſtituents for no more than three, were certainly greater violations of the conſtitution than the diſqualification of Wilkes, or any other meaſure that had been carried by the court during the adminiſtrations of Grenville and the duke of Grafton. Burke ſhewed himſelf in this publication to be indeed no republican; but every ſentence of it breathed the ſpirit of party.

Lord North was now prime miniſter; and in order to tranquillize America, he propoſed, in the beginning of his adminiſtration, to repeal the obnoxious laws of his predeceſſors in office, and to reſerve the duty on tea merely to maintain the authority of parliament. The conſequences of this conduct we have detailed elſewhere (ſee Britain, *Encycl.*); and they are too well known to all our readers. The part which Burke acted during his adminiſtration will not, in our opinion, admit of any plauſible defence. It was not indeed the part of a democrate, but of a man determined to oppoſe every meaſure of thoſe in power. In the beginning of the conteſt, he certainly diſplayed more wiſdom and patriotiſm than the miniſter; for, without entering directly into the queſtion, Whether the mother country had or had not a right to tax the colonies? he contented himſelf with warning the houſe againſt dangerous innovations. "The Americans (ſaid he) have been very ſerviceable to Britain under the old ſyſtem: do not, therefore, let us enter raſhly upon new meaſures. Our commercial intereſts have been hitherto greatly promoted by our friendly intercourſe with the colonies; do not let us endanger poſſeſſion for contingency; do not let us ſubſtitute untried theories for a ſyſtem experimentally aſcertained to be uſeful."

This was undoubtedly ſound reaſoning, and everyway becoming a lover of his country: but his continued oppoſition to government, after all Europe had leagued againſt Great Britain, was a conduct which will admit of no vindication, and for which the only poſſible apology muſt be found in that ardour of temper which made his friend Hamilton ſay, on another occaſion, "Whatever opinion Burke, from any motive, ſupports, ſo ductile is his imagination, that he ſoon conceives it to be right." In his moſt violent oppoſition, however, though his expreſſions were often extravagant and indecent, he never for a moment gave his ſupport to the metaphyſical doctrine of the *impreſcriptible rights of man*, or to the actual innovations which ſome meant to introduce on the baſis of that doctrine. His upright mind was indeed ſufficiently guarded againſt theſe novelties by what he had obſerved in France during the year 1772. Whilſt he remained in that country, his literary and political eminence made him courted by all the anti-monarchical and infidel philoſophers of the time; and in the religious ſcepticiſm and political theories of Voltaire, Helvetius, Rouſſeau, and D'Alembert, he ſaw, even at that period, the probable overthrow of religion and government. His ſentiments on this ſubject he took occaſion, immediately on his return, to communicate to the houſe of commons; and to point out the conſpiracy of atheiſm to the watchful policy of every government. He profeſſed that he was not over-fond of calling in the aid of the ſecular arm to ſuppreſs doctrines and opinions; but he recommended a grand alliance among all believers againſt thoſe miniſters of rebellious darkneſs, who were endeavouring to ſhake all the works of God eſtabliſhed in beauty and in order.

The American war proving unſucceſsful, though Great Britain never made a more glorious ſtand, Lord North and his friends retired from office; and, in February 1782, a new miniſtry was formed, at the head of which was placed the marquis of Rockingham; Lord Shelburne and Mr Fox were the ſecretaries of ſtate; and Mr Burke, who was appointed pay-maſter to the forces, exulted, rather childiſhly, in the houſe of commons, on the happineſs which was to accrue, both to the king and to the people, from the able and upright conduct of the new miniſters. The time in which the greater part of them continued in office was too ſhort to permit them to do either much good or much evil.

On the 1ſt of July the marquis of Rockingham died; and the earl of Shelburne being placed at the head of the treaſury, Fox and Burke reſigned in diſguſt, and, to the aſtoniſhment of the nation, formed the famous coalition with Lord North, whoſe meaſures they had ſo long, and ſo vehemently oppoſed. In the coalition of North and Burke there would have been nothing wonderful. In the intercourſe of private life, theſe two ſtateſmen had always met on terms of friendſhip and mutual regard; they had the ſame ideas of the excellence of the conſtitution, and the ſame averſion to innovation under the name of reform; even their ſtudies and amuſements were very ſimilar, being both men of taſte and claſſical learning; and though Burke oppoſed the taxation of America by the Britiſh parliament, his oppoſition proceeded rather from motives of prudence and expediency than from any ſettled conviction that the meaſure was unconſtitutional. But the political enmity of Fox and North had proceeded, not only to perſonal abuſe, but to profeſſions of mutual abhorrence; and perhaps there was hardly an unprejudiced perſon in the kingdom who entertained not ſuſpicions, that the unexpected union of ſuch enemies was cemented by a principle leſs pure than patriotiſm.

Mr Pitt was now chancellor of the exchequer; and when he announced to the houſe of commons the peace which was concluded in January 1783, he found the terms on which it had been made ſeverely condemned by North, Fox, Burke, and all their friends. The cenſure paſſed on it by Lord North and his followers was perfectly conſiſtent with their former conduct, and with the opinions which they had uniformly maintained; but it was with no good grace that Fox and Burke, who had offered an unconditional peace to the Dutch, and ſo frequently propoſed to recognize the independence of America, condemned the peace which had been concluded by Lord Shelburne. On this, as on many other occaſions, they acted, not as enlightened politicians, but as the rancorous leaders of a party.

In conſequence of a vote of cenſure paſſed by the commons, the miniſters reſigned their employments, and were ſucceeded by the duke of Portland, Lord North, Mr Fox, Mr Burke, and their friends. Burke had his former employment of paymaſter to the forces; Lord North and Mr Fox were ſecretaries of ſtate, and the duke of Portland was firſt lord of the treaſury. To many perſons this miniſtry had the appearance of greater ſtrength than any that had governed the kingdom ſince the time of Sir Robert Walpole; but its duration was not longer than that of the preceding. On the 18th of November, Mr Fox introduced his famous India-bill, into the merits of which it is foreign from our purpoſe to enter: ſuffice it to ſay, that after being ſtrongly ſupported by Burke, and ably oppoſed by Pitt and Dundas, it paſſed the houſe of commons by a very great majority; but was loſt in the houſe of peers, and viewed by the king in ſuch a light, that he determined on an entire change of adminiſtration.

Mr Pitt was now placed at the head of the treaſury, where he has remained ever ſince (1800), notwithſtanding the violent and powerful oppoſition which he met with at firſt from North and Fox and their coaleſced friends: the voice of the nation has been on his ſide; and that voice will always drown the bellowings of patriotiſm.

The principal events in which Burke ſignalized himſelf, ſince the year 1784, were the trial of Haſtings, the deliberations of the houſe on the propoſed regency during the lamented illneſs of the king, and the French revolution; and on each of theſe occaſions he diſplayed talents which aſtoniſhed the nation. He has, indeed, been ſeverely blamed for the pertinacity with which he proſecuted Mr Haſtings, and his conduct has been attributed to very unworthy motives; but of this there is neither proof nor probability. The temperament of his mind was ſuch, that, into whatever meaſure he entered, he entered with a degree of ardour of which cooler heads can hardly form a conception. Burke was but one member of a committee which found, or thought it found, evidences of the guilt of Haſtings; and, in forming his opinion, it is little likely that he ſhould have been biaſſed by intereſt or reſentment, whoſe delicate ſenſe of rectitude would not permit him to retain a penſion when he could no longer ſupport the party of that friend who had obtained it for him.

When the eſtabliſhment of a regency was thought neceſſary, he took the part, as it was called, of the Prince of Wales, in oppoſition to the plan propoſed by Lord Thurlow and the miniſter; and we doubt not but he was actuated by the pureſt principles: but the language which he uſed in the houſe was vehement, and ſome of his expreſſions were highly indecent. Our regard for his memory makes us wiſh to forget them.

Soon after the recovery of the king, the attention of Burke was attracted to the moſt momentous event of modern times;—an event which has convulſed all Europe, and of which, from the very firſt, his ſagacity foreſaw the conſequences. Many of his friends in Parliament, as well as numbers of wiſe and good men out of it, augured, from the meeting of the ſtates-general of France, great benefit to that nation, of which the government was conſidered as deſpotic and oppreſſive; and ſome were ſanguine enough to prognoſticate a new and happy order of things to all the nations connected with France, when its government ſhould become more free. Burke thought very differently: He was well acquainted with the genius of the French people, and with the principles of thoſe philoſophers, as they called themſelves, by whom a total revolution in church and ſtate had long been projected; and from the commencement of their career in the conſtituent aſſembly, when they eſtabliſhed, as the foundation of all legal government, the metaphyſical doctrine of *the rights of man*, he predicted that torrent of anarchy and irreligion which they have ſince attempted to pour over all Europe. Fox and ſome of the other leading men in oppoſition affected to conſider this as a vain fear; and a coolneſs took place between them and Burke, though they ſtill acted together in Parliament. At laſt, perceiving the French doctrines of liberty and equality, and atheiſm, ſpreading through this nation, not only among thoſe who had talents for ſuch diſquiſitions, but in clubs and ſocieties, of which the members could be no judges of metaphyſical reaſonings, he expreſſed his apprehenſion of the conſequences in the houſe of commons. This brought on a violent altercation between him and Fox, who was ſupported by Sheridan; and a rupture took place between theſe old friends which was never healed. He no more attended the meetings of the oppoſition members; and in 1790 he publiſhed his celebrated *Reflections on the French Revolution*.

By the friends of government this work was admired as the moſt ſeaſonable, as well as one of the ableſt, defences of the Britiſh conſtitution that ever was written; whilſt Fox and his friends, with the great body of Engliſh diſſenters, though they admitted it to be the offſpring of uncommon genius, affected to conſider it as declamatory rather than argumentative, and as inconſiſtent with the principles which its author had hitherto uniformly maintained. Many anſwers were written to it; of which the moſt conſpicuous were *Vindiciæ Gallicæ* by Mr Mac Intoſh, and *The Rights of Man* by Thomas Paine. To theſe Burke deigned not to make a direct reply. He vindicated his general principles, as well as ſome of his particular reaſonings, in *A Letter to a Member of the National Aſſembly*; and he very completely evinced the conſiſtency of his principles in his *Appeal from the New to the Old Whigs*.

Of this great work, for great it undoubtedly is, the merits as well as the demerits have been much exaggerated; and ſome have made it a queſtion, Whether it has on the whole been productive of good or harm? By the enemies of the author, it is repreſented as having given riſe to the ſpirit of diſcontent, by exciting ſuch writers as Paine and his adherents, who, but for the provocation given by *The Reflections*, might have remained in ſilence and obſcurity. This was from the firſt a very improbable ſuppoſition; for the ſpirit of democracy has at all times been reſtleſs: but ſince the appearance of Profeſſor Robiſon's *Proofs of a Conſpiracy*, and Barruel's *Hiſtory of Jacobiniſm*, it muſt be known to every reader to be a ſuppoſition contrary to fact. The conſpirators were buſy long before Burke wrote his *Reflections*; and the friends of order and religion are his debtors, for having ſo forcibly rouſed them from their ſlumber, and put them on their guard. With reſpect to compoſition, it is certainly neither ſo energetic nor ſo argumentative as the political tracts of Johnſon, to which ſome have affected to conſider it as ſuperior: but it is more poetical, gives ſcope for a greater diſplay of the knowledge of human nature; and, being written on a more intereſting ſubject, it has had a much greater number of readers than thoſe unrivalled pieces of political controverſy.

Burke being now aſſociated with Mr Pitt, continued to write from time to time memorials and remarks on the ſtate of France, and the alliance that was formed againſt the new order of things in that diſtracted country, of which ſome have been publiſhed ſince his death; and having reſolved to quit the buſtle of public life as ſoon as the trial of Mr Haſtings ſhould be concluded, he vacated his ſeat when that gentleman was acquitted, and retired to his villa at Beaconsfield, where, on the 2d of Auguſt 1794, he met with a heavy domeſtic loſs in the death of his only ſon. In the beginning of the ſame year he had loſt his brother Richard, whom he tenderly loved: but though this reiterated ſtroke of death deeply affected him, it never relaxed the vigour of his mind, nor leſſened the intereſt which he took in the public weal.

In this retreat, while he was labouring for the good of all around him, he was diſturbed by a very unprovoked attack upon his character by ſome diſtinguiſhed ſpeakers in the houſe of Peers. Soon after the death of his ſon the king was graciouſly pleaſed to beſtow a penſion on him and Mrs Burke; and this thoſe noble lords were pleaſed to repreſent as the reward of what they termed the change of his principles and the deſertion of his friends. The injuſtice of this charge muſt be obvious to every impartial mind, ſince the penſion was given after he had retired from parliament, and could not by his eloquence either ſupport the miniſtry or gall the oppoſition. He was not a man to ſubmit tamely to ſuch an inſult. He publiſhed a letter on the occaſion, addreſſed to a noble lord (Earl Fitzwilliam), in which he repels the attack on his character, and retaliates on thoſe by whom it was made, in terms of ſuch eloquent and keen ſarcaſm, as will be read with admiration as long as the language of the letter ſhall be underſtood.

Burke having employed every effort which benevolence and wiſdom could deviſe to ſtimulate civilized governments to unite in oppoſition to the impiety and anarchy of France, laboured likewiſe in private to relieve thoſe who had ſuffered exile and proſcription from the direful ſyſtem. Through his influence a ſchool was eſtabliſhed in his neighbourhood for the education of thoſe whoſe parents, for their adherence to principle, were rendered unable to afford to their children uſeful inſtruction; and that ſchool, which on his deathbed he recommended to Mr Pitt, continues to flouriſh under his powerful protection.

When the appearance of melioration in the principles and government of France induced our ſovereign to make overtures of peace to the French directory, Burke reſumed his pen; and in a ſeries of letters, intitled, *Thoughts on the Proſpect of a Regicide Peace*, diſplayed a force of genius which is certainly not ſurpaſſed, and perhaps not equalled, even in his far-famed *Reflections on the French Revolution*. This was his laſt work, and was conſidered by himſelf as in its nature teſtamentary.

From the beginning of June 1797 his health rapidly declined; but his underſtanding exerted itſelf with undiminiſhed force and uncontracted range; and his diſpoſitions retained all their amiable ſweetneſs. On the 7th of July, when the French revolution was mentioned, he ſpoke with pleaſure of the conſcious rectitude of his own intentions in what he had done and written reſpecting it; entreated thoſe about him to believe, that if any unguarded expreſſion of his on the ſubject had offended any of his former friends, no offence was by him intended; and he declared his unfeigned forgiveneſs of all who had on account of his writings, or for any other cauſe, endeavoured to do him an injury. On the day following he deſired to be carried to another room; and whilſt one of his friends, aſſiſted by ſome ſervants, was complying with his requeſt, Mr Burke faintly uttering, "God bleſs you," fell back and expired in the 68th year of his age.

From this detail, we truſt that our readers are already ſufficiently acquainted with his general character. In genius, variety of knowledge, and readineſs of expreſſion, Johnſon alone of all his contemporaries could be conſidered as his rival; and, like that great man, he took every opportunity, eſpecially during his laſt illneſs, to declare his unſhaken belief of the Chriſtian religion, his veneration for ſincere Chriſtians of all perſuaſions, and his own preference of the church of England. On the worſhip of that church he had indeed through the whole of his life been a regular and devout attendant; and the tears which the poor, in the neighbourhood of his villa, ſhed at his funeral, gave ſufficient evidence that his faith had been productive of charity. In his public conduct, the irritability of his temper, and the ardour of his imagination, ſometimes hurried him into the exceſſes of a mere party-man; but we believe that his great religious and political principles never varied. He has himſelf characteriſed his public conduct in the concluſion of his Reflections on the French Revolution, when he ſays, that "they come from one who has been no tool of power, no flatterer of greatneſs, and who in his laſt acts does not wiſh to belie the tenor of his life; from one who wiſhes to preſerve conſiſtency, but who would preſerve conſiſtency by varying his means to ſecure the unity of his end; and when the equipoiſe of the veſſel in which he ſails may be endangered by overloading it upon one ſide, is deſirous of carrying the ſmall weight of his reaſons to that which may preſerve the equipoiſe."

BURNET (James, Eſq;), better known by the title of *Lord Monboddo*, deſcended from an ancient family in the county of Mearns in Scotland. He was the eldeſt ſon of Arthur Burnet, Eſq; of Monboddo, where he was born in the year 1714. After paſſing through the uſual courſe of ſchool education, he proſecuted his ſtudies at the univerſities of Aberdeen, Edinburgh, and

Leyden, with diſtinguiſhed reputation. He was admitted an advocate in 1737; and on the 12th of February 1767, he was raiſed to the bench, by the title of Lord Monboddo, in the room of Lord Milton, appointed a judge the 4th of June 1742, and who had ſucceeded Sir John Lauder of Fountainhall, admitted November 1. 1689; ſo that he was only the third judge in ſucceſſion ſince the revolution.

Before his promotion to the bench, he had married Miſs Farquharſon, a very amiable woman, by whom he had a ſon and two daughters; whom, without regarding the difference of climate, he reared as the children of ancient Greece were reared.

From early youth Lord Monboddo's application to literary and juridical ſtudies was ſeverely diligent. Between claſſical literature and the law of Scotland, there exiſts a ſtrong connection, ariſing from the adoption of the forms and maxims of the civil law of the Romans, by the ancient legiſlators and judges of Scotland. Accordingly, while Mr Burnet roſe into reputation as a lawyer, he at the ſame time improved into profound erudition that knowledge of the Greek and Roman authors which he had acquired at ſchool and the univerſity; and his partiality to the Greek language could not fail to be ſtrengthened by his frequent converſations with Dr Blackwell, the celebrated profeſſor of that language in the Mariſchal College and Univerſity of Aberdeen.

His favourite ſtudies, however, were not ſuffered to interfere with his duty as a judge. In his native county, his integrity as *Sheriff* will be long remembered; and during the whole time that he was a Lord of Seſſion, he diſcharged the duties of his high office with an aſſiduity, a patience, a clear intelligence, and inflexible rectitude, which did honour to the court of which he was a judge. Like others, he was liable to error; but neither the awe of power, the blandiſhments of flattery, nor even compaſſion for diſtreſs, could turn Lord Monboddo aſide from what he believed to be the courſe of juſtice.

Several of the judges of the court of ſeſſion were at that period ambitious of ſhining among philoſophers and men of taſte; and Lord Kames's *Elements of Criticiſm* is a work which will be long read, and always admired. It was not, however, admired by Lord Monboddo; and he determined to vindicate the ſuperiority of the ancients over the moderns, as well in philoſophy as in belles lettres. With this view he publiſhed, in 1773, the firſt volume of his ORIGIN AND PROGRESS OF LANGUAGE; which was peruſed with mingled ſentiments of reſpect and indignation. It was better received in England than in his own country; and notwithſtanding the ridicule brought upon him by his belief in the exiſtence of *mermen*, and *men with tails*, the author felt himſelf ſufficiently encouraged to complete his plan in five volumes.

Having, as he thought, vindicated *Grecian literature*, he was induced to undertake another great work in defence of *Grecian philoſophy*, againſt the ſtill more arrogant claims, as he deemed them, of Bacon and Newton, with their followers. With this view, he publiſhed, at different times, and in ſix volumes 4to, a work intitled *Ancient Metaphyſics*, fraught, it muſt be confeſſed, with much erudition, much good ſenſe, and, ſtrange as the combination may ſeem, with much abſurdity. In the preface to the firſt volume, he declares open war againſt all modern writers of philoſophy, except Mr Harris, who was an adorer of the ancients like himſelf, Mr Baxter, and Dr Cudworth. He acknowledges Baxter's book on the Immateriality of the Soul to be a truly valuable work; and ſays of Cudworth's *Intellectual Syſtem*, that he agrees with it throughout. There is indeed ſuch a coincidence of notions in the *Intellectual Syſtem* and the *Ancient Metaphyſics*, that an ill-natured critic might be tempted to ſuſpect, that every thing valuable in the latter was borrowed from the former.

The Ancient Metaphyſics had few admirers in Scotland; but it procured for its author, from a ſcholar of Oxford, we think Mr Huntingford, the title of αλλος Αριστοτελης. His Lordſhip continued to cultivate what he called *Greek philoſophy*, and to attend his judicial duties, with indefatigable diligence till within a few days of his death, which happened at his houſe in Edinburgh, on the 26th of May 1799, at the advanced age of 85.

His private life was ſpent in the practice of all the ſocial virtues, and in the enjoyment of much domeſtic felicity. Although rigidly temperate in his habits of life, he, however, delighted much in the convivial ſociety of his friends; and among theſe he could number almoſt all the moſt eminent of thoſe who were diſtinguiſhed in Scotland for virtue, literature, or genuine elegance of converſation and manners. His ſon, a very promiſing boy, in whoſe education he took great delight, was ſnatched away from his affections by a premature death. But when it was too late for ſorrow and anxiety to avail, the afflicted father ſtifled the emotions of nature in his breaſt, and wound up the energies of his ſoul to the firmeſt tone of ſtoical fortitude. He was, in like manner, bereaved of his excellent lady, the object of his deareſt tenderneſs; and he endured the loſs with a ſimilar firmneſs, fitted to do honour either to philoſophy or to religion. In addition to his office as a judge in the court of ſeſſion, an offer was made to him of a ſeat in the court of juſticiary. But though the emoluments of the office would have made a convenient addition to his income, he refuſed to accept it, leſt its buſineſs ſhould too much detach him from the purſuit of his favourite ſtudies.

The vacations of the court of ſeſſion afforded him ſufficient leiſure to retire every year, in ſpring and in autumn, to the country; and he uſed then to dreſs in a ſtyle of ſimplicity, as if he had been only a plain farmer; and to live among the people upon his eſtate with all the kind familiarity and attention of an aged father among his grown-up children. Although the eſtate, from the old leaſes, did not afford an income of more three or four hundred pounds a-year, he would never raiſe the rents upon his old tenants, nor diſplace an old tenant, for the ſake of any augmentation of emolument offered by a richer or more enterpriſing ſtranger In imitation of the rural economy of ſome of the ancients, whom he chiefly admired, he accounted population the true wealth of an eſtate, and was deſirous of no other improvement of his lands, than that of having the number of perſons that ſhould reſide upon them, and be ſuſtained by their produce, ſuperior to that of the population of any equal portion of the lands of his neighbours.

It was at Monboddo that he had the pleaſure of receiving Dr Samuel Johnſon, with his friend James Boſwell, at the time when theſe two gentlemen were

upon

upon their well-known Tour through the Highlands of Scotland. Johnſon admired nothing in literature ſo much as the diſplay of a keen diſcrimination of human character, a juſt apprehenſion of the principles of moral action, and that vigorous common ſenſe which is the moſt happily applicable to the ordinary conduct of life. Monboddo delighted in the refinements, the ſubtleties, the abſtractions, the affectations, of literature; and, in compariſon with theſe, deſpiſed the groſſneſs of modern taſte and of common affairs. Johnſon thought learning and ſcience to be little valuable, except ſo far as they could be made ſubſervient to the purpoſes of living uſefully and happily with the world upon its own terms. Monboddo's favourite ſcience taught him to look down with contempt upon all ſublunary, and eſpecially upon all modern things; and to fit life to literature and philoſophy, not literature and philoſophy to life. James Boſwell, therefore, in carrying Johnſon to viſit Monboddo, probably thought of *pitting* them one againſt another, as two game cocks, and promiſed himſelf much ſport from the colloquial conteſt which he expected to enſue between them. But Monboddo was too hoſpitable and courteous to enter into keen contention with a ſtranger in his own houſe. There was much talk between them, but no angry controverſy, no exaſperation of that diſlike for each other's well-known peculiarities with which they had met. Johnſon, it is true, ſtill continued to think Lord Monboddo what he called *a prig* in literature; and Monboddo to cenſure Johnſon for allowing the moderns, in ſome things, to ſurpaſs the ancients.

Lord Monboddo uſed frequently to viſit London, to which he was allured by the opportunity that great metropolis affords of enjoying the converſation of a vaſt number of men of profound erudition. A journey to the capital became a favourite amuſement of his periods of vacation from the buſineſs of the court to which he belonged; and, for a time, he made this journey once a-year. A carriage, a vehicle that was not in common uſe among the ancients, he conſidered as an engine of effeminacy and ſloth, which it was diſgraceful for a man to make uſe of in travelling. To be dragged at the tail of a horſe, inſtead of mounting upon his back, ſeemed, in his eyes, to be a truly ludicrous degradation of the genuine dignity of human nature. In all his journeys, therefore, between Edinburgh and London, he was wont to ride on horſeback, with a ſingle ſervant attending him. He continued this practice, without finding it too fatiguing for his ſtrength, till he was upwards of eighty years of age. Within a few years of his death, on his return from a laſt viſit, which he made on purpoſe to take leave of all his old friends in London, he became exceedingly ill upon the road, and was unable to proceed; and had he not been overtaken by a Scotch friend, who prevailed upon him to travel the remainder of the way in a carriage, he might perhaps have actually periſhed by the way-ſide, or breathed his laſt in ſome dirty inn.

In London, his viſits were exceedingly acceptable to all his friends, whether of the literary or faſhionable world. He delighted to ſhew himſelf at court; and the king is ſaid to have taken a pleaſure in converſing with the old man with a diſtinguiſhing notice that could not but be very flattering to him. He uſed to mingle, with great ſatisfaction, with the learned and the ingenious, at the houſe of Mrs Montague. However, after the death of his friend Mr Harris, he found a very ſenſible diminution of the pleaſure he had been wont to enjoy in the ſociety of London.

A conſtitution of body, naturally framed to wear well and laſt long, was ſtrengthened to Lord Monboddo by exerciſe, guarded by temperance, and by a tenor of mind too firm to be deeply broken in upon by thoſe paſſions which conſume the principles of life. In the country he always uſed much the exerciſes of walking in the open air and of riding. The cold bath was a means of preſerving the health, to which he had recourſe in all ſeaſons, amid every ſeverity of the weather, and under every inconvenience of indiſpoſition or buſineſs, with a perſeverance invincible. He was accuſtomed, alike in winter and in ſummer, to riſe at a very early hour in the morning, and, without loſs of time, to betake himſelf to ſtudy or wholeſome exerciſe. It is ſaid that he even found the uſe of what he called the air bath, or the practice of occaſionally walking about, for ſome minutes, naked, in a room filled with freſh and cool air, to be highly ſalutary. In a word, if his peculiarities were ſtriking, his virtues, and learning, and talents, were equally ſtriking; and, taken altogether, he muſt be conſidered as a great and a good man.

BURNS (Robert), was a native of Airſhire, one of the weſtern counties of Scotland. He was the ſon of humble parents; and his father paſſed through life in the condition of a hired labourer, or of a ſmall farmer. Even in this ſituation, however, it was not hard for him to ſend his children to the pariſh-ſchool, to receive the ordinary inſtruction in reading, writing, arithmetic, and the principles of religion. By this courſe of education young Robert profited to a degree that might have encouraged his friends to deſtine him to one of the liberal profeſſions, had not his father's poverty made it neceſſary to remove him from ſchool, as ſoon as he had grown up, to earn for himſelf the means of ſupport as a hired ploughboy or ſhepherd.

The expence of education in the pariſh-ſchools of Scotland is ſo ſmall, that hardly any parents who are able to labour want the means of giving to their children at leaſt ſuch education as young Burns received. From the ſpring labours of a ploughboy, from the ſummer employment of a ſhepherd, the peaſant-youth often returns for a few months, eagerly to purſue his education at the pariſh-ſchool.

It was ſo with Burns: he returned from labour to learning, and from learning went again to labour, till his mind began to open to the charms of taſte and knowledge; till he began to feel a paſſion for books, and for the ſubjects of books, which was to give a colour to the whole thread of his future life. On nature he ſoon began to gaze with new diſcernment and with new enthuſiaſm: his mind's eye opened to perceive affecting beauty and ſublimity, where, by the mere groſs peaſant, there was nought to be ſeen but water, earth, and ſky—but animals, plants, and ſoil.

What might perhaps firſt contribute to diſpoſe his mind to poetical efforts, is one particular in the devotional piety of the Scottiſh peaſantry; it is ſtill common for them to make their children get by heart the Pſalms of David, in that verſion of homely rhymes which is uſed in their churches. In the morning and in the evening of every day, or at leaſt on the evening of every Saturday and Sunday, theſe Pſalms are ſung in ſolemn family-devotion, a chapter of the Bible is read, and extemporary prayer is fervently uttered. The whole books of the Sacred Scriptures are thus continually in the hands of almoſt every peaſant. And it is impoſſible that there ſhould not be occaſionally ſome ſouls among them, awakened to the divine emotions of genius by that rich aſſemblage which thoſe books preſent, of almoſt all that is intereſting in incidents, or pictureſque in imagery, or affectingly ſublime or tender in ſentiments and character. It is impoſſible that thoſe rude rhymes, and the ſimple artleſs muſic with which they are accompanied, ſhould not occaſionally excite ſome ear to a fond perception of the melody of verſe. That Burns had felt theſe impulſes, will appear undeniably certain to whoever ſhall carefully peruſe his *Cottar's Saturday's Night;* or ſhall remark, with nice obſervation, the various fragments of Scripture ſentiment, of Scripture imagery, of Scripture language, which are ſcattered throughout his works.

Still more intereſting to the young peaſantry are thoſe ancient ballads of love and war, of which a great number are, in the ſouth of Scotland, yet popularly known, and often ſung by the ruſtic maid or matron at her ſpinning-wheel. They are liſtened to with raviſhed ears by old and young. Their rude melody; that mingled curioſity and awe which are naturally excited by the very idea of their antiquity; the exquiſitely tender and natural complaints ſometimes poured forth in them; the gallant deeds of knightly heroiſm, which they ſometimes celebrate; their wild tales of demons, ghoſts, and fairies, in whoſe exiſtence ſuperſtition alone has believed; the manners which they repreſent; the obſolete, yet pictureſque and expreſſive, language in which they are often clothed—give them wonderful power to tranſport every imagination, and to agitate every heart. To the ſoul of Burns they were like a happy breeze touching the wires of an Æolian harp, and calling forth the moſt raviſhing melody.

Beſide all this, the Gentle Shepherd, and the other poems of Allan Ramſay, have long been highly popular in Scotland. They fell early into the hands of Burns; and while the fond applauſe which they received drew his emulation, they preſented to him likewiſe treaſures of phraſeology and models of verſification. He got acquainted at the ſame time with the poetry of Robert Ferguſon, written chiefly in the Scottiſh dialect, and exhibiting many ſpecimens of uncommon poetical excellence. The Seaſons of Thomſon too, the Grave of Blair, the far-famed Elegy of Gray, the Paradiſe Loſt of Milton, perhaps the Minſtrel of Beattie, were ſo commonly read, even among thoſe with whom Burns would naturally aſſociate, that poetical curioſity, although even leſs ardent than his, could in ſuch circumſtances have little difficulty in procuring them.

With ſuch means to give his imagination a poetical bias, and to favour the culture of his taſte and genius, Burns gradually became a poet. He was not, however, one of thoſe forward children who, from a miſtaken impulſe, begin prematurely to write and to rhyme, and hence never attain to excellence. Converſing familiarly for a long while with the works of thoſe poets who were known to him; contemplating the aſpect of nature in a diſtrict which exhibits an uncommon aſſemblage of the beautiful and the ruggedly grand, of the cultivated and the wild; looking upon human life with an eye quick and keen, to remark as well the ſtronger and leading, as the nicer and ſubordinate, features of character; to diſcriminate the generous, the honourable, the manly, in conduct, from the ridiculous, the baſe, and the mean—he was diſtinguiſhed among his fellows for extraordinary intelligence, good ſenſe, and penetration, long before others, or perhaps even himſelf, ſuſpected him to be capable of writing verſes. His mind was mature, and well ſtored with ſuch knowledge as lay within his ſearch: he had made himſelf maſter of powers of language, ſuperior to thoſe of almoſt any former writer in the Scottiſh dialect, before he conceived the idea of ſurpaſſing Ramſay and Ferguſon.

Hitherto he had converſed intimately only with peaſants on his own level; but having got admiſſion into the fraternity of free maſons, he had the fortune, whether good or bad, to attract in the lodges the notice of gentlemen better qualified than his more youthful companions to call forth the powers of his mind, and to ſhow him that he was indeed a poet. A maſonic ſong, a ſatirical epigram, a rhyming epiſtle to a friend, attempted with ſucceſs, taught him to know his own powers, and gave him confidence to try taſks more arduous, and which ſhould command ſtill higher burſts of applauſe.

The annual celebration of the ſacrament of the Lord's Supper, in the rural pariſhes of Scotland, has much in it of thoſe old popiſh feſtivals, in which ſuperſtition, traffic, and amuſement, uſed to be ſtrangely intermingled. Burns ſaw, and ſeized in it one of the happieſt of all ſubjects, to afford ſcope for the diſplay of that ſtrong and piercing ſagacity by which he could almoſt intuitively diſtinguiſh the reaſonable from the abſurd, and the becoming from the ridiculous; of that pictureſque power of fancy, which enabled him to repreſent ſcenes, and perſons, and groupes, and looks, attitude, and geſtures, in a manner almoſt as lively and impreſſive, even in words, as if all the artifices and energies of the pencil had been employed; of that knowledge which he had neceſſarily acquired of the manners, paſſions, and prejudices of the ruſtics around him, of whatever was ridiculous, no leſs than of whatever was affectingly beautiful in rural life.

A thouſand prejudices of Popiſh, and perhaps too of ruder Pagan ſuperſtition, have from time immemorial been connected in the minds of the Scottiſh peaſantry, with the annual recurrence of the Eve of the Feſtival of all the Saints or Halloween. Theſe were all intimately known to Burns, and had made a powerful impreſſion upon his imagination and feelings. He choſe them for the ſubject of a poem, and produced a piece which is almoſt to frenzy the delight of thoſe who are beſt acquainted with its ſubject; and which will not fail to preſerve the memory of the prejudices and uſages which it deſcribes, when they ſhall perhaps have ceaſed to give one merry evening in the year to the cottage fireſide.

The ſimple joys, the honeſt love, the ſincere friendſhip, the ardent devotion of the cottage; whatever in the more ſolemn part of the ruſtic's life is humble and artleſs, without being mean or unſeemly—or tender and dignified, without aſpiring to ſtilted grandeur—or to unnatural, buſkined pathos, had deeply impreſſed the imagination of the riſing poet; had, in ſome ſort, wrought itſelf into the very texture of the fibres of his ſoul. He tried to expreſs in verſe what he moſt tenderly felt, what he moſt enthuſiaſtically imagined; and produced the *Cottar's Saturday Night*.

Theſe pieces, the true effuſions of genius, informed by reading and obſervation, and prompted by its own native ardour, as well as by friendly applauſe, were ſoon handed about among the moſt diſcerning of Burns's acquaintance; and were by every new reader peruſed, and reperuſed, with an eagerneſs of delight and approbation which would not ſuffer their author long to withhold them from the preſs. A ſubſcription was propoſed, was earneſtly promoted by ſome gentlemen, who were glad to intereſt themſelves in behalf of ſuch ſignal poetical merit; was ſoon crowded with the names of a conſiderable number of the inhabitants of Airſhire, who in the proffered purchaſe ſought not leſs to gratify their own paſſion for Scottiſh poeſy, than to encourage the wonderful ploughman. At Kilmarnock were the poems of Burns for the firſt time printed. The whole edition was quickly diſtributed over the country.

It is hardly poſſible to expreſs with what eager admiration and delight they were everywhere received.— They eminently poſſeſſed all thoſe qualities which the moſt invariably contribute to render any literary work quickly and permanently popular. They were written in a phraſeology, of which all the powers were univerſally felt; and which being at once antique, familiar, and now rarely written, was hence fitted to ſerve all the dignified and pictureſque uſes of poetry, without making it unintelligible. The imagery, the ſentiments, were at once faithfully natural, and irreſiſtibly impreſſive and intereſting. Thoſe topics of ſatire and ſcandal in which the ruſtic delights; that humorous imitation of character, and that witty aſſociation of ideas familiar and ſtriking, yet not naturally allied to one another, which has force to ſhake his ſides with laughter; thoſe fancies of ſuperſtition, at which he ſtill wonders and trembles; thoſe affecting ſentiments and images of true religion, which are at once dear and awful to his heart —were all repreſented by Burns with all a poet's magic power. Old and young, high and low, grave and gay, learned or ignorant, all were alike delighted, agitated, tranſported.

In the mean time, ſome few copies of theſe faſcinating poems found their way to Edinburgh; and having been read to Dr Blacklock, they obtained his warmeſt approbation. In the beginning of the winter 1786-7 Burns went to Edinburgh, where he was received by Dr Blacklock with the moſt flattering kindneſs, and introduced to every man of generoſity and taſte among that good man's friends. Multitudes now vied with each other in patronizing the ruſtic poet. Thoſe who poſſeſſed at once true taſte and ardent philanthropy were ſoon earneſtly united in his praiſe: they who were diſpoſed to favour any good thing belonging to Scotland, purely becauſe it was Scottiſh, gladly joined the cry; thoſe who had hearts and underſtanding to be charmed, without knowing why, when they ſaw their native cuſtoms, manners, and language, made the ſubjects and the materials of poeſy, could not ſuppreſs that voice of feeling which ſtruggled to declare itſelf for Burns: for the diſſipated, the licentious, the malignant wits, and the freethinkers, he was ſo unfortunate as to have ſatire, and obſcenity, and ridicule of things ſacred, ſufficient to captivate their fancies; even for the pious he had paſſages in which the inſpired language of devotion might ſeem to come mended from his pen.

Thus did Burns, ere he had been many weeks in Edinburgh, find himſelf the object of univerſal curioſity, favour, admiration, and fondneſs. He was ſought after, courted with attentions the moſt reſpectful and aſſiduous, feaſted, flattered, careſſed, treated by all ranks as the firſt boaſt of his country, whom it was ſcarcely poſſible to honour and reward to a degree equal to his merits. In compariſon with the general favour which now promiſed to more than crown his moſt ſanguine hopes, it could hardly be called praiſe at all which he had obtained in Airſhire.

In this poſture of our poet's affairs a new edition of his poems was earneſtly called for. He ſold the copyright for one hundred pounds; but his friends at the ſame time ſuggeſted, and actively promoted, a ſubſcription for an edition, to be publiſhed for the benefit of the author, ere the bookſeller's right ſhould commence. Thoſe gentlemen who had formerly entertained the public of Edinburgh with the periodical publication of the papers of the *Mirror*, having again combined their talents in producing the *Lounger*, were at this time about to conclude this laſt ſeries of papers; yet before the Lounger relinquiſhed his pen, he dedicated a number to a commendatory criticiſm of the poems of the Airſhire bard.

The ſubſcription-papers were rapidly filled; and it was ſuppoſed that the poet might derive from the ſubſcription and the ſale of his copy-right a clear profit of at leaſt 700 pounds.

The converſation of even the moſt eminent authors is often found to be ſo unequal to the fame of their writings, that he who reads with admiration can liſten with none but ſentiments of the moſt profound contempt. But the converſation of Burns was, in compariſon with the formal and exterior circumſtances of his education, perhaps even more wonderful than his poetry. He affected no ſoft air or graceful motions of politeneſs, which might have ill accorded with the ruſtic plainneſs of his native manners. Conſcious ſuperiority of mind taught him to aſſociate with the great, the learned, and the gay, without being overawed into any ſuch baſhfulneſs as might have made him confuſed in thought, or heſitating in elocution. He poſſeſſed withal an extraordinary ſhare of plain common ſenſe or mother-wit, which prevented him from obtruding upon perſons, of whatever rank with whom he was admitted to converſe, any of thoſe effuſions of vanity, envy, or ſelf-conceit, in which authors are exceedingly apt to indulge, who have lived remote from the general practice of life, and whoſe minds have been almoſt excluſively confined to contemplate their own ſtudies and their own works. In converſation he diſplayed a ſort of intuitive quickneſs and rectitude of judgment upon every ſubject that aroſe. The ſenſibility of his heart, and the vivacity of his fancy, gave a rich colouring to whatever reaſoning he was diſpoſed to advance; and his language in converſation was not at all leſs happy than in his writings. For theſe reaſons, thoſe who had met and converſed with him once, were pleaſed to meet and to converſe with him again and again.

For ſome time he converſed only with the virtuous, the learned, and the wiſe; and the purity of his morals remained uncontaminated. But, alas! he fell, as others have fallen in ſimilar circumſtances. He ſuffered himſelf to be ſurrounded by a race of miſerable beings, who were proud to tell that they had been in company with Burns, and had ſeen Burns as looſe and as fooliſh as themſelves. He was not yet irrecoverably loſt to temperance and moderation; but he was already almoſt too much captivated with their wanton revels, to be ever more won back to a faithful attachment to their more ſober charms. He now alſo began to contract ſomething of new arrogance in converſation. Accuſtomed to be among his favourite aſſociates what is vulgarly but expreſſively called *the cock of the company*, he could ſcarcely refrain from indulging in ſimilar freedom and dictatorial deciſion of talk, even in the preſence of perſons who could leſs patiently endure his preſumption.

The ſubſcription-edition of his poems, in the mean time, appeared; and although not enlarged beyond that which came from the Kilmarnock preſs by any new pieces of eminent merit, did not fail to give entire ſatisfaction to the ſubſcribers. He was now to cloſe accounts with his bookſeller and his printer, to retire to the country with his profits in his pocket, and to fix upon a plan for his future life. He talked loudly of independence of ſpirit and ſimplicity of manners, and boaſted his reſolution to return to the plough; yet ſtill he lingered in Edinburgh, week after week, and month after month, perhaps expecting that one or other of his noble patrons might procure him ſome permanent and competent annual income, which ſhould ſet him above all neceſſity of future exertions to earn for himſelf the means of ſubſiſtence; perhaps unconſciouſly reluctant to quit the pleaſures of that voluptuous town-life to which he had for ſome time too willingly accuſtomed himſelf. An accidental diſlocation or fracture of an arm or a leg confining him for ſome weeks to his apartment, left him during this time leiſure for ſerious reflection; and he determined to retire from the town without longer delay. None of all his patrons interpoſed to divert him from his purpoſe of returning to the plough, by the offer of any ſmall penſion, or any ſinecure place of moderate emolument, ſuch as might have given him competence without withdrawing him from his poetical ſtudies. It ſeemed to be forgotten that a ploughman thus exalted into a man of letters was unfitted for his former toils, without being regularly qualified to enter the career of any new profeſſion; and that it became incumbent upon thoſe patrons who had called him from the plough, not merely to make him their companion in the hour of riot, not ſimply to fill his purſe with gold for a few tranſient expences, but to ſecure him as far as was poſſible from being ever overwhelmed in diſtreſs in conſequence of the favour which they had ſhown him, and of the habits of life into which they had ſeduced him. Perhaps indeed the ſame deluſion of fancy betrayed both Burns and his patrons into the miſtaken idea, that, after all which had paſſed, it was ſtill poſſible for him to return in cheerful content to the homely joys and ſimple toils of undiſſipated rural life.

In this temper of Burns's mind, in this ſtate of his fortune, a farm and the exciſe were the objects upon which his choice ultimately fixed for future employment and ſupport. By the ſurgeon who attended him during his illneſs, he was recommended with effect to the commiſſioners of exciſe; and Patrick Millar, Eſq. of Dalſwinton, deceived, like Burns himſelf and Burns's other friends, into an idea that the poet and exciſeman might yet be reſpectable and happy as a farmer, generouſly propoſed to eſtabliſh him in a farm, upon conditions of leaſe which prudence and induſtry might eaſily render exceedingly advantageous. Burns eagerly accepted the offers of this benevolent patron. Two of the poet's friends from Airſhire were invited to ſurvey that farm in Dumfriesſhire which Mr Millar offered. A leaſe was granted to the poetical farmer at that annual rent which his own friends declared that the due cultivation of his farm might eaſily enable him to pay. What yet remained of the profits of his publication was laid out in the purchaſe of farm-ſtock; and Mr Millar might, for ſome ſhort time, pleaſe himſelf with the perſuaſion that he had approved himſelf the liberal patron of genius; had acquired a good tenant upon his eſtate; and had placed a deſerving man in the very ſituation in which alone he himſelf deſired to be placed, in order to be happy to his wiſhes.

Burns, with his Jane, whom he now married, took up their reſidence upon his farm. The neighbouring farmers and gentlemen, pleaſed to obtain for an inmate among them the poet by whoſe works they had been delighted, kindly ſought his company, and invited him to their houſes. He found an inexpreſſible charm in ſitting down beſide his wife, at his own fireſide; in wandering over his own grounds; in once more putting his hand to the ſpade and the plough; in forming his encloſures, and managing his cattle. For ſome months he felt almoſt all that felicity which fancy had taught him to expect in his new ſituation. He had been for a time idle; but his muſcles were not yet unbraced for rural toil. He now ſeemed to find a joy in being the huſband of the miſtreſs of his affections, in ſeeing himſelf the father of her children, ſuch as might promiſe to attach him for ever to that modeſt, humble, and domeſtic life, in which alone he could hope to be permanently happy. Even his engagements in the ſervice of the exciſe did not, at the very firſt, threaten neceſſarily to debaſe him by aſſociation with the mean, the groſs, and the profligate, to contaminate the poet, or to ruin the farmer.

But it could not be: it was not poſſible for Burns now to aſſume that ſoberneſs of fancy and paſſions, that ſedateneſs of feeling, thoſe habits of earneſt attention to groſs and vulgar cares, without which ſucceſs in his new ſituation was not to be expected. A thouſand difficulties were to be encountered and overcome, much money was to be expended, much weary toil was to be exerciſed, before his farm could be brought into a ſtate of cultivation in which its produce might enrich the occupier. This was not a proſpect encouraging to a man who had never loved labour, and who was at this time certainly not at all diſpoſed to enter into agriculture with the enthuſiaſm of a projector. The buſineſs of the exciſe too, as he began to be more and more employed in it, diſtracted his mind from the care of his farm, led him into groſs and vulgar ſociety, and expoſed him to many unavoidable temptations to drunken exceſs, ſuch as he had no longer ſufficient fortitude to reſiſt. Amidſt the anxieties, diſtractions, and ſeducements which thus aroſe to him, home became inſenſibly leſs and leſs plea-

Burns.

ſing; even the endearments of his Jane's affection began to loſe their hold on his heart; he became every day leſs and leſs unwilling to forget in riot thoſe gathering ſorrows which he knew not to ſubdue.

Mr Millar and ſome others of his friends would gladly have exerted an influence over his mind which might have preſerved him in this ſituation of his affairs, equally from deſpondency and from diſſipation; but Burns's temper ſpurned all controul from his ſuperiors in fortune. He reſented, as an arrogant encroachment upon his independence, that tenor of conduct by which Mr Millar wiſhed to turn him from diſſolute conviviality, to that ſteady attention to the buſineſs of his farm, without which it was impoſſible to thrive in it. His croſſes and diſappointments drove him every day more and more into diſſipation; and this diſſipation tended to enhance whatever was diſagreeable and perplexing in the ſtate of his affairs. He ſunk, by degrees, into the boon companion of mere exciſemen; and almoſt every drunken fellow, who was willing to ſpend his money laviſhly in the alehouſe, could eaſily command the company of Burns. The care of his farm was thus neglected; waſte and loſſes wholly conſumed his little capital; he reſigned his leaſe into the hands of his landlord; and retired, with his family, to the town of Dumfries, determining to depend entirely for the means of future ſupport upon his income as an exciſe-officer.

Yet during this unfortunate period of his life, which paſſed between his departure from Edinburgh to ſettle in Dumfriesſhire, and his leaving the country, in order to take up his reſidence in the town of Dumfries, the energy and activity of his intellectual powers appeared to have been not at all impaired. In a collection of Scottiſh ſongs, which were publiſhed (the words with the muſic) by Mr Johnſon, engraver in Edinburgh, in 4 vols 8vo, Burns, in many inſtances, accommodated new verſes to the old tunes with admirable felicity and ſkill. He aſſiſted in the temporary inſtitution of a ſmall ſubſcription library, for the uſe of a number of the well-diſpoſed peaſants in his neighbourhood. He readily aided, and by his knowledge of genuine Scottiſh phraſeology and manners greatly enlightened, the antiquarian reſearches of the late ingenious Captain Groſe. He ſtill carried on an epiſtolary correſpondence, ſometimes gay, ſportive, humorous, but always enlivened by bright flaſhes of genius, with a number of his old friends, and on a very wide diverſity of topics. At times, as it ſhould ſeem from his writings of this period, he reflected, with inexpreſſible heart-bitterneſs, on the high hopes from which he had fallen; on the errors of moral conduct into which he had been hurried by the ardour of his ſoul, and in ſome meaſure by the very generoſity of his nature; on the diſgrace and wretchedneſs into which he ſaw himſelf rapidly ſinking; on the ſorrow with which his miſconduct oppreſſed the heart of his Jane; on the want and deſtitute miſery in which it ſeemed probable that he muſt leave her and their infants; nor amidſt theſe agonizing reflections did he fail to look, with an indignation half invidious, half contemptuous, on thoſe who, with moral habits not more excellent than his, with powers of intellect far inferior, yet baſked in the ſun-ſhine of fortune, and were loaded with the wealth and honours of the world, while his follies could not obtain pardon, nor his wants an honourable ſupply. His wit became from this time more gloomily ſarcaſtic; and his converſation and writings began to aſſume ſomething of a tone of miſanthropical malignity, by which they had not been before, in any eminent degree, diſtinguiſhed. But with all theſe failings, he was ſtill that exalted mind which had raiſed itſelf above the depreſſion of its original condition: with all the energy of the lion, pawing to ſet free his hinder limbs from the yet encumbering earth, he ſtill appeared *not leſs than archangel ruined!*

His morals were not mended by his removal from the country. In Dumfries his diſſipation became ſtill more deeply habitual; he was here more expoſed than in the country to be ſolicited to ſhare the riot of the diſſolute and the idle: fooliſh young men flocked eagerly about him, and from time to time preſſed him to drink with them, that they might enjoy his wicked wit. The Caledonian Club, too, and the Dumfriesſhire and Galloway Hunt, had occaſional meetings in Dumfries after Burns went to reſide there, and the poet was of courſe invited to ſhare their conviviality, and heſitated not to accept the invitation.

In the intervals between his different fits of intemperance, he ſuffered ſtill the keeneſt anguiſh of remorſe, and horribly afflictive foreſight. His Jane ſtill behaved with a degree of maternal and conjugal tenderneſs and prudence, which made him feel more bitterly the evil of his miſconduct, although they could not reclaim him. At laſt crippled, emaciated, having the very power of animation waſted by diſeaſe, quite broken-hearted by the ſenſe of his errors, and of the hopeleſs miſeries in which he ſaw himſelf and his family depreſſed; with his ſoul ſtill tremblingly alive to the ſenſe of ſhame, and to the love of virtue; yet even in the laſt feebleneſs, and amid the laſt agonies of expiring life, yielding readily to any temptation that offered the ſemblance of intemperate enjoyment, he died at Dumfries, in the ſummer of 1796, while he was yet three or four years under the age of forty, furniſhing a melancholy proof of the danger of *ſuddenly* elevating even the greateſt mind above its original level.

After his death, it quickly appeared that his failings had not effaced from the minds of his more reſpectable acquaintance either the regard which had once been won by his ſocial qualities, or the reverence due to his intellectual talents. The circumſtances of want in which he left his family were noticed by the gentlemen of Dumfries with earneſt commiſeration. His funeral was celebrated by the care of his friends with a decent ſolemnity, and with a numerous attendance of mourners, ſufficiently honourable to his memory. Several copies of verſes were inſerted in different newſpapers upon the occaſion of his death. A contribution, by ſubſcription, was propoſed, for the purpoſe of raiſing a ſmall fund, for the decent ſupport of his widow, and the education of his infant children.

From the preceding detail of the particulars of this poet's life, the reader will naturally and juſtly infer him to have been an honeſt, proud, warm-hearted man; of high paſſions and ſound underſtanding, and a vigorous and excurſive imagination. He was never known to deſcend to any act of deliberate meanneſs. In Dumfries he retained many reſpectable friends even to the laſt; and it may be doubted whether any poet of the preſent age has exerciſed a greater power over the minds of his readers. Burns has not failed to command one remarkable ſort of homage, ſuch as is never paid but to great original genius; a crowd of poetaſters ſtarted up to imitate him, by writing verſes as he had done in the Scottiſh dialect; but, *O imitatores! ſervum pecus!* To write rugged rhimes, in antiquated phraſe, is not to imitate the poetry of Burns.

BURRAMPOOTER. See SANDPU, *Encycl.*

BUTTER is a ſubſtance ſo well known, that it is needleſs to give here any definition of it; but as it is, in this country at leaſt, ſo general an article of food, that the proper methods of making and curing it have engaged the attention of ſome of our ableſt writers on agriculture, in addition to what has been ſaid on theſe ſubjects under the titles BUTTER and DAIRY (*Encycl.*) our readers will probably be pleaſed with the following method of curing it, which is practiſed by ſome farmers in the pariſh of Udney, in the county of Aberdeen, and gives to their butter a great ſuperiority above that of their neighbours.

Take two parts of the beſt common ſalt, one part of ſugar, and one part of ſaltpetre; beat them up together, and blend the whole completely. Take one ounce of this compoſition for every 16 ounces of butter, work it well into the maſs, and cloſe it up for uſe.

Dr James Anderſon, from whoſe View of the Agriculture of the County of Aberdeen this receipt is taken, ſays, that he knows of no ſimple improvement in economies greater than this is, when compared with the uſual mode of curing butter by means of common ſalt alone. "I have ſeen (continues he) the experiment fairly made, of one part of the butter made at one time being thus cured, and the other part cured with ſalt alone: the difference was inconceivable. I ſhould ſuppoſe that, in any open market, the one would ſell for 30 *per cent.* more than the other. The butter cured with the mixture appears of a rich marrowy conſiſtence and fine colour, and never acquires a brittle hardneſs nor taſtes ſalt; the other is comparatively hard and brittle, approaching more nearly to the appearance of tallow, and is much ſalter to the taſte. I have ate butter cured with the above compoſition that had been kept three years, and it was as ſweet as at firſt; but it muſt be noted, that butter thus cured requires to ſtand three weeks or a month before it is begun to be uſed. If it be ſooner opened, the ſalts are not ſufficiently blended with it; and ſometimes the coolneſs of the nitre will then be perceived, which totally diſappears afterwards."

The following obſervations reſpecting the proper method of keeping both milk and butter are by the ſame author, and we truſt may prove uſeful. Speaking ſtill of the county of Aberdeen, he ſays, "The pernicious practice of keeping milk in leaden veſſels, and ſalting butter in ſtone jars, begins to gain ground among ſome of the fine ladies in this county, as well as elſewhere, from an idea of cleanlineſs. The fact is, it is juſt the reverſe of cleanlineſs; for in the hands of a careful perſon nothing can be more cleanly than wooden diſhes, but under the management of a ſlattern they diſcover the ſecret which ſtone diſhes indeed do not.

"In return, theſe latter communicate to the butter and the milk, which has been kept in them, a poiſonous quality, which inevitably proves deſtructive to the human conſtitution. To the prevalence of this practice I have no doubt we muſt attribute the frequency of palſies, which begin to prevail ſo much in this kingdom; for the well known effect of the poiſon of lead is bodily debility, palſy—death!"

BYSAK, the firſt month of the Bengal year, beginning in April.

C.

CAFFRES, the inhabitants of Caffraria, are generally confounded with the Hottentots; but, according to M. Vaillant, there is a conſiderable difference between the manners, cuſtoms, and even appearance of theſe two nations.

The Caffres, ſays he, are generally taller than the Hottentots, more robuſt, more fierce, and much bolder. Their figure is likewiſe more agreeable, and their countenances have not that narrowneſs at the bottom, nor their cheeks thoſe prominences, which are ſo diſagreeable among the Hottentots. A round figure, a noſe not too flat, a broad forehead, and large eyes, give them an open and lively air; and if prejudice can overlook the colour of the ſkin, there are ſome Caffre women who, even in Europe, would be accounted pretty. Theſe people do not make their faces ridiculous, by pulling out their eye-brows like the Hottentots; they tattoo themſelves much, and particularly their bodies; their hair, which is frizzled very much, is never greaſed, but their bodies are liberally anointed, merely with a view to preſerve their vigour and agility.

The men generally beſtow more attention on their dreſs than the women, and are remarkably fond of beads and copper rings. The women wear hardly any of the ornaments in which the other ſavages in Africa take ſuch delight. They do not even wear copper bracelets; but their ſmall aprons, which are ſtill ſhorter than thoſe of the Hottentots, are bordered with a few rows of glaſs beads; and in this all their luxury conſiſts. It would appear that the Caffres are not ſo chaſte as the Hottentots, becauſe the men do not uſe a jackal to vail what nature teaches other men, even ſavages, to conceal. A ſmall cowl, which covers only the glans, inſtead of diſplaying modeſty, ſeems to announce the greateſt indecency. This ſmall covering adheres to a thong, which is faſtened round their girdles, merely that

that it may not be loſt; for a Caffre, if he be not afraid of being hurt or ſtung by inſects, cares very little whether his cowl be in its place or not. Our author ſaw one Caffre who, inſtead of a cowl, wore a caſe made of wood, and ornamented with ſculpture. This was a new and ridiculous faſhion, which he had borrowed from a nation of black people who lived at a great diſtance from Caffraria.

In the hot ſeaſon the Caffres go always naked, and retain nothing but their ornaments. In cold weather they wear kroſſes made of calves or oxen hides, which reach down to the ground; but whatever the weather be, both ſexes go bare-headed, except that they ſometimes, though rarely, fix a plume of feathers in their hair.

The Caffre huts are more ſpacious and higher than thoſe of the Hottentots, and have alſo a more regular form. The frames of them are conſtructed of wooden work, well put together, and very ſolid, being intended to laſt for a long time: for the Caffres, applying to agriculture, which the free Hottentots do not, remain fixed to one ſpot, unleſs ſomething unexpected interrupt their repoſe.

A more perceptible induſtry, an acquaintance with ſome of the moſt neceſſary arts of life, a little knowledge of agriculture, and a few religious dogmas, ſeem to announce that the Caffres approach much nearer to civilization than the Hottentots. They entertain a tolerably exalted idea of the Supreme Being and his power; they believe that the good will be rewarded, and the wicked puniſhed, in a future ſtate; but they have no notion of creation, which indeed was not admitted by the ſages of Greece and Rome. They practiſe circumciſion, but can give no account of its origin among them, or of the purpoſe for which the practice is continued.

Polygamy is uſed among the Caffres; and on the death of a father the male children and their mothers ſhare the ſucceſſion among them. The girls remain with their mothers without property of any kind until they can procure huſbands. One very ſingular cuſtom of the Caffres is, that they do not, in general, inter their dead, but tranſport them from the kraal to an open ditch, which is common to the whole horde. At this ditch ſavage animals feed at their leiſure on the multitude of carcaſes which are heaped together. Funeral honours are due only to kings and the chiefs of each horde, whoſe bodies are covered with a heap of ſtones collected into the form of a dome.

This nation is governed by a general, chief, or king, whoſe power is very limited. He appoints, however, the ſubordinate chiefs over the different hordes, and through them communicates his directions or orders. The arms of the Caffre are a *club*, two feet and a half in length, and where thickeſt three inches in diameter, and a plain lance or *aſſagey*. He deſpiſes poiſoned arrows, which are ſo much uſed by ſome of the neighbouring nations; and with his two ſimple weapons ſeeks always to meet his enemy face to face in the field. The Hottentot, on the contrary, concealed under a rock or behind a buſh, deals out deſtruction, without being expoſed to danger. The one is a perfidious tyger, which ruſhes treacherouſly on his prey; the other is a generous lion, which, having given warning of his approach, makes his attack boldly, and periſhes if he prevail not againſt his antagoniſt.

CALCULUS, in mathematics, denotes a certain way of performing inveſtigations and reſolutions, which occur on many occaſions, particularly in mechanical philoſophy. Thus we ſay, the *antecedental* calculus, the *algebraical* calculus, the *arithmetical* calculus, the *differential* calculus, the *exponential* calculus, the *fluxional* calculus, and the *integral* calculus. Of by much the greater part of theſe calculi ſome account has been given in the Encyclopædia Britannica; but there is one of them, of which no notice has been taken in that work. It is,

The Antecedental CALCULUS, a geometrical method of reaſoning, without any conſideration of motion or velocity, applicable to every purpoſe to which the much celebrated doctrine of fluxions of the illuſtrious Newton has been, or can be, applied. This method was invented by James Glenie, Eſq; "in which (he ſays) every expreſſion is truly and ſtrictly geometrical, is founded on principles frequently made uſe of by the ancient geometers, principles admitted into the very firſt elements of geometry, and repeatedly uſed by EUCLID himſelf. As it is a branch of general geometrical proportion, or univerſal compariſon, and is derived from an examination of the antecedents of ratios, having given conſequents and a given ſtandard of compariſon in the various degrees of augmentation and diminution they undergo by compoſition and decompoſition, I have called it the antecedental calculus. As it is purely geometrical, and perfectly ſcientific, I have, ſince it firſt occurred to me in 1779, always made uſe of it inſtead of the fluxionary and differential calculi, which are merely arithmetical. Its principles are totally unconnected with the ideas of motion and time, which, ſtrictly ſpeaking, are foreign to pure geometry and abſtract ſcience, though, in mixed mathematics and natural philoſophy, they are equally applicable to every inveſtigation, involving the conſideration of either with the two numerical methods juſt mentioned. And as many ſuch inveſtigations require compoſitions and decompoſitions of ratios, extending greatly beyond the triplicate and ſubtriplicate, this calculus in all of them furniſhes every expreſſion in a ſtrictly geometrical form. The ſtandards of compariſon in it may be any magnitudes whatever, and are of courſe indefinite and innumerable; and the conſequents of the ratios, compounded or decompounded, may be either equal or unequal, homogeneous or heterogeneous. In the fluxionary and differential methods, on the other hand, 1, or unit, is not only the ſtandard of compariſon, but alſo the conſequent of every ratio compounded or decompounded."

This method is deduced immediately from Mr Glenie's Treatiſe on the Doctrine of Univerſal Compariſon or General Proportion: And as the limits of the preſent work will not allow us to enter upon this ſubject, we therefore refer our readers to the two above mentioned treatiſes, and to the fourth volume of the Tranſactions of the Royal Society of Edinburgh.

We confeſs, however, that we do not expect ſuch great advantage from the employment of this calculus as the very acute and ingenious author ſeems to promiſe from it. The mathematical world is truly indebted to him for the clear and diſcriminating view that he has taken of the doctrine of univerſal compariſon, and we believe it to be perfectly accurate, and in ſome reſpects new. Notwithſtanding the continual occupation of mathematicians with ratios and analogies, their particular objects commonly reſtricted their manner of conceiving ratio to ſome preſent modification of it. Hence it ſeems to have happened that their conceptions of it as a magnitude have not been uniform. But Mr Glenie, by avoiding every peculiarity, has at once attributed to it all the meaſurable affections of magnitude, addition or ſubtraction, multiplication or diviſion, and ratio or proportion. He is perhaps the firſt who has roundly conſidered ratio or proportion as an affection of ratio; and it is chiefly by the employment of this undoubted affection of ratio that he has rendered the geometrical analyſis ſo comprehenſive.

But when we view this antecedental calculus, not as a method of expreſſing mathematical ſcience, but as an art, as a calculus in ſhort, and conſider the means which it muſt employ, and the notation which muſt be uſed, we become leſs ſanguine in our hopes of advantage from it. The notation cannot (we think) be more ſimple than that of the fluxionary method, juſtly called *arithmetical;* and if we inſiſt on carrying clear conceptions along with us, we imagine that the arithmetical expoſition of our ſymbols will generally be the ſimpler of the two. The *ſcience* of the antecedental calculus ſeems to conſiſt in the attainable perception of all the ſimple ratios, whether of *magnitudes* or *ratios*, or both, which concur to the formation of a compound and complicated ratio. Now this is equally, and more eaſily attainable in the fluxionary or other arithmetical method, when the conſequent is a ſimple magnitude. When it is not, the ſame proceſs is farther neceſſary in both methods, for getting rid of its complication.

We apprehend that it is a miſtake that the geometrical method is more abſtracted than the fluxionary, becauſe the latter ſuperadds to the notion of extenſion the notions of time and motion. Theſe notions were introduced by the illuſtrious inventor *for the demonſtration*, but never occupy the thoughts *in the uſe* of his propoſitions. Theſe are *geometrical* truths, no matter how demonſtrated; and when duly conſidered, involve nothing that is omitted in the antecedental calculus. We even preſume to ſay, that the complication of thought, in the contemplation of the ratios of ratios, is greater than what will generally ariſe from the additional elements, time and motion.

We do not find that any of our moſt active mathematicians have availed themſelves of the advantages of this calculus, nor do we know any ſpecimen that has been exhibited of its eminent advantages in mathematical diſcuſſions. Should it prove more fertile in geometrical expreſſions of highly compounded or complicated quantities or relations, we ſhould think it a mighty acquiſition; being fully convinced that theſe afford to the memory or imagination an object (we may call it a ſenſible picture) which it can contemplate and remember with incomparably greater clearneſs and ſteadineſs than any algebraical formula. We need only appeal to the geometrical expreſſions of many fluents, which are to be ſeen in Newton's lunar theory, in the phyſical tracts of Dr Matthew Stewart, and others who have ſhewn a partiality for this method.

It would be very preſumptuous, however, for us to ſay, that the accurate geometer and metaphyſician may not derive great advantages from proſecuting the very ingenious and recondite ſpeculations of Mr Glenie, in his doctrine of univerſal compariſon.

CALENDAR, in chronology. See *(Encycl.)* KALENDAR; and REVOLUTION, n° 184.

CALIPPIC PERIOD, in chronology, a period of 76 years, continually recurring; at every repetition of which, it was ſuppoſed by its inventor Calippus, an Athenian aſtronomer, that the mean and new full moons would always return to the ſame day and hour.

About a century before, the golden number, or cycle of 19 years, had been invented by Meton; which Calippus finding to contain 19 of Nabonaſſar's year, 4 days, and $\frac{3}{4}\frac{3}{5}\frac{1}{9}$, to avoid fractions he quadrupled it, and ſo produced his period of 76 years, or 4 times 19; after which he ſuppoſed all the lunations, &c. would regularly return to the ſame hour. But neither is this exact, as it brings them too late by a whole day in 225 years.

CALLAO, as it is called by its inhabitants, but more generally known to Europeans under the name of CAMPELLO, is a ſmall iſland, which was viſited by ſome of Lord Macartney's ſuite on their voyage to China. In conſequence of that viſit, we have the following deſcription of it in Sir George Staunton's Account of the Embaſſy.

"It lies oppoſite to, and about eight miles to the eaſtward of, the mouth of a conſiderable river on the coaſt of Cochin-china, on the banks of which is ſituated the town of Fai-foo, a place of ſome note, not far from the harbour of Turon. The bearing of the higheſt peak of Callao from this harbour is about ſouth-eaſt, diſtance thirty miles. The extreme points of the iſland lie in latitude 15° 53′, and 15° 57′ north; the greateſt length is from north-weſt to ſouth-eaſt, and is ſomewhat about five miles, and the mean breadth two miles. The only inhabited part is on the ſouth-weſt coaſt, on a ſlip of ground riſing gently to the eaſt, and contained between the bottom of a ſemilunar bay and the mountains on each ſide of it. Thoſe mountains, at a diſtance, appear as if they formed two diſtinct iſlands. The ſouthern mountain is the higheſt, and is about 1500 feet. The lower grounds contain about 200 acres. This ſmall but enchanting ſpot is beautifully diverſified with neat houſes, temples, clumps of trees, ſmall hillocks ſwelling from the plain, and richly decorated with ſhrubbery and trees of various kinds; among which the elegant areca, riſing like a Corinthian column, is eminently conſpicuous. A rill of clear water, oozing from the mountains, is contrived to be carried along the upper ridges of the vale, from whence it is occaſionally conveyed through ſluices, for the purpoſe of watering the rice grounds, and appeared, though then in the dry ſeaſon, fully ſufficient for every purpoſe for which it could be wanted.

"The houſes, in general, were clean and decent; a few were built with ſtone, and covered with tiles. One, probably the manſion of the chief perſon of the iſland, was encloſed by a ſtone wall, and the appoach to it was through a gateway between two ſtone pillars. The houſe was divided into a number of apartments, of which the arrangement did not ſeem to want either taſte or convenience. This building ſtood at the head of the principal village, which conſiſted of about thirty habitations

habitations built of wood, chiefly the bamboo. Behind the village, and on the ſide of the hill, was a cave, acceſſible only by one way, through an irregular range of rocks. Within the cave, but near its mouth, was a ſmall temple, commanding a view of the whole vale. Several other temples were diſperſed over the plain, all of which were open in front, with a colonnade before them of round wooden pillars, painted red and varniſhed. The number of houſes on the iſland ſcarcely exceeded ſixty. Behind every houſe, not immediately in the principal village, were encloſures of ſugar-canes, tobacco, and other vegetables, growing in great luxuriance. The mountains were covered with verdure, and ſeemed well calculated for rearing goats, of which the iſland produced a few.

“ Beſide the principal bay, there were ſeveral ſandy inlets, with ſmall patches of level ground behind them. Boats might eaſily land in any of theſe inlets ; but a communication between them by land appeared to be exceedingly difficult, if not entirely prevented, by the ſteep and rugged ridges which ſeparated them from each other. On this account very ſlight works, and an eſtabliſhment of a few men only, would be requiſite for the defence of the iſland, a great part of its coaſt being impregnably fortified by nature. The depth of water in the bay and road was ſufficient for ſhips of any burden, and there was perfect ſhelter from every wind except the ſouth-weſt, to which quarter it was directly open. The ſhort diſtance, however, from the continent in that direction would always prevent the ſea from riſing high, though it might not be ſufficiently near to break the force of the wind.”

The inhabitants of this iſland are ſo exceedingly ſhy and afraid of ſtrangers, that upon the approach of the Engliſh veſſel, they all, except a very few, retired on board their galleys. When the Britiſh landed, therefore, they found the doors of all the houſes open, with ſeveral domeſtic animals feeding before them, but neither man, woman, nor child within. After ſome time, however, a perſon was perceived lurking among the neighbouring trees, who, finding he was obſerved, came forward with reluctance and evident marks of fear. While he was yet at ſome diſtance, he fell upon his knees, and touched the ground with his forehead ſeveral times. On approaching to him, it was noticed that the firſt joint of every one of his fingers and toes was wanting, and as if twiſted off by violence : it was poſſible that he might have thus been treated by way of puniſhment for ſome crime, and that he was conſidered as the fitteſt perſon to be expoſed to the ſuppoſed danger of watching the movements of the ſtrangers coming aſhore. In a little time ſome others, hidden in the thickets, finding that no miſchief was ſuffered by the firſt, ventured out. None of them could underſtand the Chineſe interpreter ; and not being able to read or write, there was no converſing with them by the medium of the Chineſe characters. Recourſe was had to hieroglyphics, and rude figures were drawn of the articles which were propoſed to be purchaſed ; and this method ſucceeded tolerably well ; poultry and fruits were brought for ſale, for which high prices were given, purpoſely to conciliate the good will of thoſe iſlanders. The few that were found grew ſoon familiar ; and one old man preſſingly invited the ſtrangers to his houſe, ſituated upon an eminence, at a little diſtance. On arriving there, he introduced them to his wife, an old woman, who, after recovering from her aſtoniſhment at the ſight of figures ſo different from thoſe ſhe had ever been accuſtomed to behold, laid, in a neat manner, before them ſome fruits, ſugar, cakes, and water. On departing from the houſe, this decent and hoſpitable couple made ſigns to teſtify their deſire of ſeeing them again.”

The poſſeſſion of this iſland would be of ſuch importance to any European nation who wiſhed to trade ſecurely with Tung-quin and Cochin-china, that it is ſaid the French had formerly ſome thoughts of purchaſing it. Sir George Staunton, however, is of opinion, that the want of ſhelter in the ſouth-weſt monſoon would render it of little value, without a further ſettlement near it upon the main land of Cochin-china : and he thinks, that if a ſolid eſtabliſhment there could be productive of advantage to any European nation, it would neceſſarily be ſo to Great Britain ; becauſe, beſide the opening which it would make for the ſale of Britiſh manufactures among the people of the country, the Britiſh poſſeſſions in Hindoſtan would be ſure of a very conſiderable demand for their productions.

CAMEL, in navigation, is a machine which has been deſcribed with ſufficient accuracy in the Encyclopædia ; but the following account of its invention, given by Profeſſor Beckmann, is perhaps not unworthy of a place in this Supplement.

“ In the Zuyder-Zee, oppoſite to the mouth of the river Y, about ſix miles from the city of Amſterdam, there are two ſand banks, between which is a paſſage called the *Pampus*, which is ſufficiently deep for ſmall ſhips, but not for ſuch as are large or heavy laden. In 1672 the Dutch contrived, however, to carry their numerous fleet through this paſſage, by means of large empty cheſts faſtened to the bottom of each ſhip ; and this contrivance gave riſe to the invention of the *camel*.” In the Encyclopædia Britannica its invention is given to the famous De Wit ; in the German Cyclopædia to Meyer a Dutch engineer of very conſiderable eminence ; but the Dutch writers, almoſt unanimouſly, aſcribe the invention of the camel to a citizen of Amſterdam, who calls himſelf Meeuves Meindertſoon Bakker. “ Some make the year of the invention to have been 1688, and others 1690. Much has been ſaid of the utility of this invention ; but however beneficial it may be, we have reaſon to ſuppoſe that ſuch heavy veſſels as ſhips of war cannot be raiſed up, in ſo violent a manner, without ſuſtaining injury. A ſure proof of this is the well known circumſtance mentioned by Muſchenbroek *(Introductio ad Philoſoph. Natur.)*, that the ports of a ſhip which had been raiſed by the camel could not afterwards be ſhut cloſely.”

CAMELEON, one of the conſtellations of the ſouthern hemiſphere, near the ſouth pole, and inviſible in our latitude. There are 10 ſtars marked in this conſtellation in Sharp's catalogue.

CAMELOPARDALUS, a new conſtellation of the northern hemiſphere, formed by Hevelius, conſiſting of 32 ſtars, firſt obſerved by him. It is ſituated between Cepheus, Caſſiopeia, Perſeus, the Two Bears, and Draco ; and it contains 58 ſtars in the Britiſh catalogue.

CAMELLIA, in botany (ſee *Encycl.*), is a plant which the Chineſe call *Cha-wha*, or flower of tea, on account of the reſemblance of the one to the other, and becauſe

becauſe its petals are ſometimes mixed among the teas to increaſe their fragrance. Sir George Staunton, who calls it *Camellia Seſanqua*, ſaw it flouriſhing on the ſides and very high tops of mountains, where the ſoil conſiſted of little more than fragments of ſtone, crumbled into a ſort of coarſe earth by the joint action of the ſun and rain. It yields, he ſays, a nut, from which is expreſſed an eſculent oil, equal to the beſt which comes from Florence. On this account, it is cultivated in vaſt abundance; and is particularly valuable from the facility of its culture in ſituations fit for little elſe.

CAMPBELL (George, D. D.), ſo juſtly admired for his metaphyſical acuteneſs and various erudition, was, in 1719, born at Aberdeen, where his father, the reverend Colin Campbell, was one of the miniſters of the eſtabliſhed church. He was educated in his native city; and, after paſſing through the uſual courſe of academical learning, he ſtudied divinity under the Rev. J. Chalmers, profeſſor of divinity in Mariſchal College.—He was, in 1749, an unſucceſsful candidate for the church of Fordown, though his competitor Mr Forbes was a man of very ſlender abilities, and ſuppoſed to be attached to the conſtitution and liturgy of the church of England. It might indeed be that attachment which contributed principally to procure him the living in preference to Mr Campbell.

The living of Fordown is in the gift of the crown; and it has generally been a rule with his majeſty's miniſters, to give ſuch livings, when they become vacant, to thoſe candidates who are favoured by the majority of land-owners in the pariſh. At the era of 1749, the land-owners in ſome of the northern and middle counties of Scotland were more generally attached to the conſtitution of the church of England than to that of their own eſtabliſhment; and ſuch was certainly the caſe in the pariſh of Fordown.

But whatever was the cauſe of Mr Campbell's failure, he failed by a very ſmall number, and was not long without an eſtabliſhment. In 1750, he was preſented, by Sir Thomas Burnet of Leys, to the living of Banchary Ternan, on the Dee, about twenty miles weſt from Aberdeen. From this he was tranſlated, or, as the Scotch eccleſiaſtical phraſe is, *tranſported* to Aberdeen in 1756, and nominated one of the city miniſters, in the room of Mr John Biſſet deceaſed, a puritan of the old ſchool, whoſe ſtrictneſs and peculiarities are yet remembered by many in that place.

In 1759, on the deceaſe of principal Pollock, he was choſen principal of the Mariſchal college, and ſucceeded to the divinity chair in 1771, on Dr Alexander Gerard being tranſlated to the profeſſorſhip of divinity in King's college. Before his ſettling in Aberdeen, he married Miſs Grace Farquharſon, daughter of Mr Farquharſon of Whitehouſe, by whom he had no iſſue. This amiable woman died about a year before him. They were an eminent pattern of conjugal affection.

From this time he enjoyed a remarkable ſhare of good health and ſpirits. He had, all his life, a rooted averſion to medicine. He got the better of every ailment by a total and rigorous abſtinence from all kind of ſuſtenance whatever; and it was not till he was attacked by an alarming illneſs, about two years before his death, that he was perſuaded by his friends to call in medical aid. What nature could do, ſhe had all along performed well; but her day was over, and ſomething of art became neceſſary. Then, for the firſt time, he owned the utility of medical men, and declared his recantation of the very mean opinion he had formerly entertained of them and their art. A few months before his death, he reſigned his offices of principal, profeſſor of divinity, and one of the city miniſters, and was in all ſucceeded by Dr W. L. Brown, late of Utrecht, a man of diſtinguiſhed abilities. Dr Campbell retained all his faculties entire to the laſt, and died on the 6th of April 1796, in the 77th year of his age. His character has been ſo juſtly drawn by his ſucceſſor, that we ſhall give it to our readers in his words, adding only a circumſtance or two, which we have reaſon to think will contribute to endear his memory to every liberal and enlightened mind.

“Dr Campbell, as a public teacher, was long admired for the clearneſs and copiouſneſs with which he illuſtrated the great doctrines and precepts of religion, and the ſtrength and energy with which he enforced them. Intimately perſuaded of the truth and infinite conſequence of what relevation teaches, he was ſtrongly deſirous of carrying the ſame conviction to the minds of his hearers, and delivered his diſcourſes with that zeal which flows from ſtrong impreſſions, and that power of perſuaſion which is the reſult of ſincerity of heart, combined with clearneſs of underſtanding. He was ſatisfied, that the more the pure dictates of the goſpel were ſtudied, the more they would approve themſelves to the mind, and bring forth, in the affections and conduct, all the peaceable fruits of righteouſneſs. The unadulterated dictates of Chriſtianity, he was, therefore, only ſtudious to recommend and inculcate, and knew perfectly to diſcriminate them from the inventions and traditions of men. His chief ſtudy ever was, to direct belief to the great objects of practice; and, without theſe, he viewed the moſt orthodox profeſſion as “a ſounding braſs, and a tinkling cymbal.” But, beſides the character of a preacher of righteouſneſs, he had alſo that of a teacher of the ſcience of divinity to ſuſtain. How admirably he diſcharged this duty, and with what effect he conveyed the ſoundeſt and moſt profitable inſtruction to the minds of his ſcholars, let thoſe declare who are now in various congregations of this country, communicating to their fellow Chriſtians the fruits of their ſtudies under ſo able and judicious a teacher. Diſcarding all attachment to human ſyſtems, merely conſidered as ſuch, he tied his faith to the Word of God alone, poſſeſſed the happieſt talent in inveſtigating its meaning, and communicated to his hearers the reſult of his own inquiries, with a preciſion and perſpicuity which brought light out of obſcurity, and rendered clear and ſimple what appeared intricate and perplexed. He expoſed, without reſerve, the corruptions which ignorance, craft, and hypocriſy, had introduced into religion, and applied his talent for ridicule to the beſt of all purpoſes, to hold up to contempt the abſurdities with which the pureſt and ſublimeſt truths had been loaded.

“Placed at the head of a public ſeminary of learning, he felt all the importance of ſuch a ſituation, and uniformly directed his influence to public utility. His enlarged and enlightened mind juſtly appreciated the extenſive conſequence of the education of youth. He anticipated all the effects reſulting to the great community of mankind, from numbers of young men iſſuing, in regular ſucceſſion, from the univerſity over which he preſided, and occupying the different departments of ſocial life.

“ His benevolent heart delighted to repreſent to itſelf the ſtudents under his direction uſefully and honourably diſcharging the reſpective duties of their different profeſſions; and ſome of them, perhaps, filling the moſt diſtinguiſhed ſtations of civil ſociety. With theſe proſpects before him, he conſtantly directed his public conduct to their attainment. He never ſuffered his judgment to be warped by prejudice or partiality, or his heart to be ſeduced by paſſion or private intereſt. Thoſe mean and ignoble motives by which many are actuated in the diſcharge of important truſts, approached not his mind. A certain honourable pride, if pride it may be called, diffuſed an uniform dignity over the whole of his behaviour. He felt the man degraded by the perverſion of public character. His underſtanding alſo clearly ſhewed him even perſonal advantage attached to ſuch principles and practice, as he adopted from a ſenſe of obligation, and thoſe elevated conceptions of real worth which were ſo congenial to his ſoul. He ſaw, he experienced, eſteem, reſpect, and influence, following in the train of integrity and beneficence; but contempt, diſgrace, averſion, and complete inſignificance, cloſely linked to corruption and ſelfiſhneſs. Little minds are ſeduced and overpowered by ſelfiſh-conſiderations, becauſe they have not the capacity to look beyond the preſent advantage, and to extend to the miſery that ſtands on the other ſide of it. The ſame circumſtance that betrays the perverſity of their hearts, alſo evinces the weakneſs of their judgments.

“ His reputation as a writer is as extenſive as the preſent intercourſe of letters; not confined to his own country, but ſpread through every civilized nation. In his literary purſuits, he aimed not, as is very often the caſe, with men of diſtinguiſhed literary abilities, merely at eſtabliſhing his own celebrity, or increaſing his fortune; but had chiefly at heart the defence of the great cauſe of Religion, or the elucidation of her dictates.

“ At an early period he entered the liſts as a champion for Chriſtianity againſt one of its acuteſt opponents. He not only triumphantly refuted his arguments, but even conciliated his reſpect by the handſome and dexterous manner in which his defence was conducted. While he refuted the infidel, he ſpared the man, and exhibited the uncommon ſpectacle of a polemical writer poſſeſſing all the moderation of a Chriſtian. But while he defended Chriſtianity againſt its enemies, he was deſirous of contributing his endeavours to increaſe, among its profeſſors, the knowledge of the ſacred writings. Accordingly, in the latter part of his life, he favoured the world with a work, the fruit of copious erudition, of unwearied application, for almoſt thirty years, and of a clear and comprehenſive judgment. We have only to regret, that the other writings of the New Teſtament have not been elucidated by the ſame pen that tranſlated the Goſpels. Nor were his literary merits confined to theology, and the ſtudies more immediately connected with it. Philoſophy, and the fine arts, are alſo indebted to his genius and labours; and in him the polite ſcholar was eminently joined to the deep and liberal divine.

“ Political principles will always be much affected by general character. This was alſo the caſe with Dr Campbell. In politics, he maintained that moderation which is the ſureſt criterion of truth and rectitude, and was equally diſtant from thoſe extremes into which men are ſo apt to run on great political queſtions. He cheriſhed that patriotiſm which conſiſts in wiſhing, and endeavouring to promote the greateſt happineſs of his country, and is always ſubordinate to univerſal benevolence. Firmly attached to the Britiſh conſtitution, he was animated with that genuine love of liberty which it inſpires and invigorates. He was equally averſe to deſpotiſm and to popular anarchy; the two evils into which political parties are ſo frequently hurried, to the deſtruction of all that is valuable in government. Party-ſpirit, of whatever deſcription, he conſidered as having an unhappy tendency to pervert, to the moſt pernicious purpoſes, the beſt principles of the human mind, and to clothe the moſt iniquitous actions with the moſt ſpecious appearances. Although tenacious of thoſe ſentiments, whether in religion or politics, which he was convinced to be rational and juſt, he never ſuffered mere difference of opinion to impair his good-will, to obſtruct his good offices, or to cloud the cheerfulneſs of converſation. His own converſation was enlivened by a vein of the moſt agreable pleaſantry.”

So far was he from being influenced by jealouſy, or any portion of that corporation-ſpirit which ſometimes incites men of undoubted abilities to detract from the merit of every writer who fills not a ſtation as conſpicuous as their own, that he was loud in his praiſes of thoſe, whom men of meaner minds would have looked upon with diſguſt, as upon preſumptuous rivals. This generoſity was fully experienced by the writer of the article MIRACLE, in the Encyclopædia Britannica, who, though he had preſumed to treat the ſubject differently from Dr Campbell, received from him ſuch a teſtimony of approbation of what he had done, as he will hardly look for from any other man in ſimilar circumſtances.

Among his other qualities, which ſo much endeared him to all who had the honour of his acquaintance, Dr Campbell poſſeſſed an uncommon facility of paſſing from the graveſt to the moſt airy ſubjects, and from the livelieſt to the graveſt, without degrading the one or diminiſhing the pleaſure of the other. The infirmities of age abated not the cheerfulneſs of his temper, nor did even the perſuaſion of approaching diſſolution impair his ſerenity.

We cannot conclude this ſhort ſketch better than with a liſt of his works, in the order in which they were publiſhed. In 1752, he publiſhed a Sermon, preached before the Synod of Aberdeen.

1761. A Diſſertation on Miracles, againſt Mr Hume. This treatiſe is well known to the learned world. He obtained, and deſervedly obtained, a very high reputation, not only from the able manner in which he handled the ſubject, but from the liberal ſtyle in which he addreſſed his antagoniſt. It was ſpeedily tranſlated into French, German, and Dutch.

1771. A Sermon before the Society for Propagating Chriſtian Knowledge, Edinburgh.

——— ——— before the Synod of Aberdeen.

1776. The Philoſophy of Rhetoric, 2 vols 8vo. A work which diſcovers a clearneſs of diſcernment, and accuracy of obſervation, which juſtly entitled him to be ranked among the moſt judicious critics. He entered on this inquiry as early as 1750, when a part of the work was compoſed. The laws of elegant compoſition and criticiſm are laid down with great perſpicuity: but the moſt valuable part of the work is undoubtedly the *theory of evidence*, to which we know nothing ſuperior, perhaps nothing equal, on the ſubject, in our own or any other language. His philoſophy, in general, is the philoſophy of Dr Reid; and where he differs from that acute reaſoner reſpecting *abſtraction*, and ſome other objects of metaphyſical diſquiſition, we think it impoſſible to refuſe him the pre-eminence in every thing but ſtyle.

1777. A Sermon on the King's Faſt-day, on Allegiance, firſt printed in 4to, and afterwards, at the expence of government, ſix thouſand copies were printed in 12mo, enlarged with notes, and ſent to America, when the unhappy ſtruggle had, however, put on appearances which prevented the effect hoped for from this ſermon.

1780. An Addreſs to the People of Scotland on the Alarms which have been raiſed by what is called the Popiſh Bill. This is a powerful diſſuaſive from bigotry, and every ſpecies of religious perſecution.

1793. His *Magnum Opus*. The tranſlation of the Goſpels, with Preliminary Diſſertations, 2 vols 4to.

1800. Lectures on Eccleſiaſtical Hiſtory, a poſthumous work, in 2 vols 8vo; which, in the opinion of moſt people, ſhould have been ſuppreſſed.

CAMPHOR, or CAMPHIRE, (ſee *Encycl.*), is, in China, obtained by boiling the branches, twigs, and leaves, of the *Laurus-Camphora* in water, upon the ſurface of which it is found ſwimming in the form of an oil, or adhering, in a glutinous form, to a wooden rod, with which the boiling matter is conſtantly ſtirred. The glutinous maſs is then mixed with clay and lime, and put into an earthen veſſel, with another of the ſame ſize properly luted over it; the lower veſſel being placed over a ſlow fire, the camphor gradually ſublimes through the clay and lime, and adheres to the ſides of the upper veſſel, forming a cake of a ſhape correſponding to the cavity which received it. It is, however, leſs pure and much weaker than what is diſcovered in a ſolid ſtate among the fibres of the trunk, as turpentine is found in different ſorts of pines. In the great, but ill-peopled, iſland of Borneo, and alſo in Japan, the camphor tree is felled for the ſole purpoſe of finding this coſtly drug in ſubſtance among the ſplinters of the trunk, in the ſame manner as other trees are felled in Louiſiana merely for collecting the fruit they bear upon their ſummits. The Borneo, or Japan camphor, is pure, and ſo very ſtrong, as readily to communicate much of its odour and its virtues to other inſpiſſated oils, which thus paſs for real camphor; and this adulterated drug is ſold by Chineſe artiſts at a vaſtly lower price than they gave themſelves for the genuine ſubſtance from Borneo or Japan.

Sir George Staunton, from whom we have this account, does not inform us whether the camphor-tree of China, if felled and torn into ſplinters, would not produce as large quantities of the drug, and equally pure, as the trees of Borneo and Japan; but he aſſures us, that in China it is never ſo torn, being there a large and valuable timber-tree. "It is uſed (ſays he) in the beſt buildings of every kind, as well as for maſts of veſſels, and bears too high a price to allow of any part, except the branches, being cut up for the ſake of the drug."

CANALS OF COMMUNICATION may be of ſuch advantage in a commercial or agricultural country, that every attempt to render them more convenient, and leſs expenſive in the conſtruction, is intitled to public notice. In the Encyclopædia, an account, ſufficiently perſpicuous, is given of the common canals with locks; but in many caſes it is very difficult to provide a ſufficient quantity of water for the conſumption of a canal where many boats are to paſs. Different attempts have therefore been made, by ingenious men, to ſave water in the paſſing of boats or lighters from one lock of a canal to another; and, among theſe, perhaps none is more deſerving of public favour than the following, by the late Mr James Playfair of Ruſſel-ſtreet, architect. We ſhall ſtate his invention in his own words.

"The nature and principle of this manner of ſaving water conſiſt in letting the water which has ſerved to raiſe or fall a boat or barge from the lock, paſs into reſervoirs or ciſterns, whoſe apertures of communication with the lock are upon different levels, and which may be placed or conſtructed at the ſide or ſides of the lock with which they communicate, or in any other contiguous ſituation that circumſtances may render eligible; which apertures may be opened or ſhut at pleaſure, ſo that the water may paſs from the lock to each reſervoir of the canal, or from each reſervoir to the lock, in the following manner: The water which fills the lock, when a boat is to aſcend or deſcend, inſtead of being paſſed immediately into the lower part of the canal, is let paſs into theſe ciſterns or reſervoirs, upon different levels; then, their communications with the lock being ſhut, they remain full until another veſſel is wanted to paſs; then, again, the ciſterns are emptied into the lock, which is thereby nearly filled, ſo that only the remainder which is not filled is ſupplied from the higher part of the canal. Each of theſe ciſterns muſt have a ſurface not leſs than that of the lock, and muſt contain half as much water as is meant to be expended for the paſſing of each veſſel. The ciſtern the moſt elevated is placed twice its own depth (meaſuring by the aperture, or communicating opening of the ciſterns) under the level of the water in the higher part of the canal. The ſecond ciſtern is placed once its own depth under the firſt, and ſo on are the others to the loweſt; which laſt is placed once its own depth above the level of the water in the lower part of the canal. The apertures of the intermediate ciſterns, whatever their number may be, muſt all be equally divided into different levels; the ſurface of the water in the one being always on the level of the bottom of the aperture of the ciſtern which is immediately above. As an example of the manner and rule for conſtructing theſe ciſterns, ſuppoſe that a lock is to be conſtructed twelve feet deep, that is, that the veſſel may aſcend or deſcend twelve feet in paſſing. Suppoſe the lock ſixty feet long and ſix feet wide, the quantity of water required to fill the lock, and to paſs a boat, is 4320 cubic feet; and ſuppoſe that, in calculating the quantity of water that can be procured for ſupplying the canal, after allowing for waſte, it is found (according to the number of boats that may be expected to paſs) that there will not be above 800 cubic feet for each; then it will be neceſſary to ſave five-ſixths of the whole quantity that in the common caſe would be neceſſary: to do which ten ciſterns muſt be made (the mode of placing which is expreſſed

preſſed in the drawing, fig. 1. Plate VII.), each of which muſt be one foot deep, or deeper at pleaſure, and each muſt have a ſurface of 360 feet ſquare, equal to the ſurface of the lock. The bottom of the aperture of the loweſt ciſtern muſt be placed one foot above the level of the water in the lower part of the canal, or eleven feet under the level of the high water; the ſecond ciſtern muſt be two feet above the level of the low water; the third three feet, and ſo on of the others; the bottom of the tenth, or uppermoſt ciſtern, being ten feet above the low water, and two feet lower than the high water; and, as each ciſtern muſt be twelve inches in depth, the ſurface of the water in the higher ciſtern will be one foot under the level of the water in the upper part of the canal. The ciſterns being thus conſtructed, when the lock is full, and the boat to be let down, the communications between the lock and the ciſterns, which until then have all been ſhut, are to be opened in the following manner: firſt, the communication with the higher ciſtern is opened, which, being at bottom two feet under the level of the water in the lock, is filled to the depth of one foot, the water in the lock deſcending one foot alſo at the ſame time; that communication is then ſhut, and the communication between the lock and the ſecond ciſtern is opened; one foot more of the water then paſſes into that ciſtern from the lock, and fills it; the opening is then ſhut: the ſame is done with the third, fourth, fifth, ſixth, ſeventh, eighth, ninth, and tenth, ciſterns, one by one, until they are all filled; and when the tenth, or lowermoſt ciſtern, is filled, there remains but two feet depth of water in the lock. The communication between the lock and the lower part of the canal is then opened, and the laſt two feet depth of water is emptied into the lower part of the canal. By this means, it is evident that, inſtead of twelve feet depth of water being let deſcend into the lower part of the canal, there is only two feet depth that deſcends, or one-ſixth of the whole; therefore, inſtead of 4320 cubic feet being uſed, there are only 720 cubic feet uſed: the remainder of the water in the ciſterns being uſed as follows: When another boat is to mount, the ſluices being then ſhut, and the boat in the lock, the tenth or lowermoſt ciſtern is emptied into the lock, which it fills one foot; the communication being then ſhut, the next loweſt ciſtern, or the ninth, is emptied into the lock, which is thereby filled another foot; and ſo, in like manner, all the other ciſterns are emptied one after another, until the higher ciſtern being emptied, which fills the tenth foot of water in the lock, there remains but two feet of water to fill, which is done from the upper part of the canal by opening the higher ſluice to paſs the boat; by that means, the ſame quantity of water deſcends from the upper part of the canal into the lock, that in the other caſe deſcended from the lock into the lower part of the canal; ſo that, in both caſes, the ſame quantity of water is ſaved, that is, five-ſixths of what would be neceſſary were there no ciſterns. Suppoſe again that, upon the ſame canal, and immediately after the twelve feet lock, it would be advantageous to conſtruct one of eighteen feet; then, in order not to uſe any greater quantity of water, it will be neceſſary to have ſixteen ciſterns, upon different levels, communicating with the lock in the ſame manner. Should, again, a lock of only ſix feet be wanted, after that of eighteen, then it will only be neceſſary to have four ciſterns on different levels, and ſo of any other height of lock. The rule is this: For finding the number and ſize of the ciſterns, each ciſtern being the ſame in ſuperficies with the lock, its depth muſt be ſuch as to contain one half the quantity of water meant to be uſed in the paſſing of one boat. The depth of the lock, divided by the depth neceſſary for ſuch a ciſtern, will give, in all caſes, the whole number of ciſterns, and two more: deduct the number two, therefore, from the number which you find by dividing the depth of the lock by the depth of one ciſtern, and you have always the number of ciſterns required; which are to be placed upon different levels, according to the rule already given. The above is the principle and manner of uſing the lock, for ſaving water in canals, and for enabling engineers to conſtruct locks of different depths upon the ſame canal, without uſing more water for the deep locks than for the ſhallow ones. With regard to the manner of diſpoſing the ciſterns, the circumſtances of the ground, the declivity, &c. will be the beſt guide for the engineer."

But ſuppoſing a ſufficiency of water, or admitting that this method of Mr Playfair's of ſaving it, where defective, is adequate to his fondeſt expectations, ſtill, in paſſing numerous locks, where the riſe is conſiderable, the interruption is ſo great, that it has often been wiſhed that an eligible method of lowering and elevating boats could be deviſed, without the aſſiſtance of water-locks. Though this is evidently at firſt view practicable, and ſeveral different modes of doing it have been ſuggeſted, ſome of which have actually been carried into effect, yet all of them have been found to be attended with ſuch inconvenience as to render an improvement in this reſpect ſtill neceſſary.

In China, where water-carriage is more generally practiſed than in any kingdom of Europe, boats are raiſed and lowered from one canal into another, by ſliding them along an inclined plane: but the contrivances for effecting that purpoſe are ſo awkward, and ſuch a number of hands are required, that it has in general been deemed inexpedient to reſort to that mode of practice in Europe. Several devices, that diſcover conſiderable ingenuity, however, have been publiſhed, with a view to facilitate this operation; either by rendering the motion up the inclined plane more equable, or producing a power ſufficient to move theſe great weights. But none of them have yet been ſo ſimple in their conſtruction as could be wiſhed, nor have they afforded ſatisfaction in practice. For the greater part of them, likewiſe, patents have been granted; ſo that whatever be their value, no engineer could avail himſelf of them without previouſly purchaſing a licence from the patentee.

The following contrivance for this purpoſe is the invention of James Anderſon, LL. D. whoſe knowledge of economics is well known, and of whoſe public ſpirit there cannot be a doubt. Inſtead of applying for a patent, to ſecure to himſelf the fruits of his ingenuity, he publiſhed, for the good of his countrymen in general, his device, in the View of the Agriculture of the County of Aberdeen, which he drew up for the conſideration of the board of agriculture. He introduces it to public notice with juſtly obſerving, that it poſſeſſes at leaſt the merit of ſimplicity, in as high a degree, perhaps, as could be wiſhed ; and, " in the opinion (ſays he) of very good judges of matters of this ſort, to whom the plan has been ſhewn, it has been deemed fully adequate to the purpoſe of raiſing and lowering boats of a moderate ſize, that is, of 20 tons, or downwards ; and it is the opinion of moſt men with whom I have converſed, who are beſt acquainted with the inland navigations, that a boat of from 10 to 15 tons is better than thoſe of a larger ſize. When ſeveral are wanted to be ſent at once, they may be affixed to one another, as many as the towing-horſe can conveniently draw. Were boats of this ſize adopted, and were all the boats on one canal to be of the ſame dimenſions, it would prove a great convenience to a country in a ſtate of beginning improvements; becauſe the expence of ſuch a boat would be ſo trifling, that every farmer could have one for himſelf, and might of courſe make uſe of it when he pleaſed by the aid of his own horſe, without being obliged to have any dependence on the time that might ſuit the convenience of his neighbour ; and if two or more boats were going from the ſame neighbourhood, one horſe could ſerve the whole.

" You are to ſuppoſe that fig. 2. (Plate VII.) repreſents a bird's-eye view of this ſimple apparatus, as ſeen from above. A is ſuppoſed to be the upper reach of the canal, and B the lower reach, with the apparatus between the two. This conſiſts of three diviſions ; the middle one, extending from C to D, is a ſolid piece of maſonry, raiſed from a firm foundation below the level of the bottom of the ſecond reach : this is again divided into five parts, viz. *ddd*, where the wall riſes only to the height of the water in the upper reach, and *ee*, two pillars, raiſed high enough to ſupport the pivots of a wheel or pulley *g*, placed in the poſition there marked.

" The ſecond diviſion *h* conſiſts of a wooden coffer, of the ſame depth nearly as the water in the upper reach, and of a ſize exactly fitted to contain one of the boats. This communicates directly with the upper reach, and being upon the ſame plane with it, and ſo connected with it as to be water-tight, it is evident, from inſpection, that nothing can be more eaſy than to float a boat into this coffer from the upper reach ; the part of the wheel that projects over it being at a ſufficient height above it, ſo as to occaſion no ſort of interruption.

" Third diviſion. At *i* is repreſented another coffer, preciſely of the ſame dimenſions with the firſt. But here two ſluices, which were open in the former, and only repreſented by dotted lines, are ſuppoſed to be ſhut, ſo as to cut off all communication between the water in the canal and that in the coffer. As it was impoſſible to repreſent this part of the apparatus on ſo ſmall a ſcale, for the ſake of illuſtration it is repreſented more at large in fig. 5. where A, as before, repreſents the upper reach of the canal, and *h* one of the coffers. The ſluice *k* goes into two cheeks of wood, joined to the maſonry of the dam of the canal, ſo as to fit perfectly cloſe ; and the ſluice *f* fits equally cloſe into cheeks made in the ſide of the coffer for that purpoſe ; between theſe two ſluices is a ſmall ſpace *o*. The coffer, and this diviſion *o*, are to be ſuppoſed full of water, and it will be eaſy to ſee that theſe ſluices may be let down or drawn up at pleaſure with much facility.

" Fig. 6. repreſents a perpendicular ſection of theſe parts in the ſame direction as in fig. 5. and in which the ſame letters repreſent the ſame parts.

" Things being thus arranged, you are to ſuppoſe the coffer *h* to be ſuſpended, by means of a chain paſſed over the pulley, and balanced by a weight that is ſufficient to counterpoiſe it, ſuſpended at the oppoſite end of the chain. Suppoſe, then, that the counterpoiſe be made ſomewhat lighter than the coffer with its contents, and that the line *mn* (fig. 6.) repreſents a diviſion between the ſolid ſides of the dam of ſeparation, which terminates the upper reach and the wooden coffer, which had been cloſed only by the preſſure of its own weight (being puſhed a very little from A towards B, beyond its preciſe perpendicular ſwing), and that the joining all round is covered with liſts of cloth put upon it for that purpoſe ; it is evident that, ſo long as the coffer is ſuſpended to this height, the joining muſt be water-tight ; but no ſooner is it lowered down a little than this joining opens, the water in the ſmall diviſion *o* is allowed to run out, and an entire ſeparation is made between the fixed dam and this moveable coffer, which may be lowered down at pleaſure without loſing any part of the water it contained.

" Suppoſe the coffer now perfectly detached, turn to fig. 3. which repreſents a perpendicular ſection of this apparatus, in the direction of the dotted line *pp* (fig. 2.) In fig. 3. *h* repreſents an end view of the coffer, indicated by the ſame letter as in fig. 2. ſuſpended by its chain, and now perfectly detached from all other objects, and balanced by a counterpoiſe *i*, which is another coffer exactly of the ſame ſize, as low down as the level of the lower reach. From inſpection only, it is evident, that in proportion as the one of theſe weights riſes, the other muſt deſcend. For the preſent, then, ſuppoſe that the coffer *h* is by ſome means rendered more weighty than *i*, it is plain it will deſcend while the other riſes ; and they will thus continue till *h* comes down to the level of the lower reach, and *i* riſes to the level of the higher one.

" Fig. 4. repreſents a ſection in the direction AB (fig. 2.), in which the coffer *i* (ſeen in both ſituations) is ſuppoſed to have been gradually raiſed from the level of the lower reach B, to that of the higher A, where it now remains ſtationary ; while the coffer *h* (which is concealed behind the maſonry) has deſcended in the mean time to the level of the lower reach, where it cloſes by means of the juncture *rs*, fig. 6. (which juncture is covered with liſts of cloth, as before explained at *mn*, and is of courſe become water-tight), when, by lifting the ſluice *t*, and the correſponding ſluice at the end of the canal, a perfect communication by water is eſtabliſhed between them. If, then, inſtead of water only, this coffer had contained a boat, floated into it from the upper reach, and then lowered down, it is very plain that when theſe ſluices were removed, after it had reached the level of the lower reach, that boat might have been floated out of the coffer with as much facility as it was let into it above. Here then we have a boat taken from the higher into the lower canal ; and, by reverſing this movement, it is very obvious that it might be, with equal eaſe, raiſed from the lower into the higher one. It now only remains that I ſhould explain by what means the equilibrium between

PLATE VII.

theſe counterbalancing weights can be deſtroyed at pleaſure, and the motion of courſe produced.

“ It is very evident, that if the two correſponding coffers be preciſely of the ſame dimenſions, their weight will be exactly the ſame when they are both filled to the ſame depth of water. It is equally plain, that ſhould a boat be floated into either or both of them, whatever its dimenſions or weight may be, ſo that it can be contained afloat in the coffer, the weight of the coffer and its contents will continue preciſely the ſame as when it was filled with water only : hence, then, ſuppoſing one boat is to be lowered, or one to be raiſed at a time, or ſuppoſing one to be raiſed and another lowered at the ſame time—they remain perfectly in equilibrium in either place, till it is your pleaſure to deſtroy that equilibrium. Suppoſe, then, for the preſent, that both coffers are loaded with a boat in each, the double ſluices both above and below cloſed ; and ſuppoſe alſo that a ſtop-cock *u*, in the under edge of the ſide of the lower coffer (fig. 4. and 6.), is opened, ſome of the water which ſerved to float the boat in the coffer will flow out of it, and conſequently that coffer will become lighter than the higher one ; the upper coffer will of courſe deſcend, while the other mounts upwards. When a gentle motion has been thus communicated, it may be prevented from accelerating, merely by turning the ſtop-cock ſo as to prevent the loſs of more water, and thus one coffer will continue to aſcend, and the other to deſcend, till they have aſſumed their ſtations reſpectively ; when, in conſequence of a ſtop below, and another above, they are rendered ſtationary at the level of the reſpective canals (A).

“ Preciſely the ſame effect will be produced when the coffers are filled entirely with water.

“ It is unneceſſary to add more to this explanation, except to obſerve that the ſpace for the coffer to deſcend into muſt be deeper than the bottom of the lower canal, in order to allow a free deſcent for the coffer to the requiſite depth ; and of courſe it will be neceſſary to have a ſmall conduit to allow the water to get out of it. Two or three inches free, below the bottom of the canal, is all that would be neceſſary.

“ Where the height is inconſiderable, there will be no occaſion for providing any counterpoiſe for the chain, as that will give only a ſmall addition to the weight of the undermoſt coffer, ſo as to make it preponderate, in circumſtances where the two coffers would otherwiſe be in perfect equilibrium : but, where the height is conſiderable, there will be a neceſſity for providing ſuch a counterpoiſe ; as, without it, the chain, by becoming more weighty every foot it deſcended, would tend to deſtroy the equilibrium too much, and accelerate the motion to an inconvenient degree. To guard againſt this inconvenience, let a chain of the ſame weight, per foot, be appended at the bottom of each coffer, of ſuch a length as to reach within a few yards of the ground where the coffer is at its greateſt height (ſee fig. 3.) ; it will act with its whole weight upon the higheſt coffer while in this poſition ; but, as that gradually deſcended, the chain would reach the ground, and, being there ſupported, its weight would be diminiſhed in proportion to its deſcent ; while the weight of the chain on the oppoſite ſide would be augmented in the ſame proportion, ſo as to counterpoiſe each other exactly, in every ſituation, until the uppermoſt chain was raiſed from the ground. After which it would increaſe its weight no more; and, of courſe, would then give the under coffer that preponderance which is neceſſary for preſerving the machine ſteady. The under coffer, when it reached its loweſt poſition, would touch the bottom on its edges, which would then ſupport it, and keep every thing in the ſame poſition, till it was made lighter for the purpoſe of aſcending.

“ What conſtitutes one particular excellence of the apparatus here propoſed is, that it is not only unlimited as to the extent of the riſe or depreſſion of which it is ſuſceptible (for it would not require the expenditure of one drop more water to lower it one hundred feet than one foot) ; but it would alſo be eaſy ſo to augment the number of pulleys at any one place as to admit of two, three, four, or any greater number of boats being lowered or elevated at the ſame time ; ſo that let the ſucceſſion of boats on ſuch a canal be nearly as rapid as that of carriages upon a highway, none of them need be delayed one moment to wait an opportunity of paſſing : a thing that is totally impracticable where water-locks are employed ; for the intercourſe, on every canal conſtructed with water-locks, is neceſſarily limited to a certain degree, beyond which it is impoſſible to force it.

“ For example : ſuppoſe a hundred boats are following each other, in ſuch a rapid ſucceſſion as to be only half a minute behind each other : By the apparatus here propoſed, they would all be elevated preciſely as they came ; in the other, let it be ſuppoſed that the lock is ſo well conſtructed as that it takes no more than five minutes to cloſe and open it ; that is, ten minutes in the whole to each boat (for the lock, being once filled, muſt be again emptied before it can receive another in the ſame direction) : at this rate, ſix boats only could be paſſed in an hour, and of courſe it would take ſixteen hours and forty minutes to paſs the whole hundred ; and as the laſt boat would reach the lock in the ſpace of fifty minutes after the firſt, it would be detained fifteen hours and fifty minutes before its turn would come to be raiſed. This is an immenſe detention ; but if a ſucceſſion of boats, at the ſame rate, were to follow continually, they never could paſs at all. In ſhort, in a canal conſtructed with water-locks, not more than ſix boats, on an average, can be paſſed in an hour, ſo that beyond that extent all commerce muſt be ſtopped; but, of the plan here propoſed, ſixty, or ſix hundred, might be paſſed in an hour if neceſſary, ſo as to occaſion no ſort of interruption whatever. Theſe are advantages of a very important nature, and ought not to be overlooked in a commercial country.

“ This apparatus might be employed for innumerable other uſes as a moving power, which it would be foreign to our preſent purpoſe here to ſpecify. Nor does its power admit of any limitation, but that of the ſtrength of the chain, and of the coffers which are to ſupport the weights. All the other parts admit of

---

(A) “ It does not ſeem neceſſary to adopt any other contrivance than the above for regulating the motions ; but if it ſhould be found neceſſary, it would be eaſy to put a ratch-wheel on the ſame axle.”

being made ſo immoveably firm as to be capable of ſupporting almoſt any aſſignable weight.

" I will not enlarge on the benefits that may be derived from this very ſimple apparatus: its cheapneſs, when compared with any other mode of raiſing and lowering veſſels that has ever yet been practiſed, is very obvious; the waſte of water it would occaſion is next to nothing; and when it is conſidered that a boat might be raiſed or lowered fifty feet nearly with the ſame eaſe as five, it is evident that the interruptions which ariſe from frequent locks would be avoided, and an immenſe ſaving be made in the original expence of the canal, and in the annual repairs.

" It is alſo evident that an apparatus, on the ſame principle, might be eaſily applied for raiſing coals or metals from a great depth in mines, wherever a very ſmall ſtream of water could be commanded, and where the mine was level-free."

CANARY-BIRD, of which a deſcription is given in the Encyclopædia, was not known in Europe till towards the end of the 15th century. Even in 1555, Bellon, who about that time deſcribed all the birds then known, does not ſo much as mention it. When it was firſt brought from the Canary Iſlands, it was ſo dear that it could be purchaſed only by people of fortune, who were often impoſed upon. It was called the *ſugar-bird*, becauſe it was ſaid to be fond of the ſugar-cane, and could eat ſugar in great abundance. This is rather a ſingular circumſtance, ſugar being to many fowls a poiſon. Experiments have ſhewn that a pigeon, to which four drams of ſugar was given, died in four hours; and that a duck, which had ſwallowed five drams, did not live ſeven hours.

In the middle of the laſt century canary-birds began to be bred in Europe; and to this the following circumſtance, related by Olina, ſeems to have given occaſion: " A veſſel which, among other commodities, was carrying a number of canary birds to Leghorn, was wrecked on the coaſt of Italy; and theſe birds being thus ſet at liberty, flew to the neareſt land, which was the iſland of Elba, where they found the climate ſo favourable, that they multiplied, and perhaps would have become domeſticated, had they not been caught in ſnares; for it appears that the breed of them there has been long deſtroyed. Olina ſays that the breed ſoon degenerated; but it is probable that by much the greater part of theſe canary-birds were males, which coupling with birds of the iſland, produced mules, ſuch as are deſcribed by Geſner and other naturaliſts."

" Various treatiſes have been publiſhed in different languages, on the manner of breeding theſe birds, and many people have made it a trade, by which they have acquired conſiderable gain. It does no diſcredit to the induſtry of the Tyrolians, that they have carried it to the greateſt extent. At Ymſt there is a company, who, after the breeding ſeaſon is over, ſend out perſons to different parts of Germany and Switzerland to purchaſe birds from thoſe who breed them. Each perſon brings with him commonly from three to four hundred, which are afterwards carried for ſale, not only through every part of Germany, but alſo to England, Ruſſia, and even Conſtantinople. About ſixteen hundred are brought every year to England; where the dealers in them, notwithſtanding the conſiderable expence they are at, and after carrying them about on their backs, perhaps a hundred miles, ſell them for five ſhillings a piece. This trade, hitherto neglected, is now carried on in Schwartzwalde; and at preſent there is a citizen at Gottingen who takes with him every year to England ſeveral canary-birds and bulfinches *(loxia pyrrhula)*, with the produce of which he purchaſes ſuch ſmall wares as he has occaſion for."—*Profeſſor Beckmann's Hiſtory of Inventions and Diſcoveries.*

Canary-Seed. See PHALARIS, *Encycl.*—Profeſſor Beckmann doubts whether the plant which bears the canary-ſeed be the *phalaris* of the ancients, becauſe that name ſeems to have been given by Pliny to more than one ſpecies of graſs. He thinks it very probable, however, that the plant, which the modern botaniſts call *phalaris*, was firſt brought from the Canary Iſlands to Spain, where it began to be cultivated, as well as in the ſouth of France, as ſoon as canary-birds came into general eſteem. At preſent it is cultivated in various places, and forms no inconſiderable branch of trade, particularly in the iſland of Sicily, where it is called *Scagliuola* or *Scaghiola*. Were it not that the grains are not eaſily freed from the huſks, this plant might be cultivated for the food of man, for its ſeeds yield a good kind of meal. The phalaris has by ſeveral writers been confounded with *argol* or the *lichen rocolla* of Linnæus; but they are very different plants. See *LICHEN Rocolla* in this Supplement.

CANDLE, a thing ſo univerſally known as to need no particular deſcription. Its uſe, however, is ſo great, that every information tending to its improvement muſt, we ſhould think, be acceptable to our readers. Of the common method of making candles, whether of wax or of tallow, a ſufficient account has been given in the Encyclopædia; but candles of every kind are far from being yet brought to that degree of perfection of which they ſeem ſuſceptible. Thus, for example, the light of a candle, which is ſo exceedingly brilliant when firſt ſnuffed, is very ſpeedily diminiſhed to one half, and is uſually not more than one-fifth or one-ſixth, before the uneaſineſs of the eye induces us to ſnuff it. Hence it follows, that if candles could be made ſo as not to require ſnuffing, the average quantity of light afforded by the ſame quantity of combuſtible matter would be more than doubled. It may likewiſe be worthy of inquiry, ſince the coſt and duration of candles are eaſily aſcertainable, whether more or leſs light is obtained at the ſame expence during a given time, by burning a number of ſmall candles inſtead of one of greater thickneſs.

To determine this laſt point, a method muſt be found of meaſuring the comparative intenſities of light, for which ſee PHOTOMETER in this Supplement. With reſpect to the deſideratum firſt mentioned, we have ſome very ingenious obſervations and well-contrived experiments by Mr Nicholſon, in the ſecond number of his valuable Journal, which we ſhall here inſert nearly in the words of their author.

In every proceſs of combuſtion the free acceſs of air is of the utmoſt conſequence. When a candle has a very ſlender wick, the flame is ſmall and of a brilliant white colour; if the wick be large, the combuſtion is leſs perfect, and the flame brown; and a wick ſtill larger, not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatilized matter, which does not become ignited till it has aſcended towards the point. When the wick is

either

either very large or very long, part of this matter eſcapes combuſtion, and ſhews itſelf in the form of coal or ſmoke. The ſame things take place in the burning of a lamp; but when the wick of a lamp is once adjuſted as to its length, the flame continues nearly in the ſame ſtate for a much longer time than the flame of a candle.

"Upon comparing a candle with a lamp (ſays Mr Nicholſon), two very remarkable particulars are immediately ſeen. In the firſt place, the tallow itſelf, which remains in the unfuſed ſtate, affords a cup or cavity to hold that portion of melted tallow which is ready to flow into the lighted part of the wick. In the ſecond place, the combuſtion, inſtead of being confined, as in the lamp, to a certain determinate portion of the fibrous matter, is carried, by a ſlow ſucceſſion, through the whole length. Hence ariſes the greater neceſſity for frequent ſnuffing the candle; and hence alſo the ſtation of the freezing point of the fat oil becomes of great conſequence. For it has been ſhewn, that the brilliancy of the flame depends very much on the diameter of the wick being as ſmall as poſſible; and this requiſite will be moſt attainable in candles formed of a material that requires a higher degree of heat to fuſe it. The wick of a tallow candle muſt be made thicker in proportion to the greater fuſibility of the material, which would otherwiſe melt the ſides of the cup, and run over in ſtreams. The flame will therefore be yellow, ſmoky, and obſcure, excepting for a ſhort time immediately after ſnuffing. Tallow melts at the 92d degree of Fahrenheit's thermometer; ſpermaceti at the 133d degree; the fatty matter formed of fleſh, after long immerſion in water, melts at 127 degrees; the *pela* of the Chineſe at 145 degrees; bees-wax at 142 degrees; and bleached wax at 155 degrees. Two of theſe materials are well known in the fabrication of candles. Wax in particular does not afford ſo brilliant a flame as tallow; but, on account of its leſs fuſibility, the wick can be made ſmaller, which not only affords the advantage of a clear perfect flame, but from its flexibility it is diſpoſed to turn on one ſide, and come in contact with the external air, which completely burns the extremity of the wick to white aſhes, and thus performs the office of ſnuffing. We ſee therefore that the important object to ſociety of rendering tallow candles equal to thoſe of wax, does not at all depend on the combuſtibility of the reſpective materials, but upon a mechanical advantage in the cup, which is afforded by the inferior degree of fuſibility in the wax; and that, to obtain this valuable object, one of the following effects muſt be produced: Either the tallow muſt be burned in a lamp, to avoid the gradual progreſſion of the flame along the wick; or ſome means muſt be deviſed to enable the candle to ſnuff itſelf, as the wax candle does; or, laſtly, the tallow itſelf muſt be rendered leſs fuſible by ſome chemical proceſs. I have no great reaſon to boaſt of ſucceſs in the endeavour to effect theſe; but my hope is, that the facts and obſervations here preſented may conſiderably abridge the labour of others in the ſame purſuit.

"The makers of thermometers and other ſmall articles with the blow-pipe and lamp, give the preference to tallow inſtead of oil, becauſe its combuſtion is more complete, and does not blacken the glaſs. In this operation the heat of the lamp melts the tallow which is occaſionally brought into its vicinity by the workman. But for the uſual purpoſes of illumination, it cannot be ſuppoſed that a perſon can attend to ſupply the combuſtible matter. Conſiderable difficulties ariſe in the project for affording this gradual ſupply as it may be wanted. A cylindrical piece of tallow was inſerted into a metallic tube, the upper aperture of which was partly cloſed by a ring, and the central part occupied by a metallic piece nearly reſembling that part of the common lamp which carries the wick. In this apparatus the piece laſt deſcribed was intended to anſwer the ſame purpoſe, and was provided with a ſhort wick. The cylinder of tallow was ſupported beneath in ſuch a manner that the metallic tube and other part of this lamp were left to reſt with their whole weight upon the tallow at the ring or contraction of the upper aperture. In this ſituation the lamp was lighted. It burned for ſome time with a very bright clear flame, which, when compared with that of a candle, poſſeſſed the advantage of uniform intenſity, and was much ſuperior to the ordinary flame of a lamp in its colour, and the perfect abſence of ſmell. After ſome minutes it began to decay, and very ſoon afterwards went out. Upon examination, it was found that the metallic piece which carried the wick had fuſed a ſufficient quantity of tallow for the ſupply during the combuſtion; that part of this tallow had flowed beneath the ring, and to other remote parts of the apparatus, beyond the influence of the flame; in conſequence of which, the tube and the cylinder of tallow were faſtened together, and the expected progreſſion of ſupply prevented. It ſeems probable that, in every lamp for burning conſiſtent oils, the material ought to be ſo diſpoſed that it may deſcend to the flame upon the principle of the fountain reſervoir. I ſhall not here ſtate the obſtacles which preſent themſelves in the proſpect of this conſtruction, but ſhall diſmiſs the ſubject by remarking, that a contrivance of this nature would be of the greateſt public utility.

"The wick of a candle being ſurrounded by the flame, is nearly in the ſituation of a body expoſed to deſtructive diſtillation in a cloſe veſſel. After loſing its volatile products, the carbonaceous reſidue retains its figure, until, by the deſcent of the flame, the external air can have acceſs to its upper extremity. But, in this caſe, the requiſite combuſtion, which might ſnuff it, is not effected: for the portion of oil emitted by the long wick is not only too large to be perfectly burned, but alſo carries off much of the heat of the flame while it aſſumes the elaſtic ſtate. By this diminiſhed combuſtion and increaſed efflux of half-decompoſed oil, a portion of coal or ſoot is depoſited on the upper part of the wick, which gradually accumulates, and at length aſſumes the appearance of a fungus. The candle does not then give more than one-tenth of the light emitted in its beſt ſtate. Hence it is that a candle of tallow cannot ſpontaneouſly ſnuff itſelf. It was not probable that the addition of a ſubſtance containing vital air or oxygen would ſupply that principle at the preciſe period of time required; but as experiment is the teſt of every probability of this nature, I ſoaked a wick of cotton in a ſolution of nitre, then dried it, and made a candle. When this came to be lighted, nothing remarkable happened for a ſhort time; at the expiration of which a decrepitation followed at the lower extremity of the flame, which completely divided the wick

where

where the blackened part commences. The whole of the matter in combuſtion therefore fell off, and the candle was of courſe inſtantly extinguiſhed. Whether this would have happened in all proportions of the ſalt or conſtructions of the candle, I did not try, becauſe the ſmell of azot was ſufficiently ſtrong and unpleaſant to forbid the uſe of nitre in the purſuit. From various conſiderations, I am diſpoſed to think that the ſpontaneous ſnuffing of candles made of tallow, or other fuſible materials, will ſcarcely be effected but by the diſcovery of ſome material for the wick which ſhall be voluminous enough to abſorb the tallow, and at the ſame time ſufficiently flexible to bend on one ſide.

“ The moſt promiſing ſpeculation reſpecting this moſt uſeful article, ſeems to direct itſelf to the cup which contains the melted tallow. The imperfection of this part has already been noticed, namely, that it breaks down by fuſion, and ſuffers its fluid contents to eſcape. The Chineſe have a kind of candle about half an inch in diameter, which, in the harbour of Canton, is called a *lobchock;* but whether the name be Chineſe, or the corruption of ſome European word, I am ignorant. The wick is of cotton, wrapped round a ſmall ſtick or match of the bamboo cane. The body of the candle is white tallow; but the external part, to the thickneſs of perhaps one thirtieth of an inch, conſiſts of a waxy matter coloured red. This covering gives a conſiderable degree of ſolidity to the candle, and prevents its guttering, becauſe leſs fuſible than the tallow itſelf. I did not obſerve that the ſtick in the middle was either advantageous or the contrary; and as I now write from the recollection of this object at ſo remote a period as 25 years ago, I can only conjecture that it might be of advantage in throwing up a leſs quantity of oil into the flame than would have been conveyed by a wick of cotton ſufficiently ſtout to have occupied its place unſupported in the axis of the candle.

“ Many years ago I made a candle in imitation of the lobchock. The expedient to which I had recourſe conſiſted in adapting the wick in the uſual pewter mould: wax was then poured in, and immediately afterwards poured out: the film of wax which adhered to the inner ſurface of the mould ſoon became cool, and the candle was completed by filling the mould with tallow. When it was drawn out, it was found to be cracked longitudinally on its ſurface, which I attributed to the contraction of the wax, by cooling, being greater than that of the tallow. At preſent I think it equally probable that the cracking might have been occaſioned by too ſudden cooling of the wax before the tallow was poured in; but other avocations prevented the experiments from being varied and repeated. It is probable that the Chineſe external coating may not be formed of pure hard bleached wax.

“ But the moſt deciſive remedy for the imperfection of this cheapeſt, and in other reſpects beſt, material for candles, would undoubtedly be to diminiſh its fuſibility. Various ſubſtances may be combined with tallow, either in the direct or indirect method. In the latter way, by the decompoſition of ſoap, a number of experiments were made by Berthollet, of which an account is inſerted in the memoirs of the Academy at Paris for the year 1780, and copied into the 26th volume of the *Journal de Phyſique.* None of theſe point directly to the preſent object; beſides which, it is probable that the ſoap made uſe of by that eminent chemiſt was formed not of tallow, but oil. I am not aware of any regular ſeries of experiments concerning the mutual action of fat oils and other chemical agents, more eſpecially ſuch as may be directed to this important object of diminiſhing its ſolubility; for which reaſon I ſhall mention a few experiments made with this view.

“ 1. Tallow was melted in a ſmall ſilver veſſel. Solid tallow ſinks in the fluid, and diſſolves without any remarkable appearance. 2. Gum ſandarach in tears was not diſſolved, but emitted bubbles, ſwelled up, became brown, emitted fumes, and became criſp or friable. No ſolution nor improvement of the tallow. 3. Shell-lac ſwelled up with bubbles, and was more perfectly fuſed than the gum ſandarach in the former experiment. When the tallow was poured off, it was thought to congeal rather more ſpeedily. The lac did not appear to be altered. 4. Benzoin bubbled without much ſwelling, was fuſed, and emitted fumes of an agreeable ſmell, though not reſembling the flowers of benzoin. A ſlight or partial ſolution ſeemed to take place. The benzoin was ſofter and of a darker colour than before, and the tallow leſs conſiſtent. 5. Common reſin unites very readily with melted tallow, and forms a more fuſible compound than the tallow itſelf. 6. Camphor melts eaſily in tallow, without altering its appearance. When the tallow is near boiling, camphoric fumes fly off. The compound appeared more fuſible than tallow. 7. The acid or flowers of benzoin diſſolves in great quantities without any ebullition or commotion. Much ſmoke ariſes from the compound, which does not ſmell like the acid of benzoin. Tallow alone does not fume at a low heat, though it emits a ſmell ſomething like that of oil olive. When the proportion of the acid was conſiderable, ſmall needled cryſtals appeared as the temperature diminiſhed. The appearances of ſeparation are different according to the quantity of acid. The compound has the hardneſs and conſiſtence of firm ſoap, and is partially tranſparent. 8. Vitriolated tartar, nitre, white ſugar, cream of tartar, cryſtallized borax, and the ſalt ſold in the markets under the name of ſalt of lemons, but which is ſuppoſed to be the eſſential ſalt of ſorrel, or vegetable alkali ſuperſaturated with acid of ſugar, were reſpectively tried without any obvious mutual action or change of properties in the tallow. 9. Calcined magneſia rendered tallow opaque and turbid, but did not ſeem to diſſolve. Its effect reſembled that of lime.

“ It is propoſed to try the oxygenated acetous acid, or radical vinegar; the acid of ants, of ſugar, of borax, of galls, the tanning principle, the ſerous and gelatinous animal matter, the fecula of vegetables, vegetable gluten, bird-lime, and other principles, either by direct or indirect application. The object, in a commercial point of view, is intitled to an extenſive and aſſiduous inveſtigation. Chemiſts in general ſuppoſe the hardneſs or leſs fuſibility of wax to ariſe from oxygen; and to this object it may perhaps be advantageous to direct a certain portion of the inquiry. The metallic ſalts and calces are the combinations from which this principle is moſt commonly obtained; but the combinations of theſe with fat oils have hitherto afforded little promiſe of the improvement here ſought. The ſubject is, however, ſo little known, that experiments of the looſeſt and moſt conjectural kind are by no means to be deſpiſed.”

Thus far Mr Nicholſon : but it is probable that many of the advantages which he propoſes by theſe mixtures might be obtained merely by purifying the tallow, and keeping it in that ſtate for a long time expoſed to the air before it be formed into candles. It is certain that tallow is rendered more difficult of fuſion by age ; and this is the ſole reaſon that old candles are leſs apt to run, and therefore more valuable than ſuch as have been lately made.

CANONGOES, in Bengal, are the regiſters of land and hereditary expounders of the uſages of the country. They have their officers and deputies everywhere ; they are not liable to removal ; and all papers atteſted by them are received as authentic and deciſive in all diſputes relative to lands and their boundaries. See *Sir Charles Rouſe Boughton's Diſſertation on the Landed Property of Bengal.*

CAOUTCHOUC, ELASTIC GUM, or *Indian Rubber*, is a ſubſtance of which a pretty full account has been given in the Encyclopædia. It has there been likewiſe obſerved how uſeful it might be, if we could form it into catheters and other flexible inſtruments, by diſſolving it in a menſtruum leſs expenſive, or at leaſt more eaſily attained, than ether. Since that article was publiſhed, we have ſeen an account of ſuch a menſtruum in the *Annales de Chimie*, by M. Groſſart (Chirly) ; and of the expence of that menſtruum, or the difficulty of procuring it, no complaint will be made, when it is known to be nothing more than very hot water.

The author was led to this diſcovery by ſome experiments made with ether on caoutchouc ; of which he gives the following account :

" It appeared, even in my firſt experiments, that I was attempting too much, and giving myſelf uſeleſs trouble, in ſearching for a manner of completely diſſolving the elaſtic gum, ſo that it might be again made up in new forms. I then thought that it would be eaſier to find out a method, as it were, of ſoldering it, and of not acting upon it more than might be neceſſary to cauſe its ſoftened parts to reunite. Experience has ſhewn me, that a ſtrong preſſure made upon two pieces of caoutchouc (when brought to that ſtate of ſoftneſs) and continued until they are entirely dry, cauſed them to contract ſo ſtrong an adheſion, that the piece, being pulled out till it broke, often broke, not at the united part, but by the ſide of it.

" By means of ether I immediately ſucceeded in making theſe tubes. The method which appears to me to ſucceed the beſt is, to cut a bottle circularly in a ſpiral ſlip of a few lines in breadth. It is very eaſy to cut a bottle in ſuch a manner as to form a ſingle long ſlip, and thus unneceſſary joinings are avoided.

" The whole ſlip is to be plunged into ether until it is ſufficiently ſoftened, which comes to paſs ſooner or later according to the quality of the vitriolic ether that is employed. Half an hour frequently ſuffices ; but I have already obſerved, that there is a great diverſity in the manner in which different ſorts of vitriolic ether act, and of which the cauſe is not yet, ſo far as I know, determined.

" The ſlip being taken out, one of the extremities is to be taken hold of and rolled, firſt upon itſelf at the bottom of the tube, preſſing it ; then the rolling is to be continued, mounting ſpirally along the mould, and taking care to lay over and compreſs with the hand every edge, one againſt the other, ſo that there may not be any vacant ſpace, and that all the edges may join exactly. The whole then is to be bound hard with a tape of an inch in width, taking care to turn it the ſame way with the ſlip of elaſtic gum. The tape is to be tied up with packthread, ſo that, by every turn of the packthread joining another, an equal preſſure is given to every part : it is then left to dry, and the tube is made.

" The bandage is to be taken off with great care, that none of the outward ſurfaces, which may have been lodged within the hollows of the tape (of which the caoutchouc takes the exact impreſſion), may be pulled away. I adviſe the application of a tape before packthread, becauſe, eſpecially in the thinner tubes, we ſhould run the riſk of cutting the caoutchouc if the packthread were applied immediately upon it.

" It is eaſy to take off the tube of elaſtic gum which has been formed upon a ſolid mould of one piece : if the mould be made rather conic, it may be made to ſlide off by the ſmaller end ; at the worſt, it is eaſily accompliſhed by plunging it into hot water ; for it is ſoftened by the heat, and is diſtended : without this precaution it would be ſometimes difficult to draw it off when dry, becauſe, having been applied upon the mould whilſt it had its volume augmented by the interpoſition of the ether, the parts of the caoutchouc are drawn nearer each other by the evaporation of the interpoſed bodies.

" The great affinity between theſe two bodies is ſeen by the length of time that the odour of the ether remains, notwithſtanding the great volatility of the latter, and that the apparent dryneſs of the tube ſeems to ſhew that there is none remaining ; nevertheleſs, after a certain time, the odour diſappears entirely. One of thoſe tubes, which was made with ether after the method here deſcribed, does not retain the leaſt trace of the ſolvent. It is needleſs to ſay that it is eaſy to make tubes as thin or as thick as may be judged proper.

" Although the proceſs that I am now deſcribing is but very little expenſive, yet I have tried to employ other ſolvents in lieu of ether, becauſe it is not to be had in every place, and requires particular care in its preſervation. I have employed, with ſome ſucceſs, the eſſential oils of lavender and of turpentine: both of them ſpeedily dilate the caoutchouc, and are of no great price. The diſagreeable ſmell of the oil of turpentine becomes, perhaps, in proceſs of time, leſs diſagreeable than that of lavender. This laſt is dearer : but the difference is not ſo great as it appears at firſt; for we may make ſome advantage of the oil of lavender that is employed by the following operation : Upon plunging into alcohol the elaſtic tube prepared with the oil of lavender, the alcohol charges itſelf with the oil, and forms a very good lavender water; the ſame as would be made by an immediate mixture of oil of lavender with ſpirit of wine. Immerſion in this liquor alſo ſerves to haſten the drying of the caoutchouc inſtruments thus made by means of eſſential oils. I have made tubes with the oils of turpentine and of lavender; both are much ſlower in evaporating than ether. The oil of turpentine particularly appeared to me always to have a kind of ſtickineſs, and I know not as yet that we have any means whereby to get ſpeedily rid of its ſmell.

" Nevertheleſs there is a ſolvent which has not that inconvenience; it is cheaper, and may eaſily be procured by every one: this ſolvent is *water*. I conceive it will appear ſtrange to mention water as a ſolvent of elaſtic gum, that liquid having been always ſuppoſed to have no action upon it. I myſelf reſiſted the idea; but reflecting that ether, by being ſaturated with water, is the better enabled to act on caoutchouc, and that this gum when plunged into boiling water becomes more tranſparent at the edges, I preſumed that this effect was not due ſimply to the dilatation of its volume by the heat. I thought that, at that temperature, ſome action might take place, and that a long-continued ebullition might produce more ſenſible effects. I was not diſappointed in my expectations, and one of thoſe tubes was prepared without any other ſolvent than water and heat. I proceeded in the ſame manner as with ether: the elaſtic gum dilates but very little in boiling water; it becomes whitiſh, but recovers its colour again by drying it in the air and light. It is ſufficiently prepared for uſe when it has been a quarter of an hour in boiling water: by this time its edges are ſometimes tranſparent. It is to be turned ſpirally round the mould, in the manner we deſcribed before, and replunged frequently into the boiling water during the time that is employed in forming the tube, to the end that the edges may be diſpoſed to unite together. When the whole is bound with packthread, it is to be kept ſome hours in boiling water; after which it is to be dried, ſtill keeping on the binding.

" If we wiſh to be more certain that the connection is perfect, the ſpiral may be doubled; but we muſt always avoid placing the exterior ſurfaces of the ſlips one upon the other, as thoſe ſurfaces are the parts which moſt reſiſt the action of ſolvents. This precaution is leſs neceſſary when ether is employed, on account of its great action upon the caoutchouc.

" It might be feared that the action of water upon caoutchouc would deprive us of the advantages which might otherwiſe be expected; but theſe fears will be removed, if we conſider that the affinities differ according to the temperatures; that it is only at a very high temperature that water exerciſes any ſenſible action upon caoutchouc. I can affirm, that at 120° of Reaumur's thermometer (302° of Fahrenheit) this affinity is not ſuch as that the water can give a liquid form to caoutchouc; and it does not appear that we have any thing to fear in practice from a combination between theſe two bodies, which, though it really is a true ſolution, does not take place in any ſenſible degree but at a high temperature. It is therefore at preſent eaſy to make of caoutchouc whatever inſtruments it may be advantageous to have of a flexible, ſupple, and elaſtic ſubſtance, which is impermeable to water at the temperature of our atmoſphere, and reſiſts the action of acids as well as that of moſt other ſolvents. As to the durability of theſe inſtruments, few ſubſtances promiſe more than this, becauſe it may be ſoldered afreſh in a damaged part. Any woven ſubſtance may be covered with it; it is only required that the ſubſtance ſhould be of a nature not to be acted upon during the preparation, either by ether or by boiling water; for theſe two agents are thoſe which appear to me to merit the preference. Artiſts will frequently find an advantage in employing ether, as it requires leſs time; ſo that a perſon may make, in a ſingle day, any tube he may have occaſion for. The expence of ether is very little, ſince it is needful only to diſpoſe the caoutchouc to adhere; and being brought into that ſtate, the caoutchouc may be kept in a veſſel perfectly well cloſed. It would alſo diminiſh the expence of the ether if, inſtead of waſhing it with a large quantity of water, there ſhould be added to it only as much water as it can take up."

CAP and BUTTON, are two ſmall iſlands, or rather rocks, lying in longitude 105° 48′ 30″ eaſt; and in latitude, the former 5° 58′ 30″, the latter 5° 49′ ſouth. They were viſited by ſome of the perſons attending Lord Macartney on his embaſſy to China; and are thus deſcribed by Sir George Staunton.

" At a little diſtance they might be miſtaken for the remains of old caſtles, mouldering into heaps of ruins, with tall trees already growing upon the tops; but at a nearer view, they betrayed evident marks of a volcanic origin. Exploſions from ſubterraneous fires, produce, for the moſt part, hills of a regular ſhape, and terminating in truncated cones; but when from a ſubaqueous volcano eruptions are thrown up above the ſurface of the ſea, the materials, falling back into the water, are more irregularly diſperſed, and generally leave the ſides of the new creation naked and miſhapen, as in the inſtance of AMSTERDAM, and of thoſe ſmaller ſpots called, from ſome reſemblance in ſhape, the Cap and Button.

" In the Cap were found two caverns, running horizontally into the ſide of the rock; and in theſe were a number of thoſe birds neſts ſo much prized by the Chineſe epicures. They ſeemed to be compoſed of fine filaments cemented together by a tranſparent viſcous matter, not unlike what is left by the foam of the ſea upon ſtones alternately covered by the tide, or thoſe gelatinous animal ſubſtances found floating on every coaſt. The neſts adhere to each other, and to the ſides of the cavern, moſtly in rows, without any break or interruption. The birds that build theſe neſts are ſmall grey ſwallows, with bellies of a dirty white. They were flying about in conſiderable numbers; but they were ſo ſmall, and their flight ſo quick, that they eſcaped the ſhot fired at them. The ſame neſts are ſaid alſo to be found in deep caverns, at the foot of the higheſt mountains in the middle of Java, and at a diſtance from the ſea, from which the birds, it is thought, derive no materials, either for their food or the conſtruction of their neſts; as it does not appear probable they ſhould fly, in ſearch of either, over the intermediate mountains, which are very high, or againſt the boiſterous winds prevailing thereabouts. They feed on inſects, which they find hovering over ſtagnated pools between the mountains, and for catching which their wide opening beaks are particularly adapted. They prepare their neſts from the beſt remnants of their food. Their greateſt enemy is the kite, who often intercepts them in their paſſage to and from the caverns, which are generally ſurrounded with rocks of grey limeſtone or white marble. The neſts are placed in horizontal rows at different depths, from 50 to 500 feet. The colour and value of the neſts depend on the quantity and quality of the inſects caught, and perhaps alſo on the ſituation where they are built. Their value is chiefly determined by the uniform fineneſs and delicacy of their texture; thoſe that are white and tranſparent being moſt eſteemed, and fetching often in China their weight in ſilver.

Theſe neſts are a conſiderable object of traffic among the Javaneſe, and many are employed in it from their infancy. The birds having ſpent near two months in preparing their neſts, lay each two eggs, which are hatched in about fifteen days. When the young birds become fledged, it is thought time to ſeize upon their neſts, which is done regularly thrice a-year, and is effected by means of ladders of bamboo and reeds, by which the people deſcend into the cavern; but when it is very deep, rope ladders are preferred. This operation is attended with much danger; and ſeveral break their necks in the attempt. The inhabitants of the mountains generally employed in it begin always by ſacrificing a buffalo; which cuſtom is conſtantly obſerved by the Javaneſe on the eve of every extraordinary enterpriſe. They alſo pronounce ſome prayers, anoint themſelves with ſweet-ſcented oil, and ſmoke the entrance of the cavern with gum-benjamin. Near ſome of thoſe caverns a tutelar goddeſs is worſhipped, whoſe prieſt burns incenſe, and lays his protecting hands on every perſon preparing to deſcend into the cavern. A flambeau is carefully prepared at the ſame time, with a gum which exudes from a tree growing in the vicinity, and is not eaſily extinguiſhed by fixed air or ſubterraneous vapours. The ſwallow which builds thoſe neſts is deſcribed as not having its tail feathers marked with white ſpots, which is a character attributed to it by Linnæus; and it is poſſible that there are two ſpecies or varieties of the ſwallow, whoſe neſts are alike valuable." See *Birds-Neſts*, Encycl.

CAPE of Good Hope. See *Good Hope*, both in *Encycl.* and this *Supplement*.

CAPITAL of a Bastion, is an imaginary line dividing any work into two equal and ſimilar parts; or a line drawn from the angle of the polygon to the point of the baſtion, or from the point of the baſtion to the middle of the gorge.

CAPRA, or the She-goat, a name given to the ſtar Capella, on the left ſhoulder of Auriga, and ſometimes to the conſtellation Capricorn. Some again repreſent Capra as a conſtellation in the northern hemiſphere, conſiſting of three ſtars, compriſed between the 45th and 55th degree of latitude.—The poets fable her to be Amalthea's goat, which ſuckled Jupiter in his infancy.

CAPUT Draconis, or *Dragon's Head*, a name given by ſome to a fixed ſtar of the firſt magnitude, in the head of the conſtellation Draco.

CARP. See Cyprinus, both in the *Encycl.* and in this *Supplement*.

CARPENTRY,

1 efinition. THE art of framing timber for the purpoſes of architecture, machinery, and, in general, for all conſiderable ſtructures.

It is not intended in this article to give a full account of carpentry as a *mechanical* art, or to deſcribe the various ways of executing its different works, ſuited to the variety of materials employed, the proceſſes which muſt be followed for faſhioning and framing them for our purpoſes, and the tools which muſt be uſed, and the manner in which they muſt be handled: This would be an occupation for volumes; and though of great importance, muſt be entirely omitted here. Our only aim at preſent will be to deduce, from the principles and laws of mechanics, and the knowledge which experience and judicious inferences from it have given us concerning the ſtrength of timber, in relation to the ſtrain laid on it, ſuch maxims of conſtruction as will unite economy with ſtrength and efficacy.

This object is to be attained by a knowledge, 1ſt, of the ſtrength of our materials, and of the abſolute ſtrain that is to be laid on them; 2dly, of the modifications of this ſtrain, by the place and direction in which it is exerted, and the changes that can be made by a proper diſpoſition of the parts of our ſtructure; and, 3dly, having diſpoſed every piece in ſuch a manner as to derive the utmoſt advantage from its relative ſtrength, we muſt know how to form the joints and other connections in ſuch a manner as to ſecure the advantages derived from this diſpoſition.

2
n impor-
nt branch
mechani-
l ſcience

This is, evidently, a branch of mechanical ſcience, which makes carpentry a *liberal* art, conſtitutes part of the learning of the Engineer, and diſtinguiſhes him from the workman. Its importance in all times and ſtates of civil ſociety is manifeſt and great. In the preſent condition of theſe kingdoms, raiſed, by the active ingenuity and energy of our countrymen, to a pitch of proſperity and influence unequalled in the hiſtory of the world, a condition which conſiſts chiefly in the ſuperiority of our manufactures, attained by prodigious multiplication of engines of every deſcription, and for every ſpecies of labour, the Science (ſo to term it) of carpentry is of immenſe conſequence. We regret therefore exceedingly, that none of our celebrated artiſts have done honour to themſelves and their country, by digeſting into a body of conſecutive doctrines the reſults of their great experience, ſo as to form a ſyſtem from which their pupils might derive the firſt principles of their education. The many volumes called Complete Instructors, Manuals, Jewels, &c. take a much humbler flight, and content themſelves with inſtructing the mere workman, or ſometimes give the maſter-builder a few approved forms of roofs and other framings, with the rules for drawing them on paper; and from thence forming the working draughts which muſt guide the ſaw and the chiſſel of the workman. Hardly any of them offer any thing that can be called a principle, applicable to many particular caſes, with the rules for this adaptation. We are indebted for the greateſt part of our knowledge of this ſubject to the labours of literary men, chiefly foreigners, who have publiſhed in the memoirs of the learned academies diſſertations on different parts of what may be termed the *ſcience of carpentry*. It is ſingular that the members of the Royal Society of London, and even of that eſtabliſhed and ſupported by the patriotiſm of theſe days for the encouragement of the arts, have contributed ſo little to the public inſtruction in this reſpect. We obſerve of late ſome beginnings of this kind, ſuch as the laſt part of Nicholſon's

3
Principally indebted to foreigners for a knowledge of this ſubject.

Nicholſon's Carpenters and Joiners Assistant, publiſhed by J. Taylor, Holborn, 1797. And it is with pleaſure that we can ſay, that we were told by the editor, that this work was prompted in a great meaſure by what has been delivered in the *Encyclopædia Britannica* in the articles Roof and *Strength of Materials*. It abounds more in important and new obſervations than any book of the kind that we are acquainted with. We again call on ſuch as have given a ſcientific attention to this ſubject, and pray that they would render a meritorious ſervice to their country by imparting the reſult of their reſearches. The very limited nature of this work does not allow us to treat the ſubject in detail; and we muſt confine our obſervations to the fundamental and leading propoſitions.

4
Theory, founded on what.

The theory (ſo to term it) of carpentry is founded on two diſtinct portions of mechanical ſcience, namely, a knowledge of the ſtrains to which framings of timber are expoſed, and a knowledge of their *relative* ſtrength.

We ſhall therefore attempt to bring into one point of view the propoſitions of mechanical ſcience that are more immediately applicable to the art of carpentry, and are to be found in various articles of our work, particularly Roof and *Strength of Materials*. From theſe propoſitions we hope to deduce ſuch principles as ſhall enable an attentive reader to comprehend diſtinctly what is to be aimed at in framing timber, and how to attain this object with certainty: and we ſhall illuſtrate and confirm our principles by examples of pieces of carpentry which are acknowledged to be excellent in their kind.

5
Compoſition and reſolution of forces

The moſt important propoſition of general mechanics to the carpenter is that which exhibits the compoſition and reſolution of forces; and we beg our practical readers to endeavour to form very diſtinct conceptions of it, and to make it very familiar to their mind. When accommodated to their chief purpoſes, it may be thus expreſſed:

Plate VIII.

1. If a body, or any part of a body, be at once preſſed in the two directions AB, AC (fig. 1), and if the intenſity or force of thoſe preſſures be in the proportion of theſe two lines, the body is affected in the ſame manner as if it were preſſed by a ſingle force acting in the direction AD, which is the diagonal of the parallelogram ABDC formed by the two lines, and whoſe intenſity has the ſame proportion to the intenſity of each of the other two that AD has to AB or AC.

Such of our readers as have *ſtudied* the laws of motion, know that this is fully demonſtrated. We refer them to the article Mechanics, n° 5, &c. where it is treated at ſome length. Such as wiſh for a very accurate view of this propoſition, will do well to read the demonſtration given by D. Bernoulli, in the firſt volume of the *Comment. Petropol.* and the improvement of this demonſtration by D'Alembert in his *Opuſcles*, and in the *Comment. Taurinenſ.* The practitioner in carpentry will get more uſeful confidence in the doctrine, if he will ſhut his book, and verify the theoretical demonſtrations by actual experiments. They are remarkably eaſy and convincing. Therefore it is our requeſt that the artiſt, who is not ſo habitually acquainted with the ſubject, do not proceed further till he has made it quite familiar to his thoughts. Nothing is ſo conducive to this as the actual experiment; and ſince this only requires the trifling expence of two ſmall pulleys and a few yards of whipcord, we hope that none of our practical readers will omit it: They will thank us for this injunction.

6
Illuſtrated by experiment.

2. Let the threads A *d*, AF *b*, and AE *c* (fig. 2.), have the weights *d*, *b*, and *c*, appended to them, and let two of the threads be laid over the pulleys F and E. By this apparatus the knot A will be drawn in the directions AB, AC, and AK. If the ſum of the weights *b* and *c* be greater than the ſingle weight *d*, the aſſemblage will of itſelf ſettle in a certain determined form; if you pull the knot A out of its place, it will always return to it again, and will reſt in no other poſition. For example, if the three weights are equal, the threads will always make equal angles, of 120 degrees each, round the knot. If one of the weights be three pounds, another four, and the third five, the angle oppoſite to the thread ſtretched by five pounds will always be ſquare, &c. When the knot A is thus in equilibrio, we muſt infer, that the action of the weight *d*, in the direction A *d*, is in direct oppoſition to the combined action of *b*, in the direction AB, and of *c*, in the direction AC. Therefore, if we produce *d* A to any point D, and take AD to repreſent the magnitude of the force, or preſſure exerted by the weight *d*, the preſſures exerted on A by the weights *b* and *c*, in the directions AB, AC, are in fact equivalent to a preſſure acting in the direction AD, whoſe intenſity we have repreſented by AD. If we now meaſure off by a ſcale on AF and AE the lines AB and AC, having the ſame proportions to AD that the weights *b* and *c* have to the weight *d*, and if we draw DB and DC, we ſhall find DC to be equal and parallel to AB, and DB equal and parallel to AC; ſo that AD is the diagonal of a parallelogram ABDC. We ſhall find this always to be the caſe, whatever are the weights made uſe of; only we muſt take care that the weight which we cauſe to act without the intervention of a pulley be leſs than the ſum of the other two: if any one of the weights exceeds the ſum of the other two, it will prevail, and drag them along with it.

Now, ſince we know that the weight *d* would juſt balance an equal weight *g*, pulling directly upwards by the intervention of the pulley G; and ſince we ſee that it juſt balances the weights *b* and *c*, acting in the directions AB, AC, we muſt infer, that the knot A is affected in the ſame manner by thoſe two weights, or by the ſingle weight *g*; and therefore that *two preſſures, acting in the directions, and with the intenſities,* AB, AC, *are equivalent to a ſingle preſſure having the direction and proportion of* AD. In like manner, the preſſures AB, AK, are equivalent to AH, which is equal and oppoſite to AC. Alſo AK and AC are equivalent to AI, which is equal and oppoſite to AB.

7
Conſidered more particularly.

We ſhall conſider this combination of preſſures a little more particularly.

Suppoſe an upright beam BA (fig. 3.) puſhed in the direction of its length by a load B, and abutting on the ends of two beams AC, AD, which are firmly reſiſted at their extreme points C and D, which reſt on two blocks, but are nowiſe joined to them: theſe two beams can reſiſt no way but in the directions CA, DA; and therefore the preſſures which they ſuſtain from the beam BA are in the directions AC, AD. We wiſh to know how much each ſuſtains? Produce BA to E, taking

taking AE from a ſcale of equal parts, to repreſent the number of tons or pounds by which BA is preſſed. Draw EF and EG parallel to AD and AC; then AF, meaſured on the ſame ſcale, will give us the number of pounds by which AC is ſtrained or cruſhed, and AG will give the ſtrain on AD.

It deſerves particular remark here, that the length of AC or AD has no influence on the ſtrain, ariſing from the thruſt of BA, while the directions remain the ſame. The effects, however, of this ſtrain are modified by the length of the piece on which it is exerted. This ſtrain compreſſes the beam, and will therefore compreſs a beam of double length twice as much. This may change the form of the aſſemblage. If AC, for example, be very much ſhorter than AD, it will be much leſs compreſſed: The line CA will turn about the centre C, while DA will hardly change its poſition; and the angle CAD will grow more open, the point A ſinking down. The artiſt will find it of great conſequence to pay a very minute attention to this circumſtance, and to be able to ſee clearly the change of ſhape which neceſſarily reſults from theſe mutual ſtrains. He will ſee in this the cauſe of failure in many very great works.—By thus changing ſhape, ſtrains are often produced in places where there were none before, and frequently of the very worſt kind, tending to break the beams acroſs.

The dotted lines of this figure ſhew another poſition of the beam AD′. This makes a prodigious change, not only in the ſtrain on AD′, but alſo in that on AC. Both of them are much increaſed; AG is almoſt doubled, and AF is four times greater than before. This addition was made to the figure, to ſhew what enormous ſtrains may be produced by a very moderate force AE, when it is exerted on a very obtuſe angle.

The 4th and 5th figures will aſſiſt the moſt uninſtructed reader in conceiving how the very ſame ſtrains AF, AG, are laid on theſe beams, by a weight ſimply hanging from a billet reſting on A, preſſing hard on AD, and alſo leaning a little on AC; or by an upright piece AE, joggled on the two beams AC, AD, and performing the office of an ordinary king-poſt. The reader will thus learn to call off his attention from the means by which the ſtrains are produced, and learn to conſider them abſtractedly, merely as ſtrains, in whatever ſituation he finds them, and from whatever cauſe they ariſe.

We preſume that every reader will perceive, that the proportions of theſe ſtrains will be preciſely the ſame if every thing be inverted, and each beam be drawn or pulled in the oppoſite direction. In the ſame way that we have ſubſtituted a rope and weight in fig. 4. or a king-poſt in fig. 5. for the loaded beam BA of fig. 3. we might have ſubſtituted the framing of fig. 6. which is a very uſual practice. In this framing, the batten DA is ſtretched by a force AG, and the piece AC is compreſſed by a force AF. It is evident that we may employ a rope, or an iron rod hooked on at D, in place of the batten DA, and the ſtrains will be the ſame as before.

This ſeemingly ſimple matter is ſtill full of inſtruction; and we hope that the well-informed reader will pardon us, though we dwell a little longer on it for the ſake of the young artiſt.

By changing the form of this framing, as in fig. 7. we produce the ſame ſtrains as in the diſpoſition repreſented by the dotted lines in fig. 3. The ſtrains on both the battens AD, AC, are now greatly increaſed.

The ſame conſequences reſult from an improper change of the poſition of AC. If it is placed as in fig. 8. the ſtrains on both are vaſtly increaſed. In ſhort, the rule is general; that the more open we make the angle againſt which the puſh is exerted, the greater are the ſtrains which are brought on the ſtruts or ties which form the ſides of the angle.

The reader may not readily conceive the piece AC of fig. 8. as ſuſtaining a compreſſion; for the weight B appears to hang from AC as much as from AD. But his doubts will be removed by conſidering whether he could employ a rope in place of AC. He cannot: But AD may be exchanged for a rope. AC is therefore a ſtrut and not a tie.

In fig. 9. AD is again a ſtrut, butting on the block D, and AC is a tie: and the batten AC may be replaced by a rope. While AD is compreſſed by the force AG, AC is ſtretched by the force AF.

If we give AC the poſition repreſented by the dotted lines, the compreſſion of AD is now AG′, and the force ſtretching AC′ is now AF′; both much greater than they were before. This diſpoſition is analogous to fig. 8. and to the dotted lines in fig. 3. Nor will the young artiſt have any doubts of AC′ being on the ſtretch, if he conſider whether AD can be replaced by a rope. It cannot, but AC′ may; and it is therefore not compreſſed, but ſtretched.

In fig. 10. all the three pieces, AC, AD, and AB, are ties on the ſtretch. This is the complete inverſion of fig. 3.; and the dotted poſition of AC induces the ſame changes in the forces AF′, AG′, as in fig. 3.

Thus have we gone over all the varieties which can happen in the bearings of three pieces on one point. All calculations about the ſtrength of carpentry are reduced to this caſe: for when more ties or braces meet in a point (a thing that rarely happens), we reduce them to three, by ſubſtituting for any two the force which reſults from their combination, and then combining this with another; and ſo on.

The young artiſt muſt be particularly careful not to miſtake the kind of ſtrain that is exerted on any piece of the framing, and ſuppoſe a piece to be a brace which is really a tie. It is very eaſy to avoid all miſtakes in this matter by the following rule, which has no exception.

8
Rule for diſtinguiſhing the caſes of compreſſion and extenſion.

Take notice of the direction in which the piece acts from which the ſtrain proceeds. Draw a line in that direction *from* the point on which the ſtrain is exerted; and let its length (meaſured on ſome ſcale of equal parts) expreſs the magnitude of this action in pounds, hundreds, or tons. From its *remote* extremity draw lines parallel to the pieces on which the ſtrain is exerted. The line parallel to one piece will neceſſarily cut the other, or its direction produced: If it cut the piece itſelf, that piece is compreſſed by the ſtrain, and it is performing the office of a ſtrut or brace: if it cut its direction produced, the piece is ſtretched, and it is a tie. In ſhort, the ſtrains on the pieces AC, AD, are to be eſtimated in the direction of the points F and G *from* the ſtrained point A. Thus, in fig. 3. the upright piece BA, loaded with the weight B, preſſes the point A in the direction AE: ſo does the rope AB in the other figures, or the batten AB in fig. 5.

In general, if the ſtraining piece is within the angle formed by the pieces which are ſtrained, the ſtrains which they ſuſtain are of the oppoſite kind to that which it exerts. If it be puſhing, they are drawing; but if it be within the angle formed by their directions produced, the ſtrains which they ſuſtain are of the ſame kind. All the three are either drawing or preſſing. If the ſtraining piece lie within the angle formed by one piece and the produced direction of the other, its own ſtrain, whether compreſſion or extenſion, is of the ſame kind with that of the moſt remote of the other two, and oppoſite to that of the neareſt. Thus, in fig. 9. where AB is drawing, the remote piece AC is alſo drawing, while AD is puſhing or reſiſting compreſſion.

In all that has been ſaid on this ſubject, we have not ſpoken of any joints. In the calculations with which we are occupied at preſent, the reſiſtance of joints has no ſhare; and we muſt not ſuppoſe that they exert any force which tends to prevent the angles from changing. The joints are ſuppoſed perfectly flexible, or to be like compaſs joints; the pin of which only keeps the pieces together when one or more of the pieces draws or pulls. The carpenter muſt always ſuppoſe them all compaſs joints when he calculates the thruſts and draughts of the different pieces of his frames. The ſtrains on joints, and their power to produce or balance them, are of a different kind, and require a very different examination.

9
General expreſſion of the magnitude of the ſtrain.

Seeing that the angles which the pieces make with each other are of ſuch importance to the magnitude and the proportion of the excited ſtrains, it is proper to find out ſome way of readily and compendiouſly conceiving and expreſſing this analogy.

In general, the ſtrain on any piece is proportional to the ſtraining force. This is evident.

Secondly, the ſtrain on any piece AC is proportional to the ſine of the angle, which the ſtraining force makes with the other piece directly, and to the ſine of the angle which the pieces make with each other inverſely.

For it is plain, that the three preſſures AE, AF, and AG, which are exerted at the point A, are in the proportion of the lines AE, AF, and FE (becauſe FE is equal to AG). But becauſe the ſides of a triangle are proportional to the ſines of the oppoſite angles, the ſtrains are proportional to the ſines of the angles AFE, AEF, and FAE. But the ſine of AFE is the ſame with the ſine of the angle CAD, which the two pieces AC and AD make with each other; and the ſine of AEF is the ſame with the ſine of EAD, which the ſtraining piece BA makes with the piece AC. Therefore we have this analogy, Sin. CAD : Sin. EAD = AE : AF, and $AF = AE \times \frac{\text{Sin. EAD}}{\text{Sin. CAD}}$.—Now the ſines of angles are moſt conveniently conceived as decimal fractions of the radius, which is conſidered as unity. Thus, *Sin.* 30° is the ſame thing with 0,5, or $\frac{1}{2}$; and ſo of others. Therefore, to have the ſtrain on AC, ariſing from any load AE acting in the direction AE, multiply AE by the ſine of EAD, and divide the product by the ſine of CAD.

This rule ſhews how great the ſtrains muſt be when the angle CAD becomes very open, approaching to 180 degrees. But when the angle CAD becomes very ſmall, its ſine (which is our diviſor) is alſo very ſmall; and we ſhould expect a very great quotient in this caſe alſo. But we muſt obſerve, that in this caſe the ſine of EAD is alſo very ſmall; and this is our multiplier. In ſuch a caſe, the quotient cannot exceed unity.

But it is unneceſſary to conſider the calculation by the tables of ſines more particularly. The angles are ſeldom known any otherwiſe but by drawing the figure of the frame of carpentry. In this caſe, we can always obtain the meaſures of the ſtrains from the ſame ſcale, with equal accuracy, by drawing the parallelogram AFCG.

10
Strains propagated to the points of ſupport.

Hitherto we have conſidered the ſtrains excited at A only as they affect the pieces on which they are exerted. But the pieces, in order to ſuſtain, or be ſubject to, any ſtrain, muſt be ſupported at their ends C and D; and we may conſider them as mere intermediums, by which theſe ſtrains are made to act on thoſe points of ſupport: Therefore AF and AG are alſo meaſures of the forces which preſs or pull at C and D. Thus we learn the ſupports which muſt be found for theſe points. Theſe may be infinitely various. We ſhall attend only to ſuch as ſomehow depend on the framing itſelf.

11
Action of a ſtraining beam.

Such a ſtructure as fig. 11. very frequently occurs, where a beam BA is ſtrongly preſſed to the end of another beam AD, which is prevented from yielding, both becauſe it lies on another beam HD, and becauſe its end D is hindered from ſliding backwards. It is indifferent from what this preſſure ariſes: we have repreſented it as owing to a weight hung on at B, while B is withheld from yielding by a rod or rope hooked to the wall. The beam AD may be ſuppoſed at full liberty to exert all its preſſure on D, as if it were ſupported on rollers lodged in the beam HD; but the loaded beam BA preſſes both on the beam AD and on HD. We wiſh only to know what ſtrain is borne by AD?

All bodies act on each other in the direction perpendicular to their touching ſurfaces; therefore the ſupport given by HD is in a direction perpendicular to it. We may therefore ſupply its place at A by a beam AC, perpendicular to HD, and firmly ſupported at C. In this caſe, therefore, we may take AE, as before, to repreſent the preſſure exerted by the loaded beam, and draw EG perpendicular to AD, and EF parallel to it, meeting the perpendicular AC in F. Then AG is the ſtrain compreſſing AD, and AF is the preſſure on the beam HD.

12
The form of the abutting joint of no great importance.

It may be thought, that ſince we aſſume as a principle that the mutual preſſures of ſolid bodies are exerted perpendicular to their touching ſurfaces, this balance of preſſures, in framings of timbers, depends on the directions of their butting joints: but it does not, as will readily appear by conſidering the preſent caſe. Let the joint or abutment of the two pieces BA, AD be mitred, in the uſual manner, in the direction *f* A *f'*. Therefore, if A *e* be drawn perdendicular to A *f*, it will be the direction of the actual preſſure exerted by the loaded beam BA on the beam AD. But the reaction of AD, in the oppoſite direction A *t*, will not balance the preſſure of BA; becauſe it is not in the direction preciſely oppoſite. BA will therefore ſlide along the joint, and preſs on the beam HD. AE repreſents the load on the mitre joint A. Draw E *e* perpendicular to A*e*, and E *f* parallel to it. The preſſure AE will be balanced by the reactions *e* A and *f* A: or, the preſſure AE produces the preſſures A *e* and A *f*; of of which Af muſt be reſiſted by the beam HD, and Ae by the beam AD. The preſſure Af not being perpendicular to HD, cannot be fully reſiſted by it; becauſe (by our aſſumed principle) it reacts only in a direction perpendicular to its ſurface. Therefore draw fp, fi parallel to HD, and perpendicular to it. The preſſure Af will be reſiſted by HD with the force pA; but there is required another force iA, to prevent the beam BA from ſlipping outwards. This muſt be furniſhed by the reaction of the beam DA.—In like manner, the other force Ae cannot be fully reſiſted by the beam AD, or rather by the prop D, acting by the intervention of the beam; for the action of that prop is exerted through the beam in the direction DA. The beam AD, therefore, is preſſed to the beam HD by the force Ae, as well as by Af. To find what this preſſure on HD is, draw eg perpendicular to HD, and eo parallel to it, cutting EG in r. The forces gA and oA will reſiſt, and balance Ae.

Thus we ſee, that the two forces Ae and Af, which are equivalent to AE, are equivalent alſo to Ap, Ai, Ao, and Ag. But becauſe Af and eE are equal and parallel, and Er and fi are alſo parallel, as alſo er and fp, it is evident, that if is equal to rE, or to oF, and iA is equal to re, or to Gg. Therefore the four forces Ag, Ao, Ap, Ai, are equal to AG and AF. Therefore AG is the compreſſion of the beam AD, or the force preſſing it on D, and AF is the force preſſing it on the beam HD. The proportion of theſe preſſures, therefore, is not affected by the form of the joint.

This remark is important; for many carpenters think the form and direction of the butting joint of great importance; and even the theoriſt, by not proſecuting the general principle through *all* its conſequences, may be led into an error. The form of the joint is of no importance, in as far as it affects the ſtrains in the direction of the beams; but it is often of great conſequence, in reſpect to its own firmneſs, and the effect it may have in bruiſing the piece on which it acts, or being crippled by it.

13 rigin cf ne ſtrain n a tie- eam.

The ſame compreſſion of AB, and the ſame thruſt on the point D by the intervention of AD, will obtain, in whatever way the original preſſure on the end A is produced. Thus ſuppoſing that a cord is made faſt at A, and pulled in the direction AE, and with the ſame force, the beam AD will be equally compreſſed, and the prop D muſt react with the ſame force.

But it often happens that the obliquity of the preſſure on AD, inſtead of compreſſing it, ſtretches it; and we deſire to know what tenſion it ſuſtains? Of this we have a familiar example in a common roof. Let the two rafters AC, AD (fig. 12.), preſs on the tie-beam DC. We may ſuppoſe the whole weight to preſs vertically on the ridge A, as if a weight B were hung out there. We may repreſent this weight by the portion Ab of the vertical or plumb line, intercepted between the ridge and the beam. Then drawing bf and bg parallel to AD and AC, Ag and Af will repreſent the preſſures on AC and AD. Produce AC till CH be equal to Af. The point C is forced out in this direction, and with a force repreſented by this line. As this force is not perpendicularly acroſs the beam, it evidently ſtretches it; and this extending force muſt be withſtood by an equal force pulling it in the oppoſite direction. This muſt ariſe from a ſimilar oblique thruſt of the oppoſite rafter on the other end D. We concern ourſelves only with this extenſion at preſent; but we ſee that the coheſion of the beam does nothing but ſupply the balance to the extending forces. It muſt ſtill be ſupported externally, that it *may reſiſt*, and, by reſiſting obliquely, be ſtretched. The points C and D are ſupported on the walls, which they preſs in the directions CK and DO, parallel to Ab. If we draw HK parallel to DC, and HI parallel to CK (that is, to Ab), meeting DC produced in I, it follows from the compoſition of forces, that the point C would be ſupported by the two forces KC and IC. In like manner, making DN = Ag, and completing the parallelogram DMNO, the point D would be ſupported by the forces OD and MD. If we draw go and fk parallel to DC, it is plain that they are equal to NO and CK, while Ao and Ak are equal to DO and CK, and Ab is equal to the ſum of DO and CK (becauſe it is equal to $Ao + Ak$). The weight of the roof is equal to its vertical preſſure on the walls.

Thus we ſee, that while a preſſure on A, in the direction Ab, produces the ſtrains Af and Ag, on the pieces AC and AD, it alſo excites a ſtrain CI or DM in the piece DC. And this completes the mechaniſm of a frame; for all derive their efficacy from the triangles of which they are compoſed, as will appear more clearly as we proceed.

14 External action of a frame.

But there is more to be learned from this. The conſideration of the ſtrains on the two pieces AD and AC, by the action of a force at A, only ſhewed them as the means of propagating the ſame ſtrains in their own direction to the points of ſupport. But, by adding the ſtrains exerted in DC, we ſee that the frame becomes an intermedium, by which exertions may be made on other bodies, in certain directions and proportions; ſo that this frame may become part of a more complicated one, and, as it were, an element of its conſtitution. It is worth while to aſcertain the proportion of the preſſures CK and DO, which are thus exerted on the walls. The ſimilarity of triangles gives the following analogies:

$$\mathrm{DO} : \mathrm{DM} = \mathrm{A}b : b\mathrm{D}$$
$$\mathrm{CI}, \text{ or } \mathrm{DM} : \mathrm{CK} = \mathrm{C}b : \mathrm{A}b$$
$$\text{Therefore } \mathrm{DO} : \mathrm{CK} = \mathrm{C}b : b\mathrm{D}.$$

Or, *the preſſures on the points* C *and* D, *in the direction of the ſtraining force* A b, *are reciprocally proportional to the portions of* DC *intercepted by* A b.

Alſo, ſince Ab is = DO + CK, we have

$$\mathrm{A}b : \mathrm{CK} = \mathrm{C}b + b\mathrm{D} \text{ (or CD)} : b\mathrm{D}, \text{ and}$$
$$\mathrm{A}b : \mathrm{DO} = \mathrm{CD} : b\mathrm{C}.$$

In general, any two of the three parallel forces Ab, DO, CK, are to each other in the reciprocal proportion of the parts of CD, intercepted between their directions and the direction of the third.

And this explains a ſtill more important office of the frame ADC. If one of the points, ſuch as D, be ſupported, an external power acting at A, in the direction Ab, and with an intenſity which may be meaſured by Ab, may be ſet in equilibrio, with another acting at C, in the direction CL, oppoſite to CK or Ab, and with an intenſity repreſented by CK: for ſince the preſſure CH is partly withſtood by the force IC, or the firmneſs of the beam DC ſupported at D, the force KC will complete the balance. When we do not attend to the ſupport at D, we conceive the force Ab to be balanced by by KC, or KC to be balanced by A *b*. And, in like manner, we may neglect the ſupport or force acting at A, and conſider the force DO as balanced by CK.

15
It becomes a lever.

Thus our frame becomes a lever, and we are able to trace the interior mechanical procedure which gives it its efficacy: it is by the intervention of the forces of coheſion, which connect the points to which the external forces are applied with the ſupported point or fulcrum, and with each other.

Theſe ſtrains or preſſures A *b*, DO, and CK, not being in the directions of the beams, may be called *tranſverſe*. We ſee that by their means a frame of carpentry may be conſidered as a ſolid body: but the example which brought this to our view is too limited for explaining the efficacy which may be given to ſuch conſtructions. We ſhall therefore give a general propoſition, which will more diſtinctly explain the procedure of nature, and enable us to trace the ſtrains as they are propagated through all the parts of the moſt complicated framing, finally producing the exertion of its moſt diſtant points.

16
General propoſition.

We preſume that the reader is now pretty well habituated to the conception of the ſtrains as they are propagated along the lines joining the points of a frame, and we ſhall therefore employ a very ſimple figure.

Let the ſtrong lines ACBD (fig. 13.) repreſent a frame of carpentry. Suppoſe that it is pulled at the point A by a force acting in the direction AE, but that it reſts on a fixed point C, and that the other extreme point B is held back by a power which reſiſts in the direction BF: It is required to determine the proportion of the ſtrains excited in its different parts, the proportion of the external preſſures at A and B, and the preſſure which is produced on the obſtacle or fulcrum C?

It is evident that each of the external forces at A and B tend one way, or to one ſide of the frame, and that each would cauſe it to turn round C if the other did not prevent it; and that if, notwithſtanding their action, it is turned neither way, the forces in actual exertion are in equilibrio by the intervention of the frame. It is no leſs evident that theſe forces concur in preſſing the frame on the prop C. Therefore, if the piece CD were away, and if the joints C and D be perfectly flexible, the pieces CA, CB would be turned round the prop C, and the pieces AD, DB would alſo turn with them, and the whole frame change its form. This ſhews, by the way, and we deſire it to be carefully kept in mind, that the firmneſs or ſtiffneſs of framing depends entirely on the triangles bounded by beams which are contained in it. An open quadrilateral may always change its ſhape, the ſides revolving round the angles. A quadrilateral may have an infinity of forms, without any change of its ſides, by merely puſhing two oppoſite angles towards each other, or drawing them aſunder. But when the three ſides of a triangle are determined, its ſhape is alſo invariably determined; and if two angles be held faſt, the third cannot be moved. It is thus that, by inſerting the bar CD, the figure becomes unchangeable; and any attempt to change it by applying a force to an angle A, immediately excites forces of attraction or repulſion between the particles of the ſtuff which form its ſides. Thus it happens, in the preſent inſtance, that a change of ſhape is prevented by the bar CD. The power at A preſſes its end againſt the prop; and in doing this it puts the bar AD on the ſtretch, and alſo the bar DB. Their places might therefore be ſupplied by cords or metal wires. Hence it is evident that DC is compreſſed, as is alſo AC: and, for the ſame reaſon, CB is alſo in a ſtate of compreſſion; for either A or B may be conſidered as the point that is impelled or withheld. Therefore DA and DB are ſtretched, and are reſiſting with attractive forces. DC and CB are compreſſed, and are reſiſting with repulſive forces. DB is alſo acting with repulſive forces, being compreſſed in like manner: and thus the ſupport of the prop, combined with the firmneſs of DC, puts the frame ADBC into the condition of the two frames in fig. 8 and fig. 9. Therefore the external force at A is really in equilibrio with an attracting force acting in the direction AD, and a repulſive force acting in the direction AK. And ſince all the connecting forces are mutual and equal, the point D is pulled or drawn in the direction DA. The condition of the point B is ſimilar to that of A, and D is alſo drawn in the direction DB. Thus the point D, being urged by the forces in the directions DA and DB, preſſes the beam DC on the prop, and the prop reſiſts in the oppoſite direction. Therefore the line DC is the diagonal of the parallelogram, whoſe ſides have the proportion of the forces which connect D with A and B. This is the principle on which the reſt of our inveſtigation proceeds. We may take DC as the repreſentation and meaſure of their joint effect. Therefore draw CH, CG, parallel to DA, DB. Draw HL, GO, parallel to CA, CB, cutting AE, BF in L and O, and cutting DA, DB in I and M. Complete the parallelograms ILKA, MONB. Then DG and AI are the equal and oppoſite forces which connect A and D; for GD = CH, = AI. In like manner DH and BM are the forces which connect D and B.

The external force at A is in immediate equilibrio with the combined forces, connecting A with D and with C. AI is one of them: Therefore AK is the other; and AL is the compound force with which the external force at A is in immediate equilibrium. This external force is therefore equal and oppoſite to AL. In like manner, the external force at B is equal and oppoſite to BO; and AL is to BO as the external force at A to the external force at B. The prop C reſiſts with forces equal to thoſe which are propagated to it from the points D, A, and C. Therefore it reſiſts with forces CH, CG, equal and oppoſite to DG, DH; and it reſiſts the compreſſions KA, NB, with equal and oppoſite forces C *k*, C *n*. Draw *k l*, *n o* parallel to AD, BD, and draw C *l* Q, C *o* P: It is plain that *k* CH *l* is a parallelogram equal to KAIL, and that C *l* is equal to AL. In like manner C *o* is equal to BO. Now the forces C *k*, CH, exerted by the prop, compoſe the force C *l*; and C *n*, CG compoſe the force C *o*. Theſe two forces C *l*, C *o* are equal and parallel to AL and BO; and therefore they are equal and oppoſite to the external forces acting at A and B. But they are (primitively) equal and oppoſite to the preſſures (or at leaſt the compounds of the preſſures) exerted on the prop, by the forces propagated to C from A, D, and B. Therefore the preſſures exerted on the prop are the ſame as if the external forces were applied there in the ſame directions as they are applied to A and B. Now if we make CV, CZ equal to C *l* and C *o*,

and

and complete the parallelogram CVYZ; it is plain that the force YC is in equilibrio with *l*C and *o*C. Therefore the preſſures at A, C, and B, are ſuch as would balance if applied to one point.

Laſtly, in order to determine their proportions, draw CS and CR perpendicular to DA and DB. Alſo draw A *d*, B *f* perpendicular to CQ and CP; and draw C *g*, C *i* perpendicular to AE, BF.

The triangles CPR and BP *f* are ſimilar, having a common angle P, and a right angle at R and *f*.

In like manner the triangles CQS and AQ *d* are ſimilar. Alſo the triangles CHR, CGS are ſimilar, by reaſon of the equal angles at H and G, and the right angles at R and S. Hence we obtain the following analogies:

$$\begin{array}{lcl} \mathrm{C}o : \mathrm{CP} = \mathrm{O}n : \mathrm{PB}, = & & \mathrm{CG} : \mathrm{PB} \\ \mathrm{CP} : \mathrm{CR} = & & \mathrm{PB} : f\mathrm{B} \\ \mathrm{CR} : \mathrm{CS} = & & \mathrm{CH} : \mathrm{CG} \\ \mathrm{CS} : \mathrm{CQ} = & & \mathrm{A}d : \mathrm{AQ} \\ \mathrm{CQ} : \mathrm{C}l = \mathrm{AQ} : \mathrm{K}l, = & & \mathrm{AQ} : \mathrm{CH}. \end{array}$$

Therefore, by equality,

$$\begin{array}{lcl} \mathrm{C}o : \mathrm{C}l = & & \mathrm{A}d : f\mathrm{B} \\ \text{or } \mathrm{BO} : \mathrm{AL} = & & \mathrm{C}g : \mathrm{C}i. \end{array}$$

That is, the external forces are reciprocally proportional to the perpendiculars drawn from the prop on the lines of their direction (A).

17 tenſive ſequen-

This propoſition (ſufficiently general for our purpoſe) is fertile in conſequences, and furniſhes many uſeful inſtructions to the artiſt. The ſtrains LA, OB, CY, that are excited, occur, in many, we may ſay in all, framings of carpentry, whether for edifices or engines, and are the ſources of their efficacy. It is alſo evident, that the doctrine of the tranſverſe ſtrength of timber is contained in this propoſition; for every piece of timber may be conſidered as an aſſemblage of parts, connected by forces which act in the direction of the lines which join the ſtrained points on the matter which lies between thoſe points, and alſo act on the reſt of the matter, exciting thoſe lateral forces which produce the inflexibility of the whole. See *Strength of Materials*, Encycl.

Thus it appears that this propoſition contains the principles which direct the artiſt to frame the moſt powerful levers; to ſecure uprights by ſhores or braces, or by ties and ropes; to ſecure ſcaffoldings for the erection of ſpires, and many other moſt delicate problems of his art. He alſo learns, from this propoſition, how to aſcertain the ſtrains that are produced, without his intention, by pieces which he intended for other offices, and which, by their tranſverſe action, put his work in hazard. In ſhort, this propoſition is the key to the ſcience of his art.

We would now counſel the artiſt, after he has made the tracing of the ſtrains and thruſts through the various parts of a frame familiar to his mind, and even amuſed himſelf with ſome complicated fancy framings, to read over with care the articles *Strength of Materials* and Roof in the *Encyclopædia Britannica*. He will now conceive its doctrines much more clearly than when he was conſidering them as abſtract theories. The mutual action of the woody fibres will now be eaſily comprehended, and his confidence in the reſults will be greatly increaſed.

18 Deciſion of a diſputed and very important queſtion.

There is a propoſition (nº 19. in the article Roof) which has been called in queſtion by ſeveral very intelligent perſons; and they ſay that Belidor has demonſtrated, in his Science des Ingenieurs, that a beam firmly fixed at both ends is not twice as ſtrong as when ſimply lying on the props, and that its ſtrength is increaſed only in the proportion of 2 to 3; and they ſupport this determination by a liſt of experiments recited by Belidor, which agree *preciſely* with it. Belidor alſo ſays that Pitot had the ſame reſult in his experiments. Theſe are reſpectable authorities: but Belidor's reaſoning is any thing but demonſtration; and his experiments are deſcribed in ſuch an imperfect manner, that we cannot build much on them. It is not ſaid in what manner the battens were ſecured at the ends, any farther than that it was by *chevalets*. If by this word is meant a treſsle, we cannot conceive how they were employed; but we ſee it ſometimes uſed for a wedge or key. If the battens were wedged in the holes, their reſiſtance to fracture may be made what we pleaſe: they may be looſe, and therefore reſiſt little more than when ſimply laid on the props. They may be (and probably were) wedged very faſt, and bruiſed or crippled.

Our propoſition mentioned diſtinctly the ſecurity given to the ends of the beams. They were mortiſed into remote poſts. Our *preciſe* meaning was, that they were ſimply kept from riſing by theſe mortiſes, but at full liberty to bend up between E and I, and between

---

(A) The learned reader will perceive, that this analogy is preciſely the ſame with that of forces which are in equilibrio by the intervention of a lever. In fact, this whole frame of carpentry is nothing elſe than a *built* or *framed lever* in equilibrio. It is acting in the ſame manner as a ſolid, which occupies the whole figure compreſſed in the frame, or as a body of any ſize and ſhape whatever that will admit the three points of application A, C, and B. It is always in equilibrio in the caſe firſt ſtated; becauſe the preſſure *produced* at B by a force applied to A is always ſuch as balances it. The reader may alſo perceive, in this propoſition, the analyſis or tracing of thoſe internal mechanical forces which are indiſpenſably requiſite for the functions of a lever. The mechanicians have been extremely puzzled to find a legitimate demonſtration of the equilibrium of a lever ever ſince the days of Archimedes. Mr Vince has the honour of firſt demonſtrating, moſt ingeniouſly, the principle aſſumed by Archimedes, but without ſufficient ground, for *his* demonſtration: but Mr Vince's demonſtration is only a putting the mind into that perplexed ſtate which makes it acknowledge the propoſition, but without a clear perception of its truth. The difficulty has proceeded from the abſtract notion of a lever, conceiving it as a mathematical line—inflexible, without reflecting how it is inflexible—for the very ſource of this indiſpenſable quality furniſhes the mechanical connection between the remote preſſures and the fulcrum; and this ſupplies the demonſtration (without the leaſt difficulty) of the deſperate caſe of a ſtraight lever urged by parallel forces. See Rotation, nº 11. *Encycl.*

G and K. Our aſſertion was not made from theory alone (although we think the reaſoning incontrovertible), but was agreeable to numerous experiments made in thoſe preciſe circumſtances. Had we mortiſed the beams firmly into two very ſtout poſts, which could not be drawn nearer to each other by bending, the beam would have borne a *much* greater weight, as we have verified by experiment. We hope that the following mode of conceiving this caſe will remove all doubts.

Let LM be a long beam (fig. 14.) divided into ſix equal parts, in the points D, B, A, C, E. Let it be firmly ſupported at L, B, C, M. Let it be cut through at A, and have compaſs-joints at B and C. Let FB, GC be two equal uprights, reſting on B and C, but without any connection. Let AH be a ſimilar and equal piece, to be occaſionally applied at the ſeam A. Now let a thread or wire AGE be extended over the piece GC, and made faſt at A, G, and E. Let the ſame thing be done on the other ſide of A. If a weight be now laid on at A, the wires AFD, AGE will be ſtrained, and may be broken. In the inſtant of fracture we may ſuppoſe their ſtrains to be repreſented by Af and Ag. Complete the parallelogram, and Aa is the magnitude of the weight. It is plain that nothing is concerned here but the coheſion of the wires; for the beam is ſawed through at A, and its parts are perfectly moveable round B and C.

Inſtead of this proceſs apply the piece AH below A, and keep it there by ſtraining the ſame wire BHC over it. Now lay on a weight. It muſt preſs down the ends of BA and CA, and cauſe the piece AH to ſtrain the wire BHC. In the inſtant of fracture of *the ſame* wire, its reſiſtance Hb and Hc muſt be equal to Af and Ag, and the weight bH which breaks them muſt be equal to Aa.

Laſtly, employ all the three pieces FB, AH, GC, with the ſame wire attached as before. There can be no doubt but that the weight which breaks all the four wires muſt be $= a\,A + b$, or twice $A\,a$.

The reader cannot but ſee that the wires perform the very ſame office with the fibres of an entire beam LM held faſt in the four holes D, B, C, and E, of ſome upright poſts.

In the experiments for verifying this, by breaking ſlender bars of fine deal, we get complete demonſtration, by meaſuring the curvatures produced in the parts of the beam thus held down, and comparing them with the curvature of a beam ſimply laid on the props B and C: and there are many curious inferences to be made from theſe obſervations, but we have not room for them in this place.

19
The beſt manner of framing purlins.

We may obſerve, by the way, that we learn from this caſe, that purlins are able to carry twice the load when notched into the rafters that they carry when mortiſed into them, which is the moſt uſual manner of framing them. So would the binding joiſts of floors; but this would double the thickneſs of the flooring. But this method ſhould be followed in every poſſible caſe, ſuch as breaſt ſummers, lintels over ſeveral pillars, &c. Theſe ſhould never be cut off and mortiſed into the ſides of every upright; numberleſs caſes will occur which ſhew the importance of the maxim.

We muſt here remark, that the proportion of the ſpaces BC and CM, or BC and LB, has a very ſenſible effect on the ſtrength of the beam BC; but we have not yet ſatisfied our minds as to the *rationale* of this effect. It is undoubtedly connected with the ſerpentine form of the curve of the beam before fracture. This ſhould be attended to in the conſtruction of the ſprings of carriages. Theſe are frequently ſupported at a middle point (and it is an excellent practice), and there is a certain proportion which will give the eaſieſt motion to the body of the carriage. We alſo think that it is connected with that deviation from the beſt theory obſervable in Buffon's experiments on various lengths of the ſame ſcantling. The force of the beams diminiſhed much more than in the inverſe proportion of their lengths.

20
Ties are in general better than ſtruts.

We have ſeen that it depends entirely on the poſition of the pieces in reſpect of their points of ultimate ſupport, and of the direction of the external force which produces the ſtrains, whether any particular piece is in a ſtate of extenſion or of compreſſion. The knowledge of this circumſtance may greatly influence us in the choice of the conſtruction. In many caſes we may ſubſtitute ſlender iron rods for maſſive beams, when the piece is to act the part of a tie. But we muſt not invert this diſpoſition; for when a piece of timber acts as a ſtrut, and is in a ſtate of compreſſion, it is next to certain that it is not equally compreſſible in its oppoſite ſides through the whole length of the piece, and that the compreſſing force on the abutting joint is not acting in the moſt equable manner all over the joint. A very trifling inequality in either of theſe circumſtances (eſpecially in the firſt) will compreſs the beam more on one ſide than on the other. This cannot be without the beam's bending, and becoming concave on that ſide on which it is moſt compreſſed. When this happens, the frame is in danger of being cruſhed, and ſoon going to ruin. It is therefore indiſpenſably neceſſary to make uſe of beams in all caſes where ſtruts are required of conſiderable length, rather than of metal rods of ſlender dimenſions, unleſs in ſituations where we can effectually prevent their bending, as in truſſing a girder internally, where a caſt iron ſtrut may be firmly caſed in it, ſo as not to bend in the ſmalleſt degree. In caſes where the preſſures are enormous, as in the very oblique ſtruts of a centre or arch frame, we muſt be particularly cautious to do nothing which can facilitate the compreſſion of either ſide. No mortiſes ſhould be cut near to one ſide; no lateral preſſure, even the ſlighteſt, ſhould be allowed to touch it. We have ſeen a pillar of fir 12 inches long and one inch in ſection, when loaded with three tons, ſnap in an inſtant when preſſed on one ſide by 16 pounds, while another bore 4½ tons without hurt, becauſe it was incloſed (looſely) in a ſtout pipe of iron.

In ſuch caſes of enormous compreſſion, it is of great importance that the compreſſing force bear equally on the whole abutting ſurfaces. The German carpenters are accuſtomed to put a plate of lead over the joint. This prevents, in ſome meaſure, the penetration of the end fibres. Mr Perronet, the celebrated French architect, formed his abutments into arches of circles, the centre of which was the remote end of the ſtrut. By this contrivance the unavoidable change of form of the triangle made no partial bearing of either angle of the abutment. This always has a tendency to ſplinter off the heel of the beam where it preſſes ſtrongeſt. It is a very judicious practice.

When circumſtances allow it, we ſhould rather employ

ploy ties than ſtruts for ſecuring a beam againſt lateral ſtrains. When an upright pillar, ſuch as a flag-ſtaff, a maſt, or the uprights of a very tall ſcaffolding, are to be ſhored up, the dependence is more certain on thoſe braces that are ſtretched by the ſtrain than on thoſe which are compreſſed. The ſcaffolding of the iron bridge near Sunderland had ſome ties very judiciouſly diſpoſed, and others with leſs judgment.

We ſhould proceed to conſider the tranſverſe ſtrains as they affect the various parts of a frame of carpentry; but we have very little to add to what has been ſaid already in the article *Strength of Materials* (Encycl.), and in the article Roof. What we ſhall add in this article will find a place in our occaſional remarks on different works. It may, however, be of uſe to recal to the reader's memory the following propoſitions.

21 General theorems concerning the relative ſtrength of beams.

1. When a beam AB (fig. 15.) is firmly fixed at the end A, and a ſtraining force acts perpendicularly to its length at any point B, the ſtrain occaſioned at any ſection C between B and A is proportional to CB, and may therefore be repreſented by the product W×CB; that is, by the product of the number of tons. pounds, &c. which meaſure the ſtraining force, and the number of feet, inches, &c. contained in CB. As the loads on a beam are eaſily conceived, we ſhall ſubſtitute this for any other ſtraining force.

2. If the ſtrain or load is uniformly diſtributed along any part of the beam lying beyond C (that is, further from A), the ſtrain at C is the ſame as if the load were all collected at the middle point of that part; for that point is the centre of gravity of the load.

3. The ſtrain on any ſection D of a beam AB (fig. 16.) reſting freely on two props A and B, is $w \times \frac{AD \times DB}{AB}$ (ſee Roof, n° 19. and *Strength of Materials*, n° 92, &c. *Encycl.*) Therefore,

4. The ſtrain on the middle point, by a force applied there, is one fourth of the ſtrain which the ſame force would produce, if applied to one end of a beam of the ſame length, having the other end fixed.

5. The ſtrain on any ſection C of a beam, reſting on two props A and B, occaſioned by a force applied perpendicularly to another point D, is proportional to the rectangle of the exterior ſegments, or is equal to $w \times \frac{AC \times DB}{AB}$. Therefore

The ſtrain at C occaſioned by the preſſure on D, is the ſame with the ſtrain at D occaſioned by the ſame preſſure on C.

6. The ſtrain on any ſection D, occaſioned by a load uniformly diffuſed over any part EF, is the ſame as if the two parts ED, DF of the load were collected at their middle points *e* and *f*. Therefore

The ſtrain on any part D, occaſioned by a load uniformly diſtributed over the whole beam, is one-half of the ſtrain that is produced when the ſame load is laid on at D; and

The ſtrain on the middle point C, occaſioned by a load uniformly diſtributed over the whole beam, is the ſame which half that load would produce if laid on at C.

7. A beam ſupported at both ends on two props B and C (fig. 14.) will carry twice as much when the ends beyond the props are kept from riſing, as it will carry when it reſts looſely on the props.

8. Laſtly, the tranſverſe ſtrain on any ſection, occaſioned by a force applied obliquely, is diminiſhed in the proportion of the ſine of the angle which the direction of the force makes with the beam. Thus, if it be inclined to it in an angle of thirty degrees, the ſtrain is one half of the ſtrain occaſioned by the ſame force acting perpendicularly.

On the other hand, the relative strength of a beam, or its power in any particular ſection to reſiſt any tranſverſe ſtrain, is proportional to the abſolute coheſion of the ſection directly, to the diſtance of its centre of effort from the axis of fracture directly, and to the diſtance from the ſtrained point inverſely.

Thus in a rectangular ſection of the beam, of which *b* is the breadth, *d* the depth (that is, the dimenſion in the direction of the ſtraining force), meaſured in inches, and *f* the number of pounds which one ſquare inch will juſt ſupport without being torn aſunder, we muſt have $f \times b \times d^2$, proportional to $w \times CB$ (fig. 15.) Or, $f \times b \times d^2$, multiplied by ſome number *m*, depending on the nature of the timber, muſt be equal to $w \times CB$. Or, in the caſe of the ſection C of fig. 16. that is ſtrained by the force *w* applied at D, we muſt have $m \times f b d^2 = w \times \frac{AC \times DB}{AB}$. Thus if the beam is of ſound oak, *m* is very nearly $= \frac{1}{9}$ (ſee *Strength of Materials*, n° 116. Encycl.) Therefore we have $\frac{f b d^2}{9} = w \times \frac{AC \times CB}{AB}$.

Hence we can tell the preciſe force *w* which any ſection C can juſt reſiſt when that force is applied in any way whatever. For the above-mentioned formula gives $w = \frac{f b d^2}{9CB}$, for the caſe repreſented by fig 15. But the caſe repreſented in fig. 16. having the ſtraining force applied at D, gives the ſtrain at C $(= w) = f \times \frac{b d^2 \times AB}{9AC \times CB}$.

Example. Let an oak beam, four inches ſquare, reſt freely on the props A and B, ſeven feet apart, or 84 inches. What weight will it juſt ſupport at its middle point C, on the ſuppoſition that a ſquare inch rod will juſt carry 16,000 pounds, pulling it aſunder?

The formula becomes $w = \frac{16000 \times 4 \times 16 \times 84.}{9 \times 42 \times 42}$ or $w = \frac{86016000}{15876}$, = 5418 pounds. This is very near what was employed in Buffon's experiment, which was 5312.

Had the ſtraining force acted on a point D, half way between C and B, the force ſufficient to break the beam at C would be $= \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 21} =$ 10836 lbs.

Had the beam been ſound red fir, we muſt have taken $f =$ 10,000 nearly, and *m* nearly 8; for although fir be leſs coheſive than oak in the proportion of 5 to 8 nearly, it is leſs compreſſible, and its axis of fracture is therefore nearer to the concave ſide.

22 Of joints.

Having conſidered at ſufficient length the ſtrains of different kinds which ariſe from the form of the parts of a frame of carpentry, and the direction of the external forces which act on it, whether conſidered as impelling or as ſupporting its different parts, we muſt now

now proceed to conſider the means by which this form is to be ſecured, and the connections by which thoſe ſtrains are excited and communicated.

The joinings practiſed in carpentry are almoſt infinitely various, and each has advantages which make it preferable in ſome circumſtances. Many varieties are employed merely to pleaſe the eye. We do not concern ourſelves with theſe: Nor ſhall we conſider thoſe which are only employed in connecting ſmall works, and can never appear on a great ſcale: yet even in ſome of theſe, the ſkill of the carpenter may be diſcovered by his choice; for in all caſes it is wiſe to make every, even the ſmalleſt, part of his work as ſtrong as the materials will admit. He will be particularly attentive to the changes which will neceſſarily happen by the ſhrinking of timber as it dries, and will conſider what dimenſions of his framings will be affected by this, and what will not; and will then diſpoſe the pieces which are leſs eſſential to the ſtrength of the whole, in ſuch a manner that their tendency to ſhrink ſhall be in the ſame direction with the ſhrinking of the whole framing. If he do otherwiſe, the ſeams will widen, and parts will be ſplit aſunder. He will diſpoſe his boardings in ſuch a manner as to contribute to the ſtiffneſs of the whole, avoiding at the ſame time the giving them poſitions which will produce lateral ſtrains on truſs beams which bear great preſſures; recollecting, that although a ſingle board has little force, yet many united have a great deal, and may frequently perform the office of very powerful ſtruts.

Our limits confine us to the joinings which are moſt eſſential for connecting the parts of a ſingle piece of a frame when it cannot be formed of one beam, either for want of the neceſſary thickneſs or length; and the joints for connecting the different ſides of a truſſed frame.

23 Of building up beams. Much ingenuity and contrivance has been beſtowed on the manner of building up a great beam of many thickneſſes, and many ſingular methods are practiſed as great noſtrums by different artiſts: but when we conſider the manner in which the coheſion of the fibres performs its office, we will clearly ſee that the ſimpleſt are equally effectual with the moſt refined, and that they are leſs apt to lead us into falſe notions of the ſtrength of the aſſemblage.

24 Building up a girder or lever. 25 Joggling preferable to ſcarfing. Thus, were it required to build up a beam for a great lever or a girder, ſo that it may act nearly as a beam of the ſame ſize of one log—it may either be done by plain joggling, as in fig. 17. A, or by ſcarfing, as in fig. 17. B or C. If it is to act as a lever, having the gudgeon on the lower ſide at C, we believe that moſt artiſts will prefer the form B and C; at leaſt this has been the caſe with nine-tenths of thoſe to whom we have propoſed the queſtion. The beſt informed only heſitated; but the ordinary artiſts were all confident in its ſuperiority; and we found their views of the matter very coincident. They conſider the upper piece as graſping the lower in its hooks; and ſeveral imagined that, by driving the one very tight on the other, the beam would be ſtronger than an entire log: but if we attend carefully to the internal procedure in the loaded lever, we ſhall find the upper one clearly the ſtrongeſt. If they are formed of equal logs, the upper one is thicker than the other by the depth of the joggling or ſcarfing, which we ſuppoſe to be the ſame in both; conſequently, if the coheſion of the fibres in the intervals is able to bring the uppermoſt filaments into full action, the form A is ſtronger than B, in the proportion of the greater diſtance of the upper filaments from the axis of the fracture: this may be greater than the difference of the thickneſs, if the wood is very compreſſible. If the gudgeon be in the middle, the effect, both of the joggles and the ſcarfings, is conſiderably diminiſhed; and if it is on the upper ſide, the ſcarfings act in a very different way. In this ſituation, if the loads on the arms are alſo applied to the upper ſide, the joggled beam is ſtill more ſuperior to the ſcarfed one. This will be beſt underſtood by reſolving it in imagination into a truſſed frame. But when a gudgeon is thus put on that ſide of the lever which grows convex by the ſtrain, it is uſual to connect it with the reſt by a powerful ſtrap, which embraces the beam, and cauſes the oppoſite point to become the reſiſting point. This greatly changes the internal actions of the filaments, and, in ſome meaſure, brings it into the ſame ſtate as the firſt, with the gudgeon below. Were it poſſible to have the gudgeon on the upper ſide, and to bring the whole into action without a ſtrap, it would be the ſtrongeſt of all; becauſe, in general, the reſiſtance to compreſſion is greater than to extenſion. In every ſituation the joggled beam has the advantage; and it is the eaſieſt executed.

We may frequently gain a conſiderable acceſſion of ſtrength by this building up of a beam; eſpecially if the part which is ſtretched by the ſtrain be of oak, and the other part be fir. Fir being ſo much ſuperior to oak as a pillar (if Muſſchenbroek's experiments may be confided in), and oak ſo much preferable as a tie, this conſtruction ſeems to unite both advantages. But we ſhall ſee much better methods of making powerful levers, girders, &c. by truſſing.

Obſerve that the efficacy of both methods depends entirely on the difficulty of cauſing the piece between the croſs joints to ſlide along the timber to which it adheres. Therefore, if this be moderate, it is wrong to make the notches deep; for as ſoon as they are ſo deep that their ends have a force ſufficient to puſh the ſlice along the line of junction, nothing is gained by making them deeper; and this requires a greater expenditure of timber.

Scarfings are frequently made oblique, as in fig. 18. but we imagine that this is a bad practice. It begins to yield at the point, where the wood is crippled and ſplintered off, or at leaſt bruiſed out a little: as the preſſure increaſes, this part, by ſqueezing broader, cauſes the ſolid parts riſe to a little upwards, and gives them ſome tendency, not only to puſh their antagoniſts along the baſe, but even to tear them up a little. For ſimilar reaſons, we diſapprove of the favourite practice of many artiſts, to make the angles of their ſcarfings acute, as in fig. 19. This often cauſes the two pieces to tear each other up. The abutments ſhould always be perpendicular to the directions of the preſſures. Leſt it ſhould be forgotten in its proper place, we may extend this injunction alſo to the abutments of different pieces of a frame, and recommend it to the artiſt even to attend to the ſhrinking of the timbers by drying. When two timbers abut obliquely, the joint ſhould be moſt

full

full at the obtuſe angle of the end; becauſe, by drying, that angle grows more obtuſe, and the beam would then be in danger of ſplintering off at the acute angle.

16 We muſt not wedge too hard.

It is evident that the niceſt work is indiſpenſably neceſſary in building up a beam. The parts muſt abut on each other completely, and the ſmalleſt play or void takes away the whole efficacy. It is uſual to give the butting joints a ſmall taper to one ſide of the beam, ſo that they may require moderate blows of a maul to force them in, and the joints may be perfectly cloſe when the external ſurfaces are even on each ſide of the beam. But we muſt not exceed in the leaſt degree; for a very taper wedge has great force; and if we have driven the pieces together by very heavy blows, we leave the whole in a ſtate of violent ſtrain, and the abutments are perhaps ready to ſplinter off by a ſmall addition of preſſure. This is like too ſevere a proof for artillery; which, though not ſufficient to burſt the pieces, has weakened them to ſuch a degree, that the ſtrain of ordinary ſervice is ſufficient to complete the fracture. The *workman* is tempted to exceed in this, becauſe it ſmooths off and conceals all uneven ſeams; but he muſt be watched. It is not unuſual to leave ſome abutments open enough to admit a thin wedge reaching through the beam. Nor is this a bad practice, if the wedge is of materials which is not compreſſed by the driving or the ſtrain of ſervice. Iron would be preferable for this purpoſe, and for the joggles, were it not that by its too great hardneſs it cripples the fibres of timber to ſome diſtance. In conſequence of this, it often happens that, in beams which are ſubjected to deſultory and ſudden ſtrains (as in the levers of reciprocating engines), the joggles or wedges widen the holes, and work themſelves looſe: Therefore ſkilful engineers never admit them, and indeed as few bolts as poſſible, for the ſame reaſon: but when reſiſting a ſteady or dead pull, they are not ſo improper, and are frequently uſed.

27 Building of maſts.

Beams are built up not only to increaſe their dimenſions in the direction of the ſtrain (which we have hitherto called their depth), but alſo to increaſe their breadth or the dimenſions perpendicular to the ſtrain. We ſometimes double the breadth of a girder which is thought too weak for its load, and where we muſt not increaſe the thickneſs of the flooring. The maſt of a great ſhip of war muſt be made bigger athwartſhip, as well as fore and aft. This is one of the niceſt problems of the art; and profeſſional men are by no means agreed in their opinions about it. We do not preſume to decide; and ſhall content ourſelves with exhibiting the different methods.

28 Method ed in the rench avy.

The moſt obvious and natural method is that ſhewn in fig. 20. It is plain that (independent of the connection of croſs bolts, which are uſed in them all when the beams are ſquare) the piece C cannot bend in the direction of the plane of the figure without bending the piece D along with it. This method is much uſed in the French navy; but it is undoubtedly imperfect. Hardly any two great trees are of equal quality, and ſwell and ſhrink alike. If C ſhrinks more than D, the feather of C becomes looſe in the groove wrought in D to receive it; and when the beam bends, the parts can ſlide on each other like the plates of a coach ſpring; and if the bending is in the direction *e f*, there is nothing to hinder this ſliding but the bolts, which ſoon work themſelves looſe in the bolt-holes.

29 Another method.

Fig. 21. exhibits another method. The two halves of the beam are tabled into each other in the ſame manner as in fig. 17. It is plain that this will not be affected by the unequal ſwelling or ſhrinking, becauſe this is inſenſible in the direction of the fibres; but when bent in the direction *a b*, the beam is weaker than fig. 20. bent in the direction *e f*. Each half of fig. 20. has, in every part of its length, a thickneſs greater than half the thickneſs of the beam. It is the contrary in the alternate portions of the halves of fig. 21. When one of them is bent in the direction AB, it is plain that it drags the other with it by means of the croſs butments of its tables, and there can be no longitudinal ſliding. But unleſs the work is accurately executed, and each hollow completely filled up by the table of the other piece, there will be a lateral ſlide along the croſs joints ſufficient to compenſate for the curvature; and this will hinder the one from compreſſing or ſtretching the other in conformity to this curvature.

30 Its imperfection.

The imperfection of this method is ſo obvious, that it has ſeldom been practiſed: but it has been combined with the other, as is repreſented in fig. 22. where the beams are divided along the middle, and the tables in each half are alternate, and alternate alſo with the tables of the other half. Thus 1, 3, 4, are prominent, and 5, 2, 6, are depreſſed. This conſtruction evidently puts a ſtop to both ſides, and obliges every part of both pieces to move together. *a b* and *c d* ſhow ſections of the built-up beam correſponding to AB and CD.

No more is intended in this practice by any intelligent artiſt, than the cauſing the two pieces to act together in all their parts, although the ſtrains may be unequally diſtributed on them. Thus, in a built-up girder, the binding joints are frequently mortiſed into very different parts of the two ſides. But many ſeem to aim at making the beam ſtronger than if it were of one piece; and this inconſiderate project has given riſe to many whimſical modes of tabling and ſcarfing, which we need not regard.

31 Britiſh method;

The practice in the Britiſh dock-yards is ſomewhat different from any of theſe methods. The pieces are tabled as in fig 22. but the tables are not thin parallelopipeds, but thin priſms. The two outward joints or viſible ſeams are ſtraight lines, and the table nº 1. riſes gradually to its greateſt thickneſs in the axis. In like manner, the hollow 5 for receiving the oppoſite table, ſinks gradually from the edge to its greateſt depth in the axis. Fig. 23. repreſents a ſection of a round piece of timber built up in this way, where the full line EFGH is the ſection correſponding to AB of fig. 22. and the dotted line EGFH is the ſection correſponding to CD.

This conſtruction, by making the external ſeam ſtraight, leaves no lodgment for water, and looks much fairer to the eye: but it appears to us that it does not give ſuch firm hold when the maſt is bent in the direction EH. The exterior parts are moſt ſtretched and moſt compreſſed by this bending; but there is hardly any abutment in the exterior parts of theſe tables. In the very axis, where the abutment is the firmeſt, there is little or no difference of extenſion and compreſſion.

But this conſtruction has an advantage, which we imagine much more than compenſates for theſe imperfections, ſections, at leaſt in the particular caſe of a round maſt: it will draw together by hooping incomparably better than any of the others. If the cavity be made ſomewhat too ſhallow for the prominence of the tables, and if this be done uniformly along the whole length, it will make a ſomewhat open ſeam; and this opening can be regulated with the utmoſt exactneſs from end to end by the plane. The heart of thoſe vaſt trunks is very ſenſibly ſofter than the exterior circles: Therefore, when the whole is hooped, and the hoops hard driven, and at conſiderable intervals between each ſpell —we are confident that all may be compreſſed till the ſeam diſappears; and then the whole makes one piece, *much* ſtronger than if it were an original log of that ſize; becauſe the middle has become, by compreſſion, as ſolid as the cruſt, which was naturally firmer, and reſiſted further compreſſion. We verified this beyond a doubt, by hooping a built ſtick of a timber which has this inequality of firmneſs in a remarkable degree, and it was nearly twice as ſtrong as another of the ſame ſize.

Our maſtmakers are not without their fancies and whims; and the manner in which our maſts and yards are generally built up, is not near ſo ſimple as fig. 22.: but it conſiſts of the ſame eſſential parts, acting in the very ſame manner, and derives all its efficacy from the principles which are here employed.

32 Attended with peculiar advantages.

This conſtruction is particularly ſuited to the ſituation and office of a ſhip's maſt. It has no bolts; or, at leaſt, none of any magnitude, or that make very important parts of its conſtruction. The moſt violent ſtrains perhaps that it is expoſed to, is that of twiſting, when the lower yards are cloſe braced up by the force of many men acting by a long lever. This form reſiſts a twiſt with peculiar energy: it is therefore an excellent method for building up a great ſhaft for a mill. The way in which they are uſually built up is by reducing a central log to a polygonal priſm, and then filling it up to the intended ſize by *planting* pieces of timber along its ſides, either ſpiking them down, or cocking them into it by a feather, or joggling them by ſlips of hard wood ſunk into the central log and into the ſlips. *N. B.* Joggles of elm are ſometimes uſed in the middle of the large tables of maſts; and when ſunk into the firm wood near the ſurface, they muſt contribute much to the ſtrength. But it is very neceſſary to employ wood not much harder than the pine; otherwiſe it will ſoon enlarge its bed, and become looſe; for the timber of theſe large trunks is very ſoft.

The moſt general reaſon for piecing a beam is to increaſe its length. This is frequently neceſſary, in order to procure tie-beams for very wide roofs. Two pieces muſt be ſcarfed together.—Numberleſs are the modes of doing this; and almoſt every maſter carpenter has his favourite noſtrum. Some of them are very ingenious: But here, as in other caſes, the moſt ſimple are

33 Various methods of ſcarfing.

commonly the ſtrongeſt. We do not imagine that any, the moſt ingenious, is equally ſtrong with a tie conſiſting of two pieces of the ſame ſcantling laid over each other for a certain length, and firmly bolted together. We acknowledge that this will appear an artleſs and clumſy tie-beam; but we only ſay that it will be ſtronger than any that is more artificially made up of the ſame thickneſs of timber. This, we imagine, will appear ſufficiently certain.

The ſimpleſt and moſt obvious ſcarfing (after the one now mentioned) is that repreſented in fig. 24. n° 1. and 2. If conſidered merely as two pieces of wood joined, it is plain that, as a tie, it has but half the ſtrength of an entire piece, ſuppoſing that the bolts (which are the only connections) are faſt in their holes. N° 2. requires a bolt in the middle of the ſcarf to give it that ſtrength; and, in every other part, is weaker on one ſide or the other.

But the bolts are very apt to bend by the violent ſtrain, and require to be ſtrengthened by uniting their ends by iron plates; in which caſe it is no longer a wooden tie. The form of n° 1. is better adapted to the office of a pillar than n° 2.; eſpecially if its ends be formed in the manner ſhewn in the elevation n° 3. By the ſally given to the ends, the ſcarf reſiſts an effort to bend it in that direction. Beſides, the form of n° 2. is unſuitable for a poſt; becauſe the pieces, by ſliding on each other by the preſſure, are apt to ſplinter off the tongue which confines their extremity.

Fig. 25. and 26. exhibit the moſt approved form of a ſcarf, whether for a tie or for a poſt. The key repreſented in the middle is not eſſentially neceſſary; the two pieces might ſimply meet ſquare there. This form, without a key, needs no bolts (although they ſtrengthen it greatly); but, if worked very true and cloſe, and with ſquare abutments, will hold together, and will reſiſt bending in any direction. But the key is an ingenious and a very great improvement, and will force the parts together with perfect tightneſs. The ſame precaution muſt be obſerved that we mentioned on another occaſion, not to produce a conſtant internal ſtrain on the parts by overdriving the key. The form of fig. 25. is by far the beſt; becauſe the triangle of 26. is much eaſier ſplintered off by the ſtrain, or by the key, than the ſquare wood of 25. It is far preferable for a poſt, for the reaſon given when ſpeaking of fig. 24. n° 1. and n° 2. Both may be formed with a ſally at the ends equal to the breadth of the key. In this ſhape, fig. 25. is vaſtly well ſuited for joining the parts of the long corner poſts of ſpires and other wooden towers. Fig. 25. n° 2. differs from n° 1. only by having three keys. The principle and the longitudinal ſtrength are the ſame. The long ſcarf of n° 2. tightened by the three keys, enables it to reſiſt a bending much better.

None of theſe ſcarfed tie-beams can have more than one-third of the ſtrength of an entire piece, unleſs with the aſſiſtance of iron plates; for if the key be made thinner than one-third, it has leſs than one-third of the fibres to pull by.

We are confident, therefore, that when the heads of the bolts are connected by plates, the ſimple form of fig. 24. n° 1. is ſtronger than thoſe more ingenious ſcarfings. It may be ſtrengthened againſt lateral bending by a little tongue, or by a ſally; but it cannot have both.

34 Fiſhing a beam.

The ſtrongeſt of all methods of piecing a tie-beam would be to ſet the parts end to end, and graſp them between other pieces on each ſide, as in fig. 27. This is what the ſhip-carpenter calls *fiſhing* a beam; and is a frequent practice for occaſional repairs. Mr Perronet uſed it for the tie-beams or ſtretchers, by which he connected the oppoſite feet of a centre, which was yielding to its load, and had puſhed aſide one of the piers above four inches. Six of theſe not only withſtood a ſtrain of 1800 tons, but, by wedging behind them, he brought

brought the feet of the truſs $2\frac{1}{2}$ inches nearer. The ſtretchers were 14 inches by 11 of ſound oak, and could have withſtood three times that ſtrain. Mr Perronet, fearing that the great length of the bolts employed to connect the beams of theſe ſtretchers would expoſe them to the riſk of bending, ſcarfed the two ſide pieces into the middle piece. The ſcarfing was of the triangular kind (*Trait de Jupiter*), and only an inch deep, each face being two feet long, and the bolt paſſed through cloſe to the angle.

In piecing the pump rods, and other wooden ſtretchers of great engines, no dependence is had on ſcarfing; and the engineer connects every thing by iron ſtraps. We doubt the propriety of this, at leaſt in caſes where the bulk of the wooden connection is not inconvenient. Theſe obſervations muſt ſuffice for the methods employed for connecting the parts of a beam; and we now proceed to conſider what are more uſually called the joints of a piece of carpentry.

35
quare
oints.

Where the beams ſtand ſquare with each other, and the ſtrains are alſo ſquare with the beams, and in the plane of the frame, the common mortiſe and tenon is the moſt perfect junction. A pin is generally put through both, in order to keep the pieces united, in oppoſition to any force which tends to part them. Every carpenter knows how to bore the hole for this pin, ſo that it ſhall draw the tenon tight into the mortiſe, and cauſe the ſhoulder to butt cloſe, and make neat work; and he knows the riſk of tearing out the bit of the tenon beyond the pin, if he draw it too much. We may juſt obſerve, that ſquare holes and pins are much preferable to round ones for this purpoſe, bringing more of the wood into action, with leſs tendency to ſplit it. The ſhip carpenters have an ingenious method of making long wooden bolts, which do not paſs completely through, take a very faſt hold, though not nicely fitted to their holes, which they muſt not be, leſt they ſhould be crippled in driving. They call it *foxtail wedging*. They ſtick into the point of the bolt a very thin wedge of hard wood, ſo as to project a proper diſtance; when this reaches the bottom of the hole by driving the bolt, it ſplits the end of it, and ſqueezes it hard to the ſide. This may be practiſed with advantage in carpentry. If the ends of the mortiſe are widened inwards, and a thin wedge be put into the end of the tenon, it will have the ſame effect, and make the joint equal to a dovetail. But this riſks the ſplitting the piece beyond the ſhoulder of the tenon, which would be unſightly. This may be avoided as follows: Let the tenon T, fig. 28. have two *very* thin wedges *a* and *c* ſtuck in near its angles, projecting equally; at a very ſmall diſtance within theſe, put in two ſhorter ones *b*, *d*, and more within theſe if neceſſary. In driving this tenon, the wedges *a* and *c* will take firſt, and ſplit off a thin ſlice, which will eaſily bend without breaking. The wedges *b*, *d*, will act next, and have a ſimilar effect, and the others in ſucceſſion. The thickneſs of all the wedges taken together muſt be equal to the enlargement of the mortiſe toward the bottom.

36
oxtail
edging,

When the ſtrain is tranſverſe to the plane of the two beams, the principles laid down in nº 85, 86. of the article *Strength of Materials*, will direct the artiſt in placing his mortiſe. Thus the mortiſe in a girder for receiving the tenon of a binding joiſt of a floor ſhould be as near the upper ſide as poſſible, becauſe the girder becomes concave on that ſide by the ſtrain. But as this expoſes the tenon of the binding joiſt to the riſk of being torn off, we are obliged to mortiſe farther down. The form (fig. 29.) generally given to this joint is extremely judicious. The ſloping part *a b* gives a very firm ſupport to the additional bearing *e,d*, without much weakening of the girder. This form ſhould be copied in every caſe where the ſtrain has a ſimilar direction.

37
Oblique
mortiſe and
tenon.

The joint that moſt of all demands the careful attention of the artiſt, is that which connects the ends of beams, one of which puſhes the other very obliquely, putting it into a ſtate of extenſion. The moſt familiar inſtance of this is the foot of a rafter preſſing on the tie-beam, and thereby *drawing* it away from the other wall. When the direction is very oblique (in which caſe the extending ſtrain is the greateſt), it is difficult to give the foot of the rafter ſuch a hold of the tie-beam as to bring many of its fibres into the proper action. There would be little difficulty if we could allow the end of the tie-beam to project to a ſmall diſtance beyond the foot of the rafter: but, indeed, the dimenſions which are given to tie-beams, for other reaſons, are always ſufficient to give enough of abutment when judiciouſly employed. Unfortunately this joint is much expoſed to failure by the effects of the weather. It is much expoſed, and frequently periſhes by rot, or becomes ſo ſoft and friable that a very ſmall force is ſufficient, either for pulling the filaments out of the tie-beam, or for cruſhing them together. We are therefore obliged to ſecure it with particular attention, and to avail ourſelves of every circumſtance of conſtruction.

One is naturally diſpoſed to give the rafter a deep hold by a long tenon; but it has been frequently obſerved in old roofs that ſuch tenons break off. Frequently they are obſerved to tear up the wood that is above them, and puſh their way through the end of the tie-beam. This, in all probability, ariſes from the firſt ſagging of the roof, by the compreſſion of the rafters and of the head of the king-poſt. The head of the rafter deſcends, the angle with the tie-beam is diminiſhed by the rafter revolving round its ſtep in the tie-beam. By this motion the heel or inner angle of the rafter becomes a fulcrum to a very long and powerful lever much loaded. The tenon is the other arm, very ſhort, and being ſtill freſh, it is therefore very powerful. It therefore forces up the wood that is above it, tearing it out from between the cheeks of the mortiſe, and then puſhes it along. Carpenters have therefore given up long tenons, and give to the toe of the tenon a ſhape which abuts firmly, in the direction of the thruſt, on the ſolid bottom of the mortiſe, which is well ſupported on the under ſide by the wall-plate. This form has the farther advantage of having no tendency to tear up the end of the mortiſe. This form is repreſented in fig. 30. The tenon has a ſmall portion *a b* cut perpendicular to the ſurface of the tie-beam, and the reſt *b c* is perpendicular to the rafter.

But if the tenon is not ſufficiently ſtrong (and it is not ſo ſtrong as the rafter, which is thought not to be ſtronger than is neceſſary), it will be cruſhed, and then the rafter will ſlide out along the ſurface of the beam. It is therefore neceſſary to call in the aſſiſtance of the

whole;

whole rafter. It is in this diſtribution of the ſtrain among the various abutting parts that the varieties of joints and their merits chiefly conſiſt. It would be endleſs to deſcribe every noſtrum, and we ſhall only mention a few that are moſt generally approved of.

38 Moſt approved forms.

The aim in fig. 31. is to make the abutments exactly perpendicular to the thruſts. It does this very preciſely; and the ſhare which the tenon and the ſhoulder have of the whole may be what we pleaſe, by the portion of the beam that we notch down. If the wall-plate lie duly before the heel of the rafter, there is no riſk of ſtraining the tie acroſs or breaking it, becauſe the thruſt is made direct to that point where the beam is ſupported. The action is the ſame as againſt the joggle on the head or foot of a king-poſt. We have no doubt but that this is a very effectual joint. It is not, however, much practiſed. It is ſaid that the ſloping ſeam at the ſhoulder lodges water; but the great reaſon ſeems to be a ſecret notion that it weakens the tie-beam. If we conſider the direction in which it acts as a tie, we muſt acknowledge that this form takes the beſt method for bringing the whole of it into action.

Fig. 32. exhibits a form that is more general, but certainly worſe. What part of the thruſt that is not borne by the tenon acts obliquely on the joint of the ſhoulder, and gives the whole a tendency to riſe up and ſlide outward.

The ſhoulder joint is ſometimes formed like the dotted line *a b c d e f g* of fig. 32. This is much more agreeable to the true principle, and would be a very perfect method, were it not that the intervals *b d* and *d f* are ſo ſhort that the little wooden triangles *b c d*, *d e f*, will be eaſily puſhed off their baſes *b d*, *d f*.

Fig. 33. ſeems to have the moſt general approbation. It is the joint recommended by Price (page 7.), and copied into all books of carpentry as the *true joint* for a rafter foot. The viſible ſhoulder-joint is fluſh with the upper ſurface of the tie-beam. The angle of the tenon at the tie nearly biſects the obtuſe angle formed by the rafter and the beam, and is therefore ſomewhat oblique to the thruſt. The inner ſhoulder *a c* is nearly perpendicular to *b d*. The lower angle of the tenon is cut off horizontally as at *e d*. Fig. 34. is a ſection of the beam and rafter foot, ſhewing the different ſhoulders.

We do not perceive the peculiar merit of this joint. The effect of the three oblique abutments *a b*, *a c*, *e d*, is undoubtedly to make the whole bear on the outer end of the mortiſe, and there is no other part of the tie-beam that makes immediate reſiſtance. Its only advantage over a tenon extending in the direction of the thruſt is, that it will not tear up the wood above it. Had the inner ſhoulder had the form *e c i*, having its face *i c* perpendicular, it would certainly have acted more powerfully in ſtretching many filaments of the tie-beam, and would have had much leſs tendency to force out the end of the mortiſe. The little bit *c i* would have prevented the ſliding upwards along *e c*. At any rate, the joint *a b* being fluſh with the beam, prevents any ſenſible abutment on the ſhoulder *a c*.

Fig. 33. nº 2. is a ſimpler, and in our opinion a preferable, joint. We obſerve it practiſed by the moſt eminent carpenters for all oblique thruſts; but it ſurely employs leſs of the coheſion of the tie-beam than might be uſed without weakening it, at leaſt when it is ſupported on the other ſide by the wall-plate.

Fig. 33. nº 3. is alſo much practiſed by the firſt carpenters.

Fig. 35. is propoſed by Mr Nicholſon (page 65.) as preferable to fig. 33. nº 3. becauſe the abutment of the inner part is better ſupported. This is certainly the caſe; but it ſuppoſes the whole rafter to go to the bottom of the ſocket, and the beam to be thicker than the rafter. Some may think that this will weaken the beam too much, when it is no broader than the rafter is thick; in which caſe they think that it requires a deeper ſocket than Nicholſon has given it. Perhaps the advantages of Nicholſon's conſtruction may be had by a joint like fig. 35. nº 2.

39 Circumſtances to be attended to.

Whatever is the form of theſe butting joints, great care ſhould be taken that all parts bear alike, and the artiſt will attend to the magnitude of the different ſurfaces. In the general compreſſion, the greater ſurfaces will be leſs compreſſed, and the ſmaller will therefore change moſt. When all has ſettled, every part ſhould be *equally* cloſe. Becauſe great logs are moved with difficulty, it is very troubleſome to try the joint frequently to ſee how the parts fit; therefore we muſt expect leſs accuracy in the interior parts. This ſhould make us prefer thoſe joints whoſe efficacy depends chiefly on the viſible joint.

It appears from all that we have ſaid on this ſubject, that a very ſmall part of the coheſion of the tie-beam is ſufficient for withſtanding the horizontal thruſt of a roof, even though very low pitched. If therefore no other uſe is made of the tie-beam, one much ſlenderer may be uſed, and blocks may be firmly fixed to the ends, on which the rafters might abut, as they do on the joggles on the head and foot of a king-poſt. Although a tie-beam has commonly floors or ceilings to carry, and ſometimes the workſhops and ſtore-rooms of a theatre, and therefore requires a great ſcantling, yet there frequently occur in machines and engines very oblique ſtretchers, which have no other office, and are generally made of dimenſions quite inadequate to their ſituation, often containing ten times the neceſſary quantity of timber. It is therefore of importance to aſcertain the moſt perfect manner of executing ſuch a joint. We have directed the attention to the principles that are really concerned in the effect. In all hazardous caſes, the carpenter calls in the aſſiſtance of iron ſtraps; and they are frequently neceſſary, even in roofs, notwithſtanding this ſuperabundant ſtrength of the tie-beam. But this is generally owing to bad conſtruction of the wooden joint, or to the failure of it by time. Straps will be conſidered in their place.

There needs but little to be ſaid of the joints at a joggle worked out of ſolid timber; they are not near ſo difficult as the laſt. When the ſize of a log will allow the joggle to receive the whole breadth of the abutting brace, it ought certainly to be made with a ſquare ſhoulder; or, which is ſtill better, an arch of a circle, having the other end of the brace for its centre. Indeed this in general will not ſenſibly differ from a ſtraight line perpendicular to the brace. By this circular form, the ſettling of the roof makes no change in the abutment; but when there is not ſufficient ſtuff for this, we muſt avoid bevel joints at the ſhoulders, becauſe theſe always tend to make the brace ſlide off. The brace in fig. 36. muſt not be joined as at *a*, but as at *b*, or ſome equivalent manner. Obſerve the joints at the

the head of the main poſts of Drury Line theatre, fig. D.

40
rting
uts.

When the very oblique action of one ſide of a frame of carpentry does not extend but compreſs the piece on which it abuts (as in fig. 11.), there is no difficulty in the joint. Indeed a joining is unneceſſary, and it is enough that the pieces abut on each other; and we have only to take care that the mutual preſſure be equally borne by all the parts, and that it do not produce lateral preſſures, which may cauſe one of the pieces to ſlide on the butting joint. A very ſlight mortiſe and tenon is ſufficient at the joggle of a king-poſt with a rafter or ſtraining beam. It is beſt, in general, to make the butting plain, biſecting the angle formed by the ſides, or elſe perpendicular to one of the pieces. In fig. 36. n° 2. where the ſtraining beam *a b* cannot ſlip away from the preſſure, the joint *a* is preferable to *b*, or indeed to any uneven joint, which never fails to produce very unequal preſſures on the different parts, by which ſome are crippled, others are ſplintered off, &c.

41
irections
r placing
on ſtraps.

When it is neceſſary to employ iron ſtraps for ſtrengthening a joint, a conſiderable attention is neceſſary, that we may place them properly. The firſt thing to be determined is the direction of the ſtrain. This is learned by the obſervations in the beginning of this article. We muſt then reſolve this ſtrain into a ſtrain parallel to each piece, and another perpendicular to it. Then the ſtrap which is to be made faſt to any of the pieces muſt be ſo fixed, that it ſhall reſiſt in the direction parallel to the piece. Frequently this cannot be done; but we muſt come as near to it as we can. In ſuch caſes we muſt ſuppoſe that the aſſemblage yields a little to the preſſures which act on it. We muſt examine what change of ſhape a ſmall yielding will produce. We muſt now ſee how this will affect the iron ſtrap which we have already ſuppoſed attached to the joint in ſome manner that we thought ſuitable. This ſettling will perhaps draw the pieces away from it, leaving it looſe and unſerviceable (this frequently happens to the plates which are put to ſecure the obtuſe angles of butting timbers, when their bolts are at ſome diſtance from the angles, eſpecially when theſe plates are laid on the inſide of the angles); or it may cauſe it to compreſs the pieces harder than before; in which caſe it is anſwering our intention. But it may be producing croſs ſtrains, which may break them; or it may be crippling them. We can hardly give any general rules; but the reader will do well to read what is written in n° 36. and 41. of the article Roof, *Encycl.* In n° 36. he will ſee the nature of the ſtrap or ſtirrup, by which the king-poſt carries the tie-beam. The ſtrap that we obſerve moſt generally ill placed is that which connects the foot of the rafter with the beam. It only binds down the rafter, but does not act againſt its horizontal thruſt. It ſhould be placed farther back on the beam, with a bolt through it, which will allow it to turn round. It ſhould embrace the rafter almoſt horizontally near the foot, and ſhould be notched ſquare with the back of the rafter. Such a conſtruction is repreſented in fig. 37. By moving round the eye-bolt, it follows the rafter, and cannot pinch and cripple it, which it always does in its ordinary form. We are of opinion that ſtraps which have eye-bolts in the very angles, and allow all motion round them, are of all the moſt perfect. A branched ſtrap, ſuch as may at once bind the king-poſt and the two braces which butt on its foot, will be more ſerviceable if it have a joint. When a roof warps, thoſe branched ſtraps frequently break the tenons, by affording a fulcrum in one of their bolts. An attentive and judicious artiſt will conſider how the beams will act on ſuch occaſions, and will avoid giving riſe to theſe great ſtrains by levers.—A ſkilful carpenter never employs many ſtraps, conſidering them as auxiliaries foreign to his art, and ſubject to imperfections in workmanſhip which he cannot diſcern nor amend. We muſt refer the reader to Nicholſon's Carpenter and Joiner's Assistant for a more particular account of the various forms of ſtirrups, ſcrewed rods, and other iron work for carrying tie-beams, &c.

As for thoſe that are neceſſary for the turning joints of great engines conſtructed of timber, they make no part of the art of carpentry.

42
Examples
of different
pieces of
carpentry.

After having attempted to give a ſyſtematic view of the principles of framing carpentry, we ſhall conclude, by giving ſome examples which will illuſtrate and confirm the foregoing principles.

43
Roof of
Greenwich
chapel.

Fig. 38. is the roof of the chapel of the Royal Hoſpital at Greenwich, conſtructed by Mr S. Wyatt

	Inches Scantling.
AA, Is the tie-beam, 57 feet long, ſpanning 51 feet clear - - - -	14 by 12
CC, Queen-poſts - - - -	9×12
D, Braces - - - - -	9×7
E, Truſs beam - - - -	10×7
F, Straining piece - - - -	6×7
G, Principal rafters - - -	10×7
H, A cambered beam for the platform -	9.7
B, An iron ſtring, ſupporting the tie-beam	2×2

The truſſes are 7 feet apart, and the whole is covered with lead, the boarding being ſupported by horizontal ledgers *h*, *h*, of 6 by 4 inches.

This is a beautiful roof, and contains leſs timber than moſt of its dimenſions. The parts are all diſpoſed with great judgment. Perhaps the iron rod is unneceſſary; but it adds great ſtiffneſs to the whole.

The iron ſtraps at the rafter feet would have had more effect if not ſo oblique. Thoſe at the head of the poſts are very effective.

We may obſerve, however, that the joints between the ſtraining beam and its braces are not of the beſt kind, and tend to bruiſe both the ſtraining beam and the truſs beam above it.

44
St Paul's,
Covent
Garden.

Fig. 39. the roof of St Paul's, Covent Garden, conſtructed by Mr Wapſhot in 1796.

AA, Tie-beam ſpanning 50 feet 2 inches	16.12
B, Queen-poſt - - - - -	9×8
C, Truſs beam - - - - -	10×8
D, King-poſt (14 at the joggle) - -	9×8
E, Brace - - - - - - -	8×7½
FF, Principal brace (at bottom) - -	10×8½
HH, Principal rafter (at bottom) -	10×8½
gg, Studs ſupporting the rafter - -	8×8

This roof far excels the original one put up by Inigo Jones. One of its truſſes contains 198 feet of timber. One of the old roof had 273, but had many inactive timbers, and others ill diſpoſed. (*N. B.* The figure which we gave of it in the article Roof, copied from Price,

Price, is very erroneous). The internal truſs FCF is admirably contrived for ſupporting the exterior rafters, without any preſſure on the far projecting ends of the tie-beam. The former roof had bent them greatly, ſo as to appear ungraceful.

We think that the camber (ſix inches) of the tie-beam is rather hurtful; becauſe, by ſettling, the beam lengthens; and this muſt be accompanied by a *conſiderable* ſinking of the roof. This will appear by calculation.

45 Birmingham theatre.

Fig. 40. the roof of Birmingham theatre, conſtructed by Mr Geo. Saunders. The ſpan is 80 feet clear, and the truſſes are 10 feet apart.

A, Is an oak corbel	9×5
B, Inner plate	9×9
C, Wall plate	8×5½
D, Pole plate	7×5
E, Beam	15×15
F, Straining beam	12×9
G, Oak king-poſt (in the ſhaft)	9×9
H, Oak queen-poſt (in the ſhaft)	7×9
I, Principal rafters	9×9
K, Common ditto	4×2½
L, Principal braces	9 and 6×9
M, Common ditto	6×9
N, Purlins	7×5
Q, Straining ſill	5½×9.

This roof is a fine ſpecimen of Britiſh carpentry, and is one of the boldeſt and lighteſt roofs in Europe. The ſtraining ſill Q gives a firm abutment to the principal braces, and the ſpace between the poſts is 19½ feet wide, affording roomy workſhips for the carpenters and other workmen connected with a theatre. The contrivance for taking double hold of the wall, which is very thin, is excellent. There is alſo added a beam (marked R), bolted down to the tie-beams. The intention of this was to prevent the total failure of ſo bold a truſſing, if any of the tie-beams ſhould fail at the end by rot.

46 Drury Lane theatre.

Akin to this roof is fig. 41. the roof of Drury Lane theatre, 80 feet 3 inches in the clear, and the truſſes 15 feet apart, conſtructed by Mr Edward Grey Saunders.

A, Beams	10 by 7
B, Rafters	7×7
C, King-poſts	12×7
D, Struts	5×7
E, Purlins	9×5
G, Pole plates	5×5
I, Common rafters	5×4
K, Tie-beam to the main truſs	15×12
L, Poſts to ditto	15×12
M, Principal braces to ditto	14 and 12×12
N, Struts	8×12
P, Straining beams	12×12

The main beams are truſſed in the middle ſpace with oak truſſes 5 inches ſquare. This was neceſſary for its width of 32 feet, occupied by the carpenters, painters, &c. The great ſpace between the truſſes affords good ſtore-rooms, dreſſing-rooms, &c.

It is probable that this roof has not its equal in the world for lightneſs, ſtiffneſs, and ſtrength. The main truſs is ſo judiciouſly framed, that each of them will ſafely bear a load of near 300 tons; ſo it is not likely that they will ever be quarter loaded. The diviſion of the whole into three parts makes the exterior roofings very light. The ſtrains are admirably kept from the walls, and the walls are even firmly bound together by the roof. They alſo take off the dead weight from the main truſs one-third.

47 Remarks

The intelligent reader will perceive that all theſe roofs are on one principle, depending on a truſs of three pieces and a ſtraight tie-beam. This is indeed the great principle of a truſs, and is a ſtep beyond the roof with two rafters and a king-poſt. It admits of much greater variety of forms, and of greater extent. We may ſee that even the middle part may be carried to any ſpace, and yet be flat at top; for the truſs beam may be ſupported in the middle by an inverted king-poſt (of timber, not iron), carried by iron or wooden ties from its extremities: And the ſame ties may carry the horizontal tie-beam K; for till K be torn aſunder, or M, M, and P be crippled, nothing can fail.

The roof of St Martin's church in the Fields is conſtructed on good principles, and every piece properly diſpoſed. But although its ſpan does not exceed 40 feet from column to column, it contains more timber in a truſs than there is in one of Drury-Lane theatre. The roof of the chapel at Greenwich, that of St Paul's, Covent Garden, that of Birmingham, and that of Drury Lane theatres, form a ſeries gradually more perfect. Such ſpecimens afford excellent leſſons to the artiſts. We therefore account them a uſeful preſent to the public.

48 Project by Mr Nicho ſon.

There is a very ingenious project offered to the public by Mr Nicholſon (*Carpenter's Aſſiſtant*, p. 68.) He propoſes iron rods for king-poſts, queen-poſts, and all other ſituations where beams perform the office of ties. This is in proſecution of the notions which we publiſhed in the article Roof of the *Encycl.* (ſee nº 36, 37.) He receives the feet of the braces and ſtruts in a ſocket very well connected with the foot of his iron king-poſt; and he ſecures the feet of his queen-poſts from being puſhed inwards, by interpoſing a ſtraining ſill. He does not even mortiſe the foot of his principal rafter into the end of the tie-beam, but ſets it in a ſocket like a ſhoe, at the end of an iron bar, which is bolted into the tie-beam a good way back. All the parts are formed and diſpoſed with the preciſion of a perſon thoroughly acquainted with the ſubject; and we have not the ſmalleſt doubt of the ſucceſs of the project, and the complete ſecurity and durability of his roofs; and we expect to ſee many of them executed. We abound in iron, but we muſt ſend abroad for building timber. This is therefore a valuable project; at the ſame time, however, let us not over-rate its value. Iron is but about 12 times ſtronger than red fir, and is more than 12 times heavier; nor is it cheaper, weight for weight, or ſtrength for ſtrength.

Our illuſtrations and examples have been chiefly taken from roofs, becauſe they are the moſt familiar inſtances of the difficult problems of the art. We could have wiſhed for more room even on this ſubject. The conſtruction of dome roofs has been (we think) miſtaken, and the difficulty is much leſs than is imagined. We mean in reſpect of ſtrength; for we grant that the obliquity of the joints, and a general intricacy, increaſes the trouble of workmanſhip exceedingly. Another opportunity may perhaps occur for conſidering this ſubject.

49 ooden idges. Wooden bridges form another claſs equally difficult and important; but our limits are already overpaſſed, and will not admit them. The principle on which they ſhould all be conſtructed, without exception, is that of a truſs, avoiding all lateral bearings on any of the timbers. In the application of this principle, we muſt farther remark, that the angles of our truſs ſhould be as acute as poſſible; therefore we ſhould make it of as few and as long pieces as we can, taking care to prevent the bending of the truſs beams by bridles, which embrace them, but without preſſing them to either ſide. When the truſs conſiſts of many pieces, the angles are very obtuſe; and the thruſts increaſe nearly in the duplicate proportion of the number of angles. The proper maxims will readily occur to the artiſt who conſiders with attention the ſpecimens of centres or coombs, which we ſhall give in the article Centre.

50 raming of reat levers. With reſpect to the frames of carpentry which occur in engines and great machines, the varieties are ſuch that it would require a volume to treat of them properly. The principles are already laid down; and if the reader be really intereſted in the ſtudy, he will engage in it with ſerіouſneſs, and cannot fail of being inſtructed. We recommend to his conſideration, as a ſpecimen of what may be done in this way, the working beam of Hornblower's ſteam-engine (ſee *Steam-Engine*, n° 84. *Encycl.*) When the beam muſt act by chains hung from the upper end of arch heads, the framing there given ſeems very ſcientifically conſtructed; at the ſame time, we think that a ſtrap of wrought iron, reaching the whole length of the upper bar (ſee the figure), would be vaſtly preferable to thoſe partial plates which the engineer has put there, for the bolts will ſoon work looſe.

But when arches are not neceſſary, the form employed by Mr Watt is vaſtly preferable, both for ſimplicity and for ſtrength. It conſiſts of a ſimple beam AB (fig. 42.), having the gudgeon C on the upper ſide. The two piſton-rods are attached to wrought iron joints A and B. Two ſtrong ſtruts DC, EC reſt on the upper ſide of the gudgeon, and carry an iron ſtring ADEB, conſiſting of three pieces, connected with the ſtruts by proper joints of wrought iron. A more minute deſcription is not needed for a clear conception of the principle. No part of this is expoſed to a croſs ſtrain; even the beam AB might be ſawed through at the middle. The iron ſtring is the only part which is ſtretched; for AC, DC, EC, BC, are all in a ſtate of compreſſion. We have made the angles equal, that all may be as great as poſſible, and the preſſure on the ſtruts and ſtrings a minimum. Mr Watt makes them much lower, as A *de* B, or A δ ε B. But this is for economy, becauſe the ſtrength is almoſt inſuperable. It might be made with wooden ſtrings; but the workmanſhip of the joints would more than compenſate the cheapneſs of the materials.

We offer this article to the public with deference, and we hope for an indulgent reception of our eſſay on a ſubject which is in a manner new, and would require much ſtudy. We have beſtowed our chief attention on the ſtrength of the conſtruction, becauſe it is here that perſons of the profeſſion have the moſt ſcanty information. We beg them not to conſider our obſervations as too refined, and that they will ſtudy them with care. One principle runs through the whole; and when that is clearly conceived and familiar to the mind, we venture to ſay that the practitioner will find it of eaſy application, and that he will improve every performance by a continual reference to it. 51 Concluſion.

If this attempt to inſtruct our moſt valuable and much eſteemed artiſts ſhall appear to meet with their approbation, it may encourage us to engage in the ſerious taſk of compoſing a ſyſtem on the ſubject. But this is a great work, and will require much time and liberal contribution of knowledge from the eminent carpenters who do honour to this country by their works.

CASCABEL, the knob or button of metal behind the breech of a cannon, as a kind of handle by which to elevate and direct the piece; to which ſome add the fillet and ogees as far as the baſe-ring.

CASEMATE, or Cazemate, in fortification, a kind of vault or arch of ſtone-work, in that part of the flank of a baſtion next the curtain; ſerving as a battery to defend the face of the oppoſite baſtion, and the moat or ditch.

It is now ſeldom uſed, becauſe the batteries of the enemy are apt to bury the artillery of the caſemate in the ruins of the vault; beſide, the great ſmoke made by the diſcharge of the cannon renders it intolerable to the men. So that, inſtead of the ancient covered caſemates, later engineers have contrived open ones, only guarded by a parapet, &c.

Casemate is alſo uſed for a well with ſeveral ſubterraneous branches, dug in the paſſage of the baſtion, till the miner is heard at work, and air given to the mine.

CASSINI (James), a celebrated French aſtronomer, was born at Paris February 18. 1677, being the younger ſon of Johannes Dominicus Caſſini, of whom ſome account has been given in the *Encyclopædia*.

After his firſt ſtudies in his father's houſe, in which it is not to be ſuppoſed that mathematics and aſtronomy would be neglected, he was ſent to ſtudy philoſophy at the Mazarine college, where the celebrated Varignon was then profeſſor of mathematics. From the aſſiſtance of this eminent young man Caſſini profited ſo well, that at 15 years of age he ſupported a mathematical theſis with great honour. At the age of 17 he was admitted a member of the Academy of Sciences; and the ſame year he accompanied his father in a journey to Italy, where he aſſiſted him in the verification of the meridian at Bologna and other meaſurements. On his return he performed ſimilar operations in a journey into Holland, where he diſcovered ſome errors in the meaſure of the earth by Snell, the reſult of which was communicated to the Academy in 1702. He made alſo a viſit to England in 1696, where he was made a member of the Royal Society. In 1712 he ſucceeded his father as aſtronomer royal at the obſervatory of Paris. In 1717 he gave to the Academy his reſearches on the diſtance of the fixed ſtars; in which he ſhewed that the whole annual orbit, of near 200 millions of miles diameter, is but as a point in compariſon of that diſtance. The ſame year he communicated alſo his diſcoveries concerning the inclination of the orbits of the ſatellites in general, and eſpecially of thoſe of Saturn's ſatellites and ring. In 1725 he undertook to determine the cauſe of the moon's libration, by which ſhe ſhews ſometimes a little towards one ſide, and ſometimes a little on the other, of that half which is commonly behind or hid from our view.

In 1732 an important queſtion in aſtronomy exerciſed the ingenuity of our author. His father had determined, by his obſervations, that the planet Venus revolved about her axis in the ſpace of 23 hours; and M. Bianchini had publiſhed a work in 1729, in which he ſettled the period of the ſame revolution at 24 days 8 hours. From an examination of Bianchini's obſervations which were upon the ſpots in Venus, he diſcovered that he had intermitted his obſervations for the ſpace of three hours, from which cauſe he had probably miſtaken new ſpots for the old ones, and ſo had been led into the miſtake. The probability is, that both had fallen into ſome miſtake, or that they had proceeded on very different principles; for otherwiſe ſuch different reſults are wholly unaccountable. Dr Herſchel ſeems ſatisfied that the period of the revolution is leſs than Bianchini has made; but he does not ſay what it is, or that it is not much greater than it was ſuppoſed by Caſſini. Our author, after he had convicted Bianchini, as he thought, of error, determined the nature and quantity of the acceleration of the motion of Jupiter at half a ſecond per year, and of that of the retardation of Saturn at two minutes per year; that theſe quantities would go on increaſing for 2000 years, and then would decreaſe again. In 1740 he publiſhed his Aſtronomical Tables, and his Elements of Aſtronomy; very extenſive and accurate works.

Although aſtronomy was the principal object of our author's conſideration, he did not confine himſelf abſolutely to that branch, but made occaſional excurſions into other fields. We owe alſo to him, for example, Experiments on Electricity, or the Light produced by Bodies by Friction; Experiments on the Recoil of Fire-arms; Reſearches on the Riſe of the Mercury in the Barometer at different Heights above the Level of the Sea; Reflections on the perfecting of Burning-glaſſes; and other Memoirs.

The French Academy had properly judged, that one of its moſt important objects was the meaſurement of the earth. In 1669 Picard meaſured a little more than a degree of latitude to the north of Paris; but as that extent appeared too ſmall from which to conclude the whole circumference with ſufficient accuracy, it was reſolved to continue that meaſurement on the meridian of Paris to the north and the ſouth, through the whole extent of the country. Accordingly, in 1683, the late M. de la Hire continued that on the north ſide of Paris, and the older Caſſini that on the ſouth ſide. The latter was aſſiſted in 1700 in the continuation of this operation by his ſon our author. The ſame work was farther continued by the ſame academicians; and, finally, the part left unfiniſhed by De la Hire in the north was finiſhed in 1718 by our author, with the late Maraldi, and De la Hire the younger.

Theſe operations produced a conſiderable degree of preciſion. It appeared alſo, from this meaſured extent of ſix degrees, that the degrees were of different lengths in different parts of the meridian; and in ſuch ſort that our author concluded, in the volume publiſhed for 1718, that they decreaſed more and more towards the pole, and that therefore the figure of the earth was that of an oblong ſpheroid, or having its axis longer than the equatorial diameter. He alſo meaſured the perpendicular to the ſame meridian, and compared the meaſured diſtance with the differences of longitude as before determined by the eclipſes of Jupiter's ſatellites: whence he concluded that the length of the degrees of longitude was ſmaller than it would be on a ſphere, and that therefore again the figure of the earth was an oblong ſpheroid, contrary to the determination of Newton by the theory of gravity. Though Newton was of all men the moſt averſe from controverſy, the other mathematicians in Britain did not tamely ſubmit to concluſions in direct oppoſition to the fundamental doctrine of a philoſopher of whoſe talents the nation was juſtly proud. The conſequence was, that the French government ſent two different ſets of meaſurers, the one to meaſure a degree at the equator, the other at the polar circle; and the compariſon of the whole determined the figure to be an oblate ſpheroid, contrary to Caſſini's determination.

After a long and laborious life, James Caſſini died in April 1756, in conſequence of a fall, and was ſucceeded in the Academy and Obſervatory by the ſubject of the following article. He publiſhed, A Treatiſe on the Magnitude and Figure of the Earth; as alſo, The Elements or Theory of the Planets, with Tables; beſide an infinite number of papers in the Memoirs of the Academy, from the year 1699 to 1755.

Cassini de Thury (Ceſar François), a celebrated French aſtronomer, director of the obſervatory, penſioner aſtronomer, and member of moſt of the learned ſocieties of Europe, was born at Paris June 17. 1714, being the ſecond ſon of James Caſſini, the ſubject of the preceding memoir, whoſe occupations and talents he inherited and ſupported with great honour. He received his firſt leſſons in aſtronomy and mathematics from MM. Maraldi and Camus; and made ſuch a rapid progreſs, that when he was not more than ten years of age he calculated the phaſes of a total eclipſe of the ſun. At the age of eighteen he accompanied his father in his two journeys undertaken for drawing the perpendicular to the obſervatory meridian from Straſbourg to Breſt. From that time a general chart of France was deviſed; for which purpoſe it was neceſſary to traverſe the country by ſeveral lines parallel and perpendicular to the meridian of Paris, and our author was charged with the conduct of this buſineſs; in which he was ſo ſcrupulous as to meaſure again what had been meaſured by his father. This great work was publiſhed in 1740, with a chart ſhewing the new meridian of Paris, by two different ſeries of triangles, paſſing along the ſea coaſts to Bayonne, traverſing the frontiers of Spain to the Mediterranean and Antibes, and thence along the eaſtern limits of France to Dunkirk, with parallel and perpendicular lines deſcribed at the diſtance of 6000 toiſes from one another, from ſide to ſide of the country.

A tour which, in 1741, our author made in Flanders, in the train of the king, gave riſe, at his majeſty's inſtance, to the chart of France; relative to which Caſſini publiſhed different works, as well as a great number of the ſheets of the chart itſelf. In 1761 he undertook an expedition into Germany, for the purpoſe of continuing to Vienna the perpendicular of the Paris

ris meridian; to unite the triangles of the chart of France with the points taken in Germany; to prepare the means of extending into that country the ſame plan as in France; and thus to eſtabliſh ſucceſſively for all Europe a moſt uſeful uniformity.—Our author was at Vienna the 6th of June 1761, the day of the tranſit of the planet Venus over the ſun, of which he obſerved as much as the ſtate of the weather would permit him to do, and publiſhed the account of it in his *Voyage en Allemagne*.

Finally, M. Caſſini, always meditating the perfection of his grand deſign, profited of the peace of 1783 to propoſe the joining of certain points taken upon the Engliſh coaſt with thoſe which had been determined on the coaſt of France, and thus to connect the general chart of the latter with that of the Britiſh iſles, like as he had before united it with thoſe of Flanders and Germany. The propoſal was favourably received by the Engliſh government, and preſently carried into effect under the direction of the Royal Society, the execution being committed to the late General Roy. See the life of that general in this *Supplement*.

Between the years 1735 and 1770, M. Caſſini publiſhed, in the volumes of Memoirs of the French Academy, a prodigious number of pieces, conſiſting chiefly of aſtronomical obſervations and queſtions; among which are obſervable, reſearches concerning the parallax of the ſun, the moon, Mars, and Venus; on aſtronomical refractions, and the effect cauſed in their quantity and laws by the weather; numerous obſervations on the obliquity of the ecliptic, and on the law of its variations. In ſhort, he cultivated aſtronomy for fifty years, the moſt important for that ſcience that ever elapſed for the magnitude and variety of objects, in which he commonly ſuſtained a principal ſhare.

M. Caſſini was of a very ſtrong and vigorous conſtitution, which carried him through the many laborious operations in geography and aſtronomy which he conducted. An habitual retention of urine, however, rendered the laſt twelve years of his life very painful and diſtreſſing, till it was at length terminated by the ſmall-pox the 4th of September 1784, in the 71ſt year of his age. He was ſucceeded in the academy, and as director of the obſervatory, by his only ſon John-Dominic Caſſini, the fourth in order of direct deſcent who has filled that honourable ſtation.

CASTRAMETATION, the art or act of encamping an army.

CATACAUSTICS, or CATACAUSTIC CURVES, in the higher geometry, are the ſpecies of cauſtic curves formed by reflection.

CATACOUSTICS, or CATAPHONICS, is the ſcience of reflected ſounds; or that part of acouſtics which treats of the properties of echoes.

CATALOGUES OF BOOKS, is a ſubject of which a very curious hiſtory has been given to the world by Profeſſor Beckmann. In the Encyclopædia mention has been made of ſome of the moſt valuable catalogues, their defects pointed out, and rules given for making them more perfect; but nothing has there been ſaid of their origin, or of the uſes which might be made of the oldeſt catalogues.

According to the Profeſſor, George Willer, whom ſome improperly call Viller, and others Walter, a bookſeller at Augſburg, who kept a very large ſhop, and frequented the Franckfort fairs, firſt fell upon the plan of cauſing to be printed, before every fair, a catalogue of all the new books, in which the ſize and printers names were marked. Le Mire, better known under the name of Miræus, ſays that catalogues were firſt printed in the year 1554; but Labbe (A), Reimann (B), and Heumann (C), who took their information from Le Mire, make the year erroneouſly to be 1564. Willer's catalogues were printed till the year 1592 by Nicol. Baſſæus, printer at Franckfort. Other bookſellers, however, muſt have ſoon publiſhed catalogues of the like kind, though that of Willer continued a long time to be the principal.

In all theſe catalogues, which are in quarto and not paged, the following order is obſerved. The Latin books occupy the firſt place, beginning with the Proteſtant theological works, perhaps becauſe Willer was a Lutheran; then come the Catholic; and after theſe, books of juriſprudence, medicine, philoſophy, poetry, and muſic. The ſecond place is aſſigned to German books, which are arranged in the ſame manner.

The bookſellers of Leipſic ſoon perceived the advantage of catalogues, and began not only to reprint thoſe of Franckfort, but alſo to enlarge them with many books which had not been brought to the fairs in that city. Our author had for ſome time in his cuſtody, *Catalogus univerſalis pro nundinis Francofurtenſibus vernalibus, de anno* 1600; or, A catalogue of all the books on ſale in Book-ſtreet, Franckfort, and alſo of the books publiſhed at Leipſic, which have not been brought to Franckfort, with the permiſſion of his highneſs the elector of Saxony, to thoſe new works which have appeared at Leipſic. Printed at Leipſic by Abraham Lamberg, and to be had at his ſhop. On the September catalogue of the ſame year, it is ſaid that it is printed from the Franckfort copy with additions. He found an Imperial privilege for the firſt time on the Franckfort September catalogue of 1616: *Cum gratia et privilegio ſpeciali ſ. caeſ. maj. Proſtat apud J. Krugerum Auguſtanum.*

Reimmann ſays, that after Willer's death the catalogue was publiſhed by the Leipſic bookſeller Henning Groſſe, and by his ſon and grandſon. The council of Franckfort cauſed ſeveral regulations to be iſſued reſpecting catalogues; an account of which may be ſeen in D. Orth's *Treatiſe on the Imperial Fairs at Franckfort*. After the buſineſs of bookſelling was drawn from Franckfort to Leipſic, occaſioned principally by the reſtrictions to which it was ſubjected at the former by the cenſors, no more catalogues were printed there; and the ſhops in Book-ſtreet were gradually converted into taverns (D).

“ In the 16th century there were few libraries; and theſe, which did not contain many books, were in monaſteries,

Catalogues of Books.

naſteries, and conſiſted principally of theological, philoſophical, and hiſtorical works, with a few, however, on juriſprudence and medicine; while thoſe which treated of agriculture, manufactures, and trade, were thought unworthy of the notice of the learned, or of being preſerved in large collections. The number of theſe works was, nevertheleſs, far from being inconſiderable; and at any rate, many of them would have been of great uſe, as they would have ſerved to illuſtrate the inſtructive hiſtory of the arts. Catalogues which might have given occaſion to inquiries after books, that may be ſtill ſomewhere preſerved, have ſuffered the fate of tomb-ſtones, which, being waſted and crumbled to pieces by the deſtroying hand of time, become no longer legible. A complete ſeries of them perhaps is nowhere to be found, at leaſt I do not remember (ſays the Profeſſor) to have ever ſeen one in any library."

This loſs, however, he thinks, might be in ſome meaſure ſupplied by the catalogues of Cleſs and Draudius; who, by the deſire of ſome bookſellers, collected together all the catalogues which had been publiſhed at the different fairs in different years. The work of Cleſs has the following title: *Unius ſæculi ejuſque virorum litteratorum monumentis tum florentiſſimi, tum fertiliſſimi, ab anno* 1500 *ad* 1602 *nundinarum autumnalium incluſive, elenchus conſummatiſſimus—deſumtus partim ex ſingularum nundinarum catalogis, partim ex bibliothecis.* Auctore Joanne Cleſſio, Wineccenſi, Hannoio, philoſopho ac medico.—By the editor's preface, it appears that the firſt edition was publiſhed in 1592. The order is almoſt the ſame as that obſerved by Willer in his catalogues.

The work of Draudius, which was printed in ſeveral quarto volumes for the firſt time in 1611, and afterwards in 1625, is far larger, more complete, and more methodical. Our author, however, confeſſes, that he never ſaw a perfect copy of either edition. This catalogue conſiſts of three parts; of which the firſt has the title of *Bibliotheca claſſica, ſive Catalogus officinalis, in quo ſinguli ſingularum facultatum ac profeſſionum libri, qui in quavis fere lingua extant—recenſentur; uſque ad annum* 1624 *incluſive.* Auctore M. Georgio Draudio.—It contains Latin works on theology, juriſprudence, medicine, hiſtory, geography, and politics. The copy in the library of the univerſity of Gottingen ends at page 1304, which has, however, a catch-word, that ſeems to indicate a deficiency.—The ſecond part is intitled, *Bibliotheca claſſica ſive Catalogus officinalis, in quo philoſophici artiumque adeo humaniorum, poetici etiam et muſici libri uſque ad annum* 1624 *continentur.* This part, containing Latin books alſo, begins at page 1298, and ends with page 1654, which is followed by an index of all the authors mentioned.—A ſmaller volume, of 302 pages, without an index, has for title, *Bibliotheca exotica, ſive Catalogus officinalis librorum peregrinis linguis uſualibus ſcriptorum.* And a third part, forming 759 pages, beſides an index of the authors, is called, *Bibliotheca librorum Germanicorum claſſica;* that is, A catalogue of all the books printed in the German language till the year 1625.

We have reaſon to believe that there are other editions of this catalogue than thoſe mentioned by Profeſſor Beckmann; and it might become ſome prince or great man, for it is not a work for a bookſeller, to compare all the editions together, and publiſh a new one more correct than any that is at preſent extant. This indeed would be an expenſive and not an eaſy taſk; for our author obſerves, that all the oldeſt catalogues had the ſame faults as thoſe of later date, and that theſe faults have been copied by Draudius. Many books are mentioned which were never printed, and many titles, names, and dates, are given incorrectly; but Draudius nevertheleſs is well worth the attention of any one who may be inclined to employ his time and ingenuity on the hiſtory of literature; and his work certainly was of uſe to Haller when he compoſed his *Bibliotheca.*

Catalogues of the Stars.

Catalogues of the Stars, have uſually been diſpoſed, either as collected into certain figures called *conſtellations*, or according to their right aſcenſions, that is, the order of their paſſing over the meridian.

Of the principal catalogues, according to the firſt of theſe forms, an account has been given in the *Encyclopædia.* The firſt catalogue, we believe, that was printed in the new or ſecond form, according to the order of the right aſcenſions, is that of De la Caille, given in his Ephemerides for the ten years between 1755 and 1765, and printed in 1755. It contains the right aſcenſions and declinations of 307 ſtars, adapted to the beginning of the year 1750. In 1757 De la Caille publiſhed his *Aſtronomiæ Fundamenta*, containing a catalogue of the right aſcenſions and declinations of 398 ſtars, likewiſe adapted to the beginning of 1750. And in 1763, the year after his death, was publiſhed the *Cœlum Auſtrale Stelliferum* of the ſame author; containing a catalogue of the places of 1942 ſtars, all ſituated to the ſouthward of the tropic of Capricorn, and obſerved by him while he was at the Cape of Good Hope in 1751 and 1752; their places being alſo adapted to the beginning of 1750. In the ſame year was publiſhed his Ephemerides for the ten years between 1765 and 1775; in the introduction to which are given the places of 515 zodiacal ſtars, all deduced from the obſervations of the ſame author; the places adapted to the beginning of the year 1765.

In the Nautical Almanac for 1773, is given a catalogue of 387 ſtars, in right aſcenſion, declination, longitude, and latitude, derived from the obſervations of the late celebrated Dr Bradley, and adjuſted to the beginning of the year 1760. This ſmall catalogue, and the reſults of about 1200 obſervations of the moon, are all that the public have yet ſeen of the multiplied labours of this moſt accurate and indefatigable obſerver, although he has now (1798) been dead upwards of 38 years.

In 1775 was publiſhed a thin volume, intitled *Opera Inedita*, containing ſeveral papers of the late Tobias Mayer, and among them a catalogue of the right aſcenſions and declinations of 998 ſtars, which may be occulted by the moon and planets; the places being adapted to the beginning of the year 1756.

At the end of the firſt volume of "Aſtronomical Obſervations made at the Royal Obſervatory at Greenwich," publiſhed in 1776, Dr Maſkelyne, the preſent aſtronomer royal, has given a catalogue of the places of 34 principal ſtars, in right aſcenſion and north polar diſtance, adapted to the beginning of the year 1770.

Theſe being the reſult of ſeveral years repeated obſervations, made with the utmoſt care and the beſt inſtruments, it may be preſumed are exceedingly accurate.

In 1782, M. Bode of Berlin publiſhed a very extenſive catalogue of 5058 of the fixed ſtars, collected from

Catalogues of the Stars.

from the obſervations of Flamſteed, Bradley, Hevelius, Mayer, De la Caille, Meſſier, Monnier, D'Arqueir, and other aſtronomers; all adapted to the beginning of the year 1780; and accompanied with a celeſtial atlas or ſet of maps of the conſtellations, engraved in a moſt delicate and beautiful manner.

To theſe may be added Dr Herſchel's catalogue of double ſtars, printed in the Phil. Tranſ. for 1782 and 1783; Meſſier's nebulæ and cluſters of ſtars, publiſhed in the *Connoiſſance des Temps* for 1784; and Herſchel's catalogue of the ſame kind, given in the Phil. Tranſ. for 1786.

In 1789 Mr Francis Wollaſton publiſhed "A Specimen of a General Aſtronomical Catalogue, in Zones of North-polar Diſtance, and adapted to January 1. 1790." Theſe ſtars are collected from all the catalogues before-mentioned, from that of Hevelius downwards. This work contains five diſtinct catalogues; viz. Dr Maſkelyne's new catalogue of 36 principal ſtars; a general catalogue of all the ſtars, in zones of north-polar diſtance; an index to the general catalogue; a catalogue of all the ſtars, in the order in which they paſs the meridian; and a catalogue of zodiacal ſtars, in longitude and latitude.

Finally, in 1792, Dr Zach publiſhed at Gotha, *Tabulæ Motuum Solis;* to which is annexed a new catalogue of the principal fixed ſtars, from his own obſervations made in the years 1787, 1788, 1789, 1790. This catalogue contains the right aſcenſions and declinations of 381 principal ſtars, adapted to the beginning of the year 1800.—*Hutton's Mathematical Dictionary*.

Beſides theſe two methods of forming *catalogues* of the ſtars, Dr Herſchel has conceived a new one, in which the comparative brightneſs of the ſtars is accurately expreſſed. It is long ſince aſtronomers were firſt led to arrange the ſtars in claſſes of different magnitudes by their various degrees of brilliancy or luſtre. Brightneſs and ſize have at all times been conſidered as ſynonymous terms; ſo that the brighteſt ſtars have been referred to the claſs comprehending thoſe of the firſt magnitude; and as the ſubſequent orders of ſtars have been ſuppoſed to decreaſe in luſtre, their magnitude has been determined in the ſame decreaſing progreſſion: but the want of ſome fixed and ſatisfactory ſtandard of luſtre has been the ſource of conſiderable confuſion and uncertainty in ſettling the relative magnitudes of the ſtars. A ſtar marked 1. 2m. is ſuppoſed to be between the firſt and ſecond magnitude; but 2. 1m. intimates that the ſtar is nearly of the ſecond magnitude, and that it partakes ſomewhat of the luſtre of a ſtar of the firſt order. Such ſubdiviſions may be of ſome uſe in aſcertaining ſtars of the firſt, ſecond, and third claſſes; but the expreſſions 5m, 5.6m, 6.5m, 6m, muſt be very vague and indefinite. Dr Herſchel obſerves that he has found them ſo in fact; and he therefore conſiders this method of pointing out the different luſtre of ſtars as a reference to an imaginary ſtandard. If any dependence could be placed on this method of magnitudes, "it would follow, that no leſs than eleven ſtars in the conſtellation of the Lion, namely, β σ τ ξ A *b c d* 54, 48, 72, had all undergone a change in their luſtre ſince Flamſteed's time: For if the idea of magnitudes had been a clear one, our author, who marked β 1.2m. and γ 2m. ought to be underſtood to mean that β is larger than γ; but we now find that actually γ is larger than β. Every one of the eleven ſtars (ſays Dr Herſchel) which I have pointed out may be reduced to the ſame contradiction."

Catalogues of the Stars.

The author has pointed out the inſtances of the inſufficiency of this method, and of the uncertain concluſions that are deduced from it, in determining the comparative brightneſs of ſtars found not only in Mr Flamſteed's catalogue, but alſo in the catalogues of other aſtronomers. It is ſufficiently apparent that the preſent method of expreſſing the brightneſs of the ſtars is very defective. Dr Herſchel therefore propoſes a different mode, that is more preciſe and ſatisfactory.

"I place each ſtar (he ſays), inſtead of giving its magnitude, into a ſhort ſeries, conſtructed upon the order of brightneſs of the neareſt proper ſtars. For inſtance, to expreſs the luſtre of D, I ſay CDE. By this ſhort notation, inſtead of referring the ſtar D to an imaginary uncertain ſtandard, I refer it to a preciſe and determined exiſting one. C is a ſtar that has a greater luſtre than D, and E is another of leſs brightneſs than D. Both C and E are neighbouring ſtars, choſen in ſuch a manner that I may ſee them at the ſame time with D, and therefore may be able to compare them properly. The luſtre of C is in the ſame manner aſcertained by BCD; that of B by ABC; and alſo the brightneſs of E by DEF; and that of F by EFG.

"That this is the moſt natural, as well as the moſt effectual way to expreſs the brightneſs of a ſtar, and by that means to detect any change that may happen in its luſtre, will appear, when we conſider what is requiſite to aſcertain ſuch a change. We can certainly not wiſh for a more deciſive evidence, than to be aſſured, by actual inſpection, that a certain ſtar is now no longer more or leſs bright than ſuch other ſtars to which it has been formerly compared; provided we are at the ſame time aſſured that thoſe other ſtars remain ſtill in their former unaltered luſtre. But if the ſtar D will no longer ſtand in its former order CDE, it muſt have undergone a change; and if that order is now to be expreſſed by CED, the ſtar has loſt ſome part of its luſtre; if, on the contrary, it ought now to be denoted by DCE, its brightneſs muſt have had ſome addition. Then, if we ſhould doubt the ſtability of C and E, we have recourſe to the orders BCD and DEF, which expreſs their luſtre; or even to ABC and EFG, which continue the ſeries both ways. Now having before us the ſeries BCDEF, or if neceſſary even the more extended one ABCDEFG, it will be impoſſible to miſtake a change of brightneſs in D, when every member of the ſeries is found in its proper order except D."

In the author's journal or catalogue, in which the order of the luſtre of the ſtars is fixed, each ſtar bears its own proper name or number, *e. g.* "the brightneſs of the ſtar δ Leonis may be expreſſed by β δ ι Leonis, or better by 94—68—17 Leonis; theſe being the numbers which the three above ſtars bear in the Britiſh catalogue of fixed ſtars."

This method of arrangement occurred to Dr Herſchel ſo early as the year 1782; but he was diverted from the regular purſuit of it by a variety of other aſtronomical engagements. After many trials, he propoſed, in the Tranſactions of the Royal Society of London for 1796, the plan which appeared to him the moſt eligible. It is as follows:—Inſtead of denoting particular ſtars by letters, he makes uſe of numbers; and in his choice of the ſtars which are to expreſs the luſtre of any particular one, he directs his firſt view to perfect equality. When two ſtars ſeem to be ſimilar both in brightneſs and magnitude, he puts down their numbers together, ſeparated merely by a point, as 30.24 Leonis; but if two ſtars, which at firſt ſeemed alike in their luſtre, appeared on a longer inſpection to be different, and the preference ſhould be always decidedly in favour of the ſame ſtar, he ſeparates theſe ſtars by a comma, thus, 41,94 Leonis. This order muſt not be varied; nor can three ſuch ſtars, as 20, 40, 39, Libræ, admit of a different arrangement. If the ſtate of the heavens ſhould be ſuch as to require a different order in theſe numbers, we may certainly infer that a change has taken place in the luſtre of one or more of them. When two ſtars differ very little in brightneſs, but ſo that the preference of the one to the other is indiſputable, the numbers that expreſs them are ſeparated by a ſhort line, as 17—70 Leonis, or 68—17—70 Leonis. When two ſtars differ ſo much in brightneſs, that one or two other ſtars might be interpoſed between them, and ſtill leave ſufficient room for diſtinction, they are diſtinguiſhed by a line and comma, thus, —, or by two lines, as 32— —41 Leonis. A greater difference than this is denoted by a broken line, thus — — —29 Bootis. On the whole, the author obſerves, the marks and diſtinctions which he has adopted cannot poſſibly be miſtaken; "a point denoting equality of luſtre; a comma indicating the leaſt perceptible difference; a ſhort line to mark a decided but ſmall ſuperiority; a line and comma, or double line, to expreſs a conſiderable and ſtriking exceſs of brightneſs; and a broken line to mark any other ſuperiority which is to be looked upon as of no uſe in eſtimations that are intended for the purpoſe of directing changes."

The difficulties that attend this arrangement are not diſguiſed; but the importance and utility of it more than compenſate for the labour which it muſt neceſſarily require. By a method of this kind, many diſcoveries of changeable and periodical ſtars might probably have been made, which have eſcaped the moſt diligent and accurate obſervers. We might then, as the author ſuggeſts, be enabled to reſolve a problem in which we are all immediately concerned.

"Who, for inſtance, would not wiſh to know what degree of permanency we ought to aſcribe to the luſtre of our ſun? Not only the ſtability of our climates, but the very exiſtence of the whole animal and vegetable creation itſelf, is involved in the queſtion. Where can we hope to receive information upon this ſubject but from aſtronomical obſervations? If it be allowed to admit the ſimilarity of ſtars with our ſun as a point eſtabliſhed, how neceſſary will it be to take notice of the fate of our neighbouring *ſuns*, in order to gueſs at that of our own? That *ſtar*, which among the multitude we have dignified by the name of *ſun*, to-morrow may ſlowly begin to undergo a gradual decay of brightneſs, like β Leonis, α Ceti, α Draconis, δ Urſæ majoris, and many other diminiſhing ſtars that will be mentioned in my catalogues. It may ſuddenly increaſe, like the wonderful ſtar in the back of Caſſiopea's chair, and the no leſs remarkable one in the foot of Serpentarius; or gradually come on like β Geminorum, β Ceti, ζ Sagittarii, and many other increaſing ſtars, for which I alſo refer to my catalogues; and, laſtly, it may turn into a periodical one of 25 days duration, as Algol is one of three days, δ Cephei of five, β Lyræ of ſix, η Antinoi of ſeven days, and as many others as are of various periods."

Having thus explained the general principle on which this catalogue is formed, as we find it in the author's firſt memoir on the ſubject, we muſt refer the reader to the Doctor's own account for its particular arrangement; obſerving only that the catalogue ſubjoined comprehends nine conſtellations, which are arranged in alphabetical order, with the comparative brightneſs of the ſtars accurately ſtated. In a ſubſequent paper, publiſhed in the ſame volume, he has completely verified the utility of his method by experience, and ſhewn that there is no permanent change of luſtre in the ſtars. In the notes to his firſt catalogue he mentioned α Herculis as a periodical ſtar. By a ſeries of obſervations on this ſtar, compared with κ Ophiuchi, which was moſt conveniently ſituated for his purpoſe, he has been able not only to confirm this opinion, but to aſcertain its period. His obſervations are arranged in a table, by means of which he determines that this ſtar had gone through four ſucceſſive changes in an interval of 241 days; and therefore the duration of its period muſt be about 60 days and a quarter. This fact concurs with other circumſtances in evincing the rotatory motion of the ſtars on their axes. "Dark ſpots, or large portions of the ſurface, leſs luminous than the reſt, turned alternately in certain directions, either towards or from us, will account for all the phenomena of periodical changes in the luſtre of the ſtars, ſo ſatisfactorily, that we certainly need not look out for any other cauſe." If it be alledged that the periods in the change of luſtre of ſome ſtars, ſuch as Algol, β Lyræ, δ Cephei, and η Antinoi, are ſhort, being only 3, 5, 6, and 7 days reſpectively; while thoſe of *o* Ceti, and of the changeable ſtar in Hydra, and that in the neck of the Swan, are long, amounting to 331, 394, and 497 days; and that we cannot aſcribe phenomena ſo different in their duration to the ſame cauſe—it may be anſwered to this objection, that the force of it is founded on our limited acquaintance with the ſtate of the heavens. To the 7 ſtars, the periodical changes of which were before known, we may now add α Herculis, which performs a revolution of its changes in 60 days.

"The ſtep from the rotation of α Herculis to that of *o* Ceti is far leſs conſiderable than that from the period of Algol to the rotation of α Herculis; and thus a link in the chain is now ſupplied, which removes the objection that aroſe from the vacancy." The rotation of the fifth ſatellite of Saturn is proved by the change obſervable in its light; and "this variation of light, owing to the alternate expoſition of a more or leſs bright hemiſphere of this periodical ſatellite, plainly indicates that the ſimilar phenomenon of a changeable ſtar ariſes from the various luſtre of the different parts of its ſurface, ſucceſſively turned to us by its rotatory motion."

Beſides, we perceive a greater ſimilarity between the ſun and the ſtars, by means of the ſpots that muſt be admitted to exiſt on their ſurfaces, as well as on that of the ſun.

Dr Herſchel farther obſerves, that the ſtars, beſides a rotatory motion on their axes, may have other movements; "ſuch as nutations or changes in the inclination of their axes; which, added to bodies much flattened by quick rotatory motions, or ſurrounded by rings like Saturn, will eaſily account for many new phenomena that may then offer themſelves to our extended views." To this paper is likewiſe ſubjoined a catalogue of nine conſtellations; and the author promiſes to give the whole of them in ſucceſſive ſhort catalogues on the ſame plan.

CATENARIA, or CATENARY CURVE. See *Encycl.* and ARCH in this *Supplement*.

CATHARINE II Empreſs of all the Ruſſias, acted ſo conſpicuous a part on the theatre of the world; poſſeſſed ſuch uncommon powers of mind, highly cultivated by ſcience and literature; and was ſuch a patroneſs of ſcience and literature in others—that it cannot be deemed foreign from a work of this nature to give ſome account of the principal events of her more private life.

SOPHIA AUGUSTA FREDERICA, who, upon her marriage to the grandſon of Peter the great, aſſumed the name CATHARINA ALEXIEVNA, was born at *Stettin* on the 2d of May 1729. Her father was Chriſtian Auguſtus, prince of Anhalt Zerbſt Dornburg, at that time major general in the Pruſſian ſervice, commander in chief of the regiments of infantry, and governor of the town and fortreſs of Stettin. Her mother, who was born princeſs of Holſtein Eutin, was a woman of great parts and beauty, of nearly the ſame age with the prince-royal of Pruſſia, afterwards Frederic the Great, with whom ſhe kept up a regular correſpondence, and who afterwards contributed to the aggrandiſement of her daughter. This accompliſhed princeſs took upon herſelf the care of educating the young Sophia, whom ſhe brought up in the ſimpleſt manner, and would not ſuffer to exhibit the leaſt ſymptoms of that pride to which ſhe had ſome propenſity from her earlieſt childhood. The conſequence of this ſalutary reſtraint was, that good humour, intelligence, and ſpirit, were even then the ſtriking features of her youthful character. Being naturally addicted to reading, to reflection, to learning, and to employment, ſhe was taught the French and other faſhionable languages; and was inſtructed to read ſuch books chiefly as might make her acquainted with hiſtory and with the principles of ſcience; whilſt the doctrines of the Lutheran religion were carefully explained to her by a divine, who little thought how ſoon his illuſtrious pupil would embrace another faith.

The Empreſs Elizabeth, who then ſwayed the ſceptre of Ruſſia, had in early life been promiſed in marriage to the young prince of Holſtein Eutin, brother to the princeſs of Anhalt Zerbſt; but at the inſtant when the marriage was about to be celebrated, the prince fell ſick and died. Elizabeth, who loved him to exceſs, became inconſolable, and in the bitterneſs of her grief made a vow of celibacy. This vow, though ſenſual, and even laſcivious, ſhe kept ſo far as never publicly to acknowledge any man as a huſband; and upon her aſcending the throne of her anceſtors, ſhe called her nephew the Duke of Holſtein Gottorp to her court, where he was ſolemnly proclaimed, when fourteen years of age, Grand Duke, with the title of Imperial Highneſs, and declared ſucceſſor to the Empreſs Elizabeth. To ſecure the ſucceſſion in the family of Peter the Great, the Empreſs was very deſirous to have her nephew married; and the princeſs of Anhalt Zerbſt, not ignorant of the tender remembrance which ſhe ſtill preſerved for her brother, conceived the idea of placing, by means of it, her daughter on the throne of Ruſſia. She communicated her plan to the king of Pruſſia, who not only applauded it, but lent her his aſſiſtance to carry it into execution.

Full of ambitious hopes, therefore, the princeſs repaired with her daughter to St Peterſburg, where ſhe was received with friendſhip by Elizabeth, and where the young Sophia ſoon made a conſiderable impreſſion on the mind of the Grand Duke. As Peter was well made, of a good figure, and, though uneducated, not deſtitute of natural talents, the attachment became reciprocal; and the princeſs of Zerbſt, throwing herſelf at the feet of the empreſs, aſſured her, that the two lovers were attached to each other by a paſſion unconquerable; and, calling to her mind the love which ſhe had herſelf borne to the prince of Holſtein, conjured her to promote the happineſs of that prince's niece. The ſtratagem ſucceeded. The choice of Elizabeth was next day announced to the council and to the foreign miniſters; and preparations were made for celebrating the marriage with a magnificence worthy of the heir of the throne of the Ruſſias. In the mean time the Grand Duke was ſeized with the ſmall-pox, from which, tho' he recovered, it was with ſuch a change of features, as rendered him, from being comely, almoſt hideous, and converted the love of the young princeſs of Anhalt, if indeed ſhe ever felt for him that paſſion, into horror and diſguſt. She was not, however, of a diſpoſition to let a disfigured countenance frighten her from a throne. She embraced the Greek religion, changed her name from Sophia Auguſta Frederica to CATHARINA ALEXIEVNA, and with the entire approbation of Elizabeth was married to her nephew the Grand Duke.

For ſome time this ill-matched pair lived together, though without love, yet on terms apparently decent; but a mutual diſlike gradually took place between them, which the courtiers quickly diſcovered, and were at pains to foment into hatred. Peter was now ugly, and his mind was uninformed. Catharine, if not a beauty, was at leaſt a lovely woman, and highly accompliſhed. She could find no entertainment in his converſation, and he felt himſelf degraded by her ſuperiority. A faction was formed at court, headed by the great chancellor Beſtucheff, to exclude the Grand Duke from the throne, and to place Catharine at the head of affairs; and to accompliſh this end, every art was employed to fill the feeble mind of the empreſs with jealouſies of her nephew, and with a contempt of his character. He was repreſented at one time as extremely ambitious, and capable of the moſt daring enterpriſes, to get immediate poſſeſſion of the throne; and at another, as a wretch given up to drunkenneſs and to every unprincely vice.

The conſequence of the firſt of theſe accuſations was, that he was kept at a diſtance from his aunt, and a ſtranger to public affairs; and being wholly unemployed, that time which his education had not fitted him to fill up with reading, reflection, and rational converſation, hung ſo heavy on his mind, that it was no difficult matter for thoſe diſſipated young men, who were placed about him for that very purpoſe, to initiate him in the habits of drunkenneſs, and the other mean practices to which it was pretended he had long been devoted. In ſuch a ſchool, it was no wonder that he became a proficient in grovelling diſſipation; or that, being unpoliſhed, and even of rude manners, he choſe for his companions ſome of the loweſt of the people.

Catharine, in the mean time, languiſhed for that happineſs which ſhe could not find in the ſociety of her huſband. She was fond of pleaſure ; but it was that comparatively refined pleaſure which ſhe had enjoyed at the court of Berlin. She loved balls, muſic, and elegant converſation, and could take no ſhare in the drunken revels of Peter. Among the young men with whom he was ſurrounded, his chamberlain Soltikoff was particularly remarked for the elegance of his taſte and the graces of his perſon ; and though yet ſcarcely more than a boy in years, he was ſaid to have obtained the favours of ſeveral ladies of the court. Succeſs had made him confident and ambitious ; and his ambition prompted him to aſpire at making a conqueſt even of the Grand Ducheſs. By ſtudying her taſte, and contriving to amuſe her, he was at laſt ſucceſsful ; and obtained from her Imperial Highneſs every favour which he could wiſh : but he enjoyed not his fortune with moderation, and his enemies contrived to get him placed in an honourable office at a diſtance from the court. He was commiſſioned to repair to Stockholm, with the title of Envoy Extraordinary, to notify to the king of Sweden the birth of Paul Petrovitch, of whom the Grand Ducheſs had juſt been delivered *. The preſumptuous Soltikoff, proud of the employment, ſet off with haſte to Sweden, and left it with equal ſpeed. But ſcarcely had he quitted Stockholm, on the wings of love and ambition, when he was ſtopped on the road by a courier, who put into his hands an order for him to go immediately to Hamburg, and there to reſide in the quality of miniſter plenipotentiary from the court of Ruſſia.

Catharine for ſome time preſerved her attachment to the exiled chamberlain ; but all at once the preſence of a ſtranger, whom fortune had brought to the court of Ruſſia, made her forget the lover whom ſhe no longer ſaw. This perſon was Staniſlaus Poniatowſky, the late king of Poland, who firſt made his appearance at St Peterſburg in the train of the Britiſh ambaſſador, and very quickly gained the affections of the Grand Ducheſs. In carrying on this intrigue, the lovers were not ſo cautious as to deceive the eyes of the envious courtiers, who reported to the empreſs not only all that they ſaw, but whatever they ſuſpected. Elizabeth was incenſed, and commanded Poniatowſky to quit without delay the dominions of Ruſſia. The accompliſhed Pole obeyed ; but ſoon returned clothed with a character which made him in ſome degree independent of the empreſs.

The Count de Bruhl, then prime miniſter to the king of Poland, ſaw of what importance it was to his maſter to have a powerful intereſt at the court of Ruſſia. He was likewiſe no ſtranger to the paſſion which the Grand Ducheſs entertained for Poniatowſky ; and having got that nobleman decorated with the order of the White Eagle, he ſent him back to St Peterſburgh in the quality of miniſter plenipotentiary from the republic and king of Poland. Nor was this all that Bruhl did for the two lovers. Being informed by the chancellor Beſtucheff, that the Grand Duke and Grand Ducheſs were languiſhing in a penury unworthy of their rank, he remitted to Poniatowſky 6000 ducats, to be employed, in ſuch a manner as he might judge beſt, for ſecuring the favour of the prince and his conſort. The ambaſſador profited by theſe counſels and benefactions. He was already ſure of the Grand Ducheſs's heart, and he very quickly gained the favour of her huſband. He talked Engliſh and German with him ; drank, ſmoked, abuſed the French, and extolled the king of Pruſſia with unlimited praiſe.

The Grand Ducheſs was ſo blinded by her paſſion, that ſhe was never without Poniatowſky in her company. She devoted to him the whole of her time ; and ſhe made this intimacy ſo little a ſecret, that public report was loud to her prejudice. In the mean time ſhe was delivered of the Princeſs Anne†, who lived only fifteen months. The Grand Duke was the only perſon about court who ſeemed to know nothing of what was paſſing. His whole time was occupied in copying, with ſervile affectation, the air, the manners, the tone of the king of Pruſſia ; and in dreſſing a little army at Oranianbaum in the Pruſſian uniform. His eyes, however, were at laſt opened. Some of the courtiers, from hatred to the chancellor, who countenanced the intrigue between the Grand Ducheſs and the Poliſh ambaſſador, rouſed his jealouſy in order to deſtroy their enemy. They ſucceeded. He forbade his wife to be ſeen with Poniatowſky, and prevailed with the empreſs to deprive the chancellor of his office, and to baniſh him to an eſtate which he had 120 verſts beyond Moſcow.

Catharine had now to ſupport at once the averſion of her huſband, the indignation of the empreſs, the inſulting diſdain of a court, which a few days before was laviſh of its aſſiduities and ſmiles; and what afflicted her moſt of all, the dread of loſing for ever her favourite Poniatowſky. Her courage, however, did not forſake her. Poniatowſky was indeed recalled, and left Ruſſia, after ſuffering ſome deſerved indignities from the Grand Duke, who about this time formed a connection with one of the daughters of the Senator Vorontzoff, brother to the new chancellor. This lady, Elizabeth Romanovna Vorontzoff, was elder ſiſter to the Princeſs Daſhkoff, who acted ſo conſpicuous a part in the revolution which ſet the crown on the head of Catharine. She was beautiful, but vain ; and poſſeſſed not either the wit or the underſtanding of her ſiſter.

In the mean time the health of the empreſs viſibly declining, Catharine was very deſirous of being reconciled to her : but the irritated ſovereign would liſten to no accommodation, except on terms too humiliating for the haughty ſpirit of the Grand Ducheſs. Catharine, therefore, abſented herſelf from court, and aſked permiſſion to retire into Germany. This, as ſhe had foreſeen, was refuſed. Elizabeth was too fond of the young Paul Petrovitch to permit the departure of his mother, and thereby expoſe him to the danger of being at ſome future period declared illegitimate. She took the Grand Ducheſs again into favour ; and it is thought, that had ſhe lived a little longer than ſhe did, ſhe would have excluded Peter from the throne, and declared Paul her immediate ſucceſſor.

Whilſt the empreſs was meditating the aggrandiſement of the young prince and his mother, the Grand Duke had conceived a plan for degrading them both. He had reſolved, at the moment his aunt ſhould cloſe her eyes, to aſſemble his troops, to get himſelf proclaimed emperor, to repudiate the Grand Ducheſs, to declare the young Paul Petrovitch illegitimate, and publicly to marry his miſtreſs Elizabeth Romanovna Vorontzoff. We have ſhewn elſewhere (ſee Russia, n° 72. *Encycl.*) how this plan, when almoſt ready to be carried into execution, was betrayed to Catharine, who, ever ſince her caballing with the Chancellor Beſtucheff, had

reſolved,

† February 1758.

reſolved, by ſome means or other, to ſnatch the ſceptre from the feeble hand of her huſband. At preſent, we believe ſhe was not acquainted with it; and though ſhe had, ſhe could not now have turned it to her advantage, as her party, ever ſince the diſgrace of Beſtucheff, was without a leader of any abilities.

Amid theſe diſtractions, cauſed by the proſpect of the death of the empreſs, and the known hatred of the Grand Duke and Ducheſs to each other, Count Panin, preceptor to the young prince, devoted himſelf entirely to Catharine. He wiſhed to ſee her poſſeſſed of all the power of the empire; but he was afraid to proceed to the extremity to which ſhe propoſed to go, and to deprive Peter of the name of Emperor. He contrived therefore to procure an apparent reconciliation between the Grand Duke and his conſort, as well as between him and his aunt Elizabeth; and he had almoſt perſuaded the ſilly prince not to aſſume the ſovereign power on the death of the empreſs, till he ſhould be ſolemnly inveſted with it by a decree of the ſenate. Could he obtain this point, he knew that the power of Peter would be limited, and the authority ſecured to his wife and his ſon. He was, however, diſappointed. Catharine herſelf diſapproved of this plan, and concurred with the real friends of her huſband in adviſing him "to conform to eſtabliſhed cuſtom in aſſuming the reins of empire."

He had hardly received this advice when word was brought him that the Empreſs Elizabeth was dead (A); and the courtiers preſſed in crowds about him. He accoſted them with dignity, received the oaths of the officers of his guard, and ſeemed at once to have laid aſide his weakneſs. In an hour he got on horſeback, traverſed the ſtreets of St Peterſburgh, and diſtributed money among the multitude and the ſoldiers. He had been ſo treated by his aunt, that he could not poſſibly be grieved at her death; but in paying the laſt duties to her remains, he betrayed no indecent elation. The firſt actions of his reign were prudent and patriotic, and ſuch as would have done honour to a greater prince. He appeared to be reconciled to his wife, in whoſe company he ſpent much of his time; he recalled from priſon and baniſhment 17,000 perſons, ſome of them of rank and of great talents, who had been the victims of Elizabeth's jealous timidity; he permitted the nobility to bear arms or not at their own diſcretion, freeing them at the ſame time from the extreme ſervitude under which they had been held by his immediate predeceſſors; and he aboliſhed *the ſecret committee*, an infamous inquiſitorial tribunal, which ever ſince the reign of the father of Peter the Great had been the chief engine of Ruſſian deſpotiſm.

He neglected, however, one thing; which, among the people over whom he was appointed to reign, would have contributed more to the ſecurity of his throne than all the wiſe and beneficent edicts which he had publiſhed. He made no preparations to be crowned at Moſcow. Inſtead of complying with this ancient ceremony, and humouring the prejudices of his ſuperſtitious ſubjects, he thought of nothing but of war with Denmark, and of a perſonal interview with the king of Pruſſia in Germany. His admiration of that great monarch hurried him indeed into the moſt extravagant follies. Not contented with giving him peace, and entering into an offenſive and defenſive alliance with him, he had the meanneſs to ſolicit a commiſſion in his army, and to accept of the rank of major-general. Of this title he ſeemed more vain than of that of Emperor of all the Ruſſias. He conſtantly wore the Pruſſian uniform; introduced among his troops the Pruſſian diſcipline, which, though better than their own, was diſagreeable, becauſe it was new, and much more becauſe it was German; and he raiſed his uncle, a man of no military talents, and a foreigner, to the dignity of generaliſſimo of the Ruſſian armies; giving him at the ſame time the particular command of the horſe-guards, a body of men which had never before been under any command but that of the ſupreme head of the empire. Nor did his infatuated predilection for Germany, a country abhorred by the Ruſſians, ſtop even here: He diſbanded the noble guards which had placed Elizabeth on the throne, diſmiſſed the horſe-guards from the ſervice which they performed at court, and ſubſtituted his Holſtein guards in their place.

Whilſt he was thus alienating from himſelf the affections of the army, he contrived to diſguſt another order of men, whoſe attachment he ſhould have laboured above all things to retain. He was at pains to ſhew his preference of the Lutheran faith and worſhip to the doctrines and ceremonies of the Greek church; he attempted to make ſome alterations in the dreſs of the monks; he annexed great part of the poſſeſſions of the church to the domains of the crown; and he baniſhed the archbiſhop of Novogorod, who oppoſed theſe innovations; and found himſelf obliged ſuddenly to recal him.

He had now returned to his former courſes. He ſhut himſelf up for whole days with his miſtreſs and drunken companions; he compelled the nobility and ladies of the court to ſit in company with buffoons and comedians; he inſulted every foreign miniſter but the miniſters of Great Britain and Pruſſia; and he made no ſecret of his intention to repudiate the empreſs, declare Paul Petrovitch illegitimate, and marry the Counteſs Vorontzoff. Convinced, however, as it would ſeem, that he could not be a father, he reſolved to adopt Prince Ivan, the deſcendant of the elder brother of Peter the Great, whom Elizabeth had dethroned and confined in priſon; to declare him his ſucceſſor; and to unite him in marriage with the young princeſs of Holſtein Beck, who was then at St Peterſburgh, and whom he cheriſhed as his daughter.

This inconſiſtent and weak conduct of the emperor turned the attention of all orders of men to the empreſs, who made it her ſole employment to gain thoſe hearts which he was loſing. Inſtructed from her infancy in the arts of diſſimulation, it was not difficult for her to affect, in the ſight of the multitude, ſentiments the moſt foreign to her mind. The pupil of the French philoſophers put on the air of a bigot to the moſt ſuperſtitious ceremonies of the Greek religion, and treated the miniſters of that religion with the profoundeſt reverence. And whilſt her huſband was getting drunk

amidſt

(A) Chriſtmas-day 1761 according to the Ruſſian calendar, or the 5th of January 1762 according to ours.

amidſt a rabble of buffoons, and diſguſting every perſon of decency who approached him, ſhe kept her court with a mixture of dignity and affability, which attracted to her all who, by capacity, courage, or reputation, were capable of ſerving her.

Correct, however, as her public conduct appeared, her private life was not leſs licentious than formerly. While yet Grand Ducheſs, ſhe had formed a very tender connection with Gregory Orloff, a man of mean birth, and of no education, but poſſeſſed at once of perſonal beauty and the moſt daring courage. He had an inferior commiſſion in the artillery, while his two brothers were common ſoldiers in the regiments of guards. The intrigue which ſhe carried on with him was known only to one of her women named Catharine Ivanovna; nor did Orloff himſelf for ſome time ſuſpect the rank of the lady who ſo laviſhly conferred upon him her favours in ſecret. At laſt, finding him intrepid and diſcreet, ſhe diſcovered herſelf, unveiled to him all her ambitious deſigns, and eaſily prevailed with him and his brothers to enter with zeal into her conſpiracy againſt the emperor. Orloff likewiſe gained over Bibikoff his friend, a Lieutenant Paſſick, with other officers; and by their means eaſily ſeduced ſome regiments of the guards. The Princeſs Daſhkoff was ſtrongly attached to Catharine, we believe, from worthy motives, and had frequent meetings with Orloff on the buſineſs of the conſpiracy, without ſuſpecting that he was ſo much as known to the empreſs. Count Panin, too, and the Hetman of the Koſacks, were determined to tumble Peter from the throne; but they were not inclined to go all the lengths propoſed by Catharine and her two favourites. Hoping to enjoy the actual power of the empire themſelves, they were for declaring Paul Petrovitch emperor in the room of his father, and conferring upon his mother the name and authority only of regent; while the princeſs and Orloff, knowing the ſentiments and wiſhes of the empreſs, were reſolved to veſt her with ſovereign power, or to periſh themſelves in the hazardous attempt.

In the mean time the anniverſary of the patron ſaints of Ruſſia was at hand, when Peter had determined, at the concluſion of the feſtival, to divorce the empreſs, ſhut her up in priſon, declare her ſon illegitimate, and publicly marry his miſtreſs. As they who plan a conſpiracy are always more vigilant than thoſe againſt whom it is directed, the friends of Catharine were carefully informed of all that paſſed about the emperor, whilſt he was kept in total ignorance of their proceedings. It was therefore neceſſary for them to unite in the ſame plan, and to carry it quickly into execution; for delay or diviſions would involve them all in one common ruin. The empreſs contrived to bring over the Hetman entirely to her views; and the Princeſs Daſhkoff, by the ſacrifice, it has been ſaid, of her charms, found little difficulty in reconciling Count Panin to the ſame meaſures. They now agreed to ſeize the Tzar on his arrival at Peterhoff, an Imperial palace on the ſhore of the Gulf of Cronſtedt, where he propoſed to celebrate the approaching feſtival; and they were waiting impatiently for the moment of action, when all at once their plot was diſcovered.

Paſſick, who has been mentioned among the conſpirators, had gained the ſoldiers of the company of guards in which he was a lieutenant; but one of them, who thought that his captain was in the ſecret, aſked that officer one evening, When they were to take up arms againſt the emperor? The captain, ſurpriſed, had recourſe to diſſimulation, and eaſily drew from the ſoldier all that he knew of the conſpiracy. It was nine o'clock at night. Paſſick was put under arreſt; but found means to ſlip into the hands of a man who had been placed as a ſpy over him by the Princeſs Daſhkoff, a ſcrap of paper containing theſe words, "Proceed to execution this inſtant, or we are undone." The man was deſired to carry it to the Hetman, by whom he would be handſomely rewarded; but he hurried with it to the princeſs, who inſtantly communicated the intelligence to the other conſpirators. She herſelf put on man's apparel, and haſtened to the place where ſhe was accuſtomed to meet Orloff and his friends; where ſhe found them, as impatient as herſelf to carry their plot into immediate execution.

During this awful criſis the empreſs was at Peterhoff, at the diſtance of 25 verſts from St Peterſburgh; and one of the brothers of Gregory Orloff, named Alexius, undertook to find her out, whilſt he himſelf, with his other brother and Bibikoff his friend, repaired to the barracks for the purpoſe of inſtructing the ſoldiers of their party how to act on the firſt ſignal. Alexius Orloff carried with him a ſhort note from the Princeſs Daſhkoff, but neglected to deliver it; and the empreſs, being ſuddenly rouſed from a ſound ſleep, was much alarmed, when ſhe ſaw at the ſide of her bed a ſoldier of whom ſhe knew nothing. Her alarm was increaſed when the ſtranger ſaid, "Your majeſty has not a moment to loſe; get ready to follow me;" and inſtantly diſappeared. She roſe, however, and calling her woman Ivanovna, they diſguiſed themſelves in ſuch a manner that they could not be known by the ſentinels about the palace; and the ſoldier returning, they hurried with him to a coach which was waiting at the garden gate. Orloff took the reins, but drove with ſuch fury that the horſes ſoon fell down; and they were obliged to travel part of the way on foot. They had not, however, gone far, when they met a light country cart; and ſhe who was aſpiring to the throne of the greateſt empire in the world, was glad to enter the capital of that empire in this humble vehicle.

It was ſeven in the morning when ſhe arrived in St Peterſburgh: and to the ſoldiers, who gathered about her in great numbers, ſhe ſaid, that "her danger had driven her to the neceſſity of coming to aſk their aſſiſtance; that the Tzar had intended, that very night, to put her and her ſon to death; and that ſhe had ſo great confidence in their diſpoſitions, as to put herſelf entirely into their hands." They immediately ſhouted, "Long live the empreſs!" And the chaplain of one of the regiments fetching a crucifix, received their oaths of fidelity.

The troops, however, were not unanimous in this revolt. Though Gregory Orloff was treaſurer of the artillery, and well enough beloved by the ſoldiers, that corps refuſed to follow him until he ſhould produce the orders of Villebois their general: and that officer, withheld either by fidelity to the emperor or by fear, preſumed to ſpeak to Catharine of the obſtacles which yet remained for her to ſurmount; adding, that ſhe ought to have foreſeen them. She haughtily replied, that "ſhe had not ſent for him to aſk what ſhe ought to have foreſeen,

foreſeen, but to know how he intended to act." "To obey your Majeſty," returned Villebois; and putting himſelf at the head of his regiment, he immediately joined the conſpirators. So ripe indeed were the minds of all men for this revolt, that in the ſpace of two hours the empreſs found herſelf ſurrounded by 2000 warriors, together with great part of the inhabitants of Peterſburgh: and with that numerous train of attendants ſhe repaired to the church of Kaſan, where the archbiſhop of Novogorod, ſetting the Imperial crown on her head, proclaimed her ſovereign of all the Ruſſias, declaring, at the ſame time, Paul Petrovitch her ſucceſſor.

Matters had now proceeded by much too far to admit of any compromiſe between Catharine and her huſband: but had the infatuated Tzar put his affairs wholly into the hands of Marſhal Munich, that intrepid veteran would have tumbled the empreſs from her throne almoſt as quickly as ſhe had got poſſeſſion of it. He acted, however, a very different part. Upon receiving intelligence of what had been done at St Peterſburgh, he aſked indeed the Marſhal's advice, but ſuffered himſelf to be guided by his miſtreſs and timid companions. Through their terrors and his own irreſolution opportunities were loſt which could never be recovered; for though his Holſtein guards, with tears in their eyes, ſwore that they were all ready to ſacrifice their lives in his ſervice, and though the old Marſhal offered to lead them againſt the rebels, ſaying to the emperor, "I will go before you, and their ſwords ſhall not reach you till they have pierced my body," he was perſuaded to treat with the empreſs, to acknowledge his miſconduct, and to offer to ſhare with her the ſovereign power. At laſt he was weak enough to abandon his troops, and to ſurrender at diſcretion to his conſort; whoſe creatures hurried him from Oranienbaum to Peterhoff, ſtripped him of all his clothes, and, after leaving him for ſome time in his ſhirt, a butt to the outrages of an inſolent ſoldiery, threw over him an old morning-gown, and ſhut him up alone, with a guard at the door of his wretched apartment. On the 29th of June, O. S.* 1762, Count Panin was ſent to him by the empreſs; and after a long conference, prevailed with him to write and ſign a ſolemn reſignation of his crown, and a declaration of his utter incapacity to govern ſo great an empire.

The revolution was now complete, and Peter ſeemed to enjoy ſome compoſure of mind; but in the evening he was carried a priſoner to Ropſcha, a ſmall Imperial palace, at the diſtance of 20 verſts from Peterhoff, where he was murdered on the 17th of July, juſt one week after his depoſition. Of the manner of his death different accounts have been given. By ſome he is ſaid to have been poiſoned; by others, to have been ſtrangled by one of the Orloffs; and a few have thought that he periſhed by the ſame means as Edward II. of England. Whether the empreſs was acceſſory to his death is not known; though it is certain, that ſo far from making any inquiry after his murderers, ſhe affected to believe that he had died naturally of the *piles!*

The firſt care of Catharine was to reward thoſe who had been the principal actors in the revolt. Panin was made prime miniſter; the Orloffs received the title of Count; and the favourite Gregory was appointed lieutenant-general of the Ruſſian armies, and knight of the order of St Alexander Neſky, the ſecond order of the empire. Several officers of the guards were promoted, of whom 24 received conſiderable eſtates; and among the ſoldiers, whom ſhe treated with the greateſt affability, brandy and beer were liberally diſtributed. The Chancellor Beſtucheff, who had been the moſt inveterate enemy of Peter, was recalled from his exile, reſtored to his rank of field-marſhal, and had an annual penſion ſettled upon him of 20.000 rubles. To the friends of the emperor ſhe behaved with great moderation. Prince George, whom he had conſtituted Duke of Courland, was indeed obliged to renounce his title; but the adminiſtration of Holſtein was committed to him, and he ever after ſerved the empreſs with zeal and fidelity.

The news of the revolution was ſoon ſpread over Europe; and none of the ſovereigns, though they knew by what ſteps Catharine had mounted the throne, heſitated for a moment to acknowledge her title. She was not, however, at perfect eaſe in her own mind; nor was her right recogniſed by all her ſubjects. Though ſhe publiſhed manifeſtoes, ſetting forth the intentions of the late emperor towards her and her ſon, which made reſiſtance neceſſary; though in theſe papers ſhe attributed her elevation to the wiſhes of her people and the providence of God; and though ſhe called upon all who were ſincerely attached to the orthodox faith of the Greek church, to conſider the ſudden death of Peter as the judgment of heaven in favour of the revolution—yet in the diſtant provinces no exultations were heard; both ſoldiers and peaſants obſerved a gloomy ſilence. Even at Moſcow, ſo great was the diſaffection to Catharine's government, that it was ſome time before ſhe could venture to go to that city to be crowned; and ſhe found in it at laſt ſo cold a reception, that ſhe very quickly returned to St Peterſburgh.

Nor was this the only cauſe of her uneaſineſs. The connection between Orloff and her became viſible, and gave juſt offence to her other friends. The princeſs of Daſhkoff firſt perceived it; and when ſhe preſumed to expoſtulate with the empreſs on the meanneſs and imprudence of her paſſion, ſhe was baniſhed from the court to Moſcow. Count Panin and the Hetman ſaw with indignation that they had dethroned the grandſon of Peter the Great, to aggrandiſe a rude and low born upſtart. Cabals and conſpiracies were entered into by high and low, both againſt Catharine and againſt her favourite; and it required all her abilities and firmneſs to preſerve at once her throne and her lover. On one occaſion ſhe hoped to obtain from the Princeſs Daſhkoff ſufficient proof that Panin and the Hetman of the Koſacks were concerned in a plot which had juſt been diſcovered; and with this view ſhe wrote to her a letter of four pages, filled with the moſt tender epithets and the moſt magnificent promiſes, conjuring her in the name of their long-ſtanding friendſhip, to reveal what ſhe knew of the recent conſpiracies. With becoming magnamity, the princeſs replied, "Madam, I have heard nothing; but if I had heard any thing, I ſhould take good care how I ſpoke of it. What is it you require of me? That I ſhould expire upon a ſcaffold? I am ready to mount it."

Catharine, deſpairing of conquering ſuch a ſpirit, attempted to attach to her thoſe whom ſhe dared not to puniſh. Some of the inferior conſpirators were baniſhed to Siberia, while Panin and the Hetman, whom ſhe moſt dreaded, received additional marks of her favour. In the mean time, to gain the affections of the people

---

* July 10.

at large, ſhe paid the utmoſt attention to the adminiſtration of juſtice; formed magnificent eſtabliſhments for the education of the youth of both ſexes: founded hoſpitals for orphans, for the ſick, and for lying-in women; invited foreigners of all nations, poſſeſſed of any merit, to ſettle in different parts of her vaſt territories; increaſed the naval force of the empire; and gave ſuch encouragement to the cultivation of every elegant and uſeful art, that in the ſhort ſpace of a year and a half from her acceſſion to the throne, the national improvement of Ruſſia was viſible.

In the good fortune and glory of Catharine, no one rejoiced more ſincerely than Count Poniatowſky. He approached towards the confines of Ruſſia, and wrote to her in the tendereſt ſtyle of congratulation, requeſting permiſſion to pay his reſpects to her in the capital of her empire. It is not improbable that he flattered himſelf with the hopes that ſhe would give him her hand in marriage, and thus raiſe him to the throne of the Tzars; but ſhe had promiſed to the Empreſs Elizabeth, that ſhe would never again ſee the count; and to that promiſe ſhe at preſent adhered. She wrote to him, however, in the moſt affectionate terms; and tho' ſhe gave him no encouragement to repair to St Peterſburgh, ſhe aſſured him that ſhe had other proſpects in view for his aggrandiſement, and that he might depend upon her perpetual friendſhip: and ſhe ſoon appeared to be as good as her word. On the death of Auguſtus III. ſhe raiſed her former favourite to the throne of Poland, in oppoſition to the wiſhes of the courts of Vienna and Verſailles, as well as of a great majority of the Poliſh nobles. She defeated the intrigues of the two foreign courts by more ſkilfully conducted intrigues of her own; and by pouring her armies into the republic, ſhe ſo completely overawed the nuncios, that Poniatowſky was choſen by the unanimous ſuffrages of the diet which met for the election of a ſovereign; and, on the 7th of September 1764, was proclaimed King of Poland and Grand Duke of Lithuania, by the name of Staniſlaus Auguſtus.

Whilſt ſhe was thus diſpoſing of foreign kingdoms, ſhe was kept under perpetual dread of being tumbled from the throne of her own vaſt empire. Her want of title to that throne was now ſeen by all ranks of her ſubjects: the good qualities of Peter the third were remembered, and his failings and faults forgotten. His fate was univerſally lamented; and, except the conſpirators, who may be ſaid to have embrued their hands in his blood, there was hardly a Ruſſian who did not regret that the ſovereignty had paſſed from the ancient family of the Tzars to a foreigner, allied only by marriage to the blood royal. Even the conſpirators themſelves had loſt much of their regard for Catharine. The princeſs of Daſhkoff was a ſecond time baniſhed to Moſcow; and, to magnify her own importance, ſhe ſpoke freely of the means by which the empreſs, whom ſhe accuſed of ingratitude, had been raiſed to the throne. The inhabitants of Moſcow, who never favoured the uſurpation, were thus made ripe for a revolt. At St Peterſburgh, Count Panin felt himſelf uneaſy under the predominant influence of the favourite, and tried in vain to divert Catharine's affections to a new object. She received a few ſecret viſits from a handſome young man, and then appointed him to a lucrative and honourable employment in ſome diſtant province of the empire; when Orloff recovered his former aſcendency, which through his own careleſſneſs he had nearly loſt. In this ſtate of the public mind, conſpiracies were very frequent; and as the general object of them was to place on the throne Prince Ivan, who was again languiſhing in the dungeon from which Peter had taken him, the empreſs had given to his guard an order, ſigned by her own hand, to put that unfortunate prince to death, ſhould any attempt be made to liberate him from his priſon. An attempt was made by a very inferior officer, as ſome have ſuppoſed, by the inſtructions of Catharine, and her bloody order was inſtantly obeyed. The aſſaſſins were rewarded, and promoted in the army; but the officer who attempted to reſcue the prince was condemned to death, and ſuffered unexpectedly the ſentence of the law. The brothers and ſiſters of Ivan, who had been kept in a priſon different from his, were ſent to Denmark; and, to provide them with neceſſaries ſuitable to their rank, the empreſs made them a preſent of 200,000 rubles, and paid annually, to the maintenance of their dignity, a penſion of thirty thouſand.

The throne of Catharine was now firmly eſtabliſhed, by the death or renunciation of every perſon who was deſcended of the imperial family; and ſhe had leiſure to turn her thoughts to the aggrandiſement of the empire. It was ſoon ſeen that this was the object which ſhe had in view when ſhe raiſed Count Poniatowſky to the throne of Poland, and that ſhe was not actuated on that occaſion by any remains of her former attachment. We have elſewhere ſhewn (ſee POLAND, *Encycl.* n° 98—115) under what pretences ſhe invaded the kingdom of him who had formerly been one of her moſt favoured lovers, and by what means ſhe annexed great part of it to the territories of Ruſſia. But it is not through her wars that in this article we mean to trace her character: It is not as a ſovereign and heroine that her life is entitled to a place in a general repoſitory of arts, ſciences, and miſcellaneous literature, but as a patroneſs of art and of ſcience, and as the legiſlatrix of a vaſt empire, who employed all her talents and all her power for the civilization of a great part of the human race.

Under the article RUSSIA (*Encycl.*), we have mentioned the famous *code of laws for a great empire*, and the propoſed *convention of deputies from all the claſſes*, which Catharine and the Princeſs Daſhkoff ſo artfully employed as means to bring about the revolution which ſeated the former on the throne. The ſtates actually met in the ancient capital of the empire, and the ſovereign's inſtructions for framing a new code of laws was read amidſt reiterated burſts of applauſe. All preſent extolled the ſagacity, the wiſdom, the humanity of the empreſs; but fear and flattery had a greater ſhare in theſe exclamations than any juſt knowledge of the ſubject. The deputies of the Samoides alone had the courage to ſpeak freely. One of them ſtood up, and, in the name of himſelf and his brethren, ſaid, "We are a ſimple and honeſt people. We quietly tend our reindeer. We are in no want of a new code; but make laws for the Ruſſians, our neighbours, that may put a ſtop to their depredations." The following ſittings did not paſs ſo quietly. A debate about the liberation of the boors was carried on with ſuch warmth, that fatal conſequences were to be apprehended; and the deputies were diſmiſſed to their reſpective provinces in the manner which we have elſewhere related. Previous, however, to the diſſolution of this aſſembly, the members were required to ſignalize the meeting by ſome conſpicuous act of gratitude; and, by a general acclamation, the titles of GREAT, WISE, PRUDENT, and MOTHER OF THE COUNTRY, were decreed to the empreſs. With aſſumed modeſty ſhe accepted only of the laſt, "as the moſt benign and glorious recompence for her labours and ſolicitudes in behalf of a people whom ſhe loved."

For that people ſhe did indeed labour, and labour moſt uſefully. She introduced into the adminiſtration of juſtice the greateſt reformation of which the half-civilized ſtate of Ruſſia would perhaps admit. She ſpared neither trouble nor expence to diffuſe over the empire the light of ſcience, and the benefits of uſeful and elegant arts; and ſhe protected, as far as ſhe could, the poor from the oppreſſions of the rich. About the middle of 1767, ſhe conceived the idea of ſending ſeveral learned men to travel through the interior of her vaſt dominions, to determine the geographical poſition of the principal places, to mark their temperature, and to examine into the nature of their ſoil, their vegetable and mineral productions, and the manners of the people by whom they were inhabited. To this employment ſhe appointed Pallas, Gmelin, Euler, and many others of the higheſt eminence in the republic of letters; from whoſe journals of theſe intereſting travels large additions have been made to the general ſtock of uſeful knowledge. This ſurvey of the empire, and the maps made from it, had Catharine done nothing elſe, would alone have been ſufficient to render her name immortal. Well convinced in her own mind, that it is not ſo much by the power of arms, as by precedence in ſcience, that nations obtain a conſpicuous place in the annals of the world, with a laudable zeal ſhe encouraged artiſts and ſcholars of all denominations. She granted new privileges to the two academies of ſciences and the arts; encouraged ſuch of the youth as had behaved well in theſe national inſtitutes, to travel for farther improvement over Europe, by beſtowing upon them, for three years, large penſions to defray their expence; and, to remove as much as poſſible the Ruſſian prejudice againſt all kinds of learning, ſhe granted patents of nobility to thoſe who, during their education, had conducted themſelves with propriety, and become proficients in any branch of uſeful or elegant knowledge. Still farther to encourage the fine arts in her dominions, ſhe aſſigned an annual ſum of 5000 rubles for the tranſlation of foreign literary works into the Ruſſian language.

In the year 1768, the ſmall-pox raged at St Peterſburgh, and proved fatal to vaſt numbers of all ranks and of every age. The empreſs was deſirous to introduce the practice of inoculation among her ſubjects; and reſolved to ſet the example by having herſelf and her ſon inoculated, With this view, ſhe applied for a phyſician from England: and Dr Thomas Dimſdale of Hertford being recommended to her, he repaired with his ſon to the capital of Ruſſia, where he inoculated firſt the empreſs, then the grand duke, and afterwards many of the nobility. The experiment proving ſucceſsful, he was created a baron of the empire, appointed actual counſellor of ſtate, and phyſician to her imperial majeſty, with a penſion of L. 500 ſterling a-year, to be paid him in England, beſides L. 10,000 which he immediately received. So popular was the empreſs at this period, that, by a decree of the ſenate, the anniverſary of her recovery from the ſmall pox was enjoined to be celebrated as a religious feſtival; and it has ever ſince been obſerved as ſuch.

She was now engaged in war with the Turks, of which a ſufficient account for a work of this nature has been given under the title TURKEY *(Encycl)*; but there was one tranſaction of her and her friends, of which no mention was made in that article, though it is of importance to him who would form a juſt eſtimate of her perſonal character.

We have noticed the ſenſuality of the empreſs Elizabeth. She bore three children to the grand veneur Alexey Gregorievitch Razumoffſky, to whom, indeed, ſhe is ſaid to have been clandeſtinely married. Of theſe children the youngeſt was a girl, brought up under the name of Princeſs Tarrakanoff. Prince Radzivil, who has been mentioned in the article POLAND *(Encycl.)*, irritated at Catharine's cruelties to his countrymen, conceived the project of placing the young princeſs on the throne of her anceſtors; and, having gained over the perſons to whom her education was intruſted, he carried her off to Rome as a place of ſafety. Catharine, in return, ſeized his large eſtates; and he and the princeſs were reduced to extreme poverty. Radzivil repaired to Poland in order to learn what could be done to forward his great enterpriſe; and ſcarcely had he arrived there when an offer was made to reſtore to him his poſſeſſions, upon condition of his carrying his ward to St Peterſburgh. This he refuſed: but had the baſeneſs to promiſe, that he would give himſelf no farther concern about the daughter of Elizabeth; and he was put in poſſeſſion of all his eſtates.

By the inſtructions of the empreſs, Alexius Orloff, who nominally commanded the Ruſſian fleet at the Dardanelles, repaired to Rome, got acceſs to young Tarrakanoff, and found means to perſuade her that all Ruſſia was ready to revolt from Catharine, and place her on the throne of her mother. To convince her of his ſincerity, he pretended to feel for her the tendereſt and moſt reſpectful paſſion; and the unſuſpicious lady was induced to accept of him as a huſband. The ruffian who had aſſaſſinated the grandſon of Peter the Great, did not heſitate to ſeduce and betray his grand daughter. Under pretence of having the marriage ceremony performed according to the rites of the Greek church, he ſuborned ſome ſubaltern villains to perſonate prieſts and lawyers; thus combining profanation with impoſture againſt the unprotected and too confident Tarrakanoff.

Having been treated for ſome days, both at Rome and at Leghorn, with all the reſpect due to a ſovereign, the unſuſpecting princeſs expreſſed a wiſh to go on board a Ruſſian ſhip of war. This was juſt what Orloff wanted. Attended by a numerous and obſequious train, ſhe was rowed from the ſhore in a boat with magnificent enſigns, hoiſted upon the deck of the ſhip in a ſplendid chair, and immediately handcuffed. In vain did ſhe throw herſelf at the feet of her pretended huſband, and conjure him by every thing tender which had paſſed between them. She was carried down into the hold; the next day the veſſel ſailed for St Peterſburgh; where, upon her arrival, the princeſs was ſhut up in the fortreſs; and what became of her ſince was never known. Such were the means which Catharine ſcrupled not to employ in order to get rid of all pretenders to her throne.

Soon after this ſervice rendered to her by Alexius Orloff, ſhe diſmiſſed his brother Gregory from her favour, and connected herſelf with Vaſſiltchikoff, a ſublieutenant of the guards. The former favourite had indeed become inſolent, and, as Catharine thought, ungrateful. He aſpired to nothing leſs than the throne. From love to himſelf, and to a ſon which ſhe had born to him, ſhe offered to enter into a ſecret marriage; but with this propoſal the proud prince (A) was not ſatisfied, and hoped that his refuſal would impel her to receive him publicly as her huſband and partner in power. He was miſtaken. She diveſted him of all his employments; but gave him a penſion of 150,000 rubles, a handſome ſervice of plate, and an eſtate with 6000 peaſants upon it; and, thus enriched, he ſet out upon a journey through various parts of Europe. He returned, however, much ſooner than was expected; the new favourite was handſomely rewarded, and ſent to a diſtance; Orloff was reſtored to all his offices, and his baleful influence was again felt.

He attempted to perſuade the empreſs to diſmiſs Panin from the court; but the grand duke interpoſed in behalf of his old preceptor; and, for once, Catharine liſtened to the entreaties of her ſon. When a dreadful rebellion, under a Koſak of the name of Pugetſhoff, who pretended to be Peter III. eſcaped from his aſſaſſins, was ſhaking the throne to its foundation—the influence of Orloff was ſuch as to prevent the empreſs, for ſome time, from employing her ableſt general againſt the rebels, becauſe that general was Panin, brother to the miniſter. Danger, however, at laſt prevailed over the favourite: Panin was ſent againſt Pugetſhoff; the rebellion was cruſhed; and Catharine found leiſure to give ſomething like a legal conſtitution to the empire. In that work, the laws and regulations eſtabliſhed for the government of the various provinces, and for the equitable adminiſtration of juſtice through the whole of her vaſt dominions, evinces the greateſt wiſdom and ſagacity in their author, as well as a proper regard to the practicable liberties and rights of men. In the capital, ſhe eſtabliſhed the moſt perfect police, by which the internal tranquillity of a great city was, perhaps, ever maintained; and whilſt her private conduct was far from correct, ſhe was acting in the capacity of ſovereign, ſo as to deſerve, indeed, the appellation of *Mother of her people*.

To follow her through all her wars and intrigues with foreign courts, would ſwell this article to the ſize of a volume. Such a narrative, too, belongs rather to the hiſtory of Ruſſia than to the memoirs of Catharine; in which it is the buſineſs of the biographer to develop the private character of the woman, rather than to detail the exploits of the ſovereign. Her partition of Poland, and afterwards the annihilation of it as an independent republic; her encroachments on the territories of the grand ſignior; her formation of the armed neutrality; the influence which ſhe maintained over the courts of Sweden and Denmark; and the art with which ſhe threw the weight of Ruſſia ſometimes into the ſcale of Auſtria, and ſometimes into that of Pruſſia, juſt as the intereſts of her own dominions required the one or the other to preponderate—ſhew how admirably ſhe was qualified to guide the helm of a great empire in all its tranſactions with foreign ſtates. We ſpeak not of the equity of her proceedings; for it muſt be confeſſed, that equity formed no barrier againſt her ambition; and that ſhe never failed to ſubjugate thoſe whom ſhe pretended to take under her protection. Her ruling paſſion was to enlarge her own territories, already ſo very extenſive; and, for the attainment of that object, ſhe contrived the moſt judicious plans, which ſhe executed with vigour. In this part of her conduct, however, ſhe has been equalled by other monarchs; but in the zeal and the wiſdom with which ſhe endeavoured to introduce among her half-ſavage ſubjects the bleſſings of knowledge and induſtry, ſhe ſtands unrivalled, except, perhaps, by her predeceſſor Peter the Great. Of this we need bring no other proof, in addition to what has been already ſtated, than that ſhe founded in St Peterſburgh alone thirty-one ſeminaries, where 6800 children of both ſexes were educated at the annual expence to the government of 754,335 rubles. She ſuperintended herſelf the education of her grandchildren, and wrote for them books of inſtruction. If it be true, that "every man acquainted with the common principles of human action, will look with veneration on the writer who is at one time combating Locke, and at another making a catechiſm for children in their fourth year;" with what veneration ſhould we look upon the empreſs of Ruſſia, could we forget the means by which ſhe obtained that elevation from which ſhe frequently deſcended for a ſimilar employment: This ſhe did, not for her own deſcendants alone, but alſo for the children of others; of whom ſhe had always a great number in her apartments, who ſhared in the inſtruction given to her grandchildren, and whoſe careſſes ſhe returned with extreme complaiſance.

Her greateſt weakneſs was ſurely that groſs paſſion which her panegyriſts have dignified with the name of love; but to ſuch an appellation it had no claim, if love be any thing more than a ſexual appetite. Beſides Gregory Orloff, ſhe had not fewer than ten favourites after the death of her huſband; and of theſe ſhe ſeems to have felt a refined affection for none but Lanſkoi, a young Pole of a very ancient family, and of elegant manners, and the famous Potemkin, to whom ſhe is ſaid ſecretly to have given her hand, and who preſerved her friendſhip, if not her affection, to the end of his life. To Lanſkoi, whoſe education had been much neglected, ſhe condeſcended to become preceptrix; and, as he made great progreſs in the acquiſition of uſeful knowledge, ſhe admired in him her own creation. Potemkin, though not amiable, deſerved her favour for the fidelity and abilities with which he ſerved her, both in the council and in the field; and in him, when ſhe had ceaſed to look on him with the eyes of love, ſhe reſpected the intriguing politician and intrepid commander, who had formed plans for driving the Turks out of Europe, and ſetting her on the throne of Byzantium. Her other favourites had nothing to recommend

---

(A) She had ſome time before obtained for him a patent, creating him a prince of the Roman empire.

mend them but maſculine beauty and corporeal ſtrength. One of them, however, thought it neceſſary to have a library in the grand houſe, of which the empreſs, upon receiving him into favour, had made him a preſent; and deſired the principal bookſeller to fill his ſhelves. The man aſked him what books he would pleaſe to have. "You underſtand that better than I (replied the favourite); that is your buſineſs. You know the proper aſſortments; I have deſtined a large room to receive them. Let there be large books at the bottom, and ſmaller and ſmaller up to the top; that is the way they ſtand in the empreſs's library!" In the converſation of ſuch men the cultivated mind of Catharine could enjoy no interchange of ſentiments.

We know not whether that more than Aſiatic magnificence, which ſhe diſplayed on every public occaſion, ſhould be conſidered as an inſtance of weakneſs or of wiſdom. If ſhe delighted in balls, and maſquerades, and ſumptuous entertainments, and dreſs loaded with jewels, and every kind of ſplendid ornament, for their own ſakes, ſhe betrayed a weakneſs unworthy of that ſovereign who held in her hand the balance of Europe, and at whoſe nod the greateſt powers of Aſia trembled: but if ſhe introduced ſuch ſplendor into her court merely to divert the attention of the Ruſſians from the means by which ſhe got poſſeſſion of the throne, and to ween them from their own ſavage and ſlovenly manners; even this may perhaps be conſidered as one of her moſt maſterly ſtrokes in politics.

Her ambition was boundleſs; but, if ſuch a phraſe may be allowed, it was not always true ambition. When the French republic had eſtabliſhed itſelf on the ruins of monarchy, and was propagating new theories of government through all Europe, true ambition would ſurely have led the autocratrix of the north to unite her forces with thoſe of the coaleſced powers, in order to cruſh the horrid hydra, before its anarchical principles could be introduced among her own barbarous ſubjects. Such would certainly have been the advice of her favourite Potemkin, who longed to lead a Ruſſian army into France, even before the murder of the unfortunate Lewis. That general, however, had died in October 1791; and when Britain, Auſtria, and Pruſſia, were leagued againſt the new republic, Catharine looked coolly on, in hopes, it is probable, of availing herſelf of their weakneſs, when exhauſted by a long and bloody war. She gave refuge, indeed, in her dominions to many emigrants from France, and ſent a ſquadron of ſhips to co-operate with the navy of England: but in this laſt meaſure ſhe regarded merely her own immediate intereſt; for her crazy ſhips were repaired by Britiſh carpenters at the expence of the Britiſh government, and her officers had an opportunity of learning the evolutions of the Britiſh navy. She had likewiſe other proſpects in view when ſhe lent to the allies this ſlender aid. She meditated a new war with Turkey; and, depending upon meeting with no oppoſition, if ſhe ſhould not receive aſſiſtance from England and Auſtria, ſhe flattered herſelf with accompliſhing her darling project of driving the Ottomans out of Europe, and of reigning in Conſtantinople. But ſhe was diſappointed. On the morning of the 9th of November 1796, ſhe was ſeized with what her principal phyſician judged a fit of apoplexy; and, at 10 o'clock in the evening of the following day, expired, in the 68th year of her age, leaving behind her the character of one of the greateſt ſovereigns that ever ſwayed a ſceptre.

After this long detail of the incidents of her life, it is needleſs to inform the reader that Catharine II. had no religion, and, of courſe, no principles of morality, which could induce her in every inſtance to do to others as ſhe would have them do to her. She was a profeſſed diſciple of the French philoſophers; by ſome of whom ſhe was ridiculed, and by others cheated. The incenſe which ſhe paid to the genius of Voltaire did not hinder him from frequently breaking his jeſts upon the autocratrix of Ruſſia and her ſucceſſive favourites; and Diderot, whom ſhe careſſed, ſold to her an immenſe library, when he poſſeſſed hardly a book, and was obliged to ranſack Germany and France for volumes to enable him to fulfil his bargain. Such is the friendſhip, and ſuch the gratitude, which ſubſiſts among the amiable pupils of nature, and the philanthropic advocates for the rights of man.

CAUSE has been defined, we think, with accuracy in the Encyclopædia, and the doctrine ſtated which we believe to be true. Objections however have been made to that doctrine, of which we have endeavoured to remove ſome, under the title Action, in this Supplement; and the doctrine itſelf has been well illuſtrated (at leaſt ſuch is our opinion) in the ſupplementary article Astronomy. We have, therefore, very little to add here on the ſubject of cauſes, though it is the moſt important ſubject which can employ the mind of man. What is the relation between a phyſical cauſe and that which is termed its effect—between heat, for inſtance, and the fuſion of metals? Is it a *neceſſary connection*, or only a *conjunction*, diſcovered by experience to be *conſtant?*

If by *neceſſary* connection be meant that kind of connection of which the contrary cannot be conceived, we do not think that the connection of any phyſical cauſe with its effect can be called neceſſary. We ſee no difficulty in conceiving, that fire, inſtead of fuſing gold, might fix mercury. This *may* indeed be impoſſible; and

and we might perhaps ſee the impoſſibility, did we as completely know the nature of fire and of metals, as we know the relations of pure geometry. We know that the three angles of a plain triangle cannot poſſibly be either greater or leſs than two right angles; for in this compariſon nothing is hid from our mental view. We do not, however, perceive the impoſſibility of mercury being fixed, as clay is hardened, by heat: for of *heat*, and mercury, and clay, we know very little, and that little is the offspring of experience.

But if the connection between cauſe and effect be not *neceſſary*, are we not deprived of the means of demonſtrating the great fundamental truth of religion? We have nowhere ſaid, that the connection between cauſe and effect is not neceſſary; but only, that we do not perceive the neceſſary connection between what are called *phyſical* cauſes and their effects. That every event is, and muſt be, brought about by *ſome cauſe* or ſome *agency*, we hold to be a ſelf-evident truth, which no man can deny who underſtands the terms in which it is expreſſed; but what or where the agency is, we can very ſeldom, if ever, know, except when we think of our own voluntary actions. When a change is obſerved, we cannot doubt of its being produced by ſomething: either the thing changed is animated, and has produced the change by its own agency, juſt as we move our heads and legs by an act of volition; or if it be inanimated, and of itſelf incapable of agency, the change has been produced by ſomething external, denominated a *cauſe*. But all external cauſes, which are not likewiſe agents, in the proper ſenſe of the word, may be traced, we think, as effects up to ſome agency; and therefore, in our opinion, there is no real, ultimate, efficient cauſe but mind, or that which is endued with power. In proof of this doctrine, if it need any proof, we can only refer to what has been ſaid elſewhere on our notions of *power* and of *phyſical cauſes*. See (*Encycl.*) METAPHYSICS, n° 109, &c.—PHILOSOPHY and PHYSICS, *paſſim*—and (*Suppl.*) ACTION and ASTRONOMY.

1
Definition.

CENTER, or CENTRE, a word borrowed from the French name *ceintre* or *cintre*, given to the frame of timber, by which the brick or ſtone of arched vaulting is ſupported during its erection, and from which it receives its form and curvature.

2
Purpoſe of this article.

It is not our intention to deſcribe the variety of conſtructions which may be adopted in eaſy ſituations, where the arches are of ſmall extent, and where ſufficient foundation can be had in every part of it for ſupporting the frame. In ſuch caſes, the frequency of the props which we can ſet up diſpenſes with much care; and a frame of very ſlight timbers, connected together in an ordinary way, will ſuffice for carrying the weight, and for keeping it in exact ſhape. But when the arches have a wide ſpan, and conſequently a very great weight, and when we cannot ſet up intermediate pillars, either for want of a foundation in the ſoft bottom of a river, or becauſe the arch is turned between two lofty piers, as in the dome of a ſtately cathedral—we are then obliged to reſt every thing on the piers themſelves; and the framing which is to ſupport our arch before the keyſtone is ſet, muſt itſelf be an arch, depending on the mutual abutment of its beams. One ſhould think that this view of the conſtruction of a centre would offer itſelf at the firſt, naturally derived from the erection it was to aſſiſt: but it has not been ſo. When intermediate pillars were not employed, it was uſual to frame the mould for the arch with little attention to any thing but its ſhape, and then to croſs it and recroſs it in all directions with other pieces of timber, till it was thought ſo bound together that it could be lifted in any poſition, and, when loaded with any weight, could not change its ſhape. The frame was then raiſed in a lump, like any ſolid body of the ſame ſhape, and ſet in its place. This is the way ſtill practiſed by many country artiſts, who, having no clear principles to guide them, do not ſtop till they have made a load of timber almoſt equal to the weight which it is to carry.

But this artleſs method, beſides leading the employer into great expence, is frequently fatal to the undertaker, from the unſkilfulneſs of the conſtruction. The beams which connect its extremities are made alſo to ſupport the middle by means of poſts which reſt on them. They are therefore expoſed to a tranſverſe or croſs ſtrain, which they are not able to bear. Their number muſt therefore be increaſed, and this increaſes the load. Some of theſe croſs ſtrains are derived from beams which are preſſed very obliquely, and therefore exert a prodigious thruſt on their ſupports. The beams are alſo greatly weakened by the mortiſes which are cut in them to receive the tenons of the croſſing beams: and thus the whole is exceedingly weak, in proportion to what the ſame quantity of timber may be made by a proper diſpoſition of its parts.

3
General principles of conſtruction.

The principles from which we are to derive this diſpoſition are the general mechanical principles of carpentry, of which we have given ſome account in that article. Theſe furniſh one general rule: When we would give the utmoſt ſtrength poſſible to a frame of carpentry, every piece ſhould be ſo diſpoſed that it is ſubject to no ſtrain but what either puſhes or draws it in the direction of its length: and, if we would be indebted to timber alone for the force or ſtrength of the centre, we muſt reſt all on the firſt of theſe ſtrains; for when the ſtraining force tends to *draw* a beam out of its place, it muſt be held there by a mortiſe and tenon, which poſſeſſes but a very trifling force, or by iron ſtraps and bolts. Caſes occur where it may be very difficult to make every ſtrain a thruſt, and the beſt artiſts admit of ties; and indeed where we can admit a tie-beam connecting the two feet of our frame, we need ſeek no better ſecurity. But this may ſometimes be very inconvenient. When it is the arch of a bridge that we are to ſupport, ſuch a tie-beam would totally ſtop the paſſage of ſmall craft up and down the river. It would often be in the water, and thus expoſed to the moſt fatal accidents by freſhes, &c. Interrupted ties, therefore, muſt be employed, whoſe joint or meetings muſt be ſupported by ſomething analogous to the king-poſts of roofs. When this is judiciouſly done, the ſecurity is abundantly good. But great judgment is neceſſary, and a very ſcrupulous attention to the diſpoſition of the pieces. It is by no means an eaſy matter to diſcern whether a beam, which makes a part of our centre, is in a ſtate of compreſſion or in a ſtate of extenſion. In ſome works of the moſt eminent carpenters even of this day, we ſee pieces conſidered as ſtruts (and conſiderable dependence had on them in this capacity), while they are certainly performing the office of tie-beams, and ſhould be ſecured accordingly. This was the caſe in the boldeſt centre (we think) that has been

been executed in Europe, that of the bridge of Orleans, by Mr Hupeau. Yet it is evidently of great conſequence not to be miſtaken in this point; for when we are miſtaken, and the piece is ſtretched which we imagine to be compreſſed, we not only are deprived of ſome ſupport that we expected, but the expected ſupport has become an additional load.

4
How to diſtinguiſh a ſtrut from a tie.

To aſcertain this point, we may ſuppoſe the piers to yield a little to the preſſure of the archſtones on the centre frames. The feet, therefore, fly outwards, and the ſhape is altered by the ſinking of the crown. We muſt draw our frame anew for this new ſtate of things, and muſt notice what pieces muſt be made longer than before. All ſuch pieces have been acting the part of tie-beams.

But a centre has ſtill another office to ſuſtain; it muſt keep the arch in its form; that is, while the load on the centre is continually increaſing, as the maſons lay on more courſes of arch ſtones, the frame muſt not yield and go out of ſhape, ſinking under the weight on the haunches, and riſing in the crown, which is not yet carrying any load. The frame muſt not be ſupple; and muſt derive its ſtiffneſs, not from the cloſeneſs and ſtrength of its joints, which are quite inſignificant when ſet in competition with ſuch immenſe ſtrains, but from ſtruts or ties, properly diſpoſed, which hinder any of the angles from changing its amplitude.

5
How to ſecure ſtiffneſs and ſtrength.

It is obvious, from all that has been ſaid, that the ſtrength and ſtiffneſs of the whole muſt be found in the triangles into which this frame of carpentry may be reſolved. We have ſeen that the ſtrains which one piece produces on two others, with which it meets in one point, depends on the angles of their interſection; and that it is greater as an obtuſe angle is more obtuſe, or an acute angle more acute. And this ſuggeſts to us the general maxim, "to avoid as much as poſſible all very obtuſe angles." Acute angles, which are not neceſſarily accompanied by obtuſe ones, are not ſo hurtful; becauſe the ſtrain here can never exceed the ſtraining force; whereas, in the caſe of an obtuſe angle, it may ſurpaſs it in any degree.

Such are the general rules on this ſubject. Although ſomething of the mutual abutment of timbers, and the ſupport derived from it, has been long perceived, and employed by the carpenters in roofing, and alſo (doubtleſs) in the forming of centres, yet it is a matter of hiſtorical fact, that no general and diſtinct views had been taken of it till about the beginning of this century, or a little earlier. Fontana has preſerved the figure of the frames on which the arches of St Peter's at Rome were turned. The one employed for the dome is conſtructed with very little ſkill; and thoſe for the arches of the nave and tranſepts, though incomparably ſuperior, and of conſiderable ſimplicity and ſtrength, are yet far inferior to others which have been employed in later times. It is much to be regretted that no trace remains of the forms employed by the great architect and conſummate mechanician Sir Chriſtopher Wren. We ſhould doubtleſs have ſeen in them every thing that ſcience and great ſagacity could ſuggeſt. We are told, indeed, that his centering for the dome of St Paul's was a wonder of its kind; begun in the air at the height of 160 feet from the ground, and without making uſe of even a projecting corniche whereon to reſt it.

6
The earlieſt theory, on ſcientific principles,

The earlieſt theory of the kind that we have met with, that is propoſed on ſcientific principles, and with the expreſs purpoſe of ſerving as a leſſon, are two centres by Mr Pitot of the Academy of Sciences, about the beginning of this century. As they have conſiderable merit (greatly reſembling thoſe employed by Michael Angelo in the nave of St Peter's), and afford ſome good maxims, we ſhall give a ſhort account of them. We crave the excuſe of the artiſts if we ſhould employ their terms of art ſomewhat aukwardly, not being very familiarly acquainted with them. Indeed, we obſerve very great differences, and even ambiguity, in the terms employed.

What we ſhall deſcribe under the name of a *centre* is (properly ſpeaking) only one frame, truſs, or rib, of a centre. They are ſet up in vertical planes, parallel to each other, at the diſtance of 5, 6, 7, or 8 feet, like the truſſes or main couples of a roof. Bridging joiſts are laid acroſs them.—In ſmaller works theſe are laid ſparingly, but of conſiderable ſcantling, and are boarded over; but for great arches, a bridging joiſt is laid for every courſe of archſtones, with blockings between to keep them at their proper diſtances. The ſtones are not laid immediately on theſe joiſts, but beams of ſoft wood are laid along each joiſt, on which the ſtone is laid. Theſe beams are afterwards cut out with the chiſſel, in order to ſeparate the centre from the ring of ſtones, which muſt now ſupport each other by their mutual abutment.

7
Illuſtrated.
Plate XIV.

The centre is diſtinguiſhable into two parts, ALLB (fig. 1.) and LDL, which are pretty independent of each other, or at leaſt act ſeparately. The horizontal STRETCHER LL cuts the ſemicircle ADB half way between the ſpring and the crown of the arch; the arches AL, LD, being 45° each. This ſtretcher is divided in the ſame proportion in the points G and H; that is, GH is one half of LL, and LG, HL are each one-fourth of LL nearly. Each end is ſupported by two STRUTS EI, GI, which reſt below on a SOLE or BED properly ſupported. The interval between the heads of the ſtruts GI, HK is filled up by the STRAINING BEAM GH, abutting in a proper manner on the ſtruts (ſee CARPENTRY, *Supplement*). The extremities L, L, are united in like manner by butting joints, with the heads of the outer ſtruts. The ARCH MOULDS AP, BP, are connected with the ſtruts by croſs pieces PQ, which we ſhall call BRIDLES, which come inwards on each ſide of the ſtruts (being double), and are bolted to them. This may be called the lower part of the frame. The upper part conſiſts of the king poſt DR, ſupported on each ſide by the two ſtruts or braces ML, ON, mortiſed into the poſt, and alſo mortiſed into the ſtretcher, at the points L, N, where it is ſupported by the ſtruts below. The arches LD, LD are connected with the ſtruts by the bridles PQ, in the ſame manner as below.

8
Propriety of this arrangement.

There is a great propriety in many parts of this arrangement. The lower parts or haunches of the arch preſs very lightly on the centres. Each archſtone is lying on an inclined plane, and tends to ſlide down only with its relative weight; that is, its weight is to its tendency to ſlide down the joint as radius to the ſine of elevation of the joint. Now it is only by this tendency to ſlide down the joint that they preſs on the centering, which in every part of the arch is perpendicular to the joint: But the preſſure on the joint, ariſing from this cauſe, is much leſs than this, by reaſon of the friction of the joints. A block of dry freeſtone will not ſlide down at all; and therefore will not preſs on the centering, if the joint be not elevated 35 degrees at leaſt. But the archſtones are not laid in this manner, by ſliding them down along the joint, but are laid on the centres, and ſlide down *their* ſlope, till they touch the blocks on which they are to reſt; ſo that, in laying the archſtones, we are by no means allowed to make the great deduction from their weight juſt now mentioned, and which Mr Couplet preſcribes (Mem. Acad. Sciences, 1729). But there is another cauſe which diminiſhes the preſſure on the centres; each block ſlides down the planks on which it is laid, and preſſes on the block below it, in the direction of the tangent to the arch. This preſſure is tranſmitted through this block, in the ſame direction, to the next, and through it to the third, &c. In this manner it is plain that, as the arch advances, there is a tangential preſſure on the lower archſtones, which diminiſhes their preſſure on the frame, and, if ſufficiently great, might even puſh them away from it. Mr Couplet has given an analyſis of this preſſure, and ſhews, that in a ſemicircular arch of uniform thickneſs none of the arch ſtones below 30° preſs on the frames. But he (without ſaying ſo) calculates on the ſuppoſition that the blocks deſcend along the circumference of this frame in the ſame manner as if it were perfectly ſmooth. As this is far from being the caſe, and as the obſtructions are to the laſt degree various and irregular, it is quite uſeleſs to inſtitute any calculation on the ſubject. A little reflection will convince the reader, that in this caſe the obſtruction ariſing from friction *muſt* be taken into account, and that it *muſt not* be taken into account in eſtimating the preſſure of each ſucceſſive courſe of ſtones as they are laid. It is enough that we ſee that the preſſure of the lower courſes of archſtones on the frame is diminiſhed. Mr Couplet ſays, that the whole preſſure of a ſemicircular arch is but $\frac{4}{9}$ths of its weight; but it is much greater, for the reaſon juſt now given. We have tried, with a well made wooden model (of which the circumference was rubbed with black lead to render it more ſlippery), whether *ony* part of the wooden blocks repreſenting the archſtones were detached from the frame by the tangential preſſure of the ſuperior blocks; but we could not ſay confidently that any were ſo detached. We perceived that all kept hold of a thin ſlip of Chineſe paper (alſo rubbed with black lead) between them and the frame, ſo that a ſenſible force was required to pull it out. From a combination of circumſtances, which would be tedious to relate, we believe that the centres carry more than two-thirds of the weight of the arch before the keyſtone is ſet. In elliptical and lower pitched circular arches, the proportion is ſtill greater.

9
By a centre of M. Pitot's.

It ſeems reaſonable enough, therefore, to diſpoſe the framing in the manner propoſed by Pitot, directing the main ſupport to the upper maſs of the arch, which preſſes moſt on the frame. We ſhall derive another advantage from this conſtruction, which has not occurred to Mr Pitot.

There is an evident propriety in the manner in which he has diſtributed the ſupports of the upper part. The ſtruts which carry the king poſt ſpring from thoſe points of the ſtretcher where it reſts on the ſtruts below: thus the ſtretcher, on which all depends, bears no tranſverſe ſtrains. It is ſtretched by the ſtrut above it, and it is compreſſed in a ſmall degree between the ſtruts below it, at leaſt by the outer ones. Mr Pitot propoſes the ſtraining beam GH as a lateral ſupport to the ſtretcher, which may therefore be of two pieces: but although it *does* augment its ſtrength, it does not ſeem neceſſary for it. The ſtretcher is abundantly carried by the ſtrap, which may and ſhould ſuſpend it from the king poſt. The great uſe of the ſtraining piece is to give a firm abutment to the inner ſtruts, without allowing any lateral ſtrain on the ſtretcher. *N. B.* Great care muſt be taken to make the hold ſufficiently firm and extenſive between the ſtretcher and the upper ſtruts, ſo that its coheſion to reſiſt the thruſts from theſe ſtruts may be much employed.

The only imperfection that we find in this frame is the lateral ſtrains which are brought upon the upper ſtruts by the bridles, which certainly tranſmit to them part of the weight of the archſtones on the curves. The ſpace between the curves and ML ſhould alſo have been truſſed. Mr Pitot's form is, however, extremely ſtiff; and the cauſing the middle bridle to reach down to the ſtretcher, ſeems to ſecure the upper ſtruts from all riſk of bending.

This centre gives a very diſtinct view of the offices of all the parts, and makes therefore a proper introduction to the general ſubject. It is the ſimpleſt that can be in its principle, becauſe all the eſſential parts are ſubjected to one kind of ſtrain. The ſtretcher LL is the only exception, and its extenſion is rather a collateral circumſtance than a ſtep in the general ſupport. 10

The ſtrength of this frame

The examination of the ſtrength of the frame is extremely eaſy. Mr Pitot gives it for an arch of 60 feet ſpan, and ſuppoſes the archſtones 7 feet long, which is a monſtrous thickneſs for ſo ſmall an arch; 4 feet is an abundant allowance, but we ſhall abide by his conſtruction. He gives the following ſcantlings of the parts:

The ring or circumference conſiſts of pieces of oak 12 inches broad and 6 thick.

The ſtretcher LL is 12 inches ſquare.

The ſtraining piece GH is alſo 12 by 12.

The lower ſtruts 10 by 8.

The king poſt 12 by 12.

The upper ſtruts 10 by 6.

The bridles 20 by 8.

Theſe dimenſions are French, which is about $\frac{1}{17}$th larger than ours, and the ſuperficial dimenſions (by which the ſection and the abſolute ſtrength is meaſured) is almoſt $\frac{1}{8}$th larger than ours. The cubic foot, by which the ſtones are meaſured, exceeds ours nearly $\frac{1}{5}$th. The pound is deficient about $\frac{1}{13}$th. But ſince very nice calculation is neither eaſy nor neceſſary on this ſubject, it is needleſs to depart from the French meaſures, which would occaſion many fractional parts and a troubleſome reduction.

The arch is ſuppoſed to be built of ſtone which weighed 160 pounds per foot. Mr Pitot, by a computation (in which he has committed a miſtake), ſays, that only $\frac{11}{14}$ths of this weight is carried by the frame. We believe, however, that this is nearer the truth than Mr Couplet's aſſumption of $\frac{4}{9}$ths already mentioned.

Mr Pitot farther aſſumes, that a ſquare inch of ſound oak will carry 8640 pounds. By his language we ſhould imagine that it will not carry much more: but this is very far below the ſtrength of any Britiſh oak that we have tried; ſo far, indeed, that we rather imagine

gine that he means that this load may be laid on it with perfect ſecurity for any time. But to compenſate for knots and other accidental imperfections, he aſſumes 7200 as the meaſure of its abſolute force.

He computes the load on each frame to be 707520 pounds, which he reduces to $\frac{11}{14}$ths, or 555908 pounds.

The abſolute force of each of the lower ſtruts is 576000 (at 7200 per inch), and that of the curves 518400. Mr Pitot, conſidering that the curves are kept from bending outwards by the arch-ſtones which preſs on them, thinks that they may be conſidered as acting preciſely as the outer ſtruts EI. We have no objection to this ſuppoſition.

11 Computed.

With theſe data we may compute the load which the lower truſs can ſafely bear by the rule delivered in the article Carpentry. We therefore proceed as follows:

Meaſure off by a ſcale of equal parts as, at, each 576000, and add tv 518400. Complete the parallelogram $avxs$, and draw the vertical xc, meeting the horizontal line aC in c. Make cb equal to ca. Join xb, and complete the parallelogram $axby$. It is evident that the diagonal xy will repreſent the load which theſe pieces can carry; for the line av is the united force of the curve AP and the ſtrut IE, and as is the ſtrength of IG. Theſe two are equivalent to ax. xb is, in like manner, equivalent to the ſupport on the other ſide, and xy is the load which will juſt balance the two ſupports ax and bx.

When xy is meaſured on the ſame ſcale, it will be found = 2850000 pounds. This is more than five times the load which actually lies on the frame. It is therefore vaſtly ſtronger than is neceſſary. Half of each of the linear dimenſions would have been quite ſufficient, and the ſtruts needed only to be 5 inches by 4. Even this would have carried twice the weight, and would have borne the load really laid on it with perfect ſafety.

We proceed to meaſure the ſtrength of the upper part. The force of each ſtrut is 432000, and that of the curve is 518400; therefore, having drawn Mv parallel to the ſtrut ON, make Mv = 432000, and Ms = 432000 + 518400. Complete the parallelogram Msrv. Draw the horizontal line rk, cutting the vertical MC in k, and make ky = Mk. It is plain, from what was done for the lower part, that My will meaſure the load which can be carried by the upper part. This will be found = 1160000. This is alſo greatly ſuperior to the load; but not in ſo great a proportion as the other part. The chief part of the load lies on the upper part; but the chief reaſon of the difference is the greater obliquity of the upper ſtruts. This ſhortens the diagonal My of the parallelogram of forces. Mr Pitot ſhould have adverted to this; and inſtead of making the upper ſtruts more ſlender than the lower, he ſhould have made them ſtouter.

The ſtrain on the ſtretcher LL is not calculated. It is meaſured by $r'k'$, when My is the load actually lying on the upper part. Leſs than the ſixth part of the coheſion of the ſtretcher is more than ſufficient for the horizontal thruſt; and there is no difficulty of making the foot joints of the ſtruts abundantly ſtrong for the purpoſe.

The reader will perceive that the computation juſt now given does not ſtate the proportions of the ſtrains *actually exerted* on the different pieces, but the load on the whole, on the ſuppoſition that each piece is ſubjected to a ſtrain proportioned to its ſtrength. The other calculation is much more complicated, but is not neceſſary here.

This centre has a very palpable defect. If the piers ſhould yield to the load, and the feet of the centre fly out, the lower part will exert a very conſiderable ſtrain on the ſtretcher, tending to break it acroſs between N and L, and on the other ſide. HKF of the lower part is firmly bound together, and cannot change its ſhape, and will therefore act like a lever, turning round the point F. It will draw the ſtrut HK away from its abutment with GH, and the ſtretcher will be ſtrained acroſs at the place between H and F, where it is bolted with the bridle. This may be reſiſted in ſome degree by an iron ſtrap uniting ON and HK; but there will ſtill be a want of proportional ſtrength. Indeed, in an arch of ſuch height (a ſemicircle), there is but little riſk of this yielding of the piers; but it is an imperfection.

12 A centre on the ſame principles for an elliptical arch.

The centre (fig. 2.) is conſtructed on the ſame principle preciſely for an elliptical arch (A). The calculation of its ſtrength is nearly the ſame alſo; only the two upper ſtruts of a ſide being parallel, the parallelogram Msrv (of fig. 1.) is not needed, and in its ſtead we meaſure off on ON a line to repreſent twice its ſtrength. This comes in place of Mr' of fig. 1.—*N. B.* The calculation proceeds on the ſuppoſition that the ſhort ſtraining piece MM makes but one firm body with the king-poſt. Mr Pitot employed this piece (we preſume) to ſeparate the heads of the ſtruts, that their obliquity might be leſſened thereby: and this is a good thought; for when the angle formed by the ſtruts on each ſide is very open, the ſtrain on them becomes very great.

The ſtretcher of this frame is ſcarfed in the middle. Suppoſe this joint to yield a little, there is a danger of the lower ſtrut ON loſing its hold, and ceaſing to join in the ſupport: for when the crown ſinks by the lengthening of the ſtretcher, the triangle ORN of fig. 2. will be more diſtorted than the ſpace above it, and ON will be looſened. But this will not be the caſe when the ſinking of the crown ariſes from the mere compreſſion of the ſtruts. Nor will it happen at all in the centre, fig. 1. On the contrary, the ſtrut ON will abutt more firmly by the yielding of the foot of ML.

The figure of this arch of Mr Pitot's conſiſts of three arches of circles, each of 60 degrees. As it is elegant, it will not be unacceptable to the artiſt to have a conſtruction for this purpoſe.

13 How to conſtruct ſuch an arch.

Make BY = CD, and CZ = $\frac{1}{2}$ CY. Deſcribe the ſemicircle ZÆY, and make ZS = ZÆ. S is the centre of the ſide arches, each of 60 degrees. The centre T of

the

(A) It is the middle arch of the bridge at Liſle Adam, of which Mr Pitot had the direction. It is of 80 feet ſpan, and riſes 31 feet.

the arch, which unites theſe two, is at the angle of an equilateral triangle STS.

This conſtruction of Mr Pitot's makes a handſome oval, and very near an ellipſis, but lies a little without it. We ſhall add another of our own, which coincides with the ellipſe in eight points, and furniſhes the artiſt, by the way, a rule for drawing an infinite variety of ovals.

Let AB, DE (fig. 2. N° 2.) be the axes of an ellipſe, C the centre, and F, f the two foci. Make $Cb = CD$, and deſcribe a circle $ADbe$ paſſing through the three given points A, D, and b. It may be demonſtrated, that if from any point P of the arch AD be drawn a chord PD, and if a line PRr be drawn, making the angle $DPR = PDC$, and meeting the two axes in the points R and r, then R and r will be the centres of circles, which will form a quarter APD of an oval, which has AB and DE for its two axes.

We want an oval which ſhall coincide as much as poſſible with an ellipſis? The moſt likely method for this is to find the very point P where the ellipſis cuts the circle $ADbe$. The eaſieſt way for the artiſt is to deſcribe an arch of a circle am, having AB for its radius, and the remote focus f for its centre. Then ſet one foot of the compaſſes on any point P, and try whether the diſtance PF from the neareſt focus F is exactly equal to its diſtance Pm from that circle. Shifting the foot of the compaſſes from one point of the arch to another, will ſoon diſcover the point. This being found, draw PD, make the angle $DPr = PDr$, and R and r are the centres wanted. Then make $Cs = CR$, and we get the centres for the other ſide.

The geometer will not reliſh this mechanical conſtruction. He may therefore proceed as follows: Draw Dd parallel to AB, cutting the circle in d. Draw ed, cutting AC in N. Draw CG parallel to Ae, and make the angle $CGi = ADe$. Biſect CN in O, and join Oi. Make OM, $OM' = Oi$, and draw MP, M'P perpendicular to AB. Theſe ordinates will cut the circle $ADbe$ in the points P and P', where it is cut by the ellipſe. We leave the demonſtration as a geometrical exerciſe for the dilettante.

14 Centre for the nave of St Peter's.

We ſaid, that this centering of Mr Pitot's reſembled in principle the one employed by Michael Angelo for the nave and tranſepts of St Peter's church at Rome. Fontana, who has preſerved this, aſcribes the conſtruction of it to one of the name of San Gallo. A ſketch of it is given in fig. 3. It is, however, ſo much ſuperior, and ſo different in principle, from that employed for the cupola, that we cannot think it the invention of the ſame perſon. It is, like Pitot's, not only diviſible, but really divided into two parts, of which the upper carries by much the greateſt part of the load. The pieces are judiciouſly diſpoſed, and every important beam is amply ſecured againſt all tranſverſe ſtrains. Its only fault is a great profuſion of ſtrength. The innermoſt polygon $aghb$ is quite ſuperfluous, becauſe no ſtrain can force in the ſtruts which reſt on the angles. Should the piers yield outwards, this polygon will be looſe, and can do no ſervice. Nor is the triangle gib of any uſe, if the king-poſt above it be ſtrapped to the tie-beam and ſtraining ſill. Perhaps the inventor conſidered the king-poſt as a pillar, and wiſhed to ſecure the tie-beam againſt its croſs ſtrain. This centering, however, muſt be allowed to be very well compoſed; and we expect that the well-informed reader will join us in preferring it to Mr Pitot's, both for ſimplicity of principle, for ſcientific propriety, and for ſtrength.

There is one conſiderable advantage which may be derived from the actual diviſion of the truſs into two parts. If the tie-beam LL, inſtead of reſting on the ſtretcher EF, had reſted on a row of chocks formed like double wedges, placed above each other, head to point, the upper part of the centering might be ſtruck independent of the lower, and this might be done gradually, beginning at the outer ends of the ſtretcher. By this procedure, the joints of the arch-ſtones will cloſe on the haunches, and will almoſt relieve the lower centering, ſo that all can be pulled out together. Thus may the arch ſettle and conſolidate in perfect ſafety, without any chance of breaking the bond of the mortar in any part; an accident which frequently happens in great arches. This procedure is peculiarly adviſable for low pitched or elliptical arches. But this will be more clearly ſeen afterwards, when we treat of the internal movements of an arch of maſonry.

This may ſuffice for an account of the more ſimple conſtruction of truſſed centres; and we proceed to ſuch as have a much greater complication of principle. We ſhall take for examples ſome conſtructed by Mr Perronet, a very celebrated French architect.

15 Perronet's maxim of conſtruction.

Mr Perronet's general maxim of conſtruction is to make the truſs conſiſt of ſeveral courſes of ſeparate truſſes, independent (as he thinks) of each other, and thus to employ the joint ſupport of them all. In this conſtruction it is not intended to make uſe of one truſs, or part of one truſs, to ſupport another, as in the former ſet, and as is practiſed in the roofs of St Paul's church, Covent Garden, and in Drury Lane theatre. Each truſs ſpans over the whole diſtance of the piers, and would ſtand alone (having, however, a tottering equilibrium). It conſiſts of a number of ſtruts, ſet end to end, and forming a polygon. Theſe truſſes are ſo arranged, that the angles of one are in the middle of the ſides of the next, as when a polygon is inſcribed in a circle, and another (of the ſame number of ſides) is circumſcribed by lines which touch the circle in the angles of the inſcribed polygon. By this conſtruction the angles of the alternate truſſes lie in lines pointing towards the centre of the curve. King-poſts are therefore placed in this direction between the adjoining beams of the truſſes. Theſe king-poſts conſiſt of two beams, one on each ſide of the truſs, and embrace the truſs-beams between them, meeting in the middle of their thickneſs. The abutting beams are mortiſed, half into each half of the poſt. The other beam, which makes the baſe of the triangle, paſſes through the poſt, and a ſtrong bolt is driven through the joint, and ſecured by a key or a nut. In this manner is the whole united; and it is expected, that when the load is laid on the uppermoſt truſs, it will all butt together, forcing down the king-poſts, and therefore preſſing them on the beams of all the inferior truſſes, cauſing them alſo to abutt on each other, and thus bear a ſhare of the load. Mr Perronet does not aſſume the invention to himſelf; but ſays that it was invented and practiſed by Mr Manſard de Sagonne at the great bridge of Moulins. It is much more ancient, and is the work of the celebrated phyſician and architect Perrault; as may be ſeen in the collection of machines and inventions of that gentleman publiſhed after

ter his death, and alſo in the great collection of inventions approved of by the Academy of Sciences. It is this which we propoſe to examine.

16 Centering employed for the bridge of Cravant,

Fig 4. repreſents the centering employed for the bridge of Cravant. The arches are elliptical, of 60 feet ſpan and 20 feet riſe. The archſtones are four feet thick, and weigh 176 pounds per foot. The truſs-beams were from 15 to 18 feet long, and their ſection was 9 inches by 8. Each half of the king poſts was about 7 feet long, and its ſection 9 inches by 8. The whole was of oak. The five truſſes were 5½ feet aſunder. The whole weight of the arch was 1350000 lbs. which we may call 600 tons (it is 558). This is about 112 tons for each truſs. We muſt allow near 90 tons of this really to preſs the truſs. A great part of this preſſure is borne by the four beams which make the feet of the truſs, coupled in pairs on each ſide. The diagonal of the parallelogram of forces drawn for theſe beams is, to one of the ſides, in the proportion of 360 to 285. Therefore ſay, as 360 to 285 ; ſo is 90 to 71¼ tons, the thruſt on each foot. The ſection of each is 144 inches. We may with the utmoſt ſafety lay three tons on every inch for ever. This amounts to 432 tons, which is more than ſix times the ſtrain really preſſing the foot beams in the direction of their length ; nay, the upper truſs alone is able to carry much more than its load. The abſolute ſtrength of its foot-beam is 216 tons. It is much more advantageouſly placed ; for the diagonal of the parallelogram of forces correſponding to its poſition is to the ſide as 438 to 285. This gives $58\frac{6}{10}$ tons for the ſtrain on each foot; which is not much above the fourth part of what it is able to carry for ever. No doubt can therefore be entertained of the ſuperabundant ſtrength of this centering. We ſee that the upper row of ſtruts is quite ſufficient, and all that is wanted is to procure ſtiffneſs for it ; for it muſt be carefully kept in mind, that this upper row is not like an equilibrated arch. It will be very unequally loaded as the work advances. The haunches of the frame will be preſſed down, and the joints at the crown raiſed up. This muſt be reſiſted.

Here then we may gather, by the way, a uſeful leſſon. Let the outer row of ſtruts be appropriated to the carriage of the load, and let the reſt be employed for giving ſtiffneſs. For this purpoſe let the outer row have abundant ſtrength. The advantages of this method are conſiderable. The poſition of the beams of the exterior row is more advantageous, when (as in this example) the whole is made to reſt on a narrow foot : for this obliges us to make the laſt angle, at leaſt of the lower row, more open, which increaſes the ſtrain on the ſtrut ; beſides, it is next to impoſſible to diſtribute the compreſſing thruſts among the different rows of the truſs beams ; and a beam which, during one period of the maſon work, is acting the part of a ſtrut, in another period is bearing no ſtrain but its own weight, and in another it is ſtretched as a tie. A third advantage is, that, in a caſe like this, where all reſts on a narrow foot, and the lower row of beams are bearing a great part of the thruſt, the horizontal thruſt on the pier is very great, and may puſh it aſide. This is the moſt ruinous accident that can happen. An inch or two of yielding will cauſe the crown of the arch to ſink prodigiouſly, and will inſtantly derange all the bearings of the abutting beams : but when the lower beams already act as ties, and are quite adequate to their office, we render the frame perfectly ſtiff or unchangeable in its form, and take away the horizontal thruſt from the piers *entirely*. This advantage is the more valuable, becauſe the very circumſtance which obliges us to reſt all on a narrow foot, places this foot on the very top of the pier, and makes the horizontal thruſt the more dangerous.

But, to proceed in our examination of the centering of Cravant bridge, let us ſuppoſe that the king poſts are removed, and that the beams are joined by compaſs joints. If the pier ſhall yield in the ſmalleſt degree, both rows of ſtruts muſt ſink ; and ſince the angles (at leaſt the outermoſt) of the lower row are more open than thoſe of the upper row, the crown of the lower row will ſink more than that of the upper.

The angles of the alternate rows muſt therefore ſeparate a little. Now reſtore the king poſts ; they prevent this ſeparation. Therefore *they are ſtretched ;* therefore the beams of the lower row are alſo ſtretched; conſequently they no longer butt on their mortiſes, and muſt be held in their places by bolts. Thus it appears that, in this kind of ſagging, the original diſtribution of the load among the different rows of beams is changed, and the upper row becomes loaded beyond our expectation.

If the ſagging of the whole truſs proceed only from the compreſſion of the timbers, the caſe is different, and we *may* preſerve the original diſtribution of mutual abutment more accurately. But in this caſe the ſtiffneſs of the frame ariſes chiefly from croſs ſtrains. Suppoſe that the frame is loaded with archſtones on each ſide up to the poſts HC, *h c* ; the angles E and *e* are preſſed down, and the beams EOF, *e o* F puſh up the point F. This cannot riſe without bending the beams EOF, *e o* F; becauſe O and *o* are held down by the double king poſts, which graſp the beams between them. There is therefore a croſs ſtrain on the beams. Obſerve alſo, that the triangle EHF does not preſerve its ſhape by the connection of its joints ; for although the ſtrut beams are mortiſed into the king poſt, they are in very ſhallow mortiſes, rather for ſteadying them than for holding them together. Mr Perronet did not even pin them, thinking that their abutment was very great. The triangle is kept in ſhape by the baſe EF, which is firmly bolted into the middle poſt at O. Had theſe interſections not been ſtrongly bolted, we imagine that the centres of ſome of Mr Perronet's bridges would have yielded much more than they did ; yet ſome of them yielded to a degree that our artiſts would have thought very dangerous. Mr Perronet was obliged to load the crown of the centering with very great weights, increaſing them as the work advanced, to prevent the frames from going out of ſhape : in one arch of 120 feet he laid on 45 tons. Notwithſtanding this imperfection, which is perhaps unavoidable, this mode of framing is undoubtedly very judicious, and perhaps the beſt which can be employed without depending on iron-work.

17 For the bridge of Nogent,

Fig. 5. repreſents another, conſtructed by Perronet for an arch of 90 feet ſpan and 28 feet riſe. The truſſes were 7 feet apart, and the arch was 4½ thick ; ſo that the unreduced load on each frame was very nearly 235 tons. The ſcantling of the ſtruts was 15 by 12 inches. The principle is the ſame as that of the former. The chief difference is, that in this centre the outer truſs-beam of the lower row is not coupled with the middle row,

row, but kept nearly parallel to the outer beam of the upper row. This adds greatly to the ſtrength of the foot, and takes off much of the horizontal thruſt from the pier.

Mr Perronet has ſhewn great judgment in cauſing the polygon of the inner row of truſs beams gradually to approach the polygon of the outer row. By this diſpoſition, the angles of the inner polygon are more acute than thoſe of the outer. A little attention will ſhew, that the general ſagging of all the polygons will keep the abutments of the lower one nearer, or exactly, to their original quantity. We muſt indeed except the foot-beam. It is ſtill too oblique; and, inſtead of converging to the foot of the upper row, it ſhould have diverged from it. Had this been done, this centre is almoſt perfect in its kind. As it is, it is at leaſt ſix times ſtronger than was abſolutely neceſſary. We ſhall have occaſion to refer to this figure on another occaſion.

18 St Maxence,

This maxim is better exemplified by Mr Perronet in the centering of the bridge of St Maxence, exhibited in fig. 5 n° 2. than in that of Nogent, fig. 5. n° 1. But we think that a horizontal truſs-beam *a b* ſhould have been inſerted (in a ſubordinate manner) between the king-poſts next the crown on each ſide. This would prevent the crown from riſing while the haunches only are loaded, without impairing the fine abutments of *c d*, *c d*, when the arch is nearly completed. This is an excellent centering, but is not likely to be of much uſe in theſe kingdoms; becauſe the arch itſelf will be conſidered as ungraceful and ugly, looking like a huge lintel. Perronet ſays, that he preferred it to the ellipſe, becauſe it was lighter on the piers, which were thin. But the failure of one arch muſt be immediately followed by the ruin of all. We know much better methods of lightening the piers.

19 Neuilly, and

Fig. 6 repreſents the centering of the bridge of Neuilly, near Paris, alſo by Perronet. The arch has 120 feet ſpan, and 30 feet riſe, and is 5 feet thick. The frames are 6 feet apart, and each carries an abſolute (that is, not reduced to $\frac{11}{14}$ or to $\frac{4}{9}$) load of 350 tons. The ſtrut beams are 17 by 14 inches in ſcantling. The king poſts are of 15 by 9 each half; and the horizontal bridles, which bind the different frames together in five places, are alſo 15 by 9 each half. There are eight other horizontal binders of 9 inches ſquare.

This is one of the moſt remarkable arches in the world; not altogether on account of its width (for there are ſeveral much wider), but for the flatneſs at the crown; for about 26 feet on each ſide of the middle it was intended to be a portion of a circle of 150 feet radius. An arch (ſemicircular) of 300 feet ſpan might therefore be eaſily conſtructed, and would be much ſtronger than this, becauſe its horizontal thruſt at the crown would be vaſtly greater, and would keep it more firmly united.

The bolts of this centre are differently placed from thoſe of the former; and the change is judicious. Mr Perronet had doubtleſs found by this time, that the ſtiffneſs of his framing depended on the tranſverſe ſtrength of the beams; and therefore he was careful not to weaken them by the bolts. But notwithſtanding all his care, the framing ſunk upwards of 13 inches before the keyſtones were laid; and during the progreſs of the work, the crown roſe and ſunk, by various ſteps, as the loading was extended along it. When 20 courſes were laid on each ſide, and about 16 tons laid on the crown of each frame, it ſunk about an inch. When 46 courſes were laid, and the crown loaded with 50 tons, it ſunk about half an inch more. It continued ſinking as the work advanced; and when the keyſtone was ſet it had ſunk 13½ inches. But this ſinking was not general; on the contrary, the frame had riſen greatly at the very haunches, ſo as to open the upper part of the joints, many of which gaped an inch; and this opening of the joints gradually extended from the haunches towards the crown, in the neighbourhood of which they opened on the under ſide. This evidently aroſe from a want of ſtiffneſs in the frame. But theſe joints cloſed again when the centres were ſtruck, as will be mentioned afterwards.

☞ We have taken particular notice of the movements and twiſting of this centre, becauſe we think that they indicate a deficiency, not only of ſtiffneſs, but of abutment among the truſs beams. The whole has been too flexible, becauſe the angles are too obtuſe: This ariſes from their multiplicity. When the intercepted arches have ſo little curvature, the power of the load to preſs it inward increaſes very faſt. When the intercepted arch is reduced to one half, this power is more than doubled; and it is alſo doubled when the radius of curvature is doubled. The king-poſts ſhould have been farther apart near the crown, ſo that the quantity of arch between them ſhould compenſate for its diminiſhed curvature.

The power of withſtanding any given inequality of load would therefore have been greater, had the centre conſiſted of fewer pieces, and their angles of meeting been proportionally more acute. The greateſt improvement would have been, to place the foot of the lower tier of truſs-beams on the very foot of the pier, and to have alſo ſeparated it at the head from the reſt with a longer king-poſt, and thus to have made the diſtances of the beams on the king-poſts increaſe gradually from the crown to the ſpring. This would have made all the angles of abutment more acute, and would have produced a greater preſſure on all the lower tiers when the frame ſagged.

Fig. 7. repreſents the centering of the bridge of Orleans. The arch has 100 feet ſpan, and riſes 30, and the arch-ſtones are 6 feet long. It is the conſtruction of Mr Hupeau, the firſt architect of the bridge. It is the boldeſt work of the kind that we have ſeen, and is conſtructed on clear principles. The main abutments are few in number. Becauſe the beams of the outer polygon are long, they are very well ſupported by ſtraining beams in the middle; and the ſtruts or braces which ſupport and butt on them, are made to reſt on points carried entirely by *ties*. The inventor, however, ſeems to have thought that the angles of the inner polygon were ſupported by mutual compreſſion, as in the outer polygon. But it is plain that the whole inner polygon may be formed of iron rods. Not but that both polygons *may* be in a ſtate of compreſſion (this is very poſſible); but the ſmalleſt ſagging of the frame will change the proportions of the preſſures at the angles of the two polygons. The preſſures on the exterior angles will increaſe, and thoſe on the lower or interior angles will diminiſh moſt rapidly; ſo that the abutments in the lower polygon will be next to nothing. 20 Orleans.

thing. Such points could bear very little preſſure from the braces which ſupport the middle of the long bearings of the upper beams, and their preſſures muſt be borne chiefly by the joints ſupported by the king-poſts. The king-poſts would then be in a ſtate of extenſion. It is difficult, however, to decide what is the preciſe ſtate of the preſſure at theſe interior angles.

21 Inſtructive hiſtory of this centre

The hiſtory of the erection of this bridge will throw much light on this point, and is very inſtructive. Mr Hupeau died before any of the arches were carried farther than a very few of the firſt courſes. Mr Perronet ſucceeded to the charge, and finiſhed the bridge. As the work advanced, the crown of the frame roſe very much. It was loaded; and it ſunk as remarkably. This ſhewed that the lower polygon was giving very little aid. Mr Perronet then thought the frame too weak, and inſerted the long beam DE, making the diagonal of the quadrangle, and very nearly in the direction of the lower beam *a b*, but falling rather below this line. He now found the frame abundantly ſtrong. It is evident that the truſs is now changed exceedingly, and conſiſts of only the two long ſides, and the ſhort ſtraining beam lying horizontally between their heads. The whole centering conſiſts now of one great truſs *a* E *e b*, and its long ſides *a* E, *e b*, are truſſed up at B and *f*. Had this ſimple idea been made the principle of the conſtruction, it would have been excellent. The angle *a* DE might have been about 176°, and the polygon D *c h g* employed only for giving a ſlight ſupport to this great angle, ſo as not to allow it to exceed 180°. But Mr Perronet found, that the joint *c*, at the foot of the poſt E *c*, was about to *draw looſe*, and he was obliged to bolt long pieces of timber on each ſide of the joint, embracing both beams. Theſe were evidently acting the ſame part as iron ſtraps would have done; a complete proof that, whatever may have been the original preſſures, there was no abutment now at the point *c*, and that the beams that met there were not in a ſtate of compreſſion, but were on the ſtretch. Mr Perronet ſays that he put theſe cheeks to the joints *to ſtiffen* them. But this was not their office; becauſe the adjoining beams were not ſtruts, but ties, as we have now proved.

We may therefore conclude, that the outer polygon, with the aſſiſtance of the pieces *a b*, DE, were carrying the whole load. We do not know the diſtance between the frames; but ſuppoſing them ſeven feet apart, and the arch 6 feet thick, and weighing 170 pounds per foot, we learn the load. The beams were 16 inches ſquare. If we now calculate what they would bear at the ſame very moderate rate allowed to the other centres, we find that the beams AB and *a b* are not loaded to one-ſixth of their ſtrength.

We have given this centre as a fine example of what carpentry is able to perform, and becauſe, by its ſimplicity, it is a ſort of text on which the intelligent artiſt may make many comments. We may ſee plainly that, if the lower polygon had been formed of iron rods, firmly bolted into the feet of the king-poſts, it would have maintained its ſhape completely. The ſervice done by the beam DE was not ſo much an increaſe of abutment as a diſcharge of the weight and of the *pull* at the joint *c*. Therefore, in caſes where the feet of the truſs are *neceſſarily* confined to a very narrow ſpace, we ſhould be careful to make the upper polygon ſufficient to carry the whole load (ſay by doubling its beams), and we may then make the lower polygon of ſlender dimenſions, provided we ſecure the joints on the king-poſts by iron ſtraps which embrace a conſiderable portion of the tie on each ſide of the joint.

22 All theſe centres good in their kind.

We are far from thinking that theſe centres are of the beſt kind that could be employed in their ſituation; but they are excellent in their kind: and a careful ſtudy of them will teach the artiſt much of his profeſſion. When we have a clear conception of the ſtate of ſtrain in which the parts of a frame really are, we know what ſhould be done in order to draw all the advantage poſſible from our materials. We have ſaid in another place, that where we can give our joints ſufficient connection (as by ſtraps and bolts, or by cheeks or fiſhes), it is better to uſe ties than ſtruts, becauſe ties never bend.

We do not approve of Mr Perronet's practice of giving his truſſes ſuch narrow feet. By bringing the foot of the lower polygon farther down, we greatly diminiſh all the ſtrains, and throw more load on the lower polygon: and we do not ſee any of Mr Perronet's centres where this might not have been done. He ſeems to affect a great ſpan, to ſhew the wonders of his art; but our object is to teach how to make the beſt centre of a given quantity of materials; and how to make the moſt perfect centre, when we are not limited in this reſpect, nor in the extent of our fixed points.

23 Excellence of the centre employed for Blackfriars bridge.

We ſhall conclude this ſeries of examples with one where no ſuch affectation takes place. This is the centering of the bridge at Blackfriars, London. The ſpan of the arch is 100 feet, and its height from the ſpring is about 43. The drawing fig. 8. is ſufficiently minute to convey a diſtinct notion of the whole conſtruction. We need not be very particular in our obſervations, after what has been ſaid on the general principles of conſtruction. The leading maxim, in the preſent example, ſeems to be, *that every part of the arch ſhall be ſupported by a ſimple truſs of two legs reſting, one on each pier.* H, H, &c. are called APRON PIECES, to ſtrengthen the exterior joints and to make the RING as ſtiff in itſelf as poſſible. From the ends of this apron-piece proceed the two legs of each truſs. Theſe legs are 12 inches ſquare: They are not of an entire piece, but of ſeveral, meeting in firm abutment. Some of their meetings are ſecured by the double king-poſts, which graſp them firmly between them, and are held together by bolts. At other interſections, the beams appear halved into each other; a practice which cannot but weaken them much, and would endanger their breaking by croſs ſtrains, if it were poſſible for the frame to change its ſhape. But the great breadth of this frame is an effectual ſtop to any ſuch change. The fact was, that *no ſinking or twiſting whatever* was obſerved during the progreſs of the maſon work. Three points in a ſtraight line were marked on purpoſe for this obſervation, and were obſerved every day. The arch was more than ſix feet thick; and yet the ſinking of the crown, before ſetting the key-ſtones, did not amount to one inch.

The centre employs about one-third more timber than Perronet's great centre in proportion to the ſpan of the arch; but the circumference increaſes in a greater proportion than this, becauſe it is more elevated. In every way of making a compariſon of the dimenſions, Mr Mylne's arch employs more timber; but it is *beyond all compariſon* ſtronger. The great elevation is partly the reaſon of this. But the diſpoſition of the timbers is alſo much more advantageous, and may be copied even in the low pitched arches of Neuilly. The ſimple truſs, reaching from pier to pier for the middle point of the arch, gives the ſtrong ſupport where it is moſt of all wanted; and in the lateral points H, although one leg of the truſs is very oblique, the other compenſates for it by its upright poſition.

The chief peculiarity of this centre is to be ſeen in its baſe. This demands a more particular attention: but we muſt firſt make ſome obſervations on the condition of an arch, as it reſts on the centering after the keyſtones are all ſet, and on the gradual transference of the preſſure from the boards of the centering to the joints of the archſtones.

24
Obſervations on the ſtate of an arch as it reſts on the centering.

While all the archſtones lie on the centering, the lower courſes are alſo leaning pretty ſtrongly on each other. But the mortar is hardly compreſſed in the joints; and leaſt of all in the joints near the crown. Suppoſe the arch to be catenarian, or of any other ſhape that is perfectly equilibrated: When the centering is gradually withdrawn, all the archſtones follow it. Their wedge-like form makes this impoſſible, without the middle ones ſqueezing the lateral ones aſide. This compreſſes the mortar between them. As the ſtones thus come nearer to each other, thoſe near the crown muſt deſcend more than thoſe near the haunches, before every ſtone has leſſened its diſtance from the next by the ſame quantity; for example, by the hundredth part of an inch. This circumſtance alone muſt cauſe a ſinking in the crown, and a change of ſhape. But the joints near the crown are *already* more open than thoſe near the haunches. This produces a ſtill greater change of form before all is ſettled. Some maſons endeavour to remedy, or at leaſt to diminiſh, this, by uſing no mortar in the joints near the crown. They lay the ſtones dry, and even force them together by wedges and blocks laid between the ſtones on oppoſite ſides of the crown: They afterwards pour in fine cement. This appears a good practice. Perronet rejects it, becauſe the wedging ſometimes breaks the ſtones. We ſhould not think this any great harm; becauſe the fracture will make them cloſe where they would otherwiſe lie hollow. But, after all our care, there is ſtill a ſinking of the crown of the arch. By gradually withdrawing the centering, the joints cloſe, the archſtones begin to butt on each other, and to force aſide the lateral courſes. This abutment gradually increaſing, the preſſure on the haunches of the centering is gradually diminiſhed by the mutual abutment, and ceaſes entirely in that courſe, which is the loweſt that formerly preſſed it: it then ceaſes in the courſe above, and then in the third, and ſo on. And, in this manner, not only the centering quits the arch, gradually, from the bottom to the top, *by its own retiring from it*, but the arch alſo quits the centering *by changing its ſhape*. If the centering were now puſhed up again, it would touch the arch firſt at the crown; and it muſt *lift up* that part gradually before it come again in contact with the haunches. It is evident, therefore, that an arch, built on a centre of a ſhape perfectly ſuited to equilibration, will not be in equilibrio when the centering is removed. It is therefore neceſſary to form the centering in ſuch a manner (by raiſing the crown), that it ſhall *leave* the arch of a proper form. This is a very delicate taſk, requiring a previous knowledge of the enſuing change of form. This cannot be aſcertained by the help of any theory we are acquainted with.

But, ſuppoſe this attained, there is another difficulty: While the work advances, the centering is warped by the load laid on it, and continually increaſing on each ſide. The firſt preſſure on the centering forces down the haunches, and raiſes the crown. The arch is therefore leſs curved at the haunches than is intended: the joints, however, accommodate themſelves to this form, and are cloſe, and filled with mortar. When the maſons approach the middle of the arch, the frame ſinks there, and riſes up at the haunches. This opens all the joints in that place on the *upper* ſide. By the time that the keyſtones are ſet, this warping has gone farther; and joints are opened on the *under* ſide near the crown. It is true we are here ſpeaking rather of an extreme caſe, when the centering is *very* flexible; but this occurred to Mr Perronet in the two great bridges of Neuilly and of Mantz. In this laſt one, the crown ſunk above a foot before the key was ſet, and the joints at the haunches opened above an inch *above*, while ſome nearer the crown opened near a quarter of an inch *below*.

25
A delicate buſineſs to ſtrike the centering.

In this condition of things, it is a delicate buſineſs to ſtrike the centering. Were it removed in an inſtant, all would probably come down; for the archſtones are not yet abutting on each other, and the joints in the middle are open below. Mr Perronet's method appears to us to be very judicious. He began to detach the centering at the very bottom, on each ſide equally, where the preſſure on the centering is very ſlight. He cut away the blocks which were immediately under each archſtone. He proceeded gradually upwards in this way with ſome ſpeed, till all was detached that had been put out of ſhape by the bending of the centering. This being no longer ſupported, ſunk inward, till it was ſtopped by the abutment which it found on the archſtones near the crown, which were ſtill reſting on their blocks. During part of this proceſs, the open joints opened ſtill more, and looked alarming. This was owing to the removal of the load from the haunches of the centering. This allowed the crown to ſink ſtill more, by forcing out the arch ſtones at the haunches. He now pauſed ſome days; and during this time the two haunches, now hanging in the air, gradually preſſed in toward the centering, their outer joints cloſing in the meanwhile. The haunches were now preſſing pretty hard on the archſtones nearer the crown. He then proceeded more ſlowly, deſtroying the blocks and bridgings of theſe upper archſtones. As ſoon as he deſtroyed the ſupport of one, it immediately yielded to the preſſure of the haunch; and if the joint between it and the one adjoining toward the crown happened to be open, whether on the under or the upper ſide, it immediately cloſed on it. But in proceeding thus, he found every ſtone ſink a little while it cloſed on its neighbour; and this was like to produce a ragged ſoffet, which is a deformity. He therefore did not allow them to ſink ſo much. In the places of the blocks and bridgings which he had cut away, he ſet ſmall billets, ſtanding on their ends, between the centering and the archſtones. Theſe allowed the pendulous arch to puſh toward the crown without ſenſibly deſcending; for the billets were puſhed out of the perpendicular, and ſome of them tumbled down. Proceeding

ing in this way, he advanced to the very next courſe to the keyſtone on each ſide, the joints cloſing all the way as he advanced. The laſt job was very troubleſome; we mean the detaching the three uppermoſt courſes from the centering: for the whole elaſticity of the centering was now trying to unbend, and preſſing hard againſt them. He found that they were lifted up; for the joints beyond them, which had cloſed completely, now opened again below; but this job was finiſhed in one day, and the centre ſprung up two or three inches, and the whole arch ſunk about ſix inches. This was an anxious time; for he dreaded the great momentum of ſuch a vaſt maſs of matter. It was hard to ſay where it would ſtop. He had the pleaſure to ſee that it ſtopped very ſoon, ſettling ſlowly as the mortar was compreſſed, and after one or two days ſettling no more. This ſettling was very conſiderable both in the bridge at Neuilly and in that at Mantz. In the former, the ſinking during the work amounted to 13 inches. It ſunk ſix inches more when the blocks and bridgings were taken out, and 1½ when the little ſtandards were deſtroyed, and 1¼ more next day; ſo that the whole ſinking of the *pendulous* arch was 9½ inches, beſides what it had ſunk by the bending and compreſſion of the centering.

The crown of the centering was an arch of a circle deſcribed with a radius of 150 feet; but by the ſinking of the arch its ſhape was conſiderably changed, and about 60 feet of it formed an arch of a circle whoſe radius was 244 feet. Hence Mr Perronet infers, that a ſemicircle of 500 feet ſpan may be erected. It would no doubt be ſtronger than this arch, becauſe its greater horizontal thruſt would keep the ſtones firmer together. The ſinking of the arches at Mantz was not quite ſo great, but every thing proceeded in the ſame way. It amounted in all to 20½ inches, of which 12 inches were owing to the compreſſion and bending of the centering.

26 The foregoing obſervations exemplified.

In fig. 5. n° 1. may be obſerved an indication of this procedure of the maſonry. There may be noticed a horizontal line *a c*, and a diagonal *a b*. Theſe are ſuppoſed to be drawn on the maſonry as it would have ſtood had the frames not yielded during the building. The dotted line A*b' c'* ſhews the ſhape which it took by the ſinking of the centering. The dotted line on the other ſide was actually drawn on the maſonry when the keyſtone was ſet; and the wavy black line on the ſame ſide ſhews the form which the dotted line took by the ſtriking of the centering. The undulated part of this line cuts its former poſition a little below the middle, going without it below, and falling within it above. This ſhews very diſtinctly the movement of the whole maſonry, diſtinguiſhing the parts that were forced out and the parts which ſunk inward.

We preſume that the practical reader will think this account of the internal movements of a ſtupendous arch very inſtructive and uſeful. As Mr Perronet obſerved it to be uniformly the ſame in ſeveral very large arches which he erected, we may conclude that it is the general proceſs of nature. We by no means have the confidence in the durability or ſolidity of his arches which he prudently profeſſes to have. We have converſed with ſome very experienced maſons, who have alſo erected very great arches, and in very difficult ſituations, which have given univerſal ſatisfaction; and we have found them uniformly of opinion, that an arch which has ſettled to ſuch a proportion of its curvature as to change the radius from 150 to 244 feet, is in a very hazardous ſituation. They think the hazard the greater, becauſe the ſpan of the arch is ſo great in proportion to its weight (as they expreſs it very emphatically) or its height. The weight, ſay they, of the haunches is too ſmall for forcing together the keyſtones, which have ſcarcely any wedge-like form to keep them from ſliding down. This is very good reaſoning, and expreſſes very familiar notions. The mechanician would ſay, that the horizontal thruſt at the crown is too ſmall. When we queſtioned them about the propriety of Mr Perronet's method of removing the centering, they unanimouſly approved of its general principle, but ſaid that it was very ticklish indeed in the execution. The caſes which he narrates were new to them. They ſhould have almoſt deſpaired of ſucceſs with arches which had gone ſo much out of ſhape by the bending of the centres; becauſe, ſaid they, the ſlope of the centering, to a great diſtance from the crown, was ſo little, that the archſtones could not ſlide outwards along it, to cloſe even the under ſide of the joints which had opened above the haunches; ſo that *all* the archſtones were at too great a diſtance from each other; and a great and *general* ſubſiding of the whole was neceſſary for bringing them even to touch each other. They had *never* obſerved ſuch bendings of the centerings which they had employed, having never allowed themſelves to contract the feet of their truſſes into ſuch narrow ſpaces. They obſerved, that nothing but lighters with their maſts down can paſs under the truſſes, and that the ſides muſt be ſo protected by advanced works from the accidental ſhock of a loaded boat, that there cannot be left room for more than one. They added, that the bridges of communication, neceſſary for the expeditious conducting of the work, made all this ſuppoſed roomineſs uſeleſs: beſides, the buſineſs can hardly be ſo urgent and crowded anywhere, as to make the paſſage through every arch indiſpenſably neceſſary. Nor was the inconvenience of this obſtruction greatly complained of during the erection of Weſtminſter or Blackfriars bridges. Nothing ſhould come in competition with the *undoubted* ſolidity of the centering and the future arch; and all boaſting diſplay of talent and ingenuity by an engineer, in the exhibition of the wonders of his art, is miſplaced here.

Theſe appeared to us good reaſons for preferring the more cautious, and incomparably more ſecure, conſtruction of Mr Mylne, in which the breadth given to each baſe of the truſſes permitted a much more effective diſpoſition of the abutting timbers, and alſo enabled the engineer to make it incomparably ſtiffer; ſo that no change need be apprehended in the joints which have already cloſed, and in which the mortar has already taken its ſet, and commenced an union that never can be reſtored if it be once broken in the ſmalleſt degree, no not even by greater compreſſion.

27 The connection that is formed by mortar of lime, &c.

Here we beg leave to mention our notions of the connection that is formed by mortar compoſed of lime or gypſum. We conſider it as conſiſting chiefly, if not ſolely, in a cryſtallization of the lime or gypſum and water. As much water is taken up as is neceſſary for the formation of the cryſtals during their gradual converſion into mild calcareous earth or alabaſter, and the reſt evaporates. When the free acceſs of air is abſolutely prevented, the cryſtallization never proceeds to that ſtate, even although the mortar becomes extremely dry and hard. We had an opportunity of obſerving this accidentally, when paſſing through Maeſtricht in 1770, while they were cutting up a maſſy revetment of a part of the fortifications more than 300 years old. The mortar between the bricks was harder than the bricks (which were Dutch clinkers, ſuch as are now uſed only for the greateſt loads); but when mixed with water it made it lime-water, ſeemingly as ſtrrong as if freſh lime had been uſed. We obſerved the ſame thing in one ſmall part of a huge maſs of ancient Roman work near Romney in Kent; but the reſt, and all the *very old* mortar that we have ſeen, was in a mild ſtate, and was generally much harder than what produced any lime-water. Now when the mortar in the joints has begun its firſt cryſtallization, and is allowed to remain in perfect reſt, we are confident that the ſubſequent cryſtals, whether of lime, or of calcareous earth, or of gypſum, will be much larger and ſtronger than can ever be produced if they are once broken; and the farther that this cryſtallization has been carried, that is, the harder that the mortar has become, leſs of it remains to take any new cryſtallization. Why ſhould it be otherwiſe here than in every other cryſtallization that we are acquainted with?

28
Neceſſity of keeping the joints in their firſt ſtate.

We think therefore that it is of great conſequence to keep the joints in their *firſt* ſtate if poſſible; and that the ſtrength (as far as it depends on the mortar) is greatly diminiſhed by their opening; eſpecially when the mortar has acquired conſiderable hardneſs, which it will do in a month or ſix weeks, if it be good. The coheſion given by mortar is indeed a mere trifle, when oppoſed to a force which tends to open the joints, acting, as it generally does, with the tranſverſe force of a lever: but in ſituations where the overload on any particular archſtones tends to puſh them down through between their neighbours, like wedges, the coheſion of the mortar is then of very great conſequence.

We muſt make another obſervation. Mr Perronet's ingenious proceſs tended very effectually to cloſe the joints. It doing this, the forces which he brought into action had little to oppoſe them; but as ſoon as they were cloſed, the contact of the parts formerly open oppoſed an obſtruction incomparably greater, and immediately balanced a force which was but juſt able to turn the ſtone gently about the two edges in which it touched the adjoining ſtones. This is an important remark, though ſeemingly very trifling; and we wiſh the practitioner to have a very clear conception of it; but it would take a multitude of words to explain it. It is worth an experiment. Form a little arch of wooden blocks; and form one of theſe ſo, that when they are all reſting on the centering, it may be open at the outer joint—Remove the centering—Then preſs on the arch at ſome diſtance from the open joint.—You will find that a very ſmall preſſure will make the arch bend till that joint cloſes.—Preſs a little harder, and the arch will bend more, and the next joint will open.—Thus you will find that, by preſſing alternately on each ſide of the open joint, that ſtone can eaſily be made to flap over to either ſide; and that immediately after this is done the reſiſtance increaſes greatly. This ſhews clearly, that a very moderate force, judiciouſly employed, will cloſe the joints, but will not preſs the parts ſtrongly together. The joints therefore are *cloſed*, but *no more than cloſed*, and are hanging only by the edges by which they were hanging while the joints were open. The arch, therefore, though apparently cloſe and firm, is but looſe and tottering. Mr Perronet ſays, that his arches were firm, becauſe hardly a ſtone was obſerved to chip or ſplinter off at the edges by the ſettlement. But he had done every thing to prevent this, by digging out the mortar from between the headers, to the depth of two inches, with ſaws made on purpoſe. But we are well informed, that before the year 1791 (twenty years after the erection) the arches at Neuilly had ſunk very ſenſibly, and that very large ſplinters had flewn off in ſeveral places. It could not be otherwiſe. The original conſtruction was too bold; we may ſay needleſsly and oſtentatiouſly bold. A very gentle ſlope of the roadway, which would not have ſlackened the mad gallop of a ducal carriage, nor ſenſibly checked the laborious pull of a loaded waggon, and a proper difference in the ſize of the arches, would have made this wonderful bridge incomparably ſtronger and alſo much more elegant and pleaſing to the eye. Indeed, it is far from being as handſome as it might have been. The ellipſe is a moſt pleaſing figure to every beholder; but this is concealed as much as poſſible, and it is attempted to give the whole the appearance of a tremendous lintel. It has the oppreſſive look of danger. It will not be of long duration. The bridge at Mantz is ſtill more exceptionable, becauſe its piers are tall and ſlender. If any one of the arches fails, the reſt muſt fall in a moment. An arch of Blackfriars Bridge might be blown up without diſturbing its neighbours.

9
Mr Perronet's conſtructions too bold.

30
A bad method of ſtriking the centre.

Mr Perronet mentions another mode of ſtriking the centering, which he ſays is very uſual in France. Every ſecond bridging is cut out. Some time after, every ſecond of the remainder; after this, every ſecond of the remainder; and ſo on, till all are removed. This is never practiſed in this country, and is certainly a very bad method. It leaves the arch hanging by a number of diſtant points; and it is wonderful that any arch can bear this treatment.

31
The common method in Britain.

Our architects have generally proceeded with extreme caution. Wherever they could, they ſupported the centering by intermediate pillars, even when it was a truſſed centre, having a tie-beam reaching from ſide to ſide. The centre was made to reſt, not immediately on theſe pillars, but on pieces of timber formed like acute wedges, placed in pairs, one above the other, and having the point of the one on the thick end of the other. Theſe wedges were well ſoaped and rubbed with black lead, to make them ſlippery. When the centres are to be ſtruck, men are ſtationed at each pair of the wedges with heavy malls. They are directed to ſtrike together on the oppoſite wedges. By this operation, the whole centering deſcends together; or, when any part of the arch is obſerved to have opened its joints on the upper ſide, the wedges below that part are ſlackened. The framing may perhaps bend a little, and allow that part to ſubſide. If any part of the arch is obſerved to open its joints on the under ſide, the wedges below that part are allowed to ſtand after the reſt have been ſlackened. By this proceſs, the whole comes down gradually, and as ſlowly as we pleaſe, and the defects of every part of the arch may be attended to. Indeed the caution and moderation of our builders have commonly been ſuch, that few defects have been allowed to ſhew themſelves. We are but little acquainted with joints opening to the extent of two inches, and in ſuch a caſe would probably lift every ſtone of the arch again (b). We have not employed truſſed centerings ſo much perhaps as we ſhould have done; nor do we ſee their advantage (ſpeaking as mere builders) over centres ſupported all over, and unchangeable in their form. Such centres muſt bend a little, and require loading on the middle to keep them in ſhape. Their compreſſion and their elaſticity, are very troubleſome in the ſtriking of the centres in Mr Perronet's manner. The elaſticity is indeed of uſe when the centres are ſtruck in the way now deſcribed.

Theſe obſervations on the management of the internal movements of a great arch will enable the reader to appreciate all the merit of Mr Mylne's very ingenious conſtruction. We proceed therefore to complete our deſcription.

32 The excellence of Mr Mylne's method.

The gradual enlargement of the baſe of the piers of Blackfriars bridge enabled the architect to place a ſeries of five poſts *c*, *c*, *c*, *c*, *c*, one on each ſtap of the pier; the ingenious contexture of which made it like one ſolid block of ſtone (ſee Arch, *Supplement*). Theſe ſtruts were gradually more and more oblique, till the outer one formed an obtuſe angle with the loweſt ſide of the interior polygon of the truſs. On the top of theſe poſts was laid a ſloping SEAT or beam D of ſtout oak, the upper part of which was formed like a zig-zag ſcarfing. The poſts were not perpendicular to the under ſide of the ſeat. The angles next the pier were ſomewhat obtuſe. Short pieces of wood were placed between the heads of the poſts (but not mortiſed into them), to prevent them from ſlipping back. Each face of the ſcarf was covered with a thick and ſmooth plate of copper. The feet of the truſs were mortiſed into a ſimilar piece F, which may be called the SOLE of the truſs, having its lower ſide notched in the ſame manner with the upper ſide of D, and like it covered with copper. Between theſe two lay the STRIKING WEDGE E, the faces of which correſponded exactly with the ſlant faces of the ſeat and the ſole. The wedge was ſo placed, that the correſponding faces touched each other for about half of their length. A block of wood was put in at the broad end or baſe of this wedge, to keep it from ſlipping back during the laying the arch-ſtones. Its outer end E was bound with iron, and had an iron bolt ſeveral inches long driven into it. The head of this bolt was broad enough to cover the whole wood of the wedge within the iron ferule.

We preſume that the reader, by this time, foreſees the uſe of this wedge. It is to be driven in between the ſole and the ſeat (having firſt taken out the block at the baſe of the wedge). As it advances into the wider ſpaces, the whole truſs muſt deſcend, and be freed from the arch; but it will require prodigious blows to drive it back. Mr Mylne did not think ſo, founding his expectation on what he ſaw in the launching of great ſhips, which ſlide very eaſily on a ſlope of 10 or 12 degrees. He rather feared, that taking out the block behind would allow the wedge to be puſhed back at once, ſo that the deſcent of the truſs would be too rapid. However, to be certain of the operation, he had prepared an abundant force in a very ingenious manner. A heavy beam of oak, armed at the end with iron, was ſuſpended from two points of the centre like a battering ram, to be uſed in the ſame manner. Nothing could be more ſimple in its ſtructure, more powerful in its operation, or more eaſy in its management. Accordingly the ſucceſs was to his wiſh. The wedge did not ſlip back of itſelf; and very moderate blows of the ram drove it back with the greateſt eaſe. The whole operation was over in a very few minutes. The ſpectators had ſuſpected, that the ſpace allowed for the receſs of the wedge was not ſufficient for the ſettlement of the arch; but the architect truſted to the precautions he had taken in its conſtruction. The reader, by turning to the article Arch in this *Supplement*, will ſee that there was only the arch LY which could be expected to ſettle: accordingly, the receſs of the wedge was found to be much more than was neceſſary. However, had this not been the caſe, it was only neceſſary to take out the pieces between the poſts below the ſeat, and then to drive back the heads of the ſtruts; but this was not needed (we believe) in any of the arches. We are well aſſured that none of the arches ſunk an inch and a half. The great arch of 100 feet ſpan did not ſink one inch at the crown. It could hardly be perceived whether the arch quitted the centering gradually or not, ſo ſmall had been the changes of ſhape.

33 The great ſuperiority of the centering uſed by him.

We have no heſitation in ſaying, that (if we except ſome waſte of great timber by uncommon joggling) the whole of this performance is the moſt perfect of any that has come to our knowledge. We doubt not but that ſeveral have equalled it, or may have excelled it; but we do not know of them: and we think that the bringing forward ſuch performances is no leſs ſerviceable to the public, than it is honourable to the inventor. Nor do we ſuppoſe that any views of intereſt can be ſo powerful as to prevent an ingenious architect from communicating to the public ſuch honourable ſpecimens of his own talents. We ſhould be happy to communicate more of this kind; for we conſider it as a very important article of practical mechanics, and think that it is of conſequence to the nation that it ſhould be very generally underſtood. In every corner of the country bridges are to be built—we have everywhere good *maſons*, who are fully able to execute any practicable project, but too little acquainted with principle to invent, or to accommodate even what they know to local circumſtances, and are very apt to be duped by appearances of ingenuity, or miſled by erroneous notions of the ſtrains which are excited. We profeſs more ſcience, and

---

(b) The writer of this article can only ſay, that, after much inquiry, he has no information of any arch being received from the builder as ſufficient that had ſuffered half the change of ſhape mentioned by Mr Perronet. The arch of Dublin bridge, built by an excellent, but a very private, maſon, Mr Steeven, is 105 feet wide, with only 22 feet of riſe. It was erected (but not on a truſſed centering) without changing one full inch in its elevation; and when the centering was removed, it ſunk only $1\frac{1}{4}$th inches, and about half an inch more when the parapets were added and the bridge completely finiſhed.

and to treat the ſubject with the aſſiſtance of accurate principles: But while we are certain that every circumſtance is ſuſceptible of the moſt accurate determination, we muſt acknowledge that we have by no means attained an accurate knowledge of all the ſtrains which are produced and excited in a frame of carpentry, which is ſettling and changing its ſhape, even though it be not very complicated; far leſs are we poſſeſſed of a clear view of what happens in a maſs of maſonry in ſimilar conditions. Therefore, though we ſpeak with the ſtrong belief of our being right, we ſpeak with a ſenſe of our fallibility, and with great deference to the judgment of eminent and experienced architects and engineers. We ſhould conſider their free and candid criticiſms as the higheſt favour; and we even ſolicit them, with aſſurances of thanks, and that we will take ſome opportunity, before the cloſe of this work, to acknowledge and correct our miſtakes. We even preſume to hope, that the liberal-minded artiſt will be pleaſed with this opportunity which we give him of increaſing the national ſtock of knowledge. Let mutual jealouſy and rivalſhip reign in the breaſts, and prompt the exertions, of our reſtleſs neighbours on the continent—let them think that the dignity of man conſiſts in perpetual warfare, in which every individual feels himſelf indebted only to himſelf, freed from all the ſweet ties of domeſtic partiality, of friendſhip, and of patriotic attachment. We hope that the hearts of Britons will long continue to be warmed and *fortified* by the thoughts of mutual aſſiſtance, mutual co-operation, mutual attachment, and a patriotic preference of their countrymen to all other men. While theſe ſentiments are regulated by unſhaken honeſty, by candour, and by Chriſtian charity, we ſhall be ſecured from the *errors* of partial attachments, and yet enjoy all the pleaſures of unſophiſticated nature. Families will ſtill be bound together by the affectionate ties of blood; and the whole frame of Britiſh ſociety will be in harmony with the bonds which connect the members of each family, by their endleſs croſſings and intermixings. In this ſtate, the ſtate of ſocial nature, the man of talents will not lock up all the fruits of his exertions in his own breaſt, but will feel a pleaſure in imparting them to a ſociety that is dear to him, and on which he depends for all his beſt enjoyments. Nothing will hold the good man back when this is in his power, but the virtuous uſe which he can make of his ſuperiority in the diſcharge of his own little circle of duties. This is all that is required of true patriotiſm; and it is not too much to be expected from Britons, who feel a pleaſure in viewing their country as the great ſchool of the arts, under the patronage of a ſovereign who has done more for their improvement than all the other princes of Europe, and who (we are well aſſured) is now meditating a plan which muſt be highly gratifying to every eminent profeſſor of the arts.

34
The ſubject of this article connected with the conſtruction of wooden bridges.

THE ſubject which we have been conſidering is very cloſely connected with the conſtruction of wooden bridges. Theſe are not always conſtructed on the ſole principles of equilibrium, by means of mutual abutment. They are ſtiff frames of carpentry, where, by a proper diſpoſition, beams are put into a ſtate of extenſion, as well as of compreſſion, ſo as to ſtand in place of ſolid bodies as big as the ſpaces which the beams encloſe; and thus we are enabled to couple two, three, or four of theſe together, and ſet them in abutment with each other like mighty arch-ſtones. We ſhall cloſe this article, therefore, with two or three ſpecimens of wooden bridges, diſpoſed in a ſeries of progreſſive compoſition, ſo as to ſerve as a ſort of introduction to the art in general, and furniſh a principle which will enable the intelligent and cautious artiſt to puſh it with confidence as far as it can go.

Plate XVII.

The general problem is this. Suppoſe that a bridge is to be thrown over the ſpace AB (fig. 9.), and that this is too wide for the ſtrength of the ſize of timber which is at our command; how may this beam AB be ſupported with ſufficient effect? There are but two ways in which the middle point C (where the greateſt ſtrain is) can be ſupported: 1. It may be ſuſpended by two ropes, iron rods, or wooden ties, DC, EC, made faſt to two firm points, D, E, above it; or it may reſt on the ridge of two rafters *d*C, *e*C, which reſt on two firm points *d*, *e*, below it 2. It may be ſupported by connecting it with a point ſo ſupported; and this connection may be formed, either by ſuſpending it from this point, or by a poſt reſting on it. Thus it may hang, by means of a rod or a king-poſt FC, from the ridge F of two rafters AF, BF; or it may reſt on the ſtrut C*f*, whoſe lower extremity *f* is carried by the ropes, rods, or wooden ties A*f*, B*f*.

Whichſoever of theſe methods we employ, it follows, from the principles of carpentry, that the ſupport given to the point C is ſo much the more powerful, as we make the angle DCE, or *d*C*e*, or the equivalent angles AFB, or A*f*B, more acute.

35
The uſual and ſimpleſt method of conſtructing ſuch bridges.

Each of theſe methods may be ſuppoſed equally ſtrong. Our choice will depend chiefly on the facility of finding the proper points of ſupport D, E, *d*, *e*; except in the ſecond caſe, where we require no fixed points but A and B. The ſimple forms of the firſt caſe require a great extent of figure. Very rarely can we ſuſpend it from points ſituated as D and E. It is even ſeldom that we have depth enough of bank to allow the ſupport of the rafters *d*C, *e*C; but we can always find room for the ſimple truſs AFB. This therefore is the moſt uſually practiſed.

In the conſtruction, we muſt follow the maxims and directions preſcribed in the article CARPENTRY of this volume, and the article ROOF of the *Encycl.* The beams FA, FB muſt be mortiſed into AB, in the firmeſt manner, and there ſecured with ſtraps and bolts; and the middle muſt hang by a ſtrap attached to the king-poſt FC, or to the iron rod that is uſed for a king-poſt. No mortiſing in the point C muſt be employed; it is unneceſſary, and it is hurtful, becauſe it weakens the beam, and becauſe it lodges water, and ſoon decays by rot. The beſt practice is not to ſuſpend the beam immediately by this ſtrap, but to let it reſt, as in fig. 10. on a beam C, which croſſes the bridge below, and has its other end ſupported in the ſame manner by the other truſs.

It is evident that the length of the king-poſt has no effect on the ſupport of C. We may therefore contract every thing, and preſerve the ſame ſtrength of ſupport, by finding two points *a* and *b* (fig. 11.) in the banks, at a moderate diſtance below A and B, and ſetting up the rafters *a*F, *b*F, and ſuſpending C from the ſhortened king-poſt. In this conſtruction, when the beam AB reſts on a croſs bearer, as is drawn here, the

ſtruts

ſtruts *a* F, *b* F are kept clear of it. No connection between them is neceſſary, and it may be hurtful, by inducing croſs ſtrains on both. It will, however, greatly increaſe the ſtiffneſs of the whole. This conſtruction may ſafely be loaded with ten times the weight that AB can carry alone.

36 An improvement of that method.

Suppoſe this done, and that the ſcantling of AB is too weak for carrying the weight which may be brought on the parts AC, CB. We may now truſs up each half, as in fig 12. and then the whole will form a handſome bridge, of the ſimpleſt conſtruction poſſible. The interſections of the ſecondary braces with thoſe of the main truſs will form a hand-rail of agreeable figure.

We are not confined to the employment of an entire piece AB, nor to a rectilineal form. We may frame the bridge as in fig. 13. and in this form we diſſuade from allowing any connection with the middle points of the main braces. This conſtruction alſo may be followed till each beam AC and CB is loaded to ten times what it can ſafely bear without the ſecondary truſſing.

37 Another method.

There is another way by which a bridge of one beam may be ſupported beyond the power of the firſt and ſimpleſt conſtruction. This is repreſented in fig. 14. and fig. 15. The truſs beam FG ſhould occupy one-third of AB. The advantage of this conſtruction is very conſiderable. The great elevation of the braces (which is a principal element of the ſtrength) is preſerved, and the braces are greatly ſhortened.

This method may be puſhed ſtill farther, as in fig. 16.

38 Theſe methods combined.

And all theſe methods may be combined, by joining the conſtructions of fig. 14. and fig. 15. with that of fig. 16.

In all of them there is much room for the diſplay of ſkill, in the proper adjuſtment of the ſcantling of the timber, and the obliquity of the braces to the lengths of the different bearings. A very oblique ſtrut, or a ſlender one, will ſuffice for a ſmall load, and may often give an opportunity to increaſe the general ſtrength; while the great timbers and upright ſupports are reſerved for the main preſſures. Nothing will improve the compoſition ſo much as reflecting progreſſively. and in the order of theſe examples, on the whole. This alone can preſerve the great principle in its ſimplicity and full energy.

39 The elements of all that can be done in this art.

Theſe conſtructions are the elements of all that can be done in the art of building wooden bridges, and are to be found more or leſs obviouſly and diſtinctly in all attempts of this kind. We may aſſert, that the more obviouſly they appear, the more perfect the bridge will be. It is aſtoniſhing to what extent the principle may be carried. We have ſeen a bridge of 42 feet ſpan formed of two oak truſſes, the biggeſt timber of which did not exceed ſix inches ſquare, bearing with perfect ſteadineſs and ſafety a waggon loaded with more than two tons, drawn by four ſtout horſes. It was framed as fig. 16. nearly, with the addition of the dotted lines, and was near thirty years old; protected, however, from the weather by a wooden roof, as many bridges in Germany are.

We recollect another in the neighbourhood of Stettin, which ſeemed conſtructed with great judgment and ſpirit. It had a carrriage road in the middle about 20 feet (we think) wide, and on each ſide a foot-way about five feet wide. The ſpan was not leſs than 60 feet, and the greateſt ſcantling did not appear to exceed 10 inches by 6.

This bridge conſiſted of four truſſes, two of which formed the outſide of the bridge, and the other two made the ſeparation between the carriage road and the two foot ways. We noticed the conſtruction of the truſſes very particularly, and found it ſimilar to the laſt, except in the middle diviſion of the upper truſs, which, being very long, was double truſſed, as in fig. 17.

The reader will find in that volume of Leupold's *Theatrum Machinarum*, which he calls *Theatrum Pontificum*, many ſpecimens of wooden bridges, which are very frequent in the champain parts of Germany. They are not, in general, models of mechanic art; but the reflecting reader, who conſiders them *carefully*, will pick up here and there ſubordinate hints, which are ingenious, and may ſometimes be uſeful.

What we have now exhibited are not to be conſidered as models of conſtruction, but as elementary examples and leſſons, for leading the reader ſyſtematically into a thorough conception of the ſubject.

40 A wonderful bridge in Switzerland.

We cannot quit the ſubject without taking notice of a very wonderful bridge at Wittengen in Switzerland, ſlightly deſcribed by Mr Coxe (*Travels*, vol. I. 132.) It is of a conſtruction more ſimple ſtill than the bridges we have been deſcribing. The ſpan is 230 feet, and it riſes only 25. The ſketch (fig. 18.) will make it ſufficiently intelligible. ABC is one of two great arches, approaching to a catenarian ſhape, built up of ſeven courſes of ſolid logs of oak, in lengths of 12 or 14 feet, and 16 inches or more in thickneſs. Theſe are all picked of a natural ſhape, ſuited to the intended curve; ſo that the wood is nowhere cut acroſs the grain to trim it into ſhape. Theſe logs are laid above each other, ſo that their abutting joints are alternate, like thoſe of a brick wall; and it is indeed a wooden wall, ſimply built up, by laying the pieces upon each other, taking care to make the abutting joints as cloſe as poſſible. They are not faſtened together by pins or bolts, or by ſcarfings of any kind. They are, however, held together by iron ſtraps, which ſurround them, at the diſtance of five feet from each other, where they are faſtened by bolts and keys.

Theſe two arches having been erected (by the help, we preſume, of pillars, or a centering of ſome kind), and well butted againſt the rock on each ſide, were freed from their ſupports, and allowed to ſettle. They are ſo placed, that the intended road *a b c* interſects them about the middle of their height. The roadway is ſupported by croſs joiſts, which reſt on a long horizontal ſummer beam. This is connected with the arches on each ſide by uprights bolted into them. The whole is covered with a roof, which projects over the arches on each ſide to defend them from the weather. Three of the ſpaces between theſe uprights have ſtruts or braces, which give the upper work a ſort of truſſing in that part.

This conſtruction is ſimple and artleſs; and appears, by the attempt to truſs the ends, to be the performance of a perſon ignorant of principle, who has taken the whole notion from a ſtone arch. It is, however, of a ſtrength much more than adequate to any load that can be laid on it. Mr Coxe ſays, but does not explain how, that it is ſo contrived that any part of it can be repaired.

ed independent of the reſt. It was the laſt work of one Ulrich Grubenhamm of Tuffen, in the canton of Appenzel, a carpenter without education, but celebrated for ſeveral works of the ſame kind; particularly the bridge over the Rhine at Schafhauſen, conſiſting of two arches, one of 172 and the other of 193 feet ſpan, both reſting on a ſmall rock near the middle of the river.

While writing this article, we got an account of a wooden bridge, erected in North America, in which this ſimple notion of Grubenhamm's is mightily improved. The ſpan of the arch was ſaid to exceed 250 feet, and its riſe exceedingly ſmall. The deſcription we got is very general, but ſufficient, we think, to make it perfectly intelligible.

41 Another in North America.

In fig. 19. DD, EE, FF, are ſuppoſed to be three beams of the arch. They conſiſt of logs of timber of ſmall lengths, ſuppoſe of 10 or 12 feet, ſuch as can be found of a curvature ſuited to its place in the arch without trimming it acroſs the grain. Each beam is double, conſiſting of two logs applied to each other, ſide to ſide, and *breaking joint*, as the workmen term it. They are kept together by wedges and keys driven through them at ſhort intervals, as at K, L, &c.

The manner of joining and ſtrongly binding the two ſide pieces of each beam is ſhewn in fig. 20. The mortiſe *aicb* and *dcio*, which is cut in each half beam, is conſiderably longer on the outſide than on the inſide, where the two mortiſes meet. Two keys, BB and CC, are formed, each with a notch *bcd*, or *aio*, on its ſide; which notch fits one end of the mortiſe. The inner ſide of the key is ſtraight, but ſo formed, that when both keys are in their places, they leave a ſpace between them wider at one end than the other. A wedge AA, having the ſame taper as the ſpace juſt mentioned, is put into it and driven hard. It is evident that this muſt hold the two logs firmly together.

This is a way of uniting timber not mentioned in the article CARPENTRY; and it has ſome peculiarities worthy of notice. In the firſt place, it may be employed ſo as to produce a very ſtrong lateral connection, and would then co-operate finely with the other artificial methods of ſcarfing and tabling that we deſcribed in the article referred to. But it requires nice attention to ſome circumſtances of conſtruction to ſecure this effect. If the joints are accurately formed to each other, as if the whole had been one piece divided by an infinitely thin ſaw, this manner of joining will *keep* them all in their places. But no driving of the wedge AA will make them firmer, or cauſe one piece to preſs hard on the other. If the abutment of two parts of the half beam is already cloſe, it will remain ſo; but if open in the ſmalleſt degree, driving of the wedge will not make it tighter. In this reſpect, therefore, it is not ſo proper as the forms deſcribed in CARPENTRY.

In order that the method now deſcribed may have the effect of *drawing* the halves of the beams together, and of keeping them hard ſqueezed on each other, the joints muſt be made ſo as not to correſpond exactly. The prominent angle *aio* (fig. 21.), formed by the ends of the two half mortiſes, muſt be made a little more obtuſe than the angle *afo* of the notch of the key which this prominence is intended to fill up. Moreover, the oppoſite ſide *et* of this key ſhould not be quite ſtraight, but a very little convex. With theſe precautions, it is eaſy to ſee that, by driving the wedge AA, we cauſe the notch *afo* to take hold, firſt at the two points *a* and *o*, and then, by continuing to drive the wedge, the ſides *af*, *of*, of the notch gradually compreſs the wood of the half beams, and preſs them on each other. By continuing to drive the wedge, the mutual compreſſion of the key and the beam ſqueezes all together, and the ſpace *afoi* is completely filled up. We may ſee, from this proceſs, that the mutual compreſſion and drawing together of the timber will be greater in proportion as we make the angle *aio* more prominent, and its correſponding angle *afo* more deep; always taking care that the key ſhall be thick enough not to break in the narrow part.

This adjuſtment of the keys to the mortiſe is neceſſary on another account. Suppoſing the joints to fit each other exactly before driving the wedge, and that the whole ſhrinks a little by drying—by this the angle *aio* will become more prominent, and the angle *afo* will become more ſhallow; the joint will open at *a* and *o*, and the mutual compreſſure will be at an end.

We may alſo obſerve, that this method will not give any additional firmneſs to the abutments of the different lengths employed to piece out the arch-beam; in which reſpect it differs materially from the other modes of joining timber.

Having ſhewn how each beam is pieced together, we muſt now ſhew how a number of them are united, ſo as to compoſe an arch of any thickneſs. This is done in the very ſame way. The beams have other mortiſes worked out of their inner ſides, half out of each half of the beam. The ends of the mortiſes are formed in the ſame way with thoſe already deſcribed. Long keys BB, CC, (fig. 19.) are made to fit them properly, the notches being placed ſo as to keep the beams at a proper diſtance from each other. It is now plain that driving in a long wedge AA will bind all together.

In this manner may an arch be extended to any ſpan, and made of any thickneſs of arching. The bridge over Portſmouth river in North America was more than 250 feet in length, and conſiſted of ſeveral parallel arches of beams. The inventor (we think that his name is Bludget) ſaid that he found the ſtrength ſo great, that he could with perfect confidence make one of four times the ſpan.

We admire the ingenuity of this conſtruction, and think it very effectual for bringing the timbers into firm and uniform abutment; but we imagine that it requires equilibration, becauſe it is extremely flexible. There is nothing to keep it from bending, by an inequality of load, but the tranſverſe ſtrength of the beams. The keys and wedges can have very little power to prevent this bending. The diſtance between the beams will alſo contribute little or nothing to the ſtiffneſs; nay, we imagine that a great diſtance between them will make the frame more flexible. Could the beams be placed ſo near each other that they could be ſomehow joggled on each other, the whole would be ſtiffer; but at preſent they will bend like the plates of a coach-ſpring. But nothing hinders us from adding diagonal pieces to this conſtruction, which will give it any degree of ſtiffneſs, and will enable it to bear any inequality of loading. When completed in this manner, we imagine that it will be at leaſt equal to any conſtruction that has yet been thought of. One advantage it poſſeſſes that is very precious: Any piece that fails may

[illegible] sculp.

may be taken out, and replaced by another, without diſturbing the reſt, and without the ſmalleſt riſk. On the whole, we think it a very valuable addition to Britiſh carpentry. The method here practiſed, both for joining the parts of one beam and for framing the different beams together, ſuggeſts the moſt firm and light conſtructions for dome-roofs that can be conceived; incomparably ſuperior to any that have yet been erected. The whole may be framed, without a nail or a ſpike, into one net-like ſhell that cannot even be pulled in pieces. We may perhaps conſider this in another article; at preſent we return to the conſideration of truſſed bridges.

42 Bridges combined by ſimple addition or by compoſition.

When the width of the river exceeds what is thought practicable by a ſingle truſs, we muſt then combine, either by ſimple addition, or by compoſition, different truſſes together. We compoſe a bridge by ſimple addition when we make a frame of carpentry of an unchangeable and proper ſhape, to ſerve as one of the archſtones of a bridge of maſonry. This may eaſily be comprehended by looking at fig. 22. Each of the frames A, B, C, D, muſt be conſidered as a ſeparate body, and all are ſupported by their mutual abutment. The nature of the thing is not changed, although we ſuppoſe that the rails of the frame B, inſtead of being mortiſed into an upright $b' b'$, unconnected with the frame C, is mortiſed into the upright $c c$ of that frame, the direction and intenſity of the mutual preſſures of the two frames are the ſame in both caſes; accordingly this is a very common form of ſmall wooden bridges. It is uſual, indeed, to put diagonal battens into each: but we believe that this is more frequently done to pleaſe the eye than to produce an unalterable ſhape of each frame.

43 How to diſtinguiſh bridges formed according to theſe different methods.

To an unſkilful carpenter this bridge does not ſeem eſſentially different from the centering of Mr Hupeau for the bridge of Orleans; and indeed, in many caſes, it requires reflection, and ſometimes very minute reflection, to diſtinguiſh between a conſtruction which is only an addition of frame to frame till the width be covered, from a conſtruction where one frame works on the adjoining one tranſverſely, puſhing it in one part, and drawing it in another. The ready way for an unlettered artiſt to form a juſt notion of this point, is to examine whether he may ſaw through the connecting piece $b' b'$ from one end to the other, and make them two ſeparate frames. Whenever this cannot be done without that part opening, it is a conſtruction by compoſition. Some of the beams are on the ſtretch; and iron ſtraps, extending along both pieces, are neceſſary for ſecuring the joint. The bridge is no longer a piece of maſonry, but a performance of pure carpentry, depending on principles peculiar to that art. Equilibration is neceſſary in the firſt conſtruction; but, in the ſecond, any inequality of loading is made ineffectual for hurting the edifice, by means of the ſtretch that is made to operate on ſome other piece. We are of opinion, that this moſt ſimple employment of the diſtinguiſhing principle of carpentry, by which the beams are made to act as ties, will give the moſt perfect conſtruction of a wide bridge. One polygon alone ſhould contain the whole of the abutments; and one other polygon ſhould conſiſt entirely of ties; and the beams which form the radii, connecting the angles of the two polygons, complete the whole. By confining the attention to theſe two ſimple objects, the abutments of the outer polygon, and the joints of the inner one, may be formed in the moſt ſimple and efficient manner, without any collateral connections and dependencies, which divide the attention, increaſe the complication, and commonly produce unexpected and hurtful ſtrains. It was for this reaſon that we have ſo frequently recommended the centering of the bridge of Orleans. Its office will be completely performed by a truſs of the form of fig. 23.; where the polygon ABCDEF, conſiſting of two layers of beams (if one is not ſufficient), contains the whole abutments, and the other A$bcde$F is nothing but an iron rod. In this conſtruction, the obtuſeneſs of the angles of the lower polygon is rather an advantage. The braces Gc, Gd, which are wanted for truſſing the middle of the outer beams, will effectually ſecure the angles of the exterior polygon againſt all riſk of change. The reader muſt perceive that we have now terminated in the conſtruction of the Norman roof. We indeed think it the beſt general form, when ſome moderate declivity is not an inſuperable objection. When this is the caſe, we recommend the general plan of the centering of the bridge of Orleans. We would make the bridge (we ſpeak of a great bridge) conſiſt of four truſſes; two to ſerve as the outſides of the bridge, and two inner truſſes, ſeparating the carriage-way from the foot-paths. The road ſhould follow the courſe of the lower polygon, and the main truſs ſhould form the rails. It might look ſtrange; but we are here ſpeaking of ſtrength; and evident, but not unwieldy, ſtrength, once it becomes familiar, is the ſureſt ſource of beauty in all works of this kind.

44 The beſt general form of a wooden bridge.

Centre of Friction, is that point in the baſe of a body on which it revolves; into which, if the whole ſurface of the baſe, and the maſs of the body, were collected, and made to revolve about the centre of the baſe of the given body, the angular velocity deſtroyed by its friction would be equal to the angular velocity deſtroyed in the given body by its friction in the ſame time. See Friction in this Supplement.

Centre of Gyration, is that point in which, if the whole maſs be collected, the ſame angular velocity will be generated in the ſame time, by a given force acting at any place, as in the body or ſyſtem itſelf. This point differs from the centre of oſcillation, in as much as in this latter caſe the motion of the body is produced by the gravity of its own particles; but, in the caſe of the centre of gyration, the body is put in motion by ſome other force acting at one place only.

Centre of Oſcillation, is that point in the axis or line of ſuſpenſion of a vibrating body, or ſyſtem of bodies, in which, if the whole matter or weight be collected, the vibrations will ſtill be performed in the ſame time, and with the ſame angular velocity, as before. Hence, in a compound pendulum, its diſtance from the point of ſuſpenſion is equal to the length of a ſimple pendulum whoſe oſcillations are iſochronal with thoſe of the compound one.

Centre of Preſſure, of a fluid againſt a plane, is that point againſt which a force being applied equal and contrary to the whole preſſure, it will juſt ſuſtain it, ſo as that the body preſſed on will not incline to either ſide.—This is the ſame as the centre of percuſſion, ſuppoſing the axis of motion to be at the interſection of this plane with the ſurface of the fluid; and the centre of of preſſure upon a plane parallel to the horizon, or upon any plane where the preſſure is uniform, is the ſame as the centre of gravity of that plane.

CENTROBARICO, the ſame as centre of gravity.

CENTROBARIC **Method**, is a method of determining the quantity of a ſurface or ſolid, by means of the generating line or plane and its centre of gravity. The doctrine is chiefly compriſed in this theorem:

Every figure, whether ſuperficial or ſolid, generated by the motion of a line or plane, is equal to the product of the generating magnitude and the path of its centre of gravity, or the line which its centre of gravity deſcribes.

CERUSE, or **White-lead**, is a ſubſtance ſo much uſed in painting, and for other purpoſes, that numerous modes have been employed for the preparation of it. Of the moſt common of theſe, a ſufficient account has been given in the Encyclopædia (ſee **Ceruse**, and the ſame word **Chemistry**-*Index)*; but Lord Dundonald has diſcovered a more expeditious and facile method than any of them, which becomes the more uſeful, as the ſubſtance with which it is effected has been hitherto rejected by the chemical world as a *caput mortuum*.

His lordſhip directs common lead to be reduced to a calx, but not too fine, and to have a proportion of five-ſixth parts thereof, intimately mixed with muriat, or ſolution of potaſs. In this ſtate, he directs it to be frequently ſtirred, in order to have the new ſurfaces of the mixture expoſed to the carbonic acid of atmoſpheric air; as his lordſhip obſerves, that the effects of the carbonic acid on the alkali exiſting in the preſent ſtate of the mixture is eſſentially neceſſary, in order to effect the intended purpoſe. In this ſtate it is to be frequently ſprinkled with water, and, after the calx has been long enough immerſed with the muriat to be ſufficiently operated upon, the muriat is to be levigated by common water from the calx, and to be concentrated by evaporation, in order to be made uſe of at a future period with other calx. The calx is to be afterwards ground, levigated, and dried for uſe.

For this diſcovery, his lordſhip obtained a patent on the 18th of Auguſt 1797; and the ſucceſs which has attended the former patents of this ſcientific nobleman leads us to conclude, that the preſent diſcovery is entitled to the attention of the public.

CHAMBERS (Sir William), the celebrated architect, was deſcended of the ancient family of Chalmers in Scotland, barons of Tartas in France. His grandfather ſuffered conſiderably in his fortune by ſupplying Charles XII. of Sweden with money, &c. which that monarch repaid in baſe coin. Sir William's father reſided ſeveral years in Sweden to recover his claims; and there Sir William was born, and, at eighteen years of age, appointed ſupercargo to the Swediſh Eaſt India company. From a voyage which he made to China, he brought home the Aſiatic ſtyle of ornament, in tents, temples, moſques, and pagodas. Theſe ornaments (through the intereſt of Lord Bute) he was enabled to apply in the gardens at Kew. Patroniſed by the princeſs dowager and the king, Mr Chambers had much of the faſhionable buſineſs of the day. Under Burke's reform, he was appointed ſurveyor general of the board of works. Somerſet-houſe was worth to him at leaſt L. 2000 a-year. His *Chef d'œuvres* are his ſtaircaſes, particularly thoſe at Lord Beſborough's, Lord Gower's, and the Royal and Antiquarian Societies. The terrace behind Somerſet-houſe is a bold effort of conception. His deſigns for interior arrangements were excellent. His Treatiſe on Civil Architecture alone will immortalize his name. In private life, Sir William was hoſpitable, kind, and amiable. His ſon married Miſs Rodney; Mr Cotton, Mr Innis, and Mr Harward, married his beautiful daughters. Having been abſtemious in his youth, Sir William's conſtitution did not begin to break till he was ſeventy years of age. For the laſt three years, he was kept alive by wine and oxygenated air: and died on the 5th of March 1796. His celebrity will be laſting in the works which he has left; and as he was equally ſkilled in the theory and practice of the arts which he profeſſed, his precepts are as valuable as his works. At his death, he was fellow of the Royal and Antiquarian Societies, treaſurer of the Royal Academy, ſurveyor-general of the board of works, and knight of the Swediſh order of the Polar Star.

CHAMFER, or **Chamferet**, an ornament in architecture, conſiſting of half a ſcotia; being a kind of ſmall furrow or gutter on a column.

Universal CHARACTERS, could they be introduced, would contribute ſo much to the diffuſion of uſeful knowledge, that every attempt to make ſuch a ſcheme ſimple and practicable is at leaſt intitled to notice. Accordingly, in the *Encyclopædia Britannica*, under the word **Character**, a ſhort account is given of the principal plans of univerſal characters which had then fallen under our obſervation; but ſince that article was publiſhed, a new method of writing, by which the various nations of the earth may communicate their ſentiments to each other, has been propoſed by *Thomas Northmore*, Eſq; of Queen-ſtreet, Mayfair. It bears ſome reſemblance to that which we have given from the *Journal Literaire*, 1720, but it is not the ſame; and of the two, Mr Northmore's is perhaps the moſt ingenious. The ground-work of the ſuperſtructure differs not indeed from that of the journaliſt, being this in both, "That if the ſame numerical *figure* be made to repreſent the *ſame word* in the various languages upon earth, an univerſal character is immediately obtained." The only objection which the author or his friends ſaw to ſuch a plan, originates in the diverſity of idioms; but, as he truly obſerves, every ſchoolboy has this difficulty to encounter as often as he conſtrues Terence.

Such then was Mr Northmore's original plan: but he ſoon perceived that it was capable of conſiderable improvement; for, inſtead of uſing a figure for *every* word, it will be neceſſary to apply one only to every *uſeful* word; and we all know how few words are abſolutely neceſſary to the communication of our thoughts. Even theſe may be much abbreviated by the adoption of certain *uniform fixed* ſigns (not amounting to above 20), for the various caſes, numbers, genders, degrees of compariſon, of nouns, tenſes, and moods of verbs, &c. All words of negation, too, may be expreſſed by a prefixed ſign. A few inſtances will beſt explain the author's meaning.

Suppoſe the number 5 to repreſent the word *ſee*.
6 — — *a man*,
7 — — *happy*,
8 — — *never*,
9 — — *I*.

" I would then (ſays he) expreſs the tenſes, genders, caſes, &c. *in all languages*, in ſome ſuch *uniform* manner as following:

(1) 5 = *preſent tenſe,* — ſee,
(2) $.5$ = *perfect tenſe,* — ſaw,
(3) $:5$ = *perfect participle,* — ſeen,
(4) $5:$ = *preſent participle,* — ſeeing,
(5) $5\cdot$ = *future,* — — will ſee,
(6) $\underline{5}$ = *ſubſtantive,* — ſight,
(7) $\underline{\underline{5}}$ = *perſonal ſubſtantive,* — ſpectator,
(8) 6 = *nominative caſe,* — a man,
(9) $\ddot{6}$ = *genitive,* — — of a man,
(10) $\dddot{6}$ = *dative,* — — to a man,
(11) $\overset{\frown}{6}$ = *feminine,* — — a woman,
(12) $+6$ = *plural,* — — men,
(13) 7 = *poſitive,* — — happy,
(14) $\hat{7}$ = *comparative,* — happier,
(15) $\overset{\wedge\wedge}{7}$ = *ſuperlative,* — happieſt,
$\underline{7}$ = as above, No. 6. — happineſs,
(16) -7 = *negation,* — — unhappy.

" From the above ſpecimen, I ſhould find no difficulty in comprehending the following ſentence, though it were written in the language of the Hottentots:

$9,\ 8,\ .5,\ -\hat{7},\ \overset{\frown}{6}.$ *I never ſaw a more unhappy woman.*

" Thoſe languages which do not uſe the pronoun prefixed to the verb, as the Greek and Roman, &c. may apply it, in a ſmall character, ſimply to denominate the perſon; thus, inſtead of 9, 8, .5, *I never ſaw;* they may write, $8,\ {}_{9}.5$, which will ſignify that the verb is in the firſt perſon, and will ſtill have the ſame meaning."

Our author ſeems confident that, according to this ſcheme of an univerſal character, about 20 ſigns, and leſs than 10,000 *choſen* words (ſynonyms being ſet aſide), would anſwer all the ends propoſed; and that foreigners, by referring to their numerical dictionary, would eaſily comprehend each other. He proceeds next to ſhew how appropriate ſounds may be given to his ſigns, and an univerſal *living language* formed from the univerſal *characters.*

To attain this end, he propoſes to diſtinguiſh the ten numerals by ten monoſyllabic names of eaſy pronunciation, and ſuch as may run without difficulty into one another. To illuſtrate his ſcheme, however, he calls them, for the preſent, by their common Engliſh names; but would pronounce each number made uſe of by uttering ſeparately its component parts, after the manner of accountants. Thus let the number 6943 repreſent the word *horſe*, he would not, in the univerſal language, call a horſe *ſix thouſand nine hundred and forty-three*, but *ſix, nine, four, three*, and ſo on for all the words of a ſentence, making the proper ſtop at the end of each. In the ſame manner, a diſtinct appellation muſt be appropriated to each of the prefixed ſigns, to be pronounced immediately after the numeral to which it is an appendage. Thus if *plu* be the appellation or the ſign of the plural number, *ſix, nine, four, three, plu* will be *horſes*.

" Thus (ſays our author), I hope it is evident that about 30 or 40 diſtinct ſyllables are ſufficient for the above purpoſe; but I am much miſtaken if *eleven* only will not anſwer the ſame end. This is to be done by ſubſtituting the firſt 20 or 30 numerals for the ſigns, and ſaying, as in algebra, that a term is in the power of ſuch a number, which may be expreſſed by the ſimple word *under.* *Ex. gr.* Let 6943 repreſent the word *horſe;* and ſuppoſe four to be the ſign of the plural number, I would write the word thus, $\overset{4}{\overline{6943}}$; and pronounce it, ſix, nine, four, three, in the power of or *under* four. By theſe means eleven diſtinct appellations would be ſufficient, and time and uſe would much abbreviate the pronunciation."

To refuſe the praiſe of ingenuity to this contrivance for an univerſal language would be very unjuſt; but elocution in this manner would be ſo very tedious, that ſurely the author himſelf, when he thinks more coolly on the ſubject, will perceive, that in the living ſpeech its defects would more than balance its advantages. A *pangraph*, as he calls his univerſal character, would indeed be uſeful, and is certainly practicable; a *panleg* (if we may form ſuch a word) would not be very uſeful, unleſs it were much more perfect than it could be made according to the plan before us.

CHAUSETRAPPES. See *Crow's Feet*, Encycl.

CHEMIN des Ronds, in fortification, the way of the rounds, or a ſpace between the rampart and the low parapet under it, for the rounds to go about it.

CHEMISTRY,

1 Definition. IS a ſcience, the object of which is to aſcertain the ingredients that enter into the compoſition of bodies, to examine the nature of theſe ingredients, the manner in which they combine, and the properties reſulting from their combination.

As an art, it has been in ſome meaſure coeval with the human race; for many of the moſt important branches of manufactures could not have been conducted without at leaſt ſome knowledge of chemical combinations. As a ſcience, it can hardly be dated farther back than the middle of the 17th century; but ſince that time it has advanced with a rapidity altogether unprecedented in the annals of philoſophy. Newton laid its foundation; and ſince his days an almoſt incredible number of the moſt diſtinguiſhed names in Europe have enliſted under its banners. So rapid has this progreſs been, that though the article CHEMISTRY in the *Encyclopædia Britannica* was written only about ten years ago, the language and reaſoning of chemiſtry have been ſo greatly improved, and the number of facts have accumulated ſo much, that we find ourſelves under the neceſſity of tracing over again the very elements of the ſcience.

2 Importance of chemiſtry. Indeed, if we conſider the importance of chemiſtry, we ſhall not be ſo much ſurpriſed at the ardour with which it has been cultivated. As a ſcience, it is intimately connected with all the phenomena of nature; the cauſes of rain, ſnow, hail, dew, wind, earthquakes: even the changes of the ſeaſons can never be explored with any chance of ſucceſs while we are ignorant of chemiſtry; and the vegetation of plants, and ſome of the moſt important functions of animals, have received all their illuſtration from the ſame ſource. No ſtudy can give us more exalted ideas of the wiſdom and goodneſs of the Great Firſt Cauſe than this, which ſhews us everywhere the moſt aſtoniſhing effects produced by the moſt ſimple though adequate means, and diſplays to our view the great care which has everywhere been taken to ſecure the comfort and happineſs of every living creature. As an art, it is intimately connected with all our manufactures: The glaſs-blower, the potter, the ſmith, and every other worker in metals, the tanner, the ſoap-maker, the dyer, the bleacher, are really practical chemiſts; and the moſt eſſential improvements have been introduced into all theſe arts by the progreſs which chemiſtry has made as a ſcience. Agriculture can only be improved rationally and certainly by calling in the aſſiſtance of chemiſtry; and the advantages which medicine has derived from the ſame ſource are too obvious to be pointed out.

3 Arrangement. It is evident from the definition of chemiſtry that it muſt conſiſt in a hiſtory of the ſimple ſubſtances which enter into the compoſition of bodies, in an inveſtigation of the manner in which theſe ſubſtances combine, and in a deſcription of the properties of the compounds which they form. And this is the arrangement which we mean to purſue; reſerving to ourſelves, however, the liberty of deviating a little from it, whenever it may appear neceſſary for the ſake of perſpicuity. All our claſſifications are in fact artificial; nature does not know them, and will not ſubmit to them. They are uſeful, however, as they enable us to learn a ſcience ſooner, and to remember it better; but if we mean to derive theſe advantages from them, we muſt renounce a rigid adherence to arbitrary definitions, which nature diſclaims.

We ſhall begin by an account of the ſimpleſt bodies, and proceed gradually to thoſe which are more compound. By *ſimple bodies*, we do not mean what the ancient philoſophers called the *elements of bodies*, but merely ſubſtances which have not yet been decompounded. Very poſſibly the bodies which we reckon ſimple may be real compounds; but till this has actually been proved, we have no right to ſuppoſe it. Were we acquainted with all the elements of bodies, and with all the combinations of which theſe elements are capable, the ſcience of chemiſtry would be as perfect as poſſible; but at preſent this is very far from being the caſe.

We ſhall divide this article into four parts. The *firſt* part ſhall treat of thoſe bodies which are at preſent conſidered as ſimple; the *ſecond*, of thoſe bodies which are formed by the union of two ſimple bodies, and which, for want of a better word we ſhall call *compound bodies*; the *third*, of thoſe bodies which are formed by the union of two compound bodies; and the *fourth*, of bodies ſuch as they are preſented to us by nature in the mineral, vegetable, and animal kingdoms.

PART I. OF SIMPLE BODIES.

4 Claſſes of ſimple bodies. ALL the bodies which are at preſent reckoned ſimple, becauſe they have never been decompounded, may be reduced into ſix claſſes.

1. Oxygen,
2. Simple combuſtibles,
3. Metals,
4. Earths,
5. Caloric,
6. Light.

Theſe ſhall form the ſubjects of the ſix following chapters.

CHAP. I. *Of* OXYGEN.

Plate XVIII. 5 Method of procuring oxygen. TAKE a quantity of nitre, or ſaltpetre, as it is alſo called, and put it into a gun-barrel A (fig. 1.), the touch-hole of which has been previouſly cloſed up with metal. This barrel is to be bent in ſuch a manner, that while the cloſe end, in which the nitre lies, is put into the fire E, the open end may be plunged below the ſurface of the water, with which the veſſel B is filled. At the ſame time, the glaſs jar D, previouſly filled with water, is placed on the ſupport C, lying at the bottom of the veſſel of water B, ſo as to be exactly over the open end of the gun-barrel A. As ſoon as the nitre becomes hot, it emits a quantity of air, which iſſuing from the end of the gun-barrel, aſcends to the top of the glaſs jar D, and gradually diſplaces all the water. The glaſs jar D then appears to be empty, but is in fact filled with air. It may then be removed in the following manner: Slide it away a little from the gun-barrel and the ſupport, and then dipping any flat diſh into the water below it, raiſe it on it, and bear it away. The diſh muſt be allowed to retain a quantity of water in it, (ſee fig. 2.) Another jar may then be filled with air in the ſame manner; and this proceſs may be continued either till the nitre ceaſes to give out air, or till as many jarfuls have been obtained as are required. This method of obtaining and confining air was firſt invented by Dr Mayow, and afterwards much improved by Dr Hales. All the airs obtained by this or any other proceſs, or, to ſpeak more properly, all the airs differing from the air of the atmoſphere, have, in order to diſtinguiſh them from it, been called *gaſes*, and this name we ſhall afterwards employ.

6
Diſcovered by Prieſtley and Scheele.

The gas which we have obtained by the above proceſs was diſcovered by Dr Prieſtley on the 1ſt of Auguſt 1774, and called by him *dephlogiſticated air*. Mr Scheele of Sweden diſcovered it in 1775, without any previous knowledge of what Dr Prieſtley had done: he gave it the name of *empyreal air*. Condorcet, ſo conſpicuous during the French revolution, gave it firſt the name of *vital air*; and Mr Lavoiſier afterwards called it *oxygen gas*; a name which is now generally received, and which we ſhall adopt.

Oxygen gas may be obtained likewiſe by the following proceſs:

7
Another method.

D (in fig. 3.) repreſents a wooden trough, the inſide of which is lined with lead or tinned copper. AB is a ſhelf running along the inſide of it, about three inches from the top. C is the cavity of the trough, which ought to be a foot deep. It is to be filled with water at leaſt an inch above the ſhelf AB. In the body of the trough, which may be called the ciſtern, the jars deſtined to hold gas are to be filled with water, and then to be lifted, and placed inverted upon the ſhelf at B, with their edges a little over it. This trough, which was invented by Dr Prieſtley, has been called by the French chemiſts the *pneumato-chemical*, or ſimply *pneumatic* apparatus, and is extremely uſeful in all experiments in which gaſes are concerned. Into the glaſs veſſel E put a quantity of the black oxide (A) of manganeſe in powder, and pour over it as much of that liquid which in commerce is called *oil of vitriol*, and in chemiſtry *ſulphuric acid*, as will ſomewhat more than cover it. Then inſert into the mouth of the veſſel the glaſs tube F, ſo cloſely that no air can eſcape except through the tube. This may be done by covering the joining with a paſte made of wheat-flour and water, or any other *lute*, as ſubſtances uſed for ſimilar purpoſes are called. The end of the tube C is then to be plunged into the pneumatic apparatus D, and the jar G, previouſly filled with water, to be placed over it on the ſhelf. The whole apparatus being fixed in that ſituation, the glaſs veſſel E is to be heated by means of a lamp or a candle. A great quantity of oxygen gas ruſhes along the tub F, and fills the jar G. As ſoon as the jar is filled, it may be ſlid to another part of the ſhelf, and other jars ſubſtituted in its place, till as much gas has been obtained as is wanted.

8
Properties of oxygen.

1. Oxygen gas is colourleſs, and inviſible like common air. Like it too, it is elaſtic, and capable of indefinite expanſion and compreſſion.

9
Supports flame,

2. If a lighted taper be let down into a jar of oxgen gas, it burns with ſuch ſplendor that the eye can ſcarcely bear the glare of light, and at the ſame time time produces a much greater heat than when burning in common air. It is well known that a candle put into a well cloſed jar, filled with common air, is extinguiſhed in a few ſeconds. This is the caſe alſo with a candle encloſed in oxygen gas; but it burns much longer in an equal quantity of that gas than of common air.

10
And life.

3. It was proved long ago by Boyle, that animals cannot live without air, and by Mayow that they cannot breathe the ſame air for any length of time without ſuffocation. Dr Prieſtley and ſeveral other philoſophers have ſhewn us, that animals live much longer in the ſame quantity of oxygen gas than of common air. Count Morozzo placed a number of ſparrows, one after another, in a glaſs bell filled with common air, and inverted over water.

	H.	M.
The firſt ſparrow lived - -	3.	0
The ſecond - - - -	0	3
The third - - - -	0	1

He filled the ſame glaſs with oxygen gas, and repeated the experiment.

	H.	M.
The firſt ſparrow lived - -	5	23
The ſecond - - - -	2	10
The third - - - -	1	30
The fourth - - - -	1	10
The fifth - - - -	0	30
The ſixth - - - -	0	47
The ſeventh - - - -	0	27
The eighth - - - -	0	30
The ninth - - - -	0	22
The tenth - - - -	0	21

He then put in two together; the one died in 20 minutes, but the other lived an hour longer.

11
Exiſts in the atmoſphere.

4. Atmoſpherical air contains about 27 parts in the hundred of oxygen gas. This was firſt diſcovered by Scheele. It has been proved by a great number of experiments, that no ſubſtance will burn in common air previouſly deprived of all the oxygen gas which it contained; but combuſtibles burn with great ſplendor in oxygen gas, or in other gaſes to which oxygen gas has been added. Oxygen gas then is abſolutely neceſſary for combuſtion.

5. It has been proved alſo, by many experiments, that no breathing animal can live for a moment in any air or gas which does not contain oxygen mixed with it. Oxygen gas then is abſolutely neceſſary for reſpiration.

6. When ſubſtances are burnt in oxygen gas, or in any other gas containing oxygen, if the air be examined after the combuſtion, a great part of the oxygen will be found to have diſappeared. If charcoal, for inſtance, be burnt in oxygen gas, there will be found, inſtead of part of the oxygen, another very different gas, known by the name of carbonic acid gas. Exactly the ſame thing takes place when air is reſpired by animals; part of the oxygen gas diſappears, and its place is occupied by ſubſtances poſſeſſed of very different properties. Oxygen

gas

(A) This ſubſtance ſhall be afterwards deſcribed. It is now very well known in Britain, as it is in common uſe with bleachers and ſeveral other manufacturers.

gas then undergoes ſome change during combuſtion, as well as the bodies which have been burnt; and the ſame obſervation applies alſo to reſpiration (B).

12 Its ſpecific gravity.

* On *Phlogiſton*, ſect. i.

7. The ſpecific gravity of oxygen gas, as determined by Mr Kirwan *, is 0,00135, that of water being 1,0000, as is always the caſe when ſpecific gravity is mentioned abſolutely. It is therefore 740 times lighter than the ſame bulk of water. Its weight to atmoſpherical air is as 1103 to 1000: 116 cubic inches of oxygen gas weigh 39,03 grains troy, 116 cubic inches of common air, 35,38 grains.

13 *Affinity* explained.

8. Oxygen is capable of combining with a great number of bodies, and forming compounds. As the combination of bodies is of the utmoſt importance in chemiſtry, before proceeding farther we ſhall attempt to explain it. When common ſalt is thrown into a veſſel of pure water, it melts, and very ſoon ſpreads itſelf through the whole of the liquid, as any one may convince himſelf by the taſte. In this caſe the ſalt is combined with the water, and cannot afterwards be ſeparated by filtration or any other method merely mechanical. It may, however, by a very ſimple proceſs: Pour into the ſolution a quantity of ſpirit of wine, and the whole of the ſalt inſtantly falls to the bottom.

Why did the ſalt diſſolve in water, and why did it fall to the bottom on pouring in ſpirit of wine? Theſe queſtions were firſt anſwered by Sir Iſaac Newton. There is a certain attraction between the particles of common ſalt and thoſe of water, which cauſes them to unite together whenever they are preſented to one another. There is an attraction alſo between the particles of water and of ſpirit of wine, which equally diſpoſes them to unite, and this attraction is greater than that between the water and ſalt; the water therefore leaves the ſalt to unite with the ſpirit of wine, and the ſalt being now unſupported, falls to the ground by its gravity. This power, which diſpoſes the particles of different bodies to unite, was called by Newton *attraction*, by Bergman, *elective attraction*, and by many of the German and French chemiſts, *affinity*; and this laſt term we ſhall employ, becauſe the other two are rather general. All ſubſtances which are capable of combining together are ſaid to have an *affinity for* (C) each other: thoſe ſubſtances, on the contrary, which do not unite, are ſaid to have *no affinity* for each other. Thus there is no affinity between water and oil. It appears from the inſtance of the common ſalt and ſpirit of wine, that ſubſtances differ in the degree of their affinity for other ſubſtances, ſince the ſpirit of wine diſplaced the ſalt and united with the water. Spirit of wine therefore has a ſtronger affinity for water than common ſalt has.

In 1719 Geoffroi invented a method of repreſenting the different degrees of affinities in tables, which he called *tables of affinity*. His method conſiſted in placing the ſubſtances whoſe affinities were to be aſcertained at the top of a column, and the ſubſtances with which it united below it, each in the order of its affinity; the ſubſtance which had the ſtrongeſt affinity next it, and that which had the weakeſt fartheſt diſtant, and ſo of the reſt. According to this method, the affinity of water for ſpirit of wine and common ſalt would be marked as follows:

WATER,

Spirit of wine,
Common ſalt.

This method has been univerſally adopted, and has contributed very much to the rapid progreſs of chemiſtry.

14 Affinities of oxygen.

We ſhall proceed therefore to give a table of the affinities of oxygen.

OXYGEN,

Carbon,
Zinc,
Iron,
Mangeneſe,
Hydrogen,
Azot,
Sulphur,
Phoſphorus,
Cobalt,
Nickel,
Lead,
Tin,
Phoſphorous acid,
Copper,
Biſmuth,
Antimony,
Mercury,
Silver,
Arſenic,
Sulphurous acid,
Oil,
Nitrous gas,
Gold,
White oxide of arſenic,
Muriatic acid,
Oxide of tin,

White

(B) Mayow had in the laſt century made conſiderable progreſs towards the diſcovery of oxygen gas. He knew that only a part of the air ſupported combuſtion: This part he called *particulæ igneo-aereæ*. He knew that this part was contained in nitre: "Pars nitri aerea nihil aliud quam particulæ ejus igneo-aereæ eſt." He adds, "At non eſt eſtimandum pabulum igneo-aereum ipſum aerem eſſe, ſed tantum partem ejus majus activam ſubtilemque. Quippe lucerna vitro incluſa expirat cum tamen copia aeris ſatis ampla in eodem continetur." He knew alſo that it was this part of the air which was uſeful in reſpiration. After mentioning ſeveral experiments to prove this, he adds, "Ex dictis certo conſtat animalia reſpirando particulas quaſdam vitales eaſque elaſticas ab aere haurire." See his *Tractatus quinque Medico-Phyſici*, p. 12. and 106.—He knew alſo that this part of the air was neceſſary to combuſtion: "Et tamen certo conſtat, particulas nitro-aereas non minus quam ſulphureas ad ignem conflandum neceſſareas eſſe." *Ibid*, p. 26.

(C) We are not certain that the phraſe *affinity for* is warranted by claſſical authority; we have ventured, however, to uſe it, becauſe, as the word *affinity* in this article ſignifies a ſpecies of attraction, we thought it would be more perſpicuous to put after it the prepoſition *for*, which uſually follows the word *attraction*, than *to* or *with*, which come after *affinity* when uſed in its ordinary acceptation.

White oxide of lead?
Nitrous acid,
White oxide of manganeſe,
Water.

The reaſon of this order will appear when we treat of theſe various ſubſtances.

Chap. II. *Of* Simple Combustible Bodies.

15
Five ſimple combuſtibles.

By *combuſtibles*, we mean ſubſtances capable of combuſtion; and by *ſimple combuſtibles*, bodies of that nature which have not yet been decompounded. Theſe are only five in number, Sulphur, Phosphorus, Carbon, Hydrogen, and Azot. Were we to adhere ſtrictly to our definition indeed, we ſhould add all the metals; for they are alſo combuſtible, and have not yet been decompounded: But for the reaſons formerly given, we ſhall venture to deviate a little from ſtrict logic, and conſider them afterwards as a diſtinct claſs of ſubſtances.

Sect. I. *Of Sulphur.*

Sulphur, diſtinguiſhed alſo in Engliſh by the name of *brimſtone*, was known in the earlieſt ages. As it is found native in many parts of the world, it could not fail very ſoon to attract the attention of mankind. It was uſed by the ancients in medicine, and its fumes were employed in bleaching wool*.

* *Pliny.* lib. xxxv. c. 15.

16
Properties of ſulphur.

Sulphur is a hard brittle ſubſtance, commonly of a yellow colour, without any ſmell, and of a weak though perceptible taſte.

It is a non-conductor of electricity, and of courſe becomes electric by friction.

If a conſiderable piece of ſulphur be expoſed to a ſudden though gentle heat, by holding it in the hand, for inſtance, it breaks to pieces with a crackling noiſe†.

† *Fourcroy.*

Its ſpecific gravity is 1,990.

When heated to the temperature of 185° of Fahrenheit, it melts and becomes very fluid. If the temperature be ſtill farther increaſed, the fluidity diminiſhes; but when the ſulphur is then carried from the fire and allowed to cool, it becomes as fluid as ever before it congeals‡.

‡ *Dr Black.*

17
Flowers of ſulphur.

When ſulphur is heated to the temperature of 170°, it riſes up in the form of a fine powder, which may be eaſily collected in a proper veſſel. This powder is called *flowers of ſulphur*. When ſubſtances fly off in this manner on the application of a moderate heat, they are called *volatile*; and the proceſs itſelf, by which they are raiſed, is called *volatilization*.

Sulphur undergoes no change by being allowed to remain expoſed to the open air.

When thrown into water, it does not melt, as common ſalt does, but falls to the bottom, and remains there unchanged; it is therefore *inſoluble* in water. If, however, it be poured, while in a ſtate of fuſion, into water, it aſſumes a red colour, and retains ſuch a degree of ſoftneſs, that it may be kneaded between the fingers; but it loſes this property in a few days§.

Fourcroy.

18
ulphur ca-
able of
ryſtalli-
ing.

There are a great many bodies which, after being diſſolved in water or melted by heat, are capable of aſſuming certain regular figures. If a quantity of common ſalt, for inſtance, be diſſolved in water, and that fluid, by the application of a moderate heat, be made to fly off in the form of ſteam; or, in other words, if the water be ſlowly *evaporated*, the ſalt will fall to the bottom of the veſſel in cubes. Theſe regular figures are called *cryſtals*. Now ſulphur is capable of cryſtallizing. If it be melted, and as ſoon as its ſurface begins to congeal, the liquid ſulphur beneath be poured out, the internal cavity will exhibit long needle-ſhaped cryſtals of an octahedral figure. This method of cryſtallizing ſulphur was contrived by Rouelle.

19
Converted by combuſtion into an acid.

When ſulphur is heated to the temperature of 302° in the open air, it takes fire ſpontaneouſly, and burns with a pale blue flame, and at the ſame time emits a great quantity of fumes of a very ſtrong ſuffocating odour. When heated to the temperature of 570°, or a little higher, it burns with a bright white flame, and at the ſame time emits a vaſt quantity of fumes. If the heat be continued long enough, the ſulphur burns all away without leaving any aſhes or *reſiduum*. If the fumes be collected, they are found to conſiſt entirely of *ſulphuric acid*. By combuſtion, then, ſulphur is converted into an acid. This fact was known ſeveral centuries ago, but no intelligible explanation was given of it till the time of Stahl. That chemiſt undertook the taſk; and founded on his experiments a theory ſo exceedingly ingenious, and ſupported by ſuch a vaſt number of facts, that it was in a very ſhort time adopted with admiration by all the philoſophic world, and contributed not a little to raiſe chemiſtry to that rank among the ſciences from which the ridiculous pretenſions of the early chemiſts had excluded it.

20
Stahl's explanation of this.

According to Stahl, there is only one ſubſtance in nature capable of combuſtion, which therefore he called Phlogiston; and all thoſe bodies which can be ſet on fire contain leſs or more of it. Combuſtion is merely the ſeparation of this ſubſtance. Thoſe bodies which contain none of it are of courſe incombuſtible. All combuſtibles, except thoſe which conſiſt of pure phlogiſton (if there be any ſuch), are compoſed of an incombuſtbile body and phlogiſton united together. During combuſtion the phlogiſton flies off, and the incombuſtible body remains behind. Now when ſulphur is burnt, the ſubſtance which remains is ſulphuric acid, an incombuſtible body. Sulphur therefore is compoſed of ſulphuric acid and phlogiſton.

To eſtabliſh this theory completely, it was neceſſary to ſhew that ſulphur could be actually made by combining ſulphuric acid and phlogiſton; and this alſo Stahl undertook to perform. *Sulphat of potaſs* is a ſubſtance compoſed of ſulphuric acid and potaſs (d), and *charcoal* is a combuſtible body, and therefore, according to the theory of Stahl, contains phlogiſton: when burnt, it leaves a very inconſiderable reſiduum, and conſequently contains hardly any thing elſe than phlogiſton. He melted together in a crucible a mixture of *potaſs* and *ſulphat of potaſs*, ſtirred into it one-fourth part by weight of pounded charcoal, covered the crucible with another inverted over it, and applied a ſtrong heat to it. He then allowed it to cool, and examined its contents. The charcoal had diſappeared, and there only remained in the crucible a mixture of potaſs and ſulphur combined together,

---

(d) The nature of *potaſs* ſhall afterwards be explained. It is the *potaſh* well known in commerce in a ſtate of purity.

together, and of a darker colour than uſual, from the reſiduum of the charcoal. Now there were only three ſubſtances in the crucible at firſt, potaſs, ſulphuric acid, and charcoal: two of theſe have diſappeared, and *ſulphur* has been found in their place. Sulphur then muſt have been formed by the combination of theſe two. But charcoal conſiſts of phlogiſton and a very ſmall reſiduum, which is ſtill found in the crucible. The ſulphur then muſt have been formed by the combination of ſulphuric acid and phlogiſton. This ſimple and luminous explanation appeared ſo ſatisfactory, that the compoſition of ſulphur was long conſidered as one of the beſt demonſtrated truths in chemiſtry.

21 Unſatiſfactory. There are two facts, however, which Stahl either did not know or did not ſufficiently attend to, neither of which were accounted for by his theory. The firſt is, that ſulphur will not burn if air be completely excluded; the ſecond, that ſulphuric acid is heavier than the ſulphur from which it was produced.

22 Real explanation by Lavoiſier.

To account for theſe, or facts ſimilar to theſe, ſucceeding chemiſts refined upon the theory of Stahl, deprived his phlogiſton of *gravity*, and even aſſigned it a principle of *levity*. Still, however, the neceſſity of the contact of air remained unexplained. At laſt Mr Lavoiſier, who had already diſtinguiſhed himſelf by the extenſiveneſs of his views, the accuracy of his experiments, and the preciſion of his reaſoning, undertook the examination of this ſubject, and his experiments were publiſhed in the Memoirs of the Academy of Sciences for 1777. He put a quantity of ſulphur into a large glaſs veſſel filled with air, which he inverted into another veſſel containing mercury, and then ſet fire to the ſulphur by means of a burning-glaſs. It emitted a blue flame, and gave out thick vapours. but was very ſoon extinguiſhed, and could not be again kindled. There was, however, a little ſulphuric acid formed, which was a good deal heavier than the ſulphur which had diſappeared; there was alſo a diminution in the air of the veſſel proportional to this increaſe of weight. The ſulphur, therefore, during its converſion into an acid, muſt have abſorbed part of the air. He then put a quantity of ſulphuret of iron, which conſiſts of ſulphur and iron combined together, into a glaſs veſſel full of air, which he inverted over water (E). The quantity of air in the veſſel continued diminiſhing for eighteen days, as was evident from the aſcent of the water to occupy the ſpace which it had left; but after that period no farther diminution took place. On examining the ſulphuret, it was found ſomewhat heavier than when firſt introduced into the veſſel, and the air of the veſſel wanted preciſely the ſame weight. Now this air had loſt all its oxygen; all the oxygen of the air in the veſſel muſt therefore have entered into the ſulphuret. Part of the ſulphur was converted into ſulphuric acid; and as all the reſt of the ſulphuret was unchanged, the whole of the increaſe of weight muſt have been owing to ſomething which had entered into that part of the ſulphur which was converted into acid. This ſomething we know was oxygen. Sulphuric acid therefore muſt be compoſed of ſulphur and oxygen; for as the original weight of the whole contents of the veſſel remained exactly the ſame, there was not the ſmalleſt reaſon to ſuppoſe that any ſubſtance had left the ſulphur.

It is impoſſible, then, that ſulphur can be compoſed of ſulphuric acid and phlogiſton, as Stahl ſuppoſed; ſince ſulphur itſelf enters as a part into the compoſition of that acid. There muſt therefore have been ſome want of accuracy in the experiment by which Stahl proved the compoſition of ſulphur, or at leaſt ſome fallacy in his reaſonings; for it is impoſſible that two contradictory facts can both be true. Upon examining the potaſs and ſulphur produced by Stahl's experiment, we find them to be conſiderably lighter than the charcoal, ſulphuric acid, and potaſs originally employed. Something therefore has made its eſcape during the application of the heat. And if the experiment be conducted in a cloſe veſſel, with a pneumatic apparatus attached to it, a quantity of gas will be obtained exactly equal to the weight which the ſubſtances operated on have loſt; and this weight conſiderably exceeds that of all the charcoal employed. This gas is *carbonic acid gas*, which is compoſed of charcoal and oxygen, as will afterwards appear. We now perceive what paſſes in this experiment: Charcoal has a ſtronger affinity for oxygen at a high temperature than ſulphur has. When charcoal therefore is preſented to ſulphuric acid in that temperature, the oxygen of the acid combines with it, they fly off in the form of carbonic acid gas, and the ſulphur is left behind.

The combuſtion of ſulphur, then, is nothing elſe than the act of its combination with oxygen; and, for any thing which we know to the contrary, it is a ſimple ſubſtance.

23 Affinities of ſulphur. The affinities of ſulphur, according to Bergman, are as follows:

Lead,
Tin,
Silver,
Mercury,
Arſenic,
Antimony,
Iron,
Fixed alkalies,
Ammonia,
Barytes,
Lime,
Magneſia,
Phoſphorus?
Oils,
Ether,
Alcohol.

SECT. II. *Of Phoſphorus.*

24 Production of phoſphorus. LET a quantity of bones be burnt, or, as it is termed in chemiſtry, *calcined*, till they ceaſe to ſmoke, or to give out any odour. and let them afterwards be reduced to a fine powder. Put this powder into a glaſs veſſel, and pour ſulphuric acid on it by little at a time, till farther additions do not cauſe any extrication of air bubbles (F). Dilute the mixture with a good deal of water, agitate it well, and keep it hot for ſome hours; then paſs it through a filter. Evaporate the liquid ſlowly

---

(E) This experiment was firſt made by Scheele, but with a different view.

(F) The copious emiſſion of air bubbles is called in chemiſtry *efferveſcence*.

Phoſphorus

ſlowly till a quantity of white powder falls to the bottom. This powder muſt be ſeparated by filtration and thrown away. The evaporation is then to be reſumed; and whenever any white powder appears, the filtration muſt be repeated in order to ſeparate it. During the whole proceſs, what remains on the filter muſt be waſhed with pure water, and this water added to the liquor. The evaporation is to be continued till all the moiſture diſappears, and nothing but a dry maſs remains. Put this maſs into a crucible, and keep it melted in the fire till it ceaſes to exhale ſulphureous odours; then pour it out. When cold it aſſumes the appearance of a brittle glaſs. Pound this glaſs in a mortar, and mix it with one-third by weight of charcoal duſt. Put this mixture into an earthen ware retort, and apply a receiver containing a little water. Put the retort into a ſand bath, and increaſe the fire till it becomes red hot. A ſubſtance then paſſes into the receiver, which has the appearance of melted wax, and which congeals as it falls into the water of the receiver. This ſubſtance is *phoſphorus*.

25
Its diſcovery.

It was diſcovered by Brandt, a chemiſt of Hamburgh, about the year 1667, while he was employed in attempting to extract from human urine a liquid capable of converting ſilver into gold *.

* *Leibnitz, Melange de Berlin.*

Kunkel, another German chemiſt, hearing of the diſcovery, was anxious to find out the proceſs, and for that purpoſe aſſociated himſelf with a friend of his named Kraft. But the latter procured the ſecret from the diſcoverer; and expecting by means of it to acquire a fortune, refuſed to give any information to his aſſociate. Vexed at this treachery, Kunkel reſolved to attempt the diſcovery himſelf; and though he knew only that phoſphorus was obtained from urine, proſecuted the inquiry with ſo much zeal, that he ſucceeded, and has been deſervedly conſidered as one of the diſcoverers †.

† *Stahl's Three Hundred Experiments.*

Boyle likewiſe diſcovered phoſphorus. Leibnitz indeed affirms that Kraft taught Boyle the whole proceſs, and Kraft declared the ſame thing to Stahl. But ſurely the aſſertion of a dealer in ſecrets, and one who had deceived his own friend, on which the whole of this ſtory is founded, cannot be put in competition with the affirmation of a man like Boyle, who was one of the honeſteſt men, as well as greateſt philoſophers, of his age; and he poſitively aſſures us that he made the diſcovery without being previouſly acquainted with the proceſs ‡.

‡ *Boyle Abridged by Shaw*, iii 174.

Gahn, a Swediſh chemiſt, diſcovered, in 1769, that phoſphorus was contained in bones ‖, and Scheele (G) very ſoon after invented a proceſs for obtaining it from them. Phoſphorus is now generally procured in that manner. The proceſs deſcribed in the beginning of this ſection is that of the Dijon academicians: it differs from that of Scheele only in a ſingle particular.

‖ *Bergman's Notes on Scheffer.*

26
Its properties.

Phoſphorus, when pure, is of a clear, tranſparent, yellowiſh colour; but when kept ſome time in water, it becomes opaque, and then has a great reſemblance to white wax. Its conſiſtence is nearly that of wax: it may be cut with a knife or twiſted to pieces with the fingers. It is inſoluble in water. Its ſpecific gravity is 1,714.

It melts at the temperature of 99° *, and even at 67° it gives out a white ſmoke, and is luminous in the dark; that is to ſay, it ſuffers a ſlow combuſtion: ſo that it can only be prevented from taking fire by keeping it in a very low temperature, or by allowing it to remain always plunged in water. If air be excluded, it evaporates at 219°, and boils at 554° †. When heated to 122° (H), it burns with a very bright flame, and gives out a great quantity of white ſmoke, which is luminous in the dark; at the ſame time it emits an odour which has ſome reſemblance to that of garlic. It leaves no reſiduum; but when the white ſmoke is collected, it is found to be an *acid*. Stahl conſidered this acid as the muriatic (I). According to him, phoſphorus was compoſed of muriatic acid and phlogiſton, and the combuſtion of it was merely the ſeparation of phlogiſton. He even declared, that to make phoſphorus, nothing more was neceſſary than to combine muriatic acid and phlogiſton; and that this compoſition was as eaſily accompliſhed as that of ſulphur itſelf ‡.

* *Pelletier, Journal de Phyſique*, xxxv. 380.

† *Ibid.* 381.

27
Converted by combuſtion

‡ *Three Hundred Experiments.*

Theſe aſſertions gained implicit credit; and the compoſition and nature of phoſphorus were conſidered as completely underſtood, till Margraf of Berlin publiſhed his experiments in the year 1743. That great man, one of thoſe illuſtrious philoſophers who have contributed ſo much to the rapid increaſe of the ſcience, diſtinguiſhed equally for the ingenuity of his experiments and the clearneſs of his reaſoning, attempted to produce phoſphorus by combining together phlogiſton and muriatic acid; but though he varied his proceſs a thouſand ways, preſented the acid in many different ſtates, and employed a variety of ſubſtances to furniſh phlogiſton, all his attempts failed, and he was obliged to give up the combination as impracticable. On examining the acid produced during the combuſtion of phoſphorus, he found that its properties were very different from thoſe of muriatic acid. It was therefore a diſtinct ſubſtance. The name of *phoſphoric acid* was given to it; and it was concluded that phoſphorus was compoſed of this acid united to phlogiſton.

28
Into phoſphoric acid.

But it was obſerved in 1772 by Morveau §, that phoſphoric acid was heavier than the phoſphorus from which it was produced (K); and Boyle had long before ſhewn that phoſphorus would not burn except when in contact with air. Theſe facts were ſufficient to prove the inaccuracy of the theory concerning the compoſition of phoſphorus; but they remained themſelves unaccounted for, till Lavoiſier publiſhed thoſe celebrated experiments, which threw ſo much light on the nature and compoſition of acids.

§ *Digreſ. Academ.* p. 253.

He exhauſted a glaſs globe of air by means of an air-

(G) Crell, in his life of Scheele, informs us that Scheele was himſelf the diſcoverer of the fact. This, he ſays, clearly appears from a printed letter of Scheele to Gahn, who was before looked upon as the diſcoverer. See *Crell's Annals*, Engliſh Tranſ. I. 17.

(H) Morveau, *Encycl. Method. Chimie*, art *Affinité*.—According to Nicholſon at 160°. See his *Tranſlation of Chaptal*.

(I) This acid ſhall be afterwards deſcribed.

(K) The ſame obſervation had been made by Margraf, but no attention was paid to it.

pump; and after weighing it accurately, he filled it with oxygen gas, and introduced into it 100 grains of phoſphorus. The globe was furniſhed with a ſtop-cock, by which oxygen gas could be admitted at pleaſure. He ſet fire to the phoſphorus by means of a burning-glaſs. The combuſtion was extremely rapid, accompanied by a bright flame and much heat. Large quantities of white flakes attached themſelves to the inner ſurface of the globe, and rendered it opaque; and theſe at laſt became ſo abundant, that notwithſtanding the conſtant ſupply of oxygen gas, the phoſphorus was extinguiſhed. The globe, after being allowed to cool, was again weighed before it was opened. The quantity of oxygen employed during the experiment was aſcertained, and the phoſphorus, which ſtill remained unchanged, accurately weighed. The white flakes, which were nothing elſe than pure phoſphoric acid, were found exactly equal to the weights of the phoſphorus and oxygen, which had diſappeared during the proceſs.

29
Which is phoſphorus combined with oxygen.

Phoſphoric acid therefore muſt have been formed by the combination of theſe two bodies; for the abſolute weight of all the ſubſtances together was the ſame before and after the proceſs [*]. It is impoſſible then that phoſphorus can be compoſed of phoſphoric acid and phlogiſton, as phoſphorus itſelf enters into the compoſition of that acid (L).

Thus the combuſtion of phoſphorus, like that of ſulphur, is nothing elſe than its combination with oxygen; for during the proceſs no new ſubſtance appears except the acid, accompanied indeed with much heat and light.

30
Phoſphorus combines with ſulphur.

Phoſphorus combines readily with ſulphur, as Margraf diſcovered during his experiments on phoſphorus. This combination was afterwards examined by Mr Pelletier. The two ſubſtances are capable of being mixed in different proportions. Seventy-two grains of phoſphorus and nine of ſulphur, when heated in about four ounces of water, melt with a gentle heat. The compound remains fluid till it be cooled down to 77°, and then becomes ſolid. Theſe ſubſtances were combined in the ſame manner in the following proportions:

72	Phoſphor.	congeals at	59°
18	Sulphur		
72	Phoſphor.	at	50°
36	Sulphur		
72	Phoſphor.	at	41°
72	Sulphur		
72	Phoſphor.	at	99°
216	Sulphur		

Phoſphorus and ſulphur may be combined alſo by melting them together without any water; but the combination takes place ſo rapidly, that they are apt to ruſh out of the veſſel if the heat be not exceedingly moderate [†].

Phoſphorus is capable of combining alſo with many other bodies: the compounds produced are called *phoſphurets*.

The affinities of phoſphorus have not yet been aſcertained.

Sect. III. *Of Carbon.*

If a piece of wood be put into a crucible, well covered with ſand, and kept red hot for ſome time, it is converted into a black ſhining brittle ſubſtance, without either taſte or ſmell, well known under the name of *charcoal*. This ſubſtance contains always mixed with it ſeveral earthy and ſaline particles. When freed from theſe impurities it is called *carbon*.

31
Properties of carbon.

Charcoal is inſoluble in water. It is not affected (provided that all air be excluded) by the moſt violent heat which can be applied, excepting only that it is rendered much harder.

New-made charcoal abſorbs moiſture with avidity. When heated to a certain temperature, it abſorbs air copiouſly. La Metherie plunged a piece of burning charcoal into mercury, in order to extinguiſh it, and introduced it immediately after into a glaſs veſſel filled with common air. The charcoal abſorbed four times its bulk of air. On plunging the charcoal in water, one-fifth of this air was diſengaged. This air, on being examined, was found to contain a much ſmaller quantity of oxygen than atmoſpherical air does. He extinguiſhed another piece of charcoal in the ſame manner, and then introduced it into a veſſel filled with oxygen gas. The quantity of oxygen gas abſorbed amounted to eight times the bulk of the charcoal; a fourth part of it was diſengaged on plunging the charcoal into water [*]. It appears from the experiments of Sennebier, that charcoal when expoſed to the atmoſphere abſorbs oxygen gas in preference to *azot* [†], as the other portion of common air is called.

32
Converted into an acid.

When heated to the temperature of 370° [‡], it takes fire, and, provided it has been previouſly freed from the earths and ſalts which it generally contains, it burns without leaving any reſiduum. If this combuſtion be performed in cloſe veſſels filled with oxygen gas inſtead of common air, part of the charcoal and oxygen diſappear, and in their room is found a particular gas exactly equal to them in weight. This gas has the properties of an acid, and is therefore called *carbonic acid gas*. Mr Lavoiſier, to whom we are indebted for this diſcovery, aſcertained, by a number of very accurate experiments, that this gas was compoſed of about 28 parts of carbon and 72 of oxygen [‖].

33
Suſceptible of cryſtallization.

Carbon is ſuſceptible of cryſtallization. In that ſtate it is called *diamond*. The figure of the diamond varies conſiderably; but moſt commonly it is a hexagonal priſm terminated by a ſix-ſided pyramid. When pure it is colourleſs and tranſparent. Its ſpecific gravity is from 3,44 to 3,55. It is one of the hardeſt ſubſtances in nature; and as it is not affected by a conſiderable heat, it was for many ages conſidered as incombuſtible. Sir Iſaac Newton, obſerving that combuſtibles refracted light more powerfully than other bodies, and that the diamond poſſeſſed this property in great perfection, ſuſpected,

Phoſphoric acid therefore is compoſed of 100 parts phoſphorus and 154 oxygen.

pected, from that circumſtance, that it was capable of combuſtion. This ſingular conjecture was verified in 1694 by the Florentine academicians, in the preſence of Coſmo III. grand duke of Tuſcany. By means of a burning-glaſs, they deſtroyed ſeveral diamonds. Francis I. emperor of Germany, afterwards witneſſed the deſtruction of ſeveral more in the heat of a furnace. Theſe experiments were repeated by Rouelle, Macquer, and D'Arcet; who proved that the diamond was not merely evaporated, but actually burnt, and that if air was excluded it underwent no change.

No attempt, however, was made to aſcertain the product, till Lavoiſier undertook a ſeries of experiments for that purpoſe in 1772. He obtained *carbonic acid gas*. It might be concluded from theſe experiments, that the diamond contains carbon; but it was reſerved for Mr Tennant to ſhew that it conſiſted entirely of that ſubſtance.

34
When it forms *diamond*.

Into a tube of gold, having one end cloſed and a glaſs tube adapted to the other to collect the product, that gentleman put 2½ grains of diamonds and a quarter of an ounce of nitre (M). This tube was heated ſlowly; the conſequence of which was, that great part of the nitric acid paſſed off before the diamond took fire, and by that means almoſt the whole of the carbonic acid formed during the combuſtion of the diamond remained in the potaſs, for which it has a ſtrong affinity. To aſcertain the quantity of this carbonic acid, he diſſolved the potaſs in water, and added to the ſolution another ſalt compoſed of muriatic acid and lime. Muriatic acid has a ſtronger affinity for potaſs than for lime; it therefore combines with the potaſs, and at the ſame time the lime and carbonic acid unite and fall to the bottom of the veſſel, becauſe they are nearly inſoluble in water. He decanted off the liquor, and put the lime which contained the carbonic acid gas into a glaſs globe, having a tube annexed to it. This globe and tube he then filled with mercury, and inverted into a veſſel containing the ſame fluid. The lime by that means occupied the very top of the tube. It now remained to ſeparate the carbonic acid from the lime, which may be done by mixing it with any acid, as almoſt every other acid has a ſtronger affinity for lime than carbonic acid has. Accordingly on introducing muriatic acid, 10,3 ounce meaſures of carbonic acid gas, or nearly 9,166 grains, were ſeparated. But, according to the experiments of Lavoiſier, this gas is compoſed of 72 parts of oxygen and 28 of carbon; 9,166 grains, therefore contain 2,56 grains of carbon, which is almoſt preciſely the weight of the diamond conſumed. It follows, therefore, that it was compoſed of pure carbon*. The difficulty of burning the diamond is owing entirely to its hardneſs. Meſſrs Morveau and Tennant rendered common charcoal ſo hard by expoſing it for ſome time to a violent fire in cloſe veſſels, that it loſt much of its natural tendency to combuſtion, and endured even a red heat without catching fire †.

* *Phil. Tranſ.* 1797. p. 123.

† *Encycl. Method. Chimie, art.* Acier.

Charcoal poſſeſſes a number of ſingular properties, which render it of conſiderable importance. It is incapable of putrefying or rotting like wood, and is not therefore liable to decay through age. This property has been long known. It was cuſtomary among the ancients to *char* the outſide of thoſe ſtakes which were to be driven into the ground or placed in water, in order to preſerve the wood from ſpoiling. New-made charcoal, by being rolled up in cloths which have contracted a diſagreeable odour, effectually deſtroys it. It takes away the bad taint from meat beginning to putrefy, by being boiled along with it. It is perhaps the beſt teeth powder known. Mr Lowitz of Peterſburgh has ſhewn, that it may be uſed with advantage to purify a great variety of ſubſtances.

35
Carburets.

Carbon unites with a number of bodies, and forms with them compounds known by the name of *carburets*.

Its affinities have not yet been aſcertained.

Sect. IV. *Of Hydrogen.*

36
Method of procuring hydrogen.

Put into a glaſs veſſel furniſhed with two mouths a quantity of freſh iron filings, quite free from ruſt. Lute into one of theſe mouths the end of a crooked glaſs tube. Inſert the other end of this tube below a glaſs jar filled with water, and inverted into a pneumatic apparatus. Then pour upon the iron filings a quantity of ſulphuric acid, diluted with twice its own weight of water, and cloſe up the mouth of the veſſel. Immediately the iron filings and acid effervеſce with violence, a vaſt quantity of gas is produced, which ruſhes through the tube and fills the jar. This gas is called *hydrogen gas* (N).

It was obtained by Dr Mayow and by Dr Hales from various ſubſtances, and had been known long before in mines under the name of the *fire damp*. Mr Cavendiſh * was the firſt who examined its properties with attention. They were afterwards more fully inveſtigated by Prieſtley, Scheele, and Fontana.

* *Phil. Tranſ.* 1766.

37
Its properties.

Hydrogen, like *air*, is inviſible and elaſtic, and capable of indefinite compreſſion and dilatation.

Its ſpecific gravity differs according to its purity, Kirwan found it 0,00010 †; Lavoiſier 0,000094 ‡, or about twelve times lighter than common air.

All burning ſubſtances are immediately extinguiſhed by being plunged into this gas. It is incapable, therefore, of ſupporting combuſtion.

† *On Phlogiſton*, ſect. 1ſt.

‡ *Lavoiſier's Chemiſtry, Appendix.*

Animals, when they are obliged to breathe it, die almoſt inſtantaneouſly. Scheele, indeed, found that he could breathe it for ſome time without inconvenience §; but Fontana, who repeated the experiment, diſcovered that this was owing to the quantity of common air contained in the lungs when he began to breathe; for on expiring as ſtrongly as poſſible before drawing in the hydrogen gas, he could only make three reſpirations, and even theſe three produced extreme feebleneſs and oppreſſion about the breaſt ||.

§ *Scheele on Fire.*

|| *Jour de Phyſ.* xv. 99.

If a phial be filled with hydrogen gas, and a lighted candle be brought to its mouth, the gas will take fire, and burn gradually till it is all conſumed. If hydrogen

---

(M) Nitre is compoſed of potaſs and nitric acid; and nitric acid contains a great quantity of oxygen, which is eaſily ſeparated by heat. Diamond, when mixed with nitre, burns at a much lower heat than by any other proceſs.

(N) It was formerly called *inflammable air*, and by ſome chemiſts *phlogiſton*.

gen and oxygen gas be mixed together and kindled, they burn inſtantaneouſly, and produce an exploſion like gunpowder. The ſame effect follows when a mixture of hydrogen gas and atmoſpherical air is kindled, but the exploſion is leſs violent. Hydrogen gas will not burn except in contact with oxygen gas, nor will it burn even in contact with oxygen gas, unleſs a red heat be applied to it. If 85 parts by weight of oxygen gas, and 15 of hydrogen gas, be mixed together, and ſet on fire in a cloſe veſſel, they diſappear, and in their place there is found a quantity of water exactly equal to them in weight. This water muſt be compoſed of theſe two gaſes; for it did not previouſly exiſt in the veſſel, and no other ſubſtance except the gaſes was introduced. Water then is compoſed of oxygen and hydrogen; and the combuſtion of hydrogen is nothing elſe but the act of its combination with oxygen (o).

38
Compoſition of water.

It had been ſuppoſed, in conſequence of the experiments of Dr Prieſtley and ſeveral other philoſophers, that when hydrogen gas was allowed to remain in contact with water, it was gradually decompoſed, and converted into another gas; but Mr de Morveau[*], Mr Haſſenfratz[†], and Mr Libes[‡], have ſhewn that it undergoes no change, provided ſufficient care be taken to exclude every other gas.

39
Compounds of hydrogen gas.

Hydrogen gas diſſolves ſulphur, phoſphorus, and carbon. The compounds are called *ſulphurated*, *phoſphorated*, and *carbonated hydrogen gas*.

40
Sulphurated hydrogen gas.

1. Sulphurated hydrogen gas was firſt examined with attention by Scheele, who, together with Bergman, diſcovered many of its properties. Mr Kirwan likewiſe publiſhed a very valuable paper on the ſame ſubject. If equal parts of ſulphur and potaſs be melted together in a covered crucible, they combine together, and form a compound known by the name of *ſulphuret of potaſs*, but formerly called, from its red colour, *hepar ſulphuris*, or *liver of ſulphur*. When this ſubſtance is moiſtened with water, it gives out a quantity of ſulphurated hydrogen gas; hence this gas was at firſt called *hepatic gas*.

Mr Gengembre encloſed a bit of ſulphur in a glaſs veſſel filled with hydrogen gas, and melted the ſulphur by means of a burning-glaſs. A quantity of it diſappeared, and the hydrogen aſſumed all the properties of *hepatic gas*. Hence it follows that this gas is merely ſulphur diſſolved in hydrogen gas.

The eaſieſt method of obtaining it is to pour an acid, the muriatic for inſtance, on a quantity of the ſulphuret reduced to powder. An efferveſcence takes place, the gas is extricated, and may be collected by means of a pneumatic apparatus. The theory of this emiſſion is obvious. The ſulphur is gradually converted into ſulphuric acid, by decompoſing the water, which is always united with acids, and ſeizing its oxygen: the hydrogen of the water is thus ſet at liberty; it aſſumes the gaſeous form, and at the ſame time diſſolves part of the remaining ſulphur, for which it has a conſiderable affinity.

The ſpecific gravity of ſulphurated hydrogen gas is 0,00135[*]; it is to common air as 1106 to 1000.

It has a very fetid odour, preciſely ſimilar to that emitted by rotten eggs, which indeed is owing to the emiſſion of the very ſame gas.

It is not more reſpirable than hydrogen gas. When ſet on fire, in contact with oxygen gas, it burns with a light blue flame, without exploding, and at the ſame time a quantity of ſulphur is depoſited. The combuſtion of this gas, then, is merely the union of its hydrogen, and perhaps part of its ſulphur, with oxygen.

This gas turns ſyrup of violets to a green colour[†]. It does not ſeem capable of exiſting in atmoſpherical air without decompoſition; for the moment it comes into contact with oxygen gas, ſulphur is depoſited[‡].

41
Phoſphorated hydrogen gas.

2. Phoſphorated hydrogen gas was diſcovered by Mr Gengembre in 1783, and by Mr Kirwan ſome time after, before he became acquainted with the experiments of that gentleman. It may be procured by mixing phoſphorus with potaſs diſſolved in water, and applying a boiling heat to the ſolution. The phoſphorus is gradually converted into an acid by decompoſing the water, and uniting with its oxygen. The hydrogen aſſumes the form of a gas, and flies off after diſſolving a little of the phoſphorus. This gas may be collected by means of a pneumatic apparatus.

Phoſphorated hydrogen gas has a ſmell reſembling that of putrid fiſh. When mixed with oxygen gas or common air, it becomes luminous; and on the application of the ſmalleſt heat, it burns with aſtoniſhing rapidity[§]. The products are water and phoſphoric acid. The combuſtion of this gas therefore is nothing elſe than the union of its phoſphorus and hydrogen with oxygen, attended by an emiſſion of heat and light.

Phoſphorated hydrogen gas may alſo be formed by introducing a bit of phoſphorus into a jar containing hydrogen gas: but care muſt be taken to make this gas as dry as poſſible; for its affinity with phoſphorus is weakened in proportion to its moiſture[||].

42
Carbonated hydrogen gas.

3. Carbonated hydrogen gas ariſes ſpontaneouſly in hot weather from marſhes, but always mixed with ſeveral other gaſes. Several ſpecies of it have been lately diſcovered by the aſſociated Dutch chemiſts Bondt, Dieman, Van Trooſtwyck, and Lauwerenberg[¶]. When 75 parts of ſulphuric acid and 25 of ſpirit of wine are mixed together, a gas is extricated which ſuffers no alteration from ſtanding over water. Its ſpecific gravity is 0,00111, or it is to common air as 909 to 1000. It has a fetid odour, and burns with a ſtrong compact flame. When paſſed through ſulphur it is converted into ſulphurated hydrogen gas, and at the ſame time a quantity of carbon is depoſited in the form of a fine powder; it muſt therefore be compoſed of carbon and hydrogen gas. When burnt, the product is carbonic acid

[¶] *Ann. de Chim.* xxi. 45.

(o) The hiſtory of this great diſcovery, and the objections which have been made to it, we reſerve for the chapter which treats of *Water*, where they will be better underſtood than they could be at preſent. This ſubſtance was called *hydrogen* by the French chemiſts, becauſe it enters into the compoſition of water, from υδωρ *water*, and γινομαι *I am born*. Objections have been made to the propriety of the name, into which we ſhall not enter. It ought never to be forgotten that Newton had long before, with a ſagacity almoſt greater than human, conjectured, from its great refracting power, that water *contained a combuſtible ſubſtance.*

acid gas and water *. By making ether (P) paſs thro' a red hot glaſs tube, another carbonated hydrogen gas was formed, the ſpecific gravity of which was 0,00086. Spirit of wine, paſſed in the ſame manner, afforded a gas, the ſpecific gravity of which was 0,00053, and which burned with a paler flame than the other two. Theſe gaſes were found to contain from 80 to 74 parts of carbon, and from 20 to 26 of hydrogen. The firſt ſpecies was found to contain moſt carbon, and the laſt to contain leaſt †.

* *Ibid.*

† *Ibid.*

43
Affinities of theſe gaſes.

The affinity of hydrogen gas for theſe three combuſtibles is as follows:

Sulphur,
Carbon,
Phoſphorus (Q).

44
Attempt to decompoſe carbon

Dr Auſtin found, that by repeatedly paſſing electric exploſions through a ſmall quantity of carbonated hydrogen gas, it was permanently dilated to more than twice its original bulk. He rightly concluded, that this remarkable expanſion could only be owing to the evolution of hydrogen gas. On burning air thus expanded, he found that it required a greater quantity of oxygen than the ſame quantity of gas not dilated by electricity: An addition therefore had been made to the combuſtible matter; for the quantity of oxygen neceſſary to complete the combuſtion of any body, is always proportional to the quantity of that body. He concluded from theſe experiments, that he had decompoſed the carbon which had been diſſolved in the hydrogen gas; and that carbon was compoſed of hydrogen and azot (R), ſome of which was always found in the veſſel after the dilated gas had been burnt by means of oxygen ‡. If this concluſion be fairly drawn, we muſt expunge *carbon* from the liſt of ſimple ſubſtances, and henceforth conſider it as a compound.

‡ *Phil. Tranſ.* lxxx. 51.

45
Examined,

There was one circumſtance which ought to have prevented Dr Auſtin from drawing this concluſion, at leaſt till warranted by more deciſive experiments. The quantity of combuſtible matter had been increaſed. Now, if the expanſion of the carbonated hydrogen gas was owing merely to the decompoſition of carbon, no ſuch increaſe ought to have taken place, but rather the contrary; for the carbon, which was itſelf a combuſtible ſubſtance, was reſolved into two ingredients, hydrogen and azot, only the firſt of which burnt on the addition of oxygen and the application of heat. Dr Auſtin's experiments have been lately repeated by Mr William Henry with a great deal of accuracy §. He found that the dilatation which Dr Auſtin deſcribes actually took place, but that it could not be carried beyond a certain degree, a little more than twice the original bulk of the gas. Upon burning ſeparately by means of oxygen, two equal portions of carbonated hydrogen gas, one of which had been expanded by electricity to double its original bulk, the other not, he found that each of them produced preciſely the ſame quantity of *carbonic acid gas*. Both therefore contained the ſame quantity of carbon; conſequently no carbon had been decompounded by the electric ſhocks.

§ *Phil. Tranſ.* 1797 part 2d.

46
And found unſucceſsful.

Mr Henry then ſuſpected that the dilatation was owing to the water which every gas contains in a larger or ſmaller quantity. To aſcertain this, he endeavoured to deprive the carbonated hydrogen gas of as much water as poſſible, by making it paſs over very dry potaſs, which attracts water with avidity. Gas treated in this manner could only be expanded one ſixth of its bulk; but on admitting a drop or two of water, the expanſion went on as uſual. The ſubſtance decompounded by the electricity, then, was not the carbon, but the water in the carbonated hydrogen gas. Nor is it difficult to ſee in what manner this decompoſition is effected. Carbon, at a high temperature, has a greater affinity for oxygen than hydrogen has; for if the ſteam of water be made to paſs over red hot charcoal, it is decompoſed, and carbonic acid and hydrogen gas are formed. The electric exploſion ſupplies the proper temperature; the carbon unites with the oxygen of the water, and forms carbonic acid; and the hydrogen, thus ſet at liberty, occaſions the dilatation. Carbonic acid gas is abſorbed with avidity by water: and when water was admitted into 709 meaſures of gas thus dilated, 100 meaſures were abſorbed; a proof that carbonic acid gas was actually preſent. As to the azot which Dr Auſtin found in his dilated gas, it evidently proceeded from the admiſſion of ſome atmoſpheric air, about 73 parts of which in the 100 conſiſt of this gas: for Dr Auſtin's gas had ſtood long over water; and Drs Prieſtley and Higgins have ſhewn that air in ſuch a ſituation always becomes impregnated with azot.

47
Affinities of hydrogen.

The affinities of hydrogen have not yet been aſcertained, but perhaps they are as follows:

Oxygen,
Carbon,
Azot.

SECT. V. *Of Azot.*

48
Method of procuring azot.

If a quantity of iron filings and ſulphur, mixed together and moiſtened with water, be put into a glaſs veſſel full of air, it will abſorb all the oxygen in the courſe of a few days; but a conſiderable reſiduum of air ſtill remains incapable of any farther diminution. This reſiduum has obtained the appellation of *azotic gas*.

It

(P) Ether is a very volatile and fragrant liquid, obtained by mixing ſpirit of wine and acids, and diſtilling. It ſhall be afterwards deſcribed.

(Q) Sulphur decompoſes carbonated hydrogen gas; therefore its affinity is greater than that of carbon. The Dutch chemiſts melted phoſphorus in carbonated hydrogen gas, but no change was produced; therefore the affinity of phoſphorus is inferior to that of carbon.

(R) See next Section.—His theory was, that carbonated hydrogen gas was compoſed of hydrogen, and azot, and carbon of azot, and carbonated hydrogen gas, which comes nearly to the ſame thing with regard to the elements of carbon. It is ſingular enough, that though Dr Auſtin would not allow the preſence of carbon in carbonated hydrogen gas, he actually decompoſed it by melting ſulphur in it: the ſulphur combined with the hydrogen gas, and a quantity of carbon was precipitated. This experiment he relates without making any remarks upon it, and ſeems indeed not to have paid any attention to it.

49 Diſcovery of azot.

It was diſcovered in 1772 by Dr Rutherford, now profeſſor of botany in the univerſity of Edinburgh (s). Scheele procured it by the above proceſs as early as 1776, and proved that it was a diſtinct fluid. Mr Lavoiſier afterwards proved the ſame thing, without any previous knowledge of Scheele's diſcoveries.

The air of the atmoſphere contains about ,73 parts of azotic gas; almoſt all the reſt is oxygen gas. The eaſieſt method of procuring azotic gas is to put ſome ſulphuret of potaſs into a glaſs veſſel filled with air, and accurately cloſed, and then to apply heat to the ſulphuret. All the oxygen is abſorbed almoſt inſtantly. This method was firſt pointed out by Morveau*.

* *Nicholſon's Journal*, i. 208.

Mr Kirwan examined the ſpecific gravity of azotic gas obtained by Scheele's proceſs; it was 0,00120: it is therefore ſomewhat lighter than the atmoſpheric air; it is to atmoſpheric air as 985 to 1000†.

† *On Phlogiſton.* § 1ſt.

50 Its properties

It tinges delicate blue colours ſlightly with green‡. It is exceedingly noxious to animals; if they are obliged to reſpire it, they drop down dead almoſt inſtantly (t). No combuſtible will burn in it. This is the reaſon that a candle is extinguiſhed in atmoſpherical air as ſoon as the oxygen near it is conſumed. Mr Goettling, indeed, publiſhed, in 1794, that phoſphorus ſhone, and was converted into phoſphoric acid, in pure azotic gas. Were this the caſe, it would not be true that no combuſtible burns in this gas; for the converſion of phoſphorus into an acid, and even its ſhining, is an actual though ſlow combuſtion. Mr Goettling's experiments were ſoon after repeated by Drs Scherer and Jaeger, who found that phoſphorus does not ſhine in azotic gas when it is perfectly pure; and that therefore the gas on which Mr Goettling's experiments were made had contained a mixture of oxygen gas, owing principally to its having been only confined by water. Theſe reſults were afterwards confirmed by Profeſſor Lampadius and Profeſſor Hildebrandt. It is therefore proved beyond a doubt, that phoſphorus does not burn in azotic gas, and that whenever it appears to do ſo, there is always ſome oxygen gas preſent §.

‡ *Fourcroy, Ann. de Chim.* i. 45.

§ *Nicholſon's Journal*, ii. 8.

Azotic gas is capable of diſſolving phoſphorus, as has been proved by the experiments of Fourcroy and Vauquelin.

It diſſolves alſo a little carbon: for azotic gas obtained from animal ſubſtances, which contain a great deal of azot, when confined long in jars, depoſites on the ſides of them a black matter which has the properties of carbon*.

* *Fourcroy, Ann. de Chim.* i. 45.

Theſe two ſolutions, the properties of which have not yet been accurately examined, are called *phoſphorated and carbonated azotic gas.*

51 Production of nitric acid.

Azotic gas is capable of combuſtion. Take a glaſs tube, the diameter of which is about the ſixth part of an inch; ſhut one of its ends with a cork, through the middle of which paſſes a ſmall wire with a ball of metal at each end. Fill the tube with mercury, and then plunge its open end into a baſon of that fluid. Throw up into the tube as much of a mixture, compoſed of 13 parts of azotic and 87 parts of oxygen gas, as will fill 3 inches. Through this gas make, by means of the wire in the cork, a number of electric exploſions paſs. The volume of gas gradually diminiſhes, and in its place there is found a quantity of *nitrous acid.* This acid, therefore, is compoſed of azot and oxygen: and theſe two ſubſtances are capable of combining, or, which is the ſame thing, azotic gas is capable of combuſtion in the temperature produced by electricity, which we know to be pretty high. The combuſtibility of azotic gas, and the nature of the product, was firſt diſcovered by Mr Cavendiſh, and communicated to the Royal Society on the 2d of June 1785 (u).

52 Attempts to decompoſe azot

The affinities of azot are ſtill unknown. It has never yet been decompounded, and muſt therefore, in the preſent ſtate of our knowledge, be conſidered as a ſimple ſubſtance. Dr Prieſtley, who obtained azotic gas at a very early period of his experiments, conſidered it as a compound of oxygen gas and phlogiſton, and for that reaſon gave it the name of *phlogiſticated air.* According to the theory of Stahl, which was then univerſally prevalent, he conſidered combuſtion as merely the ſeparation of phlogiſton from the burning body. To this theory he made the following addition: Phlogiſton is ſeparated during combuſtion by means of chemical affinity: *Air* (that is, *oxygen gas*) has a ſtrong affinity for phlogiſton: Its preſence is neceſſary during combuſtion, becauſe it combines with the phlogiſton as it ſeparates from the combuſtible; and it even contributes by its affinity to produce that ſeparation: The moment the air has combined with as much phlogiſton as it can receive, or, to uſe a chemical term, the moment it is *ſaturated* with phlogiſton, combuſtion neceſſarily ſtops, becauſe no more phlogiſton can leave the combuſ-

---

(s) See his theſis *De Aere Mephitico*, publiſhed in 1772.—" Sed aer ſalubris et purus reſpiratione animali non modo ex parte fit mephiticus ſed et *aliam indolis ſuæ mutationem inde patitur.* Poſtquam enim omnis aer mephiticus (carbonic acid gas) ex eo, ope lixivii cauſtici ſecretus et abductus fuerit, *qui tamen reſtat* nullo modo ſalubrior inde evadit; nam quamvis nullam ex aqua calcis præcipitationem faciat haud minus quam antea *et flammam et vitam extinguit.* Page 17.

" Aer qui per carbones ignitos folle adactus fuit, atque deinde ab omni aere mephitico *(carbonic acid gas)* expurgatus, malignus tamen adhuc reperitur et omnino ſimilis eſt ei qui reſpiratione inquinatur. Immo ab experimentis patet hanc ſolam eſſe aeris mutationem quæ inflammationi adſcribi poteſt. Si enim accenditur materies quælibet quæ ex phlogiſto et baſi fixa atque ſimplici conſtat, *aer inde natus ne minimam aeris mephitici quantitatem in ſe continere videtur.* Sic aer in quo ſulphur aut phoſphorus urinæ combuſtus fuit, licet maxime malignus, calcem tamen ex aqua minime præcipitat. Interdum quidem ſi ex phoſphoro natus fuerit, nubeculam aquæ calcis inducit ſed tenuiſſimam, nec aeri mephitico attribuendam, ſed potius acido illi quod in phoſphoro ineſt, et quod, ut experimenta docuerunt, hoc ſingulari dote pollet." Page 19.

(t) Hence the name *azot*, given it by the French chemiſts, which ſignifies *deſtructive to life*, from α and ζων.

(u) It is remarkable enough, that the acidity of nitric acid was aſcribed by Mayow, in 1674, to the preſence of oxygen. *Indoles cauſtica ſpiritus nitri* (ſays he) *a particulis ejus igneo-aereis provenit.* Tract. p. 19.

combuſtible (v): Air ſaturated with phlogiſton is azotic gas. This was a very ingenious theory, and, when Dr Prieſtley publiſhed it, exceedingly plauſible. A great number of the moſt eminent chemiſts accordingly embraced it: But it was ſoon after diſcovered, that during combuſtion the quantity of air, inſtead of increaſing, as it ought to have done, had phlogiſton been added to it, actually diminiſhed both in volume and weight. There was no proof, therefore, that during combuſtion any ſubſtance whatever combined with air, but rather the contrary. It was diſcovered alſo, that a quantity of air combined with the burning ſubſtance during combuſtion, as we have ſeen was the caſe with ſulphur, phoſphorus, carbon, and hydrogen; and that this air had the properties of oxygen gas. Theſe diſcoveries entirely overthrew the evidence on which Dr Prieſtley's theory was founded: accordingly, as no attempt to decompound azot has ſucceeded, it has been given up by almoſt every chemiſt except Dr Prieſtley himſelf. Atmoſpheric air, as Scheele firſt proved, is compoſed of about 27 parts of oxygen and 73 of azotic gas. During combuſtion, the oxygen is abſtracted and the azotic gas remains behind.

53 Unſucceſsful.

La Metherie made an attempt to prove that azot was compoſed of oxygen and carbon (w). He took a bit of burning charcoal, extinguiſhed it in mercury, and then plunged it while hot into oxygen gas. On being plunged into water, one fourth of the gas was diſengaged, and part of it was found to conſiſt of azotic gas. From this he concluded that he had formed azotic gas by combining oxygen and carbon: But it was proved by Mr Lavoiſier, beyond the poſſibility of doubt, that oxygen and carbon form carbonic acid gas. They cannot then certainly form azot; for two contradictory facts cannot both be true. There muſt then have been ſomething overlooked in the experiment. Indeed the experiment itſelf does not warrant the concluſion which De La Metherie drew from it. He did not aſcertain whether the weight of the charcoal was diminiſhed; and, beſides, there was azot mixed with the oxygen gas which he employed, as he himſelf has informed us: And how was it poſſible for him to admit the charcoal into water without, at the ſame time, admitting ſome atmoſpherical air?

We have now deſcribed all the combuſtibles which are at preſent reckoned ſimple, except the metals. We have found, that during combuſtion all of them combine with oxygen; that no part of them is diſengaged, no part of them loſt: we have therefore concluded, that the combuſtion of theſe ſubſtances is nothing elſe but the act of their uniting with oxygen. We have ſeen, however, that none of them, except phoſphorus, was capable of uniting with oxygen at the common temperature of the atmoſphere; that, in order to produce the union, heat was neceſſary, and that the degree of this heat was different for each. Hydrogen required a red heat, and azot a ſtill greater. We have ſeen, too, that during theſe combinations a quantity of heat and light eſcaped. Now, why is heat neceſſary for theſe combinations? and whence come the heat and the light which we perceive during the combuſtion of theſe bodies? Theſe queſtions are of the higheſt importance, and can only be anſwered by a particular inveſtigation of the nature and properties of heat and light. This inveſtigation we ſhall attempt, as ſoon as we have deſcribed the *metals* and *earths*, which form the ſubject of the two following chapters.

Chap. III. *Of* Metals.

54 Properties of metals.

Metals may be conſidered as the great inſtruments of all our improvements: Without them, many of the arts and ſciences could hardly have exiſted. So ſenſible were the ancients of their great importance, that they raiſed thoſe perſons who firſt diſcovered the art of working them to the rank of deities. In chemiſtry, they have always filled a conſpicuous ſtation: at one period the whole ſcience was confined to them; and it may be ſaid to have owed its very exiſtence to a rage for making and tranſmuting metals.

55 Luſtre.

1. One of the moſt conſpicuous properties of the metals is a particular brilliancy which they poſſeſs, and which has been called the *metallic luſtre.* This proceeds from their reflecting much more light than any other body; a property which ſeems to depend partly on the cloſeneſs of their texture. This renders them peculiarly proper for mirrors, of which they always form the baſis.

56 Opacity.

2. They are abſolutely opaque, or impervious to light, even after they have been reduced to very thin plates. Silver leaf, for inſtance, $\frac{1}{160000}$ of an inch thick, does not permit the ſmalleſt ray of light to paſs throught it. Gold, however, may be rendered tranſparent; for gold leaf, $\frac{1}{180000}$ of an inch thick, tranſmits light of a lively green colour*. And it is not improbable that all the other metals, as Sir Iſaac Newton ſuppoſed, would become tranſparent, if they could be reduced to a ſufficient degree of thinneſs. It is to this opacity that a part of the excellence of the metals, as mirrors, is owing; their brilliancy alone would not qualify them for that purpoſe.

* *Nicholſon's Notes on Fourcroy.*

57 Fuſibility.

3. They may be melted by the application of heat, and even then ſtill retain their opacity. This property enables us to caſt them in moulds, and then to give them any ſhape we pleaſe. In this manner many elegant iron utenſils are formed.

58 Gravity.

4. Their ſpecific gravity is greater than that of any other body hitherto diſcovered.

5. They are better conductors of electricity than any other body.

59 Malleability.

6. But one of their moſt important properties is *malleability;* by which is meant the capacity of being extended and flattened when ſtruck with a hammer. This property enables us to give the metallic body any form we think proper, and thus renders it eaſy for us to

---

(v) This ingenious theory was firſt conceived by Dr Rutherford, as appears from the following paſſage of his theſis. "Ex iiſdem etiam deducere licet quod aer ille malignus (azotic gas) componitur ex *aere atmoſpherico cum phlogiſto unito et quaſi ſaturato.* Atque idem confirmatur eo, quod aer qui metallorum calcinationi jam inſerviit, et phlogiſton ab iis abripuit, ejuſdem plane ſit indolis." *De aere Mephitico,* p. 20.

(w) Or rather of *hydrogen,* for he conſidered carbon itſelf as a compound.

to convert them into the various inſtruments for which we have occaſion. All metals do not poſſeſs this property; but it is remarkable that almoſt all thoſe which were known to the ancients have it. Heat increaſes this property conſiderably.

60 Ductility.

7. Another property which is alſo wanting in many of the metals, is *ductility*; by which we mean the capacity of being drawn out into wire by being forced through holes of various diameters. This property has by ſome been called *tenacity*; and it doubtleſs depends upon the tenacity of the various metals.

61 Calcination

8. When expoſed to the action of heat and air, moſt of the metals loſe their luſtre, and are converted into earthy-like powders of different colours and properties, according to the metal and the degree of heat employed. Several of the metals even take fire when expoſed to a ſtrong enough heat; and after combuſtion the reſiduum is found to be the very ſame earthy-like ſubſtance. If any of theſe *calces*, as they are called, be mixed with charcoal-powder, and expoſed to a ſtrong heat in a proper veſſel, it is changed again to the metal from which it was produced. From theſe phenomena Stahl concluded, that metals were compoſed of *earth* and *phlogiſton*. He was of opinion that there was only one primitive earth, which not only formed the baſis of all thoſe ſubſtances known by the name of earths, but the baſis alſo of all the metals. He found, however, that it was impoſſible to combine any mere earth with phlogiſton; and concluded, therefore, with Becher, that there was another principle beſides earth and phlogiſton, which entered into the compoſition of the metals. To this principle Becher gave the name of *mercurial earth*, becauſe, according to him, it exiſted moſt abundantly in *mercury*. This principle was ſuppoſed to be very volatile, and therefore to fly off during calcination: and ſome chemiſts even affirmed that it might be obtained in the ſoot of thoſe chimneys under which metals have been calcined.

62 Stahl's theory of the compoſition of metals

63 Defective.

A ſtriking defect was ſoon perceived in this theory. The original metal may again be produced by heating its calx along with ſome other ſubſtance which contains phlogiſton: now, if the mercurial earth flies off during combuſtion, it cannot be neceſſary for the formation of complete metals, for they may be produced without it: if, on the contrary, it adheres always to the calx, there is no proof of its exiſtence at all. Chemiſts, in conſequence of theſe obſervations, found themſelves obliged to diſcard the mercurial principle altogether, and to conclude that metals were compoſed of earth only, united to phlogiſton. But if this be really the caſe, how comes it that theſe two ſubſtances cannot be united by art? Henkel was the firſt who attempted to ſolve this difficulty. According to him, earth and phlogiſton are ſubſtances of ſo oppoſite a nature, that it is exceedingly difficult, or rather it has been hitherto impoſſible, for us to commence their union; but after it has been once begun by nature, it is an eaſy matter to complete it. No calcination has hitherto deprived the metals of all their phlogiſton; ſome ſtill adheres to the calces. It is this remainder of phlogiſton which renders it ſo eaſy to reſtore them to their metallic ſtate. Were the calcination to be continued long enough to deprive them altogether of phlogiſton, they would be reduced to the ſtate of other earths; and then it would be equally difficult to convert them into metals, or, to uſe a chemical term, to *reduce* them. Accordingly we find that the more completely a calx has been calcined, the more difficult is its reduction. This explanation was favourably received. But after the characteriſtic properties of the various *earths* had been aſcertained, and the calces of metals were accurately examined, it was perceived that the calces differed in many particulars from all the *earths*, and from one another. To call them all the ſame ſubſtance, then, was to go much farther than either experiment or obſervation would warrant, or, rather, it was to declare open war againſt both experiment and obſervation. It was concluded, therefore, that each of the metals was compoſed of a peculiar *earthy ſubſtance* combined with phlogiſton. For this great improvement in accuracy, chemiſtry is chiefly indebted to Bergman.

64 Improved by Henkel.

65 Farther improved.

66 Still imperfect.

But there were ſeveral phenomena of calcination which had all this time been unaccountably overlooked. The calces are all conſiderably heavier than the metals from which they are obtained. Boyle had obſerved this circumſtance, and had aſcribed it to a quantity of *fire* which, according to him, became fixed in the metal during the proceſs*. But ſucceeding chemiſts paid little attention to it, or to the action of air, till Mr Lavoiſier publiſhed his celebrated experiments on calcination, in the Memoirs of the Paris Academy for 1774. He put eight ounces of *tin* into a large glaſs retort, the point of which was drawn out into a very ſlender tube to admit of eaſy fuſion. This retort was heated ſlowly till the tin began to melt, and then ſealed hermetically. This heat was applied to expel ſome of the air from the retort: without which precaution it would have expanded and burſt the veſſel. The retort, which was capable of containing 250 cubic inches, was then weighed accurately, and placed again upon the fire. The tin ſoon melted, and a pellicle formed on its top, which was gradually converted into a grey powder, that ſunk by a little agitation to the bottom of the liquid metal: in ſhort, the tin was partly converted into a *calx*. This proceſs went on for three hours; after which the calcination ſtopped, and no farther change could be produced on the metal. The retort was then taken from the fire, and found to be preciſely of the ſame weight as before the operation. It is evident, then, that no new ſubſtance had been introduced, and that therefore the increaſed weight of calces cannot, as Boyle ſuppoſed, be owing to the fixation of fire (x).

67 Refuted by Lavoiſier.

When the point of the retort was broken, the air ruſhed in with a hiſſing noiſe, and the weight of the retort was increaſed by ten grains. Ten grains of air, therefore, muſt have entered, and, conſequently, preciſely that quantity muſt have diſappeared during the calcination. The metal and its calx being weighed, were found juſt ten grains heavier than before: therefore, the air which diſappeared was abſorbed by the metal: and as that part of the tin which remained in a metallic ſtate was unchanged, it is evident that this air

---

* *Fire and flame weighed.*

(x) This experiment had been performed by Boyle with the ſame ſucceſs. He had drawn a wrong concluſion from not attending to the ſtate of the air of the veſſel. *Shaw's Boyle*, II. 394.

air muſt have united with the calx. The increaſe of weight, then, which metals experience during calcination, is owing to their uniting with air (y). But all the air in the veſſel was not abſorbed, and yet the calcination would not go on. It is not the whole, then, but ſome particular part of the air which unites with the calces of metals. By the ſubſequent diſcoveries of Prieſtley, Scheele, and Lavoiſier himſelf, it was aſcertained, that the reſiduum of the air, after calcination has been performed in it, is always pure azotic gas: It follows, therefore, that it is only the *oxygen* which combines with calces; and that a metallic calx is not a ſimple ſubſtance, but a compound. Mr Lavoiſier obſerved, that the weight of the calx was always equal to that of the metal employed, together with that of the oxygen abſorbed. It became a queſtion then, Whether metals, during calcination, loſt any ſubſtance, and conſequently, whether they contained any phlogiſton? Mr Lavoiſier accordingly propoſed this queſtion; and he anſwered it himſelf by a number of accurate experiments and ingenious obſervations. Metals cannot be calcined excepting in contact with oxygen, and in proportion as they combine with it. Conſequently they not only abſorb oxygen during their calcination, but that abſorption is abſolutely neceſſary to their aſſuming the form of a calx. If the calx of mercury be heated in a retort, to which a pneumatic apparatus is attached, to the temperature of 1200°, it is converted into pure mercury; and, at the ſame time, a quantity of oxygen ſeparates from it in a gaſeous form. As this proceſs was performed in a cloſe veſſel, no new ſubſtance could enter: The calx of mercury, then, was reduced to a metallic ſtate without phlogiſton. The weights of the metal and the oxygen gas are together juſt equal to that of the calx; the calx of mercury, therefore, muſt be compoſed of mercury and oxygen; conſequently there is no reaſon whatever to ſuppoſe that mercury contains phlogiſton. Its calcination is merely the act of uniting it with oxygen (z). The calces of lead, ſilver, and gold, may be decompoſed exactly in the ſame manner; and Mr Van Marum, by means of his great electrical machine, decompoſed alſo thoſe of tin, zinc, and antimony, and reſolved them into their reſpective metals and oxygen *. The ſame concluſions, therefore, muſt be drawn with reſpect to theſe metals. All the metallic calces may be decompoſed by preſenting to them ſubſtances which have a greater affinity for oxygen than they have. This is the reaſon that charcoal-powder is ſo efficacious in reducing them: and if they are mixed with it, and heated in a proper veſſel, furniſhed with a pneumatic apparatus, it will be eaſy to diſcover what paſſes. During the reduction, a great deal of carbonic acid gas comes over, which, together with the metal, is equal to the weight of the calx and the charcoal: it muſt therefore contain all the ingredients; and we know that carbonic acid gas is compoſed of carbon and oxygen. During the proceſs, then, the oxygen of the calx combined with charcoal and the metal remained behind. It cannot be doubted, therefore, that all the metallic calces are compoſed of the entire metals combined with oxygen; and that calcination, like combuſtion, is merely the act of this combination. All metals, then, in the preſent ſtate of chemiſtry, muſt be conſidered as ſimple ſubſtances; for they have never yet been decompounded.

68 Oxide and oxidation, what.

The words *calx* and *calcination* are evidently improper, as they convey falſe ideas; we ſhall therefore afterwards employ, inſtead of them, the words *oxide* and *oxidation*, which were invented by the French chemiſts. A metallic *oxide* ſignifies a metal united with oxygen; and *oxidation* implies the act of that union.

Metals are capable of uniting with oxygen in different proportions, and, conſequently, of forming each of them different oxides. Theſe are diſtinguiſhed from one another by their colour. One of the oxides of iron, for inſtance, is of a green colour; it is therefore called the *green oxide;* the other, which is brown, is called the *brown oxide.*

69 Number of metals.

The metals at preſent amount to 21; only 11 of which were known before the year 1730. Their names are gold, ſilver, platinum, mercury, copper, iron, tin, lead, zinc, antimony, biſmuth, arſenic, cobalt, nickel, mangancſe, tungſten, molybdenum, uranium, tellurium, titanium, chromum.

The firſt eight of theſe were formerly called *metals* by way of eminence, becauſe they are poſſeſſed either of malleability or ductility, or of both properties together; the reſt were called *ſemimetals*, becauſe they are brittle. But this diſtinction is now pretty generally laid aſide; and, as Bergman obſerves, it ought to be ſo altogether, as it is founded on a falſe hypotheſis, and conveys very erroneous ideas to the mind. The firſt

---

* *Jour. de Phyſ.* 1785.

(y) It is remarkable that John Rey, a phyſician of Perigord, had aſcribed it to this very cauſe as far back as the year 1630: But his writings had excited little attention, and had ſunk into oblivion, till after his opinion had been inconteſtibly proved by Lavoiſier. Mayow alſo, in the year 1674, aſcribed the increaſe of weight to the combination of metals with oxygen. *Quippe vix concipi poteſt* (ſays he), *unde augmentum illud antimonii (calcinati) niſi a particulis nitro-aereis igneiſque inter calcinandum* FIXIS *procedat.* Tract. p. 28. *Plane ut antimonii fixatio non tam a ſulphuris ejus externi aſſumptione, quam particulis nitro-aereis, quibus flamma nitri abundat* EI INFIXIS *provenire videatur.* Ibid. p. 29.

(z) This experiment was performed by Mr Bayen in 1774. This philoſopher perceived, earlier than Lavoiſier, that all metals did not contain phlogiſton. " Ces experiences (ſays he) vont nous detromper. Je ne tiendrai plus le langage des diſciples de Stahl, qui ſeront forcés de reſtreindre la doctrine ſur le phlogiſtique, ou d'avouer que les precipités mercurials, dont je parle, ne ſont pas des chaux metalliques, ou enfin qu'il y a des chaux qui peuvent ſe reduire ſans le concours du phlogiſtique. Les experiences que j'ai faites me force de conclure que dans la chaux mercuriale dont je parle, le mercure doit ſon *etat calcoire, non à la perte du phlogiſtique* qu'il n'a pas eſſuyée, *mais a ſa combinaiſon intime avec le fluide elaſtique,* dont le poids ajouté a celui du mercure eſt la ſeconde cauſe de l'augmentation de peſanteur qu'on obſerve dans les precipités que j'ai ſoumis a l'examen." *Jour. de Phyſ.* 1774, pages 288, 295. It was in conſequence of hearing Bayen's paper read that Lavoiſier was induced to turn his attention to the ſubject.

four metals were formerly called *noble* or *perfect metals*, becauſe their oxides are reducible by the mere application of heat; the next four were *imperfect metals*, becauſe their oxides were thought not reducible without the addition of ſome combuſtible ſubſtance; but this diſtinction alſo is now very properly exploded.

Sect. I. *Of Gold.*

70 Properties of gold.

Gold ſeems to have been known from the very beginning of the world. Its properties and its ſcarcity have rendered it more valuable than any other metal.

It is of an orange red, or reddiſh yellow colour, and has no perceptible taſte or ſmell.

No other ſubſtance can be compared with it in ductility and malleability. It may be beaten out into leaves ſo thin that one grain of gold will cover $56\frac{3}{4}$ ſquare inches. Theſe leaves are only $\frac{1}{282000}$ of an inch thick. But the gold leaf with which ſilver wire is covered has only $\frac{1}{12}$ of that thickneſs. An ounce of gold, upon ſilver wire, is capable of being extended more than 1300 miles in length.

Its tenacity is ſuch, that a gold wire $\frac{1}{10}$ of an inch in diameter is capable of ſupporting a weight of 500 pounds without breaking *.

* Macquer's Dict.

Its hardneſs is 6 (A); its ſpecific gravity 19,3. It melts at 32° of Wedgewood's pyrometer (B). When melted, it aſſumes a bright bluiſh green colour. It expands in the act of fuſion, and conſequently contracts while becoming ſolid more than moſt metals; a circumſtance which renders it leſs proper for caſting into moulds.

It requires a very violent heat to volatilize it; it is therefore, to uſe a chemical term, exceedingly *fixed.* Boyle and Kunkel kept it for ſome months in a glaſshouſe furnace, and yet it underwent no change: nor did it loſe any perceptible weight, after being expoſed for ſome hours to the utmoſt heat of Mr Parker's lens †. Mr Lavoiſier, however, obſerved, that a piece of ſilver, held over gold melted by a fire blown by oxygen gas, which produces a much greater heat than common air, was ſenſibly *gilt:* Part of the metal, then, muſt have been volatilized.

† Kirwan's Miner. i. 92.

After fuſion, it is capable of aſſuming a cryſtalline form. Tillet and Mongez obtained it in ſhort quadrangular pyramidal cryſtals.

71 Oxidation of gold.

It is capable of combining with oxygen, and forming an *oxide of gold.* There are two methods of producing this combination, *the application of heat*, and *ſolution in acids.* When it is expoſed to a very violent heat in contact with air, gold abſorbs oxygen. But the temperature muſt be very high; ſo high, indeed, that hardly any certain method of oxidating gold by heat is known, except by electricity. When the electric exploſion is tranſmitted through gold leaf placed between two plates of glaſs, or when a ſtrong charge is made to fall on a gilded ſurface—in both caſes the metal is oxidated, and aſſumes a purple colour. It has been ſaid alſo, that the ſame effect has been produced by a very violent fire; but few of the inſtances which have been adduced are well authenticated.

The other method of oxidating gold is much eaſier. For this purpoſe, equal parts of nitric and muriatic acids are mixed together (C) and poured upon gold; an effervеſcence takes place, the gold is gradually diſſolved, and the liquid aſſumes a yellow colour. It is eaſy to ſee in what manner this ſolution is produced. No metal is ſoluble in acids till it has been reduced to the ſtate of an oxide. There is a ſtrong affinity between the oxide of gold and muriatic acid. The nitric acid furniſhes oxygen to the gold, and the muriatic acid diſſolves the oxide as it forms. When nitric acid is deprived of the greater part of its oxygen, it aſſumes a gaſeous form, and is then called *nitrous gas.* It is the emiſſion of this gas which cauſes the effervеſcence. The oxide of gold may be precipitated from the nitro-muriatic acid by pouring in a little potaſs diſſolved in water, or, which is much better, a little lime; both of which have a ſtronger affinity for muriatic acid than the oxide has. This oxide is of a yellow colour.

It is probable that gold is capable of two different degrees of oxidation, and of forming two different oxides, *the yellow* and *the purple:* But neither the quantity of oxygen contained in theſe oxides, nor the differences between them, have been accurately aſcertained. The oxides of gold may be decompoſed in cloſe veſſels by the application of heat. The gold remains fixed, and the oxygen aſſumes the gaſeous form. They may be decompoſed, too, by all the ſubſtances which have a ſtronger affinity with oxygen than gold has. The affinities of the oxides of gold, according to Bergman *, are as follows:

* Bergman on Elective Attractions, Opuſc. i. 3.

Muriatic acid,
Nitro-muriatic,
Nitric,
Sulphuric,
Arſenic,
Fluoric,
Tartarous,

(A) We have borrowed from Mr Kirwan the method of denoting the different degrees of hardneſs by figures, which we think a great improvement. Theſe figures will be underſtood by Mr Kirwan's own explanation, which we here ſubjoin.

3, Denotes the hardneſs of chalk.
4, A ſuperior hardneſs, but yet what yields to the nail.
5, What will not yield to the nail, but eaſily, and without grittineſs, to the knife.
6, That which yields more difficultly to the knife.
7, That which ſcarcely yields to the knife.
8, That which cannot be ſcraped by a knife, but does not give fire with ſteel.
9, That which gives a few feeble ſparks with ſteel.
10, That which gives plentiful lively ſparks. *Kirwan's Mineralogy*, I. 38.

(B) According to the calculation of the Dijon academicians, it melts at 1298° Fahr.; according to Bergman, at 1301°.

(C) This mixture, from its property of diſſolving gold, was formerly called *aqua regia* (for gold, among the alchymiſts, was the king of metals); it is now called *nitro-muriatic acid.*

Tartarous,
Phoſphoric,
Sebacic,
Pruſſic,
Fixed alkali (D),
Ammonia.

Gold is not changed either by air or water. It does not ſeem capable of combining either with ſulphur or carbon. Mr Pelletier combined it with phoſphorus, by melting together in a crucible half an ounce of gold and an ounce of phoſphoric glaſs (E), ſurrounded with charcoal. The *phoſphuret of gold* thus produced was brittle, whiter than gold, and had a cryſtallized appearance. It was compoſed of 23 parts of gold and one of phoſphorus *. He formed the ſame compound by dropping ſmall pieces of phoſphorus into gold in fuſion †.

72 Phoſphuret of gold.

* *Ann. de Chim.* i. 71.

† *Ibid.* xiii. 104.

Gold is alſo capable of combining with moſt of the metals. Its affinities are placed, by Bergman, in the following order:

Mercury,
Copper,
Silver,
Lead,
Biſmuth,
Tin,
Antimony,
Iron,
Platinum,
Zinc,
Nickel,
Arſenic,
Cobalt,
Mangneſe;
Phoſphorus?
Sulphurets of alkalies.

Sect. II. *Of Silver.*

73 Properties of ſilver.

Silver appears to have been known almoſt as early as gold. It is a metal of a ſhining white colour, without either taſte or ſmell.

It is the moſt malleable and ductile of all metals except gold, and perhaps platinum. It can be reduced to leaves about $\frac{1}{100000}$ of an inch thick, and drawn into wire much finer than a human hair.

Its tenacity is ſuch, that a wire of ſilver, $\frac{1}{10}$th of an inch in diameter, is capable of ſuſtaining 270 pounds without breaking ‡.

Its hardneſs is 6,5 §. Its ſpecific gravity, before hammering, is 10,474; after hammering, 10,510 ||: for it is remarkable that the ſpecific gravity of almoſt all the metals is increaſed by hammering.

‡ *Macquer's Dict.*

§ *Kirwan.*

|| *Briſſon.*

It continues melted at 28° Wedgewood (F), but requires a greater heat to bring it to fuſion ¶.

¶ *Kirwan's Mineral.* ii. 107.

The experiments of the French academicians have proved that it may be volatilized, but that it requires a very violent heat.

When cooled ſlowly, it aſſumes a cryſtalline form. Tillet and Mongez obtained it in quadrangular pyramidal cryſtals, both inſulated and in groups.

74 Oxides of ſilver.

Silver may be combined with oxygen, and converted into an oxide by expoſure to a very violent heat. By this method Junker partly converted it into a *glaſs*; and Macquer, by expoſing it 20 times ſucceſſively to the heat of a porcelain furnace, obtained a *glaſs* (G) of an olive green colour *. The oxide of ſilver may alſo be formed by diſſolving the metal in an acid, and precipitating it from its ſolution by potaſs, lime, &c.: for, during its ſolution, the metal becomes oxidated. Little is known at preſent concerning the oxides of ſilver, nor whether there be more than two, the *black* and the *blue*. From the experiments of Wenzel and Bergman, it follows, that one oxide of ſilver is compoſed of about 90 parts of metal and 10 of oxygen †. The affinities of the oxides, according to Bergman, are as follows:

* *Macquer's Dict.*

† *Kirwan's Miner.* ii. 493.

Muriatic acid,
Sebacic,
Oxalic,
Sulphuric,
Saccholactic,
Phoſphoric,
Sulphurous,
Nitric,
Arſenic,
Fluoric,
Tartaric,
Citric,
Formic,
Lactic,
Acetous,
Succinic,
Pruſſic,
Carbonic,
Ammonia.

75 Sulphuret of ſilver.

When ſilver is melted with ſulphur in a low red heat, it combines with it and forms *ſulphuret of ſilver*. It is very difficult to determine the proportion of the ingredients which enter into the compoſition of this ſubſtance, becauſe there is an affinity between ſilver and its ſulphuret, which diſpoſes them to combine together. The greateſt quantity of ſulphur which a given quantity of ſilver is capable of taking up is, according to Wenzel, $\frac{13}{150}$ ‡. Sulphuret of ſilver is of a black or very deep violet colour, brittle, and much more fuſible than ſilver. If ſufficient heat be applied, the ſulphur is volatilized, and the metal remains behind in a ſtate of purity.

‡ *Ibid.* 492.

76 Phoſphuret of ſilver.

If one ounce of ſilver, one ounce of phoſphoric glaſs, and two drams of charcoal, be mixed together, and heated in a crucible, *phoſphuret of ſilver* is formed. It is

---

(D) Have the alkalies any affinity for the yellow oxide? Is not their affinity confined to the purple oxide alone? And does not this oxide act as an acid?

(E) Phoſphoric acid evaporated to dryneſs, and then fuſed.

(F) According to the Dijon academicians, it melts at 1044° Fahr.; according to Bergman, at 1000°.

(G) Metallic oxides, after fuſion, are called *glaſs*, becauſe they acquire a good deal of reſemblance, in ſome particulars, to common glaſs.

is of a white colour, and appears granulated, or as it were cryſtallized. It breaks under the hammer, but may be cut with a knife. It is compoſed of four parts of ſilver and one of phoſphorus. Heat decompoſes it by ſeparating the phoſphorus *. Pelletier has obſerved, that ſilver in fuſion is capable of combining with more phoſphorus than ſolid ſilver: for when phoſphuret of ſilver is formed by projecting phoſphorus into melted ſilver, after the crucible is taken from the fire a quantity of phoſphorus is emitted the moment the metal congeals †.

* *Pelletier, Ann de Chim.* i. 73.

† *Ibid.* xiii. 110.

Silver does not ſeem capable of combining with carbon.

77
Alloys of ſilver.

Silver is capable of combining with gold, and forming an *alloy* (H) compoſed of one part of ſilver and five of gold. That this is the proportion of the ingredients, was diſcovered by Homberg. He kept equal parts of gold and ſilver in gentle fuſion for a quarter of an hour, and found, on breaking the crucible, two maſſes; the uppermoſt of which was pure ſilver, the undermoſt the whole gold combined with $\frac{1}{6}$th of ſilver. Silver, however, may be mixed with gold in almoſt any proportion. But there is a great difference between the mixture of two ſubſtances and their chemical combination. Metals which melt nearly at the ſame temperature may be mixed from that very circumſtance in any proportion; but ſubſtances can combine chemically only in one proportion. This obſervation, which is certainly of importance, was firſt made, as far as we know, by Mr Keir ‡. The alloy of ſilver and gold is of a greeniſh colour; but its properties have not yet been accurately examined.

‡ *Tranſlation of Macquer's Dict.* art. *Alloy.*

78
Becomes tarniſhed by expoſure.

Silver is not effected by water, nor by expoſure to the air; but Mr Prouſt has remarked, that when long expoſed in places frequented by men, as in churches, theatres, &c. it acquires a covering of a violet colour, which deprives it of its luſtre and malleability. This covering, which forms a thin layer, can only be detached from the ſilver by bending it, or breaking it in pieces with a hammer It was examined by Mr Prouſt, and found to be *ſulphuret of ſilver*. He accounts for this tranſition of the ſilver into a *ſulphuret*, by ſuppoſing that a quantity of ſulphur is conſtantly formed and exhaled by living bodies *.

* *Ann. de Chim.* i. 142.

79
Its affinities.

The affinities of ſilver, according to Bergman, are as follows:

Lead,
Copper,
Mercury,
Biſmuth,
Tin,
Gold,
Antimony,
Iron,
Mangancſe,
Zinc,
Arſenic,
Nickel,
Platinum,
Sulphurets of alkalies,
Sulphur,
Phoſphorus.

SECT. III. *Of Platinum.*

THE metals hitherto deſcribed have been known to mankind from the earlieſt ages, and have been always in high eſtimation on account of their beauty, ſcarcity, ductility, and indeſtructibility. But platinum, though perhaps inferior to them in none of theſe qualities, and certainly far ſuperior in others, was unknown, as a diſtinct metal, before the year 1752 (I).

80
Diſcovery of platinum.

It has been found only in America, in Choco in Peru, and in the mine of Santa Fe, near Carthagena. The workmen of theſe mines muſt no doubt have been early acquainted with it; but they ſeem to have paid very little attention to it. It was unknown in Europe till Mr Wood brought ſome of it from Jamaica in 1741. Soon after it was noticed by Don Antonio de Ulloa, a Spaniſh mathematician, who had accompanied the French academicians to Peru in their voyage to meaſure a degree of the meridian. In the year 1752 it was examined by Scheffer of Sweden, and diſcovered by him to be a new metal, approaching very much to the nature of gold, and therefore called by him *aurum album*,

---

(H) Metals combined together are called *alloys* or *allays*.

(I) Father Cortinovis, indeed, has attempted to prove that this metal was the *electrum* of the ancients. - See the *Chemical Annals of Brugnatelli*, 1790. That the electrum of the ancients was a metal, and a very valuable one, is evident from many of the ancient writers, particularly Homer. The following lines of Claudian are alone ſufficient to prove it:

Atria cinxit ebur, trabibus ſolidatur ahenis
Culmen et in celſas ſurgunt electra *columnas.* L. I. v. 164.

Pliny gives us an account of it in his Natural Hiſtory. He informs us that it was a compoſition of ſilver and gold; and that by candle-light it ſhone with more ſplendor than ſilver. The ancients made cups, ſtatues, and columns of it. Now, had it been our platinum, is it not rather extraordinary that no traces of a metal, which muſt have been pretty abundant, ſhould be perceptible in any part of the old continent?

As the paſſage of Pliny contains the fulleſt account of electrum to be found in any ancient author, we ſhall give it in his own words, that every one may have it in his power to judge whether or not the deſcription will apply to the platinum of the moderns.

"Omni auro ineſt argentum vario pondere.—Ubicunque quinta argenti portio eſt, *electrum* vocatur. Scrobes eæ reperiuntur in Canalienſi. Fit et cura electrum argento addito. Quod ſi quintam portionem exceſſit, incudibus non reſtitit. Et electro auctoritas, Homero teſte, qui Menelai regiam auro, electro, argento, ebore fulgere tradit. Minervæ templum habet Lindos inſulæ Rhodiorum in quo Helena ſacravit calicem ex electro.—Electri natura eſt ad lucernarum lumina clarius argento ſplendere. Quod eſt nativum, et venena deprehendit. Namque diſcurrunt in calicibus arcus cœleſtibus ſimiles cum igneo ſtridore, et geminaratione prædicunt."—*Lib.* xxxiii. *cap.* iv.

album, white gold. Soon after it was examined by Lewis, Margraf, Macquer and Beaumé, Morveau, Bergman, and many other illuſtrious chemiſts.

81
Its properties.

Platinum, when pure, is of a white colour like ſilver, but not ſo bright (κ). It has no taſte nor ſmell.

It is both ductile and malleable; but the preciſe degree has not yet been aſcertained. It has been drawn into a wire of $\frac{1}{1910}$ of an inch in diameter. This wire admitted of being flattened, and had more ſtrength than a wire of ſilver or gold of the ſame ſize *.

* *Withering*

It is exceedingly difficult to fuſe it. Macquer and Beaumé ſucceeded by means of a powerful burning-glaſs. It melts more eaſily when mixed with other ſubſtances. Its fixity is ſtill greater than its infuſibility. If the ſtrongeſt fires cannot melt it, much leſs can they volatilize it.

Its hardneſs is 7,5 †. Its ſpecific gravity, after being hammered, is 23,000; ſo that it is by far the heavieſt body known.

† *Kirwan's Miner.* ii. 103.

Some of the experiments which have been made on platinum ſeem to prove that it may be oxidated by the application of a violent heat. The oxide of this metal may be eaſily formed by diſſolving platinum in nitro-muriatic acid, and precipitating it by means of an earth or potaſs. The various oxides of platinum have never yet been examined with accuracy. The one at preſent beſt known poſſeſſes, as Mr Berthollet has proved, the properties of an acid.

The *ſulphuret of platinum* is unknown.

82
Phoſphuret of platinum.

By mixing together an ounce of platinum, an ounce of phoſphoric glaſs, and a dram of powdered charcoal, and applying a heat of about 32° Wedgewood, Mr Pelletier formed a *phoſphuret of platinum* weighing more than an ounce. It was partly in the form of a button, and partly in cubic cryſtals. It was covered above by a blackiſh glaſs. It was of a ſilver white colour, very brittle, and hard enough to ſtrike fire with ſteel. When expoſed to a fire ſtrong enough to melt it, the phoſphorus was diſengaged, and burnt on the ſurface ‡.

‡ *Ann. de Chim.* i. 71.

He found alſo, that when phoſphorus was projected on red hot platinum, the metal inſtantly fuſed and formed a phoſphuret. As heat expels the phoſphorus, Mr Pelletier has propoſed this as an eaſy method of purifying platinum §.

§ *Ibid.* xiii. 105.

Platinum does not ſeem capable of combining with carbon.

It is not in the leaſt affected by the action of water or air.

83
Alloys of platinum.

1. When gold and platinum are expoſed to a ſtrong heat, they combine, and form an alloy of a much whiter colour, but nearly as ductile as gold. The proportions of the ingredients are not known. When $\frac{1}{47}$ only of the alloy is platinum, the gold is ſcarcely altered in colour.

2. Whether ſilver and platinum combine chemically has not yet been properly aſcertained. When fuſed together (for which a very ſtrong heat is neceſſary), they form a mixture, not ſo ductile as ſilver, but harder and leſs white. The two metals are ſeparated by keeping them for ſome time in the ſtate of fuſion; the platinum ſinking to the bottom from its weight. This circumſtance would induce one to ſuppoſe that there is very little affinity between them.

Sect. IV. *Of Mercury.*

Mercury, called alſo *quickſilver*, was known to the ancients, and ſeems to have been employed by them in gilding.

84
Properties of mercury.

It is of a white colour, exactly like that of poliſhed ſilver. It has no taſte, but acquires a ſlight odour when rubbed between the hands.

Its ſpecific gravity is 13,568 *.

* *Briſſon.*

It differs from all other metals in always exiſting, at the common temperature of the atmoſphere, in a ſtate of fluidity. It freezes at -39° †; or, which is the ſame thing, it ceaſes to be a ſolid, and melts whenever it is placed in a temperature above -39°. It boils at the temperature of 600°.

† See *Macnab's Experiments, Phil. Tranſ.*

From the experiments made on frozen mercury in Ruſſia, Hudſon's Bay, and Britain, we know that this metal, when ſolid, is malleable; but the extreme difficulty of examining it in that ſtate, on account of the lowneſs of the temperature, has rendered it hitherto impoſſible to aſcertain the preciſe degree either of its malleability, ductility, or hardneſs.

85
It forms three oxides;

Mercury is capable of combining with oxygen, and of forming *oxides*, differing from each other in the quantity of oxygen which they contain. The oxides of mercury, at preſent known, are the *black*, the *yellow*, and the *red*.

86
The black oxide,

1. When mercury is agitated for ſome time in contact with oxygen gas, or atmoſpheric air, it is partly converted into a greyiſh black powder, and at the ſame time part of the oxygen diſappears. This is the *black* oxide of mercury. It is not known how much oxygen it contains, nor even whether the whole of the mercury which compoſes it be actually combined with oxygen.

87
Yellow oxide,

2. The beſt way of forming the yellow oxide is to diſſolve mercury, either in boiling ſulphuric acid or in cold nitric acid. During its ſolution, it deprives theſe acids of juſt as much oxygen as is neceſſary to convert it into a yellow oxide; and if potaſs or lime be afterwards added to the ſolution, it precipitates, and may be obtained pure by waſhing it with water. It is a bright yellow-coloured powder, which acts very powerfully as an emetic. From the obſervations of Bergman, it appears that it is compoſed of about 96,8 parts of mercury, and 3,2 of oxygen ‡.

‡ *Kirwan's Miner.* ii. 489.

88
And red oxide.

3. The *red oxide* of mercury may be prepared, either by diſtilling nitric acid off the metal repeatedly, or by keeping mercury for a long time expoſed to a heat ſufficient to evaporate it while it is in contact with air. When formed by the firſt proceſs, it was formerly called *red precipitate;* when by the laſt, *precipitate per ſe.* It is a beautiful red powder, or rather ſmall red cryſtals, which have ſome eſcharotic qualities. When prepared by the ſecond proceſs, the heat muſt not be much below 600° nor much above 800°, otherwiſe no union would take place;

(κ) To this colour it owes its name. *Plata*, in Spaniſh, is *ſilver;* and *platina*, *little ſilver*, was the name firſt given to the metal. Bergman changed that name into *platinum*, that the Latin names of all the metals might have the ſame termination and gender. It was, however, firſt called *platinum* by Linnæus.

place; and it muſt be continued for ſome weeks. From the experiments of Mr Kirwan, it appears to contain 92,6 parts of mercury and 7,4 of oxygen*.

* *Kirwan's Miner.* ii. 439.

Theſe oxides may be decompoſed by the application of a heat amounting to 1200°. The oxygen flies off in the form of gas, and running mercury remains behind.

89
Their affinities.

The affinities of the oxides of mercury, according to Bergman, are as follows:

Sebacic acid,
Muriatic,
Oxalic,
Succinic,
Arſenic,
Phoſphoric,
Sulphuric,
Benzoic (L)?
Saccholactic,
Tartarous,
Citric,
Sulphurous,
Nitric,
Fluoric,
Zoonic (M)?
Acetous,
Boracic,
Pruſſic,
Carbonic.

90
Black ſulphuret of mercury.

When two parts of mercury and three parts of flowers of ſulphur are triturated for ſome time together, or when equal parts of mercury and melted ſulphur are mixed together—they combine, and form a black powder, formerly called *ethiops mineral*, and now *black ſulphuret of mercury*.

91
Red ſulphuret.

When 300 grains of mercury and 68 of ſulphur, with a few drops of ſolution of potaſs to moiſten them, are triturated for ſome time in a porcelain cup by means of a glaſs peſtle, black oxide of mercury is produced. Add to this 160 grains of potaſs, diſſolved in as much water. Heat the veſſel containing the ingredients over the flame of a candle, and continue the trituration without interruption during the heating. In proportion as the liquid evaporates, add clear water from time to time, ſo that the oxide may be conſtantly covered to the depth of near an inch. The trituration muſt be continued about two hours; at the end of which time the mixture begins to change from its original black colour to a brown, which uſually happens when a large part of the fluid is evaporated. It then paſſes very rapidly to a red. No more water is to be added; but the trituration is to be continued without interruption. When the maſs has acquired the conſiſtence of a gelly, the red colour becomes more and more bright, with an incredible degree of quickneſs. The inſtant the colour has acquired its utmoſt beauty, the heat muſt be withdrawn, otherwiſe the red paſſes to a dirty brown. This red powder is the red ſulphuret of mercury, called formerly *cinnabar*, and, when reduced to a fine powder, *vermilion* (N). The proceſs above deſcribed has been lately diſcovered by Mr Kirchoff, and is by far the ſimpleſt and cheapeſt mode of forming red ſulphuret with which we are acquainted*. Count De Mouſſin Pouſchin has diſcovered, that its paſſing to a brown colour may be prevented by taking it from the fire as ſoon as it has acquired a red colour, and placing it for two or three days in a gentle heat, taking care to add a few drops of water, and to agitate the mixture from time to time. During this expoſure, the red colour gradually improves, and at laſt becomes excellent. He diſcovered alſo, that when this ſulphuret is expoſed to a ſtrong heat, it becomes inſtantly brown, and then paſſes into a dark violet; when taken from the fire it paſſes inſtantly to a beautiful carmine red†.

* *Nicholſon's Journ.* ii. 1.
† *Ibid.* p. 7.

The difference between theſe two ſulphurets has never yet been aſcertained. One would be apt to ſuſpect at firſt that the black ſulphuret conſiſts of the real ſulphuret of mercury combined with ſulphur; the red, of the ſulphuret of mercury combined with mercury, and that the real ſulphuret of mercury was not yet accurately known. But it cannot be doubted that, during the formation of the *red ſulphuret*, according to Kirchoff's proceſs, there is an abſorption of oxygen. The phenomena above deſcribed point out *that* almoſt inconteſtibly; and we obſerved, on attempting to repeat the experiment, that the black ſulphuret, during its trituration, emitted ſulphurated hydrogen gas. Perhaps, then, the mercury may be oxidated. We ſuſpected at firſt that part of the ſulphur might be converted into an acid; but on attempting an alteration of the proceſs, in conſequence of that ſuppoſition, we could not ſucceed.

The red ſulphuret of mercury is found naturally in ſeveral parts of the world. It uſed to be prepared by forming a black ſulphuret with three parts of ſulphur and one of mercury, and then ſetting fire to it. Part of the ſulphur is burnt, and there remains behind a violet-coloured body, which is powdered and put into a glaſs veſſel, to the bottom of which a red heat is applied. A reddiſh brown ſubſtance ſublimes, which is red *ſulphuret of mercury*; but its colour is not nearly equal to that which is prepared by Kirchoff's proceſs.

92
Phoſphuret of mercury.

Mr Pelletier, after ſeveral unſucceſsful attempts to form phoſphuret of mercury, at laſt ſucceeded by diſtilling a mixture of red oxide of mercury and phoſphorus. Part of the phoſphorus combined with the oxygen of the oxide, and was converted into an acid; the reſt combined with the mercury.

Phoſphuret of mercury is of a black colour, of a pretty ſolid conſiſtence, and capable of being cut with a knife. When expoſed to the air, it exhaled vapours of phoſphorus‡.

* *Ann. de Chim.* xiii. 122.

Mercury does not ſeem capable of combining with carbon.

93
Its amalgams.

The combinations of mercury with the other metals are called *amalgams*.

1. The amalgam of gold forms very readily, becauſe there is a very ſtrong affinity between the two metals. If a bit of gold be dipped into mercury, its ſurface, by combining with mercury, becomes as white as ſilver. The

---

(L) Benzoat of mercury is decompoſed by ſulphuric acid. *Tromſdorf, Ann. de Chim.* xi. 316.

(M) Zoonic acid decompoſes the acetite of mercury. *Berthollet.*

(N) The word *vermilion* is derived from the French word *vermeil*, which comes from *vermiculus* or *vermiculum*; names given in the middle ages to the *kermes* or *coccus ilicis*, well known as a red dye. *Vermilion* originally ſignified the red dye of the kermes. See *Beckmann's Hiſt. of Inventions*, ii. 180.

The eaſieſt way of forming this amalgam is to throw ſmall pieces of red hot gold into mercury. The proportions of the ingredients are not eaſily determined, becauſe the amalgam has an affinity both for the gold and the mercury; in conſequence of which they appear to combine in any proportion. Moſt probably it is compoſed of two parts of gold and one of mercury. The combination is formed moſt readily in theſe proportions; and if too much mercury be added, it may be ſeparated by filtration. The amalgam is of a white colour, and of the conſiſtence of butter*. This amalgam cryſtallizes in quadrangular priſms; which cryſtals, according to the Dijon academicians, are compoſed of ſix parts of mercury and one of gold. It is much uſed in gilding.

* Keir's Notes on Macquer's Dict. art. Amalgam.

2. The amalgam of ſilver is made in the ſame manner. It forms dendritical cryſtals, which, according to the Dijon academicians, contain eight parts of mercury and one of ſilver. Gellert was the firſt who remarked that its ſpecific gravity was greater than that of mercury, though that of ſilver be leſs.

3. Dr Lewis attempted to form an amalgam of platinum, but hardly ſucceeded after a labour which laſted for ſeveral weeks. Mr Morveau ſucceeded by means of heat†. But a much more expeditious method has been lately diſcovered by Count Mouſſin Pouſchin. He took a dram of the orange-coloured ſalt, compoſed of *oxide of platinum and ammonia* (o), and triturated it with an equal weight of mercury in a mortar of chalcedony. In a few minutes the ſalt became brown, and afterwards acquired a greeniſh ſhade. The matter was reduced to a very fine powder. Another dram of mercury was added, and the trituration continued: The matter became grey. A third dram of mercury began to form an amalgam; and ſix drams made the amalgam perfect. The whole operation ſcarce laſted 20 minutes. Mercury was added till it amounted to nine times the weight of the ſalt, and yet the amalgam continued very tenacious. It was eaſily ſpread out under the peſtle; it received the impreſſion of the moſt delicate ſeals, and had a very cloſe and brilliant grain. This amalgam is decompoſed, and the mercury paſſes to the ſtate of black oxide by the ſimple contact of ſeveral of the metals and a great number of animal matters. This effect even takes place on rubbing it between the fingers‡.

† Ann. de Chim. xxiv. 205.

‡ Ibid.

94
Affinities.

The affinities of mercury, as aſcertained by the experiments of Morveau (p), are as follows:

Gold,
Silver,
Tin,
Lead,
Biſmuth,
Zinc,
Copper,
Antimony,
Arſenic (q),
Iron.

SECT. V. *Of Copper.*

EXCEPT gold and ſilver, copper ſeems to have been more early known than any other metal. In the firſt ages of the world, before the method of working iron was diſcovered, copper was a principal ingredient in all domeſtic utenſils and inſtruments of war. Even during the Trojan war, as we learn from Homer, the combatants had no other armour but what was made of bronze, which is a mixture of *copper and tin*. The word *copper* is derived from the iſland of Cyprus, where it was firſt diſcovered, or at leaſt wrought to any extent, by the Greeks.

95
Properties of copper.

Copper is of a pale red colour with a ſhade of yellow. Its taſte is ſtyptic and nauſeous; and when rubbed it emits a diſagreeable ſmell. It poſſeſſes a conſiderable degree of malleability, though leſs than ſilver. Its tenacity is ſuch, that a wire of $\frac{1}{10}$ of an inch in diameter can ſuſtain a weight of 299¼ pounds without breaking*.

Its hardneſs is 8†. Its ſpecific gravity, when not hammered, is 7,788; when wire-drawn, 8,878‡. The ſpecific gravity of Japan copper is 9,000§; that of Swediſh copper, 9,3243‖.

It melts at 27° Wedgewood; according to the calculation of the Dijon academicians, at 1449° Fahrenheit. When allowed to cool ſlowly, it aſſumes a cryſtalline form. The Abbe Mongé, to whom we owe many valuable experiments on the cryſtallization of metals, informs us, that theſe cryſtals are quadrangular pyramids, frequently inſerted into one another.

* Macquer's Dict.
† Kirwan's Miner. ii. 127.
‡ Briſſon.
§ Keir's Notes on Macquer's Dict.
‖ Bergman, ii. 263.

96
Brown oxide of copper.

When copper is heated red hot in contact with air, it is ſoon covered with a brown earthy cruſt, which may be eaſily ſeparated by hammering or by plunging the metal into water. If the heat be continued, another ſcale of the ſame kind ſoon forms; and by continuing the proceſs the whole metal may be converted into an earthy-like cruſt, which is merely a combination of copper and oxygen, and is therefore called *brown oxide of copper*. It is compoſed of about 84 parts of copper and 16 of oxygen*.

* Kirwan's Miner. ii. 487.

97
Blue and green oxides.

When copper is diſſolved in ſulphuric acid, and precipitated by means of lime, it falls in the form of a blue-coloured powder, which is the *blue oxide of copper*. If this oxide of copper be dried in the open air, it aſſumes a green colour, and is then called the *green oxide of copper*. This laſt oxide may alſo be produced by diſtilling a ſufficient quantity of nitric acid off copper. Little ſatisfactory is yet known with reſpect to theſe oxides; it has not even been aſcertained whether the blue and green be really two different oxides, or whether the difference in colour be owing to ſome other cauſe. It is probable, however, that the *green* oxide contains more oxygen than the blue; becauſe the blue oxide aſſumes a green colour when expoſed for ſome time to the open air, during which it may be ſuppoſed to abſorb oxygen. An experiment of Fourcroy proves inconteſtibly, that the *brown* oxide contains leſs oxygen than the green. He converted the green oxide into the brown by applying heat; and during the diſtillation obtained oxygen gas†.

† Fourcroy iii. 101.

98
Their affinities.

The affinities of the oxides of copper, according to Bergman, are as follows:

Pyro-mucous acid‡
Oxalic,
Tartarous,

‡ Schrickel.

(o) Ammonia is an alkali hereafter to be deſcribed. It is often called, in Engliſh, *hartſhorn*.

(p) We ſhall have occaſion to conſider theſe celebrated experiments afterwards.

(q) Theſe two are added from Bergman. Bergman places *lead* before tin, and zinc before biſmuth.

Tartarous,
Muriatic,
Sulphuric,
Saccholactic,
Nitric,
Sebacic,
Arſenic,
Phoſphoric,
Succinic,
Fluoric,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic,
Fixed alkalies,
Ammonia,
Fixed oils.

When copper is long expoſed to the air, its ſurface becomes covered over with a green cruſt, which is *green oxide of copper*. This oxidation never penetrates beyond the ſurface.

Copper is not attacked by water at the boiling temperature; but if cold water be allowed to remain long on its ſurface, the metal becomes partly oxidated.

99 Sulphuret of copper.

Sulphur mixes readily with copper. The combination may be formed by mixing the ingredients together and applying a pretty ſtrong heat. *Sulphuret of copper* is brittle, ſofter than copper, of a black colour externally, and within of a leaden grey. It is compoſed, according to Kirwan's experiments, of 81 parts of copper and 19 of ſulphur*.

100 Phoſphuret of copper.

Mr Pelletier formed *phoſphuret of copper* by melting together one ounce of copper, one ounce of phoſphoric glaſs, and one dram of charcoal. It was of a white colour. On expoſure to the air, it loſt its luſtre and became blackiſh†. Margraf was the firſt perſon that formed this phoſphuret. His method was to diſtil phoſphorus and brown oxide of copper together. It is formed moſt eaſily by projecting phoſphorus into red hot copper. According to Pelletier, it contains 20 parts of phoſphorus and 80 of copper‡. This phoſphuret is harder than iron: It is not ductile, and yet cannot eaſily be pulveriſed. Its ſpecific gravity is 7,1220. It cryſtallizes in tetrahedral priſms§.

* *Kirwan's Miner.* ii. 503.
† *Ann. de Chim.* i. 74.
‡ *Ibid.* xiii. 3.
§ *Sage Journ. de Phyſ.* xxxviii. 468.

101 Alloys of copper.

1. Copper combines readily with gold when the two metals are melted together. The compound is of a reddiſh colour, more fuſible than gold, but leſs ductile. The proportions of the ingredients which form this alloy are not known; nor would it be eaſy to aſcertain them, as the two metals are almoſt equally fuſible. The current gold of this country is compoſed of 11 parts of gold and one part of copper.

2. The alloy of copper and ſilver is made as eaſily as that of gold, and the properties are equally unknown. It is harder and more ſonorous than ſilver. The current ſilver coin of Britain is compoſed of 15 parts of ſilver and one of copper.

3. Platinum combines readily with copper. The alloy is much more fuſible than platinum; it is ductile, hard, takes a fine poliſh, and is not liable to tarniſh. This alloy has been employed with advantage for compoſing the mirrors of reflecting teleſcopes.

4. The amalgam of copper cannot be formed by ſimply mixing that metal with mercury, nor even by the application of heat; becauſe the heat neceſſary to melt copper ſublimes mercury. Dr Lewis has given us ſeveral proceſſes for forming this amalgam. One of the ſimpleſt is to triturate mercury with a quantity of common ſalt and verdigriſe; a ſubſtance compoſed of oxide of copper and vinegar. The theory of this proceſs is not very obvious.

102 Its affinities

The affinities of copper are, according to Bergman, as follows:

Gold,
Silver,
Arſenic,
Iron,
Mangaueſe,
Zinc,
Antimony,
Platinum,
Tin,
Lead,
Nickel,
Biſmuth,
Cobalt,
Mercury,
Sulphuret of alkali,
Sulphur,
Phoſphorus.

SECT. VI. *Of Iron.*

103 Diſcovery of iron.

Iron, the moſt abundant and moſt uſeful of all the metals, was neither known ſo early, nor wrought ſo eaſily, as gold, ſilver, and copper. For its diſcovery we muſt have recourſe to the nations of the eaſt, among whom, indeed, almoſt all the arts and ſciences firſt ſprung up. The writings of Moſes (who was born about 1635 years before Chriſt) furniſh us with the ampleſt proof at how early a period it was known in Egypt and Phœnicia. He mentions furnaces for working iron*, ores from which it was extracted†; and tells us that ſwords‡, knives§, axes‖, and tools for cutting ſtones¶, were then made of that metal. How many ages before the birth of Moſes iron muſt have been diſcovered in theſe countries, we may perhaps conceive, if we reflect, that the knowledge of iron was brought over from Phrygia to Greece by the Dactyli*, who ſettled in Crete during the reign of Minos I. about 1431 years before Chriſt; yet during the Trojan war, which happened 200 years after that period, iron was in ſuch high eſtimation, that Achilles propoſed a ball of it as one of his prizes during the games which he celebrated in honour of Patroclus (R). At that period none of their weapons were formed of iron. Now if the Greeks in 200 years had made ſo little progreſs in an art which they learned from others, how long muſt it

Αλλ' ητοι τον επεφνε ποδαρκης διος Αχιλλευς,

it have taken the Egyptians, Phrygians, Chalybes, or whatever nation firſt diſcovered the art of working iron, to have made that progreſs in it which we find they had done in the days of Moſes?

104
Its properties.

Iron, when freſh broken, is of a bluiſh grey colour. It has a ſtyptic taſte, and emits a ſmell when rubbed.

It is malleable and ductile in every temperature; and its malleability is increaſed in proportion as the temperature augments. Its tenacity is ſuch, that an iron wire $\frac{1}{10}$ of an inch in diameter ſuſtains a weight of 450 pounds without breaking *.

Its hardneſs is ſuch, that it may be eaſily reduced to powder by the application of a file. Its ſpecific gravity is 7,788. It is infuſible in the ſtrongeſt heats hitherto produced.

It is attracted by the magnet or loadſtone, and is itſelf capable of becoming magnetic; but it retains this property only for a very ſhort time.

It is not hardened by being plunged into liquids while hot, nor ſoftened by being cooled ſlowly.

Iron combines with oxygen very readily. When kindled in oxygen gas, it burns with great rapidity and ſplendor, and is in this manner converted into an oxide. It is converted into an oxide alſo when ſurrounded by moiſt air, or when plunged in water; becauſe it has a ſtronger affinity for oxygen than hydrogen has, and is therefore capable of decompoſing water.

105
Forms two oxides.

Mr Prouſt has lately proved, that there are only two oxides of iron, the *green* and the *brown* or *red*, and that all the other ſuppoſed oxides are merely mixtures of theſe two in various proportions †.

The *green oxide* may be obtained by diſſolving iron in ſulphuric acid, and then precipitating it by potaſs. It is a light, green-coloured, earthy-like ſubſtance, compoſed, as Mr Lavoiſier has ſhewn, of 27 parts of oxygen, and 73 of iron ‡. When this oxide is expoſed to the air, it quickly abſorbs more oxygen, and is converted into a brown powder, which is the *brown oxide*. Mr Prouſt has proved that it contains 52 parts of iron and 48 of oxygen. This oxide is well known under the name of *ruſt of iron*, which is generally, however, or perhaps always, combined with carbonic acid gas.

106
Their affinities.

The affinities of theſe oxides, according to Bergman, are as follows:

Gallic acid?
Oxalic acid,
Tartarous,
Camphoric §,
Sulphuric,
Saccholactic,
Muriatic,
Pyromucous ||,
Nitric,
Sebacic,
Phoſphoric,
Arſenic,
Fluoric,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic.

107
Sulphuret.

Iron unites readily with ſulphur. Sulphuret of iron, formerly called *pyrites*, is found ready formed in many parts of the world. It is not eaſy to determine the proportions of its ingredients, becauſe it is capable of combining both with iron and ſulphur, and conſequently, if there happens to be any exceſs of either during its formation, it takes it up. Perhaps the proportions are not far from equal parts of ſulphur and of iron. It is of a pale yellow or browniſh colour, and is capable of aſſuming a cryſtalline form. Its ſpecific gravity is about 4,000. When placed upon the fire it precipitates; and at a red heat loſes its yellow colour, and becomes of an iron grey, excepting its ſurface, which is of a bright red. It melts at 102° Wedgewood in a covered crucible into a bluiſh ſlag, ſomewhat porous internally *. When expoſed to air and moiſture, the ſulphur, as happens in all ſulphurets, gradually abſorbs oxygen, and is converted into an acid.

If iron filings and ſulphur be mixed together, and formed into a paſte with water, the ſulphur decompoſes the water, and abſorbs oxygen ſo rapidly, that the mixture takes fire, even though it be buried under ground. This phenomenon was firſt diſcovered by Homberg; and it is conſidered as affording an explanation of the origin of volcanoes. The native ſulphuret of iron has been obſerved more than once to take fire on being ſuddenly moiſtened with water.

108
Phoſphuret,

Iron combines readily with phoſphorus, and forms *phoſphuret of iron;* to which Bergman, who firſt diſcovered it, gave the name of *ſiderum*.

There is a particular kind of iron, known by the name of *cold ſhort iron*, becauſe it is brittle when cold, though it be malleable when hot. Bergman was employed at Upſal in examining the cauſe of this property, while Meyer was occupied at Stetin with the ſame inveſtigation; and both of them diſcovered, nearly at the ſame time, that, by means of ſulphuric acid, a white powder could be ſeparated from this kind of iron, which by the uſual proceſs they converted into a metal of a dark ſteel grey, exceedingly brittle, and not very ſoluble in acids. Its ſpecific gravity was 6,700; it was not ſo fuſible as copper; and when combined with iron rendered it *cold ſhort*. Both of them concluded that this ſubſtance was a new metal; and Bergman gave it the name of *ſiderum*. But Klaproth ſoon after recollecting that the ſalt compoſed of phoſphoric acid and iron bore a great reſemblance to the white powder obtained from cold ſhort iron, ſuſpected the preſence of

phoſphoric acid in this new metal. To decide the point, he combined phoſphoric acid and iron, and obtained, by heating it in a crucible along with charcoal powder (s), a ſubſtance exactly reſembling the new metal. Meyer, when Klaproth communicated to him this diſcovery, informed him that he had already ſatisfied himſelf, by a more accurate examination, that ſiderum contained phoſphoric acid. Soon after this Scheele actually decompoſed the white powder obtained from cold ſhort iron, and thereby demonſtrated, that it was compoſed of phoſphoric acid and iron. The ſiderum of Bergman, however, is compoſed of phoſphorus and iron, the phoſphoric acid being deprived of its oxygen during the *reduction*; or it is phoſphuret of iron. It may be formed by fuſing in a crucible an ounce of phoſphoric glaſs, an ounce of iron, and half a dram of charcoal powder. It is very brittle, and appears white when broken. When expoſed to a ſtrong heat, it melts, and the phoſphorus is diſſipated *. It may be formed alſo by melting together equal parts of phoſphoric glaſs and iron filings. Part of the iron combines with the oxygen of the phoſphoric glaſs, and is vitrified; the reſt forms the phoſphuret, which ſinks to the bottom of the crucible. It may be formed alſo by dropping ſmall bits of phoſphorus into iron filings heated red hot †. The proportions of the ingredients of this phoſpuret have not yet been determined.

* *Pelletier, Ann de Chim.* i. 104.

† *Id. Ann. de Chim.* xiii. 113.

109
And carburet of iron.

Iron likewiſe combines with carbon, and forms a *carburet*. Carburet of iron has been long known and uſed in the arts under the names of *plumbago* and *black lead*. It is of a dark iron grey or blue colour, and has ſomething of a metallic luſtre. It has a greaſy feel, and blackens the fingers, or any other ſubſtance to which it is applied. It is found in many parts of the world, eſpecially in England, where it is manufactured into pencils. It is not affected by the moſt violent heat as long as air is excluded, nor is it in the leaſt altered by ſimple expoſure to the air, or to water. Its nature was firſt inveſtigated by Scheele; who proved, by a very ingenious analyſis, that it could be converted almoſt wholly into carbonic acid gas, and that the ſmall reſiduum was iron. It follows from this analyſis, that it is compoſed of carbon and iron; for the carbon, during its combuſtion, had been converted into carbonic acid gas. By the ſubſequent experiments of Pelletier and other French chemiſts, it has been ſhewn to conſiſt nearly of nine parts of carbon to one of iron.

110
Varieties of iron.

There are a great many varieties of iron, which artiſts diſtinguiſh by particular names; but all of them may be reduced under one or other of the three following ſtates: *Wrought iron* (or ſimply *iron*), *ſteel*, and *caſt* or *raw iron*.

111
Wrought iron.

Wrought Iron is the ſubſtance which we have been hitherto deſcribing. As it has never yet been decompounded, we conſider it when pure as a ſimple body; but it has ſeldom or never been found without ſome ſmall mixture of foreign ſubſtances. Theſe ſubſtances are either ſome of the other metals, or oxygen, carbon, or phoſphorus.

112
Steel.

Steel is diſtinguiſhed from iron by the following properties.

It is ſo hard as to be unmalleable while cold, or at leaſt it acquires this property by being immerſed while ignited into a cold liquid: for this immerſion, though it has no effect upon *iron*, adds greatly to the hardneſs of *ſteel*.

It is brittle, reſiſts the file, cuts glaſs, affords ſparks with flint, and retains the magnetic virtue for any length of time.

It loſes this hardneſs by being ignited and cooled very ſlowly.

It melts at above 130° Wedgewood. It is malleable when red hot, but ſcarcely ſo when raiſed to a white heat.

It may be hammered out into much thinner plates than iron. It is more ſonorous; and its ſpecific gravity, when hammered, is greater than that of iron.

By being repeatedly ignited in an open veſſel, and hammered, it becomes *wrought iron* *.

* *Dr Pearſon* on *Wootz, Phil. Tranſ.*

113
Caſt iron.

Cast Iron is diſtinguiſhed by the following properties:

It is ſcarcely malleable at any temperature. It is generally ſo hard as to reſiſt the file. It can neither be hardened nor ſoftened as ſteel can by ignition and cooling. It is exceedingly brittle. It melts at 130° Wedgewood. It is more ſonorous than ſteel †.

† *Ibid.*

Caſt iron is converted into wrought iron by expoſing it for a conſiderable time in a furnace to a heat ſufficiently ſtrong to melt it. During the proceſs it is conſtantly ſtirred by a workman, that every part of it may be equally expoſed to the air. In about an hour the hotteſt part of the maſs begins to heave and ſwell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the converſion is completed. The heaving is evidently produced by the emiſſion of an elaſtic fluid ‡.

‡ *Beddoes, Phil. Tranſ.* 1791.

Wrought iron may be converted into ſteel by being kept for ſome hours in a ſtrong red heat, ſurrounded with charcoal powder in a covered crucible. By this proceſs, which is called *cementation*, the iron gains ſome weight.

114
Cauſe of theſe varieties.

Theſe different kinds of iron have been long known, and the converting of them into each other has been practiſed in very remote ages. Many attempts have been made to explain the manner in which this converſion is accompliſhed. According to Pliny, ſteel owes its peculiar properties chiefly to the water into which it is plunged in order to be cooled §. Beccher ſuppoſed that fire was the only agent; that it entered into the iron, and converted it into ſteel. Reaumur was the firſt who attended accurately to the proceſs; and his numerous experiments have certainly contributed to elucidate the ſubject. He ſuppoſed that iron was converted into ſteel by combining with ſaline and oily or ſulphureous particles, and that theſe were introduced by the fire. But it was the analyſis of Bergman, publiſhed in 1781, that firſt paved the way to the explanation of the nature of theſe different ſpecies of iron.

§ *Pliny*, l. xxxiv. 14.

By diſſolving in diluted ſulphuric acid 100 parts of caſt iron, he obtained 40 ounce meaſures of hydrogen; from 100 parts of ſteel he obtained 48 ounce meaſures; and from 100 parts of wrought iron, 50 ounce meaſures. Now as the hydrogen is produced by the property which iron has of decompoſing water and uniting with its oxygen, it is evident that the greater the quantity of hydrogen obtained,

---

(s) This proceſs in chemiſtry is called *reduction*.

tained, with the more oxygen does the iron combine. But the quantities of iron were equal; they ought therefore to have combined with equal quantities of oxygen. But it is evident, from the quantities of hydrogen obtained, that the caſt iron received leſs oxygen than either of the other two: caſt iron therefore muſt contain already ſome oxygen, ſince it requires leſs than the other two ſpecies in order to be ſaturated. Here then is one difference between caſt iron and the other two kinds; it contains oxygen. Steel, on the contrary, does not appear to contain any oxygen. The difference between the quantity of hydrogen produced during its ſolution and that of wrought iron, which contains no oxygen, is exceedingly ſmall, and it has been found to diminiſh in proportion to the purity of the ſteel.

From 100 parts of caſt iron Bergman obtained 2,2 of plumbago, or $\frac{1}{45}$; from 100 parts of ſteel, 0,5, or $\frac{1}{200}$; and from 100 parts of wrought iron, 0,12, or $\frac{1}{900}$. Now plumbago is compoſed of $\frac{9}{10}$ths of carbon; caſt iron therefore contains a conſiderable quantity of carbon, ſteel a ſmaller quantity, and wrought iron a very minute portion, which diminiſhes according to its purity, and would vaniſh altogether if iron could be obtained perfectly pure. Mr Grignon, in his notes on this analyſis, endeavoured to prove that plumbago was not eſſentially a part of caſt iron and ſteel, but that it was merely accidentally preſent But Bergman, after conſidering his objections, wrote to Morveau on the 18th November 1783. "I will acknowledge my miſtake whenever Mr Grignon ſends me a ſingle bit of caſt iron or ſteel which does not contain plumbago; and I beg of you, my dear friend, to endeavour to diſcover ſome ſuch, and to ſend them to me; for if I am wrong, I wiſh to be undeceived as ſoon as poſſible *." This was almoſt the laſt action of the illuſtrious Bergman. He died a few months after at the age of 49, leaving behind him a moſt brilliant reputation, which no man ever more deſervedly acquired. His induſtry, his indefatigable, his aſtoniſhing induſtry, would alone have contributed much to eſtabliſh his name; his extenſive knowledge would alone have attracted the attention of philoſophers; his ingenuity, penetration, and accurate judgment, would alone have ſecured the applauſe; and his candour and love of truth procured him the confidence and the eſteem of the world.—But all theſe qualities were united in Bergman, and conſpired to form one of the greateſt men and nobleſt characters that ever adorned human nature.

* *Morveau, Encycl. Method. Chimie*, i. 448.

The experiments of Bergman were fully confirmed by thoſe of Morveau, Vandermonde, Monge, and Berthollet, who have likewiſe thrown a great deal of additional light on the ſubject. From all theſe experiments the following deductions may be made.

Wrought iron is a ſimple ſubſtance, and if perfectly pure would contain nothing but *iron*.

Steel is iron combined with carbon. The proportion of this laſt ingredient has not yet been aſcertained; Dr Pearſon fixes it at $\frac{1}{300}$th part at a medium. Steel, in conſequence of its compoſition, has been called by ſome chemiſts *carburet of iron;* but before aſſigning it that name, which has been alſo given to plumbago, it ought to be determined what are the proportions of carbon and iron which ſaturate each other. Is it the proportion in which theſe two ſubſtances exiſt in ſteel, or that which forms plumbago? In the firſt caſe, plumbago is carburet of iron combined with carbon; in the ſecond, ſteel is carburet combined with iron. Or is it ſome intermediate proportion? Till theſe points be determined, perhaps it would be better to continue the old names than to riſk the impoſing of falſe ones.

Caſt iron is iron contaminated with various foreign ſubſtances, the proportions of which vary according to circumſtances. Theſe ſubſtances are chiefly oxide of iron and carbon, and ſometimes ſilica (T).

Bergman found a quantity of mangane ſe in the iron and ſteel which he examined; but it appears from the experiments of Vauquelin, that his method of determining the preſence of that metal was not accurate.

115 Vauquelin's analyſis of ſteel.

Mr Vauquelin * has lately analyſed four kinds of ſteel with great care, and contrived his proceſſes with much ingenuity. The reſult of his analyſis is as follows:

* *Jour. de Mines. See Nicholſon's Journal*, i. 200.

Firſt ſteel, compoſed of	Carbon, -	0,00789
	Silica, -	0,00315
	Phoſphorus, -	0,00345
	Iron, - -	0,98551
		1

Second ſteel, compoſed of	Carbon, -	0,00683
	Silica, -	0,00273
	Phoſphorus,	0,00827
	Iron, - -	0,98217
		1

Third ſteel, compoſed of	Carbon, -	0,00789
	Silica, -	0,00315
	Phoſphorus,	0,00791
	Iron, - -	0,98105
		1

Fourth ſteel, compoſed of	Carbon, -	0,00631
	Silica, -	0,00252
	Phoſphorus,	0,01520
	Iron, - -	0,97597
		1

It cannot be concluded from theſe experiments that all ſteel contains phoſphorus and ſilica; far leſs that theſe ſubſtances enter neceſſarily into the compoſition of ſteel. This *may* be the caſe, and former analyſes may not have been nice enough to detect it; but before it can be admitted, it muſt be ſhewn that theſe ſubſtances are always preſent in ſteel, and that it loſes its eſſential properties when deprived of them.

116 Alloys of iron.

Iron combines with moſt metals.

1. The alloy of gold and iron is very hard, and might, according to Dr Lewis, who examined it, be employed with advantage in forming cutting inſtruments.

2. That iron combines with ſilver is certain, but hardly any thing is known about the nature of the compound.

3. Platinum is uſually found alloyed with iron. Dr Lewis did not ſucceed in his attempts to unite theſe

---

(T) An earth which ſhall be deſcribed in the next chapter.

metals by fuſion, but he melted together caſt iron and platinum. The alloy was exceſſively hard, and poſſeſſed ductility.

4. There is very little affinity between iron and mercury; they cannot therefore be amalgamated by ſimple mixture, even with the aſſiſtance of heat. Vogel affirms that he has produced an amalgam of iron by the following proceſs: Pound one part of iron filings and two parts of alum in a mortar to a fine powder; then pour in two or three parts of mercury, and triturate till the ſubſtances be thoroughly mixed. Pour on a little water, and continue the trituration for about an hour. If then no particles of iron can be diſtinguiſhed, pour on a little more water to waſh out the alum, and then dry the amalgam. If particles of iron be perceptible, the trituration muſt be continued till they diſappear *.

5. Iron may be united to copper by fuſion, but not without conſiderable difficulty. The alloy has been applied to no uſe.

117 Its affinities. The affinities of iron, according to Bergman, are as follows:

Nickel,
Cobalt,
Mangancſe,
Arſenic,
Copper,
Gold,
Silver,
Tin,
Antimony,
Platinum,
Biſmuth,
Lead,
Mercury,
Sulphuret of alkali,
Carbon ?
Phoſphorus ?
Sulphur ?

Sect. VII. *Of Tin.*

The Phenicians were the firſt of thoſe nations which make a figure in ancient hiſtory that were acquainted with *tin*. They procured it from Spain † and from Britain, with which nations they carried on a very lucrative commerce. At how early a period they imported this metal we may eaſily conceive, if we recollect that it was in common uſe in the time of Moſes ‡.

118 Properties of tin: Tin is of a greyiſh white colour: it has a ſtrong diſagreeable taſte, and emits a peculiar ſmell when rubbed.

It is very malleable; tin-leaf, or *tinfoil* as it is called, is about $\frac{1}{1000}$th part of an inch thick, and it might be beat out into leaves as thin again if ſuch were wanted for the purpoſes of art. Its ductility, however, is exceedingly imperfect; for a tin wire $\frac{1}{10}$th of an inch in diameter, is capable of ſupporting only 49 pounds without breaking §. It is very flexible, and produces a crackling noiſe when bended.

Its hardneſs is 6 ‖. Its ſpecific gravity is 7,291; after hammering, 7,299 ¶.

It melts at the temperature 410°, according to Dr Lewis; according to the Dijon academicians, at 419°. When heated red hot in cloſe veſſels it ſublimes. It cryſtallizes in the form of a rhomboidal priſm *.

119 Oxides, Tin unites very readily with oxygen. When heated in contact with air, its ſurface ſoon becomes covered with a grey pellicle; when this is taken off, another appears ſoon after; and in this manner the whole metal may be converted into a dirty grey powder, which is the *grey oxide of tin*. It is compoſed, according to Fourcroy, of 90 parts of tin and 10 of oxygen.

When tin is heated red hot in contact with air, it takes fire *, and burns with a very lively white flame, and is gradually ſublimed. If the ſublimate be examined, it is found to conſiſt of a white powder; it is the *white oxide of tin*. The white oxide is perhaps never obtained quite pure by this proceſs; it ſeems always to contain a mixture of *grey oxide:* but it may be obtained pure by pouring nitric acid upon tin, and then drying it. That metal having a much ſtronger attraction for oxygen than azot has, decompoſes the acid with the greateſt rapidity, and aſſumes the appearance of a white powder, which is the *white oxide*. This oxide poſſeſſes many of the properties of an acid, and is therefore often called *ſtannic acid*. It ſeems to conſiſt of about 77 parts of tin and 23 of oxygen †.

The affinities of the grey oxide of tin, according to Bergman, are as follows:

Pyromucous acid ‡,
Sebacic acid,
Tartaric,
Muriatic,
Sulphuric,
Oxalic,
Arſenic,
Phoſphoric,
Nitric,
Succinic,
Fluoric,
Saccholactic,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic.

120 Sulphurets, Tin combines readily with ſulphur. This ſulphuret may be formed by fuſing the two ingredients together. It is brittle, heavier than tin, and not ſo fuſible. It is of a bluiſh colour and lamellated ſtructure, and is capable of cryſtallizing. According to Bergman, it is compoſed of 80 parts of tin and 20 of ſulphur; according to Pelletier, of 85 parts of tin and 15 of ſulphur §.

Sulphur likewiſe combines with the white oxide of tin, by mixing them together, and applying a gentle heat ‖. This compound has been called *aurum muſivum*. It is a maſs conſiſting of beautiful gold-coloured flakes, and is uſed as a paint. It is compoſed of about 40 parts of ſulphur and 60 of white oxide of tin ¶. The proceſs for making this ſubſtance was formerly very complicated. Pelletier firſt demonſtrated its real compoſition, and was hence enabled to make many important improvements in the manner of manufacturing it *.

121 Phoſphuret, Phoſphorus is eaſily combined with tin, by melting in a crucible equal parts of filings of tin and phoſphoric glaſs. Tin has a greater affinity for oxygen than phoſphorus has. Part of the metal therefore combines with the

the oxygen of the glaſs during the fuſion, and flies off in the ſtate of an oxide, and the reſt of the tin combines with the phoſphorus. The phoſphuret of tin may be cut with a knife; it extends under the hammer, but ſeparates in laminæ. When newly cut it has the colour of ſilver; its filings reſemble thoſe of lead. When theſe filings are thrown on burning coals, the phoſphorus takes fire. This phoſphuret may likewiſe be formed by dropping phoſphorus gradually into melted tin. According to Pelletier, to whoſe experiments we are indebted for the knowledge of all the phoſphurets, it is compoſed of about 85 parts of tin and 15 of phoſphorus*. Margraf alſo formed this phoſphuret, but he was ignorant of its compoſition.

122 Alloys, Tin does not ſeem capable of combining with carbon. It is capable of combining with moſt of the metals.

1. It mixes readily with gold by fuſion; but the proportions in which theſe metals combine chemically are ſtill unknown. When one part of tin and twelve of gold are melted together, the alloy is brittle, hard, and bad coloured. Twenty-four parts of gold and one of tin produce a pale coloured alloy, harder than gold, but poſſeſſed of conſiderable ductility. Gold alloyed with no more than $\frac{1}{57}$th of tin is ſcarcely altered in its properties, according to Mr Alchorne†; but Mr Tillet, who has lately examined this alloy, found, that whenever it was heated it broke into a number of pieces.

2. The alloy of ſilver and tin is hardly known. According to Gellert and ſucceeding chemiſts, it is exceedingly brittle.

3. The alloy of platinum and tin is very fuſible and brittle, at leaſt when theſe metals are mixed in equal proportions‡.

4. Mercury diſſolves tin very readily, by being poured on it when melted. This amalgam cryſtallizes in the form of cubes, according to Daubenton; but, according to Sage, in grey brilliant ſquare plates, thin towards the edges, and attached to each other ſo that the cavities between them are polygonal. It is compoſed of three parts of mercury and one of tin. The amalgam of tin is uſed to ſilver the backs of glaſs mirrors.

5. Tin unites very readily with copper, and forms alloys known by the names of *bronze* and *bell-metal*. The proportions of the ingredients cannot eaſily be aſſigned, perhaps becauſe the alloy has an affinity both for copper and tin. The ſpecific gravity of the alloy in all proportions is greater than the mean ſpecific gravity of the two metals ſeparately. When the quantity of tin is ſmall compared to that of the copper, $\frac{1}{10}$th for inſtance, the alloy is called *bronze*: it is brittle, yellow, and much heavier than copper; much more fuſible, and leſs liable to be altered by expoſure to the air. It was this alloy which the ancients uſed for ſharp-edged inſtruments before the method of working iron was brought to perfection. The *χαλκος* of the Greeks, and perhaps the *æs* of the Romans, was nothing elſe. Even their copper coins contain a mixture of tin§.

6. Tin ſeems capable of being united to iron by fuſion. That there is an affinity between theſe metals is evident from their adheſion when iron is dipt into melted tin. This is the method of making *tinplate*.

123 And affinities of tin. The affinities of tin, according to Bergman, are as follows:

Zinc,
Mercury,
Copper,
Antimony,
Gold,
Silver,
Lead,
Iron,
Manganeſe,
Nickel,
Arſenic,
Platinum,
Biſmuth,
Cobalt,
Sulphuret of alkali,
Oxygen?
Sulphur?
Phoſphorus?

Sect. VIII. *Of Lead.*

Lead appears to have been very early known. It is mentioned ſeveral times by Moſes. The ancients ſeem to have conſidered it as nearly related to tin.

124 Properties of lead. Lead is of a bluiſh white colour, ſomewhat darker than tin. When newly melted it is very bright, but ſoon becomes tarniſhed by expoſure to the air. It has ſcarcely any taſte, but emits on friction a peculiar ſmell.

It is very malleable, and may be reduced to thin plates by the hammer; but its ductility is very imperfect: a wire of lead $\frac{1}{10}$th of an inch in diameter is only capable of ſupporting a weight of $29\frac{1}{4}$ pounds*. Its hardneſs is 5†; its ſpecific gravity is 11,3523‡. Its ſpecific gravity is not increaſed by hammering, neither does it become harder, as is the caſe with other metals: a proof that the hardneſs which metals aſſume under the hammer is in conſequence of an increaſe of denſity.

It melts, according to Dr Lewis, at 540° Fahrenheit; according to the Dijon academicians, at 549°. When expoſed to a violent heat it evaporates completely.

When cooled ſlowly, after being fuſed, it cryſtallizes. The Abbé Mongez obtained it in quadrangular pyramids, lying on one of their ſides. Each pyramid was compoſed as it were of three layers. Pajot obtained it in the form of a polyhedron with 32 ſides, formed by the concourſe of ſix quadrangular pyramids§.

Lead ſtains paper or the fingers of a bluiſh black colour.

125 Its oxides. There is a ſtrong affinity between this metal and oxygen. When nitric acid is poured upon it, an efferveſcence enſues, owing to the decompoſition of the acid; the lead ſeizes oxygen from it, and is converted into a white powder, which may be obtained pure by evaporating it to dryneſs, and then waſhing it in pure water. This is the *white oxide of lead*. It is compoſed of about 95 parts of lead and five of oxygen‖. The affinities of this oxide are, according to Bergman, as follows:

Sulphuric acid,
Sebacic,
Saccholactic,
Oxalic,
Arſenic,
Tartarous,
Phoſphoric,
Muriatic,

Benzoic,

---

Benzoic (u)?
Sulphurous,
Suberic? } (*v*)
Zoonic? }
Nitric,
Pyromucous (v)?
Fluoric,
Citric,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic,
Fixed alkali.

When lead is expoſed to heat in contact with air, its ſurface is ſoon covered with a grey pellicle; when this is taken off, another ſoon forms: and in this manner the whole lead may ſoon be converted into a dirty grey powder, which ſeems to be the white oxide mixed with a little lead. When this powder is heated red hot, it aſſumes a deep yellow colour. This is the *yellow oxide* of lead, formerly called *maſſicot*. If the heat be continued, the colour is gradually changed to a beautiful red. This is the *red oxide of lead*, formerly called *minium*. It is compoſed, as Lavoiſier has ſhewn, of 88 parts of lead and 12 of oxygen *.

* *Mem. Par.* 1781.

The manner in which theſe changes are brought about is evident; the metal gradually abſorbs oxygen from the atmoſphere. This has been actually proved by experiment. Theſe oxides (if they really differ in the proportion of oxygen) reſemble acids in ſeveral of their properties. They are very eaſily converted into glaſs by fuſion. Scheele has ſhewn that there is alſo a *brown oxide of lead*, which contains more oxygen than any of the others.

126 Sulphuret,

Sulphur unites eaſily to lead by fuſion. The ſulphuret of lead is brittle, of a deep grey colour, and much leſs fuſible than lead. Theſe two ſubſtances are often found naturally combined; the compound is then called *galena*. Sulphuret of lead is compoſed, according to the experiments of Wenzel, of 868 parts of lead and 132 of ſulphur †.

† *Kirwan's Miner.* ii. 492.

127 Phoſphuret,

Phoſphuret of lead may be formed by mixing together equal parts of filings of lead and phoſphoric glaſs, and fuſing them in a crucible. It may be cut with a knife, but ſeparates into plates when hammered. It is of a white ſilver colour with a ſhade of blue, but it ſoon tarniſhes when expoſed to the air. This phoſphuret may alſo be formed by dropping phoſphorus into melted lead. It is compoſed of about 12 parts of phoſphorus and 88 of lead ‡.

‡ *Pelletier, Ann. de Chim.* xiii. 114.

128 Alloys, and

Lead combines with moſt of the other metals.

1. Little is known concerning the alloy of lead and gold. It is ſaid to be brittle.

2. The alloy of ſilver and lead is very fuſible, and neither elaſtic nor ſonorous.

3. Platinum and lead unite in a ſtrong heat: the alloy is brittle, of a purpliſh colour, and ſoon changes on expoſure to the air *.

* *Fourcroy.*

4. Mercury, when poured upon melted lead, diſſolves it readily. The amalgam is white and brilliant, and aſſumes a ſolid form. It is capable of cryſtallizing. The cryſtals are compoſed of one part of lead and one and a half of mercury †.

† *Dijon Academicians.*

5. Copper and lead combine eaſily by fuſion; but the alloy has not been applied to any uſe.

6. Iron does not unite with lead.

7. Lead and tin may be combined by fuſion. The alloy in the proportion of two parts of lead and one of tin is more ſoluble than either of the metals ſeparately. It is accordingly uſed by plumbers as a ſolder.

129 Affinities.

Lead, when taken internally, acts as a poiſon. Its affinities, according to Bergman, are as follows:

Gold,
Silver,
Copper,
Mercury,
Biſmuth,
Tin,
Antimony,
Platinum,
Arſenic,
Zinc,
Nickel,
Iron,
Sulphuret of alkali,
Sulphur,
Phoſphorus?

130 Names and marks given to the metals by the ancients.

The ancients gave to the ſeven metals laſt deſcribed (omitting *platinum*, which they did not know) the names of the planets, and denoted each of them by particular marks, which repreſented both the planet and the metal.

Gold was the Sun, and repreſented by ☉.
Silver the Moon, ☽.
Mercury Mercury, ☿.
Copper Venus, ♀.
Iron Mars, ♂.
Tin Jupiter, ♃.
Lead Saturn, ♄.

It ſeems moſt probable that theſe names were firſt given to the planets; and that the ſeven metals, the only ones then known, were ſuppoſed to have ſome relation to the planets or to the gods that inhabited them, as the number of both happened to be the ſame. It appears from a paſſage in Origen, that theſe names firſt aroſe among the Perſians (w). Why each particular metal was denominated by a particular planet it is not eaſy to ſee. Many conjectures have been made, but ſcarcely any of them are ſatisfactory.

As

(u) Benzoat of lead is decompoſed by muriatic acid. *Trommſdorf, Ann. de Chim.* xi. 317.

(*v*) Suberic acid decompoſes nitrat of lead. See *Jameſon's Mineralogy*, p. 166. Zoonic acid produces the ſame effect, as Berthollet has obſerved.

(v) Schrickel places it after the three mineral acids.

(w) *Contra Celſum*, lib vi. 22.—" Celſus de quibuſdam Perſarum myſteriis ſermonem facit. Harum rerum, inquit, aliquod reperitur in Perſarum doctrina Mithraciſque eorum myſteriis veſtigium. In illis enim duæ cæleſtes converſiones, alia ſtellarum fixarum, errantium alia, et animæ per eas tranſitus quodam ſymbolo repræſentantur, quod hujuſmodi eſt. Scala altas portas habens, in ſumma autem octava porta. Prima portarum plumbea, altera ſtannea, Lead.

131 Origin of theſe marks according to the aſtrologers;

As to the characters by which theſe metals were expreſſed, aſtrologers ſeem to have conſidered them as the attributes of the deities of the ſame name. The circle in the earlieſt periods among the Egyptians was the ſymbol of divinity and perfection; and ſeems with great propriety to have been choſen by them as the character of the ſun, eſpecially as, when ſurrounded by ſmall ſtrokes projecting from its circumference, it may form ſome repreſentation of the emiſſion of rays. The ſemicircle is, in like manner, the image of the moon; the only one of the heavenly bodies that appears under that form to the naked eye. The character ♄ is ſuppoſed to repreſent the ſcythe of Saturn; ♃ the thunderbolts of Jupiter; ♂ the lance of Mars, together with his ſhield; ♀ the looking-glaſs of Venus; and ☿ the caduceus or wand of Mercury.

132 According to the alchymiſts.

The alchymiſts, however, give a very different account of theſe ſymbols. Gold was the moſt perfect metal, and was therefore denoted by a circle. Silver approached neareſt it; but as it was inferior, it was denoted only by a ſemicircle. In the character ☿ the adepts diſcovered gold with a ſilver colour. The croſs at the bottom expreſſed the preſence of a myſterious ſomething, without which mercury would be ſilver or gold. This ſomething is combined alſo with copper; the poſſible change of which into gold is expreſſed by the character ♀. The character ♂ declares the like honourable affinity alſo; though the ſemicircle is applied in a more concealed manner: for, according to the propereſt mode of writing, the point is wanting at the top, or the upright line ought only to touch the horizontal, and not to interſect it. Philoſophical gold is concealed in ſteel; and on this account it produces ſuch valuable medicines. Of tin, one half is ſilver, and the other conſiſts of the unknown ſomething; for this reaſon the croſs with the half moon appears in ♃. In lead this ſomething is predominant, and a ſimilitude is obſerved in it to ſilver. Hence in its character ♄ the croſs ſtands at the top, and the ſilver character is only ſuſpended on the right hand behind it.

133 Their real origin.

The fact, however, according to Profeſſor Beckmann, from whom moſt of the above remarks have been taken, ſeems to be, that theſe characters are mere abbreviations of the old names of the planets. "The character of Mars (he obſerves*), according to the oldeſt mode of repreſenting it, is evidently an abbreviation of the word Θουρος, under which the Greek mathematicians underſtood that deity; or, in other words, the firſt letter Θ, with the laſt letter ς placed above it. The character of Jupiter was originally the initial letter of Ζευς; and in the oldeſt manuſcripts of the mathematical and aſtrological works of Julius Firmicus, the capital Z only is uſed, to which the laſt letter ς was afterwards added at the bottom, to render the abbreviation more diſtinct. The ſuppoſed looking-glaſs of Venus is nothing elſe than the initial letter diſtorted a little of the word Φωσφορος, which was the name of that goddeſs. The imaginary ſcythe of Saturn has been gradually formed from the two firſt letters of his name Κρονος, which tranſcribers, for the ſake of diſpatch, made always more convenient for uſe, but at the ſame time leſs perceptible. To diſcover in the pretended caduceus of Mercury the initial letter of his Greek name Στιλβων, one needs only look at the abbreviations in the oldeſt manuſcripts, where they will find that the Σ was once written as C; they will remark alſo, that tranſcribers, to diſtinguiſh this abbreviation from the reſt ſtill more, placed the C thus Ɔ, and added under it the next letter τ. If thoſe to whom this deduction appears improbable will only take the trouble to look at other Greek abbreviations, they will find many that differ ſtill farther from the original letters they expreſs than the preſent character ☿ from the C and τ united. It is poſſible alſo that later tranſcribers, to whom the origin of this abbreviation was not known, may have endeavoured to give it a greater reſemblance to the caduceus of mercury. In ſhort, it cannot be denied that many other aſtronomical characters are real ſymbols, or a kind of proper hieroglyphics, that repreſent certain attributes or circumſtances, like the characters of Aries, Leo, and others quoted by Saumaiſe."

* Hiſtory of Inventions, Engliſh tranſlation, iii. 67.

SECT. IX. *Of Zinc.*

Zinc.

134 Diſcovery of zinc.

THE ancients were acquainted with a mineral to which they gave the name of *Cadmea*, from Cadmus, who firſt taught the Greeks to uſe it. They knew that when melted with copper it formed braſs; and that when burnt, a white ſpongy kind of aſhes was volatiliſed, which they uſed in medicine*. This mineral contained a good deal of zinc; and yet there is no proof remaining that the ancients were acquainted with that metal (x). It is firſt mentioned in the writings of Albertus Magnus, who died in 1280: but whether he had ſeen it is not ſo clear, as he gives it the name of *marcaſite of gold*, which implies, one would think, that it had

* Pliny, l. 34. c. 2. and 10.

ſtannea; tertia ex ære, quarta ferrea, quinta ex ære mixto, ſexta argentea, ſeptima ex auro. Κλιμαξ ὑψιπυλος, επι δ'αιτη πυλη ογδοη. Ἡ πρωτη των πυλων μολιβδου, ἡ δευτερα κασσιτερου, ἡ τριτη χαλκου, ἡ τεταρτη σιδηρου, ἡ πεμπτη κεραστου νομισματος, ἡ ἑκτη αργυρου, χρυσου δ' ἡ ἑβδομη. Primum aſſignant Saturno tarditatem illius ſideris plumbo indicantes: alteram Veneri, quam referunt, ut ipſi quidem putant, ſtanni ſplendor et mollities; tertiam Jovi, aheneam illam quidem et ſolidam: quartam Mercurio, quia Mercurius et ferrum, uterque operum omnium tolerantes, ad mercaturam utiles, laborum patientiſſimi. Marti quintam, inæqualem illam et variam propter mixturam. Sextam, quæ argentea eſt, lunæ; ſeptimam auream ſoli tribuunt, quia ſolis et lunæ colores hæc duo metalla referunt."

Borrichius ſuſpects, with a good deal of probability, that the names of the gods in this paſſage have been tranſpoſed by tranſcribers, either through ignorance or deſign. He arranges them as follows: "Secundam portam faciunt Jovis, comparantes ei ſtanni ſplendorem et mollitiem; tertiam Veneris æratam et ſolidam; quartam Martis, eſt enim laborum patiens, æque ac ferrum, celebratus hominibus; quintam Mercurii propter miſturam inæqualem ac variam, et quia negotiator eſt; ſextam Lunæ argenteam; ſeptimam Solis auream." *Ol. Borrichius de ortu et progreſſu chemiæ.* Hafniæ, 1668, 4to, p. 29.

(x) Grignon indeed ſays, that ſomething like it was diſcovered in the ruins of an ancient Roman city in Champagne; but the ſubſtance which he took for it was not examined with any accuracy. It is impoſſible therefore to draw any inference whatever from his aſſertion. *Bulletin des fouilles d'une ville Romaine*, p. 11.

had a yellow colour (Y). The word *zinc* occurs firſt in the writings of Paracelſus, who died in 1541. He informs us very gravely, that it is a metal, and not a metal, and that it conſiſts chiefly of the aſhes of copper *. This metal has alſo been called *ſpelter*.

Zinc has never been found in Europe in a ſtate of purity, and it was long before a method was diſcovered of extracting it from its ore (Z). Henkel pointed out one in 1721, and Von Swab obtained it by diſtillation in 1742, and Margraf publiſhed a proceſs in the Berlin Memoirs in 1746 †.

135 Properties of zinc.

It is of a bluiſh white colour, ſomewhat lighter than lead. It has neither taſte nor ſmell.

It has ſome degree of malleability; for by compreſſion it may be reduced into thin plates ‡; but it cannot be drawn out into wire. It is more brittle when hot than when cold.

Its hardneſs is 6 §. Its ſpecific gravity, when compreſſed, is 7,1908 ‖; in its uſual ſtate, 6,862 ¶. It melts at about 699° Fahrenheit *.

When allowed to cool ſlowly, it cryſtallizes in ſmall bundles of quadrangular priſms, diſpoſed in all directions. If they are expoſed to the air while hot, they aſſume a blue changeable colour †.

136 Its oxides,

When zinc is kept melted in contact with air, it becomes covered with a grey pellicle, which gradually aſſumes a yellowiſh tint. By removing this pellicle from time to time, the whole of the metal may be reduced into a grey powder. This is the *grey oxide of zinc*. This oxide is probably compoſed of about 85 parts of zinc and 15 of oxygen ‡. When zinc is violently heated, it burns with a bright white flame, and at the ſame time a quantity of very light white flakes are ſublimed. Theſe flakes are the *white oxide of zinc*, which contains a good deal more oxygen than the grey oxide (A).

Zinc may alſo be oxidated by ſolution in acids, particularly the nitric acid. Whether the oxide obtained by precipitating zinc from its ſolution in that acid, or by diſtilling that acid off zinc, be really different from the white oxide, has not yet been properly aſcertained; but one would be apt to ſuſpect, from the experiments mentioned by Mr Kirwan, that it contained a good deal more oxygen *.

The affinities of the oxides, or rather of the white oxide of zinc, are, according to Bergman, as follows:

Oxalic acid,
Sulphuric,
Pyromucous †,
Muriatic,
Saccholactic,
Nitric,
Sebacic,
Tartaric,
Phoſphoric,
Citric,
Succinic,
Fluoric,
Arſenic,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic,
Ammonia.

137 Sulphuret,

There is an affinity between ſulphur and zinc, as is evident from theſe two ſubſtances being often found united; but it is very difficult to form the ſulphuret of zinc artificially, on account of the rapid oxidation and conſequent volatilization of the zinc. Morveau, however, ſucceeded in forming it.

138 Phoſphurets,

Zinc may be combined with phoſphorus, by dropping ſmall bits of phoſphorus into it while in a ſtate of fuſion. Pelletier, to whom we are indebted for the experiment, added alſo a little reſin, to prevent the oxidation of the zinc. Phoſphuret of zinc is of a white colour, a metallic ſplendor, but reſembles lead more than zinc. It is ſomewhat malleable. When hammered or filed, it emits the odour of phoſphorus. When expoſed to a ſtrong heat, it burns like zinc ‡.

Phoſphorus

(Y) The paſſages in which he mentions it are as follows:—*De Mineral.* lib. ii. cap. 11. "Marchaſita, ſive marchaſida ut quidam dicunt, eſt lapis in ſubſtantia, et habet multas ſpecies, quare colorem accipit cujuſlibet metalli, et ſic dicitur marchaſita argentea et aurea, et ſic dicitur aliis. Metallum tamen quod colorat cum non diſtillat ab ipſo, ſed evaporat in ignem, et ſic relinquitur cinis inutilis, et hic lapis notus eſt apud alchimicos, et in multis locis veniuntur.

Lib. iii. cap. 10. "Æs autem invenitur in venis lapidis, et quod eſt apud locum qui dicitur Goſelaria eſt puriſſimum et optimum, et toti ſubſtantiæ lapidis incorporatum, ita quod totus lapis eſt ſicut marchaſita aurea, et profundatum eſt melius ex eo quod purius.

Lib. v. cap. 5. "Dicimus igitur quod marchaſita duplicem habet in ſui creatione ſubſtantiam, argenti vivi ſcilicet mortificati, et ad fixionem approximantis, et ſulphuris adurentis. Ipſam habere ſulphureitatem comperimus manifeſta experientia. Nam cum ſublimatur, ex illa emanat ſubſtantia ſulphurea manifeſta comburens. Et ſine ſublimatione ſimiliter perpenditur illius ſulphureitas.

"Nam ſi ponatur ad ignitionem, non ſuſcipit illam priuſquam inflammatione ſulphuris inflammetur, et ardeat. Ipſam vero argenti vivi ſubſtantiam manifeſtatur habere ſenſibiliter. Nam albedinem præſtat Veneri meri argenti, quemadmodum et ipſum argentum vivum, et colorem in ipſius ſublimatione cæleſtium præſtare, et luciditatem manifeſtam metallicam habere vidimus, quæ certum reddunt artificem Alchimiæ, illam has ſubſtantias continere in radice ſua."

(Z) The real diſcoverer of this method appears to have been Dr Iſaac Lawſon. See *Pott*, III. Diſſ. 7. and *Watſon's Chemical Eſſays*.

(A) Pott obſerved, that it was $\frac{1}{10}$th heavier than the zinc from which it was obtained; and Mr Boyle had long before aſcertained the ſame fact.—*Shaw's Boyle*, II. 391, 394.

This oxide of zinc was well known to the ancients. Dioſcorides deſcribes the method of preparing it. The ancients called it *pompholyx*, the early chemiſts gave it the name of *lana philoſophica*. Dioſcorides compares it to wool, εριων τολυπαις αφομοιονται, v. 85. p. 352.

Phoſphorus combines alſo with the oxide of zinc, a compound which Margraf had obtained during his experiments on phoſphorus. When 12 parts of oxide of zinc, 12 parts of phoſphoric glaſs, and two parts of charcoal powder, are diſtilled in an earthen ware retort, and a ſtrong heat applied, a metallic ſubſtance ſublimes of a ſilver-white colour, which, when broken, has a vitreous appearance. This, according to Pelletier, is phoſphuret of oxide of zinc. When heated by the blowpipe, the phoſphorus burns, and leaves behind a glaſs tranſparent while in fuſion, but opaque after cooling*.

* *Pelletier, ibid.* 128.

139
Carburet,

Zinc alſo combines with carbon, and forms carburet of zinc. The French chemiſts have ſhewn that zinc generally contains ſome carbon.

140
Alloys,

Zinc combines with moſt of the metals:

1. It mixes with gold in any proportion. The alloy is the whiter and the more brittle the greater quantity of zinc it contains. An alloy, conſiſting of equal parts of theſe metals, is very hard and white, receives a fine poliſh, and does not tarniſh readily. It has therefore been propoſed by Mr Malouin† as very proper for the ſpecula of teleſcopes. One part of zinc is ſaid to deſtroy the ductility of 100 parts of gold ‡.

† *Mem. Acad. Par.* 1742.
‡ *Keir's Macquer's Dictionary.*

2. The alloy of ſilver and zinc is eaſily produced by fuſion. It is brittle.

3. Platinum combines very readily with zinc. The alloy is brittle, pretty hard, very fuſible, and of a bluiſh white colour, not ſo clear as that of zinc §.

§ *Dr Lewis.*

4. Zinc may be combined with mercury by fuſion. The amalgam is ſolid. It cryſtallizes when melted and cooled ſlowly into lamellated hexagonal figures, with cavities between them. They are compoſed of one part of zinc and two and a half of mercury ‖. It is uſed to rub on electrical machines, in order to excite electricity.

‖ *Elemens de Chim. Dijon,* t. 3.

5. Zinc combines very readily with copper. This alloy, which is called *braſs*, was known to the ancients. They uſed an ore of zinc to form it, which they called *cadmia*. This alloy was very much valued by the ancients. Dr Watſon has proved that it was to braſs which they gave the name of *orichalcum* ¶. Their *æs* was copper or rather bronze (B). Braſs is compoſed of about three parts of copper and one of zinc. It is of a beautiful yellow colour, more fuſible than copper, and not ſo apt to tarniſh. It is malleable, and ſo ductile that it may be drawn out into wire. When the alloy contains three parts of zinc and four of copper, it aſſumes a colour nearly the ſame with gold, but it is not ſo malleable as braſs. It is then called *pinchbeck*, *prince's metal*, or *Prince Rupert's metal*.

¶ *Mancheſter Tranſ.* vol. ii.

6. The alloy of iron and zinc has ſcarcely been examined: but Malouin has ſhewn that zinc may be uſed inſtead of tin to cover iron plates; a proof that there is an affinity between the two metals*.

* *Mem. Par.* 1742.

7. Tin and zinc combine eaſily. The alloy is harder than tin. This alloy is often the principal ingredient in the compound called *pewter*.

8. Mr Gmelin has ſucceeded in forming an alloy of zinc and lead by fuſion. He put ſome ſuet into the mixture, and covered the crucible, in order to prevent the evaporation of the zinc. When the zinc exceeded the lead very much, the alloy was malleable, and much harder than lead. A mixture of two parts of zinc and one of lead formed an alloy more ductile and harder than the laſt. A mixture of equal parts of zinc and lead formed an alloy differing little in ductility and colour from lead; but it was harder, and more ſuſceptible of poliſh, and much more ſonorous. When the mixture contained a ſmaller quantity of zinc, it ſtill approached nearer the ductility and colour of lead, but it continued harder, more ſonorous, and ſuſceptible of poliſh, till the proportions approached to one of zinc and 16 of lead, when the alloy differed from the laſt metal only in being ſomewhat harder†.

† *Ann. de Chim.* ix. 95.

141
And affinities.

The affinities of zinc, according to Bergman, are as follows:

Copper,
Antimony,
Tin,
Mercury,
Silver,
Gold,
Cobalt,
Arſenic,
Platinum,
Biſmuth,
Lead,
Nickel,
Iron.

Sect. X. *Of Antimony.*

The ancients were acquainted with an oxide of antimony to which they gave the names of στιμμι and *ſtibium*. Pliny ‡ informs us that it was found in ſilver ore; and we know that at preſent there are ſilver ores § in which it is contained. It was uſed as an external application to ſore eyes; and Pliny gives us the method of preparing it ‖. Galen ſuppoſes that the τετραγωνον of Hippocrates was a preparation of antimony; but this wants proof. It does not appear, however, that the ancients conſidered this ſubſtance as a metal, or that they knew antimony in a ſtate of purity (C). Who firſt extracted it from its ore we do not know; but Baſil Valentine, a chemiſt of the 16th century, is the firſt who deſcribes the proceſs.

‡ *Pliny*, l. xxxiii. c. 6.
§ *Kirwan's Miner.* ii. 110.
‖ *Pliny, ibid.*

142
Diſcovery of Antimony.

(B) The ancients do not ſeem to have known accurately the difference between copper, braſs, and bronze. Hence the confuſion obſervable in their names. They conſidered braſs as only a more valuable kind of copper, and therefore often uſed the word *æs* indifferently to denote either. It was not till a late period that mineralogiſts began to make the diſtinction. They called copper *æs cyprium*, and afterwards only *cyprium*, which in proceſs of time was converted into *cuprum*. When theſe changes took place is not known accurately. Pliny uſes *cyprium*, lib. xxxvi. c. 26. The word *cuprum* occurs firſt in Spartian, who lived about the year 290. He ſays in his life of Caracalla, *cancelli ex ære vel cupro*.

(C) Mr Roux indeed, who at the requeſt of Count Caylus analyſed an ancient mirror, found it compoſed of copper, lead, and antimony. This would go far to convince us that the ancients knew this metal, provided it could be proved that the mirror was *really* an ancient one; but this point appears to be extremely doubtful.

proceſs. To him indeed we are indebted for our acquaintance with many of the properties of this metal.

Antimony is of a white colour, with a ſhade of grey. It has a ſenſible taſte, but no ſmell *.

* Fourcroy.

143 Properties of antimony.

It is neither malleable nor ductile, but exceedingly brittle. Its ſpecific gravity, according to Briſſon, is 6,702; according to Bergman, 6,860. Its hardneſs is 6,5 †. It melts at 809° Fahrenheit ‡. If after this the heat be increaſed, the metal evaporates. On cooling it aſſumes the form of oblong cryſtals, perpendicular to the internal ſurface of the veſſel in which it cools. It is to this cryſtallization that the laminated ſtructure which antimony always aſſumes is owing.

† Kirwan's Miner. ii. 244.
‡ Bergman.

Neither air nor water have much effect on this metal.

144 Its oxides.

When antimony is beat to powder, and expoſed for ſome time to a gentle heat, it abſorbs oxygen, and is converted into a grey powder. This is the *grey oxide of antimony*. When this metal is kept for ſome time melted in contact with air, it ſublimes in the form of a white powder, formerly called *ſnow* or *white flowers of antimony*. This is the *white oxide of antimony*. This oxide may be procured alſo by pouring nitric acid on antimomy, and then evaporating to dryneſs. Antimony attracts the oxygen from the acid, and thus paſſes very rapidly into the ſtate of an oxide. This oxide ſeems to conſiſt of about 77 parts of antimony and 23 of oxygen §. The nature of theſe oxides has never yet been accurately inquired into. It is not even known at preſent whether the white oxide obtained by heat and that obtained by nitric acid contain the ſame quantity of oxygen. The experiments mentioned by Mr Kirwan make the contrary probable ‖; and yet theſe oxides have too many qualities in common to render theſe experiments concluſive. The white oxide of antimony is ſoluble in water ¶; and when fuſed, is converted into a tranſparent glaſs. The white oxide obtained by nitric acid ſeems to poſſeſs many of the properties of an acid.

§ Kirwan's Miner. ii. 489.
‖ Ibid.
¶ Rouelle.

The affinities of the grey oxide of antimony are, according to Bergman, as follows:

Sebacic acid,
Muriatic,
Benzoic (D)?
Oxalic,
Sulphuric,
Pyromucous *,
Nitric,
Tartarous,
Saccholactic,
Phoſphoric,
Citric,
Succinic,
Fluoric,
Arſenic,
Formic,
Lactic,
Acetous,
Boracic,
Pruſſic,
Carbonic.

* Schrickel.

145 Sulphurets,

Sulphur combines readily with antimony. This compound is often found native: it was formerly called antimony, and the pure metal was then called *regulus of antimony*. Sulphuret of antimony is eaſily melted by a moderate heat: if the heat be continued, the ſulphur ſublimes, and at the ſame time the antimony abſorbs oxygen, and is converted into a grey oxide. This ſulphuret is compoſed of 74 parts of antimony and 26 of ſulphur *.

* Bergman, iii. 167.

The grey oxide of antimony is alſo capable of combining with about $\frac{4}{100}$ of ſulphur. This compound, by fuſion, may be converted into glaſs. It was formerly uſed in medicine under the name of *glaſs of antimony*.

146 Phoſphuret,

When equal parts of antimony and phoſphoric glaſs are mixed together with a little charcoal powder, and melted in a crucible, phoſphuret of antimony is produced. It is of a white colour, brittle, appears laminated when broken, and at the fracture there appear a number of ſmall cubic facettes. When melted it emits a green flame, and then ſublimes in the form of a white powder. Phoſphuret of antimony may likewiſe be prepared by fuſing equal parts of antimony and phoſphoric glaſs, or by dropping phoſphorus into melted antimony †.

† Pelletier, Ann. de Chim. xiii. 132.

Antimony is capable of combining with moſt of the metals

147 Alloys,

1. Gold may be alloyed with antimony by fuſing them together. The antimony is afterwards ſeparable by an intenſe heat. This alloy is little known, and has never been applied to any uſe.

2. The alloy of ſilver and antimony is brittle, and its ſpecific gravity, as Gellert has obſerved, is greater than intermediate between the ſpecific gravities of the two metals which enter into it.

3. Platinum eaſily combines with antimony. The alloy is brittle, and much lighter than platinum ‡. The antimony cannot afterwards be completely ſeparated by heat.

4. Mercury does not eaſily combine with antimony. Mr Gellert ſucceeded in amalgamating this metal by putting it into hot mercury, and covering the whole with water.

5. Copper combines readily with antimony by fuſion. The alloy is of a beautiful violet colour, and its ſpecific gravity is greater than intermediate §.

6. Iron combines with antimony, and forms a brittle hard alloy, the ſpecific gravity of which is leſs than intermediate. The magnetic quality of iron is much more diminiſhed by being alloyed with antimony than with any other metal ‖.

7. The alloy of tin and antimony is white and brittle; its ſpecific gravity is leſs than intermediate ¶.

8. When equal quantities of lead and antimony are fuſed, the alloy is porous and brittle: three parts of lead and one of antimony form a compact alloy, malleable, and much harder than lead: 12 parts of lead and one of antimony form an alloy very malleable, and a good deal harder than lead: 16 parts of lead and one of antimony form an alloy which does not differ from lead except in hardneſs *. This alloy forms printers types.

9. Zinc and antimony form a brittle alloy, the ſpecific gravity of which is leſs than intermediate †. The alloys of antimony are little known. Gellert is almoſt the only perſon who has examined them. It would require a great number of experiments to be able to fix the proportions of their ingredients.

‡ Dr Lewis.

* Gmelin, Ann. de Chim. viii. 319.
† Gellert.

The

(D) Muriatic acid decompoſes benzoat of antimony. *Trommſdorf, Ann. de Chim.* xi. 317.

The affinities of antimony are, according to Bergman, as follows:

Iron,
Copper,
Tin,
Lead,
Nickel,
Silver,
Biſmuth,
Zinc,
Gold,
Platinum,
Mercury,
Arſenic,
Cobalt,
Sulphuret of arſenic,
Sulphur,
Phoſphorus?

SECT. XI. *Of Biſmuth.*

THE ancients appear to have known nothing of biſmuth, nor do we know who diſcovered it; but it is firſt mentioned by George Agricola, who was born about the end of the 15th century.

148 Properties of biſmuth.

Biſmuth is of a yellowiſh or reddiſh white colour, and almoſt deſtitute both of taſte and ſmell.

It is brittle. Its hardneſs is 6*. Its ſpecific gravity is 9,8227†. It melts at 460° Fahrenheit‡.

* *Kirwan.*
† *Briſſon.*
‡ *Lewis.*

When heated in cloſe veſſels, it ſublimes. When allowed to cool ſlowly after fuſion, it cryſtallizes.

Biſmuth is not altered by water. When expoſed to the air it ſoon tarniſhes.

149 Its oxides,

When biſmuth is kept fuſed in contact with air, it is gradually oxidated. When heated red hot, it emits a very faint blue flame, and its oxide evaporates in the form of a yellowiſh ſmoke. When this ſmoke is collected, it is found to conſiſt of a brown coloured powder. This is the *brown oxide of biſmuth*. It is compoſed of about 94 parts of biſmuth and 6 of oxygen§. Biſmuth decompoſes nitric acid with great rapidity, by attracting its oxygen. If the quantity of acid be conſiderable, it diſſolves the oxide as it forms; but the greater part of it may be precipitated by diluting the acid with water. This precipitate, which is a white powder, is *white oxide of biſmuth*. It is compoſed of about 84 parts biſmuth and 16 of oxygen‖.

§ *Kirwan's Miner.* ii. 489.
‖ *Ibid.*

The affinities of the oxides of biſmuth are, according to Bergman, as follows:

Oxalic acid,
Arſenic,
Tartarous,
Phoſphoric,
Sulphuric,
Sebacic,
Muriatic,
Benzoic (E)?
Nitric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Pruſſic,
Carbonic,
Ammonia.

150 Sulphuret,

Sulphur combines readily with biſmuth by fuſion. The ſulphuret of biſmuth is of a bluiſh grey colour, and cryſtallizes into beautiful tetrahedral needles. It is compoſed of 85 parts of biſmuth and 15 of ſulphur*.

* *Wenzel, Kirwan's Miner.* ii. 492.

151 Phoſphuret,

There appears to be little affinity between biſmuth and phoſphorus. Mr Pelletier attempted to produce the phoſphuret of biſmuth by various methods without ſucceſs. When he dropped phoſphorus, however, into biſmuth in fuſion, he obtained a ſubſtance which did not apparently differ from biſmuth, but which, when expoſed to the blow-pipe, gave evident ſigns of containing phoſphorus. Phoſphuret of biſmuth, according to Pelletier, is compoſed of about 96 parts of biſmuth and four of phoſphorus†.

† *Ann. de Chim.* xiii. 130.

152 Alloys,

Biſmuth combines readily with moſt of the metals.

1. Equal parts of biſmuth and gold form a brittle alloy, nearly of the ſame colour with biſmuth‡.

2. Equal parts of biſmuth and ſilver form alſo a brittle alloy, but leſs ſo than the laſt. The ſpecific gravity of both theſe is greater than intermediate§.

‡ *Keir, Macquer's Dict.*
§ *Ibid.*

3. The alloy of biſmuth and platinum is alſo very brittle. When expoſed to the air it aſſumes a purple, violet, or blue colour. The biſmuth may be ſeparated by heat‖.

‖ *Dr Lewis.*

4. Mercury diſſolves biſmuth very eaſily. The amalgam is more fluid than pure mercury, and has the property of diſſolving lead and rendering it alſo fluid¶. It is capable, however, of cryſtallizing. The cryſtals are either octahedrons, lamellated triangles, or hexagons. They are compoſed of one part of biſmuth and two of mercury*.

¶ *Cramer.*
* *Chim. Dijon,* i. 3.

5. The alloy of copper and biſmuth is not ſo red as copper.

6. Nothing is known concerning the alloy of iron and biſmuth.

7. Biſmuth and tin unite readily. A ſmall portion of biſmuth increaſes the brightneſs, hardneſs, and ſonorouſneſs of tin: it often therefore enters into the compoſition of the compound called *pewter*. Equal parts of tin and biſmuth form an alloy that melts at 280°: eight parts of tin and one of biſmuth, melt at 390°: two parts of tin and one of biſmuth, at 330°†.

† *Dr Lewis.*

8. The alloy of lead and biſmuth is of a dark grey colour, a cloſe grain, but very brittle.

9. Biſmuth does not combine with zinc.

10. The alloy of antimony and biſmuth is unknown.

Biſmuth likewiſe enters into triple compounds with metals: Two parts of lead, three of tin, and five of biſmuth, form an alloy which melts at the heat of boiling water, which is 212°.

153 And affinities.

The affinities of biſmuth, according to Bergman, are as follows:

Lead,
Silver,
Gold,

(E) Muriatic acid decompoſes benzoat of biſmuth.—*Trommſdorf, Ann. de Chim.* xi. 317.

Mercury,
Antimony,
Tin,
Copper,
Platinum,
Nickel,
Iron,
Sulphuret of alkali,
Sulphur,
Phoſphorus?

SECT XII. *Of Arſenic.*

THE word *arſenic* (αρσενικον) occurs firſt in the works of Dioſcorides, and of ſome other authors who wrote about the beginning of the Chriſtian era. It denotes in their works the ſame ſubſtance which Ariſtotle had called σανδαραχη (F), and his diſciple Theophraſtus αρσενικον, which is a reddiſh coloured mineral, compoſed of arſenic and ſulphur, uſed by the ancients in painting, and as a medicine.

The *white oxide of arſenic*, or what is known in commerce by the name of arſenic, is mentioned by Avicenna in the 11th century; but at what period the metal called *arſenic* was firſt extracted from that oxide is unknown. Paracelſus ſeems to have known it. It is mentioned by Schroeder in his Pharmacopœia publiſhed in 1649[*].

153 Properties of arſenic.

Arſenic, when pure, is of a bluiſh white colour. It is exceedingly brittle. Its hardneſs is 7[†]. Its ſpecific gravity 8,310[‡].

When expoſed to the temperature of 354° in cloſe veſſels it ſublimes[§], and cryſtallizes in regular tetrahedrons.

154 Its oxides.

It is not much altered by water. Boiling water, however, is capable of diſſolving, and retaining $\frac{1}{10000}$th of arſenic; but that part of the metal is no doubt reduced to the ſtate of an oxide[||].

When arſenic is expoſed to the open air, it very ſoon loſes its luſtre, and is gradually converted into a greyiſh black ſubſtance by combining with oxygen. This is called the *grey oxide of arſenic*.

When expoſed to a moderate heat in contact with air, it ſublimes in the form of a white powder, and at the ſame time emits a ſmell reſembling garlic. If the heat be increaſed, it burns with an obſcure bluiſh flame. This ſublimate is *white oxide of arſenic*, which is compoſed of 93 parts of arſenic and 7 of oxygen[¶].

It is of a ſharp acrid taſte, which at laſt leaves an impreſſion of ſweetneſs, and is one of the moſt virulent poiſons known. It has an alliacious ſmell. It is ſoluble in 80 parts of water at the temperature of 60°, and in 15 parts of boiling water[*]. When this ſolution is evaporated, the oxide cryſtallizes[†]. When heated to 283°, it ſublimes: if heat be applied in cloſe veſſels, it becomes pellucid like glaſs, but when expoſed to the air it ſoon recovers its former appearance. The ſpecific gravity of this glaſs is 5,000; that of the white oxide, 3,706[‡]. This oxide is capable of combining with moſt of the metals, and in general renders them brittle. Its affinities, according to Bergman, are as follows:

Muriatic acid,
Oxalic,
Sulphuric,
Nitric,
Sebacic,
Tartarous,
Phoſphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Arſenic,
Acetous,
Pruſſic,
Ammonia,
Water,
Alcohol?

Arſenic, or rather the white oxide of arſenic, is capable of combining with an additional doſe of oxygen. The compound produced is *arſenic acid*, firſt diſcovered by Scheele, which contains 91 parts of arſenic and 9 of oxygen[*].

155 Sulphuret.

Arſenic combines readily with ſulphur. When heat is applied to a mixture of white oxide of arſenic and ſulphur, the oxide is decompoſed, part of the ſulphur combines with its oxygen, and the remainder unites with the reduced metal. The ſulphuret of arſenic produced by this proceſs is of a yellow colour, and was formerly called *orpiment*. It is compoſed, according to Weſtrum, of 20 parts of arſenic and 80 of ſulphur[†]. It is often found native. If a ſtronger heat be applied, ſo as to melt the ſulphuret, it aſſumes a ſcarlet colour, and is much leſs volatile than formerly. This new compound was formerly called *realgar*. It is compoſed, according to Weſtrum, of 80 parts of arſenic and 20 of ſulphur[‡]. The difference therefore between it and orpiment is evident. During the fuſion part of the ſulphur without doubt ſublimes. It might be called *red ſulphuret of arſenic*.

156 Phoſphuret.

Arſenic combines readily with phoſphorus. The phoſphuret of arſenic may be formed by diſtilling equal parts of its ingredients over a moderate fire. It is black and brilliant, and ought to be preſerved in water. It may be formed likewiſe by putting equal parts of phoſphorus and arſenic into a ſufficient quantity of water, and keeping the mixture moderately hot for ſome time[§].

157 Alloys.

Arſenic unites with moſt metals, and in general renders them more brittle and more fuſible.

1. Melted gold takes up $\frac{1}{60}$th of arſenic[||]. The alloy is brittle and pale.

2. Melted ſilver takes up $\frac{1}{14}$th of arſenic[¶]. The alloy is brittle.

3. The alloy of platinum and arſenic is brittle and very fuſible. It was firſt formed by Scheffer. The arſenic may be ſeparated by heat.

4. The amalgam of arſenic is compoſed of five parts of mercury and one of arſenic[*].

5. Copper takes up $\frac{5}{6}$ths of arſenic[†]. This alloy is white;

(F) Pliny ſeems to make a diſtinction between ſandaracha and arſenic. See Lib. xxxiv. c. 18.

Cobalt

white; and when the quantity of arſenic contained in it is ſmall, both ductile and malleable [*]. It is called *white tombac*.

[*] Gellert.

6. Iron is capable of combining with more than its own weight of arſenic [†]. This alloy is white, brittle, and capable of cryſtallizing. It is found native [‡].

[†] Bergman, Ann. de Chim xiii. 139.

[‡] Kirwan's Miner. ii. 256.

7. The alloy of tin and arſenic is harder and more ſonorous than tin, and has much reſemblance externally to zinc. Tin often contains a ſmall quantity of arſenic.

8. Lead takes up $\frac{1}{6}$th of arſenic [§]. The alloy is brittle and dark coloured.

[§] Bergman, Ibid.

9. Zinc takes up $\frac{1}{5}$th of arſenic, antimony $\frac{1}{8}$th, and biſmuth $\frac{1}{15}$th [||].

[||] Ibid.

158
And affinities.

The affinities of arſenic, according to Bergman, are as follows:

Nickel,
Cobalt,
Copper,
Iron,
Silver,
Tin,
Gold,
Platinum,
Zinc,
Antimony,
Sulphuret of alkali,
Sulphur,
Phoſphorus.

Sect. XIII. *Of Cobalt.*

A MINERAL called *cobalt* (G), of a grey colour, and very heavy, has been uſed in different parts of Europe ſince the 15th century to tinge glaſs of a blue colour. From this mineral Brandt obtained in 1733 a new metal, to which he gave the name of *cobalt* [¶].

[¶] Act. Upſal. 1733.

159
Properties of cobalt,

Cobalt is of a white colour, inclining to a bluiſh or ſteel grey. When pure, it is ſomewhat malleable while red hot [*]. Its hardneſs is 8 [†]. Its ſpecific gravity is 8,15 (H). It requires for fuſion a heat at leaſt as great as caſt iron, which melts at 130° Wedgewood. No heat has been produced great enough to volatalize it [‡].

[*] Leonhardi.

[†] Kirwan's Miner. ii. 268.

[‡] Bergman, iv.

Cobalt, when pure, does not ſeem to be affected by air or water.

It is attracted by the magnet.

It is not oxidated by heat without very great difficulty; but it has the property of decompoſing nitric acid, and of attracting oxygen by that means with great rapidity.

160
Its oxides,

The *oxide of cobalt* is of ſo deep a blue as to appear black. The oxide procured by heat is compoſed of 88 parts of cobalt and 12 of oxygen; that by nitric acid contains about 77 parts of cobalt and 23 of oxygen [*]. Its affinities, according to Bergman, are as follows:

[*] Kirwan's Miner. ii. 268. 490.

Oxalic acid,
Muriatic,
Sulphuric,
Tartarous,
Nitric,
Sebacic,
Phoſphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Arſenic,
Boracic,
Pruſſic,
Carbonic,
Ammonia.

161
Sulphuret,

The *ſulphuret of cobalt* is not formed without difficulty. It is ſcarcely known.

162
Phoſphuret,

Phoſphuret of cobalt may be formed by heating the metal red hot, and then gradually dropping in ſmall bits of phoſphorus. It contains about $\frac{1}{15}$th of phoſphorus. It is white and brittle, and when expoſed to the air ſoon loſes its metallic luſtre. The phoſphorus is ſeparated by heat, and the cobalt is at the ſame time oxidated. This phoſphuret is much more fuſible than pure cobalt [†].

[†] Pelletier, Ann. de Chim. xiii. 134.

163
Alloys,

The combinations of cobalt with other metals have been very little examined into.

1. The alloy of gold and cobalt is not known.

2. Cobalt does not combine with ſilver by fuſion [‡]; but, according to Gellert, the alloy of ſilver and cobalt *may* be formed: it is brittle and of a grey colour [§]

3. The alloy of platinum and cobalt is unknown.

4. Mer-

[‡] Bergman's Elect. Attract

[§] Metallur. Chim.

(G) The word *cobalt* ſeems to be derived from *cobalus*, which was the name of a ſpirit that, according to the ſuperſtitious notions of the times, haunted mines, deſtroyed the labours of the miners, and often gave them a great deal of unneceſſary trouble. The miners probably gave this name to the mineral out of joke, becauſe it thwarted them as much as the ſuppoſed ſpirit, by exciting falſe hopes, and rendering their labour often fruitleſs; for as it was not known at firſt to what uſe the mineral could be applied, it was thrown aſide as uſeleſs. It was once cuſtomary in Germany to introduce into the church-ſervice a prayer that God would preſerve miners and their works from *kobalts* and ſpirits. See *Beckmann's Hiſtory of Inventions*, II. 362.

Matheſius, in his tenth ſermon, where he ſpeaks of *cadmia foſſilis* (probably cobalt ore), ſays, "Ye miners call it *kobolt;* the Germans call the black devil and the old devil's whores and hags, old and black *kobel*, which, by their witchcraft do injury to people and to their cattle."

Lehmann, Paw, Delaval, and ſeveral other philoſophers, have ſuppoſed that *ſmalt* (oxide of cobalt melted with glaſs and pounded) was known to the ancients, and uſed to tinge the beautiful blue glaſs ſtill viſible in ſome of their works; but we learn from Gmelin, who analyſed ſome of theſe pieces of glaſs, that they owed their *blue* colour, not to the preſence of *cobalt* but of *iron*.

According to Lehmann, cobalt ore was firſt uſed to tinge glaſs blue by Chriſtopher Schurer, a glaſs maker at Platten, about the year 1540.

(H) *Berg*. II. 231. According to Briſſon, 7,8119.

4. Mercury does not appear to amalgamate with cobalt.

5. The alloy of copper and cobalt is ſcarcely known.

6. The alloy of iron and cobalt is very hard, and not eaſily broken. Cobalt generally contains ſome iron, from which it is with great difficulty ſeparated.

7. The alloy of tin and cobalt is of a light violet colour.

8. Cobalt does not combine with lead by fuſion.

9. The alloy of zinc and cobalt is not formed without difficulty.

10. The alloy of antimony and cobalt is unknown.

11. Cobalt does not combine with biſmuth by fuſion *.

12. Arſenic combines very readily with cobalt. The alloy is brittle, much more fuſible, and more eaſily oxidated than pure cobalt †.

164 And affinities.

The affinities of cobalt are as follows:

Iron,
Nickel,
Arſenic,
Copper,
Gold,
Platinum,
Tin,
Antimony,
Zinc,
Sulphuret of alkali,
Sulphur,
Poſphorus?

Sect. XIV. *Of Nickel.*

A heavy mineral of a red colour is met with in ſeveral parts of Germany, which bears a ſtrong reſemblance to an ore of copper; but none of that metal can be extracted from it: for this reaſon the Germans called it *kupfer nickel* (devil's copper). Hierne mentioned it in 1694. Cronſtedt was the firſt chemiſt who examined it with accuracy. He concluded from his experiments, which were publiſhed in the Stockholm Tranſactions for 1751 and 1754, that it contained a new metal, to which he gave the name of *nickel*. — 165 Diſcovery of nickel,

Some chemiſts, particularly Mr Sage, affirmed, that it contained no new metal, but merely a compound of various known metals, which could be ſeparated from each other by the uſual proceſſes. Theſe aſſertions induced Bergman to undertake a very laborious courſe of experiments, in order if poſſible to obtain *nickel* in a ſtate of purity: for Cronſtedt had not been able to ſeparate a quantity of arſenic, cobalt, and iron, which adhered to it with much obſtinacy. Theſe experiments have been very fully detailed in the article Chemistry, in the *Encycl.* to which be beg leave to refer. Bergman has ſhewn, that nickel poſſeſſes peculiar properties, and that it can neither be reduced to any other metal, nor formed artificially by any combination of metals. It muſt therefore be conſidered as a peculiar metal. It may poſſibly be a compound, and ſo may likewiſe many other metals; but we muſt admit every thing to be a peculiar body which has peculiar properties, and we muſt admit every body to be ſimple till ſome proof be actually produced that it is a compound; otherwiſe we forſake the road of ſcience, and get into the regions of fancy and romance.

166 Its properties,

Nickel is of a greyiſh white colour, and when leſs pure inclines a little to red.

It is both ductile and malleable. Its hardneſs is 8 *. Its ſpecific gravity 9,000 †. It requires for fuſion a temperature at leaſt equal to 150° Wedgewood ‡.

It is powerfully attracted by the magnet, and is even poſſeſſed of the property of attracting iron. This induced Bergman to ſuppoſe that nickel, when pureſt, was ſtill contaminated with about one-third of iron: but as this is the only proof of its containing iron, Klaproth, with reaſon, deems it an inſufficient one, and conſiders attraction by the magnet as a property of nickel §.

167 Oxides,

When expoſed to a ſtrong heat, nickel is oxidated ſlowly. Its oxide is of a *brown* colour; if impure, it is *greeniſh*. The oxide of nickel, according to Klaproth, is compoſed of 77 parts of nickel and 23 of oxygen ¶. Its affinities, according to Bergman, are as follows:

Oxalic acid,
Muriatic,
Sulphuric,
Tartarous,
Nitric,
Sebacic,
Phoſphoric,
Fluoric,
Saccholactic,
Succinic,
Citric,
Formic,
Lactic,
Acetous,
Arſenic,
Boracic,
Pruſſic,
Carbonic,
Ammonia,
Potaſs?
Soda?

168 Sulphuret,

Cronſtedt found that nickel combined readily with ſulphur by fuſion. The ſulphuret which he obtained was yellow and hard, with ſmall ſparkling facets; but the nickel which he employed was impure.

169 Phoſphuret,

Nickel combines very readily with phoſphorus, either by fuſing it along with phoſphoric glaſs, or by dropping phoſphorus into it while red hot. The phoſphuret of nickel is of a white colour, and when broke exhibits the appearance of very ſlender priſms collected together. When heated, the phoſphorus burns, and the metal is oxidated. It is compoſed of 83 parts of nickel and 17 of phoſphorus *. The nickel, however, on which this experiment was made, was not pure.

170 Alloys,

Little is known concerning the alloys of nickel with other metals. Equal parts of ſilver and nickel form a white ductile alloy. Equal parts of copper and nickel form a red ductile alloy. The compounds which this metal forms with tin and zinc are brittle. It does not combine with mercury †. It has a very ſtrong affinity for iron, cobalt, and arſenic, and is ſcarcely ever found except combined with ſome of them.

171 And affinities.

Its affinities, according to Bergman, are as follows:

Iron,
Cobalt,
Arſenic,

Copper,

SECT. XV. *Of Manganeſe.*

[171] Diſcovery of manganeſe. THE dark grey mineral called *manganeſe*, in Latin *magneſia* (according to Boyle, from its reſemblance to the *magnet)*, has been long known and uſed in making glaſs. A mine of it was diſcovered in England by Mr Boyle. It was long ſuppoſed to be an ore of iron; but Port and Cronſtedt having demonſtrated that it contained very little of that metal, the latter referred it in his Mineralogy to a diſtinct order of earths, which he called *terræ magneſiæ*. Bergman, from its ſpecific gravity, and ſeveral other qualities, ſuſpected that it was a metallic oxide: he accordingly made ſeveral attempts to reduce it, but without ſucceſs; the whole maſs either aſſuming the form of ſcoriæ, or yielding only ſmall ſeparate globules attracted by the magnet. This difficulty of fuſion led him to ſuſpect that the metal he was in queſt of bore a ſtrong analogy to platinum. In the mean time, Dr Gahn, who was making experiments on the ſame mineral, actually ſucceeded in reducing it by the following proceſs: He lined a crucible with charcoal powder moiſtened with water, put into it ſome of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal powder, luted another crucible over it, and expoſed the whole for about an hour to a very intenſe heat. At the bottom of the crucible was found a metallic button, or rather a number of ſmall metallic globules, equal in weight to one-third of the mineral employed *. It is eaſy to ſee by what means this reduction was accompliſhed. The charcoal attracted the oxygen from the oxide, and the metal remained behind. This metal is called *manganeſe*.

172 Its properties, Manganeſe is of a greyiſh white colour. It is not malleable, and yet not ſo brittle as to be eaſily broken. Its hardneſs is 8 †. Its ſpecific gravity is 7,000 ‡. Its fuſion requires ſo great a heat, that it has been very ſeldom accompliſhed.

When reduced to powder, it is attracted by the magnet.

173 Oxides, When expoſed to the air, it very ſoon tarniſhes, and aſſumes a darker colour, till at laſt it becomes black and friable. This change is produced by the abſorption of oxygen. It takes place much more rapidly if heat be applied to the metal. The ſubſtance thus obtained is the *black oxide of manganeſe*. This oxide is found in great abundance in nature, though ſcarcely ever in a ſtate of purity. It is compoſed of 75 parts of manganeſe and 25 of oxygen §.

If a quantity of muriatic acid be poured upon this oxide, and heat applied, part of the acid combines with ſome of the oxygen of the oxide, and flies off in yellow fumes. The oxide is diſſolved in the reſt. If potaſs be added to this ſolution, a white powder is precipitated. This is the *white oxide of manganeſe*. It contains, according to Bergman, about 80 parts of manganeſe and 20 of oxygen. It ſoon attracts more oxygen when expoſed to the air, and is converted into *black oxide*.

The affinities of the white oxide, according to Bergman, are as follows:

Oxalic acid,
Citric,
Phoſphoric,
Tartarous,
Fluoric,
Muriatic,
Sulphuric,
Nitric,
Saccholactic,
Succinic,
Sebacic,
Tartaric,
Formic,
Lactic,
Acetous,
Pruſſic,
Carbonic.

The ſulphuret of manganeſe is unknown.

174 Phoſphuret, Phoſphorus may be combined with manganeſe by melting together equal parts of the metal and of phoſphoric glaſs; or by dropping phoſphorus upon red hot manganeſe. The phoſphuret of manganeſe is of a white colour, brittle, granulated, diſpoſed to cryſtallize, not altered by expoſure to the air, and more fuſible than manganeſe. When heated, the phoſphorus burns and the metal becomes oxidated *.

175 Carburet, Manganeſe combines readily with carbon by fuſion (1).

176 Alloys, Little is known concerning the alloys of manganeſe. It combines readily with copper. The compound, according to Bergman, is very malleable, its colour is red, and it ſometimes becomes green by age. Gmelin made a number of experiments to ſee whether this alloy could be formed by fuſing the black oxide of manganeſe along with copper. He partly ſucceeded, and propoſed to ſubſtitute this alloy inſtead of the alloy of copper and arſenic, which is uſed in the arts †. We believe, however, that upon trial the new alloy has been found not to anſwer.

Manganeſe combines readily with iron; indeed it has ſcarcely ever been found quite free from ſome mixture of that metal. It combines alſo very eaſily with arſenic and tin, not eaſily with zinc, and not at all with mercury ‡.

177 And affinities. The affinities of manganeſe, according to Bergman, are as follows:

Copper,
Iron,
Gold,
Silver,

* *Bergman*, ii. 211.

† *Kirwan's Miner.* ii. 288.

‡ *Hielm.*

§ *Bergman*, ii. 225.

* *Pelletier*, *Ann. de Chim.* xiii. 137.

† *Ann. de Chim.* i. 303.

‡ *Bergman*, ii. 211.

---

(1) *Bergman*, III. 379.—Sometimes manganeſe is very ſpeedily oxidated by expoſure to the air; ſometimes ſcarcely altered by it, as Klaproth and Pelletier have obſerved. Mr Kirwan ſuppoſes that the manganeſe which is ſoon altered contains carbon, and that this is the cauſe of the difference. See *Miner.* II. 288.

Silver,
Tin,
Sulphuret of alkali,
Phoſphorus?
Carbon?

The three metals, *cobalt*, *nickel*, and *mangancſe*, reſemble iron in ſeveral particulars: Like it, they are magnetic, very hard, and very difficult to fuſe: but they differ from it in ſpecific gravity, malleability, and in the properties of all their combinations with other ſubſtances; the oxides, for inſtance, of iron, cobalt, nickel, and mangancſe, poſſeſs very different qualities.

Sect. XVI. *Of Tungſten.*

178 Diſcovery of tungſten.

There is a mineral found in Sweden of an opaque white colour and great weight; from which laſt circumſtance it got the name of *tungſten*, or *ponderous ſtone*. Some mineralogiſts conſidered it as an ore of tin, others ſuppoſed that it contained iron. Scheele analyſed it in 1781, and found that it was compoſed of lime and a peculiar earthy-like ſubſtance, which he called from its properties *tungſtic acid*. Bergman conjectured that the baſis of this acid was a metal; and this conjecture was ſoon after fully confirmed by the experiments of Meſſrs D'Elhuyart, who obtained the ſame ſubſtance from a mineral of a browniſh black colour, called by the Germans *wolfram*, which is ſometimes found in tin mines. This mineral they found to contain $\frac{65}{100}$ of tungſtic acid; the reſt of it conſiſted of mangancſe, iron, and tin. This acid ſubſtance they mixed with charcoal powder, and heated violently in a crucible. On opening the crucible after it had cooled they found in it a button of metal, of a dark brown colour, which crumbled to powder between the fingers. On viewing it with a glaſs, they found it to conſiſt of a congeries of metallic globules, ſome of which were as large as a pin-head. The metal thus obtained is called *tungſten*. The manner in which it was produced is evident; tungſtic acid is compoſed of oxygen and tungſten: the oxygen combined with the carbon, and left the metal in a ſtate of purity.

179 Its Properties.

Tungſten is externally of a brown colour, internally of a ſteel grey *.

Its ſpecific gravity is 17,600 †. It is more infuſible than mangancſe ‡.

When heat is applied to tungſten it is converted into a yellow powder, compoſed of 80 parts of tungſten and 20 of oxygen §. This is the *yellow oxide of tungſten* or *tungſtic acid*.

The ſulphuret of tungſten is of a bluiſh black colour, hard, and capable of cryſtallizing.

Phoſphorus is capable of combining with tungſten ‖.

Of the alloys of tungſten we know nothing, except from the experiments of Elhuyarts, which have been tranſcribed into the article Chemistry in the *Encyclopædia*; to which, therefore, we beg leave to refer.

* Luyart.

§ Id.
‖ Pelletier, Ann. de Chim. xiii. 137.

Sect. XVII. *Of Molybdenum.*

180 Diſcovery of molybdenum.

The Greek word *molybdena*, and its Latin tranſlation *plumbago*, ſeem to have been employed by the ancients to denote various oxides of lead; but by the moderns they were applied indiſcriminately to all ſubſtances poſſeſſed of the following properties: Light, friable, and ſoft, of a dark colour and greaſy feel, and which leave a ſtain upon the fingers. Scheele firſt examined theſe minerals with attention. He found that two very different ſubſtances had been confounded together. To one of theſe, which is compoſed of carbon and iron, and which has been already deſcribed, he appropriated the word *plumbago*; the other he called *molybdena*.

Molydbena is compoſed of ſcaly particles adhering ſlightly to each other. Its colour is bluiſh, very much reſembling that of lead. Scheele analyſed it, and obtained ſulphur and a whitiſh powder, which poſſeſſed the properties of an acid, and which, therefore, he called *acid of molybdena*. Bergman firſt ſuſpected that the baſis of this acid was a metal. It was at the requeſt of Bergman and Scheele that Mr Hielm began the laborious courſe of experiments by which he ſucceeded in obtaining a metal from this acid. His method was to form it into a paſte with linſeed oil, and then to apply a very ſtrong heat. This proceſs he repeated ſeveral times ſucceſſively. Klaproth and Pelletier alſo attempted to reduce it, and with equal ſucceſs. The metal is *molybdenum* (K).

181 Its properties.

Molybdenum is externally of a whitiſh yellow colour, but its fracture is a whitiſh grey.

Hitherto it has only been procured in ſmall grains, agglutinated together in brittle maſſes.

Its ſpecific gravity is 7,500. It is almoſt infuſible in our fires.

When expoſed to a ſtrong heat, it is gradually converted into a whitiſh-coloured oxide *. When nitric acid is poured upon it, molybdenum attracts oxygen, and is converted into a *white oxide*, which poſſeſſes the properties of an acid †. This is the *molybdic acid*.

Molybdenum combines readily with ſulphur; and the compound has exactly the properties of molybdena, the ſubſtance which Scheele decompounded ‡. Molybdena is therefore *ſulphuret of molybdenum*. The reaſon that Scheele obtained from it molybdic acid was, that the metal combined with oxygen during his proceſs.

Molybdenum is alſo capable of combining with phoſphorus §.

Few of the alloys of this metal have been hitherto examined.

It ſeems capable of uniting with gold. The alloy is probably of a white colour ‖.

It combines readily with platinum while in the ſtate of an oxide. The compound is fuſible. Its ſpecific gravity is 20,00 ¶.

The alloys of molybdenum with ſilver, iron, and copper, are metallic and friable; thoſe with lead and tin are powders which cannot be fuſed *.

Sect. XVIII. *Of Uranium.*

182 Diſcovery of uranium.

There is a mineral found in the George Wagsfort mine at Johann-Georgenſtadt in Saxony, partly in a pure or unmixed ſtate, and partly ſtratified with other kinds of ſtones and earths. The firſt variety is of a blackiſh colour inclining to a dark iron grey, of a moderate ſplendor, a cloſe texture, and when broken preſents a ſomewhat uneven, and, in the ſmalleſt particles, a conchoidal ſurface. It is quite opaque, tolerably hard, and on being pounded yields a black powder. Its ſpecific gravity is about 7,500. The ſecond ſort is diſtinguiſhed

---

(K) This name was given it by Hielm.

diſtinguiſhed by a finer black colour, with here and there a reddiſh caſt; by a ſtronger luſtre, not unlike that of pitcoal; by an inferior hardneſs; and by a ſhade of green, which tinges its black colour when it is reduced to powder *.

* Klaproth, Crell's Journal, Eng. Tranſl. i. 126.

This foſſil was called *pechblende*; and mineralogiſts, miſled by the name (L), had taken it for an ore of zinc, till the celebrated Werner, convinced from its texture, hardneſs, and ſpecific gravity, that it was not a *blende*, placed it among the ores of iron. Afterwards he ſuſpected that it contained *tungsten*; and this conjecture was ſeemingly confirmed by the experiments of ſome German mineralogiſts, publiſhed in the Miners Journal †. But Klaproth, whoſe analyſes always diſplay the moſt conſummate ſkill, joined with the moſt rigid accuracy, examined this mineral about the year 1789, and found that it conſiſted chiefly of ſulphur combined with a peculiar metal, to which he gave the name of *uranium* (M).

† Ibid.

183 Its properties.

Uranium is of a dark grey colour; internally it is ſomewhat inclined to brown ‡.

‡ Ibid. 233.

Its malleability is unknown. Its hardneſs is about 6. It requires a ſtronger heat for fuſion than manganeſe. Indeed Klaproth only obtained it in very ſmall conglutinated metallic grains, forming altogether a porous and ſpongy maſs.—Its ſpecific gravity is 6,440 §.

§ Ibid.

When expoſed for ſome time to a red heat, it ſuffers no change. By means of nitric acid, however, it may be converted into a yellow powder. This is the *yellow oxide of uranium*. This oxide is found native mixed with the mineral above deſcribed. Its affinities have not yet been determined.

Uranium is capable of combining with ſulphur. The mineral from which Mr Klaproth firſt obtained it is a native ſulphuret of uranium.

Nothing is known concerning the alloys or affinities of uranium.

SECT. XIX. *Of Titanium.*

184 Diſcovery of titanium.

THERE is a mineral found in Hungary which, from its external appearance, has been called *red ſhorl*; but Klaproth, who examined it about the year 1795, diſcovered that it conſiſted chiefly of a peculiar metal, to which he gave the name of *titanium*.

185 Its properties.

Titanium is of a browniſh red colour, and conſiderable luſtre. It is brittle. Its hardneſs is 9; its ſpecific gravity 4,18.

When expoſed to a ſtrong heat in a clay crucible, it ſuffered no alteration, except that its colour became browner; but in a coal crucible it loſt its luſtre and broke to pieces.

It is found naturally cryſtallized in right-angled quadrangular priſms, longitudinally furrowed, and about half an inch in length.

No acid had any effect in oxidating it; but when mixed with five times its weight of potaſs, and heated in a porcelain furnace, it melted, and formed when cold a denſe greyiſh maſs, the ſurface of which was cryſtallized. When diſſolved in boiling water, it ſoon let fall a white powder, weighing about one-third more than the titanium employed. This is the *oxide of titanium*. Fifty grains of it were reduced by ignition to 38. While hot it was yellowiſh, but, like oxide of zinc, became white as it cooled. When heated on charcoal, it aſſumes firſt a *roſy red*, and afterwards a *ſlate blue* colour, and at laſt melts into an imperfect bead with a finely ſtriated ſurface. Mr Klaproth did not ſucceed in reducing it to the metallic ſtate.

Titanium does not ſeem to have any affinity for ſulphur *.

* M'Gregor.

186 Menachanite.

There was a ſubſtance diſcovered by Mr M'Gregor in the valley of Menachan in Cornwall, and hence called *menachanite*. Upon this ſubſtance Mr M'Gregor made a very intereſting ſet of experiments, which were publiſhed in the Journal de Phyſique for 1791. He ſuſpected it to contain a new metal. From its properties, Mr Kirwan conjectured that it was the ſame with titanium †; and this conjecture has been very lately confirmed by Mr Klaproth, who analyſed menachanite, and found it to be an ore of that metal.

† Mineral. ii. 331.

SECT. XX. *Of Tellurium.*

187 Diſcovery of tellurium.

IN the mountains of Fatzbay, near Zalethna in Tranſylvania, there is a mine called *Mariahilf*; the ore of which is wrought for the gold that it contains. Mr Muller of Reichenſtein examined it in 1782, and ſuſpected that it contained a new metal; and Bergman, to whom he had ſent ſome of the ore, was of the ſame opinion: but the quantity of the mineral which theſe chemiſts had examined was too inconſiderable to enable them to decide with certainty. Klaproth analyſed a larger quantity of it about the year 1797, and found that 1000 parts of it conſiſted of 72 parts of iron, 2,5 of gold, and 925,5 of a new metal, to which he has given the name of *tellurium* (N).

188 Its properties.

Tellurium is of a white colour like tin, approaching ſomewhat to the grey colour of lead ‡.

‡ Klaproth, Philoſophical Magazine, i. 78.

It is very brittle and friable. Its fracture is laminated. Its ſpecific gravity is 6,115.

It is as eaſily melted as lead. When ſuffered to cool quietly and gradually, it readily aſſumes a cryſtallized ſurface §.

§ Muller.

When heated by the blowpipe upon charcoal, it burns with a very lively flame of a blue colour, inclining at the edges to green. It is ſo volatile as to riſe entirely in a whitiſh grey ſmoke; at the ſame time it exhales a diſagreeable odour like that of radiſhes. This ſmoke is the *white oxide* of tellurium, which may be formed alſo by diſſolving the metal in nitro-muriatic acid, and pouring into the ſaturated ſolution a quantity of water: a white powder precipitates, which is the oxide ‖.

‖ Klaproth.

When this oxide is heated for ſome time in a retort, it melts, and appears, after cooling, of a yellow ſtraw colour, having acquired a ſort of radiated texture. When formed

---

(L) *Blende* is the name given to ores of zinc.

(M) From *Uranus* (Ουρανος), the name given by Mr Bode to the new planet diſcovered by Herſchel; which name the German aſtronomers have adopted. Mr Klaproth called the metal at firſt *uranite*; but he afterwards changed that name for *uranium*.

(N) Mr Kirwan, in the new edition of his Mineralogy, which was publiſhed before Mr Klaproth's experiments were known, gives this metal the name of *Sylvanite*.—Tellurium exiſts in ſeveral other mines in the ſame mountains.

Tellurium.

formed into a paſte with any fat oil, and diſtilled in a red heat, brilliant metallic drops are obſerved to cover the upper part of the retort, which at intervals fall to the bottom of the veſſel, and are immediately replaced by others. After cooling, metallic fixed drops are found adhering to the ſides and at the bottom of the veſſel; the remainder of the metal is reduced. Its ſurface is brilliant and almoſt always cryſtallized. When this oxide is expoſed to heat on charcoal, it is reduced with a rapidity that reſembles detonation *.

Tellurium combines with ſulphur. The ſulphuret of this metal is of a grey colour and radiated ſtructure. When placed on red hot charcoal, the metal burns as well as the ſulphur with a blue flame.

Tellurium amalgamates with mercury by ſimple trituration†.—The other properties of this metal are unknown.

189 Chromum.

A NEW metal has lately been diſcovered by Vauquelin in the red lead ore of Siberia. It is grey, very hard, brittle, and eaſily cryſtallizes in ſmall needles ‡. He has given it the name of *chromum* (o).

WE have now deſcribed all the metals at preſent known. The following table will exhibit in one view their principal properties.

190 General table of the properties of the metals.

We

191 Remarks on metallic oxides.

We have ſeen that all the metals are capable of combining with oxygen; that almoſt every one forms various oxides, containing different quantities of oxygen, and varying in colour and other properties according to the proportion of oxygen which they contain. No part of chemiſtry has more engaged the attention of philoſophers than the metallic oxides; and yet ſuch is the difficulty of the ſubject, that ſcarcely any part of chemiſtry is more imperfectly underſtood.

We neither know how many oxides every particular metal is capable of forming, nor the manner in which they are formed: neither have the differences between oxides of the ſame metallic baſe been inquired into; though there cannot be a doubt that they differ, not only in their affinities, but in many of their other properties. The *white oxide* of manganeſe, for inſtance, combines readily with acids, but the *black* is incapable of uniting with any.

Mr Prouſt, in a very valuable paper which he lately publiſhed concerning the oxides of iron *, hints that metals are only capable of two degrees of oxidation, or, which is the ſame thing, that only two different oxides can be produced from the ſame metal. We think he has proved this completely as far as iron is concerned; and probably the obſervation holds good with reſpect to many other metals. Arſenic, copper, tin, molybdenum, and perhaps even mercury, ſeem to be capable of only two degrees of oxidation; but it would require a very numerous and accurate ſet of experiments to be able to determine the matter, or even to form a probable conjecture. Analogy is certainly againſt the ſuppoſition; for it has been demonſtrated that ſome ſubſtances at leaſt are capable of combining with three different doſes of oxygen (q), and why may not this be the caſe alſo with the metals?

There is one obſervation, however, which we owe to Mr Prouſt, the truth of which cannot be doubted, and which is certainly of the higheſt importance—that metals are not capable of indefinite degrees of oxidation, but only of a certain number; and that every particular oxide conſiſts of a determinate quantity of the metal and of oxygen chemically combined. Iron, for inſtance, is not capable, as has been ſuppoſed, of uniting with oxygen in all the intermediate degrees between $\frac{27}{100}$ and $\frac{48}{100}$, and conſequently of forming 20 or 30 different oxides; it can only combine with preciſely $\frac{27}{100}$ parts, or $\frac{48}{100}$ parts, and with no other proportions; and therefore is only capable of forming two oxides, the *green* and the *brown*. In like manner, every other metal combines with certain proportions of oxygen, and forms either two oxides or more according to its nature. To talk therefore of oxidating a metal indefinitely is not accurate, except it be intended to ſignify the combining of part of it with oxygen, while the reſt remains in its natural ſtate. If iron be oxidated at all, it muſt be combined with $\frac{27}{100}$ of oxygen; if it be oxidated more than this, it muſt be combined with $\frac{48}{100}$ of oxygen.

We beg leave to add another obſervation, which we conſider as of no leſs importance, and which will ſerve in ſome meaſure to modify and explain what has been juſt now ſaid. Oxygen is capable of uniting with metals, or with any other ſubſtance for which it has an affinity, only in *one* determinate proportion. Iron, for inſtance, and oxygen can only combine in the proportion of 73 parts of iron and 27 of oxygen. Theſe two quantities ſaturate each other, and form a compound which is incapable of receiving into it any more oxygen or iron: this compound is the *green oxide of iron*. How comes it then, it will be aſked, that there is another oxide of iron, the *brown oxide*, which contains 52 parts of iron and 48 of oxygen, proportions certainly very different from 73 and 27? We anſwer, there is an affinity between the green oxide of iron and oxygen; they are capable of combining together, and of ſaturating each other in the proportion of about 71,5 parts of green oxide and 28,5 of oxygen; and the compound which they form is the *brown oxide*, which of courſe contains 52 parts of iron and 48 of oxygen: But then it is not formed by the combination of theſe two ſubſtances directly, but by the combination of the green oxide and oxygen. In like manner, the arſenic acid is not compoſed of arſenic and oxygen combined directly, but of white oxide of arſenic combined with oxygen. The very ſame thing takes place in all the other metals. We cannot at preſent prove the truth of this obſervation in a ſatisfactory manner, becauſe it would be neceſſary to draw our proofs from combinations which are yet undeſcribed; but we will have occaſion to conſider it afterwards.

We have ſeen that all the metals hitherto tried are capable of combining with ſulphur, except gold and titanium; that all of them on which the experiments have been made can be united with phoſphorus; and that three of them, iron, zinc, and manganeſe, united with carbon; and perhaps many more of them may hereafter be found capable of aſſuming the form of carburets.

We have ſeen, too, that they are capable of uniting with one another and forming alloys. This was long reckoned peculiar to metals, and it is at preſent one of the beſt criterions for determining the metallic nature of any ſubſtance. Much is wanting to render the chemiſtry of alloys complete. Many of them have never been examined; and the proportions of almoſt all of them are unknown. Neither has any accurate method been yet diſcovered of determining the affinities of metals for each other. The order of affinities which we have given for each metal was determined by Bergman; but he acknowledged himſelf that he wanted the proper data to enſure accuracy.

CHAP. IV. *Of* EARTHS.

The word *earth*, in common language, has two meanings; it ſometimes ſignifies the *globe* which we inhabit, and ſometimes the *mould* on which vegetables grow. Chemiſts have examined this mould, and have found that it conſiſts of a variety of ſubſtances mixed together without order or regularity. The greateſt part of it, however, as well as of the ſtones, which form apparently ſo large a proportion of the globe, conſiſts of a ſmall number of bodies, which have a variety of commmon properties.

---

* Ann. de Chim. xxiii. 85.—Nicholſon's Journ. i. 453.

(q) We ſhall ſee afterwards that azot is one of theſe.

perties. Theſe bodies chemiſts have agreed to claſs together, and to denominate *earths*.

192 Properties of earths.

Every body which poſſeſſes the following properties is an *earth*:

1. Inſoluble in water, or nearly ſo; or at leaſt becoming inſoluble when combined with carbonic acid.
2. Little or no taſte or ſmell; at leaſt when combined with carbonic acid.
3. Incombuſtible, and incapable while pure of being altered by the fire.
4. A ſpecific gravity not exceeding 4,9.
5. When pure, capable of aſſuming the form of a white powder.

The earths at preſent known amount to ten; the names of which are, lime, magneſia, barytes, ſtrontites, alumina, ſilica, jargonia, glucina, yttria, aguſtina.

Every one of the above characteriſtics is not perhaps rigorouſly applicable to each of theſe bodies; but all of them poſſeſs a ſufficient number of common properties to render it uſeful to arrange them under one claſs.

SECT. I. *Of Lime.*

LIME has been known from the earlieſt ages. The ancients employed it in medicine; it was the chief ingredient in their mortar; and they uſed it as a manure to fertilize their fields.

193 Method of procuring lime.

It abounds in many parts of the world, or perhaps we ſhould rather ſay, that there is no part of the world where it does not exiſt. It is found pureſt in limeſtones, and marbles and chalk. None of theſe ſubſtances, however, is, ſtrictly ſpeaking, lime; but they are all capable of becoming lime by a well-known proceſs, by keeping them for ſome time in a white heat: this proceſs is called *the burning of lime;* the product is denominated *quicklime*. This laſt ſubſtance is what we call *lime*.

194 Properties of lime.

Pure lime is of a white colour, moderately hard, but eaſily reduced to a powder.

It has a hot burning taſte, and in ſome meaſure corrodes and deſtroys the texture of thoſe animal bodies to which it is applied. It has no ſmell. Its ſpecific gravity is 2,3 *.

If water be poured on newly burnt lime, it ſwells and falls to pieces, and is ſoon reduced to a very fine powder. In the mean time, ſo much heat is produced, that part of the water flies of in vapour. If the quantity of lime ſlacked (as this proceſs is termed) be great, the heat produced is ſufficient to ſet fire to combuſtibles. In this manner veſſels loaded with lime have ſometimes been burnt. When great quantities of lime are ſlacked in a dark place, not only heat, but light alſo is emitted, as Mr Pelletier has obſerved †. When ſlacked lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime; which water may be ſeparated again by the application of a red heat; and by this proceſs the lime becomes juſt what it was before being ſlacked ‡.

195 Lime-water.

Six hundred parts of water, at the temperature of 60°, diſſolve about one part of lime; boiling hot water diſſolves about double that quantity §. This ſolution is called *lime-water*. It is limpid, has an acrid taſte, and changes vegetable blue colours to green. One ounce troy of lime-water contains about one grain of lime.

One thouſand parts of lime are capable of abſorbing, and retaining, at a heat of 600°, 228 parts of water *.

Lime has never yet been obtained in the ſtate of cryſtals.

It is incapable of being fuſed by the moſt violent heat that can be produced in furnaces, or even by the moſt powerful burning-glaſſes.

196 Sulphuret, and

Lime unites readily with ſulphur, and forms *ſulphuret of lime*. This compound may be obtained by mixing unſlacked lime and flowers of ſulphur together, and adding a little water. The heat produced by the ſlacking of the lime is ſufficient to make the ſulphur and the lime unite. This ſulphuret is of a red colour. When water is poured on it, ſulphurated hydrogen gas is emitted. The ſulphur is gradually converted into ſulphuric acid by uniting with the oxygen of the water, the hydrogen of which flies off in the form of gas, diſſolving at the ſame time a part of the ſulphur.

197 Phoſphuret of lime.

It is capable alſo of combining with phoſphorus.— The phoſphuret of lime decompoſes water by the aſſiſtance of a moderate heat, and gives out phoſphurated hydrogen gas.

198 Cauſe of the difference between limeſtone and lime.

Limeſtone and chalk, though they are capable of being converted into lime by *burning*, poſſeſs hardly any of the properties of that active ſubſtance. They are taſteleſs, ſcarcely ſoluble in water, and do not perceptibly act on animal bodies. Now, to what are the new properties of lime owing? What alteration does it undergo in the fire?

It had been long known that limeſtone loſes a good deal of weight by being burned or *calcined*. It was natural to ſuppoſe, therefore, that ſomething was ſeparated from it during calcination. Accordingly, Van Helmont, Ludovicus, and Macquer, made experiments in ſucceſſion, in order to diſcover what that *ſomething* was; and they concluded from them that it was *pure water*, which the lime recovered again when expoſed to the atmoſphere. As the new properties of lime could hardly be aſcribed to this loſs, but to ſome other cauſe, Stahl's opinion, like all the other chemical theories of that wonderful man, was generally acceded to. He ſuppoſed that the new properties which lime acquired by calcination, were owing entirely to the more minute diviſion of its particles by the action of the fire. Boyle indeed had endeavoured to prove, that theſe properties were owing to the *fixation of fire* in the lime: a theory which was embraced by Newton and illuſtrated by Hales, and which Meyer new modelled, and explained with ſo much ingenuity and acuteneſs as to draw the attention of the moſt diſtinguiſhed chemiſts. But while Meyer was thus employed in Germany, Dr Black, of Edinburgh, publiſhed thoſe celebrated experiments which form ſo brilliant an era in the hiſtory of chemiſtry.

199 According to Stahl;

200 Explained by Dr Black.

He firſt aſcertained that the quantity of water ſeparated from limeſtone during its calcination was not nearly equal to the weight which it loſt. He concluded in conſequence that it muſt have loſt ſomething elſe than mere water. What this could be, he was at firſt at a loſs to conceive; but recollecting that Dr Hales had proved, that limeſtone, during its ſolution in acids, emitted a great quantity of *air*, he conjectured that *this* might probably be what it loſt during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture verified;

---

† Jour. de Phyſ. t. 22.

‡ Dr Black.

§ Kirwan's Miner. i. 5.

* Lavoiſier.

verified ; and that the *air* and *the water* which ſeparated from the lime, were together preciſely equal to the loſs of weight which it had ſuſtained. Lime therefore owes its new properties to the loſs of *air ;* and limeſtone differs from lime merely in being combined with a certain quantity of *air :* for he found that, by reſtoring again the ſame quantity of *air* to lime, it was converted into limeſtone. This air, becauſe it exiſted in lime in a fixed ſtate, he called *fixed air.* It was afterwards examined by Dr Prieſtley and other philoſophers, found to poſſeſs peculiar properties, and to be that ſpecies of gas now known by the name of *carbonic acid gas.* Lime then is a ſimple ſubſtance, that is to ſay, it has never yet been decompounded ; and limeſtone is compoſed of carbonic acid and lime. Heat ſeparates the carbonic acid, and leaves the lime in a ſtate of purity.

201 Affinities of lime.

The affinities of lime, according to Bergman, are as follows :

Oxalic acid,
Suberic (R) ?
Sulphuric,
Tartarous,
Succinic,
Phoſphoric,
Saccholactic,
Nitric,
Muriatic,
Sebacic,
Fluoric,
Arſenic,
Formic,
Lactic,
Citric,
Benzoic,
Sulphurous,
Acetous,
Boracic,
Nitrous,
Carbonic,
Pruſſic,
Sulphur,
Phoſphorus,
Water,
Fixed oil.

Sect. II. *Of Magneſia.*

202 Diſcovery of magneſia.

About the beginning of the eighteenth century, a Roman canon expoſed a white powder to ſale at Rome as a cure for all diſeaſes. This powder he called *magneſia alba.* He kept the manner of preparing it a profound ſecret ; but in 1707 Valentini informed the public that it might be obtained by calcining the lixivium which remains after the preparation of nitre ; and two years after, Slevogt diſcovered that it might be precipitated by potaſs from the mother ley (s) of common ſalt. This powder was generally ſuppoſed to be *lime,* till Frederic Hoffman obſerved that it formed very different combinations with other bodies *. But little was known concerning its nature till Dr Black publiſhed his celebrated experiments in 1755. Margraf publiſhed a diſſertation on it in 1759, and Bergman another in 1775, in which he collected the obſervations of theſe two philoſophers, and which he enriched alſo with many additions of his own.

* Bergman, i. 365.

203 Method of procuring it.

As magneſia has never yet been found native in a ſtate of purity, it may be prepared in the following manner : *Sulphat of magneſia,* a ſalt compoſed of this earth and ſulphuric acid, exiſts in ſea-water, and in many ſprings, particularly ſome about Epſom, from which circumſtance it was formerly called *Epſom ſalt.* This ſalt is to be diſſolved in water, and half its weight of potaſs added. The magneſia is immediately precipitated, becauſe potaſs has a ſtronger affinity for ſulphuric acid. It is then to be waſhed with a ſufficient quantity of water, and dried.

204 Its properties.

Magneſia thus obtained is a very ſoft white powder, which has very little taſte, and is totally deſtitute of ſmell. Its ſpecific gravity is about 2,3 †.

It is ſoluble in about 7900 times its own weight of water at the temperature of 60° ‡.

† Kirwan's Miner. i. 8.

‡ Ibid.

Even when combined with carbonic acid (for which it has a ſtrong affinity) it is capable of abſorbing and retaining 1½ times its own weight of water, without letting go a drop ; but on expoſure to the air, this water evaporates, though more ſlowly than it would from lime.

Magneſia has never yet been obtained in a cryſtallized form.

It tinges vegetable blues of an exceedingly ſlight green.

It is not melted by the ſtrongeſt heat which it has been poſſible to apply ; but Mr D'Arcet obſerved that, in a very high temperature, it became ſomewhat agglutinated.

When magneſia and ſulphur are put into a veſſel of water, and kept for ſome time expoſed to a moderate heat, they combine, and form ſulphuret of magneſia ; which, according to Fourcroy, is capable of cryſtallizing.

The phoſphuret of magneſia has never been examined.

Effect of heat on mixtures of lime and magneſia.

Equal parts of lime and magneſia mixed together, and expoſed by Lavoiſier to a very violent heat, did not melt ; neither did they melt when Mr Kirwan placed them in the temperature of 150° Wedgewood. The following Table, drawn up by Mr Kirwan from his own experiments, ſhews the effect of heat on theſe two earths mixed together in different proportions.

Proportions.

(R) The affinity of this acid for lime is inferior to the oxalic, which decompoſes the ſuberat of lime. *Jameſon's Mineral. of Shetland and Arran,* p. 168.

(S) *The mother ley* is the liquid that remains after as much as poſſible of any ſalt has been obtained from it. Common ſalt, for inſtance, is obtained by evaporating ſea-water. After as much ſalt has been extracted from a quantity of ſea-water as will cryſtallize, there is ſtill a portion of liquid remaining. This portion is the mother ley.

Proportions.	Heat.	Effect.
80 Lime 20 Mag.	150° Wedg.	Went through the crucible.
75 Lime 25 Mag.	160	Went through the crucible.
66 Lime 33 Mag.		Went through the crucible.
20 Lime 80 Mag.	165	Did not melt.
33 Lime 66 Mag.	138	Did not melt.
30 Lime 10 Mag.	156	Melted into a fine greeniſh yellow glaſs; but the crucible was corroded throughout.

206 Affinities of magneſia. The affinities of magneſia, according to Bergman, are as follows:

Oxalic acid,
Phoſphoric,
Sulphuric,
Fluoric,
Sebacic,
Arſenic,
Saccholactic,
Succinic,
Nitric,
Muriatic,
Tartarous,
Citric,
Formic,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Pruſſic,
Sulphur,
Phoſphorus?
Water.

Sect. III. *Of Barytes.*

207 Diſcovery of barytes. A very heavy mineral is found in Sweden, Germany, and Britain, which Margraf conſidered as a compound of ſulphuric acid and lime. But Scheele and Gahn analyſed it in 1774, and found that it conſiſted of ſulphuric acid combined with a peculiar ſpecies of earth. This analyſis was ſoon after confirmed and extended by Bergman. The earth was at firſt called *terra ponderoſa, heavy earth,* on account of the great ſpecific gravity of the ſubſtance from which it was obtained. Morveau called it *barote* (from ϐαρυς, *heavy),* which Bergman changed into *barytes;* and this laſt term is now univerſally adopted.

Barytes is generally found combined either with ſulphuric or carbonic acid. From the firſt of theſe compounds, which is by far the moſt common, it may be obtained by the following proceſs:

208 Method of obtaining it. Reduce the mineral to a powder and mix it with $2\frac{1}{2}$ its weight of carbonat of ſoda (T), previouſly deprived of all its water. Expoſe the mixture to a red heat for an hour and a half, avoiding fuſion, and a double decompoſition takes place; the ſulphuric acid unites with the ſoda, while the carbonic acid combines with the barytes. Waſh it in a ſufficient quantity of water to diſſolve the compound of ſulphuric acid and ſoda, the carbonat of barytes, which is almoſt inſoluble, remains behind. Leſt it ſhould be mixed with ſome other earths, which is generally the caſe, boil it for three hours in ten times its weight of diſtilled vinegar, the ſpecific gravity of which is 1,033; by which the barytes will be diſſolved, and likewiſe the lime and magneſia, if there happen to be any; but every other earth (U) remains untouched. Pour off the ſolution, and add to it ſulphuric acid as long as any precipitate is formed. This precipitate conſiſts of the whole barytes and the lime (if there be any) combined with ſulphuric acid. Waſh it in 50 times its weight of water, and all the lime will be diſſolved. There will now remain nothing but barytes combined with ſulphuric acid, which may be decompoſed as before by carbonat of ſoda *. The carbonic acid may then be ſeparated by applying a very violent heat †; or, what is better, nitric acid may be poured upon it, which will ſeparate the carbonic acid and combine with the barytes; and then the nitric acid may be driven off by a moderate heat ‡.

209 Its properties. Barytes thus obtained is a light, ſpongy, porous body, which may be very eaſily reduced to powder. It has a harſh and more cauſtic taſte than lime; and when taken into the ſtomach, proves a moſt violent poiſon. It has no perceptible ſmell.

Its ſpecific gravity has not yet been aſcertained.

It imbibes water with a hiſſing noiſe, but, according to Dr Hope, without ſwelling or ſplitting as lime does §. However, when expoſed to the air, as Fourcroy and Vauquelin inform us, it effloreſces, cracks, burſts, ſwells up, heats, and becomes white, by abſorbing moiſture ||.

Cold water diſſolves about $\frac{1}{17}$th part of its weight of barytes, and boiling water more than half its weight. As the water cools, the barytes is depoſited in cryſtals, the ſhape of which varies according to the rapidity with which they have been formed. When moſt regular, they are flat hexagonal priſms, having two broad ſides, with two intervening narrow ones, and terminated at each end by a four-ſided pyramid, which in ſome inſtances conſtitutes the larger part of the cryſtal. When formed ſlowly, they are diſtinct and large; but when the water is ſaturated with barytes, they are depoſited rapidly, and are generally more ſlender and delicate. Then, too, they are attached to one another in ſuch a manner as to aſſume a beautiful foliacious appearance, not unlike the leaf of a fern ¶.

Theſe cryſtals are tranſparent and colourleſs, and appear to be compoſed of about 53 parts of water and 47 of

(T) Soda is an alkali, which ſhall be afterwards deſcribed. Carbonat of ſoda is ſoda combined with carbonic acid, the common ſtate in which it is obtained; potaſs might alſo be uſed.

(U) Except ſtrontites, which Pelletier has detected in this mineral.

of barytes. When expoſed to the heat of boiling water, they undergo the *watery fuſion*, or, which is the ſame thing, they melt without loſing any of the water which they contain. A ſtronger heat makes the water fly off. When expoſed to the air, they attract carbonic acid, and crumble into duſt. They are ſoluble in 17½ parts of water at the temperature of 60°; but boiling water diſſolves any quantity whatever: the reaſon of which is evident; at that temperature their own water of cryſtallization is ſufficient to keep them in ſolution *.

Water ſaturated with barytes is called *barytic water*. It has the property of converting vegetable blues to a green.

When barytes is expoſed to the blowpipe on a piece of charcoal, it fuſes, bubbles up, and runs into globules, which quickly penetrate the charcoal †. This is probably in conſequence of containing water; for Lavoiſier found barytes not affected by the ſtrongeſt heat which he could produce.

210 Sulphuret of barytes.

Barytes combines readily with ſulphur. The eaſieſt way of forming ſulphuret of barytes is to mix eight parts of ſulphat of barytes with one part of pounded charcoal, and to apply a ſtrong heat. The charcoal combines with the oxygen of the ſulphuric acid, and the compound flies off in the form of carbonic acid gas. There remains behind ſulphur combined with barytes. Sulphuret of barytes is ſoluble in water: It is of a yellow colour. It is capable of cryſtallizing; and then aſſumes a yellowiſh white colour ‡.

The phoſphuret of barytes has not been examined.

No mixture of barytes and lime, nor of barytes and magneſia, is fuſible in the ſtrongeſt heat which it has been poſſible to apply §.

211 Its affinities.

The affinities of barytes, according to Bergman, are as follows:

Sulphuric acid,
Oxalic,
Succinic,
Fluoric,
Phoſphoric,
Saccholactic,
Suberic (v)?
Nitric,
Muriatic,
Sebacic,
Citric,
Tartarous,

‡ Fourcroy.

§ Lavoiſier, Acad. Par. 1782.

Sect. IV. *Of Strontites.*

212 Diſcovery of ſtrontites.

About the year 1787, a mineral was brought to Edinburgh, by a dealer in foſſils, from the lead mine of Strontian in Argyleſhire, where it is found imbedded in the ore, mixed with ſeveral other ſubſtances. It is ſometimes tranſparent and colourleſs, but generally has a tinge of yellow or green. Its hardneſs is 5. Its ſpecific gravity varies from 3,4 to 3,726. Its texture is generally fibrous; and ſometimes it is found cryſtallized in ſlender priſmatic columns of various lengths *.

This mineral was generally conſidered as a carbonat of barytes; but Dr Crawford having obſerved ſome differences between its ſolution in muriatic acid and that of barytes, mentioned in his treatiſe on *Muriat of Barytes*, publiſhed in 1790, that it probably contains a new earth, and ſent a ſpecimen to Mr Kirwan that he might examine its properties. Dr Hope had alſo ſuſpected that its baſis differed from barytes; and accordingly he made a ſet of experiments on it in 1791, which were read to the Royal Society of Edinburgh in 1792. Theſe experiments fully proved that it contained a peculiar earth. Mr Kirwan likewiſe analyſed the ſtrontian mineral, and drew preciſely the ſame concluſions. It has been analyſed alſo by Mr Klaproth of Berlin, and Mr Pelletier of Paris. It conſiſts of carbonic acid combined with a peculiar earth, to which Dr Hope gave the name of *ſtrontites*. This appellation we ſhall adopt.

The carbonic acid may be ſeparated by a heat of 140° Wedgewood, and then the ſtrontites remains behind †.

213 Its properties.

Strontites has been found in Argyleſhire in Scotland, near Briſtol in England, and in Pennſylvania ‡. It has been found alſo in France and in Sicily. It is of a white colour. It has a pungent acrid taſte. When pounded in a mortar, the powder that riſes is offenſive to the noſtrils and lungs §. It is not poiſonous ||.

One hundred and ſixty-two parts of water, at the temperature of 60°, diſſolve nearly one part of it. The ſolution is clear and tranſparent, and converts vegetable blues to a green. Hot water diſſolves it in much larger quantities; and as it cools the ſtrontites is depoſited in colourleſs tranſparent cryſtals. Theſe are in the form of thin quadrangular plates, generally parallelograms, the largeſt of which ſeldom exceeds one-fourth of an inch in length. Sometimes their edges are plain, but they oftener conſiſt of two facets, meeting together and forming an angle like the roof of a houſe. Theſe cryſtals generally adhere to each other in ſuch a manner as to form a thin plate of an inch or more in length and half an inch in breadth. Sometimes they aſſume a cubic form. They contain about 68 parts in 100 of water. They are ſoluble in 51,4 parts of water, at the temperature of 60°. Boiling water diſſolves nearly half its weight of them. When expoſed to the air, they loſe their water, attract carbonic acid, and fall into powder ¶.

When ſtrontites is thrown into water, it attracts it with a hiſſing noiſe, much heat is produced, and it falls into powder much more rapidly than lime *.

It combines with ſulphur either by fuſion in a crucible, or by being boiled with it in water. The ſulphuret

(v) Suberic acid decompoſes muriat and nitrat of barytes. *Jameſon's Mineral. of Shetland and Arran.*

phuret is of a dark yellowiſh brown colour. It is ſoluble in water*.

214
Its affinities.

The affinities of ſtrontites, as aſcertained by Dr Hope, are as follows :

Sulphuric acid,
Oxalic,
Tartarous,
Fluoric,
Nitric,
Muriatic,
Succinic,
Phoſphoric,
Acetous,
Arſenic,
Boracic,
Carbonic.

Sect. V. *Of Silica.*

215
Method of obtaining ſilica.

If one part of powdered flints or ſand, mixed with three parts of potaſs, be put into a crucible, and kept in a ſtate of fuſion for half an hour, a brittle maſs will be formed almoſt as tranſparent as glaſs, which quickly attracts moiſture from the atmoſphere, and is entirely ſoluble in water. This ſolution is called *liquor ſilicum*, or *liquor of flints*. It was firſt accurately deſcribed by Glauber, a chemiſt who lived about the middle of the 17th century.

If an acid be poured into this liquor, a white ſpongy ſubſtance is precipitated, which may be purified from every accidental mixture by waſhing it in acids, muriatic acid for inſtance. This ſubſtance is called *ſiliceous earth* or *ſilica*. It was firſt diſtinguiſhed as a peculiar earth by Pott in 1746, though it had been known long before ; and Cartheuſer, Scheele, and Bergman, proved in ſucceſſion that it could not, as ſome chemiſts had ſuppoſed, be reduced to any other earth.

216
Its properties.

Silica, when dried, is a ſoft white powder, without either taſte or ſmell.

Its ſpecific gravity is 2,66 †.

It is inſoluble in water except when newly precipitated from the liquor ſilicum, and then one part of it is ſoluble in 1000 parts of water ‡. It has no effect on vegetable colours.

It is capable of abſorbing about one-fourth of its weight of water, without letting any drop from it ; but on expoſure to the air, the water evaporates very readily §.

Silica may be formed into a paſte with a ſmall quantity of water : this paſte has not the ſmalleſt ductility, and when dried forms a looſe, friable, and incoherent maſs ||.

Silica is capable of aſſuming a cryſtalline form. Cryſtals of it are found in many parts of the world. They are known by the name of *rock cryſtal*. When pure they are tranſparent and colourleſs like glaſs : they aſſume various forms ; the moſt uſual is a hexagonal priſm, ſurmounted with hexagonal pyramids on one or both ends, the angles of the priſm correſponding with thoſe of the pyramids. Their hardneſs is very great, amounting to eleven. Their ſpecific gravity is 2,653 ¶.

There are two methods of imitating theſe cryſtals by art. The firſt method was diſcovered by Bergman. He diſſolved ſilica in fluoric acid, the only acid in which it is ſoluble, and allowed the ſolution to remain undiſturbed for two years. A number of cryſtals were then found at the bottom of the veſſel, moſtly of irregular figures, but ſome of them cubes with their angles truncated. They were hard, but not to be compared in this reſpect with rock cryſtal *.

The other method was diſcovered by accident. Profeſſor Seigling of Erfurt had prepared a liquor ſilicum, which was more than uſually diluted with water, and contained a ſuperabundance of alkali. It lay undiſturbed for eight years in a glaſs veſſel, the mouth of which was only covered with paper. Happening to look to it by accident, he obſerved it to contain a number of cryſtals ; on which he ſent it to Mr Trommſdorff, profeſſor of chemiſtry at Erfurt, who examined it. The liquor remaining amounted to about two ounces. Its ſurface was covered by a tranſparent cruſt, ſo ſtrong that the veſſel might be inverted without ſpilling any of the liquid. At the bottom of the veſſel were a number of cryſtals, which proved on examination to be ſulphat of potaſs and carbonat of potaſs (w). The cruſt on the top conſiſted partly of carbonat of potaſs, partly of cryſtallized ſilica. Theſe laſt cryſtals had aſſumed the form of tetrahedral pyramids in groups ; they were perfectly tranſparent, and ſo hard that they ſtruck fire with ſteel †.

Silica endures the moſt violent heat without alteration.

It ſeems incapable of combining with ſulphur or phoſphorus.

217
Effect of heat on mixtures of lime and ſilica ;

1. The effect of heat upon lime and ſilica, mixed in various proportions, will appear from the following experiments of Mr Kirwan ‡.

Proportions.	Heat.	Effect.
50 Lime 50 Silica	150° Wedg.	Melted into a maſs of a white colour, ſemitranſparent at the edges, and ſtriking fire, tho' feebly, with ſteel: it was ſomewhat between porcelain and enamel.
80 Lime 20 Silica	156	A yellowiſh white looſe powder.
20 Lime 80 Silica	156	Not melted, formed a brittle maſs.

218
Magneſia and ſilica :

2. Equal part of magneſia and ſilica melt with great difficulty into a white enamel when expoſed to the moſt violent heat which can be produced §. They are infuſible in inferior heats in whatever proportion they are mixed ||.

219
Barytes and ſilica ; proportions.

3. The effect of heat on various mixtures of barytes and ſilica will appear from the following experiments of Mr Kirwan ¶.

(w) Potaſs, combined with ſulphuric acid and with carbonic acid.

¶ Mineral. i. 57.

Proportions.	Heat.	Effect.
80 Silica 20 Barytes	155° Wedg.	A white brittle maſs.
75 Silica 20 Barytes	150	A brittle hard maſs, ſemitranſparent at the edges.
66 Silica 33 Barytes	150	Melted into a hard ſomewhat porous porcelain maſs.
50 Silica 50 Barytes	148	A hard maſs not melted.
20 Silica 80 Barytes	148	The edges were melted into a pale greeniſh matter between a porcelain and enamel.
25 Silica 75 Barytes	150	Melted into a ſomewhat porous porcelain maſs.
33 Silica 66 Barytes	150	Melted into a yellowiſh and partly greeniſh white porous porcelain.

4. The effect of heat on mixtures of ſtrontites and ſilica is not known.

220 And lime, magneſia, and ſilica. 5. It follows from the experiments of Achard, that equal parts of lime, magneſia, and ſilica, may be melted into a greeniſh-coloured glaſs, hard enough to ſtrike fire with ſteel; that when the magneſia exceeds either of the other two, the mixture will not melt; that when the ſilica exceeds, the mixture ſeldom melts, only indeed with him in the following proportions; three ſilica, two lime, one magneſia, which formed a porcelain; and that when the lime exceeds, the mixture is generally fuſible *.

* *Mem. Berl. ibid.* and *Jour. de Phyſ.* xxiv.

221 Affinities of ſilica. The affinities of ſilica are as follows:

Fluoric acid,
Fixed alkali.

Sect. VI. *Of Alumina.*

222 Method of obtaining alumina. Dissolve alum in hot water, and add to the ſolution potaſs as long as any precipitate is formed. Decant off the fluid part, and waſh the precipitate in a ſufficient quantity of water, and then allow it to dry. The ſubſtance thus obtained is called *alumina*. Its properties were firſt aſcertained with accuracy by Margraf.

223 Its properties. Alumina thus obtained is a very white ſpongy powder, without any ſmell or taſte.

Its ſpecific gravity is 2,00 †. It is ſcarcely ſoluble in water, but may be diffuſed through it with great facility. With a ſmall quantity of water it forms a very tough ductile paſte, and does not readily mix with more.

† *Kirwan's Miner.* i. 9.

In its uſual ſtate of dryneſs it is capable of abſorbing 2½ times its weight of water, without ſuffering any to drop out. It retains this water more obſtinately than any of the earths hitherto deſcribed. In a freezing cold it contracts more, and parts with more of its water than any other earth; a circumſtance which is of ſome importance in agriculture *.

* *Ibid.*

Alumina has never yet been obtained in a cryſtallized form. It has no effect whatever on vegetable colours.

The moſt intenſe heat does not fuſe it, but it has the ſingular property of diminiſhing in bulk in proportion to the intenſity of the fire to which it is expoſed. It becomes at the ſame time exceedingly hard: Mr Lavoiſier rendered it capable of cutting glaſs; and Mr Boyle had long before done the ſame thing †.

† *Shaw's Boyle*, iii. 422.

224 Wedgewood's thermometer. Wedgewood took advantage of this property of alumina, and by means of it conſtructed an inſtrument for meaſuring high degrees of heat. It conſiſts of pieces of clay of a determinate ſize, and an apparatus for meaſuring their bulk with accuracy: One of theſe pieces is put into the fire, and the temperature is eſtimated by the contraction of the piece. For a more complete deſcription of this important inſtrument, we refer to the article Thermometer in the *Encycl.*

Alumina is hardly ſuſceptible of combining with ſulphur or phoſphorus; but from the experiments of La Grange, it appears to have an affinity for carbon ‡.

‡ *Nicholſon's Jour.* ii. 101.

225 Effect of heat on mixtures of lime and alumina; 1. The effect of heat on various mixtures of lime and alumina will appear from the following table §:

§ *Kirwan*, i. 56.

Proportions.	Heat.	Effect.
75 Lime 25 Alumina	150° Wedg.	Not melted.
66 Lime 33 Alumina	150	Remained a powder.
33 Lime 66 Alumina	(x)	Melted.
25 Lime 75 Alumina	(x)	Melted.
20 Lime 80 Alumina	(x)	Melted.

226 Magneſia and alumina; 2. Magneſia and alumina have no action whatever on each other, even when expoſed to a heat of 150° Wedgewood ||.

|| *Ibid.* i. 57.

227 Barytes and alumina; 3. The effect of heat on different mixtures of barytes and alumina will appear from the following experiments of Mr Kirwarn ¶.

¶ *Ibid.*

(x) Theſe three experiments were made by Ehrman: The heat was produced by directing a ſtream of oxygen gas on burning charcoal, and is the moſt intenſe which it has been hitherto poſſible to produce.

Proportions.	Heat.	Effect.
80 Alumina 20 Barytes	150° Wedg.	Scarcely hardened.
75 Alumina 25 Barytes	156	No ſign of fuſion, a looſe powder.
66 Alumina 33 Barytes	152	As the former.
50 Alumina 50 Barytes	150	As the former.
20 Alumina 80 Barytes	148	Somewhat harder, but no ſign of fuſion.
25 Alumina 75 Barytes	150	Harder, but no ſign of fuſion.

4. Nothing is known concerning the effect of heat on mixtures of ſtrontites and alumina.

228 Alumina and ſilica; 5. Equal parts of alumina and ſilica harden in the temperature of 160° Wedgewood, but do not fuſe *. Achard found them infuſible in all proportions in a heat probably little inferior to 150° Wedgewood. Mixtures of theſe two earths in various proportions form *clays*, but theſe are ſeldom uncontaminated with ſome other ingredients.

229 Lime, magneſia, and alumina; 6. From the experiments of Achard, it appears that no mixture of lime, magneſia, and alumina, in which the lime predominates, is vitrifiable, except they be nearly in the proportions of three lime, two magneſia, one alumina; that no mixture in which magneſia predominates will melt in a heat below 166°; that mixtures in which the alumina exceeds are generally fuſible, as will appear from the following table †.

3 Alumina 2 Lime 1 Magneſia	A porcelain.
3 Alumina 1 Lime 2 Magneſia	A porcelain.
3 Alumina 1 Lime 3 Magneſia	Porous porcelain.
3 Alumina 2 Lime 3 Magneſia	Porous porcelain.
3 Alumina 2 Lime 2 Magneſia	Porcelain.

230 Lime, ſilica, and alumina; 7. From the ſame experiments, and thoſe of Kirwan, we learn, that in mixtures of lime, ſilica, and alumina, when the lime exceeds, the mixture is generally fuſible either into a glaſs or a porcelain, according to the proportions. The only infuſible proportions were,

2	3	Lime
1	1	Silica
2	2	Alumina.

That if the ſilica exceeds, the mixture is frequently fuſible into an enamel or porcelain, and perhaps a glaſs; and that when the alumina exceeds, a porcelain may often be attained, but not a glaſs *.

231 Magneſia, ſilica, and alumina; 8. As to the mixtures of magneſia, ſilica, and alumina, when the magneſia exceeds, no fuſion takes place at 150°. When the ſilica exceeds, a porcelain may often be attained; and three parts ſilica, two magneſia, and one alumina, formed a glaſs. When the alumina exceeds, nothing more than a porcelain can be produced †.

232 And lime, magneſia, ſilica, and alumina. 9. Achard found that equal parts of lime, magneſia, ſilica, and alumina, melted into a glaſs. They fuſed alſo in various other proportions, eſpecially when the ſilica predominated.

233 Affinities of alumina. The affinities of alumina as as follows:

Sulphuric acid,
Nitric,
Muriatic,
Oxalic,
Arſenic,
Fluoric,
Sebacic,
Tartarous,
Succinic,
Saccholactic,
Citric,
Phoſphoric,
Formic,
Lactic,
Benzoic,
Acetous,
Boracic,
Sulphurous,
Nitrous,
Carbonic,
Pruſſic.

SECT. VII. *Of Jargonia.*

234 Diſcovery of jargonia. AMONG the precious ſtones which come from the iſland of Ceylon, there is one called *jargon*, which is poſſeſſed of the following properties.

Its colour is various, grey, greeniſh white, yellowiſh, reddiſh brown, and violet. It is often cryſtallized, either in right angular quadrangular priſms ſurmounted with pyramids, or octahedrals conſiſting of double quadrangular pyramids. It has generally a good deal of luſtre, at leaſt internally. It is moſtly ſemitranſparent. Its hardneſs is from 10 to 16: Its ſpecific gravity from 4,416 to 4,7 ‡.

It loſes ſcarcely any of its weight in a melting heat; for Klaproth found that 300 grains, after remaining in it for an hour and a half, were only one-fourth of a grain lighter than at firſt §. Neither was it attacked either by muriatic or ſulphuric acid, even when aſſiſted by heat. At laſt, by calcining it with a large quantity of ſoda, he diſſolved it in muriatic acid, and found that 100 parts of it contained 31,5 of ſilica, five of a mixture of nickel,

§ *Jour. de Phyſ.* 36. 180.

el and iron, and 68 of an earth poſſeſſed of peculiar properties. This earth has been called *jargonia*.

235 Its properties. Jargonia has a ſtrong reſemblance to alumina. It is of a white colour. Its ſpecific gravity probably exceeds 4,000.

It differs from alumina in the compounds which it forms with other bodies, in being inſoluble in a boiling ſolution of pure potaſs or ſoda, and in being infuſible by heat when mixed with theſe ſubſtances in a ſtate of dryneſs *.

* *Kirwan's Mineral.* i. p. 14.

No more of its properties are yet known.

Sect. VIII. *Of Glucina.*

236 Diſcovery of glucina. In the beryl was diſcovered, ſome time ago by Vauquelin, a new earth, to which he gave the name of *glucina*. To obtain it pure, the beryl, reduced to powder, is to be fuſed with thrice its weight of potaſs. The maſs is to be diluted with water, diſſolved in muriatic acid, and the ſolution evaporated to dryneſs. The reſiduum is to be mixed with a large quantity of water, and the whole thrown on a filter. The ſilica, which conſtitutes more than half the weight of the ſtone, remains behind; while the glucina and the other earths, combined with muriatic acid, remain in ſolution. They are to be precipitated by means of carbonat of potaſs; the precipitate is to be waſhed, and then diſſolved in ſulphuric acid. When the ſolution, after potaſs has been added to it, has been evaporated to the proper conſiſtency, alum cryſtals are gradually formed. When as many of theſe have been obtained as poſſible, carbonat of ammonia in exceſs is to be poured into the liquid, which is firſt to be filtered and then boiled for ſome time, when a white powder gradually appears. This powder is *glucina*.

237 Its properties. It is a ſoft light powder, without either taſte or ſmell, but has the property of adhering ſtrongly to the tongue. It has no action on vegetable colours, is altogether infuſible by heat, and neither hardens nor contracts in its dimenſions. It is inſoluble in water, but forms with a ſmall quantity of that liquid a paſte to a certain degree ductile. It does not combine with oxygen, nor with any of the ſimple combuſtibles; but ſulphurated hydrogen diſſolves it, and forms with it a hydroſulphuret, ſimilar in its properties to other hydroſulphurets. Glucina is ſoluble in the liquid fixed alkalies; inſoluble in ammonia, but ſoluble in carbonat of ammonia. It combines with all the acids, and forms with them ſweet taſted ſalts; and hence its name, from γλυκος, *ſweet*. Its other properties have not been examined.

Sect. IX. *Of Yttria and Aguſtina.*

238 Diſcovery and properties of yttria. Some time before 1788 was diſcovered, in the quarry of Ytterby in Sweden, a peculiar mineral, called from Profeſſor Gadolin, who firſt analyſed it, *gadolinite*. Its colour is black, and its fracture like that of glaſs. It is magnetic, and ſoft enough to be ſcratched by a knife, and ſometimes even by the nail. In this mineral a new earth has been diſcovered by various chemiſts, who have agreed to give it the name of *yttria*. When ſeparated from the other ſubſtances with which it is combined, viz. the oxides of iron and manganeſe, a little lime, and a conſiderable quantity of ſilica, it has the appearance of a fine white powder, and has neither taſte nor ſmell. It is not melted by the application of heat, has no action on vegetable blues, and is not ſoluble in water. It is likewiſe inſoluble in pure alkalies; but it diſſolves readily in carbonat of ammonia. It combines with acids, and forms with them ſalts, which have a ſweet taſte, and at the ſame time a certain degree of auſterity.

239 Diſcovery of aguſtina. Trommſdorf has lately diſcovered in the *Saxon beryl* a new earth, to which he has given the name of *Aguſtina*, becauſe the ſalts which it forms have little or no taſte. As Trommſdorf's experiments have not hitherto been repeated, the exiſtence of this earth muſt continue doubtful till the concluſions of the diſcoverer be confirmed by other philoſophers.

240 Remarks on the earths. These are all the ſimple earths that have yet been diſcovered; and the firſt four of them have a great many common properties. They tinge vegetable blues green, they have a ſtrong affinity for carbonic acid, and combine readily with all acids. They have ſometimes been called *alkaline earths*.

None of the earths have been hitherto decompounded, nor has the ſmalleſt proof ever been brought that they are compounds. We muſt therefore, in the preſent ſtate of chemiſtry, conſider them as ſimple bodies. Many attempts, indeed, have been made to ſhew that there was but one earth in nature, and that all others were derived from it. The earth generally made choice of as the ſimpleſt was ſilica (y). But none of theſe attempts, notwithſtanding the ingenuity of ſeveral of the authors, has been attended with the ſmalleſt ſhadow of ſucceſs.

We have mentioned formerly, that it was almoſt the univerſal opinion of chemiſts that metals were compoſed of ſome of the earths united to phlogiſton; but of late an attempt has been made to prove that all the earths are metallic oxides, and that they can actually be reduced to the ſtate of metals.

Baron had long ago ſuſpected that alumina had ſomewhat of a metallic nature; and Bergman had been induced, by its great weight and ſeveral other appearances, to conjecture that barytes was a metallic oxide: But the firſt chemiſt who ventured to hint that all earths might be metallic oxides was Mr Lavoiſier *. About the year 1790, ſoon after the publication of Mr Lavoiſier's book, Mr Tondi and Profeſſor Ruprecht, both of Schemnitz, announced, that they had obtained from barytes, by the application of a ſtrong heat, a metal of the colour of iron, and attracted by the magnet, which they called *borbonium*; from magneſia another, which they called *auſtrum*; a third from lime, alſo called *auſtrum*; and a fourth from alumina, which they denominated *apulum*. Their method of proceeding was to apply a violent heat to the earths, which were ſurrounded with charcoal in a Heſſian crucible, and covered with calcined bones in powder.

* *Chemiſtry*, p. 217. Eng. Tranſl.

But their experiments were ſoon after repeated by Klaproth, Savoreſi, and Tihauſki; and theſe accurate chemiſts

---

(y) Mr Sage, however, pitched upon lime.

chemiſts ſoon proved, that the pretended metals were all of them *phoſphurets of iron*. The iron, by the violence of the heat, had been extracted from the crucible, and the phoſphorus from the bones. The earths therefore muſt ſtill continue a diſtinct claſs of bodies: and, as Klaproth has obſerved, their properties are ſo exceedingly different from thoſe of metallic oxides, that the ſuppoſition of their being compoſed of the ſame ingredients is contrary to every fact, and to every analogy with which we are acquainted.

CHAP. V. *Of* CALORIC.

NOTHING is more familiar to us than *heat;* to attempt to define it therefore would be unneceſſary. When we ſay that *a perſon feels heat*, that *a ſtone is hot*, the expreſſions cauſe no difficulty; every one underſtands them perfectly: yet in each of theſe propoſitions the word *heat* has a diſtinct meaning. In the one, it ſignifies the *ſenſation* of heat; in the other, the *cauſe* of that ſenſation. This ambiguity, though of little conſequence in common life, leads unavoidably in philoſophical diſcuſſions to confuſion and perplexity. It was to prevent this that the French chemiſts made choice of the word *caloric* to ſignify the *cauſe of heat*. When I put my hand on a hot ſtone, I experience a certain ſenſation, which I call the *ſenſation of heat;* the cauſe of this ſenſation is *caloric*.

241
Whether caloric be a ſubſtance.

Concerning the nature of caloric, there are two opinions which have divided philoſophers ever ſince they turned their attention to the ſubject. Some ſuppoſe that caloric, like gravity, is merely a property of matter, and that it conſiſts, ſome how or other, in a peculiar vibration of its particles; others, on the contrary, think that it is a diſtinct ſubſtance. Each of theſe opinions has been ſupported by the greateſt philoſophers; and the obſcurity of the ſubject is ſuch, that both ſides have been able to produce exceedingly plauſible and forcible arguments. The recent diſcoveries, however, in this branch of chemiſtry, have rendered the latter opinion much more probable than the former. Indeed we do not ſee how it is poſſible to account for many of the phenomena of nature, unleſs caloric be conſidered as a ſubſtance, as we truſt ſhall appear from the inveſtigation into which we are about to enter. We mean, then, with the generality of modern chemiſts, to take it for granted that caloric is a ſubſtance, without pretending to be able to demonſtrate the truth of our opinion, but merely becauſe we conſider it as infinitely more plauſible than the other. If the receiver of an air-pump, while it contains a thermometer, be ſuddenly exhauſted of air, the thermometer ſinks ſeveral degrees, and then gradually riſes again to its former height. Now if heat be owing to vibration, how comes it that the ſmall quantity of matter remaining in the receiver is firſt inſufficient, and afterwards ſufficient to maintain the temperature? Is it not more probable that part of the caloric was carried off with the air, and that it gradually returned through the glaſs, which it is capable of pervading, though with difficulty *. When air is let into an exhauſted receiver, the thermometer, as Lambert firſt obſerved, riſes ſeveral degrees. Is not this owing to an additional quantity of caloric introduced by the air? The thermometer then ſinks ſlowly. Is not this becauſe the ſuperabundant caloric gradually pervades the glaſs and flies off? Taking it for granted then that caloric is a ſubſtance, we proceed to examine its propertis.

242
Caloric expands bodies.

1. When bodies become hot, or, which is the ſame thing, when caloric enters into them, they expand in every direction; and this expanſion is proportional to the accumulation of caloric. The firſt and moſt obvious property of caloric then is the power of expanding bodies. It does not, however, expand all ſubſtances equally, and we are ſtill ignorant of the law which it follows. All that can be done therefore is to collect facts till this law be diſcovered. A number of theſe may be ſeen in the following Table:

From

(A) This mark ‡ implies that, owing to ſome inaccuracy in making the experiments, the numbers to which it is attached are not to be depended on.

(B) The metal whoſe expanſion is here given was an alloy compoſed of three parts of copper and one of tin. The figures in ſome of the preceding columns are to be underſtood in the ſame manner. Thus in the laſt column but two, the metal conſiſted of two parts of braſs alloyed with one of zinc.

From this table, it appears that the gaſes are more expanded by caloric than fluids, and fluids more than ſolids; and that the expanſion of all bodies hitherto examined, mercury alone excepted, goes on in an increaſing ſeries.

243 Exception.

To the expanding power of caloric there is one ſingular exception: From 30° to 40° Fahrenheit, *water*, inſtead of being expanded, ſuffers a remarkable contraction, as is evident from the following table of its bulk for every degree between 30° and 40°.

	Bulk.

38 - - -	100054
39 - - -	100054
40 - - -	100054 *.

* *Blagden.*

From 40° it expands like other ſubſtances on being heated (B).

244 Thermometer.

The expanſion of bodies by caloric has furniſhed us with an inſtrument for meaſuring the various degrees of it in different ſubſtances, we mean the thermometer; and as mercury is the only fluid which expands equably, it is obviouſly the only proper one for thermometers. The thermometer uniformly uſed in this article is that of Fahrenheit, except when ſome other is particularly mentioned.

245 No body without caloric.

2. By means of the thermometer, we learn that there is no body which does not contain caloric, becauſe there is none ſo cold that it cannot be made colder: and cooling a body is nothing elſe but abſtracting a part of the caloric which it contains.

246 Equilibrium of caloric.

3. Caloric cannot be confined in any body while thoſe in its neighbourhood are colder, but continues to ruſh out till every thing is reduced to the ſame temperature. This does not proceed from the attraction of the colder bodies, but from the tendency of caloric to exiſt everywhere in an equal degree of tenſion: For when hot bodies are placed in the exhauſted receiver of an air-pump, as we learn from Mr Pictet †, or in the Torricellian vacuum, as Count Rumford has ſhewn us ‡, the caloric leaves them in the ſame manner, tho' more ſlowly, and they are equally reduced to the temperature of the ſurrounding bodies. This property has been called *the equilibrium of caloric*. The only way therefore to confine or accumulate this ſubſtance in a body, is to ſurround it with bodies which are hotter than itſelf.

† *Sur le Feu*, chap. vi.
‡ *Phil. Tranſ.* 1786, Part I.

247 The particles of caloric repel each other.

4. The equilibrium of caloric ſeems evidently to prove that its particles repel each other. This repulſion will cauſe them when accumulated in any place to fly off in every direction, and to continue to ſeparate till they are oppoſed by caloric in other bodies of the ſame relative denſity with themſelves, which, by repelling them in its turn, compels them to continue where they are. The caloric in bodies therefore is in what has been called by Mr Pictet a ſtate of *tenſion* (C). Its particles are actuated by a force which would make them ſeparate to an indefinite diſtance, were they not confined by the oppoſite force of the caloric which ſurrounds them. The *equilibrium* therefore depends on the balancing of two oppoſite forces; the repulſion between the particles of caloric in the body, which tends to diminiſh the temperature; and the repulſion between the caloric of the body and the ſurrounding caloric, which tends to raiſe the temperature. When the firſt force is greater than the ſecond, as is the caſe when the temperature of a body is higher than that of the ſurrounding bodies, the caloric flies off, and the body becomes colder. When the laſt force is ſtronger than the firſt, as is the caſe when a body is colder than thoſe which are around it, the particles of its caloric are obliged to approach nearer each other, new caloric enters to occupy the ſpace which they had left, and the body becomes hotter. When the two forces are equal, the bodies are ſaid to be of the ſame temperature, and no change takes place *.

* See *Pictet ſur le Feu*, ch. i.

It is the action of theſe oppoſite forces which makes the thermometer a meaſure of temperature. When applied to any body, it continues to riſe or fall till the caloric in it and in the body to which it is applied are of the ſame tenſion, and then it remains ſtationary. The thermometer therefore merely indicates that the temperature of the body to which it is applied is equal to its own. It is obvious that, in order to obtain the real temperature of bodies, the thermometer ſhould be ſo ſmall that the quantity of caloric, which enters or leaves it, may not materially affect the reſult.

This property of caloric ſeems to be the cauſe of the elaſticity of the gaſes, in which, as we ſhall ſhew afterwards, it exiſts in great quantities. Perhaps it is the cauſe of elaſticity in general; for we have no demonſtrative evidence that the particles of elaſtic bodies repel each other (D), and we are certain that all of them contain caloric. Perhaps alſo it is owing to this repulſive property of caloric that the particles of no body actually touch each other; for the leſs caloric we leave in a body, the nearer its particles approach to one another. The expanſion of bodies by caloric ſeems alſo to depend on the ſame property. The particles of caloric uniting with thoſe of the body, endeavour to drag them along when they recede from each other. The expanſion

---

(B) There was a curious fact concerning dilatation obſerved by Mr de Luc. A braſs rod which he uſed as a thermometer became in ſummer *habitually* longer; that is to ſay, that after being for ſome time lengthened by heat, it did not contract by the application of cold to its old length, but continued ſomewhat longer. In winter the contrary phenomenon took place. After being contracted for ſome time by cold, it did not return to its old length on the application of heat, but kept ſomewhat ſhorter. A leaden rod ſhewed theſe effects in a greater degree. Glaſs has not this quality. De Luc ſuſpects that this property is inverſely as the elaſticity of bodies. Glaſs is perfectly elaſtic, and lead is leſs elaſtic than braſs.—*Journ. de Phyſ.* xviii. 369.

(C) The phraſe was firſt uſed by Mr Volta.

(D) We acknowledge that ſeveral philoſophers of the firſt rank, Æpinus for inſtance, and Boſcovich, have ſuppoſed that the particles of all bodies both attract and repel each other: but we cannot help thinking it rather improbable (if it be poſſible) that two ſuch oppoſite properties ſhould exiſt together.

248
Bodies become lighter by being heated,

ſion of bodies therefore ought to be inverſely as their coheſion, and directly as the tenſion of the caloric which they contain. This property of caloric ſeems likewiſe to afford an explanation of a very curious fact, which was firſt, we believe, mentioned by De Luc in his Treatiſe on the Modifications of the Atmoſphere, and afterwards aſcertained by Dr George Fordyce, that bodies become abſolutely lighter by being heated. He took a glaſs globe three inches in diameter, with a ſhort neck, and weighing 451 grains; puured into it 1700 grains of water from the New river, London, and then ſealed it hermetically. The whole weighed $2150\frac{11}{12}$ grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of ſnow and ſalt till ſome of it was frozen; it was then, after being wiped firſt with a dry linen cloth, next with clean waſhed dry leather, immediately weighed, and found to be $\frac{1}{60}$th of a grain heavier than before. This was repeated exactly in the ſame manner five different times. At each, more of the water was frozen and more weight gained. When the whole water was frozen, it was $\frac{3}{10}$ths of a grain heavier than it had been when fluid. A thermometer applied to the globe ſtood at 10°. When allowed to remain till the thermometer roſe to 32°, it weighed $\frac{2}{10}$ths of a grain more than it did at the ſame temperature when fluid. We ſhall ſhew afterwards that ice contains leſs caloric than water of the ſame temperature with it. The balance uſed was nice enough to mark $\frac{1}{1000}$ part of a grain *. Morveau, too, found, much about the ſame time, that water put into veſſels hermetically ſealed, weighed more when frozen than when fluid †: and Mr Chauſſier found, that two pounds of ſulphuric acid were three grains heavier when frozen than after they had recovered their fluidity ‡.

249
And why.

Now, if the particles of caloric repel each other, bodies which contain it in great quantities muſt be ſomewhat repelled by each other. The more replete therefore that any body is with caloric, the more it will be repelled by the earth, which always contains a great quantity; and this repulſion muſt in ſome degree counteract its gravitation. This explanation was firſt ſuggeſted, we believe, by Dr Black.

250
Caloric movesmore readily upwards than downwards

The ſame property explains another curious fact diſcovered by Mr Pictet of Geneva, that caloric moves more readily vertically upwards than downwards. He took a tube of tinplate, two inches in diameter and 44 in length, and encloſed in it a bar of copper four lines in diameter and 33 inches in length, which was placed and fixed exactly in its axis. This tube was exhauſted of air, by means of an air-pump, till the manometer § ſtood at the height of four lines. It was incloſed in another tube of paſteboard, except about two inches, exactly in the middle, to which place the ſun's rays were directed for half an hour by means of a concave mirror. The ends of the copper bar were ſcooped out into concave hemiſpheres; and into each of theſe the bulb of a very ſenſible thermometer was fixed. The tube was placed vertically. The higheſt thermometer, which we ſhall call A, roſe to 95°, a hundred and one ſeconds before the loweſt B. The thermometer B roſe no higher than 95°; but the thermometer A reached 121,75°. To ſee whether this difference was owing to the thermometers, the tube was inverted, and conſequently the higheſt thermometer in the former experiment was loweſt in this. The thermometer B now roſe from 49 to 97,25 in 2810″; the thermometer A in 2763″, or 47″ ſooner than B. It was evident from this reſult, that the thermometer A was more ſenſible than the thermometer B by 47″. If this be ſubtracted from 101″, the former difference, it will leave 54″, as the difference reſulting from poſition. Theſe experiments were repeated with only this difference, that round the ends of the bar and the bulbs of the thermometers (but without touching the bulbs) ſome folds of oiled paper were wrapped to confine the caloric. The ſuperior thermometer A roſe from 50° to 106,25° in 34 minutes, which was 93′ ſooner than the inferior B: it roſe to 110,75°, the thermometer B only to 106,25°. The tube being reverſed, the thermometer A, which was now loweſt, roſe from 46° to 115,25° in 40′ 30″, or forty ſeconds ſooner than the thermometer B. This ſubtracted from 93″, as formerly, leaves 53″ for the difference of ſituation. The ſuperior thermometer mounted after the burning-glaſs was removed 0,45°, remained ſtationary for 80″, and after five minutes had only deſcended 0,45°: the other did not aſcend at all; in one minute it deſcended 0,225°, and in 6′ 8′ it deſcended 2,47°. In 22′ 50″ the inferior deſcended 63,725°, the ſuperior 61,475° *. From theſe experiments, it is obvious that the particles of caloric move ſomewhat faſter, and in ſomewhat greater quantity, upwards than downwards; owing, doubtleſs, to the repulſive power of the caloric in the earth. The ſmall quantity of air that remained in the tube may perhaps be ſuppoſed ſufficient to account for the difference, without allowing any ſuch tendency upwards in caloric. But it is evident from the experiments of the Florentine academicians on the ſame ſubject, with tubes full of air, that even when in great abundance, that fluid hardly affected the riſing of the ſuperior thermometer: ſurely then its effect muſt be altogether imperceptible when ſo little of it remained; and in the third and fourth experiments the oiled paper prevented any of the heated air from approaching the thermometer.

251
Conducting power of bodies:

5. If we take a bar of iron and a piece of ſtone of equal dimenſions, and putting one end of each into the fire, apply either thermometers or our hands to the other, we ſhall find the extremity of the iron ſenſibly hot long before that of the ſtone. Caloric therefore does not paſs through all bodies with the ſame celerity and eaſe. The power that bodies have to allow it a paſſage through them is called their *conducting power*; thoſe that allow it to paſs with facility, are called *good conductors*; thoſe through which it paſſes with difficulty, are called *bad conductors*; and thoſe which do not allow it to paſs at all, *non-conductors*.

252
Of wood and charcoal;

It is probable that all ſolids conduct heat in ſome degree, at leaſt this is the caſe with every one at preſent known. Wood and charcoal are exceeding bad conductors of caloric (E). Count Rumford informs us, that a piece of

* *Phil. Tranſ.* 1785, Part II.

† *Journ. de Phyſ.* 1785, Oct.

‡ *Journ. de Savans*, 1785, p. 493.

§ See *Manometer* in this Suppl.

* *Pictet ſur le Feu*, chap. 2.

(E) This fact merits the attention of chemiſts. It is obvious, that when metallic oxides are ſurrounded with charcoal powder, their temperature cannot be raiſed near ſo high as it otherwiſe would be. It is not unlikely that ſome part of the difficulty which has been experienced in attempting to reduce and fuſe ſeveral metallic ſubſtances may have been owing to this cauſe.

Caloric

of green oak plank was employed to ſtir the melted metal of which cannons were founding at Munich, and it was often allowed to remain a conſiderable time in the furnace; yet the caloric had penetrated to ſo inconſiderable a depth, that at the diſtance of $\frac{1}{20}$th of an inch below the ſurface, the wood did not ſeem to have been the leaſt affected by it; the colour remained unchanged, and it did not appear to have loſt even its moiſture *.

253
Of glaſs;

Glaſs, when not tranſparent (F), is alſo a very bad conductor: and this is the reaſon that it is ſo apt to crack on being heated or cooled ſuddenly; one part of it receiving or parting with its caloric before the reſt, expands or contracts, and deſtroys the coheſion.

254
Of metals;

Metals are the beſt conductors of caloric of all the ſolids hitherto examined. The conducting powers of all, however, are not equal. Dr Ingenhouſz procured cylinders of ſeveral metals exactly of the ſame ſize, and having coated them with wax, he plunged their ends into hot water, and judged of the conducting power of each by the length of wax-coating melted. From theſe experiments he concluded, that the conducting powers of the metals which he examined were in the following order †.

Silver,
Gold,
Copper, } nearly equal.
Tin, }
Platinum, }
Iron, } much inferior to the others.
Steel, }
Lead, }

255
Of ſtones and ſolids capable of melting.

Next to metals ſtone ſeems to be the beſt conductors; but this property varies conſiderably in different ſtones. Bricks are much worſe conductors than moſt ſtones. All ſolids capable of being melted become non-conductors the moment they are heated to the melting point: the caloric enters them eaſily enough, but it remains in them.

256
Whether fluids be conductors of caloric.

A queſtion has lately been agitated among philoſophers, Whether fluids be conductors of caloric? No doubt was entertained of their being not only conductors, but good conductors, till the publication of Count Rumford's Eſſays, in which the author contends, with much plauſibility of reaſoning, that though fluids *carry*, they do not *conduct* heat; or, in other words, let it paſs freely from one particle to another.

257
What led him to this opinion.

In a ſet of experiments on the communication of heat, he made uſe of thermometers of an uncommon ſize. Having expoſed one of theſe (the bulb of which was near four inches in diameter) filled with alcohol to as great a heat as it could ſupport, he placed it in a window to cool where the ſun happened to be ſhining. Some particles of duſt had by accident been mixed with the alcohol: theſe being illuminated by the ſun, became perfectly viſible, and diſcovered that the whole liquid in the tube of the thermometer was in a moſt rapid motion, running ſwiftly in oppoſite directions upwards and downwards at the ſame time. The *aſcending* current occupied the axis, the *deſcending* current the ſides of the tube. When the ſides of the tube were cooled by means of ice, the velocity of both currents was accelerated. It diminiſhed as the liquid cooled; and when it had acquired the temperature of the room, the motion ceaſed altogether. This experiment was repeated with lintſeed oil, and the reſult was preciſely the ſame. Theſe currents were evidently produced by the particles of the liquid going individually to the ſides of the tube, and giving out their caloric. The moment they did ſo, their ſpecific gravity being increaſed, they fell to the bottom, and of courſe puſhed up the warmer part of the fluid, which was thus forced to aſcend along the axis of the tube. Having reached the top of the tube, the particles gave out part of their caloric, became ſpecifically heavier, and tumbled in their turn to the bottom.

As theſe internal motions of fluids can only be diſcovered by mixing with them bodies of the ſame ſpecific gravity with themſelves, and as there is hardly any ſubſtance of the ſame ſpecific gravity with water which is not ſoluble in it, Count Rumford had recourſe to the following ingenious method of aſcertaining whether that fluid alſo followed the ſame law. The ſpecific gravity of water is increaſed conſiderably by diſſolving any ſalt in it; he added, therefore, potaſs to water till its ſpecific gravity was exactly equal to that of amber, a ſubſtance but very little heavier than pure water. A number of ſmall pieces of amber were then mixed with this ſolution, and the whole put into a glaſs globe with a long neck, which, on being heated and expoſed to cool, exhibited exactly the ſame phenomena with the other fluids. A change of temperature, amounting only to a very few degrees, was ſufficient to ſet the currents a-flowing; and a motion might at any time be produced by applying a hot or a cold body to any part of the veſſel. When a hot body was applied, that part of the fluid neareſt it aſcended; but it deſcended on the application of a cold body.

258
Proofs of the non-conducting power of water,

If caloric paſs through water only by the internal motion of its particles, as this experiment ſeems to prove, it is evident that every thing which embarraſſes theſe motions muſt retard its tranſmiſſion: and accordingly Count Rumford found this to be the caſe. He took a large lintſeed oil thermometer with a copper bulb and glaſs tube: the bulb was placed exactly in the centre of a braſs cylinder, ſo that there was a void ſpace between them all around 0,25175 of an inch thick. The thermometer was kept in its place by means of four wooden pins projecting from the ſides and bottom of the cylinder, and by the tube of it paſſing through the cork ſtopper of the cylinder. This cylinder was filled with pure water, then held in melting ſnow till the thermometer fell to 32°, and immediately plunged into a veſſel of boiling water. The thermometer roſe from 32° to 200° in 597″. It is obvious that all the caloric which ſerved to raiſe the thermometer muſt have made its way through the water in the cylinder. The experiment was repeated exactly in the ſame manner; but the water in the cylinder, which amounted to 2276 gr. had 192 gr. of ſtarch boiled in it, which rendered it much leſs fluid. The thermometer now took 1109″ to riſe from 32° to 200°. The ſame experiment was again repeated with the ſame quantity of pure water, having

192

* *Rumford's Eſſays*, ii. 229.

† *Journ. de Phyſ.* 1789, p. 68.

(F) When tranſparent, it tranſmits caloric.

192 gr. of eiderdown mixed with it, which would merely tend to embarraſs the motion of the particles. A quantity of ſtewed apples were alſo in another experiment put into the cylinder. The following Tables exhibit the reſult of all theſe experiments.

Time the Caloric was in paſſing into the Thermometer.

Temperature.	Through the Water and Starch.	Thro' the Water and Eiderdown.	Through ſtewed Apples.	Through pure Water.
	Seconds.	Seconds.	Seconds.	Seconds.
Therm. roſe from 32° to 200° in	1109	949	1096½	597
Therm. roſe 80°, *viz.* from 80° to 160°, in	341	269	335	172

Time the Caloric was in paſſing out of the Thermometer.

Temperature.	Through the Water and Starch.	Thro' the Water and Eiderdown.	Through ſtewed Apples.	Through pure Water.
	Seconds.	Seconds.	Seconds.	Seconds.
Therm. fell from 200° to 40° in	1548	1541	1749½	1032
Therm. fell 80°, *viz.* from 160° to 80°, in	468	460	520	277

Now neither the ſtarch nor the eiderdown could produce any alteration in the water except impeding its internal motions; conſequently whatever impedes theſe motions diminiſhes the conducting power of water. But this could not happen unleſs every individual particle actually went from the cylinder to the thermometer. Hence it follows that, if liquids be conductors, their conducting power is but ſmall when compared with their carrying power.

259 hewn to be inconcluſive.

All liquids, however, are capable of conducting caloric; for when the ſource of heat is applied to their ſurface, the caloric gradually makes its way downwards, and the temperature of every ſtratum gradually diminiſhes from the ſurface to the bottom of the liquid. The increaſe of temperature in this caſe is not owing to the carrying power of the liquid. By that power caloric may indeed make its way upwards through liquids, but certainly not downwards. Liquids then are conductors of caloric.

Count Rumford, indeed, has drawn a different concluſion from his experiments. He fixed a cake of ice in the bottom of a glaſs jar, covered one-fourth inch thick with cold water. Over this was poured gently a conſiderable quantity of boiling water. Now if water were a non-conductor, no caloric could paſs through the cold water, and conſequently none of the ice would be melted. The melting of the ice, then, was to determine whether water be a conductor or not. In two hours about half the ice was melted. This one would think, at firſt ſight, a deciſive proof that water is a conductor. But the Count has fallen upon a very ingenious method of accounting for the melting of the ice, without being under the neceſſity (as he tells us) of renouncing his theory that fluids are non-conductors.

It is well known that the ſpecific gravity of water at 40° is a maximum: if it be either heated above 40°, or cooled down below 40°, its denſity diminiſhes. Therefore, whenever a particle of water arrives at the temperature of 40°, it will ſink to the bottom of the veſſel. Now as the water next the ice was at 32°, it is evident that whenever any part of the hot water was cooled down to 40°, it would ſink, diſplace the water at 32°, come into contact with the ice, and of courſe melt it. The Count's ingenuity, never without reſources, enabled him to prove completely, that the ice employed in his experiment was actually melted in that manner: for when he covered the ice partially with ſlips of wood, that part which was ſhaded by the wood was not melted; and when he covered the whole of the ice with a thin plate of tin, having a circular hole in the middle, only the part exactly under the hole was melted. From theſe facts it certainly may be concluded that the ice was melted by deſcending currents of water.

But the point to be aſcertained, is not whether there were deſcending currents, but whether water be a conductor or not. Now if water be a non-conductor, by what means was the hot water cooled down to 40°? Not at the ſurface; for the Count himſelf tells us, that there the temperature was never under 108°: not by the ſides of the veſſel; for the deſcending current in one experiment was exactly in the axis: and it follows irreſiſtibly, from the experiment with the ſlips of wood, that theſe deſcending currents fell equally upon every part of the ſurface of the ice; which would have been impoſſible if theſe currents had been cooled by the ſide of the veſſel. The hot water, then, muſt have been cooled down to 40° by the cold water below it; conſequently it muſt have imparted caloric to this cold water. If ſo, one particle of water is capable of abſorbing caloric from another; that is, *water is a conductor of caloric.* After the hot water has ſtood an hour over the ice, its temperature was as follows:

At the ſurface of the ice	40°
One inch above the ice	80
Two inches - -	118
Three inches - -	128
Four inches - -	130
Seven inches - -	131

How is it poſſible to account for this gradual diminution of heat as we approach the ice, if water be a non-conductor? The water, it may be ſaid, gives out caloric at its ſurface, falls down, and arranges itſelf according to its ſpecific gravity. If ſo, how comes it that there is only one degree of difference between the temperature at 4 and at 7 inches above the ice? Thus it appears that the Count's experiment, inſtead of demonſtrating that water is a non-conductor, rather favours the common opinion that it is a conductor.

260 Mercury and oil proved to be conductors.

The Count tried whether oil and mercury be conductors in the following manner: When water was frozen in a glaſs jar by means of a freezing mixture, Count Rumford obſerved that the ice firſt began to be formed at the ſides, and gradually increaſed in thickneſs; and that the water on the axis of the veſſel, which retained its fluidity longeſt, being compreſſed by the expanſion of the ice, was forced upwards, and when completely frozen, formed a pointed projection or nipple, which was ſometimes half an inch higher than the reſt of the ice. Upon ice frozen in this manner, he poured olive oil, previouſly cooled down to 32°, till it ſtood at the height of three inches above the ice. The veſſel was ſurrounded as high as the ice with a mixture of pounded ice and water. A ſolid cylinder of wrought iron, 1$\frac{1}{4}$th inch in diameter, and 12 inches long, provided with a hollow cylindrical ſheath of thick paper, was heated to the temperature of 210° in boiling water; and being ſuddenly introduced into its ſheath, was ſuſpended from the ceiling of the room, and very gradually let down into the oil, until the middle of the flat ſurface of the hot iron, which was directly above the point of conical projection of the ice, was diſtant from it only $\frac{2}{10}$ths of an inch. The end of the ſheath deſcended $\frac{1}{10}$th of an inch lower than the end of the hot metallic cylinder. Now it is evident, that if olive oil was a conductor, caloric would paſs down through it from the iron and melt the ice. None of the ice, however, was melted; and when mercury was ſubſtituted for oil, the reſult was juſt the ſame *; conſequently it follows that neither oil nor mercury is a conductor of heat.

But this experiment is by no means ſufficiently delicate to decide the point. If a thermometer be ſubſtituted inſtead of the nipple of ice, it always riſes ſeveral degrees; whence it follows that, even in this caſe, caloric paſſes downwards; ſo that the experiment is in fact favourable to the ſuppoſition that oil and mercury are conductors.

Count Rumford therefore has not proved that fluids are non-conductors of caloric; and that they are in truth conductors, the author of this article aſcertained in the following manner: The liquid of which the conducting power was to be examined was poured into a glaſs veſſel till it filled it about half way; then a hot liquid of leſs ſpecific gravity was poured over it. Thermometers were placed at the ſurface, in the centre, and at the bottom of the cold liquid; if theſe roſe, it followed that the liquid was a conductor, becauſe the caloric made its way downwards. For inſtance, to examine the conducting power of mercury, a glaſs jar was half filled with that liquid metal, and boiling water then poured over it. The thermometer at the ſurface began immediately to riſe, then the thermometer at the centre, and laſtly that at the bottom. The firſt roſe to 118°, the ſecond to 90°, and the third to 86°: the firſt reached its maximum in 1′, the ſecond in 15′, the third in 25′. The conducting power of water was tried in the ſame manner with hot oil poured over it; and the reſult was ſimilar.

Fluids, then, as far as experiments have been made, are conductors of caloric as well as ſolids; and hence it follows that caloric is capable of making its way thro' all bodies with which we are acquainted. In this reſpect it differs from all other ſubſtances, even from light, which, as far as we know, cannot make its way through all bodies.

261
Tranſmiſſion of caloric radiant heat.

The motion of caloric through bodies is indeed of two kinds: Through ſome it ſeems to move with the ſame rapidity as through free ſpace; whilſt through others, as we have ſeen, it moves ſlowly. When it moves through a body with undiminiſhed velocity, it is ſaid to be *tranſmitted* through it; and when its velocity is prodigiouſly diminiſhed, it is ſaid to be *conducted*. Air, and all tranſparent bodies hitherto examined, have the property of *tranſmitting* caloric through them; though ſome of them, as glaſs, do not tranſmit it till after they have combined with a certain proportion of it: and probably no body tranſmits it unleſs a greater quantity enter than is capable of combining with it in the ſtate in which the body is placed. The phenomena of the tranſmiſſion of caloric are exactly ſimilar to the tranſmiſſion of light, and admit of preciſely the ſame explanation. What Scheele and ſeveral other chemiſts have called *radiant heat*, is nothing elſe than tranſmitted caloric; as has been completely proved by Dr Herſchel. See *Thermometric Spectrum* in this *Supplement*.

262
Specific caloric of bodies, what.

6. If equal quantities of water and of mercury be placed at the ſame diſtance from a fire, the mercury will become hot much ſooner than the water. After a ſufficient interval, however, both of them acquire the ſame temperature. Now caloric flows into all bodies while they continue of a lower temperature than thoſe around them, and it flows with equal rapidity into all bodies of the ſame conducting powers, as is the caſe with theſe two fluids: But if equal quantities of caloric were conſtantly flowing into the mercury and the water, and yet the water took a longer time to become hot than the mercury, it muſt require a greater quantity of caloric to raiſe water to a given temperature than it does to raiſe mercury. Bodies that require a greater quantity of caloric to raiſe them to a particular temperature than other bodies require, are ſaid to have a greater *capacity* for caloric. That the capacity for caloric is different in different bodies, was firſt obſerved by Dr Black. Dr Irvine afterwards inveſtigated the ſubject, and Dr Crawford publiſhed a great number of experiments on it in his *Treatiſe on Heat.* Profeſſor Wilcke of Stockholm alſo diſcovered the ſame property of bodies. He called the quantity of caloric neceſſary to raiſe the temperature of ſubſtances a given number of degrees, their *ſpecific caloric;* a term which we ſhall alſo employ, becauſe the phraſe *capacity for caloric* is liable to a great deal of ambiguity, and has introduced confuſion into this ſubject (F). If two ſubſtances of unequal temperatures, as water at 100° and alcohol at 50°, be mixed together, the mixture will be of a temperature different both from that of the water and the alcohol, the water will become colder and the alcohol hotter: the water will give out caloric to the alcohol till both are reduced to the ſame temperature. Now if it requires juſt as much caloric to raiſe alcohol a certain number of degrees as it does to raiſe water the ſame number, that is, if theſe two fluids are of the ſame ſpecific caloric, it is evident that the temperature of the mixture will be juſt 75°; for as ſoon as the water has given out 25° of caloric, the alcohol has acquired 25°, conſequently both will be reduced to the ſame temperature, and will remain ſtationary; but if the ſpecific caloric of the water be greater than that of the alcohol, the temperature of the mixture will be higher than 75°; for 25° of

---

* Rumford, Eſſay vii. part ii. chap. 1.

(F) The term *ſpecific caloric* has been uſed in a different ſenſe by Seguin. He uſed it for the *whole caloric* which a body contains.

of caloric in that caſe would raiſe alcohol more than 25°. If the ſpecific caloric of water be ſo much greater than that of alcohol, that what raiſes water 20° will raiſe alcohol 30°; then the temperature after mixture will be 80°, becauſe when the water has given out 20°, the alcohol will have riſen 30°, and of courſe both will be of the ſame temperature. On the contrary, if the ſpecific caloric of alcohol were greater than that of water, the temperature of the mixture would be under 75°. If the ſame quantity of caloric that raiſed alcohol 20° raiſed water 30°, then the temperature of the mixture would be 70°. Thus the ratios of the ſpecific caloric of bodies may be diſcovered by mixing them together at different temperatures.

263 Experiments on ſpecific caloric by Wilcke. The firſt ſet of experiments on this ſubject, in point of time, were probably thoſe of Mr Wilcke. They were firſt publiſhed in the Stockholm Tranſactions for 1781, but had been made long before. The manner in which they were conducted is exceedingly ingenious, and they furniſh us with the ſpecific caloric of many of the metals. The metal on which the experiment was to be made was firſt weighed accurately (generally one pound was taken), and then being ſuſpended by a thread, was plunged into a large veſſel of tinplate, filled with boiling water, and kept there till it acquired a certain temperature, which was aſcertained by a thermometer. Into another ſmall box of tinplate exactly as much water at 32° was put as equalled the weight of the metal. Into this veſſel the metal was plunged, and ſuſpended in it ſo as not to touch its ſides or bottom; and the degree of heat, the moment the metal and water were reduced to the ſame temperature, was marked by a very accurate thermometer. He then calculated what the temperature would have been if a quantity of water equal in *weight* to the metal, and of the ſame temperature with it, had been added to the ice-cold water inſtead of the metal.

Let M be a quantity of water at the temperature C, m another quantity at the temperature c, and let their common temperature after mixture be x; according to a rule demonſtrated long ago by Richman, $x=\frac{MC+mc}{M+m}$. In the preſent caſe the quantities of water are equal, therefore M and m are each $= 1$; C, the temperature of the ice-cold water $= 32$: therefore $\frac{MC+mc}{M+m} = \frac{32+c}{2}$. Now c is the temperature of the metal. Therefore if 32 be added to the temperature of the metal, and the whole be divided by 2, the quotient will expreſs the temperature of the mixture, if an equal weight of water with the metal, and of the ſame temperature with it, had been added to the ice-cold water inſtead of the metal.

He then calculated what the temperature of the mixture would have been, if, inſtead of the metal, a quantity of water of the ſame temperature with it, and equal to the metal in *bulk*, had been added to the ice-cold water. As the weights of the ice-cold water and the metal are equal, their volumes are inverſely as their ſpecific gravities. Therefore the volume of ice-cold water is to a quantity of hot water equal in volume to the metal, as the ſpecific gravity of the metal to that of the water. Let M = volume of cold water, m = volume of hot water, g = ſpecific gravity of the metal, 1 = ſpecific gravity of water; then $m : M :: 1 : g$; hence $m = \frac{M}{g} =$ (M being made $= 1$) $\frac{1}{g}$. Subſtituting this value of m in the formula, $\frac{MC+mc}{M+m} = x$, in which $M = 1$ and $C = 32$, x will be $= \frac{32g+c}{g+1}$. Therefore if the ſpecific gravity of the metal be multiplied by 32, and the temperature of the metal be added, and the ſum be divided by the ſpecific gravity of the metal + 1, the quotient will expreſs the temperature to which the ice-cold water would be raiſed by adding to it a volume of water equal to that of the metal, and of the ſame temperature with it.

He then calculated how much water at the temperature of the metal it would take to raiſe the ice-cold water the ſame number of degrees which the metal had raiſed it. Let the temperature to which the metal had raiſed the ice-cold water be = N, if in the formula $\frac{MC+mc}{M+m} = x$, x be made = N, $M = 1$, $C = 32$, m will be $= \frac{N-32}{c-N}$. Therefore if from the temperature to which the ice-cold water was raiſed by the metal 32 be ſubtracted, and if from the temperature of the metal be ſubtracted the temperature to which it raiſed the water, and the firſt remainder be divided by the laſt, the quotient will expreſs the quantity of water of the temperature of the metal which would have raiſed the ice-cold water the ſame number of degrees that the metal did.

Now $\frac{N-32}{c-N}$ expreſſes the ſpecific caloric of the metal, that of water being = 1. For (neglecting the ſmall difference occaſioned by the difference of temperature) the weight and volume of the ice-cold water are to the weight and volume of the hot water as 1 to $\frac{N-32}{c-N}$, and the number of particles of water in each are in the ſame proportion. But the metal is equal in weight to the ice-cold water; it muſt therefore contain as many particles of matter; therefore the quantity of matter in the metal muſt be to that in the hot water as 1 to $\frac{N-32}{c-N}$. But they give out the ſame quantity of caloric; which, being divided equally among their particles, gives to each particle a quantity of caloric inverſely as the bulks of the metal and water; that is, the ſpecific caloric of the water is to that of the metal as 1 to $\frac{N-32}{c-N}$ (G).

We ſhall now give a ſpecimen or two of his experiments, and the calculations founded on them, as above deſcribed.

Gold

(G) We have altered all theſe formulas to make them correſpond with Fahrenheit's thermometer. They are a good deal ſimpler when the experiments are made with Celſius's thermometer, as Mr Wilcke did. In it the freezing point is zero; and conſequently inſtead of 32 in the formula, 0 is always ſubſtituted.

Gold. *Specific Gravity* 19,040.

It is needleſs to add, that the laſt column marks the denominator of the ſpecific caloric of the metal, the numerator being always 1, and the ſpecific caloric of water being 1. Thus the ſpecific caloric of gold is $\frac{1}{19,712}$. In exactly the ſame manner, and by taking a mean of a number of experiments at different temperatures, did Mr Wilcke aſcertain the ſpecific caloric of a number of other bodies. He aſcertained at the ſame time, that the ſpecific caloric of a body did not vary with the temperature, but continued always the ſame. This will appear evident from the experiments on gold and lead above exhibited.

264 Crawford, Next, in point of time, and not inferior in ingenious contrivances to enſure accuracy, were the experiments of Dr Crawford, made by mixing together bodies of different temperatures. Theſe were publiſhed in his *Treatiſe on Heat*.

265 Lavoiſier and La Place, Several experiments on the ſpecific caloric of bodies were made alſo by Lavoiſier and De la Place, which, from the well-known accuracy of theſe philoſophers, cannot but be very valuable.

Their method was exceedingly ſimple and ingenious; it was firſt ſuggeſted by De la Place. An inſtrument was contrived, to which Lavoiſier gave the name of *calorimeter*. It conſiſts of three circular veſſels nearly inſcribed into each other, ſo as to form three different apartments, one within the other. Theſe three we ſhall call the *interior*, *middle*, and *external cavities*. The interior cavity *ffff* (ſee ſection of the inſtrument fig. 4.), into which the ſubſtances ſubmitted to experiment are put, is compoſed of a grating or cage of iron wire, ſupported by ſeveral iron bars. Its opening or mouth LM is covered by the lid HG, which is compoſed of the ſame materials. The middle cavity *bbbb* is filled with ice. This ice is ſupported by the grate *m m*, and under the grate is placed a ſieve. The external cavity *a a a a* is alſo filled with ice. We have mentioned already, that no caloric can paſs through ice. It can enter ice, indeed, but it remains in it, and is employed in melting it. The quantity of ice melted, then, is a meaſure of the caloric which has entered into the ice. The exterior and middle cavities being filled with ice, all the water is allowed to drain away, and the temperature of the interior cavity to come down to 32°. Then the ſubſtance, the ſpecific caloric of which is to be aſcertained, is heated a certain number of degrees, ſuppoſe to 212°, and then put into the interior cavity encloſed in a thin veſſel. As it cools, it melts the ice in the middle cavity. In proportion as it melts, the water runs through the grate and ſieve, and falls through the conical funnel *c c d* and the tube *x y* into a veſſel placed below to receive it. The external cavity is filled with ice, in order to prevent the external air from approaching the ice in the middle cavity and melting part of it. The water produced from it is carried off through the pipe ST. The external air ought never to be below 32°, nor above 41°. In the firſt caſe, the ice in the middle cavity might be cooled too low; in the laſt, a current of air flows through the machine and carries off ſome of the caloric. By putting various ſubſtances at the ſame temperature into this machine, and obſerving how much ice each of them melted in cooling down to 32°, it was eaſy to aſcertain the ſpecific caloric of each. Thus, if water, in cooling from 212 to 32, melted one pound of ice, and mercury ,029 of a pound; the ſpecific caloric of water was one, and that of mercury ,029. This appears by far the ſimpleſt method of making experiments on this ſubject; and muſt alſo be the moſt accurate, provided we can be certain that all the melted ſnow flows into the receiver. But from an experiment of Mr Wedgewood, one would be apt to conclude that this does not happen. He found that the melted ice, ſo far from flowing out, actually *froze* again, and choaked up the paſſage.

A table of the ſpecific caloric of various bodies was likewiſe drawn up by Mr Kirwan, and publiſhed by Magellan in his Treatiſe on Heat. 266 And Kirwan.

From all theſe ſources we have drawn up the following table, which exhibits at one view the ſpecific caloric of thoſe bodies on which experiments have hitherto been made. 267 Reſult of theſe experiments.

We have added to it a column, expreſſing the ſpecific caloric of equal bulks of the ſame bodies; which ſeems to be a more accurate way of conſidering this ſubject, and indeed the only way in which the phraſe *capacity for caloric* is intelligible. This column was formed by multiplying the ſpecific caloric of equal weights of the various ſubſtances into their reſpective ſpecific gravities.

7. If

(H) The ſpecific caloric of the ſubſtances marked * was aſcertained by Dr Crawford, thoſe marked † by Mr Kirwan, ‡ by Lavoiſier and La Place, ** by Wilcke, ‖ by Count Rumford. § Is the mean of Crawford, Kirwan, and Lavoiſier; ¶ mean of Lavoiſier and Kirwan; (*c*) mean of Crawford and Lavoiſier; (*d*) mean of Wilcke and Crawford; (*e*) mean of Wilcke, Crawford, and Kirwan.

268 Latent caloric, or

-. If a quantity of ice, at a low temperature, ſuppoſe at 20°, be ſuſpended in a warm room, it will become gradually leſs cold, as may be diſcovered by means of a thermometer, till it reaches the temperature of 32°; but there it ſtops. The ice, however, diſſolves ſlowly; and at the end of ſeveral hours, when it is all juſt melted, the thermometer ſtill ſtands at 32°. After this it begins to riſe, and ſoon reaches the temperature of the room. Here the ice continues for ſeveral hours colder than the air around it. Caloric muſt then be continually flowing into it; yet it does not become hotter: it is changed, however, into water. Ice, therefore, is converted into water by a quantity of caloric uniting with it. This caloric has been called *latent caloric*, becauſe its preſence is not indicated by the thermometer.

269 Caloric of fluidity.

It might, perhaps with more propriety, as Profeſſor Pictet obſerves *, be called *caloric of fluidity;* for there are other caſes in which caloric exiſts in bodies without raiſing their temperature. This very important diſcovery was made by Dr Black as early as 1757, and ſeems to have led the way to all the ſubſequent diſcoveries in this part of chemiſtry, which have almoſt completely changed the appearance of the ſcience: for the diſcovery that caloric may exiſt in bodies while the thermometer cannot indicate its preſence, is one of the ſtrongeſt links in the chain of facts by which the nature of combuſtion was aſcertained.

The caloric which unites with ice, and renders it fluid, appears again during the act of *freezing*. If a quantity of water be carried into a room where the temperature is below the freezing point, ſuppoſe at 20°, it cools gradually down to 32°; but it becomes no colder till it is all frozen, which takes up ſome time. The moment it is all converted into ice, it begins again to cool, and ſoon reaches the temperature of the room. In this caſe, the water is ſurrounded by a cold atmoſphere; it muſt therefore be giving out caloric conſtantly; yet it does not become colder till it is all frozen, that is to ſay, till it has loſt all its *caloric of fluidity*.

Dr Black proved, by a very accurate experiment, that the quantity of *caloric of fluidity* is ſufficient to raiſe the ſame quantity of water 140°.

All ſolids become fluid by abſorbing a quantity of caloric. Landriani proved that this is the caſe with ſulphur, alum, nitre, and ſeveral of the metals †; and it has been found to be the caſe with every ſubſtance hitherto examined. Fluidity, therefore, is owing to a union between the ſolid and a certain quantity of caloric.

The late Dr Irvine of Glaſgow advanced a theory on this ſubject different from that of Dr Black. The ſpecific caloric of water being greater than that of ice, it requires a greater quantity of caloric to raiſe it to a given temperature than it does to raiſe ice. The caloric does not therefore become *latent;* it only ſeems to do ſo from the greater ſpecific caloric of water. This theory was zealouſly adopted by Dr Crawford. Dr Black obſerved very juſtly, that it did not account for the production of fluidity at all. The ſpecific caloric of water is indeed greater than that of ice; but how is the ice convered into water? This is an objection which the advocates for Dr Irvine's, or Dr Crawford's, theory (as it has been improperly called) will not eaſily anſwer. Let us now examine whether this theory accounts for the apparent loſs of caloric. It follows from Mr Kirwan's experiments, that the ſpecific caloric of water is to that of ice as 10 to 9 (1). Dr Black proved, that as much caloric entered the ice as would have raiſed it, had it been water, 140°. Let us ſuppoſe that it would only have raiſed the ice 140°; in that caſe the melted ice ought to have been of the temperature of 158°, for 10 : 9 : : 140 : 126; but it was only 32°: Therefore 126° of caloric have diſappeared, and cannot be accounted for by the change of ſpecific caloric. Nor can the accuracy of Dr Black's experiment be ſuſpected: it has been repeated in every part of the world, and varied in every poſſible way. We cannot doubt, therefore, that caloric unites with ſubſtances, and cauſes them to become fluid, or that *there is in fact a caloric of fluidity different from ſpecific caloric.*

270 Caloric of evaporation.

Water alſo is converted into *ſteam* by uniting with caloric. Dr Black put an iron veſſel, containing four ounces of water at the temperature of 53°, upon a caſt-iron table which was red hot. The water roſe to the boiling point in three minutes; but it did not afterwards become any hotter. It evaporated, however, in 18 minutes; and the ſteam was preciſely at the temperature of 212°. During the firſt three minutes, it received 159° of caloric, and as much muſt have been entering it during every three minutes while the evaporation continued, as the temperature was always much lower than that of the table. This caloric, inſtead of raiſing the temperature of the water, was employed in converting it into ſteam. There is alſo, therefore, a quantity of latent caloric in ſteam. It might, as Mr Pictet obſerves, be called, with propriety, *caloric of evaporation*. This caloric appears again if the ſteam be condenſed. If it be made to paſs, for inſtance, through a pipe ſurrounded with cold water, it is condenſed in the pipe, and drops out from it in the form of water. The caloric of the ſteam enters into the water around the pipe, and the quantity of it in degrees may be diſcovered by the number of degrees which it raiſes that water. By an experiment of this kind, it was proved, that the caloric of evaporation would be ſufficient to heat water red hot, were it employed only in raiſing its temperature, inſtead of converting it into ſteam. It is therefore at leaſt equal to 800°. Mr Watt ſhewed afterwards that it was 920°.

Even ſpontaneous evaporation, as Dr Black firſt obſerved, is owing to the ſame cauſe: and this explains why bodies cool when water is evaporated from their ſurface;

---

* *Sur le Feu*, ch. 1.

† *Jour. de Phyſ.* xxvi.

(1) We do not know how this was aſcertained: Not by mixing water and ice ſurely; becauſe that would be taking for granted the thing to be proved; becauſe it would give a very different reſult; and what is ſtill worſe, the ſpecific caloric in that caſe would differ according to the temperature and the quantity of water. To give an inſtance: Mr Gadolin concludes, from 180 experiments made by mixing hot water and ice, that the ſpecific caloric of ice is to that of water only as 1 to 2 *; and had he varied the quantities and the temperatures, he might have obtained ſeveral other ratios.

* *Ann de Chim.* xi. 27.

ſurface; a fact which has been long known, and which has been employed in warm countries to diminiſh the temperature of liquids, and even to convert them into ice (K). That water is evaporated by uniting with caloric, and not by ſolution in air, has been proved very completely by De Luc in his Treatiſe on Meteorology.

The evaporation of alcohol, ether, and every other ſubſtance on which experiments have been made, has been found owing to the ſame cauſe. Bodies, therefore, are converted into vapour by uniting with caloric.

271 Real zero, what.

8. If caloric, as has been ſhewn, exiſts in bodies at the loweſt temperature which we are able to procure, and if it exiſts in them while the thermometer cannot diſcover its preſence—is there any method of aſcertaining its abſolute quantity in bodies? At what degree would a thermometer ſtand (ſuppoſing the thermometer capable of meaſuring ſo low) were the body to which it is applied totally deprived of caloric? or what degree of the thermometer correſponds to the real zero?

The firſt perſon (as far as we know), at leaſt ſince men began to think accurately on the ſubject, who conceived the poſſibility of determining this queſtion, was Dr Irvine of Glaſgow. He invented a theorem, in order to aſcertain the real zero, which has, we know not for what reaſon, been aſcribed by ſeveral writers to Mr Kirwan. He took it for granted (and the fact is proved by all the experiments hitherto made) that the ſpecific caloric of bodies continued the ſame in every degree of temperature, as long as they remained in the ſame ſtate, that is to ſay, as long as they continued either ſolid or fluid or in a ſtate of vapour; but that the ſpecific caloric of the ſame body while ſolid was leſs than while fluid, and leſs while fluid than while in a ſtate of vapour. He took it for granted, too, that the 140 degrees of caloric which entered ice during its ſolution without raiſing its temperature, entered merely in conſequence of the increaſed ſpecific caloric of the water, and that they were exactly proportional to this increaſed ſpecific caloric. He took it for granted, likewiſe, that the ſpecific caloric of bodies was proportional to

272 Irvine's theorem to diſcover it.

(K) Galen informs us, that the ancient Egyptians were accuſtomed to put water previouſly boiled into earthen jars, and expoſe them all night on the upper part of their houſes to the air. Before ſunriſe theſe veſſels were put into the ground, moiſtened on the outſide with water, and then ſurrounded with freſh plants; by which means the water was preſerved cool during the whole day. *Comment. in lib.* vi. *Hippoc. de morbis vulgar.* 4. 10. p. 396.

By a ſimilar proceſs, water, in the Eaſt Indies, is converted into ice.

The following ſingular paſſage, which has been pointed out to us by the ingenious Dr Barclay, lecturer on anatomy in Edinburgh, furniſhes a ſtriking proof that the ancients were led, by a very different method of reaſoning, to deduce, from their philoſophical theory of the four elements, concluſions concerning the nature of heat not very different from thoſe of the moderns.

" Sic enim res ſe habet, ut omnia, quæ alantur et quæ creſcant, contineant in ſe vim caloris; ſine qua neque ali poſſent nec creſcere. Nam omne, quod eſt calidum et igneum, cietur et agitur motu ſuo: quod autem alitur et creſcit, motu quodam utitur certo et æquabili; qui quandiu remanet in nobis, tamdiu ſenſus et vita remanet: refrigerato autem et extincto calore, occidimus ipſi et exſtinguimur. Quod quidem Cleanthes his etiam argumentis docet, quanta vis inſit caloris in omni corpore: negat enim ullum eſſe cibum tam gravem, quin is nocte et die concoquatur; cujus etiam in reliquiis ineſt calor his quas natura reſpuerit. Jam verò venæ et arteriæ micare non deſinunt, quaſi quodam igneo motu; animadverſumque ſæpe eſt, cùm cor animantis alicujus evolſum ita mobiliter palpitaret, ut imitaretur igneam celeritatem. Omne igitur quod vivit, ſive animal ſive terra editum, id vivit propter incluſum in eo calorem. Ex quo intellegi debet, eam caloris naturam, vim habere in ſe vitalem per omnem mundum pertinentem. Atque id faciliùs cernemus, toto genere hoc igneo, quod tranat omnia, ſubtiliùs explicato. Omnes igitur partes mundi (tangam autem maxumas) calore fultæ ſuſtinentur. Quod primùm in terrena natura perſpici poteſt. Nam et lapidum conflictu atque tritu elici ignem videmus; et recenti foſſione

—— *terram fumare calentem;*

atque etiam ex puteis jugibus aquam calidam trahi, et id maxumè fieri temporibus hibernis, quòd magna vis caloris, terræ contineatur cavernis; eaque hieme ſit denſior; ob eamque cauſſam, calorem inſitum in terris contineat arctiùs.

" Longa eſt oratio, multæque rationes, quibus doceri poſſit, omnia, quæ terra concipiat, ſemina, quæque ipſa ex ſe generata ſtirpibus infixa contineat, ea temperatione caloris et oriri et augeſcere. Atque aquæ etiam admixtum eſſe calorem, primùm ipſe liquor, tum aquæ declarat effuſio: quæ neque conglaciaret frigoribus, neque nive pruinaque concreſceret, niſi eadem ſe admixto calore liquefacta et dilapſa diffunderet. Itaque et aquilonibus reliquiſque frigoribus dureſcit humor: et idem viciſſim mollitur tepefactus et tabeſcit calore. Atque etiam maria agitata ventis ita tepeſcunt, ut intellegi facilè poſſit, in tantis illis humoribus eſſe incluſum calorem. Nec enim ille externus et adventicius habendus eſt tepor, ſed ex intimis maris partibus agitatione excitatus: quod noſtris quoque corporibus continget, cùm motu atque exercitatione recaleſcunt. Ipſe verò aër, qui natura eſt maxumè frigidus, minime eſt expers caloris. Ille verò et multo quidem calore admixtus eſt: ipſe enim oritur ex reſpiratione aquarum: earum enim quaſi vapor quidam aër habendus eſt. Is autem exiſtit motu ejus caloris, qui aquis continetur. Quam ſimilitudinem cernere poſſumus in his aquis, quæ efferveſcunt ſubditis ignibus. Jam verò reliqua quarta pars mundi, ea et ipſa tota natura fervida eſt, et ceteris naturis omnibus ſalutarem impertit et vitalem calorem. Ex quo concluditur, cùm omnes mundi partes ſuſtineantur calore, mandum etiam ipſum ſimili parique natura in tanta diuturnitate ſervari: eoque magis, quòd intellegi debet, calidum illud atque igneum ita in omni fuſum eſſe natura, ut in eo inſit procreandi vis et cauſſa gignendi, à quo et animantia omnia, et ea quorum ſtirpes terra continentur, et naſci ſit neceſſe et augeſcere. *Cicero de natura Deorum*, lib. ii. c. 9 *et* 10.

to their *abſolute caloric*, or to all the caloric which exiſted in each.

On theſe data he reaſoned in the following manner: Let A be a body in a ſtate of fluidity; B the ſame body in a ſtate of ſolidity. If the ſpecific caloric of A and of B be known, and if it be known how many degrees the caloric, diſengaged during the change of B into A, would raiſe the temperature of A, it may be found by an eaſy proceſs how many degrees all the caloric contained in B would raiſe the temperature of A; and the ſum of theſe two numbers will repreſent in degrees the whole quantity of caloric in A: for the quantity of caloric in A muſt be juſt equal to the caloric in B, together with what entered into it in paſſing from the ſtate of B to that of A. Let the ſpecific caloric of A be 6, that of B 1; and let the quantity of caloric diſengaged during the change of A into B be ſufficient to raiſe the temperature of A 500°. If the ſpecific caloric be proportional to the abſolute caloric, it muſt contain exactly 6 times as much caloric as B. The 500° which entered into A when it changed its ſtate, muſt be juſt 5 times as great as all the caloric of B; becauſe when added to the caloric of B, it formed the caloric in A, which is juſt 6 times as great as the caloric in B. Therefore to diſcover the caloric in B, we have only to divide 500 by 5, or, which is the ſame thing, to ſtate this proportion 6—1 : 500 : : 1 : 100. The caloric in B, therefore, in this caſe is juſt as much as would raiſe the temperature of A 100°. Therefore, if to 100°, the caloric of B, be added 500°, = caloric diſengaged in the paſſage of A to B, this will give 600°, = to all the caloric in A. Therefore, in all caſes, the difference between the numbers expreſſing the ſpecific caloric of the ſolid and fluid, is to the number expreſſing the ſpecific caloric of the ſolid, as the quantity of caloric diſengaged during the paſſage of the fluid into a ſolid is to the quantity of caloric in the fluid.

Dr Crawford embraced this theorem; and concluded, from a number of experiments made on purpoſe to aſcertain the fact, that the real zero was 1268° below 0, or 1300° below the freezing point.

273 Examined,

This ſubject deſerves to be conſidered with attention. If this theorem in fact furniſhes us with the real zero, it is one of the moſt important diſcoveries which has ever been made in chemiſtry; but if it proceeds on erroneous principles, it will only involve us in endleſs mazes of error and abſurdity.

In the firſt place, if the real zero has any meaning at all, it muſt ſignify the degree to which the thermometer (ſuppoſing it could be uſed) would ſink on being applied to a body which contained no heat. It muſt therefore be a fixed point; and were the theorem which we are examining well founded, experiments upon every different ſubſtance, if conducted with accuracy, would lead to the ſame reſult. Let us ſee whether this be the caſe.

From Dr Crawford's experiments, it follows, as we have ſeen, that the real zero is 1268° below 0.

Mr Kirwan, from comparing the ſpecific caloric of water and ice, fixed the real zero at 1048° below 0.

From the experiments of Lavoiſier and La Place on a mixture of water and quicklime, in the proportion of 9 to 16, it follows, that the real zero is 2736° below 0.

From their experiments on a mixture of 4 parts of ſulphuric acid and 3 parts of water, it follows, that the real zero is 5803,4° below 0.

Their experiments on a mixture of 4 parts of ſulphuric acid and 5 of water, place it at 2073,3° below 0.

Their experiments on $9\frac{1}{3}$ parts of nitric acid and 1 of lime, place it at $\frac{1889}{-0{,}01783}$ below 32°*.

Theſe reſults differ from one another ſo enormouſly, and the laſt of them, which makes the real zero a negative quantity, is ſo abſurd, that they are alone ſufficient to convince us that the data on which they are founded are not true. Should it be ſaid that their difference is not owing to any defect in the theorem, but to inaccuracies in making the experiments—we anſwer, that the theorem itſelf is founded on ſimilar experiments; and if experiments of this nature, even in the hands of the moſt accurate chemiſts, cannot be freed from ſuch enormous errors, how can we depend on any conſequences deduced from them? and where, then, is our evidence for the truth of the theorem?

But, farther, there is no proof whatever that the ſpecific caloric of bodies is proportional to their abſolute caloric. The ſpecific caloric of iron is greater than that of water, or even azotic gas; yet ſurely it is very improbable that iron contains more abſolute caloric than either of theſe ſubſtances.

If the ſpecific caloric of bodies has any meaning at all, it can only be, that the ſame quantity of caloric raiſes the temperature of one body a greater number of degrees than it does another. When we ſay that the ſpecific caloric of A is = 6, and that of B = 1, what do we mean, unleſs that the quantity of caloric which raiſes B 6° raiſes A only 1°, or that what raiſes B 60° or 600°, raiſes A only 10° or 100°? When we ſay that the ſpecific caloric of water is 10, and that of ice 9, do we not mean, that the quantity of caloric which raiſes the ice 10° or 100°, raiſes water only 9° or 90°? Yet during the change of ice into water, 140° of caloric enter it without raiſing its temperature; a quantity greater than what can be accounted for by the difference of ſpecific caloric by 126°. The quantity that diſappears, therefore, is *not* proportional to the difference of ſpecific caloric; and therefore any theory which depends on that ſuppoſition cannot be well founded. When water is converted into ſteam, 800° of caloric diſappear, yet the ſpecific caloric of ſteam is to that of water, according to Dr Crawford's own experiments, only as 155 to 100: ſo that no leſs than 283° diſappear, which cannot be accounted for according to this theory.

274 And found inſufficient.

Dr Irvine's theorem, therefore, is inſufficient for aſcertaining the real zero; and hitherto no method has been diſcovered which can ſolve this problem.

275 Caloric exiſts in bodies

9. If there be no body without caloric, if it exiſts in different quantities in different bodies, even when their temperatures are the ſame, and while the thermometer cannot indicate its preſence—in what ſtate does it exiſt in them? We cannot ſurely ſuppoſe that it is contained by them juſt as water is contained by a veſſel of wood or metal, or that they are filled with it in the ſame manner that a hollow globe of tinplate perforated with holes is filled with water when it is plunged into a quantity of that liquid; or that bodies are filled with caloric merely becauſe they are immerſed in an ocean of caloric. Were that the caſe, the ſpecific and abſolute caloric of bodies would always be proportional; and they would of neceſſity be inverſely as the ſpecific gravity of the reſpective bodies; becauſe the leſs the ſpecific gravity, the more room would be left for the particles

---

* See *Seguin, Ann. de Chim.* vii.

ticles of caloric. But this is by no means the caſe: the ſpecific gravity of iron, for inſtance, is greater than that of tin, yet the ſpecific caloric of iron is more than double that of tin: the ſpecific gravity of oxygen gas is greater than that of common air, yet the ſpecific caloric of the firſt of theſe ſubſtances is more than three times as great as that of the other. There muſt be ſomething, therefore, in bodies themſelves quite different from, and unconnected with, the vacuities between their particles, which diſpoſes ſome to admit more caloric than others. And what can that be but a diſpoſition in different bodies to unite with a greater or a ſmaller quantity of caloric, and to retain it with more or leſs firmneſs according to their *affinity* for it? Dr Black pointed out, long ago, by diſcovering latent heat, that caloric unites with bodies; and this ſeems to be the only real key for unfolding the actions of this extraordinary ſubſtance. If caloric be matter, can it be deſtitute of that property which all other matter poſſeſſes, we mean attraction? And if it poſſeſſes attraction, muſt it not combine with thoſe bodies that attract it juſt as other bodies combine with each other? Muſt there not be formed a chemical union between caloric and other ſubſtances, which can only be broken by chemical means, by preſenting a third body which has a greater affinity either for the caloric or the body to which it is united, than they have for each other?

276 In a ſtate of chemical combination.

277 Proved to be the caſe in liquids, vapours,

That it unites chemically with ſome bodies, at leaſt, cannot be doubted, as we have ſhewn already, that whenever a ſolid is converted into a liquid, a quantity of caloric enters, and remains in it; and that both the ſolid and the caloric loſe their characteriſtic properties. This is preciſely what takes place in every chemical union. All liquids, therefore, conſiſt of ſolids combined with caloric. We have ſeen, too, that liquids are converted into vapours by the very ſame proceſs. There are therefore, at leaſt, two very large claſſes of bodies, liquids and vapours, in which we are certain that caloric exiſts in a ſtate of chemical combination.

278 And gaſes;

There is another claſs of bodies which reſembles vapours in almoſt all their properties: theſe are the gaſes. Like them, they are inviſible and elaſtic, and capable of indefinite expanſion. Is it not probable, then, that the gaſes alſo, as well as the vapours, owe their properties to caloric? that they alſo conſiſt of their reſpective baſes combined with that ſubtile ſubſtance? This probability has been reduced to certainty by an experiment of Lavoiſier. By adding two tubes to the calorimeter formerly deſcribed, he contrived to make known quantities of air to paſs through the interior cavity, and to ſupport combuſtion. He found, that when a pound of oxygen gas was made to combine in this manner with phoſphorus, as much caloric was diſengaged as melted 87½ pounds of ice*. Now every pound of ice abſorbs as much caloric in the act of melting as is ſufficient to raiſe a pound of water 140°. Therefore the whole caloric diſengaged was ſufficient to raiſe a pound of water 12250°. All this could not have come from the phoſphorus, becauſe it had been converted into a liquid, and muſt therefore have abſorbed inſtead of parted with caloric, and becauſe the quantity of caloric diſengaged in all caſes of combuſtion is proportional, not to the combuſtible,,but to the oxygen abſorbed. Oxygen gas, then, is compoſed of oxygen and caloric: and if this be the caſe with one gas, why not with all?

We may conclude, therefore, that the gaſes, as well as liquids and vapours, owe their form to the caloric which they contain. The only difference between them and vapours is, that the latter return to their liquid ſtate by the mere action of cold; whereas moſt of the gaſes reſiſt the loweſt temperature which it has been poſſible to apply. It was natural to expect, that if caloric combined chemically with bodies, its affinity would be different for different ſubſtances, and that its affinity for ſome bodies would be ſo great that it would not leave them to combine with any other. It was natural to expect this, becauſe it is the caſe with every other ſubſtance with which we are acquainted. The difference, then, between the gaſes and vapours is not ſurpriſing. The affinity of the former for caloric is not only much greater than that of the latter, but much greater than that of any other ſubſtances.

279 And to be the cauſe of their gaſeous form.

It is owing to this ſtrong affinity between oxygen, hydrogen, and azot and caloric, that they cannot be obtained except in a gaſeous form: and we ſhall deſcribe ſeveral other ſubſtances afterwards exactly in the ſame circumſtances. Had we any ſubſtance poſſeſſed of a greater affinity for caloric than they have, we ſhould be able, by preſenting it, to deprive them of their gaſeous form. Doubtleſs there is a difference in the affinity between theſe bodies themſelves and caloric; but as all of them are already ſaturated, this difference cannot be diſcovered. If we could obtain them uncombined with caloric, that is to ſay, in a concrete ſtate, it would be eaſy to aſcertain this point. Suppoſe, for inſtance, that hydrogen had the ſtrongeſt affinity for caloric, and that we poſſeſſed it in a concrete ſtate—it would be eaſy, by preſenting it to the other gaſes, to deprive their baſes of the caloric with which they are united, and thus to obtain them alſo uncombined with any other ſubſtance.

280 Why caloric appears during combuſtion,

But though we are acquainted with no ſubſtance that has a greater affinity for caloric than the baſes of the gaſes, there are many ſubſtances which have a greater affinity for theſe baſes than caloric has. When any ſuch ſubſtance is preſented, the baſe combines with it, and the caloric is left at liberty. Thus, when phoſphorus is preſented to oxygen gas, the phoſphorus and oxygen unite together, and the caloric flies off. We are now, therefore, able to anſwer one of the queſtions propoſed at the end of the ſecond chapter, Whence comes the caloric which appears during combuſtion? It is ſeparated from the oxygen, which leaves it in order to enter into a new combination.

281 And during many chemical combinations.

The caloric alſo, which ſometimes appears when two bodies combine together, is ſet at liberty exactly in the ſame manner. When ſulphuric acid and water, for inſtance, are mixed together, a very conſiderable heat is produced; a good deal of caloric, therefore, becomes ſenſible. In this caſe, the water combines with the acid, and at the ſame time lets go the caloric with which it was formerly combined, and becomes denſer. In the ſame manner, to give another inſtance, when water is poured upon quicklime, a very great quantity of caloric becomes manifeſt. The water in this caſe combines with the quicklime, and aſſumes a concrete form, and of courſe lets go the caloric with which it was previouſly united.

282 Why certain mixtures produce cold.

10. It is no uncommon thing in nature to obſerve two bodies, after combining together, manifeſting a much ſtronger affinity for a third body than either of

---

* Lavoiſier, p. i. ch. 9.

them had while ſeparate. Thus, ſilver has no perceptible affinity for ſulphuric acid, neither has oxygen; but unite them together, and they combine with that acid very readily. A great many inſtances of the ſame kind might be produced. Were there ſubſtances, then, which, after combining together, have a greater affinity for caloric than any of them had while ſeparate, this ought not to ſurpriſe us, becauſe the ſame phenomenon is often obſerved in other bodies. Now this is actually the caſe with regard to caloric. Mix together, for inſtance, common ſalt and ſnow, the mixture inſtantly becomes liquid, and ſo cold, that it ſinks the thermometer down to zero. In this caſe, the ſnow and ſalt united have a much ſtronger affinity for caloric than either of them had while ſeparate; they attract it therefore from other bodies with which they happen to be in contact, till they have obtained a doſe ſufficient for their ſaturation; and this ſaturation they manifeſt by becoming liquid. It is for this reaſon that all ſalts produce cold during their ſolution in water, when the freezing point of the ſolution formed is below that of water. All ſuch ſolutions have a ſtrong affinity for caloric; they therefore attract it till they are ſaturated, which appears by their becoming fluid. A number of experiments have been lately made in order to procure artificial cold by means of ſuch combinations. The moſt complete ſet of experiments of that nature with which we are acquainted, is thoſe of Mr Walker, publiſhed in the Philoſophical Tranſactions for 1795. We ſhall preſent the reſult of his experiments in the following Table:

Table of Freezing Mixtures.

Mixtures.		Thermometer ſinks.
Muriat of ammonia Nitre Water	5 parts. 5 16	From 50° to 10°.
Muriat of ammonia Nitre Sulphat of ſoda Water	5 5 8 16	From 50 to 4.
Nitrat of ammonia Water	1 1	From 50 to 4.
Nitrat of ammonia Carbonat of ſoda Water	1 1 1	From 50 to 7.
Sulphat of ſoda Diluted nitric acid	3 2	From 50 to 3.
Sulphat of ſoda Muriat of ammonia Nitre Diluted nitric acid	6 4 2 4	From 50 to 10.
Sulphat of ſoda Nitrat of ammonia Diluted nitric acid	6 5 4	From 50 to 14.
Phoſphat of ſoda Diluted nitric acid	9 4	From 50 to 12.
Phoſphat of ſoda Nitrat of ammonia Diluted nitric acid	9 parts. 6 4	From 50° to 21°.
Sulphat of ſoda Muriatic acid	8 5	From 50 to 0.
Sulphat of ſoda Diluted ſulphuric acid	5 4	From 50 to 3.
Snow Common ſalt	1 1	From 32 to 0.
Snow or pounded ice Common ſalt	2 1	From 0 to —5.
Snow or pounded ice Common ſalt Muriat of ammonia and Nitre	1 5 5	From —5 to —18.
Snow or pounded ice Common ſalt Nitrat of ammonia	12 5 5	From —18 to —25.
Snow and diluted nitric acid		From 0 to —46.
Snow Diluted ſulphuric acid Diluted nitric acid	2 1 1	From —10 to —56.
Snow Diluted ſulphuric acid	1 1	From 20 to —60.

In order to produce theſe effects, the ſalts employed muſt be freſh cryſtallized, and newly reduced to a very fine powder. The veſſels in which the freezing mixture is made ſhould be very thin, and juſt large enough to hold it, and the materials ſhould be mixed together as quickly as poſſible. The materials to be employed in order to produce great cold ought to be firſt reduced to the temperature marked in the table, by placing them in ſome of the other freezing mixtures; and then they are to be mixed together in a ſimilar freezing mixture. If, for inſtance, we wiſh to produce a cold = — 46, the ſnow and diluted nitric acid ought to be cooled down to 0, by putting the veſſel which contains each of them into the 12th freezing mixture in the above table, before they are mixed together. If a ſtill greater cold is required, the materials to produce it are to be brought to the proper temperature by being previouſly placed in the ſecond freezing mixture. This proceſs is to be continued till the required degree of cold has been procured *.

283
Subſtances which contain moſt caloric.

11. From the facts already known, we may conclude, that the particles of caloric have two properties, that of repelling each other, and of attracting and being attracted by other ſubſtances. As there is no body in nature which does not contain caloric, we may ſafely conclude, that there is no body in nature which has not an affinity for it. When it unites with bodies, though the repulſion of its particles may be overcome by their attraction for the particles of the body, and by the at-

traction

---

* Walker, *Phil. Tranſ.* 1795.

traction of theſe particles for each other—we cannot ſuppoſe it annihilated: It muſt therefore be the more powerful the greater the quantity of caloric combined in any body is. Probably, then, there is moſt caloric combined with gaſes, leſs with fluids, and leaſt with ſolids. It does not follow, however, from this, that the quantity of caloric combined with any body is proportional to the diſtance between its particles, becauſe that may depend on other cauſes. Thus, though hydrogen gas is much rarer than oxygen gas, it does not follow that hydrogen is combined with more caloric than oxygen, becauſe the rarity may be owing to the ſmaller coheſive force of the particles of hydrogen allowing a ſmaller quantity of caloric to produce a greater effect.

284
Caloric may be added indefinitely to bodies,

If caloric unites *only* chemically with bodies, there ought to be a certain point of ſaturation between it and the ſubſtances with which it combines, becauſe this takes place in all other chemical combinations. Oxygen gas, for inſtance, conſiſts of a certain quantity of oxygen united with caloric. Now if this gas be a *chemical* compound, the two ingredients ought to ſaturate each other in ſuch a manner, that no more of either could be admitted. But it cannot be denied, that more caloric can ſtill be added to oxygen gas, for its temperature may be raiſed at pleaſure as high as we think proper. This, at firſt ſight, ſeems to be an inſuperable objection to the theory, that caloric only combines chemically with bodies. It ought to be remembered, however, that caloric is not ſingular in this reſpect. There are other bodies in nature, and bodies too which certainly combine with other ſubſtances only by affinity, which exhibit the very ſame phenomenon. Water is capable of combining with ſulphuric acid and many other ſalts almoſt in any proportion, at leaſt no limits have hitherto been obſerved. Oxygen, too, combines with almoſt every body in various proportions: We have ſeen, that with almoſt every metal it forms at leaſt two different oxides. Why then may not caloric be capable of uniting in the ſame manner? Allowing, therefore, that it were impoſſible to explain why bodies are capable of combining with caloric after ſaturation, this could be no objection to the theory that it only unites chemically with bodies, becauſe the ſame phenomenon is exhibited by other bodies which it cannot be doubted combine only by means of affinity.

285
And why.

The manner in which theſe other combinations are formed has been already hinted, and ſhall be conſidered more fully afterwards; at preſent we ſhall only attempt to explain the action of caloric. Let us ſuppoſe, then, that caloric is preſented to oxygen; that they combine together in a certain proportion, and ſaturate each other. The product of this combination is oxygen gas; a ſubſtance poſſeſſed of properties very different from thoſe of caloric or oxygen in a concrete ſtate; it is incapable of being decompoſed by any merely mechanical method, and exhibits all the appearances of a ſimple ſubſtance. Let us therefore conſider this compound for a moment as a ſimple ſubſtance. May it not ſtill have an affinity for caloric? and will it not, in that caſe, unite with it? Oxygen gas and caloric have an affinity for each other; accordingly when preſented to one another they combine in a certain proportion, and form a new compound, differing from oxygen gas, properly ſo called, in elaſticity, ſpecific gravity, and ſeveral other particulars. The affinity, however, between oxygen gas and caloric is much feebler than that between oxygen and caloric; for the new compound is eaſily broken, and the caloric abſorbed by many other ſubſtances. We can even conceive this new compound ſtill to have an affinity for caloric, to unite with it, and to form another compound, the affinity between the ingredients of which is ſtill feebler. And in this manner may the indefinite increaſe of temperature be accounted for.

286
Cauſe of the different conducting powers of different bodies.

Subſtances may be conceived to be conductors of caloric inverſely as their affinity for it. Good conductors may have very little affinity for caloric; and for that reaſon it may be eaſily forced through them by the repulſion of its own particles. But thoſe ſubſtances which have a great affinity for caloric, combine with it the moment it is preſented to them; and conſequently it cannot paſs through them. Thus, when it is preſented to ice, the affinity between the two ſubſtances is ſo great, that the caloric unites with the very firſt particles of ice which it meets with. The particles behind theſe cannot receive any caloric, except by attracting it from the particles with which it has already combined. But the affinity of one particle of ice for caloric cannot be greater than that of another particle of ice: and the union of two bodies cannot be broken by a force not greater than that which unites them; therefore the caloric cannot paſs from one particle to another. Conſequently, ſuppoſing all the particles to keep their places, no new caloric could enter. Juſt as when a piece of marble is put into ſulphuric acid, the cruſt of ſulphat of lime which very ſoon covers it prevents the acid from getting to the particles of marble within. But as ſoon as a particle of ice unites with caloric, water, the new compound, leaves its ſtation, and allows the caloric a paſſage to the other particles.

In the ſame manner, when caloric is preſented to water, it combines with the outermoſt ſtratum of particles, and forms with them a compound which cannot be decompoſed by the other particles of the water, becauſe their affinity for caloric is no greater than that of the particles already united with it. No more caloric, then, could gain admiſſion, were it not that (the ſpecific gravity of the new compound being inferior to that of the uncombined water) it immediately changes its place, and allows another ſtratum of particles to occupy its room. Theſe unite with caloric, and are diſplaced in their turn. And in this manner the proceſs goes on, till all the particles have combined with caloric; or, which is the ſame thing, till the whole of the water is heated.

287
How heat paſſes thro' ſolids.

But ſuppoſing the firſt ſtratum of particles to remain in their place after their union with caloric, we can conceive an affinity ſtill to ſubſiſt between the new compound, thus formed, and caloric. In that caſe the new compound, which we ſhall call A, would combine with an additional doſe of caloric, and form a ſecond compound B, differing in ſeveral reſpects from the firſt. We can conceive alſo the affinity between the firſt compound A and caloric to be inferior to that between water and caloric. In that caſe, the ſecond ſtratum of particles of water would ſeparate the additional doſe with which the firſt ſtratum had united. In this manner would two ſtratums of particles combine with caloric. The firſt ſtratum of particles would combine with another doſe of caloric, and form a ſecond compound B as before. But this compound could not now be decompoſed by the ſecond ſtratum of particles, becauſe they had already united with a doſe of caloric; and therefore their affinity for a new doſe could be no greater than that of the firſt ſtratum of particles. The proceſs of heating could go on no farther. But we can conceive the ſecond compound B, into which the firſt ſtratum has entered, ſtill to have an affinity for caloric, to combine with a doſe of it, and to form with it a third compound C. We can conceive, at the ſame time, the affinity between the ſecond compound B and caloric to be leſs than that between the firſt compound A and caloric. In that caſe, the ſecond ſtratum of particles would take this laſt doſe from the firſt ſtratum, and form with it a ſecond compound B. The third ſtratum of particles, which is ſtill uncombined with caloric, would now attract this new doſe from the ſecond ſtratum, and combine with it. And, ſuppoſing the caloric ſtill flowing towards the water, the firſt ſtratum would again form the third compound C, by uniting with a freſh doſe: this new doſe would be again attracted by the ſecond ſtratum, and the firſt ſtratum would again form the third compound C, by uniting witb another doſe of caloric. Thus three ſtratums of particles would be combined with caloric; the firſt ſtratum would contain three doſes, the ſecond ſtratum two, and the third one. The proceſs of heating would again ſtop; becauſe now the affinity of the ſecond ſtratum is no greater than that of the firſt, nor the affinity of the third ſtratum greater than that of the ſecond, nor that of the fourth than that of the third. But we can conceive an affinity ſtill to ſubſiſt between caloric and the third compound C, into which the firſt ſtratum has entered, and this affinity, at the ſame time weaker than that between the ſecond compound B and caloric. In that caſe they would combine and form a fourth compound D. This new doſe would be attracted by the ſecond ſtratum of particles, which would combine with it and form the third compound C; the third ſtratum would attract it from the ſecond, and form with it the ſecond compound B; and the fourth ſtratum would attract it from the third, and enter into the firſt compound A. The firſt ſtratum would again enter into the fourth compound D; which would be again decompoſed by the ſecond ſtratum; and the compound formed by the ſecond ſtratum, by the third ſtratum. The fourth compound D would be again formed by the firſt ſtratum, and again decompoſed by the ſecond ſtratum. It would be formed a third time, and could not now be decompoſed. Four ſtratums of particles would now have combined with caloric: the firſt ſtratum with four doſes; the ſecond, with three doſes; the third, with two; and the fourth, with one. We can conceive this proceſs to go on exactly in the ſame manner, till all the particles of water have combined with a doſe of caloric. In that caſe, the quantity of caloric combined with every ſtratum of particles would form a regular decreaſing ſeries from that part of the water at which the caloric enters to that part which is fartheſt diſtant from it. The proceſs of heating would go on very ſlowly; and the heat of that part of the water which is fartheſt diſtant from the ſource of caloric could never be nearly equal to that of the part which is neareſt to that ſource. This ſeems in fact to be the manner in which all thoſe ſolids are heated which are bad conductors of caloric: in all probability it is the way in which all ſolids are heated.

288 Bodies cool each other reciprocally, That caloric combines with bodies merely by means of affinity, ſeems at firſt ſight contrary to fact; for there is no ſubſtance whatever which may not be cooled indefinitely merely by ſurrounding it with other bodies which are colder than itſelf. Place a piece of hot iron, for inſtance, in cold water, it is very ſoon cooled down to the temperature of that liquid. This ſeems plain enough; the attraction of water for caloric is greater than that of iron: but reverſe the experiment; put hot water within cold iron, and the water is cooled in its turn down to the temperature of the iron: ſo that the iron alſo has a greater affinity for caloric, as well as the water; which is abſurd.

289 And why. But it ought to be remembered, that caloric not only poſſeſſes affinity, but that it has another property alſo, of which every other ſpecies of matter, except perhaps light, ſeems to be deſtitute, a repulſion between its own particles. It is neceſſary for all organiſed bodies, and probably for all bodies, that they ſhould poſſeſs a certain quantity of caloric; and on this account the greateſt care has been taken to ſecure its equal diſtribution. This ſeems to be one uſe at leaſt of its repulſive power; a power which is never deſtroyed, however cloſely caloric is united with other bodies. We have ſhewn already, that this power is increaſed by diminiſhing the quantity of ſurrounding caloric; and when thus increaſed to a certain degree, it may at laſt equal, and even exceed, the affinity between the caloric and the bodies to which it is united; and in that caſe part of the caloric would neceſſarily fly off. It ſeems to be in this manner that bodies reciprocally cool each other, and that they have always a tendency to an equilibrium of temperature. Thus ſteam by cold is converted into water, and water into ice. And the affinity between bodies and that caloric which is employed in regulating the temperature ſeems to be ſo weak, that the repulſion between the particles of caloric eaſily overcomes it, and reſtores the equilibrium. But the affinity between ſome ſubſtances and caloric is ſo great, that no diminution of temperature has been found ſufficient to overcome it. This is the caſe, as we have already ſeen, with oxygen gas.

290 Cauſe of the difference in the ſpecific caloric of bodies. The ſpecific caloric of bodies ſeems to depend on two things; their affinity for caloric, and the diſtance between their particles. For what is temperature but the diſpoſition of a body to part with caloric? The more caloric a body is diſpoſed to part with, we call its temperature the higher; the leſs it parts with when a colder body is applied, its temperature is ſaid to be the lower. If oxygen gas parts with no caloric to a thermometer which ſtands at —10°, we ſay its temperature is —10; yet we know that even then it contains, in all probability, much more caloric than the mercury in the thermometer does. Now the ſtronger the affinity between any ſubſtance and caloric, the greater quantity of caloric will be required before the repulſion between its particles is ſufficient to overcome this attraction; conſequently the more caloric is neceſſary to raiſe it a given number of degrees. And the farther diſtant the particles of bodies are, the farther from one another muſt the particles of caloric be to which they are united; and conſequently the weaker muſt be the repulſion between them.

We cannot deny how new this theory of the action of caloric will appear to thoſe who have been accuſtomed ed to look upon Dr Crawford's opinions on this ſubject as fully proved; nor do we pretend that it can be reconciled with theſe opinions. But this, we hope, is no proof of its falſehood. We think it can be fairly deduced from Dr Black's doctrine of latent heat: we know, too, that Bergman believed caloric capable of combining chemically with bodies: and Morveau has not only embraced the ſame opinion, but ſeems to affirm, that all the combinations into which caloric enters are chemical *. And were this queſtion to be decided by authority, we appeal to all the world, whether other three men could be produced to whoſe deciſions one would more willingly ſubmit (1). We do not, however, mean to reſt its evidence on authority; let it be compared with facts, and put to the teſt of experiment; and by its correſpondence with theſe let it ſtand or fall.

* Encyc. Method. Chim. art. Affinité.

291 Caloric haſtens ſolution, and increaſes the ſolvent power of water.

12. Caloric both haſtens the ſolution of ſalts in water, and increaſes the ſolvent power of the water; for water diſſolves a much greater quantity of almoſt every ſalt when hot than when cold. The reaſon that caloric produces theſe effects is obvious from thoſe properties of it which have been deſcribed. It haſtens ſolution by putting the particles of the fluid in motion, and thus bringing all of them in their turn into contact with the ſalt: for only thoſe particles can act as ſolvents which are in contact with the ſalt. It increaſes the ſolvent power of the fluid by combining with it, and forming a compound which has a greater affinity for the ſalt, and which therefore diſſolves more of it than the fluid alone would have done. This new compound is deſtroyed by cooling; and then the additional doſe of the ſalt which had been diſſolved is precipitated.

13. We ſhould come now to the conſideration of the two remaining queſtions propoſed at the end of the ſecond chapter, Why do bodies combine with oxygen at one temperature and not at another? And why is caloric neceſſary to produce this union? But as the difficulty of theſe queſtions is not inferior to their importance, we ſhall delay any attempt to anſwer them till we come to treat of *affinity*.

292 Methods of obtaining caloric.

14. It now only remains to conſider the methods by which caloric may be obtained in a ſenſible ſtate. Theſe methods may be reduced to four; combuſtion, percuſſion, friction, and light: the laſt of which ſhall be conſidered afterwards.

293 Combuſtion explained.

We have ſeen already, that the combuſtion of *ſimple combuſtibles and metals* is merely their combination with oxygen, during which the oxygen parts with the caloric with which it was formerly united. Now the very ſame thing takes place in other combuſtions. The combuſtible unites with oxygen, which at the ſame time gives out its caloric. The change then which the combuſtible body ſuffers is not owing to the action of caloric on it, but to its combining with oxygen. The very ſame change can be brought about without any of the uſual phenomena which attend combuſtion, ſimply by preſenting the oxygen combined with ſome other body inſtead of caloric. Nitric acid, for inſtance, is a body which contains in it a good deal of oxygen: If phoſphorus be mixed with this acid, it attracts part of the oxygen, and, without any of the uſual phenomena which attend combuſtion, is converted into phoſphoric acid. Strictly ſpeaking, then, combuſtion is nothing elſe but the combination of oxygen with the burning body, and the term might therefore be uſed in every caſe where ſuch an union takes place; and in this ſenſe indeed it is now employed by ſeveral writers. But the term *combuſtion* is in common language confined to thoſe caſes where the oxygen was previouſly combined with caloric, and where a quantity of heat and light become ſenſible; and perhaps it would be better, in order to prevent ambiguity, never to employ it in any other ſenſe. We are not yet abſolutely certain that caloric and light may not become ſenſible in other combinations beſides thoſe into which oxygen enters. There are other ſubſtances beſides oxygen capable of combining with caloric; for inſtance, hydrogen and azot: and unleſs their affinity for caloric be greater than for any other ſubſtance, they may be capable of combining with other ſubſtances, and ſeparating from caloric, at leaſt the impoſſibility of this has never yet been demonſtrated. It is improper, therefore, to appropriate the word *combuſtion* to the combinations of oxygen, till it can be ſhewn that the phenomena uſually denoted by that name are never owing to any other cauſe. There is even one caſe in which theſe phenomena preſent themſelves, in which we are next to certain that oxygen has no ſhare. There is an affinity between ſulphur and iron, and a high temperature promotes their union. When theſe ſubſtances are mixed together, and heated till they juſt begin to appear red hot, they combine together, and at the ſame time, as the Dutch chemiſts firſt obſerved, a good deal of caloric and light is evolved. The very ſame phenomena appear in a vacuum, or in any kind of air whatever. The explanation of them is very ſimple and obvious. The ſulphur or the iron, or perhaps both, had previouſly been combined with a quantity of caloric; and when they united together, this caloric of courſe ſeparated from them.

294 Whether it ever takes place when oxygen is not preſent.

295 Stahl's theory of combuſtion by the extrication of phlogiſton.

The theory of combuſtion adopted by the earlier chemiſts was very different from the preceding. Stahl, as has been already explained, conſidered combuſtion in every inſtance as owing to the ſeparation of phlogiſton; and this opinion ſoon became univerſal. He conſidered phlogiſton as the ſame thing with the element of fire; which was capable both of becoming fixed in bodies, and of exiſting in a ſtate of liberty. Two of its properties in this laſt ſtate were heat and light. The heat and the light, then, which became ſenſible during combuſtion, were nothing elſe, according to Stahl, but two properties of phlogiſton or the element of fire. Macquer, to whoſe illuſtrious labours ſeveral of the moſt important branches of chemiſtry owe their exiſtence, was, we believe, the firſt perſon who perceived a ſtriking defect in this theory of Stahl. Sir Iſaac Newton had proved that light is a body; it was abſurd, therefore, to make it a mere property of phlogiſton or the element of fire. Macquer accordingly conſidered phlogiſton as nothing elſe but light fixed in bodies. This opinion was embraced by a great number of the moſt diſtin-

296 Improved by Macquer,

---

(1) The ſame opinion has been embraced by Seguin, Pictet, Gadolin, and ſeveral other philoſophers. We did not mention them, becauſe the theory given above differs in a few particulars from theirs. But we have derived much inſtruction from their ingenious writings; and many of the facts which we have given were obtained from them.

diſtinguiſhed chemiſts; and many ingenious arguments were brought forward to prove its truth. But if phlogiſton be only light fixed in bodies, whence comes the heat that manifeſts itſelf during combuſtion? Is this heat merely a property of light? Dr Black proved that heat is capable of combining with, or becoming fixed in bodies which are not combuſtible, as in ice and water; and concluded of courſe, that it is not a property but a body. From that time heat or caloric was conſidered by the greateſt number of chemiſts as a diſtinct ſubſtance from phlogiſton.

297 Prieſtley,

Soon after this, a phenomenon, which had been obſerved from the earlieſt ages, and which probably, for that very reaſon, had been neglected, began to be attended to; that combuſtibles would not burn except in contact with air. Dr Prieſtley obſerved, that the air in which combuſtibles had been ſuffered to burn till they were extinguiſhed, had undergone a very remarkable change; for no combuſtible would afterwards burn in it, and no annimal could breathe it without ſuffocation (K). He concluded, as Dr Rutherford had done before him, that this change was owing to phlogiſton; that the air had combined with that ſubſtance; and that air was neceſſary to combuſtion, by attracting the phlogiſton, for which it had a ſtrong affinity. If ſo, phlogiſton could not be light any more than caloric; for if it ſeparated from the combuſtible merely by combining with air, it could not ſurely diſplay itſelf in the form of light. The queſtion then recurred with double force, What is phlogiſton? Dr

298 And Crawford.

Crawford, of whoſe ingenious experiments on the ſpecific caloric of bodies we have already given an account, without attempting to anſwer this queſtion, made a conſiderable improvement in the theory of combuſtion, by ſuppoſing that the phlogiſton of the combuſtible combined with the air, and at the ſame time ſeparated the caloric and light with which that fluid had been previouſly united. The heat and the light, then, which appeared during combuſtion, exiſted previouſly in the air. This theory was very different from Stahl's, and certainly a great deal more ſatisfactory. But ſtill

299 Kirwan's theory of phlogiſton

the queſtion, What is phlogiſton? remained to be anſwered. Mr Kirwan, who had already raiſed himſelf to the firſt rank among chemical philoſophers by many important diſcoveries, and many ingenious inveſtigations of ſome of the moſt difficult parts of chemiſtry, attempted to anſwer this queſtion, and to prove that phlogiſton was the ſame with hydrogen *. The ſubject was now brought to a ſtate capable of the moſt complete deciſion. Does hydrogen actually exiſt in all combuſtible ſubſtances? and is it ſeparated from them

300 Refuted.

during every combuſtion? The French chemiſts who anſwered his treatiſe, ſhewed that this is by no means the caſe; and that therefore there was no proof whatever of the identity of phlogiſton and hydrogen. And Mr Kirwan in conſequence, with that candour which diſtinguiſhes ſuperior minds, gave up his opinion as untenable.

301 Exiſtence of phlogiſton diſproved.

Mr Lavoiſier had already put the queſtion, What proof is there of the exiſtence of phlogiſton at all? There is only this ſingle proof, that ſubſtances after combuſtion are different from what they formerly were. That this difference takes place is certainly true; but it is owing, not to the ſeparation of any ſubſtance, but to the combination of one. It follows, therefore, that there is no proof whatever of the exiſtence of any ſuch ſubſtance as *phlogiſton* in nature; and of courſe we muſt conclude that no ſuch ſubſtance exiſts (L).

302 Production of caloric by percuſſion,

15. It is well known that heat is produced by the percuſſion of hard bodies againſt each other. When a piece of iron is ſmartly and quickly ſtruck with a hammer, it becomes red hot; and the production of ſparks by the colliſion of flint and ſteel is too familiar a fact to require being mentioned. No heat, however, has ever been obſerved to follow the percuſſion of liquids, nor of ſoft bodies which eaſily yield to the ſtroke.

303 Owing partly to condenſation,

It has long been known, that hammering increaſes the denſity of metals. The ſpecific gravity of iron before hammering is 7,788; after being hammered, 7,840: that of platinum before hammering is 19,50; after it, 23,00. Now condenſation diminiſhes the ſpecific caloric of bodies. After one of the clay pieces uſed in Wedgewood's thermometer has been heated to 120°, it is reduced to one half of its former bulk, though it has loſt only two grains of its weight, and its ſpecific caloric is at the ſame time diminiſhed one third †. But we cannot conceive the ſpecific caloric of a body to be diminiſhed without its giving out at the ſame time a quantity

* In his *Treatiſe on Phlogiſton.*

* *T. Wedgewood, Phil. Tranſ.* 1792.

(K) Theſe very obſervations had been made almoſt a century before by Mayow; but chemiſtry was then in its infancy; little attention was paid to them, and they had been forgotten.

(L) Mr Lavoiſier was therefore the author of what is called the *antiphlogiſtic theory* in chemiſtry, or the theory which accounts for the phenomena of chemiſtry without the aſſiſtance of phlogiſton. It has been ſo called in oppoſition to the theory of Stahl, which explained every thing by means of *phlogiſton*, and which is therefore called the *phlogiſtic theory*.

Some chemiſts have affected to omit Lavoiſier's name altogether, when they ſpoke of the antiphlogiſtic theory. According to them, that theory was founded upon the experiments and diſcoveries of other chemiſts, and Lavoiſier had no other merit but that of bringing it into public notice.

That Mr Lavoiſier, virtually at leaſt, claimed ſeveral of the diſcoveries of others, we are ſorry to be under the neceſſity of acknowledging; and that many of the experiments, brought forward to diſprove the exiſtence of phlogiſton, were firſt made by others, is known to all the world: but it is equally evident, that the firſt perſon who actually formed the theory was Lavoiſier; and ſurely the merit lies in that. It is not thoſe who collect the ſtones, and the timber, and the mortar, but he who lays the plan, and ſhews how to put the materials together, that is in reality the builder of the houſe. Who did not know, as well as Newton, that a ſtone fell to the ground, and that the planets revolved round the ſun? and yet, who but Newton could have formed the theory of gravitation? We would not be underſtood to detract any thing from the merit of the other illuſtrious philoſophers who have adorned the preſent age, many of whom are at leaſt equal, and ſome of them ſuperior to Lavoiſier: But we are afraid that envy, or ſome worſe motive, guided the pen of *one* at leaſt of the moſt active and virulent antagoniſts of that illuſtrious and unfortunate philoſopher. It muſt not, however, be concealed, that his theory of combuſtion is incomplete. See COMBUSTION in this *Supplement*.

quantity of caloric; and we know for certain that caloric is evolved during condenſation. A thermometer placed within a condenſer riſes ſeveral degrees every time air is thrown in *. We can even ſee a reaſon for this. When the particles of a body are forced nearer each other, the repulſive power of the caloric combined with them is increaſed, and conſequently a part of it will be apt to fly off. Now, after a bar of iron has been heated by the hammer, it is much harder and brittler than before. It muſt then have become denſer, and conſequently muſt have parted with caloric. It is an additional confirmation of this, that the ſame bar cannot be heated a ſecond time by percuſſion until it has been expoſed for ſome time to a red heat. It is too brittle, and flies to pieces under the hammer. Now brittleneſs ſeems in moſt caſes owing to the abſence of the uſual quantity of caloric. Glaſs *unannealed*, or, which is the ſame thing, that has been cooled very quickly, is always extremely brittle. When glaſs is in a ſtate of fuſion, there is a vaſt quantity of caloric accumulated in it, the repulſion between the particles of which muſt of courſe be very great; ſo great indeed, that they would be diſpoſed to fly off in every direction with inconceivable velocity, were they not confined by an unuſually great quantity of caloric in the ſurrounding bodies: conſequently if this ſurrounding caloric be removed, the caloric of the glaſs flies off at once, and more caloric will leave the glaſs than otherwiſe would leave it, becauſe the velocity of the particles muſt be greatly increaſed. Probably then the brittleneſs of glaſs is owing to the deficiency of caloric; and we can ſcarcely doubt that the brittleneſs of iron is owing to the ſame cauſe, if we recollect that it is removed by the application of new caloric. Part therefore of the caloric which appears in conſequence of percuſſion ſeems to proceed from the body ſtruck; and this is doubtleſs the reaſon why thoſe bodies, the denſity of which is not increaſed by percuſſion, as liquids and ſoft ſubſtances, are not heated at all.

* *Darwin, Phil. Tranſ.* 1788.

304
And partly to combuſtion.

We ſay *part* of the caloric, becauſe, often at leaſt, part of it is probably owing to another cauſe. By condenſation, as much caloric is evolved as is ſufficient to raiſe the temperature of ſome of the particles of the body high enough to enable it to combine with the oxygen of the atmoſphere. The combination actually takes place, and a great quantity of additional caloric is ſeparated by the decompoſition of the gas. That this happens during the colliſion of flint and ſteel cannot be doubted; for the ſparks produced are merely ſmall pieces of iron heated red hot by uniting with oxygen during their paſſage through the air, as any one may convince himſelf by actually examining them. Mr Lane has ſhewn that iron produces no ſparks in the vacuum of an air-pump; but Mr Kirwan has obſerved that they are produced under common ſpring water; and we know that iron at a certain temperature is capable of decompoſing water.

305
Sparks emitted by quartz ſtones on ciſion.

When quartz, rock-cryſtal (M), or other very hard ſtones, are ſtruck againſt one another they emit ſparks. If they be often made to emit ſparks above a ſheet of white paper, there are found upon it a number of ſmall black bodies, not very unlike the eggs of flies. Theſe bodies are hard but friable, and when rubbed on the paper leave a black ſtain. When viewed with a microſcope, they ſeem to have been melted. Muriatic acid changes their colour to a green, as it does that of lavas *. Theſe ſubſtances evidently produced the ſparks by being heated red hot. Lamanon (N) ſuppoſes that they are particles of quartz combined with oxygen. Were that the caſe, the phenomenon would be preciſely ſimilar to that which is produced by the colliſion of flint and ſteel. That they are particles of quartz cannot be doubted; but to ſuppoſe them combined with oxygen is contrary to all experience: for theſe ſtones never ſhew any diſpoſition to combine with oxygen even when expoſed to the moſt violent heat. La Metherie made experiments on purpoſe to ſee whether Lamanon's opinion was well founded; but they all turned out unfavourable to it. And Mongé aſcertained, that the particles deſcribed by Lamanon were pure cryſtal unaltered, with a quantity of black powder adhering to them. He concludes accordingly, that theſe fragments had been raiſed to ſo high a temperature during their paſſage through the air, that they ſet fire to all the minute bodies that came in their way †. We muſt therefore either ſuppoſe that all the caloric was produced by mere condenſation, which is not probable, or acknowledge that we cannot explain the phenomenon.

* *Lamanon, Journ. de Phyſ.* 1785.

306
Cauſe of this unknown.

† *Ann. de Chim.* xvi. 206.

307
Emiſſion of caloric on friction,

16. Caloric is not only produced by percuſſion, but alſo by friction. Fires are often kindled by rubbing pieces of dry wood ſmartly againſt one another. It is well known that heavy loaded carts ſometimes take fire by the friction between the axle-tree and the wheel. Now in what manner is the caloric evolved or accumulated by friction? Not by increaſing the denſity of the bodies rubbed againſt each other, as happens in caſes of percuſſion; for heat is produced by rubbing ſoft bodies againſt each other, the denſity of which therefore cannot be increaſed by that means, as any one may convince himſelf by rubbing his hand ſmartly againſt his coat. It is true, indeed, that heat is not produced by the friction of liquids, but then they are too yielding to

308
Not owing to condenſation,

(M) Theſe ſtones are compoſed of almoſt pure ſilica.

(N) This ingenious and unfortunate young man, to whom we are indebted for theſe facts, fell a victim to his ardour for knowledge. He accompanied La Perouſe in his laſt voyage, and was murdered with the moſt ſavage cruelty, together with La Langle and ſeveral others, by the natives of the iſland of Maouna. When a man of genius, anxious to acquire honeſt fame, and a man too ſo nobly diſintereſted as Lamanon, thus falls prematurely before he has attained the object of his wiſhes,

> " Cut off from nature's and from glory's courſe!
> " Which never mortal was ſo fond to run,"

who can withhold the tribute of regret and admiration, when they

> —— " Conjecture what he might have proved,
> " And think life only wanting to his fame."

to be ſubjected to ſtrong friction. It is not owing to the ſpecific caloric of the rubbed bodies decreaſing; for Count Rumford found that there was no ſenſible decreaſe *, nor, if there were a decreaſe, would it be ſufficient to account for the vaſt quantity of heat which is ſometimes produced by friction.

309 Nor to decreaſe of ſpecific caloric,

Count Rumford took a cannon caſt ſolid and rough as it came from the foundery; he cauſed its extremity to be cut off, and formed, in that part, a ſolid cylinder attached to the cannon $7\frac{3}{4}$ inches in diameter and $9\frac{8}{10}$ inches long. It remained joined to the reſt of the metal by a ſmall cylindrical neck. In this cylinder a hole was bored 3,7 inches in diameter and 7,2 inches in length. Into this hole was put a blunt ſteel borer, which by means of horſes was made to rub againſt its bottom; at the ſame time a ſmall hole was made in the cylinder perpendicular to the bore, and ending in the ſolid part a little beyond the end of the bore. This was for introducing a thermometer to meaſure the heat of the cylinder. The cylinder was wrapt round with flannel to keep in the heat. The borer preſſed againſt the bottom of the hole with a force equal to about 10,000 lb. avoirdupois, and the cylinder was turned round at the rate of 32 times in a minute. At the beginning of the experiment the temperature of the cylinder was 60°; at the end of 30 minutes, when it had made 960 revolutions, its temperature was 130°. The quantity of metallic duſt or ſcales produced by this friction amounted to 837 grains. Now, if we were to ſuppoſe that all the caloric was evolved from theſe ſcales, as they amounted to juſt $\frac{1}{948}$ part of the cylinder, they muſt have given out 948° to raiſe the cylinder 1°, and conſequently 66360° to raiſe it 70° or to 130°, which is certainly incredible †.

310 Nor to combuſtion;

Neither is the caloric evolved during friction owing to the combination of oxygen with the bodies themſelves or any part of them. By means of a piece of clock-work, Mr Pictet made ſmall cups (fixed on the axis of one of the wheels) to move round with conſiderable rapidity, and he made various ſubſtances rub againſt the outſides of theſe cups, while the bulb of a very delicate thermometer placed within them marked the heat produced. The whole machine was of a ſize ſufficiently ſmall to be introduced into the receiver of an air-pump. By means of this machine a piece of adamantine ſpar was made to rub againſt a ſteel cup in air: ſparks were produced in great abundance during the whole time, but the thermometer did not riſe. The ſame experiment was repeated in the exhauſted receiver of an air-pump (the manometer ſtanding at four lines); no ſparks were produced, but a kind of phoſphoric light was viſible in the dark. The thermometer did not riſe. A piece of braſs being made to rub in the ſame manner againſt a much ſmaller braſs cup in air, the thermometer (which almoſt filled the cup) roſe 0,3°, but did not begin to riſe till the friction was over. This ſhews us that the motion produced in the air carried off the caloric as it was evolved. In the exhauſted receiver it began to riſe the moment the friction began, and roſe in all 1,2°. When a bit of wood was made to rub againſt the braſs cup in the air, the thermometer roſe 0,7°, and on ſubſtituting alſo a wooden cup it roſe 2,1°, and in the exhauſted receiver 2,4°, and in air condenſed to $1\frac{1}{2}$ atmoſpheres it roſe 0,5° *. If theſe experiments be not thought concluſive, we have others to relate, which will not leave a doubt that the heat produced by friction is not connected with the decompoſition of oxygen gas. Count Rumford contrived, with his uſual ingenuity, to encloſe the cylinder above deſcribed in a wooden box filled with water, which effectually excluded all air, as the cylinder itſelf and the borer were ſurrounded with water, and at the ſame time did not impede the motion of the inſtrument. The quantity of water amounted to 18,77 lbs. avoirdupois, and at the beginning of the experiment was at the temperature of 60°. After the cylinder had revolved for an hour at the rate of 32 times in a minute, the temperature of the water was 107°; in 30 minutes more it was 178°; and in 2 hours and 30 minutes after the experiment began, the water *actually boiled*. According to the computation of Count Rumford, the caloric produced would have been ſufficient to heat 26,58 lbs. avoirdupois of ice-cold water boiling hot; and it would have required 9 wax candles of a moderate ſize, burning with a clear flame all the time the experiment laſted, to have produced as much heat. In this experiment all acceſs of water into the hole in the cylinder where the friction took place was prevented. But in another experiment, the reſult of which was preciſely the ſame, the water was allowed free acceſs *.

311 And conſequently at preſent inexplicable.

The caloric, then, which appears in conſequence of friction, is neither produced by an increaſe of the denſity, nor by an alteration in the ſpecific caloric of the ſubſtances expoſed to friction, nor is it owing to the decompoſition of the oxygen of the atmoſphere.—Whence then is it derived? This queſtion we are altogether unable to anſwer. We cannot, however, think that the concluſion which Count Rumford is diſpoſed to draw from his experiments is warranted by the premiſes. He ſuppoſes, that becauſe we cannot explain the manner that caloric is accumulated by friction, there is no ſuch ſubſtance as caloric at all, but that it is merely a *peculiar kind of motion*. We would beg leave to aſk, how the facts mentioned in the former part of this chapter, many of which were furniſhed by this ingenious philoſopher himſelf, and all of which combine to render the exiſtence of caloric as a ſubſtance probable, can be deſtroyed and ſet aſide, merely becauſe there are other phenomena in nature connected with caloric which cannot be accounted for? Were it poſſible to prove that the accumulation of caloric by friction is *incompatible* with its being a ſubſtance, in that caſe Count Rumford's concluſion would be a fair one; but this ſurely has not been done. We are certainly not yet ſufficiently acquainted with the laws of the motion of caloric (allowing it to be a ſubſtance) to be able to affirm with certainty that friction could not cauſe it to accumulate in the bodies rubbed. This we know at leaſt to be the caſe with electricity. Nobody has been hitherto able to demonſtrate, in what manner it is accumulated by friction; and yet this has not been thought a ſufficient reaſon to deny its exiſtence.

312 This no proof that caloric is not a body.

313 Analogy between caloric and electricity.

Indeed there ſeems to be a very cloſe analogy between caloric and electric matter. Both of them tend to diffuſe themſelves equally, both of them dilate bodies, both of them fuſe metals, and both of them kindle combuſtible ſubſtances. Mr Achard has proved, that electricity can be ſubſtituted for caloric even in thoſe caſes where its agency ſeems peculiarly neceſſary; for he found that, by conſtantly ſupplying a certain quantity of the electric fluid, eggs could be hatched juſt as when they are kept

---

* Nicholſon's Journ. ii. 106.

† Ibid.

* Pictet ſur le Feu, ch. 9.

* Nicholſon, ibid.

kept at the temperature of 103°. An accident indeed prevented the chickens from actually coming out; but they were formed and living, and within two days of burſting their ſhell. Electricity has alſo a great deal of influence on the heating and cooling of bodies. Mr Pictet exhauſted a glaſs globe, the capacity of which was 1200,199 cubic inches, till the manometer within it ſtood at 1,75 lines. In the middle of this globe was ſuſpended a thermometer which hung from the top of a glaſs rod fixed at the bottom of the globe, and going almoſt to its top. Oppoſite to the bulb of this thermometer two lighted candles were placed, the rays of which, by means of two concave mirrors, were concentrated on the bulb. The candles and the globe were placed on the ſame board, which was ſupported by a non-conductor of electricity. Two feet and a half from the globe there was an electrifying machine, which communicated with a braſs ring at the mouth of the globe by means of a metallic conductor. This machine was kept working during the whole time of the experiment; and conſequently a quantity of electric matter was conſtantly paſſing into the globe, which formed an atmoſphere not only within it, but at ſome diſtance round, as was evident from the imperfect manner in which the candles burned. When the experiment began the thermometer ſtood at 49,8°. It roſe to 70,2° in 732″. The ſame experiment was repeated, but no electric matter thrown in; the thermometer roſe from 49,8° to 70,2° in 1050″; ſo that the electricity haſtened the heating almoſt a third. In the firſt experiment the thermometer roſe only to 71,3°. but in the ſecond it roſe to 77°. This difference was doubtleſs owing to the candles burning better in the ſecond than the firſt experiment; for in other two experiments made exactly in the ſame manner, the maximum was equal both when there was and was not electric matter preſent. Theſe experiments were repeated with this difference, that the candles were now inſulated, by placing their candleſticks in diſhes of varniſhed glaſs. The thermometer roſe in the electrical vacuum from 52,2° to 74,7° in 1050″; in the ſimple vacuum in 965″. In the electrical vacuum the thermometer roſe to 77°; in the ſimple vacuum to 86°. It follows from theſe experiments, that when the globe and the candles communicated with each other, electricity haſtened the heating of the thermometer; but that when they were inſulated ſeparately, it retarded it *. One would be apt to ſuſpect the agency of electricity in the following experiment of Mr Pictet: Into one of the braſs cups formerly deſcribed, a ſmall quantity of cotton was put to prevent the bulb of the thermometer from being broken. As the cup turned round, two or three fibres of the cotton rubbed againſt the bulb, and without any other friction the thermometer roſe five or ſix degrees. A greater quantity of cotton being made to rub againſt the bulb, the thermometer roſe 15 degrees †.

314 lectricity nay be an gent in the eating of odies by iction.

We do not mean to draw any other concluſion from theſe facts, than that electricity is very often concerned in the heating of bodies, and that probably ſome ſuch agent is employed in accumulating the heat produced by friction. Suppoſing that electricity is actually a ſubſtance, and taking it for granted that it is different from caloric, does it not in all probability contain caloric as well as all other bodies? Has it not a tendency to accumulate in all bodies on friction, whether conductors or non-conductors? May it not then be accumulated in theſe bodies which are rubbed againſt one another? or, if they are good conductors, may it not paſs through them during the friction in great quantities? May it not part with ſome of its caloric to theſe bodies, either on account of their greater affinity or ſome other cauſe? and may not this be the ſource of the caloric which appears during friction?

Chap. VI. *Of* Light.

315 Newtonian theory of light.

By means of *light* bodies are rendered viſible. Light has been conſidered as a ſubſtance compoſed of ſmall particles moving in ſtraight lines from luminous bodies with inconceivable rapidity. The diſcoveries of Newton eſtabliſhed this opinion on the firm baſis of mathematical demonſtration; and ſince his time it has been generally embraced. Huyghens, indeed, and Euler, advanced another (o). They conſidered light as a ſubtile fluid, filling all ſpace, which rendered bodies viſible by its undulations. But they ſupported their hypotheſis rather by ſtarting objections to the theory of Newton, than by bringing forward direct proofs. Their objections, even if valid, inſtead of eſtabliſhing their own opinions, would prove only that the phenomena of light are not completely underſtood; a truth which no man will refuſe to acknowledge, whatever ſide of the queſtion he adopts. Newton and his diſciples, on the contrary, have ſhewn that the known phenomena of light are *inconſiſtent* with the undulations of a fluid, and have brought forward a great number of direct arguments, which it has been impoſſible to anſwer, in ſupport of their theory. It can hardly be doubted, therefore, that the Newtonian theory of light is the true one.

316 Velocity of light.

Dr Bradley, who, by a number of very accurate experiments, and a proceſs of reaſoning peculiarly ingenious, diſcovered the aberration of light of the fixed ſtars, has ſhewn from it that the velocity of light is to that of the earth in its orbit as 10313 to 1. Light therefore moves at the rate of 195218 miles in a ſecond.

317 Diviſible into ſeven rays.

Light, by means of a priſm, may be ſeparated into ſeven rays, differing from each other in colour; red, orange, yellow, green, blue, indigo, violet. None of theſe are capable of farther decompoſition. Marat, indeed, pretended that he had reduced them to three; but his experiments are now known to have been merely philoſophical frauds.

318 Differing in refrangibility.

When light paſſes obliquely into a denſer medium, it is *refracted towards* the perpendicular; when into a rarer, *from* the perpendicular. Sir Iſaac Newton diſcovered that the rays differed in their refrangibility in the order in which they have been named, the red being the leaſt, the violet the moſt refrangible. Mr Blair has obſerved, that the ratios of the refrangibility of the different rays, though not their order, vary ſomewhat in different mediums *.

When light paſſes within a certain diſtance of a body, parallel

* *Pictet ſur* e *Feu*. ch. 6.

† *Ibid.* ch. 9.

* *Edinburgh Phil. Tranſ.* iii.

(o) Dr Franklin did the ſame, without taking any notice of theſe philoſophers, of whoſe opinions perhaps he was ignorant. See *Tranſ. Philad.* III. 5.

parallel to which it is moving, it is bent *towards* it; when it paſſes at a greater diſtance, it is bent *from* it. The firſt of theſe properties is called *inflection*, the ſecond *deflection*. Now the rays differ in theſe properties in the order in which they were named; the red being *moſt*, the violet *leaſt*, inflexible and deflexible. This was ſuſpected by David Rittenhouſe *, but was firſt demonſtrated by the ingenious experiments of Mr Brougham †.

319 Inflection, deflection,

When light falls upon a viſible body, ſome of it is reflected back; and the more poliſhed or the whiter any ſurface is, the more light it reflects. The rays of light differ alſo in reflexity, the red being the moſt, the violet the leaſt reflexible. This diſcovery we owe to the ſame ingenious gentleman ‡.

320 And reflexity.

Theſe properties of light conſtitute the ſubject of Optics; to which we refer thoſe who wiſh to ſee them inveſtigated. We mention them here becauſe they prove that light is acted on by other bodies, that it is ſubjected to the laws of attraction, and conſequently that it poſſeſſes *gravity*.

2. The particles of light ſeem alſo, like thoſe of caloric, to poſſeſs the property of repelling one another; at leaſt their rapid motion, in all directions, from luminous bodies, ſeems to be owing to ſome ſuch property.

321 Light capable of entering bodies,

3. Light is capable of entering into bodies, and remaining in them, and of being afterwards extricated without any alteration. Father Beccaria, and ſeveral other philoſophers, have ſhewn us by their experiments, that there are a great many ſubſtances which become luminous after being expoſed to the light. This property was diſcovered by carrying them inſtantly from the light into a dark place, or by darkening the chamber in which they were expoſed. Moſt of theſe ſubſtances, indeed, loſe this property in a very ſhort time, but they recover it again on being expoſed to the light; and this may be repeated as often as we pleaſe. We are indebted to Mr Canton for ſome very intereſting experiments on this ſubject, and for diſcovering a compoſition which poſſeſſes this property in a remarkable degree. He calcined ſome common oyſter ſhells in a good coal fire for half an hour, and then pounded and ſifted the pureſt part of them. Three parts of this powder were mixed with one part of the flowers of ſulphur, and rammed into a crucible which was kept red hot for an hour. The brighteſt parts of the mixture were then ſcraped off, and kept for uſe in a dry phial well ſtopped. When this compoſition is expoſed for a few ſeconds to the light, it becomes ſufficiently luminous to enable a perſon to diſtinguiſh the hour on a watch by it. After ſome time it ceaſes to ſhine, but recovers this property on being again expoſed to the light. Light then is not only acted upon by other bodies, but it is capable of uniting with them, and afterwards leaving them without any change.

It is well known that light is emitted during combuſtion; and it has been objected to this concluſion, that theſe bodies are luminous only from a ſlow and imperceptible combuſtion. But ſurely combuſtion cannot be ſuſpected in many of Father Beccaria's experiments, when we reflect that one of the bodies on which they were made was his own hand, and that many of the others were altogether incombuſtible; and the phenomena obſerved by Mr Canton are alſo incompatible with the notion of combuſtion. His pyrophorus ſhone only in conſequence of being expoſed to light, and loſt that property by being kept in the dark. It is not expoſure to light which cauſes ſubſtances capable of combuſtion at the temperature of the atmoſphere to become luminous, but expoſure to air. If the ſame temperature continues, they do not ceaſe to ſhine till they are conſumed; and if they ceaſe, it is not the application of light, but of caloric, which renders them again luminous: but Canton's pyrophorus, on the contrary, when it had loſt its property of ſhining, did not recover it by the application of heat, except it was accompanied by light. The only effect which heat had was to increaſe the ſeparation of light from the pyrophorus, and of courſe to ſhorten the duration of its luminouſneſs. Two glaſs globes, hermetically ſealed, containing each ſome of this pyrophorus, were expoſed to the light and carried into a dark room. One of them, on being immerſed in a baſon of boiling water, became much brighter than the other, but in ten minutes it ceaſed to give out light; the other remained viſible for more than two hours. After having been kept in the dark for two days, they were both plunged into a baſon of hot water; the pyrophorus which had been in the water formerly did not ſhine, but the other became luminous, and continued to give out light for a conſiderable time. Neither of them afterwards ſhone by the application of hot water; but when brought near to an iron heated ſo as ſcarcely to be viſible in the dark, they ſuddenly gave out their remaining light, and never ſhone more by the ſame treatment: but when expoſed a ſecond time to the light, they exhibited over again preciſely the ſame phenomena; even a lighted candle and electricity communicated ſome light to them. Surely theſe facts are altogether incompatible with combuſtion, and fully ſufficient to convince us that light alone was the agent, and that it had actually entered into the luminous bodies.

It has been queſtioned, indeed, whether the light emitted by pyrophori be the ſame with that to which they are expoſed. Mr Wilſon has proved, that in many caſes at leaſt it is different, and in particular that on many pyrophori the blue rays have a greater effect than any other, and that they cauſe an extrication of red light. Mr de Groſſer has ſhewn the ſame thing with regard to the diamond, which is a natural pyrophorus *. Still, however, it cannot be queſtioned that the luminouſneſs of theſe bodies is owing to expoſure to light, and that the phenomenon is not connected with combuſtion.

322 And of being combined with them.

But light appears capable, not only of entering into bodies, but of combining with them chemically. The phenomena of the phoſphori ſeem to be inſtances of this, and a great many facts concur to prove that light enters into the compoſition of oxygen gas. When vegetables grow in the light, they give out oxygen gas; but no oxygen is extricated in the dark, even though heat be applied †. From this it is evident, that the ſeparation of this gas from plants, or perhaps the decompoſition of the water which they contain, depends upon the action of light; and that as this decompoſition is chemical, the light to produce it muſt either combine with the oxygen or the hydrogen, or at leaſt contribute to the combination of ſome other ſubſtance with one or other of them. When the oxides of gold or ſilver are expoſed to light, they are reduced to the metallic ſtate ‡, and at the ſame time a quantity of oxygen gas is extricated.

cated[*]. In this caſe, it is evident that the light muſt either combine with the oxygen or the metals. If a quantity of nitric acid be expoſed for ſome time to the light, it becomes yellow, as is well known, and a quantity of oxygen gas is found floating on its top. If it be now carried to a dark place, the oxygen is gradually abſorbed, and the acid becomes colourleſs. In this caſe, nitric acid is decompoſed by means of light, and reſolved into *nitrous acid* and oxygen gas. The light muſt therefore have combined either with the nitrous acid or the oxygen. But no change whatever appears to have been produced in the nitrous acid; for if it be obtained in the dark by any other proceſs, it has preciſely the ſame properties. The oxygen, on the contrary, is converted into a *gas*. It is more probable, then, that the light has combined with the oxygen than with the acid. Hence there is reaſon to ſuſpect that light makes one of the ingredients of oxygen gas. Caloric has already been ſhewn to make another ingredient.

323
Light which appears during combuſtion ſuppoſed combined with oxygen gas.

During combuſtion, a quantity of light as well as caloric is almoſt always evolved. We muſt conclude, therefore, that light makes a part of the compoſition either of the combuſtibles themſelves, or of the oxygen gas with which they unite. We have already ſhewn that oxygen gas probably contains light; and this probability is confirmed by another fact. Subſtances may be combined with oxygen without the emiſſion of any light, provided the oxygen be not in the ſtate of a gas. If phoſphorus, for inſtance, be put into nitric acid, it attracts oxygen, and is converted into phoſphoric acid without the emiſſion of any light. Now if the light which appears during combuſtion had been combined with the combuſtible, it ought to appear in all caſes when that combuſtible is united with oxygen, whether the oxygen has previouſly been in the ſtate of a gas or not. But as this is not the caſe, we may certainly infer, that the light which appears during combuſtion is extricated, not from the combuſtible, but from the oxygen gas. And this ſeems at preſent to be the opinion of the greater number of philoſophers.

But we muſt acknowledge, that this concluſion is not without its difficulties, and difficulties, too, which, in the preſent ſtate of chemiſtry, it does not ſeem poſſible to ſurmount.

324
Difficulties attending this opinion.

In the firſt place, it is evident, that light *may* be produced during combuſtion, though the oxygen be not in the ſtate of a gas: For if nitric acid be poured upon oil of turpentine, the oil takes fire, and burns with the greateſt rapidity, and a great deal of light is emitted. This combuſtion is occaſioned by the oxygen of the acid combining with the ingredients of the oil. It follows, therefore, if the light emitted was previouſly combined with the oxygen, that oxygen muſt contain light when not in the ſtate of a gas. Mr Prouſt has ſhewn that a great variety of ſimilar combuſtions may be produced. But what is very remarkable, by proper caution the very ſame combinations may be made to take place without the viſible emiſſion of any light. In that caſe they take place very ſlowly, as happens alſo when phoſphorus decompoſes nitric acid; ſo that the emiſſion or non-emiſſion of light ſeems to depend not upon the ſtate of the oxygen, ſo much as upon the rapidity or ſlowneſs of the combination. It is true, indeed, as the late Dr Hutton of Edinburgh obſerved, that light may be emitted in theſe ſlow combinations though it be not viſible; and this is very probably the caſe: but then the proof is deſtroyed that light exiſts in oxygen gas, from its not appearing during combinations in which the oxygen did not exiſt previouſly in a gaſeous ſtate.

In the ſecond place, the colour of the light emitted during combuſtion differs almoſt always according to the combuſtible. During the combuſtion of phoſphorus, tin, and zinc, the light emitted is white; during that of ſulphur and biſmuth, blue. Now if this light were united with the oxygen, why does it not appear always of the ſame colour, whatever be the combuſtible?

In the laſt place, the phenomena of phoſphori ſhew that light is capable of entering into other bodies as well as oxygen gas; and the emiſſion of light on the colliſion of two flint ſtones, when no oxygen gas can be decompoſed, is a proof of the ſame kind, which cannot be got over.

In the preſent ſtate of chemiſtry, therefore, it cannot be concluded, that the light emitted during combuſtion does not exiſt in the combuſtibles as well as in the oxygen.

325
Light heats bodies.

4. Light has the property of heating bodies. All bodies, however, are not heated by it. Thoſe which are perfectly tranſparent, or which allow all the light to paſs throw them, ſuffer no alteration in their temperature. Thus light may be concentrated upon water or glaſs without producing any effect. Neither does it produce much change upon thoſe bodies (mirrors for inſtance) that reflect all or nearly all the light which falls upon them. And the ſmallneſs of the alteration of temperature is always proportional to the fineneſs of the poliſh, or, which is the ſame thing, to the quantity of light which is reflected. So that we have reaſon to conclude, that if a ſubſtance could be procured which reflected all the light that fell upon it, the temperature of ſuch a ſubſtance would not be at all affected by light falling upon it. Dr Franklin expoſed upon ſnow pieces of cloth of different colours (white, red, blue, black) to the light of the ſun, and found that they ſunk deeper, and conſequently acquired heat, in proportion to the darkneſs of their colour. Now it is well known that dark-coloured bodies, even when equally expoſed to the light, reflect leſs of it than thoſe which are light-coloured. But ſince the ſame quantity falls upon each, it is evident that dark-coloured bodies muſt abſorb and retain more of it than thoſe which are light-coloured. That ſuch an abſorption actually takes place is evident from the following experiment. Mr Thomas Wedgewood placed two lumps of luminous or phoſphoreſcent marble on a piece of iron heated juſt under redneſs. One of the lumps of marble which was blackened over gave out no light; the other gave out a great deal. On being expoſed a ſecond time in the ſame manner, a faint light was ſeen to proceed from the clean marble, but none at all could be perceived to come from the other. The black was now wiped off, and both the lumps of marble were again placed on the hot iron: The one that had been blackened gave out juſt as little light as the other[*]. In this caſe, the light which ought to have proceeded from the luminous marble diſappeared: it muſt therefore have been ſtopped in its paſſage out, and retained by the black paint. Now black ſubſtances are thoſe which abſorb the moſt light, and they are the bodies which are moſt heated by expoſure to light. Cavallo obſerved, that a

---

[*] Berthollet.

[*] Phil. Tranſ. 1792.

thermometer with its bulb blackened ſtands higher than one which has its bulb clean, when expoſed to the light of the ſun, the light of day, or the light of a lamp *. Mr Pictet made the ſame obſervation; and took care to aſcertain, that when the two thermometers were allowed to remain for ſome time in a dark place, they acquired preciſely the ſame height. He obſerved, too, that when both thermometers had been raiſed a certain number of degrees, the clean one fell a good deal faſter than the other †. But it is not a ſmall degree of heat alone which can be produced by means of light. When its rays are concentrated by a burning-glaſs, they are capable of ſetting fire to combuſtibles with eaſe, and even of producing a temperature at leaſt as great, if not greater, than what can be procured by the moſt violent and beſt conducted fires. In order to produce this effect, however, they muſt be directed upon ſome body capable of abſorbing and retaining them; for when they are concentrated upon tranſparent bodies, or upon fluids, mere air for inſtance, they produce little or no effect whatever. We may conclude, therefore, in general, that in all caſes when light produces heat it is abſorbed.

326
Heat renders bodies luminous,

5. All bodies become luminous when their temperature is raiſed a certain number of degrees. No fact is more familiar than this; ſo well known indeed is it, that little attention has been paid to it. When a body becomes luminous by being heated in a fire, it is ſaid in common language to be *red hot*. It follows from all the experiments hitherto made, that the temperature at which they become red hed hot is nearly the ſame in all bodies.—It ſeems to be pretty near 800°. A red hot body continues to ſhine for ſome time after it has been taken from the fire and put into a dark place. The conſtant acceſſion, then, either of light or heat is not neceſſary for the ſhining of bodies: but if a red hot body be blown upon by a ſtrong current of air, it ceaſes to ſhine immediately ‡. Conſequently the moment the temperature of a body is diminiſhed by a certain number of degrees, it ceaſes to be luminous.

Whenever a body reaches the proper temperature, it becomes luminous, independent of any contact of air; for a piece of iron wire becomes red hot while immerſed in melted lead §.

327
Except the gaſes.

To this general law there is one remarkable exception. It does not appear that the gaſes become luminous even at a much higher temperature. The following ingenious experiment of Mr T. Wedgewood ſeems to ſet the truth of this exception in a very clear point of view. He took an earthen ware tube B (fig. 5.), bent ſo in the middle that it could be ſunk, and make ſeveral turns in the large crucible C, which was filled with ſand. To one end of this tube was fixed the pair of bellows A; at the other end was the globular veſſel D, in which was the paſſage F, furniſhed with a valve to allow air to paſs out, but none to enter. There was another opening in this globular veſſel filled with glaſs, that one might ſee what was going on within. The crucible was put into a fire; and after the ſand had become red hot, the air was blown through the earthen tube by means of the bellows. This air, after paſſing through the red hot ſand, came into the globular veſſel. It did not ſhine; but when a piece of gold wire E was hung at that part of the veſſel where the earthen ware tube entered, it became faintly luminous. A proof, that though the air was not luminous, it had been hot enough to raiſe other bodies to the ſhining temperature.

328
Inquiry into the cauſe of theſe phenomena.

6. Thus it appears that light and heat reciprocally produce each other; that the fixation of light in bodies always produces heat, and that the application of a ſufficiently ſtrong heat always occaſions the extrication of light. Are heat and light, then, owing to the ſame cauſe? Does light become caloric merely by being fixed in bodies? and does caloric aſſume the appearance of light whenever it is extricated from them? In ſhort, are caloric and light merely names for the ſame ſubſtance, called *caloric* when it is fixed in bodies, and *light* when in a ſtate of liberty?

To theſe queſtions it may be anſwered, That if caloric and light were one and the ſame ſubſtance, they ought to produce preciſely the ſame effects. Now this is not the caſe: a black body is not heated ſooner by mere caloric than any other, though the contrary takes place when both are expoſed to the light *. Heat cannot make growing vegetables exhale oxygen gas, though light does it almoſt inſtantaneouſly. When oxy-muriatic acid (a compound of oxygen and muriatic acid) is expoſed to the light, a quantity of oxygen gas flies off, and nothing remains but common muriatic acid. Light then decompoſes this acid; for if you wrap up a bottle in black cloth, ſo as to exclude light, and then expoſe it equally to the ſun, no ſuch decompoſition takes place. Now this decompoſition cannot be produced by mere caloric. If the acid be heated, it ſimply evaporates without being altered. Chaptal has proved (P), that the rays of light directed on certain parts of glaſſes, containing ſolutions of ſalts, cauſe them to cryſtallize in that part in preference to any other †. Theſe obſervations have been confirmed and extended by Mr Dorthes ‡. Now caloric produces no ſuch effects, nor has the temperature any influence on the phenomenon.

Theſe facts are ſufficient to ſhew that light and caloric, even when they have entered into bodies, produce different effects, and that therefore they have different properties (Q). But if the only difference between them were, that the one is in a ſtate of liberty, the other in that of combination, the moment light entered a body it ought to be no longer light but caloric, and conſequently ought to produce preciſely the ſame effects with caloric: And ſince this is not the caſe, we are warranted ſurely to conclude that light and caloric are not the ſame, but

(P) Petit made the ſame obſervations in 1722. See *Memoirs of the Academy of Sciences* for that year, p. 95. and 331.

(Q) We muſt acknowledge, however, that the following ingenious experiments of Profeſſor Pictet might be adduced, to prove that light and caloric poſſeſs at leaſt *one* property in common, that of moving in ſtraight lines.

He placed two concave mirrors of tin, of nine inches focus, at the diſtance of twelve feet two inches from one another. In the focus of one of them he placed a ball of iron two inches in diameter, heated ſo as not to be viſible but different ſubſtances (R). How then does caloric occaſion the appearance of light, and light that of caloric?

349
Suppoſed owing to the mutual repulſion of light and caloric.

We have ſeen already, that there is no body in nature which does not contain caloric; and light has ſuch an influence upon every thing, it produces ſuch important changes upon the animal and vegetable kingdoms, it can be extricated from ſuch a vaſt number of bodies, that in all probability we may conclude with regard to it alſo, that it exiſts in all, or in almoſt all, the bodies in nature. We have no means of aſcertaining either the quantity of light or of caloric that exiſts in bodies; but if we were to judge from the quantity which appears during combuſtion, we muſt reckon it very conſiderable. Now, may there not exiſt a repulſion between the particles of caloric and light? It is not eaſy, at leaſt, to ſee why light flies off during combuſtion with ſuch rapidity, if this be not the caſe. If ſuch a repulſion actually exiſts, it will follow that caloric and light cannot be accumulated in the ſame body beyond a certain proportion. If the caloric exceed, it will tend to drive off the light; if the light, on the contrary, happens to prevail, it will diſplace the caloric.

If caloric and light actually exiſt in all bodies, there muſt be an affinity between them and all other bodies; and this affinity muſt be ſo great, as to render ineffectual the repulſion which exiſts between light and caloric. Let us ſuppoſe now, that theſe two ſubſtances exiſt in all bodies in certain proportions, it will follow, that the more either of caloric or light is added to any body, the ſtronger muſt the repulſion between their particles become; and if the accumulation be ſtill going on, this repulſion will ſoon become great enough to balance their affinity for the body in which they exiſt, and conſequently will diſpoſe them to fly off. If caloric, for inſtance, be added to a body, whenever the body arrives at a certain temperature it becomes luminous, becauſe part of the light which was formerly combined with it is driven off. This temperature muſt depend partly upon the affinity between the body and caloric, and partly upon its affinity for light. Pyrophori, for inſtance, the affinity between which and light does not ſeem to be very great, become luminous at a very moderate temperature. This is the caſe with the pyrophorus of Canton. A great many hard bodies become luminous when they are expoſed to a moderate heat; fluor, for inſtance, carbonat of barytes, ſpar, ſea-ſhells, and a great many others, which are enumerated by Mr Thomas Wedgwood *.

The ſame ingenious gentleman has obſerved, that gold, ſilver, copper, and iron, become luminous when heated in times inverſely proportional to their ſpecific calorics †. Now the ſpecific calorics of theſe metals are in the following order:

Iron,
Copper,
Silver,
Gold.

They

* *Phil. Tranſ.* 1792, p. i.

† *Ibid.*

---

viſible in the dark; in the other was placed the bulb of a thermometer. In ſix minutes the thermometer roſe from 4° to 14° (*Reaumur*). A lighted candle, which was ſubſtituted for the ball of iron, made the thermometer riſe in one experiment from 4,6° to 14°; in another, from 4,2° to 14,3°. In this caſe both light and heat appeared to act. In order to ſeparate them, he interpoſed between the two mirrors a plate of clear glaſs. Before the interpoſition of the glaſs, the thermometer had riſen from 2° to 12°, where it was ſtationary. After the interpoſition of the glaſs it ſunk in nine minutes to 5,7°; and when the glaſs was again removed it roſe in ſeven minutes to 11,1°; yet the light which fell on the thermometer did not ſeem at all diminiſhed by the glaſs. Mr Pictet therefore concluded, that the caloric had been *reflected* by the mirror, and that it had been the cauſe of the riſe of the thermometer. In another experiment, a glaſs matraſs was ſubſtituted for the iron ball, nearly of the ſame diameter with it, and containing 2044 grains of boiling water. Two minutes after a thick ſcreen of ſilk, which had been interpoſed between the two mirrors, was removed, a Fahrenheit's thermometer, which was in the other focus, roſe from 47° to $50\frac{1}{8}$; and the moment the matraſs was removed from the focus the thermometer again deſcended. On repeating the experiment, with this variation, that the bulb of the thermometer was blackened, it roſe from $51\frac{1}{8}$ to $55\frac{1}{3}$.

The mirrors of tin were now placed at the diſtance of 90 inches from each other; the matraſs with the boiling water in one of the foci, and a very ſenſible air thermometer in the other, every degree of which was equal to $\frac{1}{20}$th of a degree of Reaumur. Exactly in the middle ſpace between the two mirrors, there was placed a very thin common glaſs mirror, ſuſpended in ſuch a manner that either ſide could be turned towards the matraſs. When the poliſhed ſide of this mirror was turned to the matraſs, the thermometer roſe only 0,5°; but when the ſide covered with tinfoil, and which had been blackened with ink and ſmoke, was turned toward the matraſs, the thermometer roſe 3,5°. In another experiment, when the poliſhed ſide of the mirror was turned to the matraſs the thermometer roſe 3°, when the other ſide 9,2°. On rubbing off the tinfoil, and repeating the experiment, the thermometer roſe 18°. On ſubſtituting for the glaſs mirror a piece of thin white paſteboard of the ſame dimenſions with it, the thermometer roſe 10°. On putting a matraſs full of ſnow into one of the foci (the mirrors in this experiment were $10\frac{1}{2}$ feet diſtant from each other), the air thermometer *ſunk* ſeveral degrees, and roſe again when the matraſs was removed. When nitric acid was poured on the ſnow, the thermometer ſunk 5° or 6° lower.

Taking it for granted that theſe experiments proved the motion of caloric in ſtraight lines like light, Mr Pictet endeavoured to diſcover the velocity of its motion. For this purpoſe he placed two concave mirrors at the diſtance of 69 feet from each other; the one of tin as before, the other of plaſter gilt, and 18 inches in diameter. Into the focus of this laſt mirror he put the air thermometer, and the bullet of iron heated as before into that of the other. A few inches from the face of the tin mirror there was placed a thick ſcreen, which was removed as ſoon as the bullet reached the focus. The thermometer roſe the inſtant the ſcreen was removed, without any perceptible interval: hence he concluded, that the time caloric takes in moving 69 feet is too ſhort to be meaſured. See *Pictet ſur le Feu*, chap. iii.

(R) See more on this ſubject under *Thermometric Spectrum* in this *Supplement*.

They become luminous, therefore, when expoſed to the ſame degree of heat, in the following order:

Gold,
Silver,
Copper,
Iron.

Now the ſmaller the ſpecific caloric of any body is, the leſs muſt be the quantity of caloric neceſſary to raiſe it a given number of degrees; the ſooner therefore muſt it arrive at the temperature at which it gives out light. It was natural to expect, then, if the emiſſion of light from a body by the application of heat be owing to the repulſion between caloric and light, that thoſe bodies ſhould become luminous ſooneſt in which that repulſion increaſes with the greateſt rapidity; and this we ſee is preciſely the caſe. The only queſtion to be determined before drawing this concluſion is, Whether the ſame quantity of caloric entered all of them? That depends upon their conducting power, which, according to Ingenhouſz, is in the following order:

Silver,
Gold,
Copper,
Iron.

We ſee, then, that this conducting power is nearly in the order in which theſe metals become luminous; ſo that the greateſt quantity of caloric would enter thoſe which become ſooneſt luminous. Now this is juſt what ought to happen, provided the expulſion of light from a luminous body, by the application of heat, be owing to the repulſion between the particles of caloric and light.

The repulſion between the different rays of light and caloric does not ſeem to be equal; the repulſion between the blue rays and caloric ſeems to be greater than that between the red rays and caloric; and the repulſion between all the rays and caloric ſeems to be directly as their refrangibility: accordingly, when heat is applied to a body, the blue rays eſcape ſooner, and at a lower temperature, than the red rays and others which are moſt refrangible. When ſulphur, for inſtance, is burnt at a low temperature, the colour of the flame is blue; and when examined by the priſm, it is found to conſiſt of the violet, indigo, blue, and ſometimes of a ſmall quantity of the green rays*; but when this ſubſtance is burnt at a high temperature, the colour of the flame is white, all the rays ſeparating together. When bodies have continued to burn for ſome time, they may be ſuppoſed to have loſt the greater part of the moſt refrangible rays; hence the red appearance of bodies, charcoal for inſtance, that have burnt for ſome time, the only rays which remain to ſeparate being the orange, yellow, and red†.

The blue rays ſeem not only to repel caloric with greater force, but likewiſe to have a greater affinity for other bodies than the red rays have; for they decompoſe the oxide of ſilver (or rather the muriat of ſilver) much ſooner, and to a greater extent, than the red rays‡: hence we ſee the reaſon why the application of the blue rays to Mr Wilſon's pyrophori and to the diamond cauſes an extrication of red rays.

We have ſeen already, that the gaſes are not heated red hot by the application of heat. It would follow from this, that the gaſes do not contain light: but the contrary is certain; for light is actually extricated during the combuſtion of hydrogen, and muſt therefore have exiſted either in the oxygen or hydrogen gas, or in both. Probably therefore the reaſon that heat does not extricate light from the gaſes is, that the affinity between their baſes and light is exceedingly ſtrong: it would therefore require a more than uſual temperature to produce its extrication; and on account of the great dilatability of theſe gaſes, which always tends to diminiſh the repulſion between the caloric and light, this temperature cannot be applied. It is eaſy to ſee, upon the ſuppoſition that there exiſts a repulſion between caloric and light, why the accumulation of light ſhould produce heat, and why light only occaſions heat in thoſe bodies that abſorb it.

Such is the theory of the cauſe of the reciprocal extrication of light and caloric by the application of theſe ſubſtances reſpectively to bodies, which has been propoſed by ſeveral ingenious chemiſts (s); and we acknowledge frankly, that it appears to us by far the moſt plauſible of all the explanations of this phenomenon with which we are acquainted.

330
Objections to which this theory is liable.

It is not, however, beyond the reach of objections, and objections too, we are afraid, altogether incompatible with its truth. Were the repulſion between caloric and light the only cauſe of the luminouſneſs of hot bodies, the continual application of heat would ſurely in time ſeparate the whole of the light which was combined with the body, and then it would ceaſe to be luminous altogether; but we have no reaſon to ſuppoſe that bodies ever ceaſe to become luminous by the continued application of heat. Claveus kept melted, and conſequently red hot, gold for months in a furnace; but he does not ſay that its luminouſneſs was diminiſhed, far leſs deſtroyed; and had ſuch a remarkable phenomenon taken place, certainly he would not have failed to inform us; but ſo far from that, he expreſsly ſays that it ſuffered no alteration (T) §.

Whether light would continue to extricate a great deal of caloric during ſo long a time, has never been tried: but we have no reaſon for ſuppoſing that its power to produce that effect is ever exhauſted; for bodies, after being expoſed to the ſun for years, and even for ages, are juſt as much heated by it as ever. But theſe effects, far from being inexhauſtible, ought, according to the theory, to come very ſpeedily to an end. It is certainly probable, then, as other philoſophers have ſuppoſed, that though light and caloric are not preciſely one and the ſame ſubſtance, they are ſome how or other intimately connected, and are either compoſed of different proportions of the ſame ingredients, or the one enters into the compoſition of the other.

* *Morgan, Phil. Tranſ.* 1785.

† *Ibid.*

‡ *Sennebier.*

§ *Shaw's Boyle*, iii. 268.

(s) Particularly by Dr Parr, who is ſaid to be the author of a paper on this ſubject, publiſhed in the *Exeter Memoirs*.

(T) A gentleman, to whom we mentioned this objection, obſerved, that in the caſe of bodies long expoſed to heat, the light which appears to proceed from them, might, in fact, be extricated from the atmoſphere by the caloric communicated to it from the heated body. This thought is new and ingenious, and might eaſily be put to the teſt of experiment. Some of the facts mentioned in the text are rather hoſtile to it; but ſhould it prove well founded, it would go far to remove moſt of the difficulties in which the theory of light is at preſent involved.

331 Scheele's theory of light and caloric.

One of the firſt theories of this kind (for the opinion of Stahl has been already diſcuſſed) was formed by Mr Scheele*, one of the moſt extraordinary men and greateſt philoſophers that ever exiſted. Without the aſſiſtance of education or of wealth, his genius burſt forth with aſtoniſhing luſtre; and at an age when moſt philoſophers are only riſing into notice, he had finiſhed a career of diſcoveries which have no parallel in the annals of chemiſtry. Whoever wiſhes to behold ingenuity combined with ſimplicity, whoever wiſhes to ſee the inexhauſtible reſources of chemical analyſis, whoever wiſhes for a model in chemical reſearches—has only to peruſe and to ſtudy the works of Scheele (T). After a vaſt number of experiments, conducted with aſtoniſhing ingenuity, he concluded, that caloric was compoſed of a certain quantity of oxygen combined with phlogiſton; that radiant heat, a ſubſtance which he ſuppoſed capable of being propagated in ſtraight lines like light, and not capable of combining with air, was compoſed of oxygen united with a greater quantity of phlogiſton, and light of oxygen united with a ſtill greater quantity. He ſuppoſed, too, that the difference between the rays depended upon the quantity of phlogiſton: the red, according to him, contained the leaſt; the violet, the moſt phlogiſton. By *phlogiſton* Mr Scheele ſeems to have meant *hydrogen*. It is needleſs therefore to examine his theory, as it is now known that the combination of hydrogen and oxygen forms not caloric but water (U). The whole fabric therefore has tumbled to the ground; but the importance of the materials will always be admired, and the ruins of the ſtructure ſhall remain eternal monuments of the genius of the builder.

* In his *Treatiſe on Fire.*

332 De Luc's theory.

Mr de Luc, ſo well known for his important meteorolgical labours, has advanced another theory†. According to him, light is a body which moves conſtantly in ſtraight lines, with ſuch rapidity that its gravitation towards other ſubſtances bears no ſenſible proportion to its motion. Light has the property of combining with another unknown ſubſtance, and the compound formed is caloric, which poſſeſſes very different properties from light. Caloric is conſtantly deſcribing helicoidal curves round an axis, which accounts for the ſlowneſs of its apparent motion. Light produces or increaſes heat, partly by increaſing the expanſive power of caloric, and partly by combining with the *unknown ſubſtance*, and forming new caloric; caloric, on the other hand, is always decompoſed when bodies become luminous. This theory is certainly ingenious, and would remove many of the difficulties which we at preſent labour under in attempting to explain the phenomena of caloric and light. It is, however, liable to other difficulties which could not be eaſily ſurmounted. But it is needleſs to examine theſe, as the theory itſelf is ſupported by no evidence whatever, and cannot therefore be admitted.

† In his *Idées ſur la Meteorologie.*

333 Hutton's theory.

Another theory has been advanced by the late Dr Hutton of Edinburgh (V); a man of undoubted genius, but of rather too ſpeculative a turn of mind, and who ſometimes involved himſelf in difficulties from his very ingenuity. All his writings diſplay evident marks of the profound philoſopher: they contain much inſtruction; and even his miſtakes are not without their uſe: but unfortunately his manner is ſo peculiar, that it is ſcarcely more difficult to procure the ſecrets of ſcience from Nature herſelf, than to dig them from the writings of this philoſopher. He ſuppoſes that there are two kinds of matter, gravitating matter and light; the laſt of which wants gravity, and conſequently neither poſſeſſes magnitude (W) nor momentum. Light has the power of being fixed in bodies; and then it becomes either caloric or phlogiſton, which differs in ſome particulars from caloric, but in what, the Doctor does not preciſely tell us.

Part of this theory we have examined already when we attempted to prove that light and caloric were different ſubſtances. The other part of the theory ſeems to involve a contradiction; for how could light become fixed in a body, unleſs it were attracted by it? and if light poſſeſſes attraction, it ſurely cannot be deſtitute of gravity; for what is gravity but *attraction* (X)?

THUS, notwithſtanding the ingenuity of the philoſophers who have attempted to inveſtigate this part of chemiſtry, the connection between light and caloric is ſtill unknown. We muſt content ourſelves, therefore, with conſidering them at preſent as diſtinct ſubſtances, and leave the ſolution of the many difficulties which at preſent perplex us to the more happy labours of future inquirers.

PART

(T) This Newton of chemiſtry died in 1786, at the age of 44. His moral character, according to Mr Erhart and others, who were the companions of his youth, and Meſſrs Gadolin, Eſpling, and thoſe who knew him in his latter days, was irreproachable and praiſe worthy. His outward appearance was not expreſſive of the great mind which lay concealed as it were under a veil. He ſeldom joined in the uſual converſations and amuſements of ſociety, having as little leiſure as inclination to do ſo; for what little time he had to ſpare from the hurry of his profeſſion (an apothecary), was conſtantly filled up in the proſecution of experiments. It was only when he received viſits from his friends, with whom he could converſe upon his favourite ſcience, that he indulged himſelf in a little relaxation. For ſuch friends he had a ſincere affection, as he had alſo for thoſe that lived at a diſtance, and even for ſuch as were not perſonally known to him. He kept up a regular correſpondence with Meſſrs Erhart, Meyer, Kirwan, Crell, and ſeveral other chemiſts. See *Crell's Life of Scheele.*

(U) This candid philoſopher afterwards acknowledged, that the proofs for the compoſition of water were complete: but we do not know exactly how he attempted to reconcile his theory of heat with the belief that water was compoſed of oxygen and hydrogen; two opinions which are certainly incompatible.

(V) See his diſſertations on different ſubjects of natural philoſophy.

(W) Indeed Dr Hutton refuſed this property to gravitating matter alſo; following, in this particular, the theory of the celebrated Boſcovich.

(X) We hope not to be accuſed of diſputing merely about the meaning of a word, till what is ſaid on this ſubject in the chapter of the preſent article, which treats of *Affinity*, has been examined.

PART II. OF COMPOUND BODIES.

Water.

TO thoſe bodies which are compoſed of *two ſimple ſubſtances* combined together, for want of a better name we have given the appellation of *compound bodies.* They may be reduced under five claſſes:

1. Water,
2. Alcohol,
3. Oils,
4. Alkalies,
5. Acids.

Theſe ſhall be the ſubject of the five following chapters; and we ſhall finiſh this part of the article with ſome obſervations on *Affinity*.

CHAP. I. *Of* WATER.

WATER is a well-known liquid, found in abundance in every part of the world, and abſolutely neceſſary for the exiſtence of animals and vegetables.

When pure, in which ſtate it can be obtained only by diſtillation, it is tranſparent, and deſtitute of colour, taſte, and ſmell.

334 Weight of water. A cubic foot of water, at the temperature of 55°, weighs, according to the experiments of Profeſſor Robiſon of Edinburgh (ſee SPECIFIC *Gravity*, Encycl.), 998,74 avoirdupois ounces, of 437,5 grains troy each, or only 1,26 ounces leſs than 1000 avoirdupois ounces; ſo that rain water, at the ſame temperature, will weigh pretty nearly 1000 ounces. The ſpecific gravity of water is always ſuppoſed = 1,000, and it is made the meaſure of the ſpecific gravity of every other body.

335 Ice. When water is cooled down to 32°, it aſſumes the form of ice. If this proceſs goes on very ſlowly, the ice aſſumes the form of cryſtalline needles, croſſing each other at angles either of 60° or 120°, as Mr de Mairan has remarked; and it has been often obſerved in large cryſtals of determinate figures. Ice, while kept at a temperature conſiderably below 32°, is very hard, and may be pounded into the fineſt duſt. It is elaſtic. Its ſpecific gravity is leſs than that of water.

336 Steam. When water is heated to the temperature of 212°, it boils, and is gradually converted into ſteam. Steam is an inviſible fluid like air, but of a leſs ſpecific gravity. It occupies about 1200 times the ſpace that water does. Its elaſticity is ſo great, that it produces the moſt violent exploſions when confined. It is upon this principle that the ſteam-engine has been conſtructed. See STEAM and *STEAM-Engine*, Encycl.

337 Boiling point of water. The phenomena of boiling are owing entirely to the rapid formation of ſteam at the bottom of the veſſel. The boiling point of water varies according to the preſſure of the atmoſphere. In a vacuum water boils at 90°; and when water is confined in Papin's digeſter, it may be almoſt heated red hot without boiling. The

338 Impregnated with various ſalts. mixture of various ſalts with water affect its boiling point conſiderably.. Mr Achard made a number of experiments on that ſubject . the reſult of which may be ſeen in the following Tables *:

CLASS I. *Salts which do not affect the Boiling Point.*

Sulphat of copper.

CLASS II. *Salts which raiſe the Boiling Point.*

A ſaturated ſolution of	Muriat of ſoda	Raiſes the boiling point	10,35°
	Sulphat of ſoda		5,6
	Sulphat of potaſs		0,9
A ſaturated ſolution of	Nitrat of potaſs	Raiſes the boiling point	3,5°
	Boracic acid		2,2
	Carbonat of ſoda		2,35

This augmentation varies with the quantity of ſalt diſſolved. In general, it is the greater the nearer the ſolution approaches to ſaturation.

CLASS III. *Salts which lower the Boiling Point.*

Borax,	In a ſmall quantity, lowers the boiling point - - - -	1,350°
	Saturated ſolution of, - -	0,22
Sulphat of magneſia,	In a ſmall quantity,	2,47
	Saturated ſolution of	1,1
Alum,	A very ſmall quantity of, - -	0,0
	A greater quantity, - -	0,7
	A ſaturated ſolution of, - -	0,0
Sulphat of lime,	in any proportion,	2,02
Sulphat of zinc,		0,45
Sulphat of iron,		0,22
Acetite of lead,		1,24

CLASS IV.

Muriat of ammonia,	Small quantity of, lowers the boiling point - - -	0,45
	Saturated ſolution of, raiſes do.	9,79
Carbonat of potaſs,	Small quantity of, lowers do.	0,45
	Saturated ſolution of, raiſes do.	11,2

339 Water compreſſible. Water was once ſuppoſed to be incompreſſible, but the contrary has been demonſtrated by Mr Canton. The Abbé Mongez made a number of experiments, long after that philoſopher, on the ſame ſubject, and obtained ſimilar reſults.

340 Opinion about its nature. Water was believed by the ancients to be one of the four elements of which every other body is compoſed; and, according to Hippocrates, it was the ſubſtance which nouriſhes and ſupports plants and animals. That water was an unchangeable element continued to be believed till the time of Van Helmont, who made plants grow for a long time in pure water: From which experiment it was concluded, that water was convertible into all the ſubſtances found in vegetables.—Mr Boyle having digeſted pure water in a glaſs veſſel hermetically ſealed for above a year, obtained a quantity of earthy ſcales; and concluded, in conſequence, that he had converted it partly into an earth *. He obtained the ſame earth by diſtilling water in a tall glaſs veſſel over a ſlow fire †. Margraf repeated the experiment with the ſame reſult, and accordingly drew the ſame concluſion. But the opinion of theſe philoſophers was never very generally received. The laſt perſon who embraced it was probably Mr Waſelton, who publiſhed his experiments on the ſubject in the *Journal de Phyſique* for 1780. Mr Lavoiſier had proved, as early as 1773, that the glaſs veſſels in which the diſtillation was performed loſt a weight exactly equal to the earth obtained. Hence it follows irreſiſtibly, that the appearance of the earth, which was ſilica, proceeded from the decompoſition of the veſſels; for glaſs contains a large proportion of ſilica. It has been ſince ſhewn by Dr Prieſtley, that water always decompoſes glaſs when applied to its ſurface for a long time in a high temperature.

We have formerly mentioned, that water is compoſed of oxygen and hydrogen. This great diſcovery has con-

---

* *Tranſ. Berlin*, 1785.

* *Shaw's Boyle*, iii. 417.

† *Ibid.* i. 267.

contributed more perhaps than any other to the advancement of the ſcience of chemiſtry, by furniſhing a key for the explanation of a prodigious number of phenomena. The evidence, therefore, on which it reſts, and the objections which have been made to it, deſerve to be examined with peculiar attention.

341
Hiſtory of the diſcovery of its compoſition.

The firſt perſon probably who attempted to diſcover what was produced by burning hydrogen gas was Scheele. He concluded, that during the combuſtion oxygen and hydrogen combined, and that the product was caloric.

In 1776 Macquer, aſſiſted by Sigaud de la Fond, ſet fire to a bottle full of hydrogen gas, and placed a ſaucer above the flame, in order to ſee whether any fuliginous ſmoke would be produced. The ſaucer remained perfectly clean; but it was moiſtened with drops of a clear liquid, which they found to be pure water *.

Next year Bucquet and Lavoiſier exploded oxygen and hydrogen gas, and made an attempt to diſcover what was the product; about the nature of which they had formed different conjectures. Bucquet had ſuppoſed that it would be carbonic acid gas; Lavoiſier, on the contrary, ſuſpected that it would be ſulphuric or ſulphurous acid. What the product was they did not diſcover; but they proved that no carbonic acid gas was formed, and conſequently that Mr Bucquet's hypotheſis was ill founded †.

In the beginning of the year 1781, Mr Warltire, at the requeſt of Dr Prieſtley, fired a mixture of theſe two gaſes contained in a copper veſſel; and obſerved, that after the experiment the weight of the whole was diminiſhed. Dr Prieſtley had previouſly, in the preſence of Mr Warltire, performed the ſame experiment in a glaſs veſſel. This veſſel became moiſt in the inſide, and was covered with a ſooty ſubſtance ‡, which Dr Prieſtley afterwards ſuppoſed to be a part of the mercury uſed in filling the veſſel §.

In the ſummer of 1781, Mr Henry Cavendiſh, who had been informed of the experiments of Prieſtley and Warltire, ſet fire to 500,000 grain meaſures of hydrogen gas, mixed with about 2½ times that quantity of common air. By this proceſs he obtained 135 grains of pure water. He alſo exploded 19,500 grain meaſures of oxygen gas with 37,000 of hydrogen gas, and obtained 30 grains of water, containing in it a little nitric acid. From theſe experiments he concluded that water was a compound.—Mr Cavendiſh muſt therefore be conſidered as the real diſcoverer of the compoſition of water. He was the firſt who aſcertained that water was produced by firing oxygen and hydrogen gas, and the firſt that drew the proper concluſion from that fact. Mr Watt, indeed, had alſo drawn the proper concluſion from the experiments of Dr Prieſtley and Mr Warltire, and had even performed a number of experiments himſelf to aſcertain the fact, before Mr Cavendiſh had communicated his; but he had been deterred from publiſhing his theory by ſome experiments of Dr Prieſtley, which appeared contrary to it ||. He has therefore a claim to the merit of the diſcovery; a claim, however, which does not affect Mr Cavendiſh, who knew nothing of the theory and experiments of that ingenious philoſopher.

Meanwhile, in the winter 1781-2, Mr Lavoiſier, who had ſuſpected that when oxygen and hydrogen gas were exploded, ſulphuric or ſulphurous acid was produced, made an experiment in order to aſcertain the fact, at which Mr Gingembre aſſiſted. They filled a bottle, capable of holding ſix pints (French), with hydrogen gas, to which they ſet fire, and then corked the bottle, after pouring into it 2 oz. (French) of lime-water. Through the cork there paſſed a copper tube, by means of which a ſtream of oxygen gas was introduced to ſupport the flame. Though this experiment was repeated three times, and inſtead of lime-water a weak ſolution of alkali and pure water were ſubſtituted, they could not obſerve any product whatever *. This reſult aſtoniſhed Mr Lavoiſier exceedingly: he reſolved, therefore, to repeat the experiment on a larger ſcale, and if poſſible with more accuracy. By means of pipes furniſhed with ſtop-cocks, he put it in his power to ſupply both gaſes as they ſhould be wanted, that he might be enabled to continue the burning as long as he thought proper.

The experiment was made by Lavoiſier and La Place on the 24th of June 1783, in the preſence of Meſſrs Le Roi, Vandermonde, ſeveral other academicians, and Sir Charles Blagden, who informed them that Mr Cavendiſh had already performed it, and that he had obtained water †. They continued the inflammation till all their ſtock of gaſes was waſted, and obtained about 295 grains of water, which, after the moſt rigid examination, appeared to be perfectly pure. From this experiment Lavoiſier concluded, that water was compoſed of oxygen and hydrogen. Mr Mongé ſoon after performed the ſame experiment, and obtained a ſimilar reſult: and it was ſoon after repeated again by Lavoiſier and Meuſnier on a ſcale ſufficiently large to put the fact beyond doubt ‡.

342
Proofs of the compoſition of water.

The proofs that water is a compound are of two kinds; it has been actually compoſed, and it has been decompoſed.

343
Experiment of Lavoiſier and Meuſnier.

With regard to the compoſition of water, we ſhall relate the celebrated experiment made by Lavoiſier and Meuſnier in the month of February 1785, in the preſence of a numerous deputation from the academy of ſciences, and ſo many other ſpectators, that it may he conſidered as having been performed in public. Every precaution was taken to enſure ſucceſs. The gaſes had been prepared with care, and held for ſome time over a ſolution of potaſs, in order to deprive them of any acidity which they might accidentally contain; and before entering into the glaſs globe where they were to be burnt, they were made to paſs over newly calcined potaſs, to deprive them of the water which they might happen to retain in ſolution. The hydrogen gas had been obtained by paſſing ſteam through iron at a white heat; the oxygen gas was procured from the red oxide of mercury. The combuſtion took place in a large glaſs globe, into which the gaſes were admitted by means of tubes furniſhed with ſtop-cocks; and the moſt ingenious contrivances were employed to aſcertain exactly the quantities of each which were conſumed (y). The whole machine is deſcribed at large by Mr Meuſnier in the Memoirs of the Academy of Sciences for 1782.

* *Macquer's Dictionary*, art. *Gas, inflammable.*

† *Mem. Par.* 1781, 470.

‡ *Prieſtley*, v. 395.

§ *Phil. Tranſ.* lxxiv. 332.

|| *Ibid.* lxxv. 130.

* *Mem. Par.* 1781, p. 470.

† *Ibid.* p. 472.

‡ *Ibid.* p. 474.

(y) A variety of inſtruments have been invented by the French chemiſts for that purpoſe. Theſe inſtruments they have denominated *Gazometers*.

The quantities of gas employed, after deducting the 432 grains of reſiduum which were not conſumed, were 2794,76 grains of oxygen gas, and 471,125 of hydrogen gas. After taking from theſe 32,25 grains, = the humidity of which the oxygen gas was deprived by the calcined potaſs, and 44,25 grains, = the weight which the hydrogen loſt by the ſame proceſs, there remains altogether 3188,4 grains of gas.

The quantity of water obtained amounted to 3219 grains; the ſpecific gravity of which was to diſtilled water as 1,0051 to 1. This quantity was 30 grains more than the gas employed. The difference, no doubt, was owing to a ſmall error in eſtimating the weight of the gaſes; which indeed it is extremely difficult to avoid, as the weight is altered by the ſmalleſt difference of temperature. This water had a ſlight ſmell, and a taſte ſenſibly acid; it reddened ſlightly blue paper, and efferveſced with the carbonat of potaſs. 1152 grains of that water being ſaturated with potaſs, and evaporated to dryneſs, left 20 grains of a ſalt which melted on the fire like nitre. It follows from this experiment, that the quantity of acid contained in the whole water would not have been quite ſufficient to have formed 56 grains of nitre.

The reſiduum weighed, as has been already obſerved, 432 grains; its volume was equal to 444 grains of oxygen gas; it was diminiſhed by nitrous gas (z) preciſely as gas would be which contained 0,24 parts of oxygen: it rendered lime-water ſomewhat turbid, which indicated the preſence of carbonic acid gas.

From the compariſon of the weights, and volumes of the gaſes conſumed, it was concluded that water conſiſts of 0,85 parts, by weight, of oxygen, and 0,15 of hydrogen.

344 Experiment of Le Fevre de Gineau.

This experiment was ſoon after repeated by Mr Le Fevre de Gineau upon a ſtill larger ſcale, and in the preſence of a great number of ſpectators. It continued for no leſs than 12 days, and was performed with the moſt rigorous exactneſs of which experiments of that nature will admit *.

The oxygen gas employed, which had been procured from the black oxide of mangaueſe, occupied the ſpace of 35085,1 cubic inches, and weighed 18298,5 grains.

The hydrogen gas was obtained by diſſolving iron in diluted ſulphuric acid. Its volume was 7496,7 cubic inches, and its weight 4756,3 grains.

	Grains.
The two gaſes therefore amounted to -	23054,8
From which taking the reſiduum after combuſtion, which amounted to - -	2831,0
There remains for the quantity conſumed	20223,8
The water found in the glaſs globe after the combuſtion amounted to - - -	20139,0
And there were carried off by the reſiduum	54,0
In all - -	20193,0

Which is juſt 30 grains leſs than the weight of the gaſes which diſappeared, or $\frac{1}{657}$ part of their weight. This difference aroſe from the ſame difficulties which attended the experiment of Lavoiſier. As the errors are on different ſides, we are warranted to conclude that this was the caſe, and that it was not owing to any real difference between the gaſes and the product.

The water was examined in the preſence of Meſſrs Lavoiſier, Le Roi, Mongé, Berthollet, Bayen, and Pelletier. Its ſpecific gravity was to that of diſtilled water as 1,001025 to 1. It contained no ſulphuric nor muriatic acids; yet it had an acid taſte, and converted vegetable blues to a red. 6606 grains of it required for ſaturation 36 grains of carbonat of potaſs, and furniſhed by evaporation 26,5 grains of cryſtals of nitre. The whole water, therefore, would have required 109,7 grains of carbonat of potaſs for ſaturation.

This water affected lime-water a little; and it was found that the reſiduum of the gas contained ſome carbonic acid gas. This reſiduum formed a 19th part of the volume of the two gaſes employed, and an eight of their weight. It contained 462 grains of carbonic acid gas, or about $\frac{1}{8}$th part; the reſt was azotic gas, with about $\frac{1}{12}$th of oxygen.

This experiment gave the proportions of oxygen and hydrogen in water as follows:

Oxygen - - -	,848
Hydrogen - -	,152
	1,000

This is ſo near the determination of Mr Lavoiſier, that it muſt be conſidered as a very ſtrong confirmation of it.

345 Experiment of Seguin, Fourcroy, and Vauquelin.

In the year 1790, another ſimilar experiment was performed by Seguin, Fourcroy, and Vauquelin, in the preſence of a number of commiſſioners appointed by the Academy of Sciences. Every precaution was taken to aſcertain the quantity of gas employed with the utmoſt exactneſs, and to exclude all atmoſpherical air as completely as poſſible.

The hydrogen gas was procured by diſſolving zinc in ſulphuric acid diluted with 7 parts of water. The oxygen gas was obtained by diſtilling oxy-muriat of potaſs (A).

The quantity of hydrogen gas employed amounted to 862,178 grains troy. The quantity of oxygen gas amounted to 13475,198 cubic inches (French). Its purity was ſuch, that it contained three cubic inches of azotic gas in the 100. The whole gas, therefore, contained 404,256 cubic inches. There were likewiſe in the glaſs veſſel in which the combuſtion took place 15 cubic inches (French) of atmoſpheric air, which conſiſted of 11 cubic inches of azotic and four of oxygen gas. So that the whole oxygen gas employed amounted to 13074,942 cubic inches; and it contained beſides 415,256 cubic inches of azotic gas. They aſcertained by experiment, that a cubic inch of this oxygen gas, thus diluted with $\frac{3}{100}$ of azot, weighed ,4040 of a grain troy. Now, according to the experiments of Lavoiſier, a cubic inch (French) of azotic gas weighs only ,3646 of a grain troy. Conſequently the weight of pure oxygen gas is greater than ,4040; and by calculation they ſhewed it to amount to ,4051 of a grain troy. The weight of the whole oxygen gas employed, therefore, was 5296,659 grains troy; and that of the azotic gas mixed with it 151,402 grains troy.

The

(z) This gas ſhall be afterwards deſcribed. It has the property of abſorbing almoſt inſtantaneouſly the oxygen gas with which it comes into contact. It is therefore often uſed, in order to diſcover how much oxygen gas exiſts in any mixture.

(A) A ſalt compoſed of oxy-muriatic acid and potaſs.

Water.

The combuſtion continued 185 hours; and during all that time our philoſophers never quitted the laboratory. The flame was exceedingly ſmall, and the heat produced by no means great. This was owing to the very ſmall ſtream of hydrogen, which was conſtantly flowing into the veſſel.

The water obtained amounted to 5943,798 grains troy, or 12 oz. 7 dwts. and 15,798 grains. It exhibited no mark of acidity, and appeared in every reſpect to be pure water. Its ſpecific gravity was to that of diſtilled water as 18671 to 18670; or nearly as 1,000053 to 1.

The reſiduum of gas in the veſſel after combuſtion amounted to 987 cubic inches (French); and on being examined, was found to conſiſt of the following quantities of gaſes :

Azotic gas, - - - - - -	467 cubic inches.
Carbonic acid gas, - - -	39
Oxygen gas, - - - - - -	465
Hydrogen gas, - - - -	16
Total - -	987

The weight of which is as follows :

Azotic gas, - - - - - - -	170,258 gr. troy.
Carbonic acid gas, - - - -	23,306
Oxygen gas, - - - - - - -	188,371
Hydrogen gas, - - - - -	0,530
Total, - -	382,465

Now the weight of the whole gaſes employed was, - - - - 6310,239 gr. troy.
That of the water obtained, and of the reſiduum, - - - - 6326,263

Or - - - - - - - - - 16,024 grains more than had been employed. This ſmall quantity muſt have been owing to common air remaining in the tubes, and other parts of the apparatus, in ſpite of all the precautions that were taken to prevent it ; if it did not rather proceed from unavoidable errors in their valuations.

	Gr. Troy
The quantity of azotic gas introduced was	151,178
The quantity found in the reſiduum was	170,258
There was therefore a ſurplus of - - -	19,080 gr.

As ſufficient precautions had been taken to prevent the introduction of carbonic acid gas, the quantity found in the reſiduum muſt have been formed during the proceſs. There muſt therefore have been a ſmall quantity of carbon introduced. Now zinc often contains carbon, and hydrogen has the property of diſſolving carbon : probably, then, the carbon was introduced in this manner. The carbonic acid found in the reſiduum amounted to 23,306 grains, which, according to Lavoiſier's calculation, is compoſed of 8,958 grains of carbon, and 14,348 grains of oxygen.

Subtracting theſe 8,958 grains of carbon, and the ,530 of a grain of hydrogen, which remained in the veſſel, from the total of hydrogen introduced, there will remain 852,690 grains for the hydrogen that diſappeared.

Subtracting the 14,348 grains of oxygen which entered into the compoſition of the carbonic acid, and the reſiduum of oxygen, which amounted to 188,371 grains, the quantity of oxygen that diſappeared will amount to 5093,940 grains.

Water.

Hydrogen that diſappeared, -	852,690 gr. troy.
Oxygen, - - - - - - - -	5093,940
- Total, - -	5946,630
Quantity of water obtained,	5943,798
Which is leſs than the gaſes conſumed by - - - - -	2,832 grains [*].

Such are the principal experiments upon which the opinion is founded that water is a compound. Let us examine them, and ſee whether they are ſufficient to eſtabliſh that opinion. The circumſtances which chiefly claim our attention, and which have been chiefly inſiſted on, are theſe :

346
Objections to the compoſition of water examined.

1. The whole of the gaſes was not conſumed.

2. In the reſiduum were found ſeveral ſubſtances which were not introduced, and which muſt therefore have been formed during the combuſtion.

3. The water obtained was ſeldom perfectly pure. It generally contained ſome nitric acid.

4. As only part of the gaſes were conſumed, and as all gaſes contain water in them, might not the gas which diſappeared have been employed in forming the other ſubſtances found in the reſiduum? and might not the water obtained have been merely what was formerly diſſolved in the gaſes, and which had been precipitated during the experiment?

That the whole of the gaſes was not conſumed will not ſurpriſe us, if we recollect that it is impoſſible for that to take place, allowing them to be perfectly pure, except they be mixed in preciſely the proper proportions ; and not even then, except every particle of them could be raiſed to the proper temperature. Now how can this be done in experiments of that nature ?

But how is it poſſible to procure a large quantity of gas completely pure ? And ſuppoſing it were poſſible, how can every particle of atmoſpheric air be excluded ? In the laſt experiment, notwithſtanding every precaution, 15 cubic inches (French) were admitted ; and there is reaſon to believe from the reſults, that the quantity was even conſiderably greater than this. But if any atmoſpheric air be admitted, there muſt be a reſiduum of azotic gas.

In the firſt experiment, it had been previouſly aſcertained that the oxygen gas employed contained $\frac{1}{12}$th of azotic, or about 233,05 grains ; and the reſiduum contained at moſt 329,1 grains, or 96,05 grains more than what had for certain pre-exiſted in the gaſes.

In the ſecond experiment, the azot in the reſiduum amounted at moſt to $\frac{1}{8}$th of the oxygen gas employed. But the oxygen was procured from the black oxide of manganeſe, which always yields a quantity of azot as well as of carbonic acid. It has been aſcertained, that the azot, mixed with oxygen gas procured in that manner, often exceeds $\frac{1}{8}$th.

In the third experiment, the azotic gas found in the reſiduum amounted to 170,258 grains; and the quantity contained in the gaſes before combuſtion amounted to 151,178 grains : the ſurplus, therefore, amounted to 19,08 grains.

Now, is it not much more probable that theſe inconſiderable quantities of azot, which in the laſt experiment amounted to no more than $\frac{1}{112}$ part by weight of the whole gas employed, pre-exiſted in the gaſes before the combuſtion began, though their extreme minuteneſs prevented them from being diſcovered, than that they were formed during the experiment : a ſup-

---

[*] Ann. de Chim. viii. 225.

poſition which is directly contradicted by a great number of well aſcertained facts.

As to the carbonic acid gas, which in the ſecond experiment amounted to $\frac{1}{49}$th of the gaſes employed, it was evidently derived from the manganeſe, which almoſt conſtantly contains it. And when carbonic acid is once mixed with oxygen, it is difficult to ſeparate it by means of lime-water, except a large quantity be uſed, as Mr Cavendiſh has well obſerved. The reaſon is, that oxygen gas has the property of diſſolving carbonic acid, as Mr Welter has remarked *. Mr le Fevre de Gineau aſcertained by experiment, that 1870 cubic inches of oxygen gas, which did not affect lime-water, loſt between $\frac{1}{18}$th and $\frac{1}{40}$th of its weight when waſhed in *milk of lime* (B).

* *Ann. de Chim.* iii. 91.

In a ſecond experiment, he previouſly waſhed the two gaſes in milk of lime, and the reſiduum after combuſtion contained *no* carbonic acid gas. In a third experiment he waſhed only the oxygen, and obtained products equally free from carbonic acid. It is certain, then, that the *carbonic acid* is but an accidental mixture. As to the carbonic acid of the third experiment above related, which amounted only to $\frac{1}{112}$ part of the gaſes employed, the ſource of it has been already pointed out.

As to the nitric acid, the quantity of nitre obtained in Mr Lavoiſier's experiment was 56 grains; which, according to Mr Kirwan's calculation, contain 30,156 grains of nitric acid; a quantity conſiderably leſs than $\frac{1}{100}$th part of the gaſes which diſappeared. In the ſecond experiment, the nitre obtained amounted to 80,7 grains; which, according to Kirwan, contain 43,456 grains of nitric acid, or leſs than $\frac{1}{459}$th part of the gaſes conſumed. Now, as nitric acid is compoſed of oxygen and azot, both of which were preſent in the veſſel, it is eaſy to ſee how it was produced. And that its production is merely accidental, and not neceſſary, is evident from the laſt experiment, in which no nitric acid was formed. It has been aſcertained, indeed, that the formation of this acid during theſe experiments is quite arbitrary. It never is formed when the combuſtion goes on ſo ſlowly as to produce but little heat, as Seguin has aſcertained †; becauſe oxygen and azot do not combine except at a high temperature. Nor is it formed even at a high temperature, as Mr Cavendiſh has proved ‡, except there be a deficiency of hydrogen; becauſe hydrogen has a ſtronger affinity for oxygen than azot has.

† *Ann. de Chim.* ix. 48.

‡ *Phil. Tranſ.* 1784.

The quantity of water obtained in the firſt experiment was juſt 30 grains more than the weight of the gaſes which had diſappeared: the water obtained in the ſecond was preciſely 30 grains leſs than the gaſes conſumed: and in the third experiment, the difference was only 16 grains. The quantities of gas operated upon were large; in all of the experiments ſeveral thouſand grains, and in one of them above 20 thouſand. Now, how is it poſſible that the water produced ſhould correſpond ſo exactly with the gaſes conſumed (for the differences are ſo ſmall as not to merit any attention), unleſs the water had been formed by the combination of theſe gaſes?

Dr Prieſtley, however, who made a great many experiments on this ſubject, drew from them a very different concluſion; and thought he had proved, that during the combuſtion the two gaſes combined, and that the combination was nitric acid. This theory was adopted, or rather it was ſuggeſted, by Mr Keir, who has ſupported it with a great deal of ingenuity *.

* *Keir's Dictionary*, art. *Nitrous Acid.*

Let us examine theſe experiments of Dr Prieſtley †, and ſee whether they warrant the concluſions he has drawn from them. The gaſes were exploded in veſſels of copper. He found that the quantity of water obtained was always *leſs* than that of the gaſes which he had uſed. He obtained alſo a conſiderable quantity of nitric acid. In the experiment made on the largeſt quantity of the gaſes, and from which he draws his concluſions, the quantity of liquid obtained amounted to 442 grains. This liquid was examined by Mr Keir. It was of a green colour, 72 grains of brown oxide of copper were depoſited in it, and it contained a ſolution of nitrat of copper (copper combined with nitric acid). Mr Keir analyſed this liquor: It conſiſted of pure water and nitrat of copper; and Mr Keir concluded that the nitric acid formed amounted to $\frac{1}{20}$th of the oxygen gas employed. Mr Berthollet, however, has ſhewn that it could not have amounted to more than $\frac{1}{44}$th part ‡. Let us ſuppoſe, however, that it amounted to $\frac{1}{20}$th. A quantity of oxygen and hydrogen gas has diſappeared: What has become of them? They have combined, ſays Dr Prieſtley, and formed nitric acid. This nitric acid is only $\frac{1}{20}$th of their weight: Dr Prieſtley ſuppoſes, however, that it contains the whole oxygen and hydrogen that exiſted in theſe gaſes, and that all the reſt of the weight of theſe gaſes was owing to a quantity of water which they had held in ſolution. Oxygen gas, then (for we ſhall neglect the hydrogen, which Dr Prieſtley was not able to bring into view at all), is compoſed of one part of oxygen and 19 of water. Where is the proof of this? Dr Prieſtley informs us, that he aſcertained by experiment that half the weight of carbonic acid gas was pure water. Suppoſing the experiment accurate (C), what can be concluded from it? Surely to bring it forward in proof, that oxygen gas conſiſts of $\frac{19}{20}$th parts, or almoſt wholly of water, is downright trifling. It is impoſſible, therefore, from Dr Prieſtley's experiments, allowing his ſuppoſitions and conjectures their utmoſt force, to account for the diſappearing

† *Phil. Tranſ.* 1788.

‡ *Ann de Chim.* iii. 86.

(B) Lime mixed with water till it is of the thickneſs of *milk*, or rather of *cream*.

(C) He informs us that the carbonat of barytes does not yield its carbonic acid by means of heat (this Dr Hope has ſhewn to be a miſtake); but that, when the vapours of water are paſſed over it, the gas is diſengaged: and he determines, by the water miſſing, how much has combined with the gas. According to him, 60 grains of water enter into the compoſition of 147 grains of gas. But, beſides aſſigning too ſmall a weight to the gas, he forgot that its temperature was high, and that therefore it was capable of combining with much more water than in its uſual ſtate: nor did he aſcertain whether more of this water was depoſited on the veſſels; and yet, by neglecting this precaution, Morveau has ſhewn that Mr Kirwan, in a ſimilar experiment, obtained a reſult nine times greater than it ought to have been. *Encycl. Method. Chim.* art. *Air.*

pearing of the two gaſes, or the appearance of the water, without admitting that this liquid was actually compoſed of oxygen and hydrogen. If we add to this, that no oxygen gas has hitherto (as far as we know at leaſt) been procured abſolutely free from ſome admixture of azot, and that his oxygen was always procured either from red oxide of lead, or from black oxide of mangaueſe, or red oxide of mercury, all of which ſubſtances yield a conſiderable proportion of azot; that in one experiment, in which he obſerves that his oxygen was *very pure*, as it had been obtained from red oxide of mercury, Mr Berthollet (D) aſcertained, by actually making the experiment, that part of the *very ſame* oxide which Dr Prieſtley had employed yielded a gas, $\frac{2}{3}$d of which was azot *; if we add, that it has been proved beyond the poſſibility of doubt, and to Dr Prieſtley's own ſatisfaction, that nitric acid is compoſed of oxygen and azot—we ſhall find it no difficult matter to explain the origin of that acid in Dr Prieſtley's experiments: and if we recollect that in Seguin's experiment, upon a much larger ſcale indeed than Dr Prieſtley's, no nitric acid at all was formed, it will be impoſſible for us to believe for a moment that the compound formed by oxygen and hydrogen is nitric acid. Thus Dr Prieſtley's experiments rather confirm than deſtroy the theory of the compoſition of water. We obtain from them, however, one curious piece of information, that the preſence of copper increaſes the quantity of nitric acid formed. This curious fact, with a variety of others of a ſimilar nature, will perhaps afterwards claim our attention; but at preſent we muſt conſider another theory which this phenomenon ſuggeſted, and which was firſt propoſed, we believe, by Mr de la Metherie (E).

* *Ann. de Chim.* iii. 94.

Had the French chemiſts, it has been ſaid, employed copper veſſels in their experiments, they would have obtained three times the quantity of nitric acid. This acid, therefore, muſt in their experiments have been decompoſed, after having been formed, for want of a baſe to combine with; and the azot which appeared in the reſiduum was owing to this decompoſition. Hydrogen and oxygen, therefore, do not form water, but azot (F). Let us examine the experiment of Mr Le Fevre by this theory, as the quantity of azot was accurately aſcertained. The nitric acid obtained amounted to 43,456 grains; three times that quantity is 130,368 grains, into which 23054 grains of gas were converted; which is impoſſible. Or even ſuppoſing that the decompoſition had been going on during the whole experiment, which is directly contrary to Dr Prieſtley's experiments, and which there is no reaſon whatever to ſuppoſe, but every reaſon againſt—ſtill the whole azot amounted only to $\frac{1}{8}$th of the quantity of gas employed, allowing this gas to have contained no azot, which was evidently not the caſe. It appears, then, that this hypotheſis, even if it could be admitted, would be totally inadequate to account for the phenomena. But if we were to examine it by Mr Seguin's experiment, its abſurdity would be ſtill more glaring. In that experiment the azotic gas amounted to only 19 grains, and the quantity of gas which diſappeared was 5946 grains: ſo that were the hypotheſis true, oxygen and hydrogen gas would conſiſt of one part of oxygen and hydrogen and 312 parts of water; a ſuppoſition ſo enormouſly abſurd, that it is impoſſible for any perſon even to advance it.

It is impoſſible, therefore, for the phenomena which attend the combuſtion of oxygen and hydrogen gas to be accounted for in any way conſiſtent with common ſenſe, except we ſuppoſe that water is formed.

347
Decompoſition of water.

But the experiments above related, concluſive as they appear, are not the only ones by which this important fact has been aſcertained. Meſſrs Van Trooſtwyk and Dieman, aſſiſted by Mr Cuthbertſon, filled a ſmall glaſs tube, $\frac{1}{8}$th of an inch in diameter and 12 inches long, with diſtilled water. One end of this tube was ſealed hermetically; but, at the ſame time, a ſmall gold wire had been paſſed through it. Another wire paſſed thro' the open end of the tube, and could be fixed at greater or ſmaller diſtances from the firſt wire. By means of theſe wires, they made a great number of electrical exploſions paſs through the water. Bubbles of air appeared at every exploſion, and collected at the top of the tube. When electric ſparks were paſſed through this air, it exploded and diſappeared almoſt completely. It muſt therefore have conſiſted of a mixture of oxygen and hydrogen gas, and this gas muſt have been formed by the decompoſition of the water: for they had taken care to deprive the water before hand of all its air, and they uſed every precaution to prevent the acceſs of atmoſpherical air; and, beſides, the quantity of gas produced did not diminiſh, but rather increaſed, by continuing to operate a number of times upon the ſame water, which could not have been the caſe had it been merely air diſſolved in water: nor would atmoſpherical air have exploded and left only a very ſmall reſiduum, not more than $\frac{1}{80}$th part. They had taken care alſo to prove that the electric ſpark did not contribute to form hydrogen gas; for on paſſing it through ſulphuric and nitric acids, the product was not hydrogen, but oxygen gas *.

* *Jour. de Phyſ.* xxxv. 369.

Theſe experiments have been ſince repeated by Dr Pearſon, aſſiſted by Mr Cuthbertſon. He produced, by means of electricity, quantities of gas from water, amounting to 56,5488 cubes of $\frac{1}{10}$th of an inch each; on nitrous gas being added to which, it ſuffered a diminution

---

(D) Mr Berthollet had ſupplied Dr Prieſtley with the oxide. He had received two ounces of it from Mr Le Blanc, one of which he ſent to Dr Prieſtley, and the other he reſerved.

(E) Another favourite theory of La Metherie was, that gaſes themſelves are deſtitute of gravity, and that they owe their whole weight to the water with which they are combined: that during combuſtion the water of the two gaſes is depoſited; and that the gaſes themſelves eſcape through the veſſel and are loſt. He complains bitterly that this theory had never been noticed by his antagoniſts; as if it were neceſſary to refute a hypotheſis which is not ſupported by any proof whatever, and as if it had not been proved that oxygen increaſes the weight of metals, and conſequently poſſeſſes gravity.

(F) This, as has been formerly explained, was the original opinion of Dr Prieſtley; to which, though he does not explain himſelf fully, he evidently ſtill adheres. There is then no difference between his theory and this, except what relates to the decompoſition of the nitric acid.

nution of bulk, and nitrous acid appeared to have been formed: It muſt therefore have contained oxygen gas. When oxygen gas was added to the remainder, and an electric ſpark paſſed through it, a diminution took place preciſely as when oxygen and hydrogen gas are mixed: It muſt therefore have contained hydrogen. When an electric ſpark was paſſed through the gas thus produced from water, the gas diſappeared, being no doubt converted into water *.

Such are the proofs by which the compound nature of water is aſcertained; and we do not believe that any phyſical fact whatever can be produced which is ſupported by more complete evidence.

But what becomes of the caloric which was previouſly combined with theſe gaſes? It paſſes through the veſſel and is loſt, and its weight is too inconſiderable to make any ſenſible variation in the quantity of the product. If we were to judge from analogy, we would conclude, that the oxygen and hydrogen, while in the ſtate of gas, are probably ſomewhat lighter than after they are condenſed into water; but the difference, if it exiſts, can ſcarcely be ſenſible.

348 Combination and affinity of water.

Water is capable of combining with a vaſt number of ſubſtances: all bodies, indeed, which are ſoluble in water form a chemical union with it.

Its affinity for other bodies is doubtleſs various, tho' we have no method of aſcertaining this difference, except in thoſe bodies which have no affinity, or but a very ſmall affinity, for each other; and it is only in a few even of theſe that this difference can be aſcertained. If muriat of barytes be poured into lime-water, the lime is precipitated, owing, no doubt, to the ſuperior affinity of the muriat for water. Several very curious inſtances of the affinity of different ſalts for water have been mentioned by Mr Quatremere Dijonval. When the ſolutions of nitrat of lime and nitrat of magneſia in water are mixed together, the nitrat of magneſia is precipitated. Muriat of magneſia is alſo precipitated by muriat of lime, and ſulphat of magneſia by ſulphat of lime: ſo that it would ſeem that the ſalts which have magneſia for their baſis, have a leſs affinity for water than thoſe whoſe baſis is lime †.

Water has the property of diſſolving oxygen gas. If a quantity of common air be confined for ſome time above water, the whole of the oxygen is abſorbed, and nothing but the azotic gas remains. This fact was firſt obſerved by Mr Scheele.

CHAP. II. *Of* ALCOHOL.

349 Diſcovery of alcohol.

WINE has been known from the earlieſt ages. The Scriptures inform us, that Noah planted a vineyard and drank wine; and the heathen writers are unanimous in aſcribing the invention of this liquor to their earlieſt kings and heroes. Beer, too, ſeems to have been diſcovered at a very remote period. It was in common uſe in Egypt in the time of Herodotus ‡. Tacitus informs us, that it was the drink of the Germans §. Whether the ancients had any method of procuring ardent ſpirits from theſe or any other liquors, does not appear. The Greeks and Romans ſeem to have been ignorant of ardent ſpirits altogether, at leaſt we can diſcover no traces of any ſuch liquor in their writings. But among the northern nations of Europe, intoxicating liquors were in uſe from the earlieſt ages. Whether theſe liquors reſembled the beer of the Germans, we do not know. It is certain, at leaſt, that the method of procuring ardent ſpirits by diſtillation was known in the dark ages; and it is more than probable that it was practiſed in the north of Europe much earlier. They are mentioned expreſsly by Thaddæus, Villanovanus, and Lully *.

350 Method of procuring it.

Ardent ſpirits, ſuch as brandy, for inſtance, rum, and whiſky, conſiſt almoſt entirely of three ingredients, water, *alcohol* or *ſpirit of wine*, to which they owe their ſtrength, and a ſmall quantity of a peculiar oil, to which they owe their flavour.

The alcohol may be ſeparated from the water by the following proceſs. Into the whiſky or other ardent ſpirit a quantity of potaſs is to be put, which has juſt immediately before been expoſed for about half an hour in a crucible to a red heat, in order to deprive it of moiſture. Potaſs in this ſtate has a ſtrong attraction for water; it accordingly combines with the water of the ſpirit, and the ſolution of potaſs thus formed ſinks to the bottom of the veſſel, and the alcohol, which is lighter, ſwims over it, and may eaſily be decanted off; or, what is perhaps better, the ſolution of potaſs may be drawn off from below it by means of a ſtop-cock placed at the bottom of the veſſel. It is impoſſible to fix the quantity of potaſs which ought to be uſed, becauſe that muſt depend entirely on the ſtrength of the ſpirit; but it is of no conſequence though the potaſs employed be a little more than enough. The alcohol thus obtained contains a little potaſs diſſolved, which may be ſeparated by diſtilling it in a water bath with a very ſmall heat. The alcohol paſſes over, and leaves the potaſs behind. It is proper not to diſtil to dryneſs. This proceſs is firſt mentioned by Lully. Alcohol may be obtained in the ſame manner from wine and from beer; which liquids owe their ſtrength entirely to the quantity of that ſubſtance which they contain.

351 Its properties.

Alcohol is a tranſparent liquor, colourleſs like water, of a pleaſant ſmell, and a ſtrong penetrating agreeable taſte.

It is exceedingly fluid, and has never been frozen, though it has been expoſed to a cold ſo great that the thermomer ſtood at —69° †.

Its ſpecific gravity when pure is about 0,800.

It is exceedingly volatile, boiling at the temperature of 176°; in which heat it aſſumes the form of an elaſtic fluid, capable of reſiſting the preſſure of the atmoſphere, but which condenſes again into alcohol when that temperature is reduced. In a vacuum it boils at 56°, and exhibits the ſame phenomena: ſo that were it not for the preſſure of the atmoſphere, alcohol would always exiſt in the form of an elaſtic fluid, as tranſparent and inviſible as common air. This ſubject was firſt examined with attention by Mr Lavoiſier ‡. The fact, however, had been known long before.

Alcohol has a ſtrong affinity for water, and is miſcible with it in all proportions. The ſpecific gravity of all the different mixtures, in every proportion, and in all the different degrees of temperature, from 32° to 100°, has been lately aſcertained with great accuracy by Sir Charles Blagden and Mr Gilpin. But as a very full account of theſe intereſting experiments has been given in the Encyclopædia in the article SPIRITUOUS *Liquors*, we do not think ourſelves at liberty to repeat it here.

If alcohol be ſet on fire, it burns all away with a blue flame without leaving any reſiduum. Boerhaave obſerved,

obſerved, that when the vapour which eſcapes during this combuſtion is collected in proper veſſels, it is found to conſiſt of nothing but water. Junker had made the ſame remark: and Dr Black ſuſpected, from his own obſervations, that the quantity of water obtained, if properly collected, exceeded the weight of the alcohol conſumed. This obſervation was confirmed by Lavoiſier; who found that the water produced during the combuſtion of alcohol exceeded the alcohol conſumed by about $\frac{1}{7}$th part[*].

352 Opinions oncerning ts compo- ition.

Different opinions were entertained by chemiſts about the nature of alcohol. Stahl thought that it was compoſed of a very light oil, united by means of an acid to a quantity of water. According to Junker, it was compoſed of phlogiſton, combined with water by means of an acid. Cartheuſer, on the other hand, affirmed, that it contained no acid, and that it was nothing elſe than pure phlogiſton and water. But theſe hypotheſes were mere aſſertions ſupported by no proof whatever. Lavoiſier was the firſt who attempted to analyſe it.

353 Lavoiſier's analyſis.

He ſet fire to a quantity of alcohol in cloſe veſſels, by means of the following apparatus: BCDE (fig. 6.) is a veſſel of marble filled with mercury. A is a ſtrong glaſs veſſel placed over it, filled with common air, and capable of containing about 15 pints (French). Into this veſſel is put the lamp R filled with alcohol, the weight of which has been exactly determined. On the wick of the lamp is put a ſmall particle of phoſphorus. The mercury is drawn up by ſuction to the height IH. This glaſs communicates by means of the pipe LK with another glaſs veſſel S filled with oxygen gas, and placed over a veſſel of water T. This communication may be ſhut up at pleaſure by means of the ſtop-cock M.

Things being thus diſpoſed, a crooked red-hot iron wire is thruſt up through the mercury, and made to touch the phoſphorus. This inſtantly kindles the wick, and the alcohol burns. As ſoon as the flame begins to grow dim, the ſtop-cock is turned, and a communication opened between the veſſels S and A; a quantity of oxygen gas ruſhes in, and reſtores the brightneſs of the flame. By repeating this occaſionally, the alcohol may be kept burning for ſome time. It goes out, however, at laſt, notwithſtanding the admiſſion of oxygen gas.

The reſult of this experiment, which Mr Lavoiſier repeated a great number of times, was as follows:

The quantity of alcohol conſumed amounted to 76,7083 grains troy.

The oxygen gas conſumed amounted to 266,82 cubic inches, and weighed 90,506 grains troy.

The whole weight of the ſubſtances conſumed, therefore, amounted to 167,2143 grains.

After the combuſtion, there were found in the glaſs veſſel 115,41 cubic inches of carbonic acid gas, the weight of which was 78,1192 grains troy. There was likewiſe found a conſiderable quantity of water in the veſſel, but it was not poſſible to collect and weigh it. Mr Lavoiſier, however, eſtimated its weight at 89,0951 grains; as he concluded, with reaſon, that the whole of the ſubſtances employed were ſtill in the veſſel. Now the whole contents of the veſſel conſiſted of carbonic acid gas and water; therefore the carbonic acid gas and water together muſt be equal to the oxygen gas and alcohol which had been conſumed.

But 78,1192 grains of carbonic acid gas contain, according to Mr Lavoiſier's calculation[†], 55,279 grains of oxygen: 90,506 grains, however, of oxygen gas had diſappeared; therefore 35,227 grains muſt have been employed in forming water.

35,227 grains of oxygen gas require, in order to form water, 6,038 grains of hydrogen gas; and the quantity of water formed by this combination is 41,265 grains. But there were found 89,095 grains of water in the glaſs veſſel; therefore 47,83 grains of water muſt have exiſted ready formed in the alcohol.

It follows from all theſe data, that the 76,7083 grains of alcohol, conſumed during the combuſtion, were compoſed of

22,840 Carbon,
6,038 Hydrogen,
47,830 Water.
―――――
76,7[*]

Such were the conſequences which Mr Lavoiſier drew from his analyſis. He acknowledged, however, that there were two ſources of uncertainty, which rendered his concluſions not altogether to be depended upon. The firſt was, that he had no method of determining the quantity of alcohol conſumed, except by the difference of weight in the lamp before and after combuſtion; and that therefore a quantity might have evaporated without combuſtion, which, however, would be taken into the ſum of the alcohol conſumed. But this error could not have been great; for if a conſiderable quantity of alcohol had exiſted in the ſtate of vapour in the veſſel, an exploſion would certainly have taken place. The other ſource of error was, that the quantity of water was not known by actual weight, but by calculation.

354 Ingredients of alcohol.

To this we may add, that Mr Lavoiſier was not warranted to conclude from his experiment, that the water found in the veſſel, which had not been formed by the oxygen gas uſed, had exiſted in the alcohol in the ſtate of water: he was intitled to conclude from his data, that the ingredients of that water exiſted in the alcohol before combuſtion; but not that they were actually combined in the ſtate of water, becauſe that combination might have taken place, and in all probability did partly take place, during the combuſtion. It follows, therefore, from Mr Lavoiſier's experiments, that alcohol, ſuppoſing he uſed it perfectly pure, which is not probable, is compoſed of

0,2988 parts carbon,
0,1840 parts hydrogen,
0,5172 parts oxygen.
―――――
1,0000

But it gives us no information whatever of the manner in which theſe ingredients are combined. That alcohol contains oxygen, has been proved by a very ingenious ſet of experiments performed by Meſſrs Fourcroy and Vauquelin. When equal parts of alcohol and ſulphuric acid are mixed together, a quantity of caloric is diſengaged, ſufficient to elevate the temperature of the mixture to 190°. Bubbles of air are emitted, the liquor becomes turbid, aſſumes an opal colour, and at the end of a few days a deep red. When examined, the ſulphuric acid is found to have ſuffered no change; but the alcohol is decompoſed, partly converted into water and partly into ether, a ſubſtance which we ſhall deſcribe immediately. Now, it is evident that the alcohol could not have been converted into water unleſs it had contained oxygen[*].

When equal parts of ſulphuric acid and alcohol are mixed together and heat applied, the mixture boils at 208°,

208°, and a liquid equal to half the weight of the alcohol comes over into the receiver. This liquid is *ether*.

355 Ether.

Ether is obſcurely hinted at in ſome of the older chemical authors, but little attention was paid to it till a paper appeared in the Philoſophical Tranſactions for 1730, written by a German, who called himſelf *Frobenius* (G), containing a number of experiments on it. In this paper it firſt received the name of *ether*.

356 Its properties.

Ether is limpid and colourleſs, of a very fragrant ſmell, and a hot pungent taſte. Its ſpecific gravity is 0,7394. It is exceedingly volatile, boiling in the open air at 98°, and in a vacuum at —20°. Were it not therefore for the preſſure of the atmoſphere, it would always exiſt in a gaſeous ſtate. Ether unites with water in the proportion of ten parts of the latter to one of the former*. It is exceedingly inflammable, and, when kindled in the ſtate of vapour, burns with rapidity, or rather explodes, if it be mixed with oxygen gas.

357 Theory of its formation.

Chemiſts entertained various opinions reſpecting the nature of ether. Macquer ſuppoſed that it was merely alcohol deprived by the acid of all its water. But it was generally believed that the acid entered partly into its compoſition. Since the nature of acids has become better known, a great number of philoſophers have ſuppoſed that ether is merely alcohol combined with a quantity of oxygen furniſhed by the acid. The real compoſition of this ſingular ſubſtance has been lately aſcertained by the experiments of Fourcroy and Vauquelin.

" A combination (ſay they) of two parts of ſulphuric acid and one part of alcohol elevates the temperature to 201°, becomes immediately of a deep red colour, which changes to black a few days afterwards, and emits a ſmell perceptibly ethereal.

" When we carefully obſerve what happens in the combination of equal parts of alcohol and concentrated ſulphuric acid expoſed to the action of caloric in a proper apparatus, the following phenomena are ſeen :

" 1. When the temperature is elevated to 208°, the fluid boils, and emits a vapour which becomes condenſed by cold into a colourleſs, light, and odorant liquor, which from its properties has received the name of *ether*. If the operation be properly conducted, no permanent gas is diſengaged until about half the alcohol has paſſed over in the form of ether. Until this period there paſſes abſolutely nothing but ether and a ſmall portion of water, without mixture of ſulphurous or of carbonic acid.

" 2. If the receiver be changed as ſoon as the ſulphurous acid manifeſts itſelf, it is obſerved that no more ether is formed, but the ſweet oil of wine, water, and acetous acid, without the diſengagement hitherto of a ſingle bubble of carbonic acid gas. When the ſulphuric acid conſtitutes about four-fifths of the maſs which remains in the retort, an inflammable gas is diſengaged, which has the ſmell of ether, and burns with a white oily flame. This is what the Dutch chemiſts have called *carbonated hydrogen gas*, or *olefiant gas*, becauſe when mixed with the oxy-muriatic acid it forms oil. At this period the temperature of the fluid contained in the retort is elevated to 230° or 234°.

" 3. When the ſweet oil of wine ceaſes to flow, if the receiver be again changed, it is found that nothing more paſſes but ſulphurous acid, water, carbonic acid gas; and that the reſiduum in the retort is a black maſs, conſiſting for the moſt part of ſulphuric acid thickened by carbon.

" The ſeries of phenomena here expoſed will juſtify the following general inductions :

" 1. A ſmall quantity of ether is formed ſpontaneouſly, and without the aſſiſtance of heat, by the combination of two parts of concentrated ſulphuric acid and one part of alcohol.

" 2. As ſoon as ether is formed, there is a production of water at the ſame time ; and while the firſt of theſe compoſitions takes place, the ſulphuric acid undergoes no change in its intimate nature.

" 3. As ſoon as the ſulphurous acid appears, no more ether is formed, or at leaſt very little ; but then there paſſes the ſweet oil of wine, together with water and acetous acid.

" 4. The ſweet oil of wine having ceaſed to come over, nothing further is obtained but the ſulphurous and carbonic acids, and at laſt ſulphur, if the diſtillation be carried to dryneſs.

" The operation of ether is therefore naturally divided into three periods : the firſt, in which a ſmall quantity of ether and water are formed without the aſſiſtance of heat ; the ſecond, in which the whole of the ether which can be obtained is diſengaged without the accompaniment of ſulphurous acid; and the third, in which the ſweet oil of wine, the acetous acid, the ſulphurous acid, and the carbonic acid, are afforded. The three ſtages have no circumſtance common to all, but the continual formation of water, which takes place during the whole of the operation.

" The ether which is formed without the aſſiſtance of caloric, and the carbon which is ſeparated without decompoſition of the ſulphuric acid, prove that this acid acts on alcohol in a manner totally different from what has hitherto been ſuppoſed. It cannot, in fact, be affirmed, that the acid is altered by the carbon, becauſe daily experience ſhews that no ſenſible attraction takes place between theſe two bodies in the cold; neither can it be affected by the hydrogen ; for in that caſe ſulphurous acid would have been formed, of which it is known that no trace is exhibited during this firſt period. We muſt therefore have recourſe to another ſpecies of action, namely, the powerful attraction exerciſed by the ſulphuric acid upon water. It is this which determines the union of the principles which exiſt in the alcohol, and with which the concentrated acid is in contact : but this action is very limited if the acid be ſmall in quantity ; for an equation of affinity is ſoon eſtabliſhed, the effect of which is to maintain the mixture in a ſtate of repoſe.

" Since it is proved that ether is formed in the cold by the mixture of any quantities of alcohol and ſulphuric acid, it is evident that a maſs of alcohol might be completely changed into ether and vegetable acid by uſing a ſufficient abundance of ſulphuric acid. It is equally evident that the ſulphuric acid would not by this means undergo any other change than that of being diluted with a certain quantity of water. This obſervation proves that alcohol contains oxygen, becauſe water cannot exiſt without this principle, which muſt be afforded by the alcohol only, ſince the ſulphuric acid ſuffers no decompoſition.

" We muſt not, however, imagine, from theſe facts, that ether is alcohol minus oxygen and hydrogen. Its properties alone would contradict this ; for a quantity of carbon proportionally greater than that of the hydrogen

---

* Count de Lauraguais.

(G) The name was ſuppoſed to have been feigned.

drogen is at the ſame time ſeparated. It may, in fact, be conceived that the oxygen, which in this caſe combines with the hydrogen to form water, not only ſaturated that hydrogen in the alcohol, but likewiſe the carbon. So that, inſtead of conſidering ether as alcohol minus hydrogen and oxygen, we muſt, by keeping an account of the precipitated carbon and the ſmall quantity of hydrogen contained in the water which is formed, regard it as alcohol plus hydrogen and oxygen.

"The foregoing are the effects produced by a combination of alcohol and ſulphuric acid, ſpontaneouſly produced without foreign heat. Let us, in the next place, obſerve how this combination is effected when caloric is added. The phenomena are then very different, tho' ſome of the reſults are the ſame.

"In the firſt place, we muſt obſerve, that a combination of ſulphuric acid and alcohol in equal parts does not boil at leſs than 207 degrees of temperature, while that of alcohol alone boils at 176. Now ſince ebullition does not take place till the higher temperature, it is clear that the alcohol is retained by the affinity of the ſulphuric acid, which fixes it more conſiderably. Let us alſo conſider that organic bodies, or their immediate products, expoſed to a lively briſk heat, without the poſſibility of eſcaping ſpeedily enough from its action, ſuffer a partial or total decompoſition, according to the degree of temperature. Alcohol undergoes this laſt alteration when paſſed through an ignited tube of porcelain. By this ſudden decompoſition it is converted into water, carbonic acid, and carbon. The reaſon, therefore, why alcohol is not decompoſed when it is ſubmitted alone to heat in the ordinary apparatus for diſtillation, is, that the temperature at which it riſes in vapours is not capable of effecting the ſeparation of its principles; but when it is fixed by the ſulphuric acid or any other body, the elevated temperature it undergoes, without the poſſibility of diſengagement from its combination, is ſufficient to effect a commencement of decompoſition, in which ether and water are formed, and carbon is depoſited. Nothing more therefore happens to the alcohol in theſe circumſtances than what takes place in the diſtillation of every other vegetable matter in which water, oil, acid, and coal, are afforded.

"Hence it may be conceived that the nature of the products of the decompoſition of alcohol muſt vary according to the different degrees of heat; and this explains why at a certain period no more ether is formed but the ſweet oil of wine and acetous acid. In fact, when the greateſt quantity of the alcohol has been changed into ether, the mixture becomes more denſe, and the heat which it acquires previous to ebullition is more conſiderable. The affinity of the acid for alcohol being increaſed, the principles of this acid become ſeparated; ſo that, on the one hand, its oxygen ſeizes the hydrogen, and forms much water, which is gradually volatilized; while, on the other, the ether retaining a greater quantity of carbon, with which at that temperature it can riſe, affords the ſweet oil of wine. This laſt ought therefore to be conſidered as an ether containing an extraordinary portion of carbon, which gives it more denſity, leſs volatility, and a lemon yellow colour.

"During the formation of the ſweet oil of wine, the quantity of carbon which is precipitated is no longer in the ſame proportion as during the formation of ether.

"What we have here ſtated concerning the manner in which ether is formed by the ſimultaneous action of the ſulphuric acid and heat, appears ſo conformable to truth, that nearly the ſame effects may be produced by a cauſtic fixed alkali. In this caſe alſo a kind of ether and a ſweet oil of wine are volatilized, and coal is precipitated. It is therefore only by fixing the alcohol that the ſulphuric acid permits the caloric to operate a ſort of decompoſition. It may alſo be urged as a proof of this aſſertion, that the ſulphuric acid, which has ſerved to make ether as far as the period at which the ſweet oil of wine begins to appear, is capable of ſaturating the ſame quantity of alkali as before its mixture with the alcohol *".

Ether may alſo be obtained by means of ſeveral other acids. The different liquids thus formed are diſtinguiſhed by prefixing the name of the acid uſed in the proceſs. Thus the ether above deſcribed is called *ſulphuric ether;* that obtained by means of nitric acid, *nitric ether,* and ſo on. There are ſeveral minute ſhades of difference between theſe various ethers, which have not yet been properly inquired into.

358 Subſtances ſoluble in alcohol.

Alcohol is capable of diſſolving a great many bodies. A conſiderable number of theſe, with the quantities ſoluble, is exhibited in the following tables.

359 Its affinities.

The affinities of alcohol are very imperfectly known. Thoſe ſtated by Bergman are as follows:

Water,
Ether,
Volatile oil,
Sulphurets of alkalies.

Chap. III. *Of* Oils.

360 Diſcovery of oil.

Oil, which is of ſuch extenſive utility in the arts, was known at a very remote period. It is mentioned in Geneſis, and during the time of Abraham was even uſed in lamps [*]. The olive was very early cultivated, and oil extracted from it in Egypt. Cecrops brought it from Sais, a town in Lower Egypt, where it had been cultivated from time immemorial, and taught the Athenians to extract oil from it. In this manner the uſe of oil became known in Europe [†]. But the Greeks ſeem to have been ignorant of the method of procuring light by means of lamps till after the ſiege of Troy [‡]; at leaſt Homer never mentions them, and conſtantly deſcribes his heroes as lighted by torches of wood.

Oils are divided into two claſſes, *Fixed* and *Volatile*; each of which is diſtinguiſhed by peculiar properties.

361 Fixed oils.

I. The fixed oils, called alſo *fat* or *expreſſed* oils, are numerous, and are obtained, partly from animals and partly from vegetables, by ſimple expreſſion. As inſtances, we ſhall mention whale oil or train oil, obtained from the blubber of the whale; olive oil, obtained from the fruit of the olive; lintſeed oil and almond oil, obtained from lintſeed and almond kernels. Fixed oils may alſo be obtained from poppy ſeeds, hemp ſeeds, beech maſt, and many other vegetable ſubſtances.

All theſe oils differ from each other in ſeveral particulars, but they alſo poſſeſs many particulars in common. Whether the oily principle in all the fixed oils is the ſame, and whether they owe their differences to accidental ingredients, is not yet completely aſcertained, as no proper analyſis has hitherto been made; but it is exceedingly probable, as all the oils hitherto tried have been found to yield the ſame products. In the preſent ſtate of our knowledge, it would be uſeleſs to give a particular deſcription of all the fixed oils, as the differences between them have not even been accurately aſcertained. We ſhall content ourſelves, therefore, with giving the characters which diſtinguiſh fixed oils in general, and an analyſis of one oil, by way of ſpecimen.

362 Their properties.

Fixed oils are inſoluble in alcohol, which diſtinguiſhes them from volatile oils. They are alſo inſoluble in water.

They have an unctuous feel, are tranſparent while fluid, are deſtitute of ſmell, and have a mild inſipid kind of taſte.

They are all ſuſceptible of becoming ſolid by expoſure to a ſufficient degree of cold. Olive oil and almond oil freeze at 10½ degrees [‡].

They are capable of being converted into vapour by heat; but require for that purpoſe a temperature conſiderably ſuperior to that of boiling water. Olive oil boils at 600°, and moſt of the fixed oils hitherto tried require nearly the ſame degree of heat.

When in the ſtate of vapour they take fire on the approach of an ignited body, and burn with a yellowiſh white flame. It is upon this principle that candles and lamps burn. The tallow or oil is firſt converted into the ſtate of vapour in the wick; it then takes fire, and ſupplies a ſufficient quantity of heat to convert more oil into vapour; and this proceſs goes on while any oil remains. The wick is neceſſary to preſent a ſufficiently ſmall quantity of oil at once for the heat to act upon. If the heat were ſufficiently great to keep the whole oil at the temperature of 600°, no wick would be neceſſary, as is obvious from oil catching fire ſpontaneouſly when it has been raiſed to that temperature.

363 Analyſis of olive oil.

Mr Lavoiſier analyſed olive oil by burning it in preciſely the ſame apparatus as that which he employed for analyſing alcohol.

The

---

[*] Withering, Phil. Tranſ. lxxii. 336.

[†] Macquer, ibid.

[‡] Witbering, Ibid.

[§] Macquer, ibid.

[*] Gen. xv. 17.

[†] Herodot. lib. ii. 59. and 62.

[‡] Chaptal's Chemiſtry, Engliſh Tranſl. iii. 43.

The quantity of oil conſumed amounted to 15,79 grains troy.

The quantity of oxygen gas amounted to 50,86 gr. troy. The whole amount therefore of the ſubſtances conſumed during the combuſtion is 66,65 grains troy.

The carbonic acid obtained amounted to 44,50 gr. There was alſo a conſiderable quantity of water, the weight of which could not be accurately aſcertained: but as the whole of the ſubſtances conſumed were converted into carbonic acid gas and water, it is evident that if the weight of the carbonic acid be ſubtracted from the weight of theſe ſubſtances, there muſt remain preciſely the weight of the water. Mr Lavoiſier accordingly concluded, by calculation, that the weight of the water was 22,15 grains. Now the quantity of oxygen in 44,50 grains of carbonic acid gas is 32,04 grains, and the oxygen in 22,15 grains of water is 18,82 grains; both of which taken together amount to 50,86 grains, preciſely the weight of the oxygen gas employed. There does not appear therefore to be any oxygen in olive oil.

The quantity of carbon in 44,50 grains of carbonic acid gas is 12,47 grains; and the quantity of hydrogen in 22,15 grains of water is 3,32 grains; both of which, when taken together, amount to 15,79 grains, which is the weight of the oil conſumed.

It follows, therefore, from this analyſis, that 15,79 grains of olive oil are compoſed of

12,47 Carbon,
3,32 Hydrogen.

Olive oil therefore is compoſed of about

79 Carbon,
21 Hydrogen.
100*

In what manner theſe ſubſtances are combined, cannot be learned from this analyſis. Whether they combine directly, and ſaturate each other in that proportion, as is moſt probable -or whether the hydrogen is combined previouſly with a part of the carbon, and that compound combining with a certain quantity of carbon, forms oil, is altogether uncertain. Yet theſe queſtions are of the utmoſt importance; and till the method of ſolving them be diſcovered, we never can acquire any preciſe ideas about the conſtituent parts of a great number of ſubſtances, which, though formed ultimately of the ſame ingredients, differ very much in their properties from one another; as wax and oil; alcohol, ſugar, and ether.

364
Rancidity.

When fixed oils are expoſed to the atmoſphere, they become thick, acquire a brown colour, and a peculiarly unpleaſant ſmell: they are then ſaid to be *rancid.* When oil is poured upon water, ſo as to form a thin layer on its ſurface, and is in that manner expoſed to the atmoſphere, theſe changes are produced much ſooner, the oil becomes thicker, and aſſumes an appearance very much reſembling wax. Berthollet, who firſt examined theſe phenomena with attention, aſcribed them to the action of light: but Sennebier obſerved, that no ſuch change was produced on the oil though ever ſo long expoſed to the light, provided atmoſpherical air was excluded; but that it took place on the admiſſion of oxygen gas, whether the oil was expoſed to the light or not *. It cannot be doubted, then, that it is owing to the combination of oxygen. All ſubſtances that are capable of ſupplying that principle, the metallic oxides for inſtance, and ſeveral of the acids, produce the ſame effect upon oils; and it is a known fact, that oil is capable of reducing many of the metallic oxides to the metallic ſtate, and conſequently that it has a ſtronger affinity for oxygen.

Mr Chaptal has ſuppoſed that oils become rancid merely becauſe they contain a quantity of mucilage, with which the oxygen combines; and that when oxygen combines with fixed oils, it produces a different effect, converting them into what is called *drying oils.*

It is certain that oils contain a quantity of mucilage; but ſome change is evidently produced on the oils themſelves by rancidity; for no agitation in water is capable of reſtoring them to their former ſtate, although water deprives them of their mucilage.

365
Drying oils.

Drying oils, ſo called becauſe they are capable of *drying* completely when ſpread out, a property which renders them uſeful in painting, ſeem, as Sennebier obſerves, to be completely deprived of mucilage; for, in order to render an oil drying, it muſt be boiled, which evaporates or decompoſes all the mucilage: they ſeem alſo to loſe part of their hydrogen †.

366
Fixed oils diſſolve ſulphur.

Fixed oils are capable of diſſolving ſulphur at their boiling temperature. The ſolution is very fetid, owing to a partial decompoſition of the oil. Hydrogen gas flies off, having a quantity of ſulphur diſſolved in it. When the ſolution cools, the ſulphur cryſtallizes.

367
And phoſphorus.

Fixed oils diſſolve phoſphorus. The ſolution is luminous, from the ſlow combuſtion of the phoſphorus.

Fixed oils are capable of combining with many of the metallic oxides. The compounds are called *metallic ſoaps.* Several of the oxides are decompoſed by being boiled in oils.

Fixed oils combine alſo with the alkaline earths and with alumina. The compounds are called *earthy ſoaps.*

368
Their affinities.

The affinities of the oils are as follows:

Lime,
Barytes,
Fixed alkalies,
Magneſia,
Ammonia,
Oxide of mercury,
Other metallic oxides (H),
Alumina.

Nitric acid,
Muriatic,
Sulphurous,
Sulphuric,
Acetous,
Sulphur,
Phoſphorus (I).

369
Volatile oils.

II. Volatile oils, called alſo *eſſential oils,* are all obtained from vegetables. They have a ſtrong aromatic ſmell, and a pungent acrid taſte. They are ſo volatile that they may be diſtilled by the heat of boiling water. They are ſoluble in alcohol, but not in water. They evaporate on the application of heat, without leaving any ſtain behind them, which is not the caſe with the fixed oils. By this teſt, accordingly, it is eaſy to diſcover whether they have been adulterated with any of the fixed oils. Let a drop of the volatile oil fall upon a ſheet of writing paper, and then apply a gentle heat

---

† Berthollet.

(H) Their order not well aſcertained.

(I) The firſt column was aſcertained by Berthollet. The laſt is to be conſidered as unconnected with the firſt. On account of the affinity of theſe two claſſes of bodies for each other, it has not been poſſible to diſcover which of them has the greateſt affinity for oil.

heat to it. If it evaporates without leaving any ſtain upon the paper, the oil is pure; but if it leaves a ſtain, it has been contaminated with ſome fixed oil or other.

Volatile oils are very numerous, and differ from one another, in fluidity and weight, in their freezing point, and in ſeveral other particulars. Little attention has been paid to the greateſt part of them, becauſe few of them have been found of any uſe. The principal quality for which they are valued is their odour. Some of them are obtained by expreſſion, as oil of bergamot, lemons, oranges; others by diſtillation, as oil of peppermint, thyme, lavender, &c. It would be uſeleſs, even if it were poſſible, to give a particular deſcription of all the volatile oils.

370 Their properties. They are more inflammable than the fixed oils; a quality which they owe to their volatility. As far as experiments have hitherto been made, they ſeem to conſiſt of carbon and hydrogen; but nothing is known concerning the proportions of theſe ingredients. They thicken when expoſed to the air, probably by combining with oxygen, and form *reſins* (K).

When expoſed to cold, or when kept for a long time, ſome of them depoſite cryſtals reſembling the acid of benzoin (L).

They diſſolve ſulphur, and form what have been called *balſams of ſulphur*.

They are capable of combining with moſt of the ſubſtances that unite with fixed oils. Their affinities, which certainly differ from thoſe of fixed oils, have not yet been properly aſcertained.

Chap. IV. *Of* Alkalies.

371 Properties of alkalies. Substances poſſeſſed of the following properties are called *alkalies*:

1. Incombuſtible.
2. Capable of converting vegetable blues to a green.
3. A hot cauſtic taſte.
4. Very ſoluble in water, even when combined with carbonic acid.

There are three alkalies, *potaſs*, *ſoda*, and *ammonia*. The two firſt are called *fixed* alkalies, becauſe a very violent heat is neceſſary to volatilize them; the laſt is called *volatile* alkali, becauſe it very eaſily aſſumes a gaſeous form, and is conſequently diſſipated by a very moderate degree of heat.

Sect. I. *Of Potaſs*.

372 Method of procuring potaſs. If a ſufficient quantity of wood be burnt to aſhes, and theſe aſhes be afterwards waſhed repeatedly with water till it comes off free from any taſte, and if this liquid be filtrated and evaporated to dryneſs, the ſubſtance which remains behind is *potaſs*; not, however, in a ſtate of purity, for it is contaminated with ſeveral other ſubſtances; but ſufficiently pure to exhibit many of its properties. In this ſtate, it occurs in commerce under the name of *potaſh*. It may be purified conſiderably, by putting it in a crucible, keeping it red hot for ſome time; then diſſolving it in water, filtrating it, and evaporating it again to dryneſs. By the following method it may be obtained nearly pure: Mix together equal quantities of nitre and carbon, and put them by little and little into a red hot crucible. They burn with a vivid flame, and leave behind them a quantity of potaſs. This is to be diſſolved in water, filtrated, and evaporated to dryneſs. Or potaſs may be obtained by burning tartar wrapt up in brown paper and placed in a crucible (M).

The potaſs procured by theſe laſt proceſſes is exceedingly white; it is not, however, quite pure; for it is combined with a ſubſtance which blunts all its properties conſiderably. This ſubſtance is carbonic acid gas; from which it may be ſeparated by diſſolving it, and mixing with it an equal quantity of lime made into a paſte with water. The lime has a greater affinity for carbonic acid gas, and therefore combines with it; and the pure potaſs remains diſſolved in the water, and may be ſeparated from the lime by filtrating the mixture This proceſs, however, muſt be performed in cloſe veſſels; for there is a little carbonic acid gas in the atmoſphere, which would again combine with the potaſs if it were allowed to ſtand expoſed to the air.

It is then to be evaporated till a thick pellicle appears on its ſurface, and afterwards allowed to cool; and all the cryſtals which have formed are to be ſeparated, for they conſiſt of foreign ſalts. The evaporation is then to be continued in an iron pot; and, during the proceſs, the pellicle which forms on the ſurface is to be carefully taken off with an iron ſkimmer. When no more pellicle appears, and when the matter ceaſes to boil, it is to be taken off the fire, and muſt be conſtantly agitated while cooling with an iron ſpatula. It is then to be diſſolved in double its own weight of cold water. This ſolution is to be filtered and evaporated in a glaſs retort till it begin to depoſite regular cryſtals. If the maſs conſolidates ever ſo little by cooling, a ſmall quantity of water is to be added, and it muſt be heated again. When a ſufficient number of cryſtals have been formed, the liquor which ſwims over them, and which has aſſumed a very brown colour, muſt be decanted off, and kept in a well-cloſed bottle till the brown matter has ſubſided, and then it may be evaporated as before, and more cryſtals obtained. The cryſtals may then be diſſolved in pure water. By this proceſs, which was invented by Mr Lowitz of Peterſburgh *, potaſs may be obtained in a ſtate of the greateſt purity. The ſhape of its cryſtals is very different, according to the way in which they have been produced. When allowed to form in the cold, they are octahedrons in groups, and contain 0,43 of water: When formed by evaporation

* Nicholſon's i. 164.

(K) Reſins are concrete vegetable juices; the diſtinguiſhing property of which is inſolubility in water and ſolubility in alcohol. *Common reſin*, or *roſin*, from which they derive their name, is one of them; and ſealing wax conſiſts almoſt entirely of another.

(L) See a paper by Margueron on this ſubject, *Ann. de Chim.* xxi. 174.

(M) That potaſs was known to the ancient Gauls and Germans, cannot be doubted, as they were the inventors of ſoap, which, Pliny informs us, they compoſed of aſhes and tallow. Theſe aſhes (for he mentions the aſhes of the beech tree particularly) were nothing elſe but potaſs; not, however, in a ſtate of purity. *Plinii*, lib. xviii. c. 51. The κονια, too, mentioned by Ariſtophanes and Plato, appears to have been a ley made of the ſame kind of aſhes.

tion on the fire, they aſſume the figure of very thin tranſparent blades of extraordinary magnitude, which, by an aſſemblage of lines croſſing each other in prodigious numbers, preſent an aggregate of cells or cavities, commonly ſo very cloſe, that the veſſel may be inverted without loſing one drop of the liquid which it contains†.

Pure potaſs is ſo exceedingly corroſive, that when applied to any part of the body, it deſtroys it almoſt inſtantaneouſly. On account of this property, it has been called *cauſtic*, and is often uſed by ſurgeons under the name of the *potential cautery*, to open abſceſſes, and deſtroy uſeleſs or hurtful excreſcences.

373
Black's diſcovery of the cauſe of its cauſticity.

As potaſs is never obtained at firſt in a ſtate of purity, but always combined with carbonic acid, it was long before chemiſts underſtood to what the changes produced upon it by lime were owing. According to ſome, it was deprived of a quantity of mucilage, in which it had formerly been enveloped; while, according to others, it was rendered more active by being more comminuted. At laſt, in 1756, Dr Black publiſhed the celebrated experiments which we have ſo often mentioned; in which he proved, by the moſt ingenious and ſatisfactory analyſis, that the *potaſs* which the world had conſidered as a ſimple ſubſtance, was really a compound, conſiſting of potaſs and carbonic acid; that lime deprived it of this acid; and that it became more active by becoming more ſimple.

374
Meyer's theory.

While Dr Black was thus occupied in Scotland, Mr Meyer was employed in Germany in the ſame reſearches; from which, however, he drew very different concluſions. His Eſſays on Lime appeared in 1764. Pouring into lime-water a ſolution of potaſs (*carbonat of potaſs*), he obtained a precipitate, which he found not to differ from limeſtone. The alkali had therefore deprived the lime of its cauſticity and its active properties; and theſe very properties it had itſelf acquired. From which he concluded, that the cauſticity of lime was owing to a particular acid with which it had combined during its calcination. The alkali deprived the lime of this acid, and therefore had a ſtronger affinity for it. To this acid he gave the name of *acidum pingue* or *cauſticum*. It was, according to him, a ſubtile elaſtic mixt, analogous to ſulphur, approaching very nearly to the nature of fire, and actually compoſed of an acid principle and fire. It was expanſible, compreſſible, volatile, aſtringent, capable of penetrating all veſſels, and was the cauſe of cauſticity in lime, alkalies, and metals. This theory was exceedingly ingenious, and it was ſupported by a vaſt number of new and important facts. But notwithſtanding the reputation and acknowledged genius and merit of its author, it never gained many followers; becauſe the true theory of cauſticity, which had been already publiſhed by Dr Black, ſoon became known on the continent; and, notwithſtanding ſome oppoſition at firſt, ſoon carried conviction into every unprejudiced mind. Even Mr Meyer himſelf readily acknowledged its truth and importance, though he did not at firſt, on that account, give up his own theory.

When potaſs is expoſed to the action of fire, it firſt becomes ſoft, and melts into a tranſparent liquid at the commencement of ignition.

When expoſed to the air, it attracts moiſture very faſt, and is ſoon converted into a liquid. It attracts, at the ſame time, carbonic acid gas, for which it has a very ſtrong affinity. It is impoſſible, then, to keep potaſs in a ſtate of purity, except in very cloſe veſſels.

375
Sulphuret of potaſs.

It unites readily with ſulphur, and forms *ſulphuret of potaſs*. This compound may be formed two ways; either by melting the ingredients together, or by boiling them in water, and then filtrating the ſolution. Sulphuret of potaſs when dry, in which ſtate it is obtained by the firſt proceſs, is of a brown colour. It is ſoluble in water, and very ſoon attracts moiſture.

While dry it produces no change upon the air of the atmoſphere, as Meſſrs Dieman, Van Trooſtwyck, Nieuwland, and Bondt, aſcertained by experiment *. But when moiſtened with water, it very ſoon abſorbs all the oxygen gas which happens to be in the veſſel in which it is encloſed, and leaves nothing but azotic gas. This fact was firſt obſerved by Scheele, and induced him to uſe ſulphuret of potaſs for an *eudiometer*, or inſtrument to meaſure the quantity of oxygen contained in any given portion of atmoſpheric air.

If ſulphuret of potaſs be allowed to remain moiſt, and in contact with the atmoſphere, it is gradually converted into ſulphat of potaſs by the ſulphur combining with oxygen, and forming ſulphuric acid. At the ſame time the ſulphuret emits a fetid ſmell, which is known to be the odour of ſulphurated hydrogen gas. The ſulphuret then decompoſes the water with which it is mixed. Very little ſulphurated hydrogen gas, however, is emitted, except an acid (the ſulphuric, for inſtance) be poured upon the mixture, and then it is given out very copiouſly. The reaſon of this is, that there is an affinity between the potaſs and this gas. Accordingly it is retained by the potaſs after it is formed. But as the acids have a much ſtronger affinity for potaſs, as ſoon as any of them is poured in the gas is obliged to ſeparate †.

If liquid ſulphuret of potaſs be kept in cloſe veſſels, it is not decompoſed except in part; becauſe as ſoon as the alkali is ſaturated with the ſulphurated hydrogen gas, the action of the ſulphur on the water is at an end ‡.

The explanation of the action of this ſulphuret on the atmoſphere, which the Dutch chemiſts above-mentioned give from theſe data, is as follows:

Sulphuret of potaſs decompoſes water; ſulphurated hydrogen gas is formed, and abſorbed by the alkali. This gas has a ſtrong affinity for oxygen, which it abſorbs from the atmoſphere: the hydrogen combines with this oxygen, and forms water; and the ſulphur is again precipitated, or rather left combined with the potaſs. Water is again decompoſed by the attraction of the ſulphur for oxygen; new ſulphurated hydrogen gas is again formed; again abſorbed; again attracts oxygen gas; and is again decompoſed. And this proceſs goes on till the whole of the ſulphur has combined with oxygen, and conſequently till the ſulphuret is converted into a ſulphat §.—The only part of this theory which requires confirmation, is the action of ſulphurated hydrogen gas on oxygen gas, and the conſequent formation of water. And this they have rendered not improbable, by ſhewing that ſulphurated hydrogen gas combined with alkali has the property of abſorbing oxygen gas from the atmoſphere ||.

376
Phoſphuret of potaſs.

Potaſs unites with phoſphorus by fuſion, and forms a phoſphuret of potaſs. Little is known concerning its properties, except that it produces phoſphurated hydrogen gas.

Potaſs ſeems alſo capable of combining with carbon.

Potaſs does not combine with the metals; but it unites with many of their oxides.

When

---

* Nicholſon, i. 164.

* Ann. de Chim. xiv. 294.

† Ibid.

‡ Ibid.

§ Ibid.

|| Ibid. p. 305.

When a ſolution of potaſs is boiled upon ſilica recently procured, it diſſolves part of it. As the ſolution cools, it aſſumes the appearance of a jelly, even though previouſly diluted with 17 times its own weight of water *.

* Bergman, ii. 32.

377 Glaſs. When equal parts of ſilica and potaſs are melted together, they combine and form *glaſs*. A ſubſtance which, whether we conſider its hardneſs, beauty, and tranſparency, its amazing ductility, while hot, or the difficulty of decompoſing it, muſt be allowed to be one of the moſt uſeful compounds ever invented by man.

When the quantity of potaſs is double or triple that of the ſilica, the glaſs is ſoluble in water, and forms what is called *liquor ſilicum*.

Potaſs ſeems alſo capable of combining in the ſame manner with barytes, lime, magneſia, and alumina; but theſe combinations have never been examined with attention. Lime, however, is often added to the materials for making glaſs, and is ſuppoſed to increaſe its hardneſs and ſolidity.

The metallic oxides have the property of rendering glaſs more fuſible, and of communicating various colours to it; they accordingly very often make a part of its compoſition. The colours communicated by theſe oxides will appear from the following Table:

Metallic Oxides.	Colour communicated to Glaſs.
Oxide of gold and tin, -	Purple.
Silver, - - -	Yellow or golden.
Iron, - - -	Pale green.
Lead, - - -	Colourleſs.
Zinc, - - -	White.
Antimony, -	Green (N).
Arſenic, - -	White.
Cobalt, - - -	Blue.
Nickel, - - -	Blue (O).
Mangaueſe, -	Red.
Tungſten, - -	Colourleſs.
Molybdenum, -	Colourleſs.
Uranium, - -	Grey (opaque).
Titanium, - -	White (opaque).
Tellurium, - -	White.
Chromum, - -	Green.

378 Soap. Potaſs combines readily with fixed oils, and forms the compound known by the name of *ſoap*.

379 Potaſs, whether a compound. Potaſs has never yet been decompoſed. Several chemiſts, indeed, have conjectured, that it was a compound of lime and azot; and ſome perſons have even endeavoured to prove this by experiment; but none of their proofs are at all ſatisfactory. We ought, therefore, in ſtrict propriety, to have aſſigned it a place in the firſt part of this article: but this would have ſeparated the alkalies from each other, and would have introduced a confuſion into the article, which would have more than counterbalanced the logical exactneſs of the arrangement. Beſides, we are certain, from a variety of facts, that all the alkalies are compounds: One of them has actually been decompounded; and the other two have been detected in the act of formation, though the ingredients which compoſe them have not hitherto been diſcovered.

Whether potaſs contains lime is a different queſtion. Were we to judge from analogy, we ſhould ſuppoſe, that the four alkaline earths, and the three alkalies, poſſeſs one common principle. They have a great number of common properties, and perhaps ought to be claſſed altogether under the name of *alkalies*.

That azot enters into the compoſition of all theſe bodies, as Fourcroy has conjectured, is far from improbable. One alkali, as we ſhall ſoon ſee, actually contains azot. But no concluſion can be drawn till future diſcoveries have lifted off the veil which at preſent obſtructs our view.

380 Its affinities. The affinities of potaſs are as follows:

Sulphuric acid,
Nitric,
Muriatic,
Sebacic,
Fluoric,
Phoſphoric,
Oxalic,
Tartarous,
Arſenic,
Succinic,
Citric,
Formic,
Lactic,
Benzoic,
Sulphurous,
Acetous,
Saccholactic,
Boracic,
Nitrous,
Carbonic,
Pruſſic,
Oil,
Sulphur,
Phoſphorus,
Water.

The place of the metallic oxides has not yet been aſcertained.

SECT. II. *Of Soda.*

SODA, called *mineral alkali*, becauſe it is found in the earth, was known to the ancients under the names of νιτρον and *nitrum* (P). It was long confounded with potaſs; and perhaps was never properly diſtinguiſhed from it till Du Hamel publiſhed a paper on the ſubject in 1736.
