212. But he found the diſſipation greatly affected by the different ſtates of humidity of the air. Sauſſure's hygrometer has its ſcale diſtinctly related to the quantity of water diſſolved in a cubic foot of the air. The following little Table ſhews an evident relation to this in the diſſipation of electricity:

Hygrometer.	Grains water in cubic foot.	Diſſipation per minute.
69	6,197	$\frac{1}{60}$
75	7,295	$\frac{1}{41}$
80	8,045	$\frac{1}{29}$
87	9,221	$\frac{1}{14}$

Hence it follows, that the diſſipation is very nearly in the triplicate ratio of the moiſture of the air. Thus if

$$\frac{60}{41} \text{ be conſidered as } = \left.\overline{\frac{7,197}{6,180}}\right|^{m} \text{ we have } m = 2,764$$

$$\frac{60}{29} \;\ldots\ldots\; = \left.\overline{\frac{8,045}{6,180}}\right|^{m} \text{ gives } \quad m = 2,76$$

$$\frac{60}{14} \;\ldots\ldots\; = \left.\overline{\frac{9,220}{6,180}}\right|^{m} \text{ gives } \quad m = 3,61$$

Hence, at a medium, $m = 3,40$.

We ſhould have obſerved, that the ingenious author took care to ſeparate this diſſipation by immediate contact with the air, from what was occaſioned by the imperfect inſulation afforded by the ſupports.

213 Diminution of repulſion is double of the diſſipation.

It muſt alſo be remarked here, that the immediate object of obſervation in the experiments is the diminution of repulſion. This is found to be, in any given ſtate of the air, a certain proportion of the whole repulſion at the moment of diminution: but this is double of the proportion of the denſity of the electric fluid: for it muſt be recollected, that the repulſions by which we judge of the diſſipation are mutual, exerted by every particle of fluid in the ball *t* of Coulomb's electrometer, on every particle in the ball *a*. It is therefore proportional to the electric denſity of each; and therefore, during the whole diſſipation, the denſities retain their primitive proportion; therefore, the diminution of the repulſion being as the diminution of the products of the denſities, it is as the diminution of the ſquares of either. If therefore the denſity be repreſented by d, the mutual repulſion is repreſentable by d^2, and its momentary diminution by the fluxion of d^2; that is, by $2\dot{d}d$, or $2\dot{d} \times d$. Now $2\dot{d} \times d$ is to d^2 as $2\dot{d}$ is to d; and therefore the diminution of repulſion obſerved in our experiment bears to the whole repulſion twice as great a proportion as the diminution of denſity, or the quantity of fluid diſſipated bears to the whole quantity at the moment. For example, if we obſerve the repulſion diminiſhed $\frac{1}{40}$, we conclude that $\frac{1}{80}$ of the fluid has eſcaped.

214. Mr Coulomb has not examined the proportion between the diſſipations from bodies of different ſizes. A great and a ſmall ſphere, communicating by a very long canal, have ſuperficial denſities, and tendencies to eſcape, inverſely proportional to the diameters. A body of twice the diameter has four times the ſurface; and tho' the tendency to eſcape be twice as ſmall, the ſurface is four times as great. Perhaps the greater ſurface may compenſate for the ſmaller denſity, and the quantity of fluid actually gone off may be greater in a large ſphere. This may be made the ſubject of trial.

215 Diſſipation depends on the ſtate of the air.

It muſt be kept in mind, that the law of diſſipation aſcertained by theſe experiments, relates to one given ſtate of the air, and that it does not follow that in another ſtate, containing perhaps the ſame quantity of water, the diſſipation ſhall be the ſame. The air is ſuch a hetea heterogeneous and variable compound, that it may have very different affinities with the electric fluid. Mr Coulomb thought that he ſhould infer from his numerous experiments, that the diſſipation did not increaſe in the ratio of the cube of the water diſſolved in the air, unleſs it was nearly as much as it could diſſolve in that temperature This indeed is conformable to general obſervation: for air is thought dry when it dries quickly any thing expoſed to it; that is, when not nearly ſaturated with moiſture. Now it is well known, that what is thought dry air is favourable to electricity.

216 Diſſipation by imperfect inſulators.

The diſſipation along imperfect inſulators is brought about in a way ſomewhat different from the manner of its eſcaping by electrifying the contiguous air and going off with it. It ſeems to be chiefly, if not ſolely, along the ſurface of the inſulating ſupport that the electricity is diffuſed, and that the diffuſion is produced there chiefly by the moiſture which adheres to it. It is not very eaſy to form a clear notion of the manner, but Mr Coulomb's explanation ſeems as ſatisfactory as any we have ſeen.

Procedure thereof.

Water adheres to all bodies, ſticking to their ſurfaces. This adheſion prevents it from going off when electrified; and it is therefore ſuſceptible of a higher degree of electrification. If we ſuppoſe that the particles of moiſture are uniformly diſpoſed along the ſurface, leaving ſpaces between them, the electricity communicated to one particle muſt attain a certain denſity before it can fly acroſs the inſulating interval to the next. Therefore, when ſuch an imperfect conductor is electrified at one end, the electricity, in paſſing to the other, will be weakened at every ſtep. If we take three adjacent particles *a*, *b*, *c*, of this conducting matter, we learn, from nº 105, that the motion of *b* is ſenſibly affected only by the difference of *a* and *c*; and therefore that the paſſage of electricity from *b* to *c* requires that this difference be ſuperior or equal to the force neceſſary for clearing this coercive interval. Let a particle paſs over. The electric denſity of the particle *b* of conducting matter is diminiſhed, while the denſity of the particle on the other ſide of *a* remains as before. Therefore ſome will paſs from *a* to *b*, and from the particle preceding *a* to *a*; and ſo on, till we come to the electrified end of this imperfect inſulator. It is plain from this conſideration, that we muſt arrive at laſt at a particle beyond *c*, where the whole repulſion of the preceding particle is juſt ſufficient to clear this interval. Some will come over, whoſe repulſion, now acting in the oppoſite direction, will hinder any fluid from ſupplying its place in the particle which it has quitted. Here the transference will ſtop, and beyond this the inſulation is complete. There is therefore a mathematical relation between the inſulating power and the length of the canal, which may be aſcertained by our theory; and thus another opportunity obtained for comparing it with obſervation. That this inveſtigation may be as ſimple as poſſible, we may take a very probable caſe, namely, where the inſulating, or, to name it more graphically, the coercive, interval is equal in every part of the canal.

217 Theory thereof.

Let R be the coercive power of the inſulator; that is, let R be the force neceſſary for clearing the coercive interval. Let a ball C (fig. 36.) be ſuſpended by a ſilk thread AB, and let C repreſent the quantity of its redundant fluid; and let the denſity in the different points of the canal be as the ordinates AD, P*d*, &c. of ſome curve line D*d*B, which cuts the axis in B where the thread begins to inſulate completely. Let P*p* be an element of the axis. Draw the ordinate *pf*, the tangent *df*F, and the normal *d*E, and *fe* perpendicular to P*d*. Let AC be = *r*, AP = *x*, P*d* = *y*. Then P*p* = $\dot{x}$, and *de* = $-\dot{y}$. We have ſeen that the only ſenſible action on the particle of fluid in P is $-\frac{y\dot{y}}{\dot{x}}$ (ſee nº 105), when the action of the redundant fluid in the globe on the particle P, having the denſity *y*, is repreſented by $\frac{Cy}{(r+x)^2}$. Therefore we have $\frac{y\dot{y}}{\dot{x}} =$ R, the coercive power of the thread. This is ſuppoſed to be conſtant. Therefore $\frac{Pd \times de}{Pp}$ is equal to ſome conſtant line R. But P*p*, or *fe* : *de* = P*d* : PE. Therefore the ſubnormal PE is a conſtant line. But this is the property of the parabola alone; and the curve of denſity D*d*B is a parabola, of which the parameter is 2 PE, or 2 R.

218 Variation of denſity in the inſulator.

Cor. 1. The denſities in different points of an imperfect inſulator are as the ſquare roots of their diſtance from the point of complete inſulation: For $Pd^2 : AD^2 = BP : BA$.

219 Length neceſſary for inſulation ÷ denſity².

2. The length of canal required for inſulating different denſities of electricity are as the ſquares of the denſities. For $AB = \frac{AD^2}{2PE}$; and PE has been ſhewn to be a conſtant quantity. Indeed we ſee in the demonſtration, that BP would inſulate a ball, whoſe electric denſity is P*d*, and $BA : BP = AD^2 : Pd^2$.

220 Alſo ÷ $\frac{1}{\text{coercion}}$.

3. The length neceſſary for inſulation is inverſely as the coercive force of the canal, and may be repreſented generally by $\frac{D^2}{R}$. For AB is $= \frac{DA^2}{2PE} = \frac{D^2}{2R}$.

Mr Coulomb has verified theſe concluſions by a very ſatisfactory ſeries of experiments, by the aſſiſtance of his delicate electrometer, which is admirably ſuited for this trial. The ſubject is ſo intereſting to every zealous ſtudent of electricity, that Mr Canton, Dr B. Wilſon, Mr Waitz, Wilcke, and others, have made experiments for eſtabliſhing ſome meaſure of the conducting powers of different ſubſtances. It was one of the firſt things that made the writer of this article ſuppoſe that electric action was in the inverſe duplicate ratio of the diſtances: for, as early as 1763, he had found that the lengths of capillary tubes neceſſary for inſulation were as the ſquares of the repulſions of the ball which they inſulated. The mode of reaſoning offers of itſelf, and the fluxionary expreſſion of the inſulating power, *viz.* $\frac{d\dot{d}}{\dot{x}}$ led immediately to a force proportional to $\frac{1}{x^2}$. Numerous experiments were made, which we do not give here, becauſe the public are already poſſeſſed of thoſe of Mr Coulomb.

Explanation of the efficacy of Volta's *condenſer*.

This diſcuſſion explains, in a ſatisfactory manner, the operation of the condenſer, as deſcribed by Mr Volta. The weak degrees of electricity, which are rendered ſufficiently ſenſible by the inſulation of the plate of dry marble, are completely inſulated by the perhaps thin ſtratum that has been ſufficiently dried, while the reſt conducts with an efficacy ſufficient for permitting the accumulation.

221. When we reflect on the theory now delivered, we ſee that the formulæ determine the diſtribution of the fluid along an imperfect conductor in a certain manner, on the ſuppoſition that a *certain determinate* doſe has been imparted to the ball: Becauſe this doſe, by diffuſing itſelf from particle to particle of the conducting matter, will diffuſe itſelf all the way to B, in ſuch a manner that the repulſion ſhall everywhere be in equilibrio with the *maximum* of the coercive force of the inſulating interval. But it muſt be farther noticed, that this reſiſtance is not *active*, but coercitive, and we may compare it to friction or viſcidity. Any repulſion of electric fluid, which falls ſhort of this, will not diſturb the ſtability of the fluid ſpread along the canal, according to any law whatever. So that if AD repreſent the electric denſity of the globe, and remain conſtant, any curve of denſity will anſwer, if $\frac{d\dot{d}}{x}$ be everywhere leſs than R. It is therefore an indeterminate problem to aſſign, in general, the diſpoſition of fluid in the canal. The denſity is as the ordinates of a parabola only on the ſuppoſition that the maximum of R is everywhere the ſame. And, in this caſe, the diſtances AB is a minimum: for, in other caſes of denſity, we muſt have $\frac{d\dot{d}}{\dot{x}}$ leſs than R. If, therefore, we vary a ſingle element of the curve D d B, in order that the ſtability of the fluid may not be diſturbed, having $\dot{d}$ conſtant, we muſt neceſſarily have $\dot{x}$ larger, that $\frac{d\dot{d}}{\dot{x}}$ may ſtill be leſs than R; that is, we muſt lengthen the axis.

We ſee alſo, that to aſcertain the diſtribution in a conducting canal is a determinate problem; whereas, in imperfect conductors, it is indeterminate, but limited by the ſtate of the fluid, when it is ſo diſpoſed that in every point the action of the fluid is in equilibrio with the maximum of reſiſtance. This conſideration will be applied to a valuable purpoſe in the article MAGNETISM.

222 Explanation of a curious and important fact; and method of increaſing a charge.

This doctrine gives, in our opinion, a very ſatisfactory explanation of the curious obſervations of Mr Brookes and Mr Cuthbertſon, mentioned in nº 167. namely, that damping the inſide of a coated jar diminiſhes the riſk of exploſion, and enables it to hold a higher charge. We learn here, that there is no denſity ſo great but that the leaſt imperfect conductor will inſulate it, if long enough; and that the coercive quality of an imperfect conductor may be conceived ſo conſtituted from A towards B, that the denſities ſhall diminiſh in any ratio that we pleaſe, ſo that the variation of denſity (the cauſe of motion) may everywhere, even to the inſulating point B, be very ſmall. However great the conſtipation at the edge of the metallic coating may be, an imperfect conductor may be continued outward from that edge, and may be ſo conſtituted, that the conſtipation ſhall diminiſh by ſuch gentle gradations, that an exploſion ſhall be impoſſible. An uniform dampneſs will not do this, but it will diminiſh the abruptneſs of the variation of denſity. The ſtate of denſity beyond the edge of the coating of a charged jar, very clean and dry, may be repreſented by the parabolic arch D i a. This may be changed by damping, or properly dirtying (to uſe Mr Brookes's phraſe), to D f B; which is evidently preferable. We think it by no means difficult to contrive ſuch a continuation of imperfectly conducting coating. Thus, if gold leaf can be ground to an impalpable powder, it may be mixed with an oil varniſh in various proportions. Zones of this gold varniſh may be drawn parallel to the edge of the coating, decreaſing in metal as they recede from the edge. By ſuch contrivances it may be poſſible to increaſe the retentive power to a great degree.

223 Cautions in deducing meaſures from experiments.

This doctrine farther teaches us, that many precautions muſt be taken when we are making experiments from which meaſures are to be deduced; and it points them out to the mathematician. In particular, when bodies, ſupported by inſulators, are electrified to a high degree, the ſupports may receive a quantity of fluid, which may greatly diſturb the reſults; and this quantity, by exerting but a weak action on the parts of the canal, may continue for a very long time, and not be removed but with great difficulty. In ſuch caſes, it will be neceſſary to uſe new ſupports in every experiment. Not knowing, or not attending to this circumſtance, many erroneous opinions have been formed in ſome delicate departments of electrical reſearch.

Mr Coulomb's experiments on this ſubject are chiefly valuable for having ſtated the relation between the intenſity of the electricity, or, as he expreſſes it, the electric denſity, and the lengths of ſupport neceſſary for the complete inſulation. But, as the abſolute intenſities have all been meaſured by his electrometer, and he has not given its particular ſcale, we cannot make much uſe of them till this be done by ſome electrician.

224 Inſulating powers of various ſubſtances.

Mr Coulomb found that a thread of gum lac was the moſt perfect of all inſulators, and is not leſs than ten times better than a ſilk thread as dry as it can be made, if we meaſure its excellence by its ſhortneſs. In a conſiderable number of experiments, he found that a thread of gum lac, of 1,5 inches long, inſulated as well as a fine ſilk thread of 15 inches. When the thread of ſilk was dipped in fine ſealing-wax, it was equal to the pure lac, if ſix inches long, or four times its length. If we meaſure their excellence by the intenſities with which they inſulate, lac is three times better than the dry thread, and twice as good as the thread dipped in ſealing-wax: ſo that a fibre of ſilk, even when included in the lac, diminiſhes its inſulating power. We alſo learn that the diſſipation along theſe ſubſtances is not entirely owing to moiſture condenſed or adherent on their ſurfaces, but to a ſmall degree of conducting power. We have repeated many of theſe experiments, and find that the conducting power of ſilk thread depends greatly on its colour. When of a brilliant white, or if black, its conducting power ſeems to be the greateſt, and a high golden yellow, or a nut brown, ſeemed to be the beſt inſulators; doubtleſs the dyeing drug is as much concerned as the fibre.

Glaſs, even in its dryeſt ſtate, and in ſituations where moiſture could have no acceſs to it, *viz.* in veſſels containing cauſtic alkali dried by red heat, or holding freſh made quicklime, appeared in our experiments to be conſiderably better than ſilk; and where drawn into a ſlender thread, and covered with gum lac (melted), inſulated when three times the length of a thread of lac; but we found at the ſame time, that extreme fineneſs was neceſſary, and that it diſſipated in proportion to the ſquare of its diameter. It was remarkably hurt by having a bore, however fine, unleſs the bore could alſo

be

be coated with lac. Human hair, when completely freed from every thing that water could waſh out of it, and then dried by lime, and coated with lac, was equal to ſilk. Fir, and cedar, and larch, and the roſe-tree, when ſplit into filaments, and firſt dried by lime, and afterwards baked in an oven which juſt made paper become faintly brown, ſeemed hardly inferior to gum lac.

The *white woods*, as they are called, and mahogany, were much inferior. Fir baked, and coated with melted lac, ſeems therefore the beſt ſupport when ſtrength is required. The lac may be rendered leſs brittle by a minute portion of pure turpentine, which has been cleared of water by a little boiling, without ſenſibly increaſing its conducting power. Lac, or ſealing wax, diſſolved in ſpirits, is far inferior to its liquid ſtate by heat.

Theſe obſervations may be of uſe for the conſtruction of electrical machines of other electrics than glaſs.

General reflections.

We have now given a compariſon of the hypotheſis of Mr Æpinus with the chief facts obſerved in electricity, diverſified by every circumſtance that ſeemed likely to influence the reſult, or which is of importance to be known. We truſt that the reader will agree with us in ſaying that the agreement is as complete as can be expected in a theory of this kind; and that the application not only ſeems to explain the phenomena, but is practically uſeful for directing us to the procedures which are likely to produce the effect we wiſh. Thus, ſhould our phyſiological opinions ſuggeſt that copious transference of fluid is proper, our hypotheſis points out the moſt effectual and the moſt convenient methods for producing it. We learn how to conſtipate the fluid in a quieſcent ſtate, or how to abſtract as much of it as poſſible from any part of a patient; we can do this even in the internal parts of the body. We had once an opportunity of ſeeing what we thought the cure of a paralyſis of the gullet. Electricity was tried, firſt in the way of ſparks, and then ſmall ſhocks taken acroſs the trachea. Theſe could not be tolerated by the patient. The ſurgeon wiſhed to give a ſhock to the œſophagus without affecting the trachea. We recommended a leaden piſtol bullet at the end of a ſtrong wire, the whole dipped in melted ſealing wax. This was introduced a little way, we think not more than three inches, into the gullet, which the palſy permitted. A very ſlight charge was given to it in a few ſeconds; and the firſt ſhock produced a convulſion in the muſcle, and the ſecond removed the diſorder completely. Here the ball formed the inner, and the gullet the outer, coating of the Leyden phial.

The theory of Æpinus is only a hypotheſis.

Notwithſtanding the flattering teſtimony given by the great conformity of this doctrine with the phenomena, we ſtill chooſe to preſent it under the title of a hypotheſis. We have never ſeen the electric fluid in a ſeparate ſtate; nor have we been able to ſay in what caſes it abounds, or when it is deficient. After what we have ſeen in the late experiments of that philanthropic philoſopher Count Rumford on the production of heat by friction, we think that we cannot be too cautious on what grounds we admit inviſible agents to perform the operations of Nature. We think that all muſt acknowledge that thoſe experiments tend very much to ſtagger our belief in the exiſtence of a fluid *ſui generis*, a fire, heat, caloric, or what we pleaſe to call it; and all will acknowledge, that no better proofs can be urged for the exiſtence of an electric fluid.

225

The reality of an electric fluid is denied.

Accordingly, many acute and ingenious perſons have rejected the notion of the exiſtence of an electric fluid and have attempted to ſhew that the phenomena proceed, not from the preſence of a peculiar *ſubſtance*, but from peculiar *modes*; as we know that ſound, and ſome concomitant motions and other mechanical appearances, are the reſults of the elaſtic undulations of air; and as Lord Bacon and others have explained the effects of fire by elaſtic undulations of the integrant particles of tangible matter.

Requiſites for a juſt theory.

We have ſeen nothing, however, of this kind that appears to give any explanation of the motions, preſſures, and other mechanical appearances of electricity. We peremptorily require, that every doctrine which claims the name of an explanation, ſhall be perfectly conſiſtent with the acknowledged laws of mechaniſm; and that the explanation ſhall conſiſt in pointing out thoſe mechanical laws of which the facts in electricity are particular inſtances. It is no difficult matter to preſent an intricate or complex phenomenon to our view, in ſuch a form that it ſhall have ſome reſemblance to ſome other complex phyſical fact, more familiar, perhaps, but not better underſtood. The ſpecious appearance of ſimilarity, and the more familiar acquaintance with the other phenomenon, diſpoſe us to conſider the compariſon as a ſort of explanation, or, at leaſt, an illuſtration, and to have a ſort of indolent acquieſcence in it as a theory.

But this will not do in the preſent queſtion: For we have here ſelected a particular circumſtance, the obſerved motions occaſioned by electricity, and called *attractions* and *repulſions*—a circumſtance which admits of the moſt accurate examination and compariſon with any explanation that is attempted. In ſuch a caſe, a vague picture would ſpeedily vaniſh into air, and prove to be nothing but figurative expreſſions.

226

No advantage is gained by the hypotheſis of two fluids.

Many philoſophers, and among them ſome reſpectable mathematicians, have ſupported the doctrine of Du Fay, Symmer, Cigna, &c. who employ two fluids as agents in all electrical operations. It muſt be granted that there are ſome appearances, where the explanation by means of two fluids ſeems, at firſt ſight, more palpable and eaſier conceived. But whenever we attempt to obtain *meaſures*, and to ſay what will be the preciſe kind and degree of the action, we find ourſelves obliged to aſſign to the particles of thoſe fluids actuating mechanical forces preciſely equivalent to thoſe aſſigned by Æpinus to his ſingle fluid. Then we have to add ſome myſterious unexplained connections, both with each other and with the other particles of tangible matter. If we except Mr Prevoſt, in his *Eſſai ſur les Forces Magnetiques et Electriques*, we do not recollect an author who has ventured to ſubject his ſyſtem to ſtrict examination, by pointing out to us the laws of action according to which he conceives the particles influence each other. We ſhall have a proper opportunity, in the article Magnetism, to give this author's theory the attention it really merits. We venture to ſay, that all the chemical theories of electricity labour under theſe inconveniences, and have acquired their influence merely from the inattention of their partiſans

tiſans to the laws of mechanical motion, and require, in order to reconcile them with theſe laws, the adoption of powers ſimilar to Æpinus's attractions and repulſions. Slight reſemblances to phenomena, which ſtand equally in need of explanation, have contented the partiſans of ſuch theories, and figurative language and metaphorical conceptions have taken place of preciſe diſcuſſion. It would be endleſs to examine them all.

227 Hypotheſis of Profeſſor Ruſſel.

The moſt ſpecious of any that we know was publicly read in the univerſity of Edinburgh by the late Mr James Ruſſel, Profeſſor of natural philoſophy; a perſon of the moſt acute diſcernment, and an excellent reaſoner. It was delivered to his pupils, not as a *theory*, but as a *conjecture*, founded on Lord Kames's theory of ſpontaneous evaporation, which had obtained a very general reception; a conjecture, ſaid the Profeſſor, founded on ſuch reſemblances as made a ſimilarity of operation very probable, and was an incitement and direction to the philoſopher to a proper train of experimental diſcuſſion. We ſay this on the authority of his pupils in the years 1767, 1768, and 1769, and of ſome notes in his own hand-writing now in our poſſeſſion.

Mr Ruſſel conſidered the electrical phenomena as the reſults of the action of a ſubſtance which may be called the *electrical fluid*, which is connected with bodies by attractive and repulſive forces acting at a diſtance, and diminiſhing as the diſtance increaſes.

Mr Ruſſel ſpeaks of the electric fluid as a compound of ſeveral others; and, particularly, as containing elementary fire, and deriving from it a great elaſticity, or mutual repulſion of its particles. This, however, is different from the elaſticity or mutual repulſion of the particles of air, becauſe it acts at a diſtance; whereas the particles of air act only on the adjoining particles. By this conſtitution, bodies containing more electric fluid than the ſpaces around them repel each other.

The particles of this electric fluid attract the particles of other bodies with a force which diminiſhes by diſtance.

The characteriſtic ingredient of this fluid is *ELECTRICITY properly ſo called*. This is united with the elaſtic fluid by chemical affinity, which Mr Ruſſel calls *elective attraction*, a term introduced into chemiſtry by Dr Cullen and Dr Black. This extends to all diſtances, but not preciſely by the ſame law as the mutual repulſion of the particles of the other fluid, and in general, it repreſſes the repulſions of that fluid while in this ſtate of compoſition. This *electricity*, moreover, attracts the particles of other bodies, but with certain elections. Non-electric or conducting bodies are attracted by it at all diſtances, but electrics act on it only at very ſmall and inſenſible diſtances. At ſuch diſtances its particles alſo attract each other.

By this conſtitution, the compound electric fluid repels its own particles at all conſiderable diſtances, but attracts at very ſmall diſtances. It attracts conducting bodies at all diſtances, but non-conductors only at very ſmall diſtances. The phenomena of light and heat are conſidered as marks of partial decompoſition, and as proofs of the preſence of elementary fire in the compound: the ſmell peculiar to electricity, and the effect on the organ of taſte, are proofs of decompoſition and of the complex nature of the fluid.

Bodies (conductors) containing electric fluid, repel each other at conſiderable diſtances, but, if forced very near, attract each other. Electrics can contain it only in conſequence of the *electricity* in the compound. Part of this electricity muſt be attached to the ſurface in a non-elaſtic ſtate; becauſe when it is brought ſo near as to be attracted, its particles are within the ſpheres of each other's action, and this redoubled attraction overcomes the repulſion occaſioned by its union with the other ingredient; and the electric fluid is partly decompoſed, and the *electricity*, properly ſo called, adheres to the ſurface of the electric, *as the water of damp air adheres to a cold pane of glaſs in our windows*. Alſo, by this conſtitution, electric fluid may appear in two ſtates; elaſtic, like air, when entire; and unelaſtic, like water, when partly decompoſed by the attraction of electrics.

Electricity may be forced into this unelaſtic union by various means; by friction, which forces the electric fluid contained in the air into cloſe contact, and thus occaſions this decompoſition of the fluid and the union of its *electricity* with the ſurface. This operation is compared by Mr Ruſſel to the forcible wetting of ſome powders, ſuch as lycoperdon, which cannot be wetted without ſome difficulty and mechanical compreſſion; after which it adheres to water ſtrongly. It may be thus united in ſome natural operations, as is obſerved in the melting and freezing of ſome ſubſtances in contact with electrics; and it may be thus forced into union by means of metallic coatings, into which the electric fluid is forced by an artful employment of its mutual repulſions. This operation is compared to the condenſation of the moiſture of damp air by a cold pane of the window; and the evacuation of the other ſide of the coated pane is compared to the evaporation of the moiſture from the other ſide of the window, pane in conſequence of the heat which muſt emerge from the condenſed vapour. We find in the Profeſſor's notes above-mentioned many ſuch partial analogies, employed to ſhew the ſtudents that ſuch things are ſeen in the operations of Nature, and that his conjecture merits attention.

The intelligent reader will ſee that the general reſults of this conſtitution of the electric fluid will tally pretty well with the ordinary electrical phenomena; and, accordingly, this *conjecture* was received with great ſatisfaction. We remember the being much pleaſed with it, as we heard it applied by Mr Ruſſel's pupils, many of whom will recollect what is here put on record. But the attentive reader will alſo ſee, that all this intricate combination of different kinds of attraction and repulſion is nothing but mere accommodations, of hypothetical forces to the phenomena. How incomparably more beautiful is the ſimple hypotheſis of Æpinus, which, without any ſuch accommodations tallies ſo preciſely with all the phenomena that have yet been obſerved? Here no diſtinction of action is neceſſary, and all the varieties are conſequences of a circumſtance perfectly agreeable to general laws; namely, that the internal ſtructure of ſome ſubſtances may be ſuch as obſtructs the motion of the electric fluid through the pores—Nothing is more likely.

228 Hypotheſis of Mr de Luc.

Several years after the death of the Scotch Profeſſor in 1773, a theory very much reſembling this acquired great authority, being propoſed to the philoſophers by the celebrated naturaliſt Mr de Luc. This gentleman having long cultivated the ſtudy of meteorology with unwearied aſſiduity and great ſucceſs, and

and having been ſo familiarly converſant with expanſive fluids, and the affinities of their compounds, was diſpoſed to ſee their operations in almoſt all the changes on the ſurface of this globe. Electricity was too buſy an actor in our atmoſphere to eſcape his particular notice. While the mechanical philoſophers endeavoured to explain its effects by accelerating forces attracting and repelling, Mr de Luc endeavoured to explain them by means of the expanſive properties of aeriform fluids and gaſes, and by their chemical affinities, compoſitions, and decompoſitions. He had formed to himſelf a peculiar opinion concerning the conſtitution of our atmoſphere, and had explained the condenſation of moiſture, whether of ſteam or of damp aeriform fluids, in a way much more refined than the ſimple theory of Dr Hooke, *viz.* ſolution in air. He conſiders the compound of air and fire as the *carrier* of the water held in ſolution in damp air, and the fire as the general carrier of both the air and the moiſture. Even *fire* is conſidered by him as a *vapour*, of which *light* is the *carrier*. When this damp air or ſteam is applied to a cold ſurface, ſuch as that of a glaſs pane, it is decompoſed. The water is attracted by the pane by chemical affinity, and attaches itſelf to the ſurface. The fire, thus ſet at liberty, acts on the pane in another way, producing the equilibrium of temperature, and the expanſion of the pane. Acting in the ſame manner on the moiſture which chances to adhere to the other ſide, in a proportion ſuited to its temperature, it deſtroys their union, enters into chemical combination with the moiſture, and fits it for uniting with the air on the other ſide, or carries it off. Having read Mr Volta's theory of *electric influences*, by which that philoſopher was enabled to give a ſcientific narration and arrangement of the phenomena of the *electrophorus* newly invented by himſelf, and which is called an explanation of thoſe phenomena, Mr de Luc imagined that he ſaw a cloſe analogy between thoſe *influences* on the plates of the electrophorus and the *hygroſcopic* phenomena of the condenſation and evaporation of moiſture. In ſhort, he was ſtruck with the reſemblance between the condenſation of moiſture on one ſide of a glaſs pane, and its evaporation from the other; and the accumulation of electric fluid on one ſide of a coated pane, and the abſtraction of it from the other. Subſequent examination pointed out to him the ſame analogy between all other *hygroſcopic* and *electric* phenomena.

He therefore immediately formed a ſimilar opinion concerning the electric operations. It may be expreſſed briefly as follows:

229. The electrical phenomena are the operations of an expanſive ſubſtance, called the *electric fluid*. This conſiſts of two parts: 1. *Electric matter*, which is the gravitating part of the compound; and *electric deferent fluid*, or *carrying fluid*, by which alone the electric matter ſeems to be carried from one body to another. The reſemblance between the hygroſcopic and electrical phenomena are affirmed to be *.

1. As watery vapour or ſteam is compoſed of fire, the deferent fluid, and water, the gravitating part, ſo *electric fluid* is compoſed of the *electric deferent fluid*, and *electric matter*.

2. As *vapours* are partly decompoſed when too denſe for their temperature, and then their *deferent fluid* becomes free, and ſhews itſelf as *fire*; ſo *electric fluid* that is too denſe is decompoſed, and its *deferent fluid* manifeſts itſelf in the *phoſphoric* and *fiery* phenomena of *electricity*.

3. As *fire* quits the *water* of *vapour*, to unite itſelf with a body leſs warm; ſo the *electric deferent* quits the *electric matter*, in part, to go to other bodies which have proportionally leſs of it.

In this analogy, however, there is a diſtinction. *Fire*, in quitting the *water* in *vapour*, remains actuated by nothing but its expanſive force; remains free, and extends itſelf till the equilibrium of temperature is reſtored; but the *electric deferent*, when diſengaged from *electric matter*, in order to reſtore its peculiar equilibrium, is actuated by *tendencies* to diſtinct bodies, and acts by this *tendency* in thus reſtoring the *electric equilibrium*; and it is only in conſequence of this *tendency* that it quitted the *electric matter*. This *tendency* is then directed to ſome body in the vicinity.

4. As the *fire* of *vapour* pervades all bodies, to reſtore the *equilibrium of temperature*, depoſiting the *water*; ſo the *electric deferent* quits the *electric matter*, to reſtore the *electric equilibrium* in an inſtant, and for this purpoſe pervades all bodies, depoſiting on them the *electric matter* which it carried, but differently, according to their natures.

5. As *fire* and *water*, while compoſing *vapour*, retain their *tendencies* and *affinities* by which they produce the *hygroſcopic* phenomena; ſo the ingredients of the *electric fluid*, even in their ſtate of union, retain their *tendencies* and *affinities*, which produce the greateſt part of the *electric phenomena*.

6. In particular, the *electric matter* retains its *tendencies* and *affinities*; and farther, the *electric affinities* are, like the *hygroſcopic*, without any choice.

Here, however, there is a farther diſtinction. The affinities of *water* reſpect only *hygroſcopic* ſubſtances; but thoſe of *electric matter* reſpect all ſubſtances, and therefore reſpect the common atmoſpheric fluids.

7. When *fire* quits the *water* of *vapour*, to form the *equilibrium of temperature*, it remains in the place where *vapour* moſt abounds, but is partly *latent*, not exerting its powers; ſo in the reſtoration of the equilibrium of the *electric deferent* among neighbouring bodies, thoſe which have proportionally moſt *electric matter* alſo retain moſt *deferent fluid*, but in a *latent* ſtate.

8. As two maſſes of *vapour* may be in *expanſive equilibrium* (which others call balancing each others elaſticity), although the *vapours* contain very different proportions of *fire* and *water*; ſo two maſſes of *electric fluid* may be in *expanſive equilibrium*, although one contains much more *electric matter* in the ſame bulk, provided that the *electric deferent* be alſo more copious.

The chief diſtinction that mingles with theſe analogies is, that the *affinity* of *water* to *hygroſcopic* ſubſtances operates only in contact, whereas *electric matter* tends to diſtant bodies; and theſe diſtances are very different in regard to different bodies.

Such is the reſemblance which has appeared ſo ſtrong to Mr de Luc. It is evidently the ſame which furniſhed the conjecture to Mr Ruſſel, and which he conſidered mechanically, in order to explain the phenomena of electric motions to ſtudents of mechanical philoſophy. The only reſemblance ſeems to us to appear in the condenſation of moiſture contained in damp air.

Mr de Luc, led by the habits of his former ſtudies, attempts,

---

* See *Idées ſur la Meteorologie*, § 266. &c.

attempts to explain every thing by the relations which were moſt familiar to him, *affinities* and *expanſive forces.* Let us attend a little to the manner in which he explains one or two of the moſt general facts.

1. *The conditions of conductors and non-conductors.*

230. This diſtinction depends on the differences in the *tendency* to diſtant bodies: there are great differences in theſe diſtances according to the nature of the bodies; and from this ariſe great differences of phenomena, independent of inſulation or non-inſulation, which are only the ſenſible diſtinctions of theſe claſſes of bodies. *Electric matter* tends to *conductors* at great diſtances; but having reached them it does not adhere, and remains free to move round them, being dragged by the *deferent fluid;* but its tendency to *non-conductors* is only at ſmall and inſenſible diſtances; and having come into contact, it adheres, and can no longer be dragged by the *deferent fluid.*

Hence the operation of *conductors* and *non conductors;* and there is no other foundation for the notion of *idio-electrics* and *non-electrics*, or electrics by communication. A part of a *non-conductor* takes as much *electric matter* as it can from the ſubſtance furniſhing it; but cannot communicate it to another part, except very ſlowly; therefore, to communicate it to the whole ſurface, we muſt cover it with a conductor (Surely this is a diſtinction in the body, independent of the diſtance of mutual tendency!).

Hence, too, the property of *non-conductors* by which the electric fluid is *benumbed* (*engourdi*) or cramped; therefore we can accumulate a great deal in them; and it will remain long, being *benumbed;* and if it be determined to quit them at once, the current will be much more denſe than when quitting an equal conducting ſurface.

Since *conductors* do not fix the *electric fluid*, it *muſt circulate round them.* It is urged to this motion by its *expanſive power*, by which it would diſperſe from a body with inconceivable velocity, and perhaps the rapidity of its motion would decompoſe it, and cauſe ſome *light* to emerge; but it is at the ſame time impelled by its *tendency* to bodies. Thus, by theſe two forces, it runs to a *conducting body*, and muſt circulate round it as the planets do round the ſun. In this circulation, if it come to any great projection, it cannot follow the outline, becauſe ſo abrupt; it therefore flies off at all points and protuberances. It will be the more difficult to keep to an abrupt outline as the ſtratum in circulation is more copious or deeper, becauſe a greater maſs is with greater difficulty turned round a ſharp angle. It is more inclined to eſcape if another body be near, and it immediately becomes a ſatellite to that body.

Thus all bodies get a ſhare of electric fluid, circulating round conductors, and *benumbed* or *cramped* in *non-conductors.* Bodies of this laſt claſs receive their portion by the air as *hygroſcopic ſubſtances* receive their water by the *fire.*

All the differences in the tendencies to bodies proceed from the *electric matter.* The *deferent fluid* follows other laws; namely, 1. Its tendency to all ſubſtances is greater than that of the *electric matter* to any one. 2. The tendency (and alſo that of the *electric matter*) is always from the body which contains moſt of it to that which contains leaſt. 3. The body which contains moſt of the one alſo contains moſt of the other. 4. The *deferent fluid* has a particular affinity (chemical) with the *electric matter.* 5. All theſe tendencies are leſſened by an increaſe of diſtance. 6. The *electric matter*, when compoſing *electric fluid*, has more or leſs *expanſive force* as it is united to more or leſs *deferent fluid.*

Explanation of Charged Plates.

231. Mr de Luc ſays (§ 286.), that his SYSTEM was ſuggeſted by Volta's *Theory of Electric Influences.* Theſe (ſays he) had been pretty well generaliſed before, but with little improvement to the ſcience, till Mr Volta diſcovered a circumſtance which, in his opinion, connected by a general theory many phenomena which had formerly no obſerved relation to any thing. This was, that *when a body electrified poſitively brings a neighbouring body communicating with the ground into the negative ſtate, its own poſitive electricity is weakened while it remains in that neighbourhood, but is recovered when the other body is removed.* " Such is the diſtinguiſhing law of Mr Volta's theory, which brings all the phenomena of electric influences under his theory, beginning with thoſe of coated glaſs, which were formerly ſo obſcure, becauſe they were not referred to their true cauſe, &c.

" My SYSTEM (Mr de Luc ſays) concerning the nature of the *electric fluid* explains the laws of Mr Volta's theory; and of conſequence explains, like it, all the phenomena which it comprehends: but it reaches much farther, ſeeing that more general laws comprehend a greater number of phenomena.

" In the phenomena of coated glaſs, I plainly ſaw one of the procedures of *watery vapour.* Suppoſe a glaſs pane, moiſtened on both ſides, and having the temperature of the ſurrounding bodies. Suppoſe that warmer *vapour* comes to one ſide. It is condenſed on the ſurface; that is, it is decompoſed, the *water* adheres to the ſurface, and the *fire* penetrates the glaſs, heats it, and increaſes the evaporation from the other ſide, by entering into combination with the *water*, and carrying it off with it. More *vapour* is condenſed on the ſide A; more *fire* reaches the ſide B, and carries off more *water.* But as this happens only becauſe the *fire* alſo raiſes the *temperature* of the pane, it is evident that the condenſation on the ſide A, and the evaporation from B, muſt gradually ſlacken, and the *maximum of accumulation* in A, and of evaporation from B, will take place when the temperature of the pane is the ſame with that of the hot *vapour.*

" The electrical phenomena of coated glaſs are perfectly ſimilar. The *electric fluid* reaches the ſide A, is decompoſed, and the *electric matter* is there *benumbed* and fixed. The *deferent fluid* penetrates the pane, and carries off the *electric matter* from the ſide B. This goes on, but ſlackens; and the maximum of accumulation and evacuation obtains when the ſide A has acquired the ſame intenſity of electricity with the charging machine. More is accumulated in A than is abſtracted from B; becauſe B is farther from the ſource (he might have added, that part of the fire is expended in raiſing the temperature of the pane): but the accumulation is inactive, becauſe the *electric matter* is *benumbed* and fixed. Though the *electric matter* is much diminiſhed in B, yet the *electric fluid* in its coating has as much expanſive force as that of the ground; becauſe

becauſe it has a ſurplus of deferent fluid. The abſolute quantity of *electric matter* in both ſides is ſomewhat augmented."

132. This explanation of the Leyden phial comprehends the whole of Mr de Luc's theory; and the conſtitution of the electric fluid, and its various affinities, expanſive powers and tendencies, are all aſſigned to it in ſubſerviency to this explanation, or deduced from thoſe phenomena. As the author, in all his writings, claims ſome ſuperiority over other naturaliſts for more general and comprehenſive views, and for more ſcrupulous attention to preciſion and meaſurement, and particularly for more ſolicitude that no natural agent be omitted that has any ſhare in the procedure—he ſurely will not be offended, although we ſhould ſtate ſuch difficulties and objections as occur to us in the conſideration of this SYSTEM (as he chooſes to call it) of electricity.

We wiſh that it had been expreſſed in the plain and preciſe language of mechanical and chemical ſcience; for he reaſons entirely from the nature of expanſive forces, tendencies, and affinities. His language will appear to ſome readers, as it does to us, rather to expreſs the conduct of intelligent beings, acting with choice, and for a purpoſe, than the laws of lifeleſs matter. His account would have been leſs agreeable, it is true, but more inſtructive, and leſs apt to be miſtaken. Metaphorical language is ſeldom uſed without the riſk of metaphorical conceptions; and the reader is very apt to think that he has acquired a notion of the ſubject, while he is really thinking of a thing of a different nature. We apprehend that a great deal of this happens in this inſtance, and that when the narration is ſtripped of its figurative language, it will be found without that connection and analogy which it ſeems to poſſeſs.

We alſo wiſh that the explanation had been derived from ſome well-eſtabliſhed principle. The whole of it is *profeſſedly* founded on a reſemblance between the *phenomena* of electricity, and ſome things ſaid of watery vapour; but theſe are not the *phenomena* of watery vapour, but Mr de Luc's *hypotheſis* (he will pardon us the term, which we prefer to *ſyſtem*) concerning *watery vapours*. We do not think it philoſophical to explain one hypotheſis by another. Our illuſtrious countrymen, Bacon and Newton, diſapproved of this practice; and their rules of philoſophiſing have ſtill currency among philoſophers. Explanation, in our opinion, is the pointing out ſome acknowledged general fact in nature, and ſhewing that the particular phenomenon is an example of it. We do not ſee this in Mr de Luc's explanation; becauſe we do not ſee the *facts* in the caſe of watery vapours to which the *phenomena* of electricity are ſaid to have a reſemblance. The phenomena we mean are chiefly the *motions*, and the *transferences* of the powers producing ſuch motions; we do not ſpeak of the *light*, and ſome other phenomena, becauſe Mr de Luc does not ſpeak of them in this explanation. We ſhall even admit the *transference* as a *phenomenon*, although we do not ſee any ſubſtance transferred: but we ſee a power of producing certain motions where that power did not formerly appear; and the appearance of this power is all the authority adduced, even by Mr de Luc, for the transference. We muſt now add, that the electric phenomena, which Mr de Luc calls like the phenomena of watery vapour, are all *ſuppoſitions*; and that therefore the explanation is a ſyſtem of ſuppoſitions, *framed* ſo as to be like the ſyſtem of watery vapour. For Mr de Luc will grant, that, on the one hand, we ſee nothing like the water in the electric phenomena; and, on the other hand, there is nothing in watery vapour like the motions of the electrometers, which are the only PHENOMENA from which Mr de Luc profeſſes to reaſon.

We alſo fear that the very curious experiments of Count Rumford on the melting of ice, and the propagation of heat through liquids, will oblige Mr de Luc to change the taſks of the ingredients, both of *vapour* and of *electric* fluid. *Water*, and not *fire*, ſeems to be the *carrier* or *deferent fluid*; and we think that Franklin and Æpinus have made it highly probable that electricity, and not air, is the carrier.

We have alſo great difficulty in conceiving (indeed we cannot conceive) how the *deferent fluid*, from which the *electric matter* has been detached by its ſuperior *affinity* with the ſide A, can overcome the *ſame ſuperior affinity* of the *electric matter* with the ſide B (A), and carry it off; how the *deferent fluid* penetrates the non-conducting pane, in order to carry off the *electric matter* in the form of *fluid*; and how it cannot do this, except by means of a *conducting canal*, into which *it is expreſſly ſaid that it does not penetrate*. It muſt not be ſaid that it runs along the ſurface of this canal: for the ſmalleſt wire will be a ſufficient conductor, covered a foot thick with ſealing wax. This indeed, according to Mr de Luc, allows the deferent *fluid* to paſs; but it muſt alſo, according to him, ſtrain it pretty clear of all *electric matter*. For we cannot help thinking, that the proceſs (although purely ideal) has a cloſer reſemblance to what we ſhould obſerve in a ſtream of muddy water poured on a ſtrainer, both ſides of which are previouſly foul. If we were diſpoſed to amuſe ourſelves with a figurative hypotheſis, we could give one on the principle of filtration that is very pretty, and pat to the purpoſe, of glaſs coated, and charged and diſcharged by conducting canals.

With reſpect to the ſuggeſtion of this theory by Volta's theory of electric influences, and the ignorance of naturaliſts before that time of the true ſtate of things, we muſt obſerve, that Mr Ruſſel propoſed the ſame analogy to the conſideration of his hearers many years before; and it was very generally known. The electric influences had been fully detailed by Æpinus and Wilcke in 1759, and applied with peculiar addreſs and force of evidence by Mr Cavendiſh before 1771; and they were deſcribed nearly in the ſame way by Lane, Lichtenberg, and others.

And with reſpect to Mr Volta's general principle, which Mr de Luc prizes ſo highly, and by which he explains every thing, we muſt obſerve, that *it is not true as a phenomenon in electricity*; but, on the contrary, *the poſitive ſtate of a body is rendered ſtronger, or more remarkable, by inducing the negative ſtate on a neighbouring body*. See n° 52. and 66.—Mr Volta was miſled by the appearances of the electrophorus, which had engaged all his attention, and modelled all his notions on theſe ſubjects.
His-

(A) We may here aſk, How comes there to be ſuch a quantity of electric matter already lodged in B?—Is it benumbed? or in what ſtate is it?

His obſervations had been confined to diſks; and though theſe are excellent inſtruments for producing very ſenſible effects, they are quite unfit for examining the general nature of electric influences. Even without much knowledge of dynamics, a perſon muſt perceive that the action of their different parts on the electrometer may be very different, by reaſon of their different poſitions and diſtances from it. Beſides, the electrometers of the apparatus deſcribed by Mr de Luc in ſect. 440. &c. *did not* indicate the real condition of the diſks to which they were attached, but the condition of the remote ends of overcharged conductors of conſiderable length. Therefore, although all the electrometers fell lower when the other group of diſks was brought near, the poſitive ſtate of the neareſt diſk was greatly augmented. The moſt unexceptionable apparatus for this purpoſe would be a row of poliſhed balls on inſulating ſtands, placed in contact, the whole charged poſitive; and when another ſuch group, or a long body, is brought near, let the balls be ſeparated at once, and examined apart by a very ſmall electrometer, made in the form of our figure 8. We preſume to ſay that, if the other group is properly managed, and made to communicate thoroughly with the ground, the poſitive electricity of the balls neareſt to it will be found greatly augmented, and that every one of them will be found in that preciſe ſtate of electrification that is pointed out by the Æpinian theory. Mr de Luc has made and narrated the experiments with the diſks, and the curious figures obſerved by Lichtenbergh, with great judgment and fidelity; and they are claſſical and valuable experiments for the examination of the theory. We may here mention a very neat way of executing the apparatus of balls, which was practiſed by a young friend, who was ſo kind as to make the experiments for us, when our thoughts were turned to Mr de Luc's theory. Each ball was mounted on a ſlender glaſs rod varniſhed. The lower end of the ſtalk was fixed in a little block of wood which had a ſquare hole through it, by which it ſlided ſteadily along a horizontal bar of mahogany, ſupported at the ends about an inch from the table. The balls were made to ſeparate at once, and equally, from each other, by a chequer jointed frame, ſuch as is ſeen in the toyſhops, carrying a company of foot ſoldiers, who open and cloſe their ranks and files by pulling or puſhing the ends of the frame. Taking out the pins of the middle joints of this chequered frame-work, and widening the holes for receiving the glaſs ſtalks, it is plain that all the balls will ſeparate at once, in the very ſtate of electricity in which they were when in the neighbourhood of the non-inſulated group. This apparatus conſiſted of ſix balls. We found the ball next the other group much more ſtrongly poſitive than before bringing that group near; and it was generally the third ball which ſeemed equally electric in both ſituations. We added nine balls more, connecting the whole by a ſimilar contrivance; and found it a moſt inſtructive apparatus for the theory of the diſtribution of the electric fluid. We wiſh that it had occurred to us when the n° 62, &c. were under conſideration.

With reſpect to the condition in which the electric matter is ſaid to be lodged in the ſide A of the coated pane, where Mr de Luc ſays that it is fixed, *engourdi*, in the *non-conducting ſurface* (which condition Mr de Luc conſiders as characteriſtic of ſuch ſubſtances), we muſt ſay that the deſcription of its ſtate is by no means agreeable to what we have obſerved. The powers of this *electric matter* are no more *benumbed* or enervated (it is a very unphiloſophical phraſe), than if it were in a *conducting* body at the ſame diſtance from the oppoſite coating. If coatings be applied to a block of glaſs of two or three inches in thickneſs, and if the electrification be ſo moderate that it would not fly from the one coating to the other when the glaſs is removed—no ſenſible difference will be found between the electricity of the two coatings with or without the glaſs. The electric matter in the ſide A has not its powers *engourdi;* they are *balanced* by the powers of the ſide B.

But how will Mr de Luc explain the charging a pane negatively? How will he bring off a quantity of *electric matter*, greater (according to his own account) than what will be *benumbed* on the other ſide? Nay, we muſt aſk, where does he find it? Is there a quantity already *benumbed* there? What is to revive it?

Let us now conſider a little the conſtitution of the ingredients of this electric fluid, by which all theſe things are brought about. And in doing this, let us baniſh, when poſſible, all figurative language; and, in the preciſe and dry phraſeology of dynamics, let us ſpeak of the motion of ſingle particles of the *electric fluid*, *deferent fluid*, and *electric matter*. By *expanſive power*, muſt certainly be meant ſuch a power as that by which air, gaſes, inflamed gunpowder, ſteam, and the like, enlarge their bulk, and which is clearly manifeſted as a mechanical preſſure, by burſting veſſels, impelling bullets or piſtons, &c. as well as by the actual enlargement of the bulk of the fluid. We have no other indications of its being a *force;* and therefore our notions of its mode of acting muſt be derived ſolely from what we *underſtand* of this power in air or the other fluids. Newton's *Principia* are our authority for ſaying that all that we know of it is, that it acts as a number of corpuſcles would act, which repel each other with a force inverſely proportional to their diſtances; this action not extending beyond the adjoining corpuſcle, not even to the ſecond. We know a good deal of the propagation of preſſure and progreſſive motion through ſuch a fluid, when it is confined in a veſſel, or ſyſtem of veſſels, of any form, and ſome few ſimple circumſtances which take place in the elaſtic undulations which may be excited and propagated through it. We have but a *very indiſtinct notion* of the motions which one maſs of ſuch a fluid will produce in another maſs, when both are at liberty to expand. This is very indiſtinct; but we are certain that it will be like the motion of two maſſes of air blown or driven againſt each other. Now theſe electric fluids, by their expanſive powers, muſt act like thoſe others with which we are more familiarly acquainted. And here we venture to ſay, that the appearances in electricity are ſo far from being like theſe, that we cannot imagine any thing more remarkably different. We ſhall mention but one thing. Every mark that we have for the preſence of *electric fluid* obliges us to grant, that in an overcharged body it is crowded into the external ſurface, ſo that the quantity has little or no relation to the quantity of matter in any body, but merely to its ſurface. This is quite unlike air, or any other expanſive fluid, which is uniformly diſtributed through the whole ſpace comprehended by the ſurface which bounds it. We never ſaw any thing

like

like ſtreams of this *electric fluid*, impelling or any way acting on each other, except in the transference by ſparks; and there it was indeed like the motions of air, for it was not *electric fluid*, nor *electric matter*, but *electrified air*.

Let us next conſider the *tendencies* by which the relations of theſe expanſive fluids to other bodies are produced, and the electric motions are ſaid to be explained. We obſerve that Mr de Luc avoids the uſe of the words *attraction* and *repulſion*, ſo much employed by the Britiſh philoſophers. He conſiders theſe tendencies as determinate impulſions, and adopts the doctrine of *Le Sage of Geneva*, who has not only laid Newton under great obligations, by a mechanical explanation of gravity, but has alſo explained expanſion, elaſticity, chemical affinity, and all ſpecific tendencies, to the ſatiſfaction of the moſt eminent mathematicians. To ſuch only Mr de Luc profeſſes to addreſs himſelf, who are not contented with a doctrine which ſuppoſes bodies to act where they are not. But, unfortunately, Mr le Sage has never obliged the world with this explanation. We are not moſt eminent mathematicians; but we are able to prove, that Mr le Sage's favourite theorem, mentioned by Mr de Luc in § 157, 158, as demonſtrated by Mr Prevoſt, the editor of *Lucrece Neutonien*, is a complete dereliction of the firſt principles of Mr le Sage, and is alſo incompatible with mechanical laws. Mr de Luc ſhould have given a demonſtration of the theorem on which all his ſyſtem reſted; otherwiſe it is only reviving "*dixit philoſophus, ergo verum.*"

But let us ſee what theſe tendencies perform. Mr de Luc ſays, that the fluid, ſetting out from a body by its expanſive power, would move in a ſtraight line with inconceivable velocity, and would immediately deſert even this globe, were it not deflected by its tendency to other bodies. We do not ſee whence this immenſe velocity is derived. But let it go off; it is deflected from its rectilineal courſe by its tendency to ſome conducting body, which it reaches, but cannot, nor does not enter; and therefore *muſt continually circulate round it, as the planets circulate round the ſun*, following its outline, if not too abrupt, but flying off from all points in the direction of the axis of the point, &c. Here we are at home; for this is a plain dynamical problem of central forces. All that we ſhall ſay on this head is, that Mr de Luc has certainly not conſidered the planetary motions with attention, when he hazarded this very comprehenſive propoſition. If he will take the trouble to do this, he will ſee that every part of it is inconſiſtent with the acknowledged laws of mechaniſm, and that the motions are abſolutely impoſſible. Beſides, we know that it will not fly off from a hundred points placed together, which is a ſtill more abrupt line, if they do not project beyond the brim of a pit in which they ſtand; yet this pit only makes the outline more abrupt. We farther believe, that no perſon can form to himſelf any diſtinct notion of ſuch circulations round every conducting body; they will be more numerous, and infinitely more confuſed and jarring, than all the vortices of Des Cartes. How can ſuch motions take place round a bunch of braſs wire buried in ſealing wax? Yet he muſt grant that they really happen there; or what prevents the *electric fluid* from being *ſtrained* clear of all electric matter in paſſing through the air?

We would alſo aſk, why the tendency is always *from the body containing moſt of the fluid to that containing leaſt?* It is not enough to ſay that it is ſo: this would only be contriving a thing to ſuit a purpoſe; a reaſon ſhould be given if we pretend to explain. Now the tendency to a diſtant body *is to the matter* in that body, without any relation to the fluid in it, or in the body from which it came.

On the whole, we cannot think this theory is any thing but telling a ſtory of ideal beings, in very figurative language, which gives it ſome animation and intereſt. The different affinities, tendencies, and powers, are only ways of expreſſing certain *ſuppoſed* events, and ſuited to thoſe events: but it gives no explanation of the *obſerved mechanical phenomena* of electricity, ſhewing from acknowledged principles that they muſt be ſo.

What a difference between this laboured and intricate mechaniſm, and the ſimple, perſpicuous, and diſtinct theory of Æpinus! Even Mr Ruſſel's explanation is more intelligible, and more applicable to the *motions* which are really obſerved. That gentleman ſaw the neceſſity of conſidering them as the ſubjects of *mechanical diſcuſſion*, and that all that was wanted was to find out what law of diſtant action would tally with the phenomena. The Scotch philoſopher was careful to warn his hearers that he only propoſed a *conjecture*. The Swede calls his performance *Tentamen Theoriæ*, &c. and begins and concludes it with expreſsly ſaying, that it is only a *hypotheſis*. The Engliſh nobleman calls his diſſertation an *Attempt* to explain ſome of the phenomena, &c. None of theſe philoſophers call their works a SYSTEM, which comprehends all theories, whether that of Volta or of any other ſucceſsful inquirer.

We hope to be excuſed for treating ſo largely of this ſubject. It ſtruck us as a very proper example of the bad conſequences of indulging in figurative language. It muſt be very ſeducing, when ſo ſcrupulous and ſo eminent a philoſopher as Mr de Luc is led aſtray by it.

233. We conclude this long article by obſerving, that whatever may be the fate of Mr Æpinus's *hypothetical theory*, his claſſification of the facts, and his preciſe determination of the *mechanical phenomena* to be expected from any propoſed ſituation and condition of the ſubſtances, will ever remain, and be an unerring direction in future experiments; and the whole is an illuſtrious ſpecimen of ingenuity, addreſs, and good reaſoning. We hope to make this ſtill more evident, when we apply it to the quiet and manageable phenomena of MAGNETISM

Pondere et menſurâ.

APPENDIX;

CONTAINING AN ABSTRACT OF MR COULOMB'S EXPERIMENTS.

MR COULOMB in the *Mem. de l'Acad. de Paris* for 1786, relates ſeveral experiments made for aſcertaining the diſpoſition or diſtribution of the electric fluid in an overcharged body. Their general reſults were,

1. That the fluid is diſtributed among bodies according to their figure, without any elective affinity to any kind of ſubſtance.

For when a ball, or body of conducting matter, and of any ſhape, is electrified to any particular degree, as indicated by his electrometer, if it be touched by another equal and ſimilar body, ſimilarly ſituated in reſpect of the touching points, the electricity is always reduced to $\frac{1}{2}$.

2. In an overcharged conducting body, the fluid diffuſes itſelf entirely along the ſurface, without penetrating into the interior parts.

The conducting body AB (fig. 37.) had pits *a*, *b*, &c. made in various parts of its ſurface. They were half an inch in diameter, and ſome of them $\frac{1}{10}$th, others $\frac{2}{10}$ths, others $\frac{3}{10}$ths, &c. in depth. *c* repreſents the edge of a ſmall circle of gilt paper, $\frac{1}{7}$th of an inch in diameter, fixed perpendicularly on the end of a fine thread of gum lac. The body was electrified and touched with this little electroſcope, by ſetting it flat down on the ſurface. The circle *c* was then preſented to an electrometer which moved 90 degrees by a force not exceeding $\frac{1}{6000}$th of a French grain. When this contact was made with the even ſurface of the conductor, it was ſtrongly electrified, and particularly when it touched any eminence, or the ends of long cylinders, &c. The paper being exceedingly thin, and placed in full contact, it may be ſuppoſed to bring off with it the quantity of fluid correſponding to that part of the ſurface, or rather a greater quantity. But when it was made to touch the bottom, even of the ſhalloweſt of theſe pits, it did not affect the electrometer in the leaſt.

He demonſtrates the following elementary theorem:

The attraction or repulſion being ſuppoſed to be proportional to the inverſe of any power *m* of the diſtance; that is, being as $\frac{1}{x^m}$: if *m* be greater than 3, the action of all the maſſes of fluid which are at a finite diſtance is nothing in compariſon with the action in contact; and therefore the fluid muſt be uniformly diffuſed, in the ſame way as if each particle acted only on the adjoining particles.

But if *m* be leſs than 3, for example, if *m* be 2, as ſeems to be the caſe in electricity, the action of all the maſſes at a finite diſtance is not infinitely ſmall in compariſon with the action in contact, and the redundant fluid muſt go toward the ſurface, and no redundant fluid will be retained in the interior parts. The demonſtration is to this effect:

Let A *a* BF (fig. 38.) be a perfectly conducting body of any ſhape, and let *d a e* be a thin ſlice ſeparated from the reſt by the plane *de;* let *d c e* be preciſely equal and ſimilar to *d a e*, and let *a b c* be perpendicular to the ſeparating plane; then the action of all the particles in the thin ſlice *d a e* (when eſtimated in the direction *a b*) on the particle *b*, muſt balance the action of all the reſt of the fluid in the body; for *b* is ſuppoſed to be at reſt. Now, as the law of continuity will be obſerved in *any* diſtribution of the fluid, *through the whole body*, it is plain that, by taking *a b* ſufficiently ſmall, the difference of denſity at *a* and at *c* may be infinitely ſmall; therefore the action of the fluid in *dae* will be infinitely near to an equilibrium with the action of *d c e;* and the action of the fluid in the reſt of the body on the particle *b* will be infinitely ſmall. This cannot be, when the action of a maſs of fluid at a finite diſtance is not infinitely ſmall in compariſon with the action in contact, unleſs we ſuppoſe that the quantity of fluid at a finite diſtance is alſo infinitely ſmall, or nothing; that is, unleſs the whole redundant fluid is conſtipated on the ſurface, and the interior parts are merely ſaturated.

The preceding propoſitions are quite analogous to propoſitions in Mr Cavendiſh's diſſertation in the Philoſophical Tranſactions for 1771.

In the Memoirs of the ſame Academy for 1787, Mr Coulomb endeavours to aſcertain the denſity of the fluid in different bodies which touch each other. When the bodies do not differ extremely in magnitude, he determines this by the immediate application of them to the electrometer; but when one is extremely ſmall in compariſon with the other, he firſt determines the force of the large body, and then touches it 20 or 40 times with the ſmall one, till the force of the large body is reduced to $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, &c. The general reſult was, that when the ſurfaces of the ſpheres had the proportion expreſſed in the firſt column of the following Table, then the denſity in the ſmall one had the proportion expreſſed by the numbers of the ſecond column, and never attained the magnitude 2.

1	1
4	1,08
16	1,3
64	1,65
Infinite	2

This is extremely different from the proportions which obtain when the two ſpheres communicate by very long ſlender canals, which he found exactly conformable to the determinations of the theory: but in Mr Coulomb's experiments the ſpheres touched each other, and had no other communication.

He then endeavours to aſcertain the denſity of the fluid in the different parts of the ſurface of theſe touching ſpheres, in order to obtain ſome experimental knowledge of the diſtribution. He touched them (while in mutual contact) with the little paper circle, and examined its electricity by his electrometer, and made his eſtimation on the ſuppoſition that it brought off one-half of the electricity of the touched part.

When the globes were equal, he found the denſity to be 0 in the point of contact, and ſcarcely ſenſible till he took the paper 30 degrees from the point of contact. From this it increaſed rapidly to 60°; ſlowly from thence to 90°; and from thence to 180° it was almoſt uniform. The denſities were nearly

0	at	0°
1	—	30
4	—	60
5	—	90
6	—	180

He alſo found, that the more the globes differed in bulk, the more is the denſity changed in the ſmall globe, and it is the more uniform in the great one, increaſing rapidly from 0, at the point of contact, to about 7°, and beyond this being ſenſibly uniform.

Hence we may conclude, that the electricity is diffuſed with almoſt perfect uniformity in a globe communicating with another at a great diſtance by a ſlender canal (as Mr Cavendiſh has demonſtrated); while, from the reaſoning employed before, it is probable that it is alſo uniformly diffuſed all along the canal; and therefore, that the quantities in two ſuch globes are very nearly as the diameters, and the denſities inverſely as the diameters, as Mr Cavendiſh demonſtrated, on the ſuppoſition that the fluid in the canal is incompreſſible.

He found that a ſmall globe, placed between two equally large ones, ſhewed electricities of the ſame kind with that of the other two, when the radius of the great

[illegible]

great one was not more than five times that of the middle one, but ſhewed no electricity when the diſproportion was greater.

When three equal globes were in contact, the denſity of fluid in the middle globe was $\frac{\cdot 1}{1,34}$ of that of the other two. A ſmall globe being removed to a very ſmall diſtance from an overcharged great one, *after having been in contact*, ſhewed oppoſite electricity in the fronting point; when a little farther off, it was neutral; and beyond this, it was overcharged.

The diameters being 11 and 8, the fronting point of the ſmall one was negative till the diſtance was 1; here it was neutral, and when it was removed farther, it was poſitive. When the diameters were 11 and 4, the ſmall globe was negative till their diſtance was 2, where it was neutral. When the diameters were 11 and 2, the diſtance which rendered the ſmall globe neutral in the fronting point was $2\frac{1}{2}$.

All theſe facts are perfectly conformable to a mathematical deduction, from the ſuppoſition that the redundant fluid is ſpread over the ſurface, and that the interior points are neutral. If any ſort of doubt ſhould remain in the minds of thoſe who are not converſant in ſuch diſcuſſions, it muſt be greatly removed by the fact, that it is quite indifferent whether one or both globes be ſolid, or be an extremely thin ſhell.

When an electrified body is touched with a long wire, and by another of equal diameter and length, coated to any thickneſs with lac or ſealing wax, the two wires take off preciſely the ſame quantity of electricity. This was demonſtrated by touching a globe repeatedly till the electricity was reduced to $\frac{1}{2}$

Hence we muſt conclude, that the electric fluid does not form active atmoſpheres around bodies, by the action of whoſe particles in contact (mathematical or phyſical) the phenomena of attraction and repulſion are produced, but by the action of the fluid in the body, agreeable to the theory of Æpinus.

Such are the obſervations of Mr Coulomb They are extremely valuable, becauſe they confirm in the completeſt manner the legitimate conſequences of the theory.

We think that the materiality of that which is transferred from place to place in the exhibition of electric phenomena, is greatly confirmed by ſome obſervations of Mr Wilſon's in the Pantheon. When a ſpark was taken from the whole of the long wire extended in that vaſt theatre, the ſenſation was ſo different from a ſpark which conveyed even a much greater quantity of fluid from a pretty large, but compact, ſurface, that they could hardly be compared. The laſt was like the abrupt twitch with the point of a hooked pin, as if pulling off a point of the ſkin; the ſpark from the long wire was more like the forcible piercing with a needle, not very ſharp, breaking the ſkin, and puſhing it inward. We had this account from the Doctor in converſation. He aſcribed it, with ſeeming juſtice, to the momentum acquired by the fluid accelerated along that great extent of wire.

lectricity, *Animal Electricity*. See Galvanism, in this Supplement.

lectrometer. ELECTROMETER, is an inſtrument which meaſures the quantity of electricity in any electrified body. The moſt common electrometers are deſcribed in the article Electricity *(Encycl.)*, n° 27, and 182—233. A very valuable one is likewiſe deſcribed in n° 85. of the article Electricity in this volume; but there are ſtill two electrometers, of which we have hitherto given no account, though they are of ſuch value, that to paſs them unnoticed would be unpardonable. The firſt, which is incomparably the moſt accurate and delicate inſtrument of the kind that we have ſeen, was invented by Mr Coulomb, and is adapted to aſcertain the ſmalleſt quantity of redundant electricity. The ſecond is a late invention of Mr Cuthbertſon, the ingenious improver of the air-pump, and is employed only to meaſure the charge of large jars and batteries.

Electrometer, by *Mr Coulomb* of the Royal Academy of Sciences at Paris, deſcribed in the Memoirs for 1785.

Mr Coulomb had made ſome experiments in examination of Dr Hook's theory of ſprings "*ut tenſio ſic vis*;" and found, that it was ſurpriſingly exact, in regard to the force neceſſary for twiſting elaſtic wires. Having ſuſpended a nicely turned metal cylinder by a fine wire in the direction of its axis, and having given it ſeveral turns, and left it to regain its natural poſition, he obſerved, that it performed all its revolutions of untwiſting and twiſting in times preciſely equal, whether theſe oſcillations were of a few degrees, or conſiſted of ſeveral revolutions. He thence concluded, that the force with which the wire endeavoured to regain its natural poſition was exactly proportional to its diſtance from it. Electrometer. Engaged, ſoon after, by order from the Miniſter of Marine, in an examination of the phenomena of the mariner's compaſs, he took this method of ſuſpending his needles, in order to obtain exact meaſures of the forces which cauſed them to deviate from the magnetic meridian. He made ſome obſervations with needles ſo ſuſpended; which are highly valuable to the philoſopher engaged in that ſtudy. When his ſucceſs in this reſearch had fully gratified his wiſhes, he turned his thoughts to the examination of the law of electric action by the help of an electrometer ſuſpended in the ſame manner. It is conſtructed as follows:

ABDC (fig. 1.) repreſents a glaſs cylinder, 12 Plate XXVII. inches in diameter and in height. This is covered by a glaſs plate fitted to it by a projecting fillet on the under ſurface. This cover is pierced with two round holes of $1\frac{3}{4}$th inches in diameter. One of them *f* is in the centre, and it receives the lower end of the glaſs tube *f h*, of 24 inches height, which is fixed in the hole with a cement made of ſealing wax, or other electric ſubſtance. The top of this tube receives the braſs collar H (fig. 2. n° 3.), bored truly cylindrical, and having a ſmall ſhoulder, which reſts on the top of the tube. This collar is faſtened with cement, and receives the hollow cylinder Φ (fig. 2. n° 2.), to which is joined the circular plate *a b*, divided on the edge into 360 degrees. It is alſo pierced with a round hole G in the centre, which receives the cylindrical pin *i* (fig. 2. n° 1.), having a milled head *b*, and an index *i o*, whoſe point is bent down, ſo as to mark the diviſions on the circle *a b*. This pin turns ſtiffly in the hole G, and the cylinder Φ turns ſteadily in the collar H. To the lower end of the centre pin is faſtened a little pincer *q*, formed like the end of a port-crayon, and tightened by the ring *q*, ſo as to hold faſt the ſuſpenſion wire, the lower end of which is graſped by a ſimilar pincer P *o* (fig. 3.), tightened by the ring *φ*. The lower end *φ o* is cylindrical, and it is of ſuch weight as to ſtrain the wire perfectly ſtraight, but without any riſk of breaking it. It may be made half of the weight that will juſt break it.

This pincer is enlarged at C, and pierced with a hole, which receives tightly the arm *g* C *q* of the electrometer. This is eight inches long, and conſiſts of a dry ſilk thread, or ſlender ſtraw of ſome graſs completely dried, and dipped in melted gum lac or fine ſealing wax, and held upright before a clear fire, till it form a ſlender cylinder of about $\frac{1}{10}$th of an inch in diameter. This occupies ſix of the eight inches, from *g* to *q*: the remaining two inches is a fine thread of the lac or ſealing wax, as it drains off in forming the arm. At *a* is a ball of pith of elder or fine cork, one-fourth or one-half of an inch in diameter, made very ſmooth, and gilded. It is balanced by a vertical circle *g* of paper, of large dimenſions, ſtiffened with varniſh. The reſiſtance of the air to this plane ſoon checks the oſcillations of the arm.

The whole is ſeen in its place in fig. 1. where the arm hangs horizontally about the middle of the height of the great cylinder. In its oſcillations the ball *a* moves round in a circle, whoſe centre is in the axis of the whole inſtrument. Its ſituation is indicated by a graduated circle Z O Q, drawn on a ſlip of paper, and adhering to the glaſs with varniſh. The electrified body, whoſe action is to be obſerved, is another ſmall ball of cork *t*, alſo gilt, or a braſs ball well poliſhed. This is carried by a ſtalk of gum lac *m φ*, incloſing a dry ſilk thread. This ſtalk is graſped by a clamp of cleft deal, or any ſimilar contrivance which lies firm on the glaſs cover. When this ball is let down through the hole *m*, it ſtands ſo as to touch the ball *a* on the arm when that ball is oppoſite *o* on the graduated circle.

To electrify the ball *t*, we employ the inſulating handle, fig. 4. which is a ſlender ſtick of ſealing wax or lac, holding a metal wire that carries a ſmall poliſhed metal ball. We touch with it ſome electrified body, ſuch as the prime conductor of a machine, the knob of a jar, &c. Introduce this electrified ball cautiouſly into the hole *m*, and touch the ball *t* with it. The ball *a* is immediately repelled, and goes to a diſtance, twiſting the ſuſpenſion-wire, till the force of twiſt exerted by the wire balances the mutual repulſion of the balls *t* and *a*.

Such is the proceſs for examining the law of electric action. But when we would examine the action of different bodies in different ſtates, another apparatus is wanted. This is repreſented by the piece *c* A *d* (fig. 5.), conſiſting of a plug of ſealing wax A, which fits tight into the hole *m*, and is pierced by the wire *c d*, hooked at *c*, to receive a wire connecting it occaſionally with an electrified body, and having below a poliſhed metal ball *d*.

The inſtrument is fitted for obſervation in the following manner: Turn the milled button *b* at top, till the twiſt-index *i o* is on the mark *o* of the twiſt circle. Then turn the whole in the collar H, till the ball *a* ſtands oppoſite to the mark *o* of the paper circle *z* OQ, and at the ſame time touches the ball *t* or *d*.

The obſervation is made thus: The ball *t* is electrified as already ſaid, and *a* is repelled, and retires from *t*, twiſting the wire, and, after a few oſcillations, ſettles at a diſtance correſponding to the repulſion. Now turn the twiſt-index, ſo as to force the ball *a* nearer to *t*. We eſtimate the force of this new repulſion by adding the motion of the twiſt-index to the angle at which the ball firſt reſted. By turning the twiſt-index ſtill more, we bring the balls ſtill nearer, and have a meaſure of another repulſion.—And thus may we obtain as many meaſures as we pleaſe.

In this way Coulomb aſcertained the relation between the repulſion and the diſtance to be the inverſe duplicate ratio of the diſtances. He diſcovered the law of diſſipation by air in contact, and the relation which this bears to the primitive repulſion, by obſerving the gradual approach of *a* to *t* as the electricity diſſipates from both, and by ſlackening the twiſt-index till the ball *a* retires to its primitive diſtance. He aſcertained the diſſipation along imperfect conductors and the length neceſſary for inſulation, by completely inſulating the ball *t*, and obſerving the loſs by air in contact with it, and then ſliding a metal rod down the inſulating ſtalk, till the diſſipation began to exceed what took place by the air alone. He examined the proportion of redundant fluid in communicating bodies, by connecting them alternately with the piece, fig. 5.; as alſo by electrifying one ball, and obſerving its repulſive force, and then ſharing its electricity with another, and obſerving the diminution. He examined the graduation of his electrometer, by ſharing the electricity of one ball with an equal ball, which gave him the poſition that indicated one-half; and, by repeating this, for one-fourth, &c. in the ſame manner as we practiſed and related in ELECTRICITY (*Suppl.*), n° 141, &c.

An example of one or two of thoſe trials will give a clear conception of the concluſions deduced from theſe obſervations.

The ball *t* was introduced and electrified; *a* was repelled, and ſettled at 40°; the index was twiſted 140°, which brought *a* to 20; and the time was noted. The electricity gradually diſſipated, and *a* came nearer to *t*. The index was untwiſted 30°, and *a* retired a little beyond 20°; but on waiting a few ſeconds, it ſtood exactly at 20°. The time was again noted. The interval was exactly three minutes. The concluſion from the experiment was as follows:

When the ball was brought to 20°, the repulſion was evidently 140 + 20, or 160. Three minutes afterwards it was 210 + 20, or 130; and 30° were loſt in three minutes, or 10° per minute. The mean force was 145. Therefore the mean loſs per minute was $\frac{10}{145}$. Obſerve alſo, that the primitive force correſponding to the diſtance was 40; and the force correſponding to 20 was 160, or inverſely as 20^2 to 40^2.

But obſerve, that the diſtances were not meaſured by the angles, but by the chord of the angles. The obliquity of action muſt alſo be accounted for; and the real lever is leſs than the arm, in the proportion of radius to the coſine of $\frac{1}{2}$ the angle.

The wire uſed by Coulomb in his firſt experiments on the law of action was of ſuch ſtrength, that $\frac{1}{340}$th of a French grain, applied at the point *a*, held it faſt till

till the twiſt-index was turned 360°; ſo that one degree correſponded to $\frac{1}{111400}$ of a grain. A foot of this wire weighed $\frac{1}{15}$th of a grain. Experience having ſhewn that this was a ſenſibility far exceeding what was neceſſary for the meaſures that he had in view, and made the inſtrument too delicate for common uſes, he ſubſtituted much ſtronger and ſhorter wires, and recommends much ſmaller dimenſions for the whole inſtrument. We have made two of only five inches in diameter and 14 inches high; the arm *a g* being $2\frac{1}{2}$ inches, and the ſuſpenſion a ſingle fibre of ſilk, carrying 30 grains. It is far more ſenſible than Bennet's gold leaf electrometer. The ſame inſtrument, with a ſilver wire ſuſpenſion, and a thread of lac projecting from the end *g*, as an index to coincide more cloſely with the ſcale, is ſufficiently nice for all experiments of meaſurement. It is always proper to have the diameter of the cylinder double the length of the arm, that the action of the glaſs may not diſturb the poſition of the arm. It is greatly improved by having a round hole in the bottom of the inſtrument, in which the cylinder C *o* of the lower pincer may hang freely: this prevents much tedious oſcillation. For ordinary experiments, for meaſuring charges of batteries, and the like, a much leſs delicate inſtrument, with a ſuſpenſion-wire ſtrained at both ends, is abundantly delicate, and vaſtly more manageable. The wire ſhould extend as far below the arm as above it, and ſhould be graſped below, by a pincer turning by a milled head in a hole at the end of a ſlender ſpring. This enables us to adjuſt the inſtrument ſpeedily. Having placed the twiſt-index at o, turn this lower button gently till the ball *a* points exactly to o on the paper circle. Even in this coarſeſt ſtate we have found it more delicate, and much more exact, than the electrometer deſcribed in Electricity (*Suppl.*), n° 85. which was much more coſtly, and liable to accidents. Coulomb's electrometer has the great advantage of waſting very little electricity; whereas Henly's, or Brookes's, or de Luc's, waſte it very faſt when it is intenſe.

We improved it greatly by taking away the apparatus with the ball *t*, and ſubſtituting the piece, fig. 5. for it, after changing its conſtruction a little. Inſtead of the wire *c d*, we uſed the ſmalleſt glaſs tube that we could varniſh on the inſide, by drawing through it a ſilk thread dipped in varniſh. Having varniſhed it with lac both within and without, a braſs ball *d* was fixed on its lower end, and a fine wire, with a ball at top, was put down into the tube, ſo as to touch the ball below. When the plug was fitted into the hole *m* once for all, the ſituation of the ball *d* ſuffered no alteration. When delicate experiments are to be made, the upper ball *c* is touched by the charger, fig. 4. which electrifies *d*. C is immediately drawn out with a glaſs forceps; and thus *d* is left completely inſulated. When external electricity, ſuch as the faint electricity of the atmoſphere is to be examined, the wire is allowed to remain in the tube.—*N. B.* A ſcrupulous experimenter, who may object to the ſtraining ſpring recommended above, may ſubſtitute a ſmall weight, which will be conſtant in its action.

The reader will obſerve, that this electrometer, as hitherto managed, meaſures only repulſions. It is not ſo eaſy to meaſure attractions with it; and Mr Coulomb was obliged to take a very circuitous method, during which a great deal of electricity was diſſipated. In this reſpect, the electrometer deſcribed in the article Electricity (*Suppl.*) has the advantage; but in every other reſpect, Mr Coulomb's is the fineſt electrometer that has yet been publiſhed, giving *abſolute* meaſures, and this with great accuracy. The Hon. Mr Cavendiſh has employed the conſtruction in his moſt valuable experiments on the force of gravity (*Phil. Tranſ.* 1798, Part II.); an experiment which Newton would have been delighted with obſerving.

Cuthbertſon's Electrometer is thus deſcribed by himſelf in the laſt number of the ſecond volume of *Nicholſon's Philoſophical Journal.* GH (fig. 6.) is an oblong piece of wood, about 18 inches in length and ſix in breadth, in which are fixed three glaſs ſupporters, D, E, F, mounted with braſs balls, *a*, *c*, *b*. Of theſe ſupporters E and F are exactly of the ſame length; but D is four inches ſhorter. Under the braſs ball *a* is a long braſs hook; the ball *c* is made of two hemiſpheres, the under one being fixed to the braſs mounting, and the upper turned with a groove to ſhut upon it, ſo that it can be taken off at pleaſure. The ball *b* has a braſs tube fixed to it, about three inches long, cemented on the top of F, and the ſame ball has a hole at the top, of about one-half inch diamater, correſponding with the inſide of the tube. AB is a ſtraight braſs wire, with a knife-edged centre in the middle, placed a little below the centre of gravity, and equally balanced with a hollow braſs ball at each end, the centre, or axis, reſting upon a proper ſhaped piece of braſs fixed in the inſide of the ball *c*; that ſide of the hemiſphere towards *c* is cut open, to permit the end *c* A of the balance to deſcend till it touches the ball *a*, and the upper hemiſphere C is alſo cut open to permit the end *c* B to aſcend; *i* is a weight, weighing a certain number of grains, and made in the form of a pin with a broad head; the ball B has two holes, one at the top, and the other at the bottom; the upper hole is ſo wide, as to let the head of the pin paſs through it, but to ſtop at the under one, with its ſhank hanging freely in *b*; *k* is a common Henley's quadrant electrometer; and when in uſe it is ſcrewed upon the top of *c*.

It is evident, from the conſtruction, that if the foot ſtand horizontal, and the ball B be made to touch *b*, it will remain in that poſition without the help of the weight *i*; and if it ſhould by any means receive a very low charge of electric fluid, the two balls *b*, B, will repel each other; B will begin to aſcend, and, on account of the centre of gravity being above the centre of motion, the aſcenſion will continue till A reſt upon *a*. If the balance be ſet again horizontal, and the pin *i* be put into its place in B, it will cauſe B to reſt upon *b*, with a preſſure equal to that weight, ſo that more electric fluid muſt be communicated than formerly before the balls will ſeparate; and as the weight in B is increaſed or diminiſhed, a greater or leſs quantity of electric fluid will be required to effect a ſeparation.

When this inſtrument is to be applied to a jar, or battery, one end of a wire L muſt be inſerted into a hole in *b*, and the other end into a hole of any ball proceeding from the inſide of a battery, as M. A chain, or wire, or any body through which the charge is to paſs, muſt be hung to the hook at *m*, and carried from thence to the outſide of the battery, as is repreſented by the line N. *k* muſt be ſcrewed upon *c*, with its index towards A. The reaſon of this inſtrument being added, is to ſhew, by the index continuing to riſe, that the charge of the battery is increaſing, becauſe the other

other part of the inſtrument does not act till the battery has received its required charge.

It is almoſt needleſs to obſerve that this inſtrument conſiſts of three electrometers, viz. Henley's electrometer, Lane's diſcharging electrometer conſiderably improved, and Brookes's ſteelyard electrometer improved likewiſe. By this combination and theſe improvements, we poſſeſs all that can be required in an electrometer for batteries and large jars; for, by *k*, we ſee the progreſs of the charge; by the ſeparation of B *b*, we have the repulſive power in weight; and by the ball A, the diſcharge is cauſed when the charge has acquired the ſtrength propoſed.

In the journal from which this abſtract is taken, the reader will find ſome curious experiments made with batteries by means of this electrometer; but one will be ſufficient to explain its uſe. Prepare the electrometer in the manner ſhewn in the figure, with the jar M annexed, which contains about 168 ſquare inches of coating. Take out the pin in B, and obſerve whether the ball B will remain at reſt upon *b*; if not, turn the adjuſting ſcrew at C till it juſt remains upon A. Put into B the pin, marked *i*, weighing 15 grains; take two inches of watch-pendulum wire, fix to each end a pair of ſpring tongs, as is repreſented at G *m*, hook one end to *m*, and the other to the wire N, communicating with the outſide of the jar; let the uncoated part of the jar be made very clean and dry; and let the prime conductor of an electrical machine, or a wire proceeding from it, touch the wire L; then, if the machine be put in motion, the jar and electrometer will charge, as will be ſeen by the riſing of the index of *k*; and when charged high enough, B will be repelled by *b*, and A will deſcend and diſcharge the jar through the wire which was confined in the tongs, and the wire will be fuſed and run into balls. The ingenious author, by breathing through a glaſs pipe into the jar, damped it a little in the inſide. Then loading B with a pin of 30 grains, he obtained ſuch a charge as fuſed eight inches of watch pendulum wire, diſpoſed exactly as the two inches were diſpoſed in the former experiment. By repeating and varying his experiments, he found that double quantities of electrical fluid, in the form of a diſcharge, will melt four times the length of wire of a certain diameter.

ELECTROPHORUS. See ELECTRICITY in this *Supplement*.

ELEPHAS, the ELEPHANT. See *Encyclopædia*; where the natural hiſtory of this huge and ſagacious animal is detailed at conſiderable length. Since that article was publiſhed, we have ſeen the third volume of the Aſiatic Reſearches, in which ſome important queſtions, which we were then obliged to leave in uncertainty, ſeem to be decided by John Corſe, Eſq. They relate, 1*ſt*, To the mode in which elephants copulate; which Buffon aſſerts (and in proof of his aſſertion adduces the ſtructure and poſition of the generative organ in the female) to be performed while that female remains recumbent on the back; but which Mr Corſe inſiſts from ocular evidence, takes place after the manner in which the horſe copulates with the mare. 2*d*, To the method of receiving nouriſhment from the mother; which is not, as Buffon avers, by the trunk, but by the mouth, which ſucks the dug, while the trunk of the young animal graſps it round to preſs out the milk. 3*d*, To the period of their going with young; which Mr Corſe conceives cannot be leſs than two years; whereas Buffon and Pennant aſſign only nine months for the geſtation of their young. His reaſons for this ſuppoſition are unanſwerable, and ſhall be given in his own words.

"As far as I know, the exact time an elephant goes with young has not yet been aſcertained; but it cannot be leſs than two years, as one of the elephants brought forth a young one, twenty one months and three days after ſhe was taken. She was obſerved to be with young in April or May 1788, and ſhe was only taken in January preceding; ſo that it is very likely ſhe muſt have had connection with the male ſome months before ſhe was ſecured, otherwiſe they could not have diſcovered that ſhe was with young, as a fœtus of leſs than ſix months cannot well be ſuppoſed to make any alteration in the ſize or ſhape of ſo large an animal The young one, a male, was produced October 16, 1789, and appeared in every reſpect to have arrived at its full time. The gentleman to whom it belongs examined its mouth a few days after it was brought forth, and found that one of its grinders on each ſide had partly cut the gum."

When Mr Corſe wrote his memoir, the young elephant was active and well, and beginning to eat a little graſs. In Africa the Hottentots feed on the elephant; and M. Vailant declares, that an elephant's foot, when baked in their manner, is a moſt delicious morſel.

ELEPHANTIASIS (ſee MEDICINE, n° 352. *Encycl.*) is one of the moſt dreadful maladies with which the human race is anywhere afflicted. It is not indeed common, if it be found at all, in the temperate climates of Europe; but it is frequent in the Eaſt and Weſt Indies, where it too often baffles the ſkill of the ableſt phyſicians. In the ſecond volume of the Aſiatic Reſearches we have the following preſcription for its cure:

"Take of fine freſh white arſenic one tólá, or 105 grains; of picked black pepper ſix times as much: let both be well beaten at intervals for four days ſucceſſively in an iron mortar, and then reduced to an impalpable powder in one of ſtone with a ſtone peſtle, and thus completely levigated, a little water being mixed with them. Make pills of them as large as tares or ſmall pulſe, and keep them dry in a ſhady place. One of thoſe pills muſt be ſwallowed morning and evening with ſome betel leaf, or in countries where betel is not at hand, with cold water: if the body be cleanſed from foulneſs and obſtructions by gentle cathartics and bleeding before the medicine is adminiſtered, the remedy will be ſpeedier."

This preſcription, we are told, is an old ſecret of the Hindoo phyſicians, which they conſider as a powerful remedy againſt all corruptions of the blood, whether occaſioned by the elephantiaſis or the venereal diſeaſe, which they call the *Perſian* fire, and which they apply likewiſe to the cure of cold and moiſt diſtempers, or palſy, diſtortions of the face, relaxation of the nerves, and ſimilar diſeaſes. As the Hindoos are an ingenious and ſcientific people, it might be worth ſome European phyſician's while to make trial of this ancient medicine in the Weſt Indies, where the elephantiaſis or kindred diſeaſes prove ſo frequently fatal.

ELEVATION, in architecture, denotes a draught or deſcription of the principal face or ſide of a building; called alſo its *upright* or *orthography*.

ELLIPSE, or ELLIPSIS, is one of the conic ſections,

ELECTROMETER. PLATE XXVII.

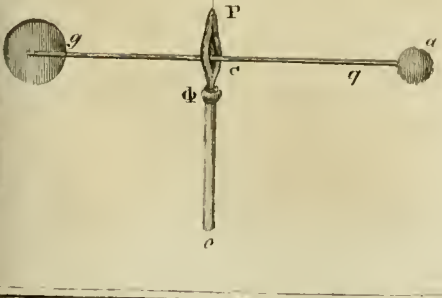
Fig. 3.



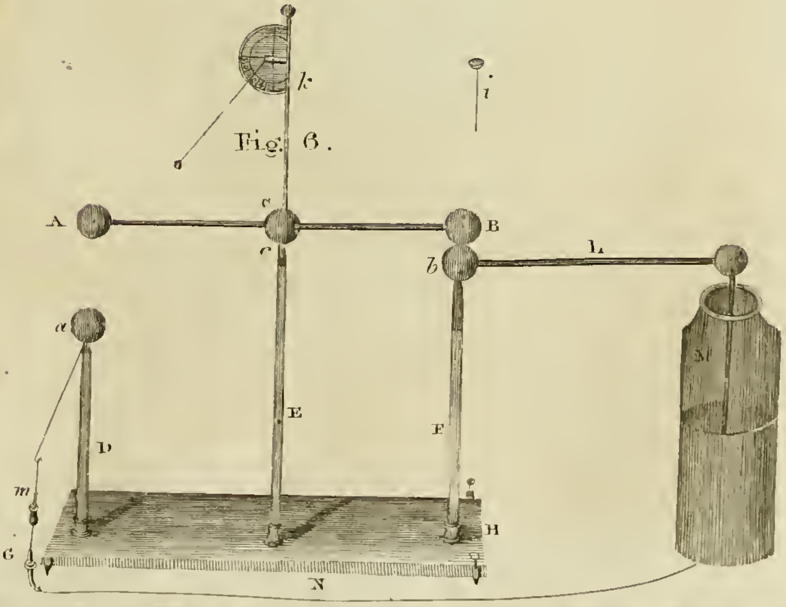


Fig. 6.

D. Lizars Sculpt.

tions, popularly called an *oval;* being called an *ellipſe* or *ellipſis* by Apollonius, the firſt and principal author on the conic ſections, becauſe in this figure the ſquares of the ordinates are *leſs* than, or *defective* of, the rectangles under the parameters and abſciſſes. See *Conic Sections*, Encycl.

ELLIPSOID, is an elliptical ſpheroid, being the ſolid generated by the revolution of an ellipſe about either axis.

ELLIPTOIDE, an infinite or indefinite ellipſis, defined by the indefinite equation $ay^{m+n} = bx^{m} . \overline{a - x}^{n}$ when *m* or *n* are greater than 1: for when they are each = 1, it denotes the common ellipſe.

There are ſeveral kinds or degrees of elliptoides, denominated from the exponent $m + n$ of the ordinate *y*. As the cubical elliptoide, expreſſed by $ay^{3} = bx^{2} . \overline{a - x}$; the biquadratic, or furſolid $ay^{4} = bx^{2} . \overline{a - x}^{2}$; &c.

EMINENTIAL equation, a term uſed by ſome algebraiſts, in the inveſtigation of the areas of curvilineal figures, for a kind of aſſumed equation that contains another equation eminently, the latter being a particular caſe of the former.

ENAMELLING of Vessels for the Kitchen. In the year 1779 the Society of Emulation in Paris propoſed as a prize queſtion, " To diſcover a compoſition fit for making kitchen utenſils which ſhould be free from the diſadvantages attending copper, lead, tinned veſſels, glazed earthen-ware, &c. which ſhould be as ſtrong as poſſible, leſs coſtly than the veſſels uſed at preſent, and which ſhould be able to bear the higheſt degree of kitchen fire, and the moſt ſudden changes from heat to cold."

In conſequence of this propoſal, Mr Sven Rinman of the Royal Academy of Stockholm, without any intention of being a candidate for the premium offered by the Society of Emulation, inſtituted a ſet of experiments on ſmall veſſels of copper and hammered iron, with the view of giving to them a coating of what may properly be called *enamel*, which ſhould not have the defects of tinning, and which, when applied to iron, ſhould take from it the inconveniency of ruſting, and of blackening many ſorts of victuals when they are dreſſed in it. Theſe experiments he ſubmitted to the academy, of which he was a member; and as we think them important, we ſhall lay the ſubſtance of them before our readers.

The moſt common, and the cheapeſt, kind of white enamel that is to be met with in the ſhops (which is an opaque white glaſs, compoſed of powdered quartz, of glaſs of lead, and of calx of tin), was tried for coating kitchen-utenſils; and he found that it was excellent for the purpoſe, as it produced a coating, which was not only clean and agreeable in its appearence, but poſſeſſed likewiſe all the power of reſiſting the action of fire and of acids that could be deſired. But, as it is very difficult to apply, is very dear for common uſe, and is beſides conſidered as not being capable of reſiſting violent blows or falls, he made various experiments with ſubſtances of leſs price; of which the following are certainly worthy of being related.

1. The white ſemi-tranſparent fluor ſpar was reduced into a fine powder, with an equal quantity of unburnt gypſum, and afterwards calcined in a ſtrong fire with a white heat; the whole being, from time to time, carefully ſtirred. The veſſel which he intended to coat, having firſt been wetted by dipping it in water, had as much of the aforeſaid powder applied to its inſide, by means of a very fine ſilk ſieve, as would adhere to it of itſelf, or could be made to do ſo by preſſing it with the finger. After this veſſel had been dried and gradually heated, it was expoſed to a ſudden and violent heat, partly in a coal-fire, kept up by a pair of bellows (the veſſel being at the ſame time covered, ſo that no coals or aſhes could fall into it), and partly in an aſſaying furnace.

In the coal-fire, and with a heat as violent as is commonly uſed to make copper-ſolder run, the mixture was melted, in about the ſpace of a minute, into an opaque white enamel, which evenly covered the ſurface of the copper, and fixed itſelf pretty firmly to the metal; it alſo bore hard blows without breaking, and reſiſted the trials made by boiling things in it, and by applying acids to it. The forementioned mixture was alſo reduced into a fine powder in a glaſs mortar, and made into a ſort of thin paſte with water; it was then applied to the veſſel with a ſmall bruſh, an operation as eaſy as that of applying any other wet colouring matter. He likewiſe tried this paſte, by covering veſſels with it in the ſame way the potters apply their common glazing for ſtone-ware. By both the above-mentioned proceſſes he obtained a very ſmooth coating, particularly by the latter, which is more quickly performed. When the paſte is applied, the veſſel ſhould be made a little warm, ſo alſo ſhould the paſte itſelf.

If the conſtituent parts of theſe two ſubſtances be conſidered (that is to ſay, that gypſum is compoſed of calcareous earth ſaturated with vitriolic (ſulphuric) acid, and fluor ſpar of a particular acid united to ſiliceous earth; alſo, that the whole, when put into the fire without the addition of any other ſubſtance, is, of all earthy or ſtony mixtures, that which the moſt eaſily melts into an opaque white glaſs, not very brittle), and if, on the other hand, the action of acids be attended to—we ſhall eaſily conceive theſe ſubſtances muſt attach themſelves ſtrongly to copper, and that the varniſh formed by them cannot afterwards be diſſolved or acted upon by acids.

The greateſt difficulty attending on this ſimple mixture is, the ſtrong and ſudden heat neceſſary to apply it with effect, that heat being greater than is commonly to be obtained in an aſſaying furnace. On that account, M. Rinman endeavoured to render it more fuſible by the addition of ſome other ſubſtance.

Of his experiments made with this view, ſome failed, and others ſucceeded. We ſhall record only ſuch as were ſucceſsful, and at ſame time attended with ſuch moderate expence as not to preclude them from common uſe.

2. With the ſubſtances employed in his firſt experiment, which, with the author, we ſhall henceforth call n° 1. he mixed an equal quantity of what is called *fuſible glaſs (vitrum fuſibile)*, compoſed of ſix parts of lime, four of fluor ſpar, two of quartz reduced into a fine powder, and one tenth of a part of manganeſe; the whole having been calcined, and ground with water in the manner colours are ground, he ſpread it on the veſſel with a bruſh. This mixture ran pretty well upon the copper in the coal fire; it alſo attached itſelf very ſtrongly to it, and produced an enamel which was firm and hard, and ſeemed likely to bear wear; but it was of a dark grey colour, and without any brillian-

cy. The mixture did not melt more readily in the aſſaying furnace.

Two parts of n° 1. with one part of the fuſible glaſs, and a quarter of a part of mangaueſe, had nearly the ſame effect. This laſt mixture, indeed, was rather more eaſily melted, but it had a darker colour.

3. Eight parts of n° 1. with one half of a part of borax, one quarter of a part of nitre, and half a part of manganeſe, were melted, in the ſpace of ten minutes, into a brown liver-coloured glaſs; which, in the aſſaying furnace, produced upon the copper veſſel a black enamel, which had a dull ſurface. In other reſpects it was firm, even, and hard; but it did not ſufficiently cover the veſſel by a ſingle application, nor was it capable of reſiſting the action of acids.

4. One part of the brown glaſs mentioned in the laſt experiment, with three parts of n° 1. became in the aſſaying furnace with a red heat, almoſt as fluid as the laſt, and held an even and ſmooth ſurface; but it was of a dark colour, and had not any brilliancy. It was not ſenſibly acted upon by vitriolic (ſulphuric) acid.

5. Four parts of n° 1. mixed with one half of a part of litharge, were melted in a crucible, with the help of the bellows, in five minutes, ſo as to become as fluid as water. This mixture, during the fuſion, emitted a ſmell of ſulphureous acid, and formed an opaque glaſs of a ſtraw colour; which, after being ground, as uſual, and ſpread upon a copper veſſel, produced an enamel which covered the veſſel very evenly, and was without bubbles. It was likewiſe, perhaps, the hardeſt of all, but could not be melted in the aſſaying furnace, requiring a ſtronger fire kept up by the bellows. It preſerved its ſtraw colour, but without any luſtre, and reſiſted the action of acids better than the common glazing of the potters.

6. Mr Rinman mixed together equal quantities of gypſum, fluor ſpar, and what the potters call *white lead* (A), and which ſerves for the baſis of their glazing. This mixture, after being calcined, melted in five minutes, with the aſſiſtance of a pair of bellows, into a very white, hard, and opaque enamel, which was very eaſily poured out of the crucible. This enamel, treated like the others, ran very freely, equally, and without bubbles, by the heat of the aſſaying furnace. It was alſo pretty hard and ſtrong, but without any luſtre, and had green and yellow ſpots, occaſioned by the acids of the gypſum and flour ſpar, which had acted upon the copper during the fuſion of the enamel. It, however, bore melting two or three times, and then appeared of a white colour; it was but very little affected by other acids.

7. Equal parts of fluor ſpar, of gypſum, of litharge, and of pure flint glaſs, powdered and mixed together, melted in five minutes, by the help of a pair of bellows, and produced a white and hard glaſs, very like that of the laſt experiment, but rather harder. After being applied on the veſſel in the uſual manner, it formed, with the greateſt heat of an aſſaying furnace, an enamel of a yellowiſh white colour, firm and hard, but without luſtre. In order to avoid the formation of bubbles, care was taken (as ought always to be done in enamelling) to remove the veſſel from the fire as ſoon as it had acquired a brilliant appearance therein, or as ſoon as the enamel was completely melted.

8. Twelve parts of glaſs of lead, or of litharge, with eight parts of flint glaſs, and two of flowers of zinc, were melted, in the ſpace of ſeven minutes, into a clear yellow glaſs, which, when uſed for enamelling, was diſpoſed to form bubbles; but, by continuing the heat for a longer time, the bubbles were diſperſed, and he obtained a pretty good enamel, of a yellow brown colour with a greeniſh caſt, very hard and firm. It reſiſted the action of the vegetable acids, like the enamels already ſpoken of, but it was a little attacked by the mineral acids.

9. He powdered and mixed together five parts of flour ſpar, five parts of gypſum, two parts of minium, one half of a part of borax, two parts of flint glaſs, one half of a part of calx of tin, and only one twenty-fifth of a part of calx of cobalt. This mixture was melted in a crucible in ſix minutes, by help of the bellows, and produced an opaque glaſs of a pearl colour, a little inclining to blue, on account of the calx of cobalt. It was pretty hard, and, after being ground with water in the uſual way, it became of a very good conſiſtence, ſo as to be very fit for ſpreading over veſſels, to which it adhered very ſtrongly. If any bubbles formed on the veſſel during its drying, they might be rubbed down with the finger, and the whole ſurface rendered ſmooth and even. After being warmed, and gradually heated, it was put into an aſſaying furnace made very hot with birch charcoal, which had been juſt kindled under the muffle. After a minute it melted, and began to appear brilliant; ſo that he found it neceſſary to take out the veſſel very quickly, which was already very evenly coated with a thick, and ſufficiently hard, enamel, the ſurface of which, however, had no brilliancy.

The colour remained always inclining to green, becauſe the copper had been a little attacked by the acids of the gypſum and flour ſpar during the fuſion; but in other reſpects this enamel was very firm, was very little hurt by ſlight blows, and bore very well ſudden changes of heat and cold. Weak acids had no action upon it; but he had ſome reaſon to think that it would, in length of time, have been acted upon, to a certain degree, by vitriolic (ſulphuric) acid. Its colour, except the forementioned ſhade of green, was white, with a dull, and rather changeable ſurface.

The calx of cobalt which has been juſt mentioned, and which Mr Rinman made uſe of merely with the intention of obtaining a fine colour, was prepared by ſaturating a ſolution of cobalt in aquafortis (nitric acid) with common ſalt, and evaporating to dryneſs; by which means he obtained a fine roſe-coloured calx. A very ſmall quantity of this calx, when mixed with any fuſible glaſs, gives it a beautiful blue colour.

Of the various ſpecies of enamel, which had been deſcribed in the courſe of theſe experiments, and which may be all applied, with more or leſs advantage, to kitchen utenſils, the leaſt expenſive are n^{os} 1, 2, and 5; but they are alſo thoſe which require the greateſt heat. On the other hand, n° 9. may be recommended as

---

(A) This ſubſtance is itſelf a mixture, being compoſed of four parts of lead and one of tin.

as the moſt eaſy of fuſion, and, at the ſame time, very durable when uſed for coating veſſels in which victuals are to be dreſſed, which is here the principal object, and is of far greater importance than the brilliant appearance reſulting from the enamel generally uſed by artiſts, which however may be employed when the ſaving of expence is not regarded.

The enamels hitherto deſcribed are not applicable to veſſels made of iron, though they may be employed to cover copper with great advantage. Iron will not indeed bear the common practice of enamellers, namely, to be put into the fire and taken out again ſeveral times; for the ſparks which fly from iron, when in a hot fire, detach and carry off the enamel from the parts contiguous to thoſe where the ſparks are formed. The acids, too, of the gypſum and fluor ſpar, made uſe of in the enamels already mentioned, acted upon the iron during the fuſion of the enamel, from which reſulted bubbles and bare ſpots, which entirely ſpoiled the appearance of the work. Our author therefore continued his experiments with a view to diſcover a proper enamel for veſſels made of this metal.

10. He reduced into a very fine powder, and ground together, nine parts of minium (red oxide of lead), ſix parts of flint glaſs, two parts of pure potaſh, two parts of purified nitre, and one part of borax. This mixture was put into a large crucible, which it only half filled; he covered the crucible ſo that no coals could fall into it, and gradually increaſed the fire under it. When the effervеſcence had entirely ceaſed, he cauſed the mixture to melt, by uſing the bellows for four or five minutes; by theſe means he obtained a clear and compact glaſs, which he poured out of the crucible upon a piece of marble. Having quenched it in water, and reduced it to a very fine powder in a glaſs mortar, he ground it with water to the conſiſtence of a very thin paſte. He then covered an iron veſſel with it on both ſides, which, after having dried and heated it by degrees, he put under a muffle well heated in an aſſaying furnace. The enamel melted very readily in the ſpace of half a minute, and with a very brilliant appearance. He immediately withdrew the veſſel, and let it cool: it was found to be entirely coated with a beautiful enamel of a black colour; which colour appeared to be cauſed by a thin layer of calcined iron, which might be ſeen through the tranſparency of the enamel.

A copper veſſel having been covered with the ſame enamel, the fine colour of the copper was viſible through the thin coat of glaſs; and it was as well defended from ruſt by this coating as it would have been by an enamel of a ſtronger kind.

11. To hinder the colour of the metal from being ſeen through the coating, he added to the mixture, uſed in the preceding experiment, only one hundredth part of the calx of cobalt deſcribed in n° 9. The whole was melted into a beautiful blue glaſs; it was prepared for enamelling, and applied in the manner before deſcribed, upon another iron veſſel. The enamel proved to be ſmooth, thick, and brilliant, like the preceding, but it covered the veſſel more perfectly; it was of a fine blue colour, with ſome black ſpots in thoſe parts where it had been moſt thinly applied.

12. The glaſs of n° 10. reduced into powder, and ground with potters white lead, of which mention has already been made, melted with the ſame facility; it produced a very ſmooth enamel, of a grey colour, but more firm and hard than the former, and, on account of the addition made to it, of a ſtill leſs price. By mixing with the ſame glaſs a ſmall quantity of crocus martis, he obtained a very fine enamel, of a dark red colour, not to mention other colours in it ſtill more beautiful. The crocus martis he uſed in this experiment was prepared from a ſolution of iron in aqua regia (nitro-muriatic acid), which was evaporated to dryneſs, and the matter thus edulcorated and calcined.

13. In order to render the forementioned enamel more ſolid, and to give it what is called *body*, he melted together a mixture of twelve parts of flint glaſs, eighteen parts of minium, four parts of potaſh, four parts of nitre, two parts of borax, three parts of calx of tin, and one eighth part of calx of cobalt, obſerving always the uſual precautions. He obtained a glaſs of a light blue colour, which, after having been ground with water, and ſpread upon ſmall iron baſins, or tea cups, produced, by means of a briſk fire in an aſſaying furnace, an enamel which was ſmooth and even, and of a pearl colour. The coating was of a proper thickneſs, to obtain which requires a certain degree of dexterity and practice. He alſo tried to paint upon this enamel with what is called *mineral purple (purpura mineralis)*, which he uſed with a little powdered quartz, nitre, and borax; it produced a very beautiful red colour.

Though this laſt mentioned compoſition is more beautiful when applied upon iron, and more even than the preceding, it has the diſadvantage, on account of the ſalts which it contains, of not reſiſting the action of the ſtronger vegetable acids, and ſtill leſs that of the mineral ones. But as a veſſel when coated with this enamel bears, without any injury, ſudden changes of heat and cold, and alſo to have any greaſy mixtures baked or boiled in it (even thoſe which are of a cauſtic alkaline nature, or thoſe which contain the uſual weak acids which are uſed in the preparation of our food), it may be applied to veſſels of various kinds, among others, to tea cups; particularly as it is neither brittle nor ſubject to crack, provided it is not expoſed to violent blows. It is hardly neceſſary to ſay, that this enamel can only be applied upon veſſels made of hammered iron, and not upon thoſe of caſt iron, theſe laſt being always too thick to be heated with ſufficient quickneſs; for the greater is the ſpace of time neceſſary to make the veſſels red hot, the greater is the quantity of ſcales formed upon them, and, of courſe, the enamel becomes more injured.

Our author makes ſome other judicious obſervations on the enamel for iron, of which he has deſcribed the compoſition, and ſays, that, independent of its uſe for coating kitchen utenſils, it might be made to ſerve many other purpoſes, ſuch as preſerving things made of that metal, not only from ruſt, but alſo, as he proved by experiment, to a certain degree, from calcination.

ENCAUSTIC PAINTING. See PAINTING in this *Supplement*.

ENFIELD (William, L. L. D.), well known in the learned world by ſeveral uſeful and elegant publications, was born at Sudbury, on March 29. O. S. 1741, of parents in a humble walk of life, but of very reſpectable characters. His amiable diſpoſition and promiſing talents early recommended him to the Rev.

Mr Hextall, the diſſenting miniſter of that place, who took great care of his education, and infuſed into his young mind that taſte for elegance in compoſition which ever afterwards diſtinguiſhed him.

In his 17th year he was ſent to the academy at Daventry, then under the direction of the Rev. Dr Aſhworth, where he paſſed through the uſual courſe of inſtruction preparatory to the office of the miniſtry; and with ſuch ſucceſs did he cultivate the talents of a preacher, and of an amiable man in ſociety, that, on leaving the academy, he was at once choſen, in 1763, miniſter of the very reſpectable congregation of Benn's Garden in Liverpool.

In that agreeable town he paſſed ſeven of the happieſt years of his life, very generally beloved and eſteemed. He married, in 1767, the daughter of Mr Holland draper in Liverpool, with whom he paſſed all the reſt of his days in moſt cordial union. His literary reputation was extended, during his reſidence in this place, by the publication of two volumes of ſermons, which were very well received, and have ſerved to grace many pulpits beſides that in which they were originally preached. A collection of hymns and of family prayers, which he alſo publiſhed at Liverpool, did credit to his taſte and judgment.

About 1770, he was invited to take a ſhare in the conduct of the academy at Warrington, and alſo to occupy the place of miniſter to the diſſenting congregation there, both vacant by the death of the Rev. Mr Seddon. His acceptance of this honourable invitation was a ſource of variety of mixed ſenſations and events to him, of which anxiety and vexation compoſed too large a ſhare for his happineſs. No aſſiduity on his part was wanting in the performance of his various duties; but the diſeaſes of the inſtitution were radical and incurable; and perhaps his gentleneſs of temper was ill adapted to contend with the difficulties, in matter of diſcipline, which ſeem entailed on all diſſenting academies, and which, in that ſituation, fell upon him, as the domeſtic reſident, with peculiar weight. He always, however, poſſeſſed the reſpect and affection of the beſt diſpoſed of the ſtudents; and there was no reaſon to ſuppoſe that any other perſon, in his place, could have prevented that diſſolution which the academy underwent in 1783.

During the period of his engagement there, his indefatigable induſtry was exerted in the compoſition of a number of works, moſtly, indeed, of the claſs of uſeful compilations, but containing valuable diſplays of his powers of thinking and writing. The moſt conſiderable was his "Inſtitutes of Natural Philoſophy" (quarto, Johnſon, 1783); a clear and well-arranged compendium of the leading principles, theoretical and experimental, of the ſciences compriſed under that head. And it may be mentioned, as an extraordinary proof of his diligence and power of comprehenſion, that, on a vacancy in the mathematical department of the academy, which the ſtate of the inſtitution rendered it impoſſible to ſupply by a new tutor, he prepared himſelf, at a ſhort warning, to fill it up; and did fill it with credit and utility, though this abſtruſe branch of ſcience had never before been a particular object of his ſtudy. He continued at Warrington two years after the academy had broken up, taking a few private pupils.

In 1785, receiving an invitation from the principal diſſenting congregation at Norwich, he accepted it, and firſt fixed his reſidence at Thorpe, a pleaſant village near the city, where he purſued his plan of taking a limited number of pupils to board in his houſe. He afterwards removed to Norwich itſelf; and, at length, fatigued with the long cares of education, entirely ceaſed to receive boarders, and only gave private inſtructions to two or three ſelect pupils a few hours in the morning. This too he at laſt diſcontinued, and devoted himſelf ſolely to the duties of his congregation, and the retired and independent occupations of literature. Yet, in a private way and ſmall circle, few men had been more ſucceſsful in education, of which many ſtriking examples might be mentioned, and none more ſo than the members of his own family. Never, indeed, was a father more deſervedly happy in his children; but the eldeſt, whom he had trained with uncommon care, and who had already, when juſt of age, advanced in his profeſſional career ſo far as to be choſen town-clerk of Nottingham, was moſt unfortunately ſnatched away by a fever a few years ſince.

This fatal event produced effects on the doctor's health which alarmed his friends. The ſymptoms were thoſe of *angina pectoris*, and they continued till the uſual ſerenity of his mind was reſtored by time and employment. Some of the laſt years of his life were the moſt comfortable: employed only in occupations which were agreeable to him, and which left him maſter of his own time; witneſſing the happy ſettlement of two of his daughters; contracted in his living within the domeſtic privacy which he loved; and connected with ſome of the moſt agreeable literary companions, and with a ſet of the moſt cordial and kind-hearted friends that perhaps this iſland affords, he ſeemed fully to enjoy life as it flowed, and indulged himſelf in pleaſing proſpects for futurity. Alas! an unſuſpected and incurable diſeaſe was preparing a ſad and ſudden change: a ſchirrous contraction of the rectum, the ſymptoms of which were miſtaken by himſelf for a common laxity of the bowels, brought on a total ſtoppage, which, after a week's ſtruggle, ended in death. Its gradual approach gave him an opportunity to diſplay all the tenderneſs, and more than the uſual firmneſs of his nature. He died November 3. 1797, amidſt the kind offices of mourning friends, and his laſt hours were peace!

Beſides the literary performances already mentioned, Dr Enfield completed, in 1791, the laborious taſk of an abridgment of "Brucker's Hiſtory of Philoſophy," which he compriſed in two volumes quarto. It may be truly ſaid, that the tenets of philoſophy and the lives of its profeſſors were never before diſplayed in ſo pleaſing a form, and with ſuch clearneſs and elegance of language. Indeed it was his peculiar excellence to arrange and expreſs other mens ideas to the utmoſt advantage. Perhaps, at the time of his deceaſe, there was not in England a more perfect maſter of what is called the middle ſtyle in writing, combining the qualities of eaſe, elegance, perſpicuity, and correctneſs, entirely free from affectation and ſingularity, and fitted for any ſubject. If his caſt of thought was not original, yet it was free, enlarged, and manly. What he was in the capacity of a teacher of religion, his ſeveral congregations will teſtify with grateful and affectionate remembrance. Few miniſters have paid ſuch unremitting attention to the perfection of their pulpit compo-

Enfield || Engrafting.

ſitions; nor was it only by detached diſcourſes that he inculcated the truths of morality and religion, but by methodical plans of inſtruction, drawn up with great care and comprehenſion. The valuable ſtores of this kind which he left behind him will not be conſigned to oblivion; but, it is hoped, will inform and improve numbers to whom the voice of the preacher could never have extended. In delivery, his manner was grave and impreſſive, depending rather on the weight of juſt enunciation than on the arts of oratory. Little need be added to this ſketch of the moral qualities of the excellent man above commemorated. If moderation, compliancy, and gentleneſs were ever prevalent in him to a degree of exceſs, who that knew him will blame an exceſs which opened his ſoul to every emotion and office of affection and friendſhip?

This account of Dr Enfield, which is taken from the *Monthly Magazine*, is acknowledged by its author to be the effuſion of friendſhip; but we believe that the panegyric, though high, is in general juſt. It is our duty, however, to warn our readers againſt placing implicit confidence in the Doctor's repreſentation of ancient philoſophy; for though we have frequently found him correct, and have therefore quoted him with approbation ourſelves, we have likewiſe found him ſometimes miſtaking the ſenſe of his authors. In a work like his, miſtakes were indeed unavoidable; for when he reſolved to compreſs the ſubſtance of Brucker's five volumes within the compaſs of two, he could not avoid ſometimes giving what he thought the *ſenſe* of the ancients, when accuracy required their very *words* to be given. This we believe to be the ſource of thoſe errors in his elegant hiſtory, which we have heard others unjuſtly attribute to deſign; for had it been his *deſign* to deceive, he would not ſurely have ſtored his margin with references to enable every reader to detect the deceit.

ENGINEER, is the appellation of him whoſe profeſſion it is to contrive or make any kind of uſeful engine or machine. He is denominated either a civil or military engineer, according as the objects of his profeſſion reſpect civil or military purpoſes. See FORTIFICATION, *Encycl.* and MACHINE in this *Supplement*.

ENGONASIS, in aſtronomy, the ſame as Hercules, one of the northern conſtellations.

ENGRAFTING. See GRAFTING, *Encycl.* where it is ſaid that there is little hope of producing mixed fruits by engrafting one tree upon another of the ſame claſs. We confeſs ourſelves to be unwilling to relinquiſh this opinion; but it would be very unfair to withhold from the public any fact which ſeems to militate againſt it, and has come to our knowledge. We ſhall therefore tranſcribe from the *Philoſophical Magazine* the following communication from Dr Thornton, lecturer on medical botany at Guy's Hoſpital, reſpecting a ſuppoſed *luſus naturæ*, which he conſiders as the conſequence of engrafting.

In the firſt volume of the *Philoſophical Tranſactions*, N° 29. publiſhed November 1667, you have the following communication, intitled,

Enneadecateris || Scotch Epiſcopalians.

“Some Hortulan Experiments about the engrafting of Oranges and Lemons or Citrons, whereby is produced an individual Fruit, half Orange and half Lemon, growing together as one Body upon the ſame Tree.”

We have here orange trees (ſaith the intelligence from Florence) that bear a fruit which is citron on one ſide and orange on the other. They have been brought hither out of other countries, and they are now much propagated by engrafting. This was confirmed to us (ſays the editor of the Tranſactions of the Royal Society) by a very ingenious Engliſh gentleman, who aſſerted, that himſelf not only had ſeen, but bought of them, anno 1660, in Paris, whither they had been ſent by Genoa merchants; and that on ſome trees he had found an orange on one branch and a lemon on another branch (which is not ſo remarkable as what follows); as alſo, one of the ſame fruit, half orange and half lemon; and ſometimes three quarters of one and a quarter of the other.

In the third part of the Reports of the Board of Agriculture, among the foreign communications, we ſee, with equal pleaſure and aſtoniſhment, an account of the American apple, which, by a peculiar mode of budding (A), is half ſweet and half ſour, half white and half red, without the leaſt confuſion of the reſpective halves.

At Mr Maſon's, floriſt, Fleet-ſtreet, oppoſite the Bolt and Tun, there is a production now, September 1798, to be ſeen half peach and half nectarine. It has all the ſoftneſs and yellow down of the peach, and the ſleek red ſmoothneſs of the nectarine; ſuppoſed to be a *luſus naturæ*, but probably is rather the ſportings of art than of nature, and which perhaps will be the cauſe why we ſhall in future ſee many other ſuch vegetable wonders, which, as we ſee, were known to our anceſtors.

ENNEADECATERIS, in chronology, a cycle or period of 19 ſolar years, being the ſame as the golden number and lunar cycle, or cycle of the moon.

EPAULE, or ESPAULE, in fortification, the ſhoulder of the baſtion, or the angle made by the face and flank, otherwiſe called the angle of the epaule.

EPISCOPACY, the government of the church by dioceſen biſhops. See *Encycl.*

SCOTCH EPISCOPALIANS, are a ſociety of Chriſtians, certainly as reſpectable, if not ſo numerous, as any other in the kingdom which diſſents from the worſhip and diſcipline of the eſtabliſhed church. For many years, however, the public worſhip of that ſociety was proſcribed by the legiſlature; and there is reaſon to ſuſpect that its real principles are not yet univerſally underſtood. If this be ſo, it ſurely becomes the editors of a work in which ſome account is given of almoſt every denomination of Chriſtians down to the novel ſect which ſtyles its members BEREANS, to do juſtice to the venerable remains of what was once the eſtabliſhed church of their native country.

1 Eſtabliſhment of Epiſcopacy in Scotland.

That the reformation from popery was, in Scotland, tumultuous and irregular, is known to all Europe; and very few of our readers can be ignorant that there was

---

(A) the manner in which the extraordinary nectarine-peach firſt produced in this country was effected, was by inſerting the bud of one fruit upon the ſtock bearing a different ſort.

neither order in the reformed church, nor decency in her worſhip, till James VI. with much addreſs, accompliſhed the eſtabliſhment of a very moderate epiſcopacy. To this form of church-government the better part of the nation was ſufficiently attached; and it continued to be the eccleſiaſtical polity, ſupported by the ſtate, till the grand rebellion, when it was overthrown by the partizans of the *national covenant*. It was reſtored, however, in 1662; and again aboliſhed in 1689 by that convention which placed the Prince and Princeſs of Orange on the ancient throne of the Scottiſh monarchs.

2
No liturgy uſed in the Scotch church,

Theſe events are ſo univerſally known, that it is ſufficient in this place barely to mention them; but there are probably many of our readers who do not know that, during the whole period of her legal eſtabliſhment, the Scotch epiſcopal church had no public liturgy. It appears indeed, that the firſt reformers made uſe of the Engliſh book of common prayer; and there is on record ſufficient evidence that John Knox himſelf, though he diſapproved of ſome things in that book, had no objection either to ſtated forms of prayer in general, or to a ſubordination among the miniſters of the goſpel; but his ſucceſſor Andrew Melvil, who poſſeſſed neither his learning nor his worth, had influence enough to introduce into the church a perfect parity of miniſters, and to excite among the people a very general abhorrence of liturgical worſhip. So rooted indeed was that abhorrence, that, as every one knows, an attempt to introduce into the church of Scotland a book of common prayer, copied with ſome alterations from that of England, produced the *ſolemn league and covenant*, which involved in one common ruin the unfortunate Charles and his darling Epiſcopacy. At the reſtoration of the monarchy, the Epiſcopal conſtitution of the church was reſtored, but no new attempt was made to eſtabliſh the uſe of a public liturgy; and except at the ordinations of the clergy, when the Engliſh forms were uſed, no ſervice book was ſeen in a Scottiſh church.

3
Except at ordinations.

For ſome years after Epiſcopacy had ceaſed to be the religion of the ſtate, the deprived clergy made no alteration in their modes of ſocial worſhip. Having refuſed to transfer to King William that allegiance which they had ſworn to King James, they were treated, during his reign, with ſuch ſeverity, that on the Lord's day they durſt not venture further than to officiate "in their own hired houſes, where they received ſuch friends as choſe to come in unto them;" and in thoſe ſmall congregations, if congregations they may be called, they continued to pray, if not extempore, at leaſt without book, till the acceſſion of Anne to the throne of her anceſtors. The attachment of that Princeſs, not only to the conſtitution, but alſo to the worſhip of the church of England, was well known to them; and they very reaſonably thought, that they could not more effectually recommend themſelves to her protection than by adopting the uſe of the Engliſh liturgy, which the moſt enlightened among them had long profeſſed to admire. It was accordingly introduced by degrees into Scotland; and an act of parliament being paſſed on the 3d of March 1712, "to prevent the diſturbing of thoſe of the Epiſcopal communion in that part of Great Britain called Scotland, in the exerciſe of their religious worſhip, and in the uſe of the liturgy of the church of England," that liturgy was univerſally adopted by the Scotch Epiſcopalians; and public chapels, which had hitherto been prohibited, were everywhere built, and well frequented.

4
Introduction of the Engliſh liturgy.

That thoſe who had refuſed allegiance to King William and Queen Anne ſhould ſcruple to pay it to a new family, clogged as it was by ſo many oaths, can excite no wonder; nor is it at all wonderful that, for their attachment to the abdicated family, the public worſhip of the Scotch Epiſcopalians was, after the inſurrection of 1715 and 1716, laid under ſome reſtraints. Theſe, however, were neither rigorouſly ſevere, nor of long duration; and by the year 1720, their congregations were as numerous as formerly, conſiſting, eſpecially in the northern counties, of men of all ranks, even ſuch as held offices of truſt under the eſtabliſhed government, who frequented the Epiſcopal chapels in preference to the pariſh churches.

Hitherto the Epiſcopalians had been ſafely conducted through all dangers and difficulties by the prudence of Dr Roſe, the deprived biſhop of Edinburgh; but ſoon after his death, which happened on the 20th of March 1720, diviſions broke out among them, which threatened to prove more fatal to their church than any perſecution to which they had yet been ſubjected. For reaſons which will be ſeen afterwards, it is proper to trace thoſe diviſions from their ſource.

5
Sources of diviſion among the Scotch Epiſcopalians.

No native of Britain, who knows any thing of the hiſtory of his country, can be ignorant that Dr Sancroft, the archbiſhop of Canterbury, and five other biſhops, were at the Revolution deprived of their ſees by an act of parliament; becauſe, like the Scotch biſhops, they could not bring themſelves to transfer to King William and Queen Mary that allegiance which they had ſo lately ſworn to King James. As thoſe prelates were extremely popular for the vigorous oppoſition which they had given to ſome of the Popiſh projects of the late king, and as a number of inferior clergymen, of great eminence for piety and learning, were involved in the ſame fate with them—it need not excite great ſurpriſe, that a ſweeping deprivation, which, in all its circumſtances, was perhaps without a precedent in eccleſiaſtical hiſtory, produced a ſchiſm in the church of England. The deprived clergy, conſidering the biſhops who were placed in the ſees thus vacated as intruders, and all who adhered to them as ſchiſmatics, opened ſeparate chapels under the authority of the primate and his nonjuring ſuffragans; and contended, that they and their adherents conſtituted the only orthodox and catholic branch of the church in England.

Both churches, however, made uſe of the ſame liturgy; and during the lives of the deprived prelates, there was no other apparent difference in their worſhip than what neceſſarily reſulted from their paying allegiance to different ſovereigns. But this uniformity was not of long duration. The biſhops, who had been poſſeſſed of ſees before the Revolution, were ſcarcely dead, when their ſucceſſors, being under no civil reſtraint, found, in the principles which they had brought with them from the eſtabliſhment, the means, not only of dividing their own little church, but likewiſe of ſowing the ſeeds of diſſenſion among their brethren in Scotland.

It has been obſerved elſewhere *, that in the church of England there are three opinions reſpecting the nature and end of the Lord's Supper, which, in oppoſition to each other, have been all patroniſed by men of great eminence for theological learning. It appears, indeed,

---

* Supper of the Lord, *Encycl.*

Scotch Epiſcopalians.

indeed, from the firſt liturgy ſet forth by authority in the reign of King Edward VI. that the reformers of that church from the errors of popery unanimouſly held the Lord's Supper to be a euchariſtical ſacrifice; and this opinion, which has been adopted by great numbers in every age ſince, ſeems to have been the moſt prevalent of the three among thoſe clergy who were deprived of their livings at the Revolution. It is indeed countenanced by ſeveral paſſages in the preſent order for the adminiſtration of the Lord's Supper; and therefore, though there are other things in that order which cannot be eaſily reconciled to it, archbiſhop Sancroft and his ſuffragans, whatever their own opinions might be, choſe not to widen the breach between themſelves and the eſtabliſhment, by deviating in the ſmalleſt degree from the form in which they had been accuſtomed to celebrate that ſacrament. Their ſucceſſors, however, in office, were men of different diſpoſitions. Conſidering themſelves as totally unconnected with the ſtate, and no longer bound by the act of uniformity, one party, at the head of which was biſhop Collier, the celebrated eccleſiaſtical hiſtorian (A), judged it proper to make ſuch alterations in the communion office as might render it more ſuitable to their own notions of the Lord's Supper, and bring it nearer, both in matter and form, to the moſt ancient liturgies of the Chriſtian church.

Of the propoſed alterations, ſome were perhaps proper in their circumſtances; whilſt others, to ſay the beſt of them, were certainly needleſs, if not inexpedient. They were accordingly *all* oppoſed by another powerful party of nonjurors; and the queſtions in diſpute were referred, firſt to Dr Roſe, the deprived biſhop of Edinburgh, and afterwards to Dr Atterbury and Dr Potter, the biſhops of Rocheſter and Oxford. What judgment the two Engliſh prelates gave in this controverſy we know not; but that of biſhop Roſe did him much honour. Declining the office of umpire between the parties, he recommended mutual forbearance and occaſional communion with each other, according to either form; and employed a gentleman, well verſed in eccleſiaſtical literature, to prove that ſuch a compliance of biſhop's with each others innocent prejudices was not uncommon in the pureſt times.

Theſe diſputes among the Engliſh nonjurors, and the appeal which was made to Dr Roſe, drew, more cloſely than hitherto it had been drawn, the attention of the Scotch Epiſcopal clergy, not only to their own liturgy, which had been authoriſed by King Charles I. but likewiſe to the moſt ancient liturgies extant, as well as to what the fathers of the firſt three centuries have taught concerning the nature of the Lord's Supper. The conſequence was, that ſuch of them as were ſcholars ſoon diſcovered, that the Scotch communion office approached much nearer to the moſt ancient offices than the Engliſh; and a powerful party was formed for reviving the uſe of it in Scotland.

Had thoſe men aimed at nothing farther, it is probable they would have met with very little oppoſition. Their opponents, who, in general, were leſs learned than they, were ſo ſtrongly attached to the houſe of Stuart, that they would have adopted almoſt any thing ſanctioned by the royal martyr's authority; but the advocates for the Scotch office knew not where to ſtop. They wiſhed to introduce ſome other uſages of the primitive church; ſuch as the commemoration of the faithful departed, and the mixture of the euchariſtic cup (See *Supper of the Lord*, n° 2. and 3. *Encycl.*); and their brethern, perceiving no authority from Charles I. for theſe things, and being accuſtomed to conſider them as Popiſh practices, a violent controverſy was ready to burſt forth about what every enlightened mind muſt conſider as matters of very little importance.

6 Revival of ancient uſages.

That the euchariſtic cup was in the primitive church mixed with a little water, is a fact incontrovertible; that the practice was harmleſs and decent, it is wonderful that any man ſhould deny: but that ſuch a mixture is *eſſential* to the ſacrament, we cannot believe, for the reaſons aſſigned in the article referred to; and therefore it ought ſurely to have been no object of contention.

That the faithful departed were commemorated in the primitive church long before the invention of purgatory, is known to every ſcholar; that in thoſe days ſuch a commemoration tended to invigorate the faith and the charity of Chriſtians, it would, in our opinion, be very eaſy to preve; and that at preſent every Chriſtian prays in private for his deceaſed friends, we have proved elſewhere by arguments, of the confutation of which we are under no apprehenſion (See *Greek-church* in this *Supplement*): but we ſee not the *neceſſity* of introducing ſuch prayers into public worſhip at any period; and we perceive impropriety in doing it at a period when, from various circumſtances, they may cauſe weak brethren to err. But thoſe who pleaded for the revival of this practice in the beginning of the current century, were blinded by their very erudition (B); and thoſe who oppoſed it ſeem not to have been acquainted with

---

(A) This very learned, though violent man, of whom the reader will find ſome account in the *Encyclopædia*, was, with Dr Hickes and others, conſecrated by the deprived prelates, for the purpoſe of preſerving the Epiſcopal ſucceſſion in what they conſidered as the true church of England.

(B) Paradoxical as this aſſertion may at firſt ſight appear, nothing is more certain than that erudition, and even ſcience, if *partially* cultivated, is as likely to blind as to enlighten the underſtanding. When a man devotes all his time, and all his attention, to *one* purſuit, he contracts ſuch a fondneſs for it, as gradually to conſider it as the *only* valuable purſuit, which will infallibly lead to truth, and to nothing but truth; and in this diſpoſition of mind, he is ready to embrace the moſt extravagant abſurdity to which it may conduct him. Of this the reader will find one very ſtriking inſtance in page 547 of this volume, where the celebrated Euler appears ſo devoted to his darling analyſis, as to place implicit confidence in it, even when he himſelf ſeems ſenſible that it had led him to a concluſion contrary to common ſenſe, and the nature of things. That Dr Bentley was a very eminent philologiſt, is univerſally known; that his emendatory criticiſms on the Claſſics are often happy, no man will deny; and yet, miſled by his favourite purſuits, he never pronounces more dogmatically than when the dogma which he utters is untenable. We appeal to his criticiſms on Milton. Perhaps there is not a man alive with the workings of a benevolent and devout mind, or indeed to have known in what the eſſence of a prayer conſiſts.

The ancient uſages, however, were not the only ſubjects which, on the death of biſhop Roſe, furniſhed matter for controverſy among the Scotch Epiſcopalians. That excellent prelate, together with the deprived archbiſhop of Glaſgow, and the deprived biſhop of Dunblain, had, from time to time, as they ſaw occaſion, raiſed to the Epiſcopal dignity ſome of the moſt deſerving Preſbyters of the church; but it was reſolved, for what reaſon we do not very well know, that none of the new biſhops ſhould be appointed to vacant dioceſes during the life of any one prelate who had poſſeſſed a legal eſtabliſhment; ſo that biſhop Roſe, who ſurvived all his brethren, was for ſeveral years the eccleſiaſtical governor of the whole Epiſcopal church in Scotland. On his death, therefore, though there were four biſhops in Scotland, and two Scotch biſhops reſiding in London, there was not one of thoſe prelates who could claim to himſelf the authority of a dioceſan over any portion of the Catholic church. This they at firſt unanimouſly acknowledged; and one of them, in the name of himſelf and his brethren, recommended to the clergy of the dioceſe of Edinburgh to elect, after the primitive plan, a ſucceſſor to their late venerable dioceſan. The advice was followed; the election was made, and approved by the biſhops: and Dr Fullarton, the biſhop choſen, became biſhop of Edinburgh, by the ſame means and the ſame authority as, in the primitive church, St Cyprian became biſhop of Carthage, or Cornelius biſhop of Rome.

The clergy in other diſtricts, following the example of thoſe in Edinburgh, dioceſan Epiſcopacy was about to be revived throughout all Scotland upon principles purely eccleſiaſtical, when ſome of the biſhops, whom Dr Roſe had left behind him merely for preſerving the Epiſcopal ſucceſſion, conceived a new and very extraordinary conſtitution for the Scotch Epiſcopal church. Whether they were envious of their colleagues, and offended that none of the elections had fallen upon them; whether they were ſo ignorant as not to know that dioceſan Epiſcopacy had ſubſiſted long before the converſion of the Roman empire, in abſolute independence on the ſtate; or that they were actuated, as there is reaſon to ſuſpect, by ſome political principle which they could not with ſafety avow;—ſo it was, that they oppoſed dioceſan Epiſcopacy of every kind, and propoſed to govern the whole Scotch church by a college of biſhops. Againſt this unprecedented ſcheme the more learned biſhops oppoſed all their influence; and, being exceedingly diſagreeable to the inferior clergy, it was very ſoon abandoned by its authors themſelves, who, after ſome acrimonious controverſy, were glad to come to an agreement with their dioceſan brethren.

7
College of biſhops.

8
Thoſe diviſions healed.

Of this agreement, or *concordate* as it was called, the following were the principal articles: 1. "That the Scotch or Engliſh liturgy, and no other, might be indifferently uſed in the public ſervice; and that the peace of the church ſhould not be diſturbed by the introduction of any of the ancient uſages which had lately excited ſuch diſſenſions. 2. That no man ſhould thenceforward be conſecrated a biſhop of the Scotch church without the conſent and approbation of the majority of the biſhops. 3. That the biſhops, by a majority of voices, ſhould chooſe one of their number to preſide in the meetings of his brethren, and to convocate ſuch meetings when he judged them neceſſary: that this preſident ſhould be ſtyled *Primus Epiſcopus*, or more ſhortly *Primus*; but that he ſhould not poſſeſs metropolitical power, or claim any kind of juriſdiction without the bounds of his own dioceſe or diſtrict. 4. That upon the vacancy of any dioceſe or diſtrict, the preſbyters ſhould neither elect, nor ſubmit to, another biſhop, without receiving a mandate by the Primus, iſſued with the conſent of the majority of his colleagues."

This concordate was in 1731-2 ſubſcribed by all the biſhops then in Scotland, who immediately became dioceſans, and thought no more of the college ſyſtem. It was afterwards, with a few additions, for aſcertaining more preciſely the prerogatives of the Primus; for regulating the conduct of ſynods; for exempting biſhops from the juriſdiction of other biſhops, in whoſe diſtricts they might chance to reſide; and for preventing inferior clergymen from deſerting their congregations, or removing from one diſtrict to another, without the conſent of the biſhops of both—thrown into the form of canons; and theſe canons have continued to be the code of the Scotch Epiſcopal church down to the preſent day.

9
Political opinions.

The members, and more eſpecially the clergymen of this church, had always been conſidered as unduly attached to the family of Stuart; and though there was undoubtedly at firſt ſome ground for that ſuſpicion, the writer of this article knows, from the moſt incontrovertible evidence, that it was continued too long, and carried by much too far. Jacobitiſm was imputed

---

alive who will refuſe to Dr Warburton the praiſe of learning and ingenuity. The addreſs with which he detects the double doctrines of the ancient philoſophers, is ſometimes almoſt aſtoniſhing; yet, miſled by his own ardour in this purſuit, he diſcovers hidden meanings everywhere, and has found a rational ſyſtem of religion in ſome of the ancient myſteries, where there is every reaſon to believe that nothing in reality was to be found but atheiſm and vice. Juſt ſo it is with the ardent reader of the Chriſtian fathers. If he devote all his time to the ſtudy of their writings, he not only becomes enamoured of his employment, but acquires gradually ſuch a veneration for the character of his maſters (and venerable they undoubtedly are) as renders him afraid to queſtion any thing which they advance, and unable to diſtinguiſh between their teſtimony, which is deſerving of all credit, and their reaſonings, which are often inconcluſive. We truſt it is needleſs to diſclaim any wiſh to diſcourage, by this note, the ſtudy either of the Chriſtian fathers, the Greek philoſophers, philological criticiſm, or the modern analyſis; we only wiſh to diſſuade men of letters from devoting their whole time to any *one* purſuit whatever; for they may depend upon it, that ſuch *partial* ſtudies contract the mind. One of the moſt eminent mathematicians at preſent in England is reported to have declared his contempt of the *Paradiſe Loſt*, becauſe he found in it nothing *demonſtrated!*

ted to the ſociety as its diſtinguiſhing tenet ; but the members of that ſociety have at all times contended, that their diſtinguiſhing tenets were the apoſtolical inſtitution of Epiſcopacy, and in the exerciſe of thoſe powers which are purely ſpiritual, the independency of the church upon the ſtate. In politics, indeed, they have unanimouſly maintained, that the only ruler of princes or *legiſlatures* is God, and not the people. They are, of courſe, no friends to the faſhionable doctrine of reſiſtance, which they believe to be not only condemned in expreſs terms by Chriſt and two of his apoſtles, but to be alſo the ſource of that anarchical tyranny which lately deluged Europe with blood. They conſider a limited monarchy, like that of Britain, as the moſt perfect form of civil government which the world has ever ſeen; and hereditary monarchy is infinitely preferable to one that is elective: and with reſpect to the title of the monarch, when they take a retroſpective view of the origin of all civil governments, they cannot but look upon a permanent and unqueſtioned eſtabliſhment as an indication of the plan and determination of Providence furniſhing the beſt right to a crown which any modern ſovereign can claim.

10
Perſecution

Surely theſe are harmleſs opinions; and yet the worſhip of thoſe who held them was, in 1746 and 1748, laid under ſuch reſtraints as were calculated to produce diſaffection where it did not previouſly exiſt. Two laws were then enacted againſt the Scotch Epiſcopalians ; which, under the pretence of eradicating their attachment to the houſe of Stuart, were ſo contrived as to preclude ſuch of their clergy as were willing to pay allegiance to the reigning ſovereign, and to pray for the royal family by name, from reaping the ſmalleſt benefit from their loyalty. The experiment was tried by ſome of them ; of whom one venerable perſon, who was never ſuſpected of undue attachment to the houſe of Stuart, is ſtill alive; but he, and his complying brethren, had their chapels burnt, and were themſelves impriſoned, as if they had been the moſt incorrigible Jacobites. This was a kind of perſecution which, ſince the Reformation, has had no precedent in the annals of Britain. A prieſt of the church of Rome, by renouncing the errors of Popery, has at all times been qualified to hold a living in England ; a diſſenting miniſter, of whatever denomination, might at any time be admitted into orders, and riſe to the higheſt dignities of the Engliſh church;—but while the laws of 1746 and 1748 remained in force, there was nothing in the power of a Scotch Epiſcopal clergyman to do from which he could reap the ſmalleſt benefit. By taking the oaths to government, he was not qualified to hold a living in England, or even to enjoy a toleration in Scotland ; and his clerical character being acknowledged by the Engliſh Biſhops, he could not by thoſe prelates be canonically reordained.

11
Toleration.

Upon the clergy, however, thoſe laws of uncommon rigour were not long rigorouſly executed. After a few years, the burning of chapels, and the impriſoning of miniſters, were occurrences far from frequent ; but the laws to which we allude affected likewiſe the political privileges of ſuch laymen as frequented the Epiſcopal chapels : and in that part of their operation, thoſe laws were never relaxed till 1792, when they were wholly repealed, and the Epiſcopalians in Scotland tolerated like other well affected diſſenters from the national eſtabliſhment.

12
Faith of the Scotch Epiſcopal church.

While Epiſcopacy was the eſtabliſhed form of church government in Scotland, the clergy of that church ſubſcribed a confeſſion of faith ſummed up in twenty-five articles, which the reader will find in the hiſtory attributed to John Knox. It is ſufficient to obſerve in this place, that in eſſentials it differs little from the articles of moſt other reformed churches ; and in every thing which does not immediately relate to *papiſtry*, it is moderate and unexceptionable ; perhaps more ſo than the preſent confeſſion of either of the Britiſh churches. During the period which intervened between the Revolution and the year 1792, no ſubſcription was indeed required from Scotch Epiſcopalian clergymen to any ſummary of Chriſtian doctrine ; but at their ordinations, thoſe clergy ſolemnly profeſſed their belief of all the canonical books of the Old and New Teſtaments ; declared their perſuaſion that thoſe books contain ſufficiently all doctrines neceſſary to ſalvation, through faith in Jeſus Chriſt ; and were obliged to read daily in their chapels the Engliſh book of Common Prayer, which contains the Apoſtles, Nicane, and Athanaſian creeds. But now thoſe clergymen are enjoined by act of parliament to ſubſcribe the 39 articles of the church of England ; ſo that the principles of their faith are well known. No doubt there are differences of opinion among them about the ſenſe of ſome of thoſe articles ; and it is well known that there are ſimilar differences among the Engliſh clergy themſelves: but there is every reaſon to believe, that the faith of the Scotch Epiſcopalians has, in every important point, been at all times orthodox.

13
Their worſhip.

We are aware, that they have been repreſented as unfriendly to the Engliſh ſervice ; but ſuch a repreſentation appears to be either a wilful falſehood, or the offspring of ignorance. The only reformed liturgy that ever had the ſanction of a civil eſtabliſhment in Scotland, is *the Book of Common Prayer, and Adminiſtration of the Sacraments, and other parts of Divine Service* authoriſed by King Charles I. In that book, the order of adminiſtration of the Lord's Supper differs in ſome particulars from the Engliſh order, and is unqueſtionably better adapted to the opinions of thoſe who conſider that holy ordinance either as an euchariſtical ſacrifice, or as a feaſt upon a ſacrifice. In the one or other of theſe lights, the Lord's Supper is viewed by a great majority of the Scotch Epiſcopalians ; and of courſe the Scotch communion office is uſed in a great majority of their chapels : but it is not uſed in them all. Their biſhops, who, when in England, communicate with the eſtabliſhed church, leave the inferior clergy at liberty to uſe either the Engliſh or the Scotch form, as is moſt agreeable to themſelves and to the people among whom they miniſter ; and to ſilence the clamour of ſymbolizing with the church of Rome, which was ſome years ago either ignorantly or maliciouſly raiſed againſt them, they altered the *arrangement* of the Scotch prayer of conſecration, ſo as not only to bring it nearer to the moſt primitive forms, but alſo to make it abſolutely inconſiſtent with the real preſence, as taught either by the church of Rome or by the Lutheran churches. On this ſubject, ſee *Greek-Church*, n° 17. in this *Supplement*.

14
Engliſh clergymen in Scotland.

Thus have we given a ſhort view of the diſtinguiſhing principles of what muſt ſurely be conſidered as a very reſpectable ſociety of Chriſtians, and the only reformed *Epiſcopal* ſociety in that part of Great Britain called Scotland. There are, indeed, chapels in Scotland diſtinct from the church of which we have been treating, where the Engliſh liturgy is read by clergymen who have received Epiſcopal ordination either in England or in Ireland; but thoſe chapels being all independent of each other, and under the inſpection of no biſhop, the perſons who frequent them ſeem to be rather Congregationaliſts than Epiſcopalians, and certainly do not conſtitute what can, with any propriety, be called an *Epiſcopal church*.

EQUANT, in aſtronomy, a fanciful circle, introduced into ſcience to remove ſome of the defects of the Ptolemaic ſyſtem of the univerſe. In this artificial ſyſtem of epicycles and eccentric circles, the idea of circular and equable motion was by no means abandoned; but while each of the heavenly bodies revolved in its own orb, the centre of that orb was ſuppoſed to be carried at the ſame time round the circumference of another circle. The more obvious inequalities were thus explained with a geometrical preciſion. With all its nice combination, however, of circles, the ſyſtem was ſoon found to have defects; to remove which, the fine contrivance of the equant was introduced. Though the angular motion of a planet viewed from the earth was confeſſed to be unequal, a point could be conceived from which it would be ſeen to move with perfect uniformity. That point was made the centre of the equant, and lay at the ſame diſtance from the centre of the eccentricity on the one ſide, as the earth was removed on the other. "Nothing (ſays Dr Smith, from whom this account of the equant is taken) can more evidently ſhew how much the repoſe and tranquillity of the imagination is the ultimate end of philoſophy, than the invention of this equalizing circle."

EQUATION OF A CURVE. See ALGEBRA (*Encycl.*) Part III. chap. ii.

Secular EQUATION, in aſtronomy. See ASTRONOMY in this *Supplement*, nº 25—38.

EQUICURVE CIRCLE, the ſame with CIRCLE *of Curvature*, which ſee in this Supplement.

ERGETT EL KRANE } Two Abyſſinian ſhrubs of
ERGETT Y'DIMMO } the genus MIMOSA, which ſee *Encycl.*

ERKOOM, an Abyſſinian bird, part of a large tribe, "in which (ſays Mr Bruce) the greateſt variety lies in his beak and horn. The horn he wears ſometimes upon the beak and ſometimes upon the forehead above the root of the beak." This bird is by naturaliſts called the *Indian crow* or *raven;* and our author, though he ſeems to think this claſſification improper, admits that he has one charecteriſtic of the raven; he walks, and does not hop or jump in the manner that many others of that kind do; but then he at times runs with very great velocity, and, in running, very much reſembles the turkey or buſtard when his head is turned from you.

The colour of the eye of this bird is of a dark brown, or rather reddiſh, caſt, but darker ſtill as it approaches the pupil; he has very large eyelaſhes, both upper and lower, but eſpecially his upper. From the point of the beak to the extremity of the tail is three feet ten inches; the breadth, from one point of the wing to the other extended, is ſix feet, and the length twenty-two inches; the length of the neck ten inches, and its thickneſs three inches and a half; the length of the beak, meaſuring the opening near the head ſtraight to the point, ten inches; and from the point of the beak to the root of the horn, ſeven inches and three eighths. The whole length of the horn is three inches and a half. The length of the horn, from the foot to the extremity where it joins the beak, is four inches. The thickneſs of the beak in front of the opening is one inch and ſeven eighths. The thickneſs of the horn in front is one inch and five eighths. The horn in height, taken from the upper part of the point to the beak, two inches. The length of the thighs ſeven inches, and that of the legs ſix inches and five eighths. The thickneſs in profile ſeven lines, and in front four lines and a half. It has three toes before and one behind, but they are not very ſtrong, nor ſeemingly made to tear up carcaſes. The length of the foot to the hinder toe is one inch ſix lines, the innermoſt is one inch ſeven lines, the middle two inches two lines, and the laſt outer one two inches one line. This bird is all of a black, or rather black mixed with ſoot-colour; the large feathers of the wing are ten in number, milk-white both without and within. The tip of his wings reaches very nearly to his tail; his beak and head meaſured together are eleven inches and a half, and his head three inches and a quarter. At his neck he has thoſe protuberances like the Turkey-cock, which are light blue, but turn red upon his being chafed, or in the time the hen is laying.

The erkoom, though not eaſily raiſed, flies (ſays our author) both ſtrong and far. It has a rank ſmell, and is ſaid in Abyſſinia to feed upon dead carcaſes. This, however, he thinks a miſtake, as he never ſaw it following the army, nor approaching a dead carcaſe; and as often as he had occaſion to open this bird, he found in its ſtomach nothing but the green ſcarabeus or beetle. It builds in large thick trees, always, if it can, near churches; has a covered neſt like that of a magpie, but four times as large as the eagle's. It places its neſt firm upon the trunk, without endeavouring to make it high from the ground: the entry is always on the eaſt ſide.

ETON is a place which, on account of its college, ſhould not be omitted in a repoſitory of arts, ſciences, and literature; and as no notice is taken of it in the *Encyclopædia*, we ſhall deviate for once from the plan which we had laid down for this Supplement, and which is, not to admit into it deſcriptions of places in our own iſland that may be viſited by the greater part of our readers with little trouble.

Though in a different county, namely, Buckinghamſhire, Eton may be ſaid to be one and the ſame town with Windſor, for which ſee *Encycl.* It is pleaſantly ſituated on the banks of the Thames, in a delightful valley, which is of a remarkably healthy ſoil. Its college was founded by Henry VI. for the ſupport of a provoſt and ſeven fellows, one of whom is vice-provoſt, and for the education of ſeventy King's ſcholars, as thoſe are called who are on the foundation. Theſe, when properly qualified, are elected, on the firſt Tueſday in Auguſt, to king's college Cambridge, but they are not removed till there are vacancies in the college, and then they are called according to ſeniority; and after they have been three years at Cambridge, they claim a fellowſhip. Beſides thoſe on the foundation there

there are ſeldom leſs than three hundred ſcholars, and often many more, who board at the maſters houſes, or within the bounds of the college. The ſchool is divided into upper and lower, and each of theſe into three claſſes. To each ſchool there is a maſter and four aſſiſtants or uſhers. The revenue of the college is about L. 5000 a-year. Here is a noble library, and in the great court is a fine ſtatue of the founder, erected at the expence of a late provoſt Dr Godolphin dean of St Paul's. The chapel is in a good ſtyle of Gothic architecture. The ſchools and other parts, which are in the other ſtyle of building, are equally well, and ſeem like the deſign of Inigo Jones.

At Eton there is a ſingular, and we think a laudable, feſtival called the *Montem*, celebrated triennially (formerly duennially) by the ſcholars of the ſchool upon Whit-Tueſday. The following account of this feſtival, taken from the Monthly Magazine, will probably be acceptable to many of our readers.

It commences by a number of the ſenior boys taking poſt upon the bridges or other leading places of all the avenues around Windſor and Eton ſoon after the dawn of day. Theſe youths ſo poſted are chiefly the beſt figures, and the moſt active of the ſtudents; they are all attired in fancy dreſſes of ſilks, ſatins, &c. and ſome richly embroidered, principally in the habits or faſhion of running footmen, with poles in their hands; they are called *ſalt-bearers*, and demand ſalt, i. e. a contribution from every paſſenger, and will take no denial.

When the contribution is given, which is *ad libitum*, a printed paper is delivered with their motto and the date of the year, which paſſes the bearer free through all other ſalt-bearers for that day, and is as follows, viz.

"Pro more et monte,
1799, (A)
Vivant Rex et Regina."

Theſe youths continue thus collecting their ſalt at all the entrances for near ſeven miles round Windſor and Eton, from the dawn of day until about the cloſe of the proceſſion, which is generally three o'clock in the afternoon.

The proceſſion commences about twelve o'clock at noon, and conſiſts of the Queen's and other bands of muſic; ſeveral ſtandards borne by different ſtudents; all the Etonian boys, two and two, dreſſed in officers uniforms; thoſe of the king's foundation wearing blue, the others ſcarlet uniforms, ſwords, &c.

The Grand Standard-bearer.

The Captain, or Head Boy of Eton School.

The Lieutenant, or Second Boy.

His Majeſty, attended by the Prince of Wales, and other male branches of the royal family on horſeback, with their ſuite.

The Queen and Princeſſes in coaches, attended by their ſuite.

Band of muſic, followed by a great concourſe of the Nobility and Gentry in their carriages and on horſeback.

The proceſſion commences in the great ſquare at Eton, and proceeds through Eton to Slough, and round to Salt Hill, where the boys all paſs the king and queen in review, and aſcend the Montem: here an oration is delivered, and the grand ſtandard is diſplayed with much grace and activity by the ſtandard bearer, who is generally ſelected from among the ſenior boys.

There are two extraordinary ſalt-bearers appointed to attend the king and queen, who are always attired in fanciful habits, in manner of the other ſalt-bearers already deſcribed, but ſuperbly embroidered. Theſe ſalt-bearers carry each an embroidered bag, which not only receives the royal ſalt, but alſo whatever is collected by the out-ſtationed ſalt-bearers. The donation of the king and queen, or, as it is called upon this occaſion, the *royal ſalt*, is always fifty guineas each; the Prince of Wales thirty guineas; all the other princes and princeſſes twenty guineas each. As ſoon as this ceremony is performed, the royal family return to Windſor. The boys are all ſumptuouſly entertained at the tavern at Salt Hill; and the beautiful gardens at that place are laid out for ſuch ladies and gentlemen as chooſe to take any refreſhments, the different bands of muſic performing all the time in the gardens.

About ſix o'clock in the evening all the boys return in the ſame order of proceſſion as in the morning (with the exception only of the royal family), and, marching round the great ſquare in Eton ſchool, are diſmiſſed. The captain then pays his reſpects to the royal family at the queen's lodge, Windſor, previous to his departure for King's College, Cambridge; to defray which expence, the produce of the montem is preſented to him; and upon Whit-Tueſday, in the year 1796, it amounted to more than 1000 guineas. The day concludes by a brilliant diſplay of beauty, rank, and faſhion, a promenade on Windſor Terras, bands of muſic performing, &c. and the ſcene highly enlivened and enriched by the affable condeſcenſion of the royal family, who indiſcriminately mix with the company, and parade the Terrace till nearly dark.

SPONTANEOUS EVAPORATION. See WEATHER, n° 17, &c. *Encycl.*

EUDIOMETER, an inſtrument for aſcertaining the purity of the atmoſpherical air. Many have been the contrivances of chemiſts for this purpoſe (ſee EUDIOMETER, *Encycl.*); but perhaps the beſt eudiometer is that of *Morveau* (or *Guyton*, as he now chooſes to call himſelf), of which mention has been made in CHEMISTRY, n° 420. in this Supplement. The following ſhort deſcription will make the nature and uſe of this inſtrument plain to every reader.

AB, (Plate XXVIII.) repreſents a ſmall glaſs retort with a long neck; its whole capacity being from ſeven to nine ſolid inches. It muſt be choſen of ſuch a curvature that, when the neck is ſet upright, the bulb may form at its lower part a cavity to retain the matters introduced. The extremity of the neck of this retort is ground with emery to enter the glaſs tube CD, which is open at both ends, and about 12 or 15 inches in length. The retort then cloſes the tube in the manner of a ground ſtopper, and intercepts all external communication. A cylindrical glaſs veſſel F is provided, of the form of a common jar, in which the glaſs tube CD may be entirely plunged beneath the level of the water. Laſtly, the ſulphuret of potaſh is prepared and broken into pieces ſufficiently ſmall to be introduced

---

(A) Or whatever the year may be.

into the retort. Theſe are to be incloſed, dry and even hot, in a bottle for uſe. Theſe conſtitute the whole apparatus and preparation of materials.

When it is required to examine an aeriform fluid, by ſeparating its oxygen, two or three pieces of the ſulphuret, of the ſize of a pea, are put into the retort. It is then filled with water, taking care to incline it ſo that all the air may paſs out from the bulb. The orifice of the retort is then to be cloſed, and inverted into the pneumatic tube, in order that the gas propoſed for examination may be tranſferred into it in the uſual manner. By an eaſy manœuvre of alternately inclining the retort in different directions, all the water is made to flow out of the bulb in which the ſulphuret remains. When this is done, the retort is placed in the vertical ſituation, and its extremity introduced into the tube of glaſs CD, which muſt always be under water. A ſmall lighted taper is then to be placed under the bulb. To ſupport the retort in its poſition, the jar is provided with a wooden cover, in which there is a notch to receive it.

The firſt impreſſion of the heat dilates the gaſeous fluid ſo much that it deſcends almoſt to the bottom of the tube, which is diſpoſed expreſsly for its reception; otherwiſe the partial eſcape would prevent an accurate determination of its change of bulk. But as ſoon as the ſulphuret begins to boil, the water quickly riſes, not only in the inferior tube, but likewiſe in the neck of the retort, notwithſtanding the application, and even the increaſe of the heat.

If the fluid be abſolutely pure vital air, the abſorption is total. In this caſe, to prevent the rupture of the veſſel by too ſudden refrigeration, the aſcent of the water muſt be rendered ſlower, either by removing the taper, or by increaſing the perpendicular height; which will not prevent the abſorption from continuing while any gas remains which is proper to ſupport combuſtion.

If the fluid be common air, or oxygen mixed with any other gas, the quantity of water which has entered the retort muſt be accurately meaſured after the cooling. It repreſents the volume of air abſorbed. Care muſt be taken to incloſe the remaining gas under the ſame preſſure, by plunging the retort to the level of the line at which the incloſed water reſts, before the orifice is ſtopped.

This operation of meaſuring, which is very eaſy when meaſuring veſſels are at hand, may be habitually performed by a ſlip of paper paſted on the neck of the retort, upon which diviſions are drawn from obſervation, and which muſt be covered with varniſh to defend it from the action of the water.

EUDOXUS of Gnidus was a celebrated philoſopher of the ſchool of Pythagoras. His firſt preceptor was Archytas, by whom he was inſtructed in the principles of geometry and philoſophy. About the age of twenty-three he came to Athens; and though his patrimony was ſmall, by the generous aſſiſtance of Theomedon a phyſician, he was enabled to attend the ſchools of the philoſophers, particularly that of Plato. The liberality of his friends afterwards ſupported him during a viſit to Egypt, where he was introduced by Ageſilaus to king Nectanebis II. and by him to the Egyptian prieſts. It has been ſaid that he accompanied Plato into Egypt; but this is inconſiſtent with chronology; for Nectanebis II. reigned in Egypt from the ſecond year of the hundred and fourth Olympiad, to the ſecond year of the hundred and ſeventh; and it was before Plato opened his ſchool, that is, before the ninety-eighth Olympiad, about the fortieth year of his age, that he viſited Egypt. Eudoxus is highly celebrated by the ancients for his ſkill in aſtronomy; but none of his writings on this or any other ſubject are extant. Aratus, who has deſcribed the celeſtial phenomena in verſe, is ſaid to have followed Eudoxus. He flouriſhed about the ninety-ſeventh Olympiad, and died in the fifty-third year of his age. *Enfield's Hiſt. of Philoſophy.*

EVECTION is uſed by ſome aſtronomers for the libration of the moon, being an inequality in her motion, by which, at or near the quadratures, ſhe is not in a line drawn through the centre of the earth to the ſun, as ſhe is at the ſyzygies, or conjunction and oppoſition, but makes an angle with that line of about 2° 51′. The motion of the moon about her axis only is equable; which rotation is performed exactly in the ſame time as ſhe revolves about the earth; for which reaſon it is that ſhe turns always the ſame face towards the earth nearly, and would do ſo exactly, were it not that her monthly motion about the earth, in an eliptic orbit, is not equable; on which account the moon, ſeen from the earth, appears to librate a little upon her axis, ſometimes from eaſt to weſt, and ſometimes from weſt to eaſt; or ſome parts in the eaſtern limb of the moon go backwards and forwards a ſmall ſpace, and ſome that were conſpicuous are hid, and then appear again.

The term *evection* is uſed by ſome aſtronomers to denote that equation of the moon's motion which is proportional to the ſine of double the diſtance of the moon from the ſun, diminiſhed by the moon's anomaly. This equation is not yet accurately determined; ſome ſtate it at 1° 30′, others at 1° 16′, &c. It is the greateſt of all the moon's equations, except the equation of the centre. *Hutton's Dictionary.*

EVENLY EVEN NUMBER. See NUMBER, *Encycl.*

EVENLY Odd Number. See NUMBER, *Encycl.*

EVOLVENT, in the higher geometry, a term uſed by ſome writers for the involute or curve reſulting from the evolution of a curve, in contradiſtinction to that evolute or curve ſuppoſed to be opened or evolved. See EVOLUTE and INVOLUTE, *Suppl.*

EVOLUTE, in the higher geometry, a curve firſt propoſed by Huyghens, and ſince much ſtudied by mathematicians. It is any curve ſuppoſed to be evolved or opened, by having a thread wrapped cloſe upon it, faſtened at one end, and beginning to evolve or unwind the thread from the other end, keeping the part evolved or wound off tight ſtretched; then this end of the thread will deſcribe another curve, called the *involute*. Or the ſame involute is deſcribed the contrary way, by wrapping the thread upon the evolute, keeping it always ſtretched. For the INVOLUTION and EVOLUTION *of Curves*, ſee INVOLUTION in this Supplement.

Imperfect EVOLUTE, a name given by M. Reaumur to a new kind of evolute. The mathematicians had hitherto only conſidered the perpendiculars let fall from the involute on the convex ſide of the evolute: but if other lines not perpendicular be drawn upon the ſame points, provided they be all drawn under the ſame angle, the effect will ſtill be the ſame; that is, the oblique lines will all interſect in the curve, and by their interſections form the infinitely ſmall ſides of a new curve, to which they would be ſo many tangents. Such a curve is a kind of evolute, and has its radii; but it is an imperfect one, ſince the radii are not perpendicular to the firſt curve or involute.

EUPHON, a muſical inſtrument invented lately by Dr Chladni of Wittenberg, well known by his various publications on philoſophical ſubjects, eſpecially the theory of muſical ſounds. The euphon conſiſts of forty-two immoveable parallel cylinders of glaſs of equal length and thickneſs; but its conſtruction, tone, and the method of playing it, are totally different from thoſe of the harmonica, with which indeed it has nothing in common but the glaſs. See Harmonica, *Encycl.*

Dr Chladni gives the following account of his invention. In his 19th year he began to learn to play the harpſichord; and he afterwards read a great many of the principal works on the theory of muſic, by which he found that the phyſico-mathematical part of that ſcience was far more defective than other branches of natural philoſophy. Being therefore poſſeſſed with an idea that his time could not be better employed than in endeavouring to make diſcoveries in this department, he accordingly tried various experiments on the vibrations of ſtrings and the different kinds of vibration in cylindric pieces of wood, firſt diſcovered, through calculation, by the elder Euler; and found, that though a great deal had been ſaid on the nature of theſe elaſtic bodies, yet the manner of vibration and the proportion of tones in other elaſtic bodies, which do not proceed, as in the former, in ſtraight lines, but depend on the vibration of whole ſurfaces, were totally unknown, and that the little which had been written on that ſubject, by ſome authors, did not correſpond with nature. He had already long remarked, that every plate of glaſs or metal emitted various tones according as it was held and ſtruck in different places; and he was deſirous to diſcover the cauſe of this difference, which no one had ever examined. He fixed in a vice the axle of a braſs plate which belonged to a poliſhing machine, and found, that by drawing the bow of a violin over it, he produced very different tones, which were ſtronger and of longer duration than thoſe obtained merely by ſtriking it.

The obſervation, that not only ſtrings but alſo other elaſtic bodies may be made to produce ſounds by drawing a violin bow over them, Dr Chladni does not give as a diſcovery of his own; as the ſo called iron violin has been long known, and as he had read of an inſtrument conſtructed in Italy*, where glaſs or metal bells were made to ſound by means of two or more violin bows drawn over them. But the idea of employing this inſtrument to examine vibrating tones was firſt entertained by himſelf. Having accurately remarked the tones produced by the abovementioned metal plate, he found that they gave a progreſſion which correſponded with the ſquares of 2, 3, 4, &c.

In all pro- ability the *armonica* f the Abbé Mazzuchi.

Not long before he had read, in the Tranſactions of the Royal Society of Gottengen, the obſervations of Mr Lichtenberg on the phenomena produced by ſtrewing pounded reſin over a glaſs plate or cake of reſin, and he repeated many of his experiments. This led him to the idea that, perhaps, the various vibratory movements of ſuch a plate would be diſcovered by a diverſity of phenomena, if he ſtrewed over it ſand or any thing of the like kind. By this experiment there was produced a ſtar-formed figure; and the author, having continued his reſearches, publiſhed the reſult of them in a work entitled, Diſcoveries reſpecting the Theory of Sound, printed at Leipſic in 1787.

Whilſt he was employed in theſe inveſtigations, he reſolved to invent a new muſical inſtrument; and he began to conſider whether it might not be poſſible by rubbing glaſs tubes in a ſtraight line, with the wet fingers, to produce ſounds in the ſame manner as is done in the harmonica by rubbing them circularly. That glaſs tubes, like thoſe in his euphon, would not merely by ſuch rubbing emit any tones, he had long known by theory and experience; and he therefore applied himſelf to the ſolution of the difficult queſtion, in what manner the inſtrument ought to be conſtructed to anſwer the intended purpoſe? After various fruitleſs attempts for a year and a half, during which his imagination was ſo full of the idea, that ſometimes in his dreams he thought he ſaw the inſtrument and heard its tones, that is, like thoſe of the harmonica, but with more diſtinctneſs and leſs confuſion, he at length, in a ſtate between ſleeping and waking, obtained a ſolution of the problem which had given ſo much employment to his thoughts. On the ſecond of June 1789, being tired with walking, he ſat down on a chair, about nine in the evening, to enjoy a ſhort ſlumber; but ſcarcely had he cloſed his eyes when the image of an inſtrument, ſuch as he wiſhed for, ſeemed to preſent itſelf before him, and terrified him ſo much that he awoke as if he had been ſtruck by an electric ſhock. He immediately ſtarted up in a kind of enthuſiaſm; and made a ſeries of experiments, which convinced him that what he had ſeen was perfectly right, and that he had it now in his power to carry his deſign into execution. He made his experiments and conſtructed his firſt inſtrument in ſo private a manner, that no perſon knew any thing of them. On the 8th of March 1790 his firſt inſtrument of this kind was completed; and in a few days he was able to play on it ſome eaſy pieces of muſic. It was now neceſſary to give to this inſtrument, as it was entirely new, a new name; and that of *euphon*, which ſignifies an inſtrument that has a pleaſant ſound, appeared to him the moſt proper.

It was not, however, brought to perfection at once, for he made a ſecond inſtrument which was an improvement of the firſt, and a third which was an improvement of the ſecond. In ſound, indeed, and particularly in the higher tones, the firſt was equal to either of the other two; but the conſtruction was deficient in ſtrength, ſo that every week ſome hours were neceſſary to keep it in proper repair; and it was impoſſible to convey it the diſtance of a mile without almoſt totally deſtroying it. Dr Chladni alſo, for want of better tubes, employed thoſe uſed for thermometers, and marked the whole and half tones by a coating of ſealing-wax on the under ſide; but as the wax, owing to the moiſture and vibration, often cracked and flew off, it was attended with danger to the eyes. It was therefore extremely difficult to give to the conſtruction of the inſtrument ſufficient ſtrength; but this the inventor at length accompliſhed, ſo that his new euphon cannot be injured or put out of tune either by playing or by carriage. The third inſtrument was ſomewhat different from the firſt and ſecond; as the fore part, which in the two former roſe upwards with an oblique angle, ſtood at right angles, ſo that it could be tranſported with eaſe in a particular carriage made for that purpoſe. Inſtead of the thermometer tubes uſed in the firſt, the Doctor now employs tubes of different colours. In the ſecond inſtrument thoſe for the whole tones were of dark green glaſs; but he uſed for the half tones, in both, a milk white kind of glaſs. In a word, the euphon has ſome reſemblance to a ſmall writing-deſk. When opened, the abovementioned glaſs tubes, of the thickneſs of the barrel of a quill and about 16 inches long, are ſeen in a horizontal poſition. They are wetted with water, by means of a ſponge, and ſtroked with the wet fingers in the direction of their length, ſo that the increaſe of the tone depends merely on the ſtronger or weaker preſſure, and the ſlower or quicker movement of the fingers. The number of tubes at preſent is forty-two. In the back part there is a perpendicular ſounding-board divided in the middle, through which the tubes paſs. It appears therefore that the euphon ought not to be conſidered as an altered or improved harmonica, but as a totally new and different inſtrument. In regard to ſweetneſs of ſound, it approaches very near to the harmonica; but it has ſeveral advantages which no unprejudiced perſon, who examines both inſtruments, will deny.

1. It is ſimpler, both in regard to its conſtruction and the movement neceſſary to produce the ſound, as neither turning nor ſtamping is required, but merely the movement of the finger. 2. It produces its ſound ſpeedier; ſo that as ſoon as it is touched you may have the tone as full as the inſtrument is capable of giving it; whereas, in the harmonica, the tones, particularly the lower ones, muſt be made to increaſe gradually. 3. It has more diſtinctneſs in quick paſſages; becauſe the tones do not reſound ſo long as in the harmonica, where the ſound of one low tone is often heard when you wiſh only to hear the following tone. 4. The uniſon is purer than is generally the caſe in the harmonica, where it is difficult to have perfect glaſſes, which in every part give like tones with mathematical exactneſs. It is however as difficult to be tuned as the harmonica. 5. It does not affect the nerves of the performer; for a perſon ſcarcely feels a weak agitation in the fingers; whereas in the harmonica, particularly in concords of the lower notes, the agitation extends to the arms, and even through the whole body of the performer. 6. The expence of this inſtrument will be much leſs in future than that of the harmonica. 7. When one of the tubes breaks, or any other part is deranged, it can be ſoon repaired, and at very little expence; whereas, when one of the glaſſes of the harmonica breaks, it requires much time, and is very difficult to procure another capable of giving the ſame tone as the former, and which will correſpond ſufficiently with the ſeries of the reſt.

EUPHORBIA (See *Encycl.*). Of this plant three new ſpecies were diſcovered by Le Vaillant during his Plate XXVIII. fig. 1. laſt travels into the interior parts of Africa. The firſt, which he calls the Cucumber-Euphorbia, adheres to the earth no otherwiſe than by a few ſlender roots. It riſes to the height of nine or ten inches only; and exactly reſembles a cucumber, of which it has the bent ſhape. It contains abundance of milky juice, which appeared to him as cauſtic as that of the great euphorbia. Its colour, which is a yellowiſh-green, tinted with a beautiful ſhade of violet towards the root, gives it a very attractive appearance: but woe betide the man who ſhould be tempted to eat of it! as it is a virulent poiſon. The ſecond, to which he gave the name of the Melon-ribbed Euphorbia, does not riſe more than three or Fig 2. four inches from the ground, to which it adheres by a collection of fibrous roots, iſſuing from ſeveral tubercles diſpoſed in the manner of a crown. The ſtem forms a flatted globe excavated at the ſummit, and has ribs like the apple which in France is called *calville blanche*. Theſe ribs are elevated, thick, and convex, have a greeniſh colour, and are marked with brown tranſverſal bands. From the ſummit of the ribs iſſue ſeveral little tufts of pedunculate flowers. The third he called the Caterpillar-Euphorbia, becauſe when he firſt found Fig. 3. it, he thought he perceived on it ſeveral beautiful caterpillars. The deſcription of it in a few words is as follows: From a very large tuberous root, which here and there throws out a few thready fibres, iſſue ſeveral ſtalks almoſt of the length of the finger: they creep along the ground, are twiſted, woody, deſtitute of leaves, and furniſhed with ſeveral rows of round tubercles, each guarded by two prickles.

All theſe kinds of euphorbia are to be dreaded, the laſt two in particular; becauſe being low and mixed with the herbage like muſhrooms, animals, as they feed, run the riſk of eating them with their paſture. Our author confirms the account which has been given in the *Encyclopædia* of the ſavages poiſoning the reſervoirs of water with this plant, in order to procure the game which ſhall drink of it. To effect the death of the animal, it is neceſſary that the poiſon reach the blood and mingle with it. Yet, unconceivable as it may be, the animal, though poiſoned, is not the leſs wholeſome food, as our author ſays he has experienced. However great may be the proportion of euphorbia thrown into a pond of water, he is perſuaded that it never diffuſes itſelf through the whole maſs. It is his opinion, that the poiſon is a reſinous juice, which, being from its nature incapable of combining with water, ſwims on the ſurface, and there forms a ſhining greeniſh oil, which with a little attention may be diſcerned by the naked eye when the ſurface is ſmooth. I tried (ſays he) the qualities of this oil on myſelf, taking with a ſtraw, from the ſurface of the baſin, a ſingle drop, which I put upon my tongue; and it gave me that kind of burning pain which a cauſtic occaſions. I then took up ſome water from the reſervoir in the hollow of my hand, and blowing off the oily fluid which ſwam on the ſurface, I dipped the end of my tongue into the remainder, but could not perceive in it the ſlighteſt taſte different from that of water itſelf. He ſeems to think that milk is an antidote to the poiſon of euphorbia; becauſe he ſqueezed ſome of the juice into a baſon of milk and gave it to an ape, which ſwallowed part of it without the leaſt injury. He confeſſes, however, that the doſe was trifling.

EUSTYLE, is the beſt manner of placing columns, with regard to their diſtance; which, according to Vitruvius, ſhould be four modules, or two diameters and a quarter.

EXCENTRIC, or Excentric Circle, in the ancient Ptolomaic aſtronomy, was the very orbit of the planet itſelf, which it was ſuppoſed to deſcribe about the earth, and which was conceived excentric with it; called alſo the deferent.

Inſtead of theſe excentric circles round the earth, the moderns make the planets deſcribe elliptic orbits about the ſun; which accounts for all the irregularities of their motions, and their various diſtances from the earth, &c. more juſtly and naturally.

EXCENTRIC, or *Excentric Circle*, in the new aſtronomy, is the circle deſcribed from the centre of the orbit of a planet, with half the greateſt axis as a radius; or it is the circle that circumſcribes the elliptic orbit of the planet.

EXCHANGE. See *Encycl.* under that word, and likewiſe under *Bills of Exchange*, where the antiquity of ſuch bills, eſpecially among the Chineſe, is mentioned. In Profeſſor Beckmann's Hiſtory of Inventions the reader will find an ordinance of the year 1394 concerning the acceptance of bills of exchange, and alſo copies of two bills of the year 1404, which ſufficiently prove that the method of tranſacting buſineſs by bills of exchange was fully eſtabliſhed in Europe ſo early as the fourteenth century; and that the preſent form and terms were even then uſed. The ordinance, which was iſſued by the city of Barcelona, decreed that bills of exchange ſhould be accepted within twenty-four hours after they were preſented, and that the acceptance ſhould be written on the back of the bill.

But there are queſtions relating to bills of exchange of much greater importance than their antiquity; and theſe queſtions are not yet decided. For inſtance, Ought a bill of exchange to be conſidered by the law merely as a *depoſit* belonging to the drawer, and ſucceſſively confided to the remittees? or ſhould it be conſidered as transferable *property*, at all times abſolutely veſted in the holder, whoſe neglect therefore, when it vitiates the value, falls wholly on himſelf?

In a work publiſhed 1798 by Profeſſor Buſch of Hamburgh, entitled, *Additions to the Theoretical and Practical Delineation of Commerce* (A), the reader will find ſome arguments, which, to ſay the leaſt of them, are certainly plauſible, to prove that bills of exchange ought to be at all times conſidered as the abſolute property of the holder. This theory is then applied to the difficult and ſtill unſettled caſe of the holder of a bill having many indorſements, where the drawer, drawee, and early indorſers, have all failed. It is evident that, if the holder proves under each bankruptcy the whole amount of the bill, he will receive much more than his due. May he make his election where to prove the whole demand, and where to prove the reſidue? or ought he not (which ſeems moſt equitable) to be compelled to prove his debt againſt his immediate predeceſſor only?—the aſſignees of that predeceſſor proving in their turn, in like manner (each party once only), back to the drawer. This is a caſe of great importance to diſcounters, and the reader will find ſome judicious obſervations on it in the Profeſſor's work.

EXEGESIS, or EXEGETICA, in algebra, is the finding, either in numbers or lines, the roots of the equation of a problem, according as the problem is either numeral or geometrical.

EXPECTATION OF LIFE, in the doctrine of life annuities, is the ſhare, or number of years of life, which a perſon of a given age may, upon an equality of chance, expect to enjoy.

By the expectation or ſhare of life, ſays Mr Simpſon (*Select Exerciſes*, p. 273), is not here to be underſtood that particular period which a perſon hath an equal chance of ſurviving; this laſt being a different and more ſimple conſideration. The expectation of a life, to put it in the moſt familiar light, may be taken as the number of years at which the purchaſe of an annuity, granted upon it, without diſcount of money, ought to be valued. Which number of years will differ more or leſs from the period abovementioned, according to the different degrees of mortality to which the ſeveral ſtages of life are incident. Thus it is much more than an equal chance, according to the table of the probability of the duration of life which the ſame author has given us, that an infant, juſt come into the world, arrives not to the age of ten years; yet the expectation or ſhare of life due to it, upon an average, is near twenty years. The reaſon of which wide difference is the great exceſs of the probability of mortality in the firſt tender years of life, above that reſpecting the more mature and ſtronger ages. Indeed if the numbers that die at every age were to be the ſame, the two quantities above ſpecified would alſo be equal; but when the ſaid numbers become continually leſs and leſs, the expectation muſt of conſequence be the greater of the two.

EXPONENTIAL CALCULUS, the method of differencing, or finding the fluxions of exponential quantities, and of ſumming up thoſe differences, or finding their fluents.

EXPONENTIAL *Curve*, is that whoſe nature is defined or expreſſed by an exponential equation; as the curve denoted by $a^x = y$, or by $x^x = y$.

EXPONENTIAL *Equation*, is one in which is contained an exponential quantity: as the equation $a^x = b$, or $x^x = a b$, &c.

EXPONENTIAL *Quantity*, is that whoſe power is a variable quantity; as the expreſſion a^x, or x^x. Exponential quantities are of ſeveral degrees and orders according to the number of exponents or powers, one over another.

EXTRA-CONSTELLARY STARS, ſuch as are not properly included in any conſtellation.

Extra-Mundane Space, is the infinite, empty, void ſpace, which is by ſome ſuppoſed to be extended beyond the bounds of the univerſe, and conſequently in which there is really nothing at all. The phraſe *extramundane ſpace* has been ſo long in uſe among our beſt writers, that it is now impoſſible to baniſh it from the language; and yet it has been the ſource of ſome extravagant miſtakes. Many philoſophers conſider ſpace as ſomething *real*, diſtinct both from body and mind; and no leſs a man than Dr Clarke conſidered it as an attribute of the Deity. Yet we think nothing more evident, than that if body had never exiſted, ſpace would never have been thought of; and if this be ſo, extramundane ſpace, inſtead of denoting any *real* thing, or attribute infinitely extended, can mean nothing more than the *poſſibility* of enlarging the corporeal univerſe, however widely extended it may be. See METAPHYSICS, *Encycl.* Part II. ch. iv.

(A) Profeſſor Buſch publiſhed in 1792 a work entitled *A Theoretical and Practical Delineation of Commerce.*

EXTRADOS, the outſide of an arch of a bridge, vault, &c. See Arch in this *Supplement*.

EXTREMES Conjunct, and *Extremes Disjunct*, in ſpherical trigonometry, are, the former the two circular parts that lie next the aſſumed middle part; and the latter are the two that lie remote from the middle part. Theſe were terms applied by Lord Napier in his univerſal theorem for reſolving all right-angled and quadrantal ſpherical triangles, and publiſhed in his *Logarithmorum Canonis Deſcriptio*, ann. 1614. In this theorem, Napier condenſes into one rule, in two parts, the rules for all the caſes of right angled ſpherical triangles, which had been ſeparately demonſtrated by Pitiſcus, Lanſbergius, Copernicus, Regiomontanus, and others. In this theorem, neglecting the right angle, Napier calls the other five parts circular parts, which are, the two legs about the right angle, and the complements of the other three, viz. of the hypothenuſe, and the two oblique angles. Then taking any three of theſe five parts, one of them will be in the middle between the other two, and theſe two are the extremes conjunct when they are immediately adjacent to that middle part, or they are the extremes disjunct when they are each ſeparated from the middle one by another part.

F.

FACE or Façade, in architecture, is ſometimes uſed for the front or outward part of a building, which immediately preſents itſelf to the eye; or the ſide where the chief entrance is, or next the ſtreet, &c.

FALCONRY, is a ſpecies of ſport, about the antiquity of which there has been ſome diſpute. Under the word Hawking, *Encycl.* we have deduced what we thought ſufficient evidence of its being practiſed among the Thracians, and likewiſe among the Britons before the invaſion of this iſland by the Romans. Flavius Blondus, however, and Laurentius Valla, both writers of the 15th century, and the latter, one of the moſt learned men of his time, affirm that no nation or people were accuſtomed to catch either land or water fowls with any rapacious bird trained for the purpoſe.

We were pleaſed to ſee our own opinion, ſo different from this, completely eſtabliſhed by the learned labours of Profeſſor Beckmann. So early (ſays he) as the time of Cteſias (and he refers to the page and edition of his author) hares and foxes were hunted in India by means of rapacious birds. The account of Ariſtotle *, however, is ſtill more to the purpoſe, and more worthy of notice. "In Thrace (ſays he) the men go out to catch birds with hawks. The men beat the reeds and buſhes which grow in marſhy places, in order to raiſe the ſmall birds, which the hawks purſue and drive to the ground, where the fowlers kill them with poles." The ſame account is to be found in another book aſcribed alſo to Ariſtotle; and which appears, at any rate, to be the work of an author not much younger. Reſpecting Thrace, which is ſituated above Amphipolis, a wonderful thing is told, which might appear incredible to thoſe who had never heard it before. It is ſaid that boys go out into the fields, and purſue birds by the aſſiſtance of hawks. When they have found a place convenient for their purpoſe, they call the hawks by their names, which immediately appear as ſoon as they hear their voices, and chaſe the birds into the buſhes, where the boys knock them down with ſticks and ſeize them. What is ſtill more wonderful, when theſe hawks lay hold of any birds themſelves, they throw them to the fowlers; but the boys, in return, give them ſome ſhare of the prey. *De mirabilibus auſcultat.* cap. 128.

In this paſſage, there are two additions which render the circumſtance ſtill more remarkable. The firſt is, that the falcons appeared when called by their names; and the ſecond, that of their own accord they brought to the fowlers whatever they caught themſelves. Nothing is here wanting but the ſpaniel employed to find out game, the hood which is put upon the head of the hawk while it ſtands on the hand, and the thong uſed for holding it, to form a ſhort deſcription of falconry as ſtill practiſed. Our falconers, when they have taken the bird from the hawk, give him, in return, a ſmall ſhare of it; and in the like manner the Thracian hawks receive ſome part of their booty.

Other writers after Ariſtotle, ſuch as Antigonus, Ælian, Pliny, and Phile, have alſo given an account of this method of fowling. Ælian, who ſeldom relates any thing without ſome alteration or addition, ſays, that in Thrace nets were uſed, into which the birds were driven by the hawks; and in this he is followed by the poet Phile. Ælian, alſo, in another place deſcribes a manner of hunting with hawks in India, which, as we are told by ſeveral travellers, is ſtill practiſed in Perſia, where it is well underſtood, and by other eaſtern nations.

The Indians (ſays he) hunt hares and foxes in the following manner: They do not employ dogs, but eagles, crows, and, above all, kites, which they catch when young, and train for that purpoſe. They let looſe a tame hare or fox, with a piece of fleſh faſtened to it, and ſuffer theſe birds to fly after it, in order to ſeize the fleſh, which they are fond of, and which, on their return, they receive as the reward of their labour. When thus inſtructed to purſue their prey, they are ſent after wild foxes and hares in the mountains; theſe they follow in hopes of obtaining their uſual food, and ſoon catch them and bring them back to their maſters, as we are informed by Cteſias. Inſtead of the fleſh, however, which was faſtened to the tame animals, they receive as food the entrails of the wild ones which they have caught.

It ſeems, therefore, that the Greeks received from India

* *Hiſt Animat*, lib. ix. cap. 6.

dia and Thrace the firſt information reſpecting the method of fowling with birds of prey; but it does not appear that this practice was introduced among them at a very early period. In Italy, however, it muſt have been very common, for Martial and Apuleius ſpeak of it as a thing every where known: the former calls a hawk the fowler's ſervant.

The Profeſſor traces the hiſtory of this art with great learning down to the preſent time. It was carried to the higheſt perfection at the principal courts of Europe (he ſays) in the 12th century, when the ladies kept hawks, which were as much fondled by thoſe who wiſhed to gain their favour as lap dogs are at preſent. Among the oldeſt writers on falconry, as an art, he reckons Demetrius, who about the year 1270 was phyſician to the Emperor Michael Paleologus. His book, written in Greek, was firſt printed at Paris in 1612 with a Latin tranſlation; but its precepts (ſays our author) would be thought of very little value at preſent. For an account of the modern art of FALCONRY, ſee *Encyclopædia*.

FALK (John Peter), known to the world as one of the ſcientific travellers employed by the late Empreſs of Ruſſia to explore her vaſt dominions, was born in Weſtrogothia, a province in Sweden, about the year 1727. He ſtudied medicine in the univerſity of Upſal, and went through a courſe of botany under the celebrated Linnæus, to whoſe ſon he was tutor. He publicly defended the diſſertation (A) which that famous botaniſt had compoſed on a new ſpecies of plants, which he called *aſtromeria*.

In the year 1760, he was ſo deeply affected with depreſſion of ſpirits, that M. de Linné, in the view of obliging him to take exerciſe and diſſipation, ſent him to travel over the iſland of Gothland, to make a collection of the plants it produces, and the various kinds of corals and corallines which the ſea leaves on its ſhores. This voyage was attended with no diminution of his diſtemper, which found a continual ſupply of aliment in a ſanguine melancholy temperament, in a too ſedentary way of life, and in the bad ſtate of his finances.

Profeſſor Forſkael having left Upſal for Copenhagen in 1760, Falk followed him thither, in the deſign of applying, by the advice of M. de Linné, to be appointed aſſiſtant to M. Forſkael in his famous journey thro' Arabia; but notwithſtanding all the pains that M. Œder, and ſeveral other men of literary reputation at Copenhagen, took in his behalf, his application failed, as the ſociety that were to go on that important expedition was already formed. Obliged, with much diſcontent, to return, he herboriſed as he travelled, and enriched the Flora Suecica with ſeveral new diſcoveries.

A man in office at St Peterſburgh having written to M. Linné to ſend him a director for his cabinet of natural hiſtory, M. Falk accepted the poſt, which led him to the chair of profeſſor of botany at the apothecaries garden at St Peterſburgh, a place that had been long vacant. His hypochondriac complaint ſtill continued to torment him. When the Imperial Academy of Sciences was preparing in 1768 the plan of its learned expeditions, it took M. Falk into its ſervice, though his health was uncertain. He was recalled in 1771; but having got only to Kaſan in 1773, he there obtained permiſſion to go and uſe the baths of Kiſliar, from which he returned again to Kaſan at the end of the year, with his health apparently better.

But his diſeaſe ſoon returned with redoubled violence. From the month of December 1773 he had never quitted his bed, nor taken any other nouriſhment than bread dried in the Swediſh manner (knækebrœd), of which he ſcarcely took once a day ſome mouthfuls dipped in tea. At firſt he received the viſits of a few friends; but afterwards denied himſelf to them, and was reduced to the ſtricteſt ſolitude. When M. Georgi, member of the ſociety of natural hiſtory at Berlin, who had been deſtined to aſſiſt and relieve the profeſſor in the duties of his expedition, went to ſee him on this occaſion, nothing ſeemed left of him but a ſkeleton of a wild and terrifying aſpect. The few words he drew from him conſiſted in complaints, occaſioned by a hoſt of diſeaſes which kept his body in torture, and threw him into the moſt cruel ſleepleſſneſs. The laſt evening M. Georgi kept him company till midnight. He ſpoke little, and ſaid nothing that could give reaſon to ſuſpect the deſign he was meditating. His hunter, and at the ſame time his truſty ſervant, offered to ſit up with him the night; but he could not be perſuaded to conſent.

M. Georgi being requeſted the next day, March 31, to come to the lodging of the unfortunate gentleman, he found him lying before his bed, covered with blood; beſide him lay a razor, with which he had given himſelf a ſlight wound in the throat, the fatal piſtol, and a powder-horn; all together preſenting a tremendous ſpectacle. He had put the muzzle of the piſtol againſt his throat, and, reſting the pommel upon his bed, he diſcharged the contents in ſuch a manner, that the ball, having gone through his head, had ſtuck in the cieling. His ſoldier had ſeen him ſtill ſittting up in his bed at four o'clock, at which time he uſually fell into a ſhort ſlumber. In his chamber was found a note written the evening before, betraying throughout the diſtracted ſtate of his mind, but nothing declaratory of his deſign, or that was of any importance.

M. Falk, like all hypochondriac perſons, was not very communicative, and on certain occaſions was diſtruſtful. But, at the ſame time, he was of a ſedate temper, complaiſant, and upright, which made it a very eaſy matter to bear with him, and ſecure to him the indulgence of all his acquaintance. His extreme ſobriety had enabled him to make ſome ſavings from his pay, though he was very beneficent; it was not, therefore, indigence that drove him to this act of violence. He was of a cold conſtitution, preferring ſolitude and quiet to ſociety, to the company of his friends, and to ordinary amuſements, which yet he did not ſhun, except in the latter period of his life. As to religion, he ſhewed on all occaſions more reſpect for it than any ſtrong effuſions of zeal. It was ſolely to be aſcribed to the violence of his diſtemper, and the weakneſs of mind which it brought on, that led him to put a period to his days. The fate of this unfortunate ſcholar was generally and juſtly lamented.

His papers were found in the greateſt diſorder. They contain,

---

(A) In the collection known under the title of *Linnæi Amænitates Academicæ*.

contain, however, very uſeful and important relations. He particularly made it his buſineſs to inquire about the Kirguiſes, and other Tartarian nations; and as he frequently remained for the ſpace of nine months together in the ſame place, he was enabled to procure ſatisfactory notions concerning the objects of his inveſtigations. The Imperial Academy, in 1774, appointed Profeſſor Laxmann to arrange his manuſcripts in order for publication; which was done accordingly.

FARMER (Richard, D. D.), ſo well known as one of the commentators on Shakeſpeare, was a man of ſuch pleaſing, though ſingular manners, that we regret the very imperfect account which we muſt give of his life. One of us, who had the pleaſure of being a little known to him, has been ſo much delighted with the natural eaſe and pleaſantry of his converſation, that we made all the inquiries which we judged requiſite to enable us to draw up ſuch a biographical ſketch of this agreeable man as might be acceptable to our readers, and not unworthy of his character; but theſe inquiries were made in vain. Thoſe to whom we applied knew little more of the incidents of his life than what we had previouſly found in a miſcellany, of which the writers ſeem to conſider it as a principle of duty to vilify the character of every perſon who, like Dr Farmer, is the friend of order, and the enemy of ſudden or rapid innovations. To that miſcellany, therefore, we muſt be beholden for many facts; but we ſhall certainly copy none of its malevolence.

Dr Farmer was born at Leiceſter 1735; but what was the ſtation of his father we have not learned. Of his ſchool education he received part, perhaps the whole, in his native town; and from ſchool he was removed to the univerſity of Cambridge, where he devoted himſelf chiefly to claſſical learning and the belles lettres. In 1757 he was admitted to the degree of bachelor of arts; in 1760 to that of maſter of arts; a bachelor of divinity in 1767, and a doctor of divinity in 1775; in which year he was alſo elected maſter of Emanuel on the deceaſe of Dr Richardſon, and principal librarian on the deceaſe of Dr Barnardiſton.

The diſturbances in America having by this time become ſerious, the univerſity of Cambridge, with numberleſs other loyal bodies, voted an addreſs to the king, approving of the meaſures adopted by government to reduce the factious coloniſts to their duty. The addreſs, however, was not carried unanimouſly. It was, of courſe, oppoſed by JEBB, ſo well known for his free opinions in politics and religion, and by ſome others, of whom one man, a member of the CAPUT, carried his oppoſition ſo far, as actually to refuſe the key of the place which contained the ſeal neceſſary on ſuch occaſions. In this emergency, Dr Farmer, who was then vice-chancellor, is ſaid to have forced open the door with a ſledge-hammer; an exploit which his democratical biographers affect to ridicule, by calling it *his courtly zeal*, and the occaſion of all his ſubſequent preferments.

If it be indeed true that he broke the door in pieces with his own hands, his conduct muſt be acknowledged to have been not very decorous; but if the office which he filled be taken into conſideration, we apprehend it would be as difficult to prove that conduct eſſentially wrong, as to vindicate the obſtinate arrogance of him who occaſioned it. The ſeal was the property of the univerſity, of which this outrageous ſupporter of the bill of rights was but an individual member. The univerſity had reſolved that it ſhould be employed for a certain purpoſe, which it was the duty of the vice chancellor to carry into effect; and ſince the ſeal was refuſed to him, he had no alternative but to get poſſeſſion of it by force. We hope, however, that he employed a ſervant to break the door; and, indeed, as vice-chancellor, he muſt have had ſo many ſervants at his command, that it is not conceivable he would wield the ſledge hammer himſelf.

Some time after this he was made a prebendary of Canterbury, we believe through the recommendation of Lord North, then premier; and it was at Canterbury that the writer of this ſketch had the happineſs of being introduced to him, and witneſſing his hoſpitality. After enjoying his prebend for ſeveral years, he reſigned it on being preferred, by the preſent premier, to a reſidentiaryſhip of St Paul's; and we have reaſon to believe that he declined a biſhopric, which was offered to him as a reward for the conſtitutional principles which he was at pains to propagate, not only in his college, but, as far as his influence went, through the whole univerſity.

It has been ſaid that the delights of the pipe and the bottle in Emanuel parlour outweighed, in his eſtimation, the dazzling ſplendor of the mitre; but he had other and better reaſons for preferring a private to a public ſtation. In early life, at leaſt before he was advanced in years, he had felt the power of love, and had ſuffered ſuch a diſappointment as ſunk deep in his mind, and for a time threatened his underſtanding. From that period, though he retained his faculties entire, he acquired ſome peculiarities of manner, of which he was ſo far conſcious as to be ſenſible that they would hardly become the character of a biſhop: being likewiſe ſtrongly attached to dramatic entertainments, which, if we miſtake not, the Engliſh biſhops never witneſs, and delighting in clubs, where he could have rational converſation without ſtate or ceremony of any kind—he very wiſely preferred his reſidentiaryſhip to the higheſt dignity in the church. At the time of his death, which happened in the autum of 1797, he was a fellow of the Royal and Antiquarian Societies, maſter of Emanuel college, principal librarian of the public library in the univerſity, one of the canons reſidentiary of St Paul's, chancellor of the dioceſe of Lichfield and Coventry, and prebendary of Worceſter.

Though a good claſſical ſcholar, Dr Farmer has been celebrated only for that kind of literature which is connected with the Engliſh drama; and having a ſtrong predilection for old Engliſh writers, he ranked high among the commentators upon Shakeſpeare. His 'Eſſay upon the Learning of Shakeſpeare,' dedicated to Mr Cradock, the intelligent reſident of Gumley-Hall in Leiceſterſhire, has paſſed through ſeveral editions. This eſſay was, in fact, the firſt foundation of his fame, which an unconquerable indolence prevented him from carrying to that height to which the exerciſe of his literary talents could not have failed to raiſe it. So great indeed was his love of eaſe, that after having announced for ſubſcriptions a hiſtory of Leiceſterſhire, and actually begun to print it, rather than ſubmit to the fatigue of carrying it through the preſs, he returned the ſubſcriptions, and preſented the MSS. and plates to Mr Nichols,

Nichols, the reſpectable printer of the Gentleman's Magazine, who has ſince carried on the hiſtory with a degree of ſpirit, ability, and induſtry, perhaps unprecedented in this department of literature.

Indolence and the love of eaſe were indeed the Doctor's chief characteriſtics; and to them, with the diſappointment already mentioned, may be attributed a want of propriety in his external appearance, and in the uſual forms of behaviour belonging to his ſtation. The prevailing features of his character diſtinguiſhed themſelves by ſeveral oddities: There were three things, it was ſaid, which the maſter of Emanuel loved, *viz.* old port, old clothes, and old books; and three things which no one could perſuade him to perform, *viz.* to riſe in the morning, to go to bed at night, and to ſettle an account. When in Cambridge, if an old houſe were pulled down, the maſter of Emanuel was always there in an old blue great coat, and a ruſty hat. When in London, he was ſure to be found in the ſame garb at an old book-ſtall, or ſtanding at the corner of a dirty lane, poring through his glaſs at an old play-bill.

This character is not drawn by a friendly pencil; but it is nevertheleſs not unjuſt. His inattention to the common decencies of dreſs and behaviour was notorious, inſomuch that, in the company of ſtrangers, the eccentricity of his appearance and of his manners made him ſometimes be taken for a perſon half crazed. The writer of this ſketch ſaw him one morning at Canterbury dreſſed in ſtockings of unbleached thread, brown breeches, and a wig not worth a ſhilling; and when a brother prebendary of his, remarkable for elegance of manners, and propriety of dreſs, put him in mind that they were to attend on the archbiſhop, Dr Farmer replied, that it had totally eſcaped him; but he went home, and dreſſed himſelf like a clergyman. That he ſat late reading, and occaſionally drinking brandy and water, cannot be denied; and it is literally true, that he could not eaſily be prevailed upon to ſettle his accounts. His accounts with ſome of his pupils, when tutor of his college, were never ſettled to the day of his death; and the young gentlemen not unfrequently took advantage of this unconquerable indolence to borrow of him conſiderable ſums, well knowing that there was little chance of a demand being ever made upon their parents. One gentleman, in particular, told a friend of ours, who was himſelf a penſioner of Emanuel, that when he left that college, he was near fifty pounds in debt to Dr Farmer; "a debt (ſaid he) which I would have ſcrupulouſly paid, but, after repeated ſolicitations, I could get no bill from him."

Having been a warm partizan of government during the American war, it will readily be believed that Dr Farmer was the determined enemy of levellers and anarchiſts. He was ſuch a whig as thoſe who placed King William on the throne; and of courſe deemed a violent tory by our preſent republicans, of whom, to ſay the truth, he could hardly ſpeak with temper. By his enemies he is admitted to have been a man of generoſity. As he obtained money eaſily, ſo he parted with it eaſily. Whilſt he was always ready to relieve diſtreſs, his bounty was frequently beſtowed on the patronage of learned men and learned publications. He was, accordingly, a favourite with all good men who knew him. In his own college he was adored; in the univerſity he had, for many years, more influence than any other individual; and, with all his eccentricities, his death was a loſs to that learned body, which, in the opinion of ſome of its members, will not ſoon be made up.

A ſhort time before his death, his character was thus juſtly and ably drawn by the celebrated Dr Parr:

"Of any undue partiality towards the maſter of Emanuel College, I ſhall not be ſuſpected by thoſe perſons who know how little his ſentiments accord with mine, upon ſome eccleſiaſtical, and many political matters. From rooted principle and ancient habit he is a tory; I am a whig; and we have both of us too much confidence in each other, and too much reſpect for ourſelves, to diſſemble what we think, upon any grounds, or to any extent. Let me then do him the juſtice which, I am ſure, that he will ever be ready to do to me. His knowledge is various, extenſive, and recondite. With much ſeeming negligence, and perhaps, in later years, ſome real relaxation, he underſtands more, and remembers more, about common and uncommon ſubjects of literature, than many of thoſe who would be thought to read all the day and meditate half the night. In quickneſs of apprehenſion, and acuteneſs of diſcrimination, I have not often ſeen his equal. Through many a convivial hour have I been charmed by his vivacity: and upon his genius I have reflected, in many a ſerious moment, with pleaſure, with admiration, but not without regret that he has never concentrated and exerted all the great powers of his mind in ſome great work, upon ſome great ſubject. Of his liberality in patroniſing learned men I could point out numerous inſtances. Without the ſmalleſt propenſities to avarice, he poſſeſſes a large income; and, without the mean ſubmiſſion of dependence, he is riſen to a high ſtation. His ambition, if he has any, is without inſolence; his munificence is without oſtentation; his wit is without acrimony; and his learning without pedantry."

FASCINATION, the art of bewitching, enchantment, an unſeen inexplicable influence. Under the title SERPENS (*Encycl.* n° 22.) we have mentioned ſeveral inſtances of the faſcinating power of the rattleſnake, which were related by men of character, and certainly gained ſome degree of credit among men of ſcience. In Vaillant's New Travels into the Interior Parts of Africa, an account is given of ſimilar inſtances of faſcination by African ſervants, ſome of them witneſſed by himſelf, and others reported to him by men of veracity.

On the confines of the European colony, at a place called *Swart-land*, our traveller ſaw a ſhrike on the branch of a tree, tremble as if in convulſions, whilſt it uttered the moſt piercing cries of diſtreſs. Cloſer attention led him to diſcover upon the next branch of the ſame tree a large ſerpent, that, with ſtretched-out neck, and fiery eyes, though perfectly ſtill, was gazing on the poor animal. He ſhot the ſerpent; but, in the mean time, the bird had died. Having meaſured the diſtance between the place where the ſhrike was ſeen in convulſions and that occupied by the ſerpent when it was ſhot, he found it to be three feet and a half; which convinced him and his attendants that the bird had not died either from the bite or the poiſon of its enemy. Indeed he ſtripped it before the whole company, and made them obſerve that it was untouched, and had not received the ſlighteſt wound.—In another diſtrict of Africa, during the courſe of the ſame travels, he ſaw a ſmall mouſe die in convulſions, occaſioned by the faſcinating power of a ſerpent, at the diſtance of two yards from it; and when he conſulted his Hottentots upon this incident, they expreſſed, he ſays, no ſort of aſtoniſhment, but aſſured him that the ſerpent had the faculty of attracting and faſcinating ſuch animals as it wiſhed to devour.

We have already had occaſion to remark how regardleſs this author is of inconſiſtencies in his narrative; and we perceive ſomething like an inconſiſtency in the narratives before us. Though his Hottentots expreſſed no ſurpriſe at the faſcination of the mouſe, and declared that nothing was more common, he ſays expreſsly, that to thoſe who witneſſed the faſcination of the ſhrike, the fact appeared ſo extraordinary, that they could hardly believe it, even after they had ſeen it.

The moſt wonderful inſtance of faſcination which we have anywhere met with, was that of a Captain in the Dutch ſervice at the Cape, who, after aſſuring our traveller that it is an event which happens very frequently, proceeded thus: "My teſtimony ought to have the more weight, as I had once nearly become myſelf a victim to this faſcination. While in garriſon at Ceylon, and amuſing myſelf, like you, in hunting in a marſh, I was, in the courſe of my ſport, ſuddenly ſeized with a convulſive and involuntary trembling, different from any thing I had ever experienced, and at the ſame time was ſtrongly attracted, and in ſpite of myſelf, to a particular ſpot of the marſh. Directing my eyes to this ſpot, I beheld, with feelings of horror, a ſerpent of an enormous ſize, whoſe look inſtantly pierced me. Having, however, not yet loſt all power of motion, I embraced the opportunity before it was too late, and ſaluted the reptile with the contents of my fuſee. The report was a taliſman that broke the charm. All at once, as if by a miracle, my convulſion ceaſed; I felt myſelf able to fly; and the only inconvenience of this extraordinary adventure was a cold ſweat, which was doubtleſs the effect of my fear, and of the violent agitation my ſenſes had undergone."

This inſtance of faſcination differs in one very material circumſtance from the two ſomewhat ſimilar inſtances mentioned in the *Encyclopædia*. In both theſe, the eyes of the perſons faſcinated were fixed on the eyes of the ſnake; but here the Dutch Captain was ſtrongly attracted towards the ſerpent before he ſaw, or even ſuſpected, that ſo formidable an enemy was in his neighbourhood. If the ſtory therefore be true, the effect which he deſcribes could not poſſibly have been the effect of fear, but of ſome unſeen influence on his whole nervous ſyſtem.

The ſubject has of late attracted the attention of men of ſcience, whoſe local ſituation gives them an opportunity of making experiments upon different ſerpents, with a view to aſcertain whether they really poſſeſs or not this moſt unaccountable of all powers. In the year 1796 was printed at Philadelphia, *a Memoir concerning the Faſcinating Faculty which has been aſcribed to the Rattle-ſnake, and other American Serpents*, by Benjamin Smith Barton, M. D. Profeſſor of natural hiſtory and botany in the univerſity of Pennſylvania. In this memoir, the manner in which the faſcinating power is ſuppoſed to be exerted is thus ſtated by the ingenious profeſſor:

"The ſnake, whatever its ſpecies may be, lying at the bottom of the tree or buſh upon which the bird or ſquirrel ſits, fixes its eyes upon the animal it deſigns to faſcinate or enchant. No ſooner is this done, than the unhappy animal is unable to make its eſcape. It now begins to utter a moſt piteous cry, which is well known by thoſe who hear it, and underſtand the whole machinery of the buſineſs, to be the cry of a creature enchanted. If it is a ſquirrel, it runs up the tree for a ſhort diſtance, comes down again, then runs up, and, laſtly, comes lower down. 'On that occaſion (ſays an honeſt, but rather credulous writer*), it has been obſerved, that the ſquirrel always goes down more than it goes up.' The ſnake ſtill continues at the root of the tree, with its eyes fixed on the ſquirrel, with which its attention is ſo entirely taken up, that a perſon accidentally approaching, may make a conſiderable noiſe without the ſnake's ſo much as turning about. The ſquirrel, as before mentioned, comes always lower, and at laſt leaps down to the ſnake, whoſe mouth is already wide open for its reception. The poor little animal then, with a piteous cry, runs into the ſnake's jaws, and is ſwallowed at once, if it be not too big; but if its ſize will not allow it to be ſwallowed at once, the ſnake licks it ſeveral times with its tongue, and ſmoothens it, and by that means makes it fit for ſwallowing."

From Dr Barton's memoir, it appears that the North American Indians are by no means of one opinion reſpecting the faſcinating power of the rattle-ſnake. Some intelligent friends of his, well acquainted with the manners, religious opinions, and ſuperſtitious prejudices of thoſe people, informed him, that though they had often heard the Indians ſpeak of the ingenuity of theſe reptiles in catching birds, ſquirrels, &c. they did not recollect having ever heard them ſay that ſnakes *charm* birds. On the other hand, however, a Mohegan Indian told the Doctor himſelf, that the Indians are of opinion, that the rattle-ſnake can charm, or betwitch, ſquirrels and birds, and that it does this with its rattle, which it ſhakes, thereby inviting the animals to deſcend from the trees, after which they are eaſily caught. According to this Indian, his countrymen do not think that the ſnake, in any manner, accompliſhes the buſineſs with its eyes. A Choktah Indian aſſured the Doctor, that the rattle ſnake does charm birds, &c.; but he was honeſt enough to confeſs, that he did not know in what manner it does it. The interpreter, through whom the converſation was carried on with this Indian, ſaid that the ſnake charms by means of its rattle.

This opinion of the interpreter was the opinion of Dr Mead. That eminent naturaliſt, controverting, about fifty years ago, the common opinion, that Providence has furniſhed the rattle-ſnake with its rattle to give warning to travellers, was the firſt who aſſerted that this ſingular appendage is given to the animal to terrify ſquirrels and ſmall birds, which are then ſo ſtupified by the ſight of ſo formidable an enemy, that at length they drop down, and become its prey; and that this is what the Indians call *faſcination*. The ſame opinion has been adopted by profeſſor Blumenbach of Gottingen, who, in his Manual of Natural Hiſtory, thus expreſſes himſelf on this curious ſubject:

"That ſquirrels, ſmall birds, &c. fall down ſpontaneouſly from trees into the mouth of the rattle-ſnake, lying

---

* *Profeſſor Peter Kalm.*

lying below them, is an undiſputed fact; and is the leſs ſurpriſing, as the like phenomena have been remarked in regard to other ſnakes, and alſo toads, hawks, and cats; all of which, in certain circumſtances, as appears, have the power of drawing towards them ſmall animals, merely by fixing their eyes ſtedfaſtly on them. In regard to the rattle-ſnake, this effect is produced by the rattle in its tail, the hiſſing noiſe of which makes ſquirrels, &c. whether through curioſity, miſtake, or terror, ſeem to approach the animal as it were ſpontaneouſly. At any rate, I know, from the information of intelligent eye-witneſſes, that it is a common ſtratagem of the young ſavages in America to conceal themſelves in the buſhes, where they imitate the hiſſing noiſe of the rattle-ſnake, and by theſe means attract ſquirrels, which they are then enabled to catch."

To this opinion Dr Barton oppoſes an inſuperable objection. It is, that this faſcinating power is by no means peculiar to the rattle-ſnake. With regard to the ſtratagem of the ſavages, he thinks that Dr Blumenbach has been impoſed upon; as neither he, nor any other perſon of whom he made the inquiry, ever heard of ſuch a ſtratagem. The young Indians, he ſays, place a reed croſs-wiſe in their mouth, and by a tremulous motion of the lips, imitate the cry of young birds; by which means they entice the old ones, ſo that they can eaſily ſhoot them: And this practice may have given riſe to the ſtory of their imitating the hiſſing noiſe of the rattle-ſnake.

Some have ſuppoſed that ſerpents, under certain circumſtances, emit from their bodies a ſtupifying vapour; and that it is this vapour which produces the effect called *faſcination*: But againſt this opinion Dr Barton alleges the following arguments: "I know, indeed (ſays he), that in ſome of the larger ſpecies of ſerpents, inhabiting South America and other countries, there is evolved in the ſtomach, during the long and tedious proceſs of digeſtion in theſe animals, a vapour or a gas, whoſe odour is intenſely fetid. I have not, however, found that this is the caſe with the rattle-ſnake, and other North American ſerpents, that I have examined. But my own obſervations on this head have not been very minute. I have made inquiry of ſome perſons (whoſe prejudices againſt the ſerpent tribe are not ſo powerful as my own), who are not afraid to put the heads and necks of the black ſnake, and other ſerpents that are deſtitute of venemous fangs, into their mouths, and have been informed, that they never perceived any diſagreeable ſmell to proceed from the breath of theſe animals. I have been preſent at the opening of a box which contained a number of living ſerpents; and although the box had been ſo cloſe as to admit but a very ſmall quantity of freſh air, although the obſervation was made in a ſmall warm room, I did not perceive any peculiarly diſagreeable effluvium to ariſe from the bodies of theſe animals. I am, moreover, informed by a member of this ſociety *, who has, for a conſiderable time, had a rattle-ſnake under his immediate care, that he has not obſerved that any diſagreeable vapour proceeds from this reptile. On the other hand, however, it is aſſerted by ſome creditable perſons of my acquaintance, that a moſt offenſive odour, ſimilar to that of fleſh in the laſt ſtage of putrefaction, is continually emanating from every part of the rattle-ſnake, and ſome other ſpecies of ſerpents. This odour extends, under certain circumſtances, to a conſiderable diſtance from the body of the animal. Mr William Bartram aſſures me, that he has obſerved 'horſes to be ſenſible of, and greatly agitated by it, at the diſtance of forty or fifty yards from the ſnake. They ſhewed (he ſays) their abhorrence by ſnorting, winnowing, and ſtarting from the road, endeavouring to throw their riders, in order to make their eſcape." This fact, related by a man of rigid veracity, is extremely curious; and, in an eſpecial manner, deſerves the attention of thoſe writers who imagine that this fetid emanation from ſerpents is capable of affecting birds, at ſmall diſtances, with a kind of aſphyxy. It even gives *ſome* colour of probability to the ſtory related by Metrodorus, and preſerved in the Natural Hiſtory of Pliny *."

Some experiments, however, which were made in Philadelphia a little before the Doctor compoſed his memoir, ſeem to have been deciſive not only as to the fetor, but as to every thing which reſembles faſcination in the rattle-ſnake. Birds which were put into a cage which contained a rattle-ſnake, flew or ran *from* the reptile, as though they were ſenſible of the danger to which they were expoſed. The ſnake made many attempts to catch the birds, but could ſeldom ſucceed. When a dead bird was thrown into the cage, the ſnake devoured it immediately. He ſoon caught and devoured a living mole, an animal much more ſluggiſh than the bird. Dr Barton himſelf ſaw a ſnow-bird (ſee EMBERIZE, *Encycl.*) in a cage with a large rattle-ſnake. The little animal had been thus impriſoned for ſeveral hours when he firſt ſaw it, but it exhibited no ſigns of fear. It hopped about from the floor of the cage to its rooſt, and frequently perched on the ſnake's back. Its chirp was nowiſe tremulous, but perfectly natural. It ate the ſeeds which were put into the cage; and by its whole actions moſt evidently demonſtrated that its ſituation was not uneaſy.

Having thus diſpoſed of the doctrines of ſome of his predeceſſors, Dr Barton proceeds to ſay: "The reſult of not a little attention to the ſubject has taught me, that there is but one wonder in the buſineſs;—the wonder that the ſtory ſhould ever have been believed by a man of underſtanding and of obſervation." Faſcination, we are informed, is almoſt entirely limited to birds that build low, and "in almoſt every inſtance, I found that the ſuppoſed faſcinating faculty of the ſerpent was exerted upon the birds at the particular ſeaſon of their laying their eggs, of their hatching, or of their rearing their young, ſtill tender and defenceleſs. I now began to ſuſpect that the cries and fears of birds ſuppoſed to be faſcinated originated in an endeavour to protect their neſt or young. My inquiries have convinced me that this is the caſe."

The rattle-ſnake, which is the lazieſt of all the ſerpent tribe, never moves in a ſpiral manner or climbs up trees; but the black-ſnake, and ſome other ſpecies of the genus coluber, do. When impelled by hunger, and incapable of ſatiſfying it by the capture of animals on the ground, they begin to glide up trees or buſhes upon which a bird has its neſt. The bird is not ignorant of the ſerpent's object. She leaves her neſt, whether it contains eggs or young ones, and endeavours to oppoſe the reptile's progreſs. In doing this, ſhe is actuated by the ſtrength of her inſtinctive attachment to her eggs, or of affection to her young. Her cry is melancholy,

---

* *Lib.* 28. *Cap.* 14.

her motions are tremulous. She expoſes herſelf to the moſt imminent danger. Sometimes ſhe approaches ſo near the reptile that he ſeizes her as his prey. But this is far from being univerſally the caſe. Often ſhe compels the ſerpent to leave the tree, and then returns to her neſt.

It is a well known fact, that among ſome ſpecies of birds, the female, at a certain period, is accuſtomed to compel the young ones to leave the neſt; that is, when the young have acquired ſo much ſtrength that they are no longer entitled to all her care. But they ſtill claim ſome of her care. Their flights are aukward, and ſoon broken by fatigue. They fall to the ground, where they are frequently expoſed to the attacks of the ſerpent, which attempts to devour them. In this ſituation of affairs, the mother will place herſelf upon a branch of a tree or buſh, in the vicinity of the ſerpent. She will dart upon the ſerpent, in order to prevent the deſtruction of her young: but fear, the inſtinct of ſelf-preſervation, will compel her to retire. She leaves the ſerpent, however, but for a ſhort time, and then returns again. Oftentimes ſhe prevents the deſtruction of her young, attacking the ſnake with her wings, her beak, or her claws. Should the reptile ſucceed in capturing the young, the mother is expoſed to leſs danger; for, whilſt engaged in ſwallowing them, he has neither inclination nor power to ſeize upon the old one. But the appetite of the ſerpent tribe is great: the capacity of their ſtomachs is not leſs ſo. The danger of the mother is at hand when the young are devoured. The ſnake ſeizes upon her: and this is the cataſtrophe, which crowns the tale of faſcination!

FAUSSE BRAYE, in fortification, an elevation of earth, about three feet above the level ground, round the foot of the rampart on the outſide, defended by a parapet about four or five fathoms diſtant from the upper parapet, which parts it from the berme and the edge of the ditch. The fauſſe-braye is the ſame with what is otherwiſe called *Chemin des rondes*, and *Baſſe enceinte;* and its uſe is for the defence of the ditch.

FEATHER-EDGED, is a term uſed by workmen for ſuch boards as are thicker on one edge, or ſide, than on the other.

FELTING, the method of working up wool or hair into a kind of cloth or ſtuff, without either ſpinning or weaving it. In this country felting it little practiſed except in hat-making; and as nine-tenths of thoſe who are employed in the manufacturing of hats know nothing of the principles on which they proceed, the following obſervations on the mechaniſm of felting muſt to them be both agreeable and uſeful. They are by M. Monge, and taken from the *Annales de Chemie.*

If we examine, in a microſcope, human hair, wool, the hair of a rabbit, hare, beaver, &c. however great the magnifying power of the inſtrument may be, the ſurface of each hair appears perfectly ſmooth and even; or at leaſt, if any inequalities are to be perceived, they ſeem rather to ariſe from ſome difference in the colour and tranſparency of particular parts of theſe ſubſtances than from the irregularity of their ſurfaces; for their image, when viewed by a ſolar microſcope, is terminated by even lines, without any roughneſs. The ſurface of theſe objects, however, is by no means ſmooth; on the contrary, it appears to be formed either of *lamellæ* which cover each other from the root to the point, pretty much in the ſame manner as the ſcales of a fiſh cover the animal from the head to the tail; or, more probably, of zones placed one over the other, like what is obſerved in the ſtructure of horns: to this conformation it is that the ſubſtances here treated of owe their diſpoſition to what is called felting.

If, with one hand, we take hold of a hair by the root, and draw it between two fingers of the other, from the root towards the point, we are hardly ſenſible of any friction or reſiſtance, nor can we diſtinguiſh any ſound; but if, on the contrary, we hold the hair at the point, and draw it between the fingers, from the point toward the root, we are ſenſible of a reſiſtance which did not exiſt in the former caſe; a ſort of tremulous motion is likewiſe produced, which is not only perceptible to the touch, but may alſo be diſtinguiſhed by the ear.

It is evident, therefore, that the texture of the ſurface of a hair is not the ſame from the root towards the point as from the point towards the root; and that a hair, when graſped, muſt offer more reſiſtance in ſliding or moving progreſſively towards the point than towards the root; *i. e.* in moving with its point foremoſt.

If a hair, after being taken hold of by the fore-finger and thumb, be rubbed by them, in the longitudinal direction of the hair, a progreſſive motion takes place, and this motion is always towards the root. This effect does not at all depend on the nature of the ſkin of the fingers or its texture; for if the hair be turned, ſo that the point is placed where the root was, the movement then becomes contrary to what it was before; that is to ſay, it is always directed towards the root.

What is obſerved, in the above inſtance, is entirely analogous to what happens when country children, by way of ſport, introduce an ear of rye or barley between the wriſt and the ſhirt, the points of the beards of which are directed outwards. By the various motions of the arm, this ear, ſometimes catching againſt the ſhirt, ſometimes againſt the ſkin, takes a progreſſive motion backwards, and ſoon gets up to the arm-pit. It is very clear that this effect is produced by the beards of the ear, and indeed chiefly by the aſperities upon thoſe beards; which, being all directed towards the point, do not permit the ear to move in any other direction than towards that part to which it was united to the ſtalk. There is no doubt that it is the ſame with reſpect to hair; and that its ſurface is beſet with aſperities, which, being laid one upon the other, and turned towards the points, permit no motion but towards the root.

A tight knot, made in the middle of a hair, is very difficult to untie by the uſual means, on account of the extreme thinneſs of the hair; but if we place the hair in the bend of the hand, ſo that the knot is in a line with the little finger, and, after graſping the hair by cloſing the hand, we ſtrike the fiſt ſeveral times againſt the knee, the aſperities of one end of the hair being now in a contrary direction to thoſe of the other, each of the ends recedes a little, one of them one way, the other the contrary way; the knot is thereby opened, and, by introducing a pin into the eye which is formed, it is very eaſy to finiſh untying it.

Theſe obſervations, which it would be uſeleſs to multiply, relate to long hair, that having been taken as an example; but they apply with equal propriety to wool, furs, and in general to every kind of animal hair. The ſurface of all theſe is therefore to be conſidered as compoſed of hard *lamellæ* placed one upon another, like tiles, from the root to the point; which *lamellæ* allow the progreſſive motion of the hair towards the root, but prevent a ſimilar motion towards the point.

From what has been ſaid, it is eaſy to explain why the contact of woollen ſtuffs is rough to the ſkin, while that of linen or cotton cloths is ſmooth; the reaſon is, the aſperities upon the ſurface of the fibres of the wool (notwithſtanding the flexibility of each particular fibre), by fixing themſelves in the ſkin, produce a diſagreeable ſenſation, at leaſt till we are accuſtomed to it; whereas the ſurface of the fibres of hemp or flax, of which linen is made, being perfectly ſmooth, do not cauſe any ſuch ſenſation. It is alſo evident, that the injury ariſing to wounds or ſores, from the application of wool, does not proceed from any chemical property, but is occaſioned ſolely by the conformation of the ſurface of the fibres: the aſperities of which attach themſelves to the raw and expoſed fleſh, which they ſtimulate and irritate to ſuch a degree as to produce inflammation.

This conformation is the principal cauſe of that diſpoſition to what is called felting, which the hair of all animals in general poſſeſſes.

The hatter, by ſtriking the wool with the ſtring of his bow (ſee Hat, *Encycl.*), ſeparates the hairs from each other, and cauſes them to ſpring up in the air; the hairs fall again on the table, in all poſſible directions, ſo as to form a layer of a certain thickneſs, and the workman covers them with a cloth, which he preſſes with his hands, moving them backwards and forwards in various directions. This preſſure brings the hairs againſt each other, and multiplies their points of contact; the agitation of them gives to each hair a progreſſive motion toward the root; by means of this motion the hairs are twiſted together, and the *lamellæ* of each hair, by fixing themſelves to thoſe of other hairs which happen to be directed the contrary way, keep the whole in that compact ſtate which the preſſure makes it acquire. In proportion as the maſs becomes compact, the preſſure of the hands ſhould be increaſed; not only to make it more cloſe, but alſo to keep up the progreſſive motion and twiſting of the hairs, which then takes place with greater difficulty: but throughout the whole of this operation, the hairs fix themſelves only to each other, and not to the cloth with which they are covered, the fibres of which, as we have already ſaid, are ſmooth, and have not that diſpoſition to felting which we have deſcribed above.

It may not be amiſs here to explain why that hair which is intended for making hats is always cut off with a ſharp inſtrument (although that cannot be done without loſing a part of its length), and not plucked out by the roots, as might be done after ſoftening the ſkin: the reaſon is, the bulb of the hair, which in the latter caſe would come out with it, would render that end which was fixed in the ſkin thick and obtuſe; and it would conſequently be leſs diſpoſed to introduce itſelf among the contiguous hairs, and to contribute by its progreſs motion to the contexture of the maſs.

The above deſcribed conformation of the ſurface of hairs and wool is not the only cauſe which produces their diſpoſition to felting. It is not ſufficient that every hair poſſeſſes the forementioned tendency to move progreſſively towards the root, and that the inclined *lamellæ*, by hooking themſelves to each other, preſerve the maſs in that ſtate to which compreſſion has brought it; but it is alſo neceſſary that the hairs ſhould not be ſtraight, like needles; if they were ſo, preſſing and rubbing them together would merely cauſe them to continue their progreſſive motion, without changing their direction; and the effect of thoſe operations would only be to make them move from the centre of the maſs, without producing any compactneſs in it. Every hair muſt therefore be twiſted or curled in ſuch a manner that the extremity which is towards the root may be diſpoſed to change its direction perpetually, to twiſt itſelf about other hairs, and to incline towards itſelf again, in caſe it ſhould be determined thereto by any change in the poſition of the reſt of its length. It is becauſe wool has naturally this crooked form that it is ſo proper for felting, and that it may be made uſe of for that purpoſe without undergoing any previous preparation.

But the hairs of the beaver, the rabbit, the hare, &c. being naturally ſtraight, cannot be employed alone in felting till they have undergone a preliminary operation; which conſiſts in rubbing or combing them, before they are taken off the ſkin, with a bruſh dipped in a ſolution of mercury in aquafortis (nitric acid). This liquor, acting only on one ſide of the ſubſtance of the hairs, changes their direction from a right line, and gives them that diſpoſition to felting which wool naturally poſſeſſes.

When the hairs are not intended to enter into the body of the maſs, but are only to be employed in making a ſort of external coating, ſuch as is ſometimes given to the outer ſurface of hats, the operation juſt mentioned need not be performed; but the felt on which they are to be fixed being finiſhed; the hair is uniformly ſpread upon the ſurface to which the coating is to be applied; and, being covered with a cloth, it is preſſed with the hands, and agitated for a certain time. By theſe means, the hairs introduce themſelves, by the root, a certain depth into the felt, and are there fixed by their *lamellæ* in ſuch a manner as not to be eaſily extracted. A particular direction is afterwards given to them by means of a bruſh, and they are made to keep this direction by having a hot iron paſſed over them. If the agitation were continued for a longer time, theſe hairs, not having their ſtraightneſs deſtroyed by the operation before deſcribed, would paſs entirely through the felt, going out at the oppoſite ſurface, as each hair follows exactly the direction it acquired at the beginning.

It is owing to the very ſame circumſtances which make wool and hair capable of felting, that woollen cloth is thickened by fulling. See Fulling in this Supplement.

FERGUSSON (Robert), who at an early period of life obtained a conſiderable degree of celebrity as a Scottiſh poet, was born at Edinburgh on the 5th of September 1750, according to a manuſcript account of him with which we have been favoured by a relation. In the biographical ſketch prefixed to the Perth edition of his poems he is ſaid to have been born in 1751.

His father William Ferguſſon poſſeſſed, as well as himſelf, ſome talents for poetry; but, marrying early, and being wiſer than his ſon, he abandoned the muſes for trade, and was employed in different mercantile houſes, firſt in Aberdeen and afterwards in Edinburgh. At the time of his death he was an accountant in the Britiſh Linen Hall; but never acquired any thing like opulence.

During the years of infancy and childhood, the conſtitution of our poet was ſo weak, that little hopes were entertained of his arriving at manhood. By the care, however, and attention of his parents, he gradually acquired ſtrength, and at the age of ſix was put to an Engliſh ſchool, where his proficiency in reading and reciting was uncommonly great. At the age of ſeven he was ſent to the high ſchool of Edinburgh, where he continued four years, and with very little labour made a rapid progreſs in the knowledge of the Latin tongue; but for ſome reaſon or other he was removed from the high ſchool to the grammar ſchool of Dundee, whence, after two years, he was ſent to the univerſity of St Andrew's. A gentleman of the name of Ferguſſon had left burſaries in that univerſity for the education of two boys of the ſame name; and Mr William Ferguſſon having with difficulty obtained one of them for his ſon, was induced to educate him at St Andrew's in preference to Edinburgh.

Though at no period of his life a ſevere ſtudent, our poet's attainments in ſcience were ſuch as to keep alive in the univerſity the hopes which had been formed of him at ſchool; and he was confeſſedly the firſt mathematician of his ſtanding. On this account we are told that he became the favourite of Dr Wilkie, who was then profeſſor of natural philoſophy in the univerſity of St Andrew's; but it is not improbable that the Doctor valued him as much for his poetical genius as for his ſkill in geometry; for Wilkie was a poet himſelf, and Mr Ferguſſon had already written ſeveral ſmall poems which attracted conſiderable notice, as well from the profeſſors as from his fellow-ſtudents. But whatever was the bond of union, Dr Wilkie patroniſed the youthful poet; and the poet ſhewed afterwards that he was not ungrateful. Upon the Doctor's death, he publiſhed, in the Scottiſh dialect, a beautiful eclogue to his memory, in which the peculiar merits of that eccentric genius are appreciated with great judgment. See WILKIE, in this Supplement.

During the laſt winter that he reſided in St Andrew's, our poet had collected materials for a tragedy on the death of Sir William Wallace, and had even completed two acts of the play; but having ſeen a ſimilar work on the ſame ſubject, he abandoned his deſign; "becauſe (ſaid he to a friend) whatever I publiſh ſhall be original, and this tragedy might be conſidered as a copy."

Having finiſhed his ſtudies at the univerſity, he returned to Edinburgh without reſolving on any permanent employment. His father had deſigned him for the church; but he was now dead, and our author turned a deaf ear to the intreaties of his mother, and of every other friend who endeavoured to perſuade him to fulfil his father's intention. He was then adviſed to ſtudy phyſic; but he declined it, becauſe, he ſaid, that, when reading the deſcription of diſeaſes, he fancied that he felt the ſymptoms of them all in himſelf. To the law, however, he could not ſtart the ſame objection; and he began to ſtudy it, but made no progreſs. At this his relation and the editor of his poems expreſs no ſurpriſe; for, according to them, it was a ſtudy the moſt improper for him, as it could not be expected that a genius ſo lively would ſubmit to the drudgery of that dry and ſedentary profeſſion.

That the law was a very improper profeſſion for a man of his narrow fortune is indeed true; but we truſt that his two biographers will not conſider us as intending any offence to them, if we embrace the preſent opportunity of expoſing the folly of a very common remark, that a lively genius cannot ſubmit to what is abſurdly called a dry ſtudy. We might inſtance different lawyers at our own bar, who, with great poetical talents in their youth, have riſen to the ſummit of their profeſſion; but to avoid perſonal diſtinctions at home, we ſhall take our examples from England. The genius of the late Earl of Mansfield was at leaſt as lively as that of Mr Ferguſſon, and if he had pleaſed he could have been equally a poet; yet he ſubmitted to the drudgery of ſtudying a law ſtill drier than that of Scotland. To the fine taſte of Atterbury biſhop of Rocheſter, and to his claſſical compoſitions both in proſe and verſe, no man is a ſtranger who is at all converſant in Engliſh literature: yet that elegant ſcholar and poet, after he had riſen to the dignity of Dean of Carliſle, ſubmitted to the drudgery of ſtudying, through the medium of barbarous Latin, the eccleſiaſtical law of England from the earlieſt ages; and declared, that by dint of perſeverance he came in time to reliſh it as much as the ſtudy of Homer and Virgil Whatever be thought of Milton's political principles, no man can read his controverſial writings, and entertain a doubt but that he could have ſubmitted to the drudgery of ſtudying the law.

The truth is, and it is a truth of great importance, that a man of real vigour of mind may bring himſelf to delight in any kind of ſtudy which is uſeful and honourable. Such men were Lord Mansfield, the Biſhop of Rocheſter, and Milton; but, whether through ſome radical defect in his nervous ſyſtem, or in conſequence of early diſſipation, Mr Ferguſſon, with many eſtimable qualities, was ſo utterly deſtitute of this mental vigour, that rather than ſubmit to what his friends call drudgery, he ſeems to have looked with a wiſhful eye to ſome ſinecure place.

With this view he paid a viſit to an uncle who lived near Aberdeen, a man of great learning and in opulent circumſtances, in hopes that, by his intereſt, he might be ſettled in a poſt ſuitable to his merit: But how deluſive were his hopes! His uncle indeed received him with every mark of affection; but his fondneſs gradually cooled, and at the end of ſix months he ordered him abruptly to leave his houſe, without having endeavoured to procure for him any ſettlement.

To a mind like Ferguſſon's, feelingly alive, ſuch treatment from ſo near a relation, to whom he had always behaved with becoming reſpect, muſt have been dreadfully galling. Stung with indignation, he returned to his mother's at Edinburgh; and as ſoon as he recovered from a ſevere illneſs, brought upon him by diſappointment and the fatigue of his journey, he compoſed two elegies; one on "The Decay of Friendſhip," and the other "Againſt Repining at Fortune," both occaſioned by his adventure in the North. How much he felt the daſhing of his hopes, is apparent from the following pathetic lines in the Decay of Friendſhip:

But,

But, ah! theſe youthful ſportive hours are fled,
  Theſe ſcenes of jocund mirth are now no more;
No healing ſlumbers 'tend my humble bed,
  No friends condole the ſorrows of the poor.

And what avail the thoughts of former joy?
  What comfort bring they in the adverſe hour?
Can they the canker-worm of Care deſtroy,
  Or brighten Fortune's diſcontented lour?

So deſtitute was he at this period, that he ſubmitted to copy papers in the commiſſary clerk's office, we believe at ſo much the ſheet; but not liking the employment, and quarrelling with the commiſſary clerk-depute, he ſoon left the office in diſguſt.

Hitherto he had lived rather in obſcurity; and happy had it been for him if in that obſcurity he had been ſuffered to remain; happy had it been for him, had his converſation been leſs faſcinating, and his company leſs courted by the frolic and the gay. Poſſeſſing an inexhauſtible fund of wit, the beſt good nature, much modeſty, and great goodneſs of heart, he was viewed with affection by all to whom he was known; but his powers of ſong, and almoſt unrivalled talents for mimickry, led him oftener into the company of thoſe who wiſhed for him merely to enliven a ſocial hour, than of ſuch as by their virtue were inclined, and by their influence were able, to procure him a competent ſettlement for life. The conſequence of this was great laxity of manners. His moral principles indeed were never corrupted, nor, as we have reaſon to believe, his faith in revelation ſhaken; but there is no doubt but that, courted as he was by the ſyren voice of pleaſure, he yielded to many temptations, and in the hours of ebriety committed actions which, in his cooler moments, he reflected on with abhorrence.

His conſcience was indeed frequently rouſed. Being on a viſit to a friend at Haddington, and ſauntering one day near the churchyard, he was accoſted by a clergyman, who ſeemed to be no ſtranger to the kind of life which he led. This judicious divine contrived to draw his attention to the ſhortneſs of time, the length of eternity, death and judgment, and the awful ſtate that awaits the wicked in an unſeen world; and the converſation made a deep impreſſion on his mind. It ſeemed, however, to be effaced from his memory by the diſſipation of Edinburgh, till it was recalled with double effect by the following accident:

In the room adjoining to that in which he ſlept was a ſtarling, which being ſeized one night by a cat that had found its way down the chimney, awaked Mr Ferguſſon by the moſt alarming ſcreams. Having learned the cauſe of the alarm, he began ſeriouſly to reflect how often he, an immortal and accountable being, had in the hour of intemperance ſet death at defiance, though it was thus terrible in reality even to an unaccountable and ſinleſs creature. This brought to his recollection the converſation of the clergyman, which, aided by the ſolemnity of midnight, wrought his mind up to a pitch of remorſe that almoſt bordered on frantic deſpair. Sleep now forſook his eyelids; and he roſe in the morning, not as he had formerly done, to mix again with the ſocial and the gay, but to be a recluſe from ſociety, and to allow the remembrance of his paſt follies to prey upon his vitals. All his vivacity now forſook him; thoſe lips which were formed to give delight, were cloſed as by the hand of death; and "on his countenance ſat horror plum'd."

From this ſtate of gloomy deſpondency, however, he began gradually to recover; and, except that a ſettled melancholy was viſible in his countenance, his health was completely reſtored, when one evening he fell and cut his head ſo dreadfully, that from the loſs of blood he became delirious. In this deplorable ſtate he continued for ſeveral months, till, being quite exhauſted by want of ſleep and conſtant ſpeaking, he expired on the 16th of October 1774. He was interred in the Canongate churchyard, where his friends erected a monument to his memory, which has been ſince removed to make way for a larger and more elegant monument by his enthuſiaſtic admirer the late poet Burns.

Thus died Robert Ferguſſon, a young man of the brighteſt genius and of the beſt heart, who, had he joined prudence to his uncommon talents, muſt have riſen to great eminence in the republic of letters; but, as a late juvenile poet has obſerved of him——

Complete alike in head and heart,
But wanting in the prudent part,
He prov'd a poet's lot.

Of his poems no general character can be given. The ſubjects of them are ſometimes uncommon and generally local or temporary. They are of courſe very unequal. But ſuch of them as are in the Scottiſh dialect have been univerſally admired by his countrymen; and when it is conſidered that they were compoſed amidſt a round of diſſipation, they will be allowed to furniſh complete evidence of his genius and his taſte.

FERMAT (Peter), who was counſellor of the parliament of Toulouſe in France, flouriſhed in the 17th century, and died in 1663. He was a man of great talents, and a very general ſcholar; but being contemporary and intimately connected with Des Cartes, Merſenne, Torricelli, and Huygens, he was naturally led to devote much of his time to the mathematical ſciences. He was (ſays Dr Hutton) a firſt rate mathematician, and poſſeſſed the fineſt taſte for pure and genuine geometry, which he contributed greatly to improve, as well as algebra.

Fermat was author of, 1. A Method for the Quadrature of all ſorts of Parabolas.—2. Another on Maximums and Minimums: which ſerves not only for the determination of plane and ſolid problems, but alſo for drawing tangents to curve lines, finding the centres of gravity in ſolids, and the reſolution of queſtions concerning numbers: in ſhort, a method very ſimilar to the fluxions of Newton.—3. An Introduction to Geometric Loci, plane and ſolid.—4. A Treatiſe on Spherical Tangencies: where he demonſtrates in the ſolids the ſame things as Vieta demonſtrated in planes.—5. A Reſtoration of Apollonius's two Books on Plane Loci.—6. A General Method for the dimenſion of Curve Lines. Beſides a number of other ſmaller pieces, and many letters to learned men; ſeveral of which are to be found in his *Opera Varia Mathematica*, printed at Toulouſe, in folio, 1679.

FERMENTATION is a chemical proceſs which has been already conſidered in the *Encyclopædia*, and will be again reſumed in this *Supplement* under the title *Animal and Vegetable Substances*. In this place we mean nothing more than to give ſuch directions, principally

cipally from Mr Richardſon of Hull, for the proper fermentation of malt liquors as have not been fully detailed in the article BREWING (*Encycl.*).

This author controverts, we do not think very ſucceſsfully, the concluſions drawn by Mr Henry from the experiments, of which the reader will find an account in the article FERMENTATION (*Encycl*); but it is not his theory with which we are at preſent concerned, but his practice as that of an experienced and enlightened brewer. Having treated of *Worts*, and the proper method of boiling them, for which ſee WORT in this *Supplement*, and having given an hiſtorical view of the proceſs of fermentation, of which a pretty accurate abridgement is inſerted in the articles BREWING and FERMENTATION (*Encycl.*), he proceeds thus:

" The agency of air, in the buſineſs of fermentation, is very powerful; but as all fermentable ſubjects have an abundant ſupply, we are rather to provide for the egreſs of their own, than to ſuffer the admiſſion of the external air, by which a great number of the fine, volatile, oleaginous parts of the ſubject would be carried off, and a proportionate injury in flavour and ſpirituoſity ſuſtained. Hence ſuch a covering ſhould be provided for the gyle-tun as would barely allow the eſcape of the common air produced by the operation; whilſt the *gas*, or fixed air, from its greater denſity, reſting upon the ſurface of the beer the whole depth of the curb, prevents the action of the external air, and conſequently the eſcape of thoſe fine and valuable parts juſt mentioned.

" But towards the conluſion of vinous fermentation, this aerial covering begins to loſe its efficacy; which points out the neceſſity of then getting the beer into caſks as ſoon as poſſible, that the conſequences may be prevented, of expoſing ſo large a ſurface, liable to ſo copious an evaporation. Amongſt theſe, a loſs of ſpirituoſity is not the leaſt; for this evaporation is more and more ſpirituous, as the action approaches the completion of vinous fermentation; and that once obtained, the loſs becomes ſtill more conſiderable, if ſtill expoſed to the air; whence it might be termed the diſtillation of Nature, in which ſhe is ſo much ſuperior to art, that the ethereal ſpirit riſes pure and unmixed, whilſt the higheſt rectification of the ſtill produces at beſt but a compound of aqueous and ſpirituous parts.

" Nor is this entirely conjecture. Experience teaches us, that we cannot produce ſo ſtrong a beer in ſummer, *ceteris paribus*, as in winter; the reaſon is, not becauſe the action of fermentation does not realize ſo much ſpirit in warm weather, but becauſe the fermenting liquor, after the perfection of vinoſity, continues ſo long in a ſtate of rarefaction, that the ſpirituous parts are diſſipated in a much greater degree at that time than at any other, in a ſimilar ſtate of progreſſion. And this doctrine of natural diſtillation ſeems to account for that increaſe of ſtrength obtainable from long preſervation, in well cloſed caſks, and, more particularly ſo, in glaſs bottles; for Nature, in her efforts to bring about her grand purpoſe of reſolving every compound into its firſt principles, keeps up a perpetual internal ſtruggle, as well as an external evaporation; and if the latter be effectually prevented, the former muſt be productive of additional ſpirituoſity, ſo long as the action keeps within the pale of vinous fermentation.

" In order to maintain a due regulation of the fermenting power, and to anſwer the ſeveral purpoſes of the operation, a ſcrupulous attention to the degree of heat at which the action commences, and a particular regard to the quality and quantity of the ferment employed, are indiſpenſably neceſſary." The degree of heat muſt be aſcertained by the thermometer, and regulated by experience: the quantity of yeaſt can be aſcertained only by the intention of the artiſt.

FEZZAN is a kingdom in the anterior of Africa, placed in the vaſt wilderneſs as an iſland in the ocean. The following account of it was given to Mr Lucas the African traveller by an old ſhereef, a native of Fezzan; and that account was confirmed by the governor of Meſurata, who had himſelf viſited Fezzan, and who, having treated the traveller with great kindneſs, ought not to be ſuſpected of having wantonly deceived him.

According to this account, Fezzan is ſituated to the ſouth of Meſurata (ſee MESURATA in this *Suppl.*), and the traveller from the latter place to the former arrives in eight days at Wadan, where refreſhments are procured for the caravan. From thence in five hours they reach the deſart of Soudah, where no vegetable is ſeen to grow but the talk, a tree from which the lemon-coloured wood is taken which forms handles for tools. The paſſage of the deſart takes up ſome days, when the traveller finds a miſerable village, producing nothing but dates, brackiſh water, and Indian corn; from this village a day's journey conducts to the town of Sebbah, where are the remains of an ancient caſtle, and other venerable ruins, and in four days more he reaches Mourzouk, the capital of Fezzan.

This city is ſituated on the banks of a ſmall river, ſurrounded by a high wall for defence, and is diſtant from Meſurata 390 computed miles. Eaſtward of Mourzook is the town of Queela, in which are the remains of ancient buildings; the ſize of the ciſterns, and the conſtruction of the vaulted caves, exhibit inſtances of ancient ſplendour. South of which place is Jermah, diſtinguiſhed by numerous and majeſtic ruins, on which are many inſcriptions. Teſſouwa lies eaſtward, near which was a river which the ſhereef remembers, but is now overwhelmed in the moving ſands. N. E. from Mourzouk, diſtant about 120 miles, is the large town of Temmiſwa, where the caravans of pilgrims from Bornou and Nigritia, by way of Cairo to Mecca, provide their ſtores for the deſart.

In the town or province of Mendrah is a large quantity of *trona*, a ſpecies of foſſil alkali, that floats on the ſurface or ſettles on the banks of its ſpreading lakes, great quantity of which is ſent to Tripoli, and ſhipped for Turkey, Tunis, and Morocco; at the latter place it is uſed as an ingredient in the red dye of the leather. Mendrah is about 60 miles ſouth of Fezzan. The territory of Fezzan extends but little weſtward, being confined by barren mountains. The ſmaller towns of this kingdom are ſaid to be about one hundred; theſe towns are chiefly inhabited by huſbandmen and ſhepherds; in every town a market is regularly held; mutton and goat's fleſh are ſold by the quarter, uſually from thirty-two to forty grains of gold, or from four to five ſhillings Engliſh. The fleſh of camels is dearer, and divided into ſmaller parts.

The houſes are of clay, with flat roofs compoſed of branches of trees, on which earth is laid; this is ſufficient in a climate where it never rains. The heats in ſummer, from April to November, are intenſe, and the hot winds blow from the ſouth-eaſt, ſouth, and ſouth-weſt, with ſuch violence as to threaten ſuffocation; when it changes to the weſt or north-weſt a reviving freſhneſs enſues.

The dreſs of the inhabitants is like that of the Moors of Barbary, conſiſting of a large pair of trowſers, a ſhirt which hangs over the trowſers, a kind of waiſtcoat without ſleeves, and a jacket with tight ſleeves: over the jacket is a looſe robe which reaches below the knee, a girdle of crimſon, and a long cloth called a *barrakan* or *alhaicque*, like a highland plaid, is worn; ſtockings of leather, laced like half-boots, and ſlippers; on the head a red cap and turban; ſometimes over the whole they throw a long cloak with a hood, called a *burnooſe*. In ſummer they throw off all but the ſhirt and the cap.

The people bear very high degrees of heat, but any cold affects them ſenſibly. Their diſeaſes are chiefly of the inflammatory and putrid kind; the ſmall pox is common. Their old women are their principal phyſicians. For pains in the head they cup and bleed; for thoſe in the limbs, they bathe in the hot lakes. They have a multitude of noxious and loathſome animals; the air is crowded with moſquitos, and their perſons are over-run with the vermin which affect the beggars of Europe.

In their perſons they incline to the negro, of a deep ſwarthy complexion, with curly black hair; they are tall, but indolent, inactive, and weak. In their common intercourſe, diſtinction of rank ſeems to be forgotten; rich and poor, maſter and man, converſe, eat, and drink together; they are, however, generous and hoſpitable.

An extenſive plain compoſes the kingdom of Fezzan: the ſoil is generally a light ſand, the ſprings are abundant, and few regions in Africa exhibit a richer vegetation. The land produces the talk, the white thorn, date trees, the olive and lime, apricot, pomegranate, and fig: Indian corn and barley are the favourite objects of cultivation; of wheat there is little raiſed. The tame animals are, the ſheep, cow, goat, and camel; and the wild are, the oſtrich, antelopes of various kinds, one of which is called the huadee, which when chaſed plunges with addreſs from a precipice, and lights on its hams.

The food of the lower claſs conſiſts of flour of Indian corn, ſeaſoned with oil and fruit; thoſe of ſuperior rank eat wheat bread and fleſh. Fezzan produces much ſalt; the water has in general a mineral taſte, but the favourite beverage is a liquor from the date tree, which acquires, when fermented, an intoxicating ſtrength. In religion they are rigid Mahomedans, but tolerant. Their government monarchical; their preſent king is deſcended from one of the ſhereefs of Taffilet, who about 400 years ſince obtained the crown. Till the preſent century the kingdom was independent, when the Baſhaw of Tripoli conquered and made it tributary; the reigning ſovereign has nearly thrown off this yoke. In Fezzan, the deſcendants of the prophet are highly privileged, their property and perſons are inviolable; they are exempt from certain puniſhments. This claſs are in general either princes or merchants.

The revenue is compoſed of a tax on towns and villages, a tax on every camel load of goods (except proviſions) which enters the capital, fines for offences, lands of perſons dying without heirs, and a tax on gardens and date trees. Gold duſt by weight is the chief medium of payment; but for convenience they are furniſhed with ſmall papers of gold duſt of different values, from two *xarbes* or one and a half upwards; for ſmaller articles corn or flour are uſed as a medium. One grain of gold is equal to 1$\frac{1}{5}$d. ſterling. The Fezzan grain is the ſame as in England.

The juſtice of the ſovereign is highly extolled; ſmall offences are puniſhed by the baſtinado, and the puniſhments increaſe to fine, impriſonment, and death. Truſting to their natural defence, their towns are without guard, and they have no ſtanding forces. The only war the ſhereef remembered was undertaken againſt a people inhabiting the mountains of Tibeſti, which is ſeparated from the people of Fezzan by a wide and ſandy deſart. Theſe people are wild and ſavage, and had plundered a caravan belonging to the king, who ſent an army of between 3 and 4000 men againſt and ſubdued them. The country of theſe people produces much ſenna. The vales of Tibeſti are ſaid to be fertile in corn and paſture for cattle, particularly camels. The people live in huts, and profeſs various religions, ſome the Mahomedan, others are attached to their ancient idolatry.

The people of Fezzan carry on a conſiderable trade with Tripoli, Bornou, Nigritia, &c. At the end of October, when the heats are abated, the caravans depart from Mourzouk in ſmall parties of ten or twelve, unleſs in time of war. They lay in proviſions of dates, meal, and mutton ſalted, dried in the ſun, and boiled in oil or fat. The merchants have agents in the chief towns, to whom they ſend the ſlaves they purchaſe.

The caravans to Tripoli carry the *trona*, ſenna, gold and ſlaves brought from the ſouthern countries; and in return bring back cutlery, woollen, ſilks, dollars, copper, and braſs.

That to Bornou carries braſs and copper, for the currency of the country, imperial dollars, and various manufactures; but of their own produce only a preparation of dates, and meal of Indian corn; and they take in return ſlaves, gold duſt, and civet.

To Caſhna, an empire in Nigritia, they carry cowries, braſs to make rings and bracelets, horſes, ſeveral kinds of manufactures, and the Gooroo nuts; and in return take gold duſt, ſlaves, cotton cloth, dyed goats ſkins, hides, ſenna, and civet, for the countries ſouth of the Niger, where alſo they convey ſabre blades and Dutch knives, coral, braſs beads, looking glaſſes, dollars, &c. and receive back gold duſt, ſlaves, cotton cloths, goat ſkins, Gooroo nuts, cowries, and ivory.

A caravan of pilgrims ſets out likewiſe in the autumn of every ſecond or third year from Mourzouk, the capital of Fezzan, to Mecca. They proceed to Temeſſa, over the mountain of Ziltan, and thence to Sibhul, a place ſubject to Tripoli; and thence nearly in a line with the Mediterranean ſea to Cairo, and thence to Mecca by the cuſtomary route.

As not one celeſtial obſervation has been taken to determine any latitude between Benin and Tripoli, all the poſitions are fixed by eſtimation, reckoning fifteen or ſixteen miles for a day's journey. Mr Rennell places

Mourzouk, the capital of Fezzan, in lat. 27°. 20′, or 260 miles from Maſurata.

FIGURATE NUMBERS are ſuch as do or may repreſent ſome geometrical figure, ſuch as a triangle, pentagon, or pyramid, &c. Theſe numbers are treated of at great length by Maclaurin in his Fluxions; Simſon in his Algebra; and Malcolm in his Arithmetic; but the following account of them by Dr Hutton is as perſpicuous as any that we have ſeen:

Figurate numbers are diſtinguiſhed into orders, according to their place in the ſcale of their generation, being all produced one from another, viz. by adding continually the terms of any one, the ſucceſſive ſums are the terms of the next order, beginning from the firſt order, which is that of equal units 1, 1, 1, 1, &c.; then the ſecond order conſiſts of the ſucceſſive ſums of thoſe of the firſt order, forming the arithmetical progreſſion 1, 2, 3, 4, &c.: thoſe of the third order are the ſucceſſive ſums of thoſe of the ſecond, and are the triangular numbers 1, 3, 6, 10, 15, &c; thoſe of the fourth order are the ſucceſſive ſums of thoſe of the third, and are the pyramidal numbers 1, 4, 10, 20, 35, &c.; and ſo on, as below:

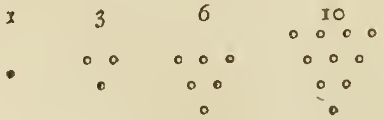
Order.	*Name.*	*Numbers,*				
1.	Equals,	1,	1,	1,	1,	1, &c.
2.	Arithmeticals,	1,	2,	3,	4,	5, &c.
3.	Triangulars,	1,	3,	6,	10,	15, &c.
4.	Pyramidals,	1,	4,	10,	20,	35, &c.
5.	2d Pyramidals,	1,	5,	15,	35,	70, &c.
6.	3d Pyramidals,	1,	6,	21,	56,	126, &c.
7.	4th Pyramidals,	1,	7,	28,	84,	210, &c.

The above are all conſidered as different ſorts of triangular numbers, being formed from an arithmetical progreſſion whoſe common difference is 1. But if that common difference be 2, the ſucceſſive ſums will be the ſeries of ſquare numbers: if it be 3, the ſeries will be pentagonal numbers, or pentagons; if it be 4, the ſeries will be hexagonal numbers, or hexagons; and ſo on. Thus:

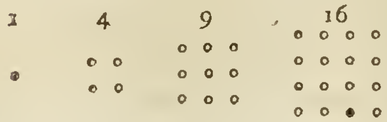
Arithmeticals.	*1ſt Sums,* or *Polygons.*	2d *Sums,* or 2d *Polygons.*
1, 2, 3, 4	Tri. 1, 3, 6, 10	1, 4, 10, 20
1, 3, 5, 7	Sqrs. 1, 4, 9, 16	1, 5, 14, 30
1, 4, 7, 10	Pent. 1, 5, 12, 22	1, 6, 18, 40
1, 5, 9, 13	Hex. 1, 6, 15, 28	1, 7, 22, 50
&c.		

And the reaſon of the names triangles, ſquares, pentagons, hexagons, &c. is, that thoſe numbers may be placed in the form of theſe regular figures or polygons, as here below:

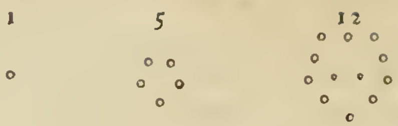
Triangles.



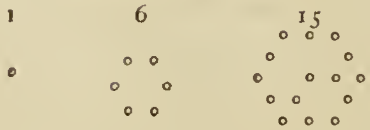
Squares.



Pentagons.



Hexagons.



But the figurate numbers of any order may alſo be found without computing thoſe of the preceding orders; which is done by taking the ſucceſſive products of as many of the terms of the arithmeticals 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the number which denominates the order of figurates required, and dividing thoſe products always by the firſt product. Thus the triangular numbers are found by dividing the products 1×2, 2×3, 3×4, 4×5, &c. each by the firſt product 1×2; the firſt pyramids by dividing the products $1 \times 2 \times 3$, $2 \times 3 \times 4$, $3 \times 4 \times 5$, &c. by the firſt $1 \times 2 \times 3$. And, in general, the figurate numbers of any order n, are found by ſubſtituting ſucceſſively 1, 2, 3, 4, 5, &c. inſtead of x in this general expreſſion $\frac{x \,.\, x+1 \,.\, x+2 \,.\, x+3 \,.\, \&c.}{1 \,.\, 2 \,.\, 3 \,.\, 4 \,.\, \&c.}$; where the factors in the numerator and denominator are ſuppoſed to be multiplied together, and to be continued till the number in each be leſs by 1 than that which expreſſes the order of the figurates required.

FILTER (See *Encycl.*) It is well known that veſſels made of a particular kind of porous ſtone are employed as filtering baſins for freeing water, intended to be drunk, from various kinds of impurity. In ſea voyages ſuch filtering baſins muſt be highly uſeful; and they are frequently found uſeful at land where no water can be had but from ſtagnant pools, or ſprings flowing through clay. The ſtone, however, of which they are made is not every where to be found; and therefore different perſons have endeavoured to employ the art of the potter to ſupply their place.

In the year 1790 a patent was granted to a female potter, for her invention of the following compoſition for this purpoſe; viz. four equal parts, out of nine equal parts, of tobacco-pipe clay; and five equal parts, out of nine equal parts, of coarſe ſea, river, drift, or pit ſand; theſe two materials, in the above proportions, are ſufficient for the purpoſe of making ſmall baſins, and other veſſels, to contain a quantity not exceeding one gallon of water, or other liquid. But the compoſition, when confined to theſe two materials, and in theſe proportions, often flies or cracks in the fire, if larger baſins, or other veſſels, are attempted to be made with it. She, therefore, in the ſecond inſtance, compoſes her filtering baſins of equal parts of tobacco-pipe clay and coarſe ſea, river, drift, or pit ſand; in the third inſtance, of three equal parts, out of nine equal parts, of tobacco-pipe clay; one equal part, out of nine equal parts, of Stourbridge clay, or clay from the ſurface of coal mines, or any other clay of the ſame quality; one equal part, out of nine equal parts, of Windſor, or other loam, of the ſame quality with Windſor loam ; and four equal parts, out of nine equal parts, of coarſe river, ſea, drift, or pit ſand. Or, in the fourth inſtance, of four equal parts, out of eight equal parts, of tobacco-pipe clay ; three equal parts, out of eight equal parts, of coarſe ſea, river, drift, or pit ſand ; and one equal part, out of eight equal parts, of that burnt ground clay of which crucibles are made.

If the lady who invented, or pretends to have invented, theſe baſins, have a right to her patent, far be it from us to wiſh our readers of any deſcription to incroach upon it ; but as the uſe of the materials of which her baſins are made was known to potters before ſhe was born, they may certainly compound theſe materials in proportions different from hers, without doing her any legal injury. As ſhe varies her own proportions ſo much, we think it probable that ſome proportion differing a little from them all, may anſwer the purpoſe of filtering veſſels equally well ; and it is almoſt needleſs to add, that with this precaution any potter may make ſuch veſſels, for which he would undoubtedly have a great demand.

A patent has likewiſe been granted to Mr Joſhua Collier of Southwark for a very ingenious contrivance for filtering and ſweetening water, oil, and all other liquids. Of this contrivance, which combines the application of machinery with the antiſeptic properties of charcoal (See CHEMISTRY n° 34. *Supplement*), we ſhall give a detailed account.

Fiſh-oil is one of the liquids which he had it particularly in view to free from all its impurities in ſmell, taſte, and colour ; and the chemical proceſs employed by him for this purpoſe, conſiſts in pouring a quantity of any ſpecies of fiſh-oil, or a mixture of different ſorts of fiſh-oil, into any convenient veſſel, which is to be heated to the temperature of 110 or 120 degrees of Fahrenheit's ſcale, and then adding of cauſtic mineral alkali, of the ſpecific gravity commonly deſcribed as 1.25, or of ſuch ſtrength that a phial containing 1000 grains of diſtilled water will contain 1250 grains of theſe lees, a quantity equal to four parts of the 100 by weight of the quantity of oil ; the mixture is then to be agitated, and left to ſtand a ſufficient time for the ſalts and ſediments to ſubſide ; it is then drawn off into another veſſel, containing a ſufficient quantity of freſh burnt charcoal, finely powdered, or any other ſubſtance poſſeſſing antiſeptic properties, in a powdered or divided ſtate, with an addition of a ſmall proportion of diluted ſulphuric acid, ſufficient only to decompoſe the ſmall quantity of ſaponaceous matter ſtill ſuſpended in the oil, which appears by the oil becoming clear at the ſurface : the contents of this veſſel are alſo agitated, and the coaly ſaline and aqueous particles left to ſubſide ; after which the oil is paſſed through proper ſtrainers, herein after deſcribed, and is thereby rendered perfectly tranſparent and fit for uſe.

The principle of the improved ſtrainers, or filtering machines, conſiſts in the means applied to combine hydroſtatic preſſure, which increaſes according to the perpendicular height of the fluid, with the mode of filtering *per aſcenſum*, thereby procuring the new and peculiar advantage that the fluid and its ſediment take oppoſite directions. A great advantage attending this invention is, that the dimenſions of the chamber in which the ſediment is received, may be varied, while the filtering ſurface remains the ſame. To adapt the machines not only to the purpoſe of families, work-houſes, hoſpitals, public charities, the navy, or the merchant ſervice, but alſo to all the purpoſes of oil-men, of diſtillers, of the laboratory, the brewery, &c. chambers of various capacities muſt be provided for the ſediment and precipitated matter. With reſpect to the oil-trade, the ſpace required is very great, eſpecially for ſpermaceti, or Braſil bottoms. In the various purpoſes of the laboratory, no limits can be fixed, but all dimenſions will be occaſionally required : in diſtilleries and breweries they may be ſmaller in proportion ; and in that deſigned for water and for domeſtic uſe, a very ſmall chamber will be ſufficient. When water is to be ſweetened, or freed from any putrid or noxious particles, it paſſes, in its way to the filtering chamber, through an iron-box, or cylinder, containing charcoal finely powdered, or any other antiſeptic ſubſtance inſoluble in water, the water being forced into it by hydroſtatic preſſure, through a tube of any ſufficient height. This box has two apertures to receive and deliver the fluid, and theſe are opened and cloſed by cocks, or ſcrews, or any other method uſed for ſuch purpoſes ; and being affixed to the machine by other ſcrews, may be eaſily detached from the ſame. Thus, whenever the charcoal begins to loſe its antiſeptic properties, the box is removed and heated till it is red hot ; by which means the foreign matter eſcapes through the ſmall apertures ; after which the box is cooled, and the charcoal becomes ſweet, pure, and equally fit for uſe as at firſt, though the proceſs be ever ſo often repeated.

Another part of the invention conſiſts in filtering machines in the form of ſtills, in which charcoal may be repeatedly burned after any fluid ſubſtances have paſſed through it, for the purpoſe of freeing them either from putrid or noxious particles, or of diſcharging their colouring matter ; which filtering ſtills are ſo contrived, that the fluid may paſs through in any quantity, without diſplacing the charcoal : the part of the fluid remaining interſperſed among the charcoal, may be driven over by heat, and be employed for many inferior purpoſes of the arts or manufactures. Laſtly, the heat may be raiſed ſo as to purify the charcoal, as has been before deſcribed in the machines for water. The flue of thoſe ſtills is ſo conſtructed that water may be employed to cool them without the loſs of time requiſite for their gradually parting with their heat to the ſurrounding atmoſphere, ſo as to be fit for a ſubſequent operation.

But it was not merely to the purifying of oils and various liquids that Mr Collier turned his attention. To his filtering apparatus are attached inſtruments for aſcertaining the comparative qualities of oils, which depend in part on the principle of their ſpecific gravities ; ſpermaceti oil, contraſted with other fiſh oils, being as 875 to 920. For this purpoſe, a glaſs veſſel of any convenient ſhape is made uſe of, furniſhed with a bubble alſo of glaſs, and a thermometer. If the oil is pure, this bubble ſinks, when the mercury riſes to a certain ſtandard, by the application of the hand, or any other heat to the veſſel containing the oil. If the ſpermaceti oil is impure, the bubble will ſtill float, though it is of the temperature required ; and the degree of impure, or foreign matter, will be ſhewn by the ſtate of the thermometer at which the bubble ſinks.

Filter.

To determine what tendency oils uſed for burning have to congeal in cold weather, a freezing mixture is put in a phial of thin glaſs, or any other convenient veſſel; into this a thermometer is immerſed, and a ſingle drop of the oil, under experiment, ſuffered to fall on the outſide of the veſſel, where it immediately congeals: as the cold produced by the mixture gradually ceaſes, it is eaſy to obſerve by the thermometer at what point of temperature the oil becomes fluid, and runs down the ſide of the glaſs.

Plate XXIII.

A ſhort deſcription of this apparatus will make its principles plain to every reader. A (fig. 1.) is the ciſtern into which the water or other liquor to be filtered is put. B B is a tube opening into the bottom of the ciſtern A, and bent along the bottom of the machine conveying the fluid into CCC the filtering chamber, which is covered with leather bound down round its circular rim, and through which leather the water is percolated. DD, The baſon riſing above the level of the chamber and receiving the filtered liquor. E, The ſpout by which it runs off into a pitcher or other veſſel. F, Another ſpout furniſhed with a cock to draw off the foul water from the chamber when neceſſary. GGG, The air tube, which begins above the level of the chamber, is covered with a button, which ſaves the leather from being cut, and has a ſmall lateral aperture for the air to be carried off. This pipe paſſes along the bottom and up the ſide, and riſing above the level of the water in the ciſtern, is there cloſed, except a ſmall lateral aperture through which the air eſcapes. H, A guard or rim with croſs bars put over the leather to keep it from being forced up by the water. It is faſtened down by means of two notches on oppoſite ſides of the guard, by which it locks into two ſtaples rivetted into the bottom of the baſon. I, The lid ſliding down to cover the water from duſt, and ſuſpended at pleaſure by means of KK, two ſprings on each tube for that purpoſe. LMNO, A cylindrical box containing charcoal, which is connected with the above by means of the tube P, and a continuation of the tube B. LM, The water tube B continued below the charcoal apparatus, ſo that the fluid may paſs through the ſame into the cylinder, from whence it enters the chambers at P, ſo as to be filtered through the leather as before deſcribed. RR, Collars which may be unſcrewed at pleaſure, ſo as to detach the charcoal apparatus whenever the charcoal requires to be purified by heat. SS, Two cocks to direct the fluid through the charcoal cylinder, or immediately into the filtering chamber.

Fig. 2. A, A tub or ciſtern containing the oil to be filtered, and ſupplying a tube of ſufficient height for the hydroſtatic preſſure to operate. BB, A main tube of wood, tin, leather, or cloth, to which any number of bags, of the ſize and ſhape of corn ſacks, or any CC, convenient ſize or ſhape may be connected. Theſe are bound to DDD, ſtraight double iron bars, furniſhed with a hinge at one end and a ſcrew at the other, by opening which the bags may be emptied. F, A trough underneath, made to receive the filtered oil from the receivers EEE.

Fig. 3. A, A funnel caſk or ciſtern, into which the fluid is put which paſſes down. B, A tube fitted into the ſame, through which it enters. C, An iron ſtill, or ſtill of any other ſubſtance capable of ſuſtaining heat, full of finely powdered and ſifted charcoal, through the head of which the fluid paſſes into any receiver. D, A fire-place of any conſtruction to drive over the fluid remaining interſperſed among the charcoal, and alſo to purify the charcoal by an increaſe of temperature when required. E, A cock to let water into the flues to cool the apparatus for a ſubſequent operation.

Fire.

Fig. 4. The trial glaſs with its thermometer.

FIRE. See that article *Encycl.* and Caloric and Combustion, *Chemistry-Index* in this *Suppl.*

* *Extinction of Fire* is ſometimes a matter of ſo much conſequence, that every thing which promiſes to be effectual for that purpoſe is worthy of attention. In the nineteenth number of Mr Nicholſon's Journal of Philoſophy, Chemiſtry, and the Arts, we have the following compoſition for extinguiſhing fire, invented by M. Von Aken.

Burnt alum - - - - -	pounds	30
Green vitriol powdered - - -		40
Cinabreſe, or red ochre in powder -		20
Potter's clay, or other clay, alſo powdered		200
Water - - - - - - -		630

With 40 meaſures of this mixture an artificial fire was extinguiſhed under the direction of the inventor by three perſons, which would have required the labour of 20 men and 1500 meaſures of common water. Sig. Fabbroni was commiſſioned to examine the value of this invention, and found in his comparative trials with engines of equal power, worked by the ſame number of men, that the mixture extinguiſhed the materials in combuſtion in one ſixth part leſs time, and three eighths leſs of fluid than when common water was uſed. He obſerved, as might indeed have been imagined from the nature of the material, that the flame diſappeared wherever the mixture fell, and that the ſaline, metallic, and earthy matters, formed an impenetrable lute round the hot combuſtible matter, which prevented the acceſs of the air, and conſequently the renewal of the deſtructive proceſs.

This recipe, Mr Nicholſon informs us, is taken from N° 85. of *Giornale Letterario di Napoli*, in which it was inſerted in the form of a letter from Sig. Fabbroni to Sig. D. Luigi Targioni of Naples; and the author of the letter eſtimates the price of the compoſition at about one halfpenny per pound.

The reaſon aſſigned by Mr Nicholſon for giving this abridged account a place in his valuable work, will be admitted by him and the public as a ſufficient reaſon for our adopting it into our's. It is, that ſuch inventions are worthy of the attention of philoſophers and economiſts, even though in the firſt applications they may prove leſs advantageous than their inventors may be diſpoſed to think. It is ſcarcely probable that this practice in the large way, with an engine throwing upwards of 200 gallons (value about L. 3, 10s.) each minute, would be thought of or adopted, or that a ſufficient ſtore of the materials would be kept in readineſs; ſince at this rate the expenditure for an hour would demand a proviſion to the amount of L. 210 ſterling. But in country places the proceſs, or ſome variation of it, might be applied with ſufficient profit in the reſult; more eſpecially if it be conſidered that common ſalt or alum, or ſuch ſaline matter as can be had and mixed with the water, together with clay, chalk, or lime, ochreous earth or common mud, or even theſe laſt without any ſalt, may anſwer the purpoſe of the

the lute with more or leſs effect, and extinguiſh an accidental fire with much greater ſpeed and certainty than clear water would do.

Fire-Balls are meteors, of which ſome account has been given in the *Encyclopædia*, as well as of various hypotheſes which have been framed reſpecting their nature and their origin. Since that article was publiſhed, a new and very ſingular hypotheſis has been framed by Profeſſor Chladni of Wittenberg, who maintains it by arguments, which, however fanciful, are yet worthy of the reader's notice *.

He ſuppoſes that fire-balls, inſtead of being collections of the electrical fluid floating in the higheſt regions of our atmoſphere, are maſſes of very denſe matter formed in far diſtant parts of ſpace, and ſubjected to ſimilar laws with the planets and comets. He endeavours to prove that their component parts muſt be denſe and heavy; becauſe their courſe ſhews, in ſo apparent a manner, the effects of gravity; and becauſe their maſs, though it diſtends to a monſtrous ſize, retains ſufficient conſiſtency and weight to continue an exceedingly rapid movement through a very large ſpace, without being decompoſed or diſſolved, notwithſtanding the reſiſtance of the atmoſphere. It ſeems to him probable, that this ſubſtance is by the effect of fire reduced to a tough fluid condition; becauſe its form appears ſometimes round and ſometimes elongated, and as its extending till it burſts, as well as the burſting itſelf, allows us to ſuppoſe a previous capability of extenſion by elaſtic fluidity. At any rate, it appears to be certain, that ſuch denſe matter at ſo great a height is not collected from particles to be found in our atmoſphere, or can be thrown together into large maſſes by any power with which we are acquainted; that no power with which we are acquainted is able to give to ſuch bodies ſo rapid a projectile force in a direction almoſt parallel to the horizon; that the matter does not riſe upwards from the earth, but exiſts previouſly in the celeſtial regions, and muſt have been conveyed thence to our earth. In the opinion of Dr Chladni, the following is the only theory of this phenomenon that agrees with all the accounts hitherto given, which is not contrary to nature in any other reſpect, and which beſides ſeems to be confirmed by various maſſes found on the ſpot where fire-balls fell.

As earthy, metallic, and other particles form the principal component parts of our planets, among which iron is the prevailing part, other planetary bodies may therefore conſiſt of ſimilar, or perhaps the ſame component parts, though combined and modified in a very different manner. There may alſo be denſe matters accumulated in ſmaller maſſes, without being in immediate connection with the larger planetary bodies diſperſed throughout infinite ſpace; and which, being impelled either by ſome projecting power or attraction, continue to move until they approach the earth or ſome other body, when, being overcome by its attractive force, they immediately fall down. By their exceedingly great velocity, ſtill increaſed by the attraction of the earth and the violent friction in the atmoſphere, a ſtrong electricity and heat muſt neceſſarily be excited; by which means they are reduced to a flaming and melted condition, and great quantities of vapour and different kinds of gaſes are thus diſengaged, which diſtend the liquid maſs to a monſtrous ſize, till, by a ſtill farther expanſion of theſe elaſtic fluids, it muſt at length burſt. Dr Chladni thinks alſo, that the greater part of the *ſhooting ſtars*, as they are called, are nothing elſe than fire-balls; which differ only from the latter in this, that their peculiarly great velocity carries them paſt the earth at a greater diſtance, ſo that they are not ſo ſtrongly attracted by it as to fall down; and therefore, in their paſſage through the high regions of the atmoſphere, occaſion only a tranſient electric flaſh, or actually take fire for a moment, and are again ſpeedily extinguiſhed, when they get to ſuch a diſtance from the earth that the air becomes too much rarefied for the exiſtence of fire.

The grounds on which Dr Chladni ſupports this opinion are various relations, well authenticated, of the motions of thoſe meteors, and the phenomena which accompany their burſting. Beſides thoſe mentioned in the *Encyclopædia*, he lays a particular ſtreſs on the account which he received from *M. Baudin*, Profeſſor of philoſophy at Pau, of a remarkable fiery meteor ſeen in Gaſcony on the 24th of July 1790. On the evening of that day M. Baudin was in the court of the caſtle of Marmes with a friend, the atmoſphere being perfectly clear, when they ſuddenly found themſelves ſurrounded by a whitiſh light, which obſcured that of the full moon, then ſhining with great luſtre. On looking upwards, they obſerved, almoſt in their zenith, a fire-ball of a larger diameter than the moon, and with a tail equal in length to five or ſix times the diameter of the body. The ball and the tail were of a pale white colour, except the point of the latter, which was almoſt as red as blood. The direction of this meteor was from ſouth to north.

“Scarcely (ſays M. Baudin) had we looked at it for two ſeconds when it divided itſelf into ſeveral portions of conſiderable ſize, which we ſaw fall in different directions, and almoſt with the ſame appearance as the burſting of a bomb. All theſe different fragments became extinguiſhed in the air; and ſome of them, in falling, aſſumed that blood-red colour which I had obſerved in the point of the tail. It is not improbable that all the reſt may have aſſumed the ſame colour; but I remarked only thoſe which proceeded in a direction towards Mormes, and which were particularly expoſed to my view.

“About two minutes and a half, or three minutes after, we heard a dreadful clap of thunder, or rather exploſion, as if ſeveral large pieces of ordnance had been fired off together. The concuſſion of the atmoſphere by this ſhock was ſo great, that we all thought an earthquake had taken place. The windows ſhook in their frames, and ſome of them, which probably were laid to and not cloſely ſhut, were thrown open. We were informed next day, that in ſome of the houſes at Houga, a ſmall town about half a mile diſtant from Mormes, the kitchen utenſils were thrown from the ſhelves; ſo that the people concluded there had been an earthquake. But as no movement was obſerved in the ground below our feet, I am inclined to think that all theſe effects were produced merely by the violent concuſſion of the atmoſphere.

“We proceeded into the garden while the noiſe ſtill continued, and appeared to be in a perpendicular direction above us. Some time after, when it had ceaſed, we heard a hollow noiſe, which ſeemed to roll along

the

---

* *Phil.Mag* os 5 and 7.

the chain of the Pyrenees in echoes, for the diſtance of 15 miles. It continued about four minutes, becoming gradually more remote, and always weaker; and at the ſame time we perceived a ſtrong ſmell of ſulphur.

"While we were endeavouring to point out to ſome perſons preſent the place where the meteor had divided itſelf, we obſerved a ſmall whitiſh cloud, which aroſe perhaps from the vapour of it, and which concealed from us the three ſtars of the Great Bear, lying in the middle of thoſe forming the ſemicircle. With ſome difficulty, however, we could at laſt diſtinguiſh theſe ſtars again behind the thin cloud. There aroſe, at the ſame time, a freſh gentle breeze.

"From the time that elapſed between the burſting of the ball and the exploſion which followed, I was inclined to think that the meteor was at the height of at leaſt ſeven or eight miles, and that it fell four miles to the north of Mormes. The latter part of my conjecture was ſoon confirmed by an account which we received, that a great many ſtones had fallen from the atmoſphere at Juliac, and in the neighbourhood of Barbotan. One of theſe places lies at the diſtance of about four miles to the north of Mormes, and the other at about the diſtance of five to the north-north-weſt."

M. de Carrits Barbotan, the friend who was with the Profeſſor in the court and garden of Mormes when the meteor firſt attracted their attention, was at Juliac two days afterwards, and confirmed to him the truth of this circumſtance. It appeared, likewiſe, from the account of ſeveral intelligent perſons, highly worthy of credit, that the meteor burſt at a little diſtance from Juliac, and that the ſtones which fell were found lying in a ſpace almoſt circular, about two miles in diameter. They were of various ſizes. Some were *ſeen to fall*, which, when found, weighed 18 or 20 pounds, and which had ſunk into the earth from two to three feet. M. de C. Barbaton tranſmitted one weighing 18 pounds to the Academy of Sciences at Paris; and M. Baudin was told, that ſome were found which weighed even 50 pounds. He examined a ſmall one, and found it very heavy in proportion to its ſize: it was black on the outſide; of a greyiſh colour in the inſide, and interſperſed with a number of ſmall ſhining metallic particles. On ſtriking it with a piece of ſteel, it produced a few ſmall dark red ſparks, not very lively. A mineralogiſt, to whom a like piece of ſtone from the ſame meteor was ſhewn at Paris, deſcribed it as a kind of grey ſlag mixed with calcareous ſpar, the ſurface of which exhibited vitrified blackiſh calx of iron. The Profeſſor was told alſo, that ſome ſtones were found totally vitrified.

Such (ſays Dr Chladni) is the account given by Baudin of this meteor; the phenomena of which he endeavours to explain from accumulations in the upper parts of the atmoſphere.

According to all the obſervations hitherto made with any accuracy on fire-balls, the height at which they were firſt perceived was always very conſiderable, and by comparing the angles under which they were ſeen from different points, often 19 German miles, and even more; their velocity, for the moſt part, ſeveral miles in a ſecond; and their ſize always very great, often a quarter of a mile, and even more, in diameter. They were all ſeen to fall moſtly in an oblique direction; not one of them ever proceeded upwards. All of them have appeared under the form of a globular maſs, ſometimes a little extended in length, and highly luminous; having behind it a tail, which, according to every appearance, was compoſed of flames and ſmoke. All of them burſt after they were ſeen to move through a large ſpace, ſometimes over ſeveral diſtricts, with an exploſion which ſhook every thing around. In every inſtance where there has been an opportunity of obſerving the fragments that fell after they burſt, and which ſometimes have ſunk to the depth of ſeveral feet into the earth, they were found to conſiſt of ſcorious maſſes, which contained iron in a metallic or calcined ſtate, pure, or elſe mixed with different kinds of earth and ſulphur. All the ancient and modern accounts, written partly by naturaliſts and partly by others, are ſo eſſentially ſimilar, that the one ſeems to be only a repetition of the other. This conformity in accounts, the authors of which knew nothing of thoſe given by others, and who could have no intereſt in fabricating ſimilar tales, can ſcarcely have ariſen from accident or fiction, and gives to the related facts, however inexplicable many of them may ſeem, every degree of credibility.

In the third volume of Pallas's Travels, we have an account of a maſs of iron diſcovered by him in Siberia, which Dr Chladni conſiders as having been undoubtedly a fire-ball, or the fragment of a fire-ball. This problematical maſs was found between Kraſnojarſk and Abekanſk in the high ſlate mountains, quite open and uncovered. It weighed 1600 pounds; had a very irregular and ſomewhat compreſſed figure like a rough granite; was covered externally with a ferruginous kind of cruſt; and the inſide conſiſted of malleable iron, brittle when heated, porous like a large ſea ſponge, and having its interſtices filled with a brittle hard vitrified ſubſtance of an amber yellow colour. This texture and the vitrified ſubſtance appeared uniformly throughout the whole maſs, and without any traces of ſlag or artificial fire.

Dr Chladni ſhews, with a great deal of ingenuity, that this maſs neither originated by the wet method, nor could have been produced by art, the burning of a foreſt, by lightning, or by a volcanic eruption. It appears to him, therefore, in the higheſt degree probable, that it is of the ſame nature with fire-balls, or, as they have ſometimes been called, *flying dragons*. The Tartars, as we are informed by Pallas, conſidered this maſs as a ſacred relic which had dropped down from heaven; and this circumſtance Dr Chladni conſiders as no ſlight confirmation of his opinion, which he farther ſupports by the following reaſonings:

"1. As fire-balls conſiſt of denſe and heavy ſubſtances, which, by their exceedingly quick movement, and the friction thence excited by the atmoſphere, become electric, are reduced to a ſtate of ignition, and melted by the heat, ſo that they extend to a great ſize, and burſt; it thence follows, that in places where fragments, produced by the burſting of a fire-ball, have been found, ſubſtances endowed with all theſe properties muſt alſo have been found. Iron, however, the principal component part of all the maſſes hitherto found (and he ſpeaks of many beſides that of Pallas), poſſeſſes all theſe properties in a very eminent degree. The weight and toughneſs of the principal component parts of fire-balls, which muſt be very conſiderable, ſince, with the greateſt poſſible diſtention, they retain conſiſtence enough to proceed with the utmoſt velocity through ſuch an immenſe ſpace without decompoſition of their maſs, and without their progreſs being obſtructed by the reſiſtance of the air, agree perfectly well with melted iron; their dazzling white light has by many obſervers been compared to that of melted iron ; iron alſo exhibits the ſame appearances of flaming, ſmoking, and throwing out ſparks, and all theſe phenomena are moſt beautiful when they take place in vital air. Of the extenſion by elaſtic fluids expanded by the heat, and of the contraction which follows from cold, traces may be diſcovered in the internal ſpongy nature of the iron maſſes which have been found, and in the globular depreſſions of the exterior hard cruſt ; the latter of which gives us reaſon to ſuppoſe, that in theſe places there have been air-bubbles, which, on cooling, ſunk down. The mixture of ſulphur found in various maſſes, agrees alſo exceedingly well with the phenomena of fire-balls, and eſpecially with the great inflammability of ſulphur in very thin impure air ; for it is well known that ſulphur in an air-pump will take fire in air in which few other bodies could do the ſame. In regard to thoſe maſſes in which no ſulphur was found, this may have ariſen from the ſulphur eſcaping in vapour, ſince ſome time after the appearance of fire-balls a ſtrong ſmell of ſulphur has been perceived. The brittleneſs of the Siberian iron maſs when heated, may ariſe from ſome ſmall remains of ſulphur, which may perhaps be the cauſe of the facility with which fragments of this maſs, as well as of another found at Aix-la-Chapelle, could be roaſted.

“ 2. The whole texture of the maſſes betrayed evident ſigns of fuſion. This, however, cannot have been occaſioned by any common, natural, or artificial fire; and particularly for this reaſon, becauſe iron ſo malleable is not fuſible in ſuch fire, and when it is fuſed with the addition of inflammable matters, loſes its malleability, and becomes like common raw iron. The vitrified ſubſtance in the Siberian maſs is equally incapable of being fuſed in a common fire. The fire, then, muſt have been much ſtronger than that produced by the common, natural, and artificial means ; or the fuſion muſt have been effected by the force of exceedingly ſtrong electricity ; or perhaps both cauſes may have been combined together.

“ 3. It is totally incomprehenſible how, on the high ſlate mountains, where the Siberian maſs was found, at a conſiderable diſtance from the iron mines ; in the chalky ſoil of the extenſive plains of America, where for a hundred miles around there are no iron mines, and not even ſo much as a ſtone to be found ; and at Aix-la-Chapelle, where, as far as the author knows, there are no iron works—ſo many ferruginous particles could be collected in a ſmall ſpace as would be neceſſary to form maſſes of 1600, 15,000, and 17,000, up to 33,600 pounds. This circumſtance ſhews that theſe maſſes could as little have been fuſed by lightning as by the burning of a foreſt or of foſſile coal. Theſe maſſes were found quite expoſed and uncovered, and not at any depth in the earth, where we can much more readily admit ſuch an accumulation of ferruginous particles to have been melted by the effects of lightning.

“ Should it be aſked how ſuch maſſes originated, or by what means they were brought into ſuch an inſulated poſition ? this queſtion would be the ſame as if it were aſked how the planets originated. Whatever hypotheſes we may form, we muſt either admit that the planets, if we except the many revolutions which they may have undergone, either on or near their ſurface, have always been ſince their firſt formation, and ever will be the ſame ; or that Nature, acting on created matter, poſſeſſes the power to produce worlds and whole ſyſtems, to deſtroy them, and from their materials to form new ones. For the latter opinion there are, indeed, more grounds than for the former, as alternations of deſtruction and creation are exhibited by all organiſed and unorganiſed bodies on our earth ; which gives us reaſon to ſuſpect that Nature, to which greatneſs and ſmallneſs, conſidered in general, are merely relative terms, can produce more effects of the ſame kind on a larger ſcale. But many variations have been obſerved on diſtant bodies, which, in ſome meaſure, render the laſt opinion probable. For example, the appearing and total diſappearing of certain ſtars, when they do not depend upon periodical changes. If we now admit that planetary bodies have ſtarted into exiſtence, we cannot ſuppoſe that ſuch an event can have otherwiſe taken place, than by conjecturing that either particles of matter, which were before diſperſed through infinite ſpace in a more ſoft and chaotic condition, have united together in large maſſes by the power of attraction ; or that new planetary bodies have been formed from the fragments of much larger ones that have been broken to pieces, either perhaps by ſome external ſhock, or by an internal exploſion. Let whichever of theſe hypotheſes be the trueſt, it is not improbable, or at leaſt not contrary to nature, if we ſuppoſe that a large quantity of ſuch material particles, either on account of their too great diſtance, or becauſe prevented by a ſtronger movement in another direction, may not have united themſelves to the larger accumulating maſs of a new world ; but have remained inſulated, and, impelled by ſome ſhock, have continued their courſe through infinite ſpace, until they approached ſo near to ſome planet as to be within the ſphere of its attraction, and then by falling down to occaſion the phenomena before mentioned.”

Whether Chladni be a philoſopher of the French ſchool we know not ; but ſome parts of his theory tend ſtrongly towards materialiſm ; and the arguments by which he attempts to prop thoſe parts are peculiarly weak. When he talks of *Nature* producing worlds, he either ſubſtitutes Nature for Nature's God, or utters jargon which has no meaning. In what ſenſe the word Nature is uſed by every philoſopher of a ſound mind, we have elſewhere been at ſome pains to ſhew (ſee River, n° 116. *Encycl.*); but how abſurd would it be to ſay, that the ſyſtem of general laws, by which the Author and Governor of the univerſe connects together its various parts, and regulates all their operations, poſſeſſes, independently of Him, “ the power to produce worlds and whole ſyſtems, to deſtroy them, and from their materials to form new ones !”

As Chladni admits, or talks as if he admitted, the creation of matter, it would be wrong to impute to him this abſurdity ; but if by *Nature* he means God, and he can conſiſtently mean nothing elſe, we beg leave to affirm, that it is *directly contrary* to every notion which we can form of Nature in *this ſenſe*, "to ſuppoſe that a large quantity of material particles, either on account of the *diſtance*, or becauſe prevented by a *ſtronger movement* in another direction, have not united themſelves to the larger accumulating maſs of a new world, but remained inſulated, and impelled by ſome ſhock, have continued their courſe through infinite ſpace, &c." Is there any diſtance to which God cannot reach, or any movement ſo ſtrong as to reſiſt his power? Our author's language is indeed confuſed, and probably his ideas were not very clear. When he ſpeaks of the particles of matter being at firſt diſperſed through infinite ſpace, and afterwards united by the power of attraction, he revives the queſtion which was long ago diſcuſſed between Newton and Bentley, and diſcuſſed in ſuch a manner as ſhould have ſilenced for ever the bablings of thoſe who form worlds by attraction.

"The hypotheſis (ſays Newton) of matter's being at firſt evenly ſpread through the heavens, is, in my opinion, inconſiſtent with the hypotheſis of innate gravity without a ſupernatural power to reconcile them; and therefore infers a Deity. For if there be innate gravity, it is impoſſible now for the matter of the earth, and all the planets and ſtars, to fly up from them, and become evenly ſpread through all the heavens, without a ſupernatural power; and certainly that which can never be hereafter without a ſupernatural power, could never be heretofore without the ſame power." Dr Chladni, indeed, does not ſay that his particles of matter were *evenly* diſperſed through infinite ſpace; but ſuch muſt be his meaning, if he has any meaning: for matter *unevenly* diſperſed muſt, by an innate attraction, be united as ſoon as it exiſts, and ſo united as not to leave ſmall fragments of it to wander, we know not why, through the trackleſs void. Turn matter on all ſides, make it eternal or of late production, finite or infinite, there can be no regular ſyſtem produced but by a voluntary and meaning agent; and therefore, if it be true that fire-balls are maſſes of denſe matter, coeval with the planetary ſyſtem, exiſting in the celeſtial regions, and thence conveyed to our earth, they muſt have been formed, and their motions impreſſed upon them, by the Author of Nature for ſome wiſe purpoſe, though by us that purpoſe may never be diſcovered. One thing ſeems pretty clear, that wherever they may be formed, the phenomena attending their burſting, account ſufficiently for the notions of thunderbolts which have been generally entertained in all ages, and in every country.

Greek-Fire (ſee *Wild-Fire*, *Encycl.*). In the ſecond volume of Mr Nicholſon's Philoſophical Journal, we have the following receipt for making this compoſition, taken from ſome manuſcripts of Leonard de Vinci, who flouriſhed in the end of the fifteenth and beginning of the ſixteenth centuries, and who appears to have advanced far before his contemporaries in phyſical ſcience. Take the charcoal of willow, nitre, brandy, reſin, ſulphur, pitch, and camphor. Mix the whole together over the fire. Plunge a woollen cord in the mixture, and form it into balls, which may afterwards be provided with ſpikes. Theſe balls, being ſet on fire, are thrown into the enemy's veſſels. It is called the Greek fire, and is a ſingular compoſition, for it burns even upon the water. Callinicus the architect taught this compoſition to the Romans (of Conſtantinople), who derived great advantage from it, particularly under the emperor Leo, when the Orientals attacked Conſtantinople. A great number of their veſſels were burned by means of this compoſition.

The compoſition of the Greek fire thus given by Vincini is found in nearly the ſame words in ſome of the writings of Baptiſta Porta; whence it appears that both authors derived their information from the ſame ſource. A compoſition which burnt without acceſs to the atmoſphere could not fail to fill the minds of our forefathers with wonder; but the modern diſcoveries in chemiſtry have diſcloſed the ſecret, by ſhewing, that the combuſtion is carried on by means of the oxygen contained in the nitre.

Raſant or *Razant Fire*, is a fire from the artillery and ſmall arms, directed parallel to the horizon, or to thoſe parts of the works of a place that are defended.

Running Fire is when ranks of men fire one after another; or when the lines of an army are drawn out to fire on account of a victory; in which caſe each ſquadron or battalion takes the fire from that on its right, from the right of the firſt line to the left, and from the left to the right of the ſecond line, &c.

FISHING, the art of catching fiſh. See Angling, Fishery, and Fishing, &c. *Encycl.*

Chineſe Fishing. We venture to give this appellation to ſome very ingenious contrivances of the people of China for catching in their lakes, not only fiſh, but water-fowl. For the purpoſe of catching fiſh they have trained a ſpecies of pelican, reſembling the common corvorant, which they call the *Leu-tze*, or fiſhing-bird. It is brown, with a white throat, the body whitiſh beneath, and ſpotted with brown; the tail is rounded, the irides blue, and the bill yellow. Sir George Staunton, who, when the embaſſy was proceeding on the ſouthern branch of the great canal, ſaw thoſe birds employed, tells us, that on a large lake, cloſe to the eaſt ſide of the canal, are thouſands of ſmall boats and rafts, built entirely for this ſpecies of fiſhery. On each boat or raft are ten or a dozen birds, which, at a ſignal from the owner, plunge into the water; and it is aſtoniſhing to ſee the enormous ſize of fiſh with which they return, graſped within their bills. They appeared to be ſo well trained, that it did not require either ring or cord about their throats to prevent them from ſwallowing any portion of their prey, except what their maſter was pleaſed to return to them for encouragement and food. The boat uſed by theſe fiſhermen is of a remarkable light make, and is often carried to the lake, together with the fiſhing birds, by the men who are there to be ſupported by it.

The ſame author ſaw the fiſhermen buſy on the great lake Wee-chaung hee; and he gives the following account of a very ſingular method practiſed by them for catching the fiſh of the lake without the aid of birds, of net, or of hooks.

To one ſide of a boat a flat board, painted white, is fixed, at an angle of about 45 degrees, the edge inclining towards the water. On moonlight nights the boat is ſo placed that the painted board is turned to the moon, from whence the rays of light ſtriking on the whitened ſurface, give to it the appearance of moving water; on which the fiſh being tempted to leap as on their element, the boatmen, riſing with a ſtring the board, turn the fiſh into the boat.

Water-fowl are much ſought after by the Chineſe and are taken upon the ſame lake by the following ingenious device. Empty jars or gourds are ſuffered to float about upon the water, that ſuch objects may become familiar to the birds. The fiſherman then wades into the lake with one of thoſe empty veſſels upon his head, and walks gently towards a bird; and lifting up his arm, draws it down below the ſurface of the water without any diſturbance or giving alarm to the reſt, ſeveral of whom he treats in the ſame manner, until he fills the bag he had brought to hold his prey. The contrivance itſelf is not ſo ſingular, as it is that the ſame exactly ſhould have occurred in the new continent, as Ulloa aſſerts, to the natives of Carthagena, upon the lake Cienega de Teſias.

FISTULA Lachrymalis is a diſeaſe which, in all its ſtages, has been treated of in the article Surgery, chap. xiv. *Encycl.* A work, however, has been lately publiſhed by James Ware ſurgeon, in which there is the deſcription of an operation for its cure conſiderably different from that moſt commonly uſed, and which, while it is ſimple, the author's experience has aſcertained to be ſucceſsful.

In the cure of this diſeaſe, which is very troubleſome, and not very uncommon, it is a well known practice to inſert a metallic tube in the naſal duct of the lachrymal canal: but the advantage derived from this operation is not at all times laſting. Among other cauſes of failure, Mr Ware notices the lodgment of inſpiſſated mucus in the cavity of the tube. To remedy this defect, he recommends the following operation.

“ If the diſeaſe has not occaſioned an aperture in the lachrymal ſac, or if this aperture be not ſituated in a right line with the longitudinal direction of the naſal duct, a puncture ſhould be made into the ſac, at a ſmall diſtance from the internal juncture of the palpebræ, and nearly in a line drawn horizontally from this juncture towards the noſe with a ſpear-pointed lancet. The blunt end of a ſilver probe, of a ſize rather ſmaller than the probes that are commonly uſed by ſurgeons, ſhould then be introduced through the wound, and gently, but ſteadily, puſhed on in the direction of the naſal duct, with a force ſufficient to overcome the obſtruction in this canal, and until there is reaſon to believe that it has freely entered into the cavity of the noſe. The poſition of the probe, when thus introduced, will be nearly perpendicular; its ſide will touch the upper edge of the orbit; and the ſpace between its bulbous end in the noſe and the wound in the ſkin will uſually be found, in a full-grown perſon, to be about an inch and a quarter, or an inch and three-eighths. The probe is then to be withdrawn, and a ſilver ſtyle, of a ſize nearly ſimilar to that of the probe, but rather ſmaller, about an inch and three-eighths in length, with a flat head, like that of a nail, but placed obliquely, that it may ſit cloſe on the ſkin, is to be introduced through the duct, in place of the probe, and to be left conſtantly in it. For the firſt day or two after the ſtyle has been introduced, it is ſometimes adviſable to waſh the eye with a weak ſaturnine lotion, in order to obviate any tendency to inflammation which may have been excited by the operation; but this in general is ſo ſlight, that our author has rarely had occaſion to uſe any application to remove it. The ſtyle ſhould be withdrawn once every day for about a week, and afterwards every ſecond or third day. Some warm water ſhould each time be injected through the duct into the noſe, and the inſtrument be afterwards replaced in the ſame manner as before. Mr Ware formerly uſed to cover the head of the ſtyle with a piece of diachylon plaſter ſpread on black ſilk, but has of late obviated the neceſſity for applying any plaſter by blackening the head of the ſtyle with ſealing wax.

“ The effect (ſays he) produced by the ſtyle, when introduced in the way above mentioned, at firſt gave me much ſurpriſe. It was employed with a view ſimilar to that with which Mr Pott recommends the introduction of a bougie; viz. to open and dilate the naſal duct, and thus to eſtabliſh a paſſage, through which the tears might afterwards be conveyed from the eye to the noſe. I expected, however, that whilſt the ſtyle continued in the duct the obſtruction would remain, and of courſe that the watering of the eye, and the weakneſs of the ſight, would prove as troubleſome as they had been before the inſtrument was introduced. I did not imagine that any eſſential benefit could reſult from the operation until the ſtyle was removed, and the paſſage thereby opened. It was an agreeable diſappointment to me to find that the amendment was much more expeditious. The watering of the eye almoſt wholly ceaſed as ſoon as the ſtyle was introduced; and in proportion as the patient amended in this reſpect, his ſight alſo became more ſtrong and uſeful. The ſtyle, therefore, ſeems to act in a twofold capacity: firſt, it dilates the obſtructed paſſage; and then, by an attraction ſomewhat ſimilar to that of a capillary tube, it guides the tears through the duct into the noſe.

“ The wound that I uſually make into the ſac, if the ſupperative proceſs has not formed a ſuitable aperture in this part, is no larger than is juſt ſufficient to admit the end of the probe or ſtyle; and this, in general, in a little time, becomes a fiſtulous orifice, through which the ſtyle is paſſed without occaſioning the ſmalleſt degree of pain. The accumulation of matter in the lachrymal ſac, which, previous to the operation, is often copious, uſually abates ſoon after the operation has been performed; and, in about a week or ten days, the treatment of the caſe becomes ſo eaſy, that the patient himſelf, or ſome friend or ſervant who is conſtantly with him, is fully competent to do the whole that is neceſſary. It conſiſts ſolely in withdrawing the ſtyle two or three times in the week, occaſionally injecting ſome warm water, and then replacing the inſtrument in the ſame way in which it was done before.

“ It is not eaſy to aſcertain the exact length of time that the ſtyle ſhould be continued in the duct. Some have worn it many years, and, not finding any inconvenience from the inſtrument, are ſtill afraid and unwilling to part from it. Others, on the contrary, have diſuſed it at the end of about a month or ſix weeks, and have not had the ſmalleſt return of the obſtruction afterwards.”

The author relates ſo many ſucceſsful caſes of this operation, that we thought it our duty to record his method in this Supplementary volume of our general repoſitory of arts and ſciences; for a ſucceſsful practice, as well in ſurgery as in phyſic, muſt reſt on the baſis of experience.

Oblique or Second FLANK, or *Flank of the Curtain*, is that part of the curtain from whence the face of the oppoſite baſtion can be ſeen, being contained between the lines raſant and fichant, or the greater and leſs lines of defence; or the part of the curtain between the flank and the point where the fichant line of defence terminates.

Covered, Low, or *Retired* FLANK, is the platform of the caſemate, which lies hid in the baſtion, and is otherwiſe called the *orillon*.

Fichant FLANK,' is that from whence a cannon playing, fires directly on the face of the oppoſite baſtion.

Raſant or *Razant* FLANK, is the point from whence the line of defence begins, from the conjunction of which with the curtain the ſhot only raſeth the face of the next baſtion, which happens when the face cannot be diſcovered but from the flank alone.

FLIE or FLY, that part of the mariner's compaſs on which the thirty-two points of the wind are drawn, and over which the needle is placed, and faſtened underneath.

FLOATING BODIES are ſuch as ſwim on the ſurface of a fluid, of which the moſt important are ſhips, and all kinds of veſſels employed in war and in commerce. Every ſeaman knows of how much conſequence it is to determine the ſtability of ſuch veſſels, and the poſitions which they aſſume when they float freely and at reſt on the water. To accompliſh this, it is neceſſary to ſtate the principles on which that ſtability and theſe poſitions depend; and this has been done with ſo much ingenuity and ſcience by GEORGE ATWOOD, Eſq; F. R. S. in the Philoſophical Tranſactions for the year 1796, that we are perſuaded a large claſs of our readers will thank us for inſerting an abſtract of his memoir in this place.

A floating body is preſſed downwards by its own weight in a vertical line that paſſes through its centre of gravity; and it is ſuſtained by the upward preſſure of a fluid, acting in a vertical line that paſſes through the centre of gravity of the immerſed part; and unleſs theſe two lines be coincident, ſo that the two centres of gravity may be in the ſame vertical line, the ſolid will revolve on an axis, till it gains a poſition in which the equilibrium of floating will be permanent. Hence it appears, that it is neceſſary, in the firſt place, to aſcertain the proportion of the part immerſed to the whole; for which purpoſe the ſpecific gravity of the floating body muſt be known; and then it muſt be determined, by geometrical or analytical methods, in what poſitions the ſolid can be placed on the ſurface of the fluid, ſo that the two centres of gravity already mentioned may be in the ſame vertical line when a given part of the ſolid is immerſed under the ſurface of the fluid. When theſe preliminaries are ſettled, ſomething ſtill remains to be done. Poſitions may be aſſumed in which the circumſtances juſt recited concur, and yet the ſolid will aſſume ſome other poſition in which it will permanently float. If a cylinder, *e. g.* having its ſpecific gravity to that of the fluid on which it floats as 3 to 4, and its axis to the diameter of the baſe as 2 to 1, be placed on the fluid with its axis vertical, it will ſink to a depth equal to a diameter and a half of the baſe; and while its axis is preſerved in a vertical poſition by external force, the centres of gravity of the whole ſolid and of the immerſed part will remain in the ſame vertical line: but when the external force that ſuſtained it is removed, it will decline from its upright poſition, and will permanently float with its axis horizontal. If the axis be ſuppoſed to be half of the diameter of the baſe, and be placed vertically, the ſolid will ſink to the depth of three-eighths of its diameter; and in that poſition it will float permanently. If the axis be made to incline to the vertical line, the ſolid will change its poſition until it ſettles permanently with the axis perpendicular to the horizon.

Whether, therefore, a ſolid floats permanently, or overſets when placed on the ſurface of a fluid, ſo that the centre of gravity of the ſolid and that of the part immerſed ſhall be in the ſame vertical line, it is ſaid to be in a poſition of equilibrium; and of this equilibrium there are three ſpecies, viz. the equilibrium of ſtability, in which the ſolid floats permanently in a given poſition; the equilibrium of inſtability, in which the ſolid, though the two centres of gravity already mentioned are in the ſame vertical line, ſpontaneouſly overſets, unleſs ſupported by external force; and the equilibrium of indifference, or the inſenſible equilibrium, in which the ſolid reſts on the fluid indifferent to motion, without tendency to right itſelf when inclined, or to incline itſelf farther.

If a ſolid body floats permanently on the ſurface of a fluid, and external force be applied to incline it from its poſition, the reſiſtance oppoſed to this inclination is termed the ſtability of floating. Among various floating bodies, ſome loſe their quieſcent poſition, and ſome gain it, after it has been interrupted, with greater facility and force than others.

Some ſhips at ſea (*e. g.*) yield to a given impulſe of the wind, and ſuffer a greater inclination from the perpendicular than others. As this reſiſtance to heeling or pitching, duly regulated, has been deemed of importance in the conſtruction of veſſels, ſeveral eminent mathematicians have inveſtigated rules for determining the ſtability of ſhips from their known dimenſions and weight, without recurring to actual trial. To this claſs we may refer Bouguer, Euler, Fred. Chapman, and others; who have laid down theorems for this purpoſe, founded on a ſuppoſition that the inclinations of ſhips from their quieſcent poſitions are evaneſcent, or, in a practical ſenſe, very ſmall.

"But ſhips at ſea (ſays our ingenious author) are known to heel through angles of 10°, 20°, or even 30°; and therefore a doubt may ariſe how far the rules, demonſtrated on the expreſs condition that the angles of inclination are of evaneſcent magnitude, ſhould be admitted as practically applicable in caſes where the inclinations are ſo great."—"If we admit that the theory of ſtatics can be applied with any effect to the practice of naval architecture, it ſeems to be neceſſary that the rules, inveſtigated for determining the ſtability of veſſels, ſhould be extended to thoſe caſes in which the angles of inclination are of any magnitude likely to occur in the practice of navigation."

A ſolid body placed on the ſurface of a lighter fluid, at the depth correſponding to the relative gravities, cannot change its poſition by the combined actions of its weight and the preſſure of the fluid, except by revolving on ſome horizontal axis which paſſes through the centre of gravity: but as many axes may be drawn through this point of the floating body in a direction parallel to the horizon, and the motion of the ſolid reſpects one axis only, this axis muſt be determined by the figure of the body and the particular nature of the caſe. When this axis of motion, as it is called, is determined,

termined, and the ſpecific gravity of the ſolid is known, "the poſitions of permanent floating will be obtained, firſt by finding the ſeveral poſitions of equilibrium through which the ſolid may be conceived to paſs, while it revolves round the axis of motion; and ſecondly, by determining in which of thoſe poſitions the equilibrium is permanent, and in which of them it is momentary and unſtable."

Such as we have now briefly ſtated are the general principles on which are founded Mr Atwood's inveſtigations for determining the poſitions aſſumed by homogeneous bodies, floating on a fluid ſurface; and alſo for determining the ſtability of ſhips and of other floating bodies. We cannot farther accompany him in his elucidation of them, in the problems to the ſolution of which they lead, and in the important practical purpoſes of naval architecture to which they are referred. The whole paper, comprehending no leſs than 85 pages, is curious and valuable; it abounds with analytical and geometrical diſquiſitions of the moſt elaborate kind; and it ſerves to enlarge our acquaintance with a ſubject that is not only highly intereſting to the ſpeculative mathematician, but extremely uſeful in its practical application.

With this latter view, the author ſeems to have directed his attention to the various objects of inquiry which this article comprehends. They are ſuch as intimately relate to the theory of naval architecture, ſo far as it depends on the pure laws of mechanics, and they contribute to extend and improve this theory. The union of thoſe principles that are deduced from the laws of motion, with the knowledge which is derived from obſervation and experience, cannot fail to eſtabliſh the art of conſtructing veſſels on its true baſis, and gradually to lead to farther improvements of the greateſt importance and utility. To this purpoſe, the author obſerves, that

"If the proportions and dimenſions adopted in the conſtruction of individual veſſels are obtained by exact geometrical menſurations, and calculations founded on them, and obſervations are made on the performance of theſe veſſels at ſea; experiments of this kind, ſufficiently diverſified and extended, ſeem to be the proper grounds on which theory may be effectually applied in developing and reducing to ſyſtem thoſe intricate, ſubtil, and hitherto unperceived cauſes, which contribute to impart the greateſt degree of excellence to veſſels of every ſpecies and deſcription. Since naval architecture is reckoned amongſt the practical branches of ſcience, every voyage may be conſidered as an experiment, or rather as a ſeries of experiments, from which uſeful truths are to be inferred towards perfecting the art of conſtructing veſſels: but inferences of this kind, conſiſtently with the preceding remark, cannot well be obtained, except by acquiring a perfect knowledge of all the proportions and dimenſions of each part of the ſhip; and ſecondly, by making and recording ſufficiently numerous obſervations on the qualities of the veſſel, in all the varieties of ſituation to which a ſhip is uſually liable in the practice of navigation."

In the valuable miſcellany entitled the *Philoſophical Magazine*, there is a paper on this ſubject by Mr John George Engliſh, teacher of mathematics and mechanical philoſophy; which, as it is not long, and is eaſily underſtood, we ſhall take the liberty to tranſcribe.

"However operoſe and difficult the calculations neceſſary to determine the ſtability of nautical veſſels may, in ſome caſes, be, yet they all depend, ſays this author, upon the four following ſimple and obvious theorems, accompanied with other well-known ſtereometrical and ſtatical principles.

"*Theorem* 1. Every floating body diſplaces a quantity of the fluid in which it floats, equal to its own weight: and conſequently, the ſpecific gravity of the fluid will be to that of the floating body, as the magnitude of the whole is to that of the part immerſed.

"*Theorem* 2. Every floating body is impelled downward by its own eſſential power, acting in the direction of a vertical line paſſing through the centre of gravity of the whole; and is impelled upward by the reaction of the fluid which ſupports it, acting in the direction of a vertical line paſſing through the centre of gravity of the part immerſed: therefore, unleſs theſe two lines are coincident, the floating body thus impelled muſt revolve round an axis, either in motion or at reſt, until the equilibrium is reſtored.

"*Theorem* 3. If by any power whatever a veſſel be deflected from an upright poſition, the perpendicular diſtance between two vertical lines paſſing through the centres of gravity of the whole, and of the part immerſed reſpectively, will be as the ſtability of the veſſel, and which will be poſitive, nothing, or negative, according as the metacentre is above, coincident with, or below, the centre of gravity of the veſſel.

"*Theorem* 4. The common centre of gravity of any ſyſtem of bodies being given in poſition, if any one of theſe bodies be moved from one part of the ſyſtem to another, the correſponding motion of the common centre of gravity, eſtimated in any given direction, will be to that of the aforeſaid body, eſtimated in the ſame direction, as the weight of the body moved is to that of the whole ſyſtem.

"From whence it is evident, that in order to aſcertain the ſtability of any veſſel, the poſition of the centres of gravity of the whole, and of the part immerſed, muſt be determined; with which, and the dimenſions of the veſſel, the line of floatation, and angle of deflection, the ſtability or power either to right itſelf or overturn, may be found.

"In ſhips of war and merchandiſe, the calculations neceſſary for this purpoſe become unavoidably very operoſe and troubleſome; but they may be much facilitated by the experimental method pointed out in the New Tranſactions of the Swediſh Academy of Sciences, firſt quarter of the year 1787, page 48.

"In river and canal boats, the regularity and ſimplicity of the form of the veſſel itſelf, together with the compact diſpoſition and homogeneal quality of the burden, render that method for them unneceſſary, and make the requiſite calculations become very eaſy. Veſſels of this kind are generally of the ſame tranſverſe ſection throughout their whole length, except a ſmall part in prow and ſtern, formed by ſegments of circles or other ſimple curves; therefore a length may eaſily be aſſigned ſuch, that any of the tranſverſe ſections being multiplied thereby, the product will be equal to the whole ſolidity of the veſſel. The form of the ſection ABCD is for the moſt part either rectangular, as in fig. 1. trapezoidal as in fig. 2. or mixtilineal

Plate XXVIII.

tilineal as in fig. 3. in all which MM repreſents the line of floatation when upright, and EF that when inclined at any angle MXE; alſo G repreſents the centre of gravity of the whole veſſel, and R that of the part immerſed.

“ If the veſſel be loaded quite up to the line AB, and the ſpecific gravity of the boat and burden be the ſame, then the point G is ſimply the centre of gravity of the ſection ABCD; but if not, the centres of gravity of the boat and burden muſt be found ſeparately, and reduced to one by the common method, namely, by dividing the ſum of the momenta by the ſum of weights, or areas, which in this caſe are as the weights. The point R is always the centre of gravity of the ſection MMCD, which, if conſiſting of different figures, muſt alſo be found by dividing the ſum of the momenta by the ſum of the weights as common. Theſe two points being found, the next thing neceſſary is to determine the area of the two equal triangles MXE, MXF, their centres of gravity *o*, *o*, and the perpendicular projected diſtance *n n* of theſe points on the water line EF. This being done, through R, and parallel to EF, draw RT = a fourth proportional to the whole area MMCD, either triangle MXE or MXF, and the diſtance *n n*; through T, and at right angles to RT or EF, draw TS meeting the vertical axis of the veſſel in S the metacentre; alſo through the points G, B, and parallel to ST, draw NGW and BV; moreover through S, and parallel to EF, draw WSV, meeting the two former in V and W; then SW is as the ſtability of the veſſel, which will be poſitive, nothing, or negative, according as the point S is above, coincident with, or below, the point G. If now we ſuppoſe W to repreſent the weight of the whole veſſel and burden (which will be equal to the ſection MMCD multiplied by the length of the veſſel), and P to repreſent the required weight applied at the gunwale B to ſuſtain the veſſel at the given angle of inclination; we ſhall always have this proportion: as VS : SW : : W : P; which proportion is general, whether SW be poſitive or negative; it muſt only, in the latter caſe, be ſuppoſed to act upward to prevent an overturn.

“ In the rectangular veſſel, of given weight and dimenſions, the whole proceſs is ſo evident, that any farther explanation would be unneceſſary. In the trapezoidal veſſel, after having found the points G and R, let AD, BC be produced until they meet in K. Then, ſince the two ſections MMCD, EFDC are equal, the two triangles MMK, EFK are alſo equal; and therefore the rectangle EK × KF = KM × KM = $\overline{\text{KM}^2}$; and ſince the angle of inclination is ſuppoſed to be known, the angles at E and F are given. Conſequently, if a mean proportional be found between the ſines of the angles at E and F, we ſhall have the following proportions:

“ As the mean proportional thus found : ſine ∠ E : : KM : KF, and as the ſaid mean proportional : ſine ∠F : : KM : KE; therefore ME, MF become known: from whence the area of either triangle MXE or MXF, the diſtance *n n*, and all the other requiſites, may be found.

“ In the mixtilineal ſection, let AB = 9 feet = 108 inches, the whole depth = 6 feet = 72 inches, and the altitude of MM the line of floatation 4 feet or 48 inches; alſo let the two curvelinear parts be circular quadrants of two feet, or 24 inches radius each. Then the area of the two quadrants = 904·7808 ſquare inches, and the diſtance of their centres of gravity from the bottom = 13·8177 inches very nearly; alſo the area of the included rectangle *a b i e* = 1440 ſquare inches, and the altitude of its centre of gravity 12 inches; in like manner, the area of the rectangle AB *c d* will be found = 5184 ſquare inches, and the altitude of its centre of gravity 48 inches: therefore we ſhall have

Momentum of the two quad.	= 904·7808	×	13·8177	= 12501·98966016
Moment. of the rectan. *a b i e*	= 1440·	×	12	= 17280·
Moment. of the rectan. AB*c d*	= 5184·	×	48	= 248832· .
	7528·7808			278613·98966016

“ Now the ſum of the momenta, divided by the ſum of the areas, will give $\frac{278613\cdot98966016}{7528\cdot7808} = 37\cdot006$ inches, the altitude of G, the centre of gravity of the ſection ABCD above the bottom. In like manner, the altitude of R, the centre of gravity of the ſection MMCD, will be found to be equal $\frac{123093\cdot98966016}{4936\cdot7808}$ = 24·934 inches; and conſequently their difference, or the value of GR = 12·072 inches, will be found.

Suppoſe the veſſel to heel 15°, and we ſhall have the following proportion; namely, As radius : tangent of 15 : : MX = 54 inches : 14.469 inches = ME or MF; and conſequently the area of either triangle MXE or MXF = 390·663 ſquare inches. Therefore, by theorem 4th, as 4936·7808 : 390·663 : : 72 = *n n* = $\frac{2}{3}$ AB : 5·6975 inches = RT; and, again, as radius : ſine of 15° : : 12.072 = GR : 3·1245 inches = RN; conſequently RT—RN = 5·6975—3·1245 = 2·573 inches = SW, the ſtability required.

“ Moreover, as the ſine of 15° : radius : : 5·6975 = RT : 22·013 = RS, to which, if we add 24·934, the altitude of the point R, we ſhall have 46·947 for the height of the metacentre, which taken from 72, the whole altitude, there remains 25·053; from which, and the half width = 54 inches, the diſtance BS is found = 59·529 inches very nearly, and the angle SBV = 80°—06′—42″; from whence SV = 58·645 inches.

Again: Let us ſuppoſe the mean length of the veſſel to be 40 feet, or 480 inches, and we ſhall have the weight of the whole veſſel equal to the area of the ſection MMCD = 4936.7808 multiplied by 480 = 2369654·784 cubic inches of water, which weighs exactly 85708 pounds avoirdupois, allowing the cubic foot to weigh 62.5 pounds.

“ And, finally, as SV : SW (*i. e.*) as 58·645 : 2·573 : : 85708 : 3760 +, the weight on the gunwale which will ſuſtain the veſſel at the given inclination. Therefore a veſſel of the above dimenſions, and weighing 38 tons, 5 cwts. 28 lbs. will require a weight of 1 ton, 13 cwts. 64 lbs. to make her incline 15°.

“ In this example, the deflecting power has been ſuppoſed to act perpendicularly on the gunwale at B; but if the veſſel is navigated by ſails, the centre velique muſt be found; with which, and the angle of deflection, the projected diſtance thereof on the line SV may be obtained; and then the power, calculated as above

neceſſary

neceſſary to be applied at the projected point, will be that part of the wind's force which cauſes the veſſel to heel. And converſely, if the weight and dimenſions of the veſſel, the area and altitude of the ſails, the direction and velocity of the wind be given, the angle of deflection may be found."

FLUENT, or FLOWING QUANTITY, in the doctrine of fluxions, is the variable quantity which is conſidered as increaſing and decreaſing; or the fluent of a given fluxion, is that quantity whoſe fluxion being taken, according to the rules of that doctrine, ſhall be the ſame with the given fluxion. See FLUXIONS, *Encycl.*

FLUIDS (MOTION IN). See HYDROSTATICS and RESISTANCE OF FLUIDS, *Encycl.* and MOTION in this *Supplement*.

FOGEDAR, the military governor of a ſubordinate diſtrict in India, who has ſometimes the additional office of collecting the revenues.

FOLIATE, a name given by ſome to a curve of the 2d order, expreſſed by the equation $x^3+y^3=axy$, being one ſpecies of defective hyperbolas, with one aſymptote, and conſiſting of two infinite legs croſſing each other, forming a ſort of leaf. It is the 42d ſpecies of Newton's Lines of the 3d Order.

FORCER, in mechanics, is properly a piſton without a valve. For, by drawing up ſuch a piſton, the air is drawn up, and the water follows; then puſhing the piſton down again, the water, being prevented from deſcending by the lower valve, is forced up to any height above, by means of a ſide branch between the two.

FORDYCE (James, D. D.), ſo well known to ſerious readers by his ſermons to young women, and other ſpecimens of pulpit eloquence, was born at Aberdeen in the year 1720. His father was a man much eſteemed, and held, more than once, the office of chief magiſtrate in his native city; and his mother was a woman of good ſenſe, amiable temper, and exemplary piety. This reſpectable pair had the ſingular felicity of tranſmitting ſuperior talents to almoſt every individual of a numerous family; of one of which, viz. David Fordyce, the reader will find ſome account in the *Encyclopædia*.

The ſubject of this memoir, who was their fourth ſon, acquired, as well as his brother, the rudiments of claſſical learning at the grammer ſchool of Aberdeen, whence he was removed to the Mariſchal college and univerſity in the ſame city. Having completed a regular courſe of ſtudy both in philoſophy and theology, he was licenſed, when very young, according to the forms of the church of Scotland, to be a preacher of the goſpel; and was ſoon afterwards preferred to the place of ſecond miniſter in the collegiate church of Brechin in the county of Angus. After remaining there for ſome years, he received a preſentation to the church of Alloa near Stirling; and though the inhabitants of that pariſh were prepoſſeſſed in favour of another miniſter whom they knew, and prejudiced againſt Mr Fordyce whom they did not know; ſo narrow minded and totally deſtitute of taſte was his colleague in Brechin, that he judged it expedient to hazard the conſequences of a removal. He was aware that he entered on his new charge under a conſiderable degree of popular odium; but he thought it more probable that he ſhould be able to overcome that odium, than conciliate the affections of a ſour fanatic. In this expectation he was not deceived. The prejudices of the good people in Alloa were very quickly removed, not more by the able and impreſſive manner in which he conducted the public ſervices of the Lord's day, than by the amiable and condeſcending ſpirit with which he performed the more private duties of viſiting and catechiſing in the different diſtricts of his pariſh; duties which, as they were wont to be performed by the Scotch clergy, contributed much more than preaching to the religious inſtruction of the lower claſſes of the people.

It was during his reſidence at Alloa that Mr Fordyce firſt diſtinguiſhed himſelf as an author by the ſucceſſive publication of the three following ſermons. The firſt, upon the eloquence of the pulpit, was annexed to "the Art of Preaching" by his brother David; the ſecond, upon the methods of promoting edification by public inſtitutions, was preached at the ordination of the Rev. Mr Gibſon miniſter of St Ninian's, a neighbouring pariſh, in the year 1754, and publiſhed, with the charge and notes, in 1755; and the third, upon the deluſive and perſecuting ſpirit of popery, was preached the ſame year before the ſynod of Stirling and Perth; and being publiſhed, came very quickly to a ſecond edition. But the ſermon which moſt ſtrongly arreſted the attention, both of the audience before which it was delivered, and of the public to which, in 1760, it was given from the preſs, was that on the *folly, infamy, and miſery of unlawful pleaſure*, preached before the General Aſſembly of the Church of Scotland. The choice of ſuch a ſubject, on ſuch an occaſion, excited the ſurpriſe of all his hearers, and tempted the younger part of them to ſmile at the very reading of the text; but this unſeaſonable mirth was ſoon converted into ſerioufneſs. The picture exhibited in this ſermon is the work of a maſter; and we have been aſſured by a friend who heard it preached, that the ſpirit and elegance of the compoſition was ſo ſeconded by the ſolemnity and animation with which it was delivered, that it made a very ſtriking impreſſion, not only upon the more reſpectable part of the audience, but upon minds of noted levity: It raiſed indeed its writer's fame as a pulpit orator to an unrivalled eminence among his brethren in Scotland.

About this time, and we believe in conſequence of this ſermon, Mr Fordyce received from the univerſity of Glaſgow a diploma, creating him Doctor in Divinity; and if there is yet any thing honourable in academical degrees, proſtituted as they have long been by an undiſtinguiſhing diſtribution, the honour could not have been conferred with greater propriety on any man in the church to which he then belonged.

In that church he did not long remain. Soon after the publication of this ſingular ſermon, and his conſequent acquiſition of academical honours, he accepted of an invitation from a ſociety of Proteſtant diſſenters, who had their place of meeting in Monkwell-ſtreet, London, to become colleague and ſucceſſor to their paſtor, who was then old and infirm, and who died, indeed, in the ſpace of a few months. This gave occaſion to the Doctor to diſplay his oratory once more both from the pulpit and the preſs in a ſermon on the death of Dr Lawrence. He was now ſole paſtor to the congregation of Monkwell-ſtreet; and preached for many years with great powers of eloquence and fervour of piety, to an audience always crowded and often overflowing.

When a preacher obtains, with or without merit, an uncommon ſhare of popularity, a conſiderable proportion of his hearers will ever conſiſt of thoſe, who are guided in their choice rather by curioſity and faſhion, than by ſound judgment. The attachments of ſuch people are as capricious and variable as their minds; and they change their preacher as they change their dreſs, not from their own taſte, for in general they have none; but from the deſire of being where others are, of doing what others do and of admiring what others admire. Dr Fordyce appreciated juſtly the value of ſuch mens approbation, and knew it eventually by experience; but he was more than compenſated for the loſs of hearers of this deſcription by the ſteady adherence of others, whoſe eſteem was moſt deſirable, becauſe it was grounded upon the dictates of a ſound underſtanding.

At laſt, about Chriſtmas 1782, when his health, which had long been declining, rendered it neceſſary, in his own opinion, and in the opinion of his phyſicians, to diſcontinue his public ſervices, he reſigned his charge in Monkwell-ſtreet, and retired to a villa in Hampſhire, in the neighbourhood of the Earl of Bute, who honoured him with his friendſhip, and to whoſe valuable library he had free acceſs. Afterwards he removed to Bath, where having, with Chriſtian patience, ſuffered much from an aſthmatic complaint, to which he had been ſubject for ſome years, on the 1ſt of October 1796 he expired without a groan.

Were we to hazard an opinion of Dr Fordyce's intellectual powers from ſuch a peruſal of his works as we muſt acknowledge to have been haſty, we would ſay that he was a man of genius rather than of judgment; that his imagination was the predominant faculty of his mind; and that he was better fitted, by an addreſs to the paſſions, to enforce the practice of virtue, than, by the exertions of his own underſtanding, to vindicate ſpeculative truth, or to detect the ſophiſtry of error. From this remark, we cannot be ſuſpected of a wiſh to leſſen his character in the public eſteem; for his talents, as they appear to us, are ſurely of more value to a preacher than thoſe which are perhaps better adapted to literary or ſcientific purſuits. In none of his works indeed do we perceive any evidence either of profound ſcience, or of various erudition; though we doubt not but thoſe works are every thing which their author intended them to be. Of his ſermons to young women, which have attracted moſt general notice, it would be preſumptuous in us to give a character; for though we ſat down many years ago to read them, we could not get through; and we have never made a ſecond attempt. As far as we can depend upon what we recollect of theſe far-famed diſcourſes, the cenſure paſſed on them by Mrs Wolſtoncraft ſeems to be juſt. Their author, however, was certainly qualified to excel, and actually did excel as a preacher. We have already mentioned with approbation three or four of his occaſional ſermons; but perhaps the fineſt ſpecimen of pulpit oratory which ever fell from his pen, is the charge which he delivered at the ordination of his ſucceſſor in the meeting of Monkwell-ſtreet. It is indeed one of the moſt valuable diſcourſes of the kind that we have ſeen, and ſhould be read with attention by every clergyman of every denomination, who wiſhes to diſcharge his duty with credit to himſelf and with advantage to his people.

The effect of Dr Fordyce's addreſſes from the pulpit was much heightened, not only by an action and an elocution, which he ſtudied with care and practiſed with ſucceſs; but by the figure of his perſon, which was peculiarly dignified, and by the expreſſion of his countenance, which was animated at all times, but animated moſt of all when lighted up by the ardour of his ſoul in the ſervice of God. By ſome of his hearers, it was obſerved that, on many occaſions, he ſeemed not merely to ſpeak, but to look conviction to the heart. His eye, indeed, was particularly bright and penetrating, and he had carefully attended to the effect which an orator may often produce upon an audience by the judicious uſe of that little, but invaluable organ.

With reſpect to his theological ſentiments, we are aſſured (A) they were in no extreme, but liberal, rational, and manly. He ſeems to have been untainted by that rage of innovation, which of late has ſo completely disfigured the creed, as well religious as political, of the great body of Engliſh diſſenters. The conſequence was, that he lived on terms of friendſhip with men of very oppoſite ſentiments; with Price a republican and Arian, and with Johnſon, who, though he hated a whig and a Preſbyterian, reſpected talents and worth wherever he found them.

We ſhall conclude this ſhort ſketch of Dr Fordyce's life and character with the following liſt of his works, of which ſome have been tranſlated into ſeveral languages. 1. A Sermon and Charge, at the ordination of the Rev. Mr Gibſon Miniſter of St Ninian's, 1754. 2. Another Ordination Sermon on the Eloquence of the Pulpit, annexed to his brother's "Art of Preaching," 1754. 3. A Sermon on the Spirit of Popery, 1754. 4. A Sermon on the Folly, Infamy, and Miſery of Unlawful Pleaſure, 1760. 5. A Sermon on the Death of Dr Lawrence, 1760. 6. Sermons to Young Women, 2 vols. 1765. 7. A Sermon on the Character and Conduct of the Female Sex, 1776. 8. Addreſſes to Young Men, 2 vols. 1777. 9. A Charge at the Ordination of the Rev. James Lindſay, in Monkwell-ſtreet, 1783. 10. Addreſſes to the Deity, 1785. 11. Poems, 1786. 12. A Diſcourſe on Pain, 1791. He alſo re-publiſhed, with an additional character, "The Temple of Virtue, a Dream," written by his brother David.

FORMULA, a theorem or general rule or expreſſion, for reſolving certain particular caſes of ſome problem, &c. So $\frac{1}{2}s + \frac{1}{2}d$ is a general formula for the greater of two quantities whoſe ſum is s and difference d; and $\frac{1}{2}s - \frac{1}{2}d$ is the formula, or general value, for the

---

(A) By his ſucceſſor in Monkwell-ſtreet, to whoſe ſermon, preached on occaſion of the Doctor's death, our readers are indebted for every thing valuable in this ſhort memoir.

the leſs quantity. Alſo $\sqrt{dx - x^2}$ is the formula, or general value of the ordinate to a circle, whoſe diameter is *d*, and abſciſs *x*.

FORSTER (John Reinhold, LL. D.) profeſſor of natural hiſtory in the univerſity of Halle, member of the academy of ſciences at Berlin, and of other learned ſocieties, was born at Dirſchau, in Weſt Pruſſia, in the month of October 1729, and was formerly a Proteſtant clergyman at Dantzick. He had a numerous family, and the emoluments of his office were ſlender. He therefore quitted Dantzick, and went, firſt to Ruſſia, and thence to England, in queſt of a better ſettlement than his own country afforded. In the diſſenting academy at Warrington he was appointed tutor in the modern languages, with the occaſional office of lecturing in various branches of natural hiſtory. For the firſt department he was by no means well qualified; his extraordinary knowledge of languages, ancient and modern, being unaccompanied by a particle of taſte; and his uſe of them being all barbarous, though fluent. As a natural hiſtorian, a critic, geographer, and antiquary, he ranked much higher; but unfortunately theſe were acquiſitions of little value in his academical department.

At length he obtained the appointment of naturaliſt and *philoſopher* (if the word may be ſo uſed) to the ſecond voyage of diſcovery undertaken by Capt. Cook; and from 1772 to 1775 he accompanied that immortal navigator round the world. On his return he reſided in London till the improper conduct of himſelf and his ſon made it expedient for them both to leave the kingdom. Fortunately he received an invitation to Halle, where, for 18 years, he was a member of the philoſophical and medical faculties. Among his works are: An Introduction to Mineralogy, or, An accurate Claſſification of Foſſils and Minerals, &c. London, 1768, 8vo. A Catalogue of the Animals of North America, with ſhort Directions for collecting, preſerving, and tranſporting all kinds of Natural Curioſities, London, 1771, 8vo. Obſervations made during a Voyage round the World, on Phyſical Geography, &c. London, 1778. He was the author of a great many productions in Engliſh, Latin, or German, and of ſeveral papers in the Philoſophical Tranſactions. He tranſlated into Engliſh, Bougainville's Voyage round the World, and Kalm's, Boſſu's, and Reidſel's Travels. He was employed likewiſe, when in England, in the Critical Review; and he wrote various detached papers on different ſubjects, which have been inſerted in foreign journals and the tranſactions of learned academies.

He died at Halle on the 16th of December 1798, in the 70th year of his age.

FORSTER (George), the ſon of the preceding, was born at Dantzick, and accompanied his father to England when he was about twelve years of age. He was entered a ſtudent in the academy at Warrington, and ſoon acquired a very perfect uſe of the Engliſh tongue. He alſo diſtinguiſhed himſelf greatly by his attainments in ſcience and literature in general; adding to an excellent memory, quick parts and a fertile imagination. His temper was mild and amiable; in which he much differed from his father, one of the moſt quarrelſome and irritable of men; by which diſpoſition, joined to a total want of prudence in common concerns, he loſt almoſt all the friends his talents had acquired him, and involved himſelf and family in perpetual difficulties.

The caſe was very different with the ſubject of this memoir; for when Dr Forſter was appointed naturaliſt to Captain Cook, his ſon, through the intereſt of the friends whom his good nature had made, was aſſociated with him in his office. The voyage continued during the ſpace of three years; and on their return the two Forſters publiſhed jointly a botanical work in Latin, containing the characters of a number of new *genera* of plants, diſcovered by them in their circumnavigation. Thus far they acted properly in the ſervice of government for the advancement of ſcience; but in publiſhing another work their conduct was not proper.

The father had come under an engagement not to publiſh ſeparately, from the authoriſed narrative, any account of the voyage; and this engagement he and his ſon were determined to violate. An account of the voyage, therefore, was publiſhed in Engliſh and German by *George*; and the language, which is correct and elegant, was undoubtedly his; but thoſe who knew both him and his father, are ſatisfied that the matter proceeded from the joint ſtock of their obſervations and reflections. Several parts of the work, and particularly the elaborate inveſtigations relative to the languages ſpoken by the natives of the South Sea Iſlands, and the ſpeculations concerning their ſucceſſive migrations, are thought to be ſtrongly impreſſed with the genius of the elder Forſter.

That a work thus ſurreptitiouſly uſhered into the world was not patroniſed by thoſe with whom the authors had ſo ungratefully broken faith, could excite no wonder, even though the publication itſelf had been otherwiſe unexceptionable; but this was far from being the caſe. It abounds with reflections injurious to the government whoſe ſervants they had been, and not juſt to the navigators employed on voyages of diſcovery. The younger Forſter, too, had ſome time before publiſhed a book replete with factious ſentiments; and the coldneſs with which he and his father were both treated in conſequence of ſuch conduct, determined them to leave London.

We have already related all that we know of the father, who was recommended to our notice only by his connection with the illuſtrious Cook; and of the ſon, there is a ſhort account in the Monthly Magazine, by Charles Pougens, fraught with thoſe impious and ſeditious reflections which ſo frequently diſgrace a miſcellany, which would otherwiſe be highly valuable. According to this author, George Forſter was deſirous to ſettle in France. Avaricious of glory, and an idolator of liberty, Paris was the city moſt ſuitable to his taſte and character of any in Europe. Notwithſtanding this, he was ſoon conſtrained to leave it: the intereſt of his family demanded this ſacrifice; for a learned man, who ſails round the world, may enrich his memory, but he will not better his fortune. He was accordingly obliged to accept the place of profeſſor of natural hiſtory in the univerſity of Caſſel. But his factious ſpirit accompanied him whitherſoever he went. It is well known, that the petty princes of Germany have long been in the practice of hiring out their troops to more opulent ſovereigns engaged in war. This practice, which we are not diſpoſed to defend, not only ſcandalized our Coſmopolite, but ſo irritated

ritated his temper and offended his pride, becauſe, forſooth, the Prince of Heſſe-Caſſel would not by *him* be perſuaded to relinquiſh it, that he did every thing in his power, we are told, to withdraw himſelf from a ſituation ſo unſuitable to a thinking being. Every thing in his power! Did the Prince retain him in the univerſity contrary to his inclination? The univerſity of Caſſel muſt be contemptible indeed, if the prelections of ſuch a man as George Forſter were of ſuch conſequence to it.

He got away, however; and the ſenate of Poland having offered him a chair in the univerſity of Wilna, Forſter accepted of the invitation. But although this office was very lucrative, and the enlightened patriots of that country did not neglect to procure him all the literary ſuccours of which he ſtood in need, he could not be long happy in a ſemi-barbarous nation, in which liberty was ſuffered to expire under the intrigues of Ruſſia and Pruſſia.

On this, with wonderful conſiſtency, the man who could not endure the deſpotiſm of Heſſe, or even the ariſtocracy of England, accepted of the propoſitions of that friend to liberty Catharine II.; who, jealous of every ſpecies of glory, wiſhed to ſignalize her reign, by procuring to the Ruſſian nation the honour of undertaking, after the example of England and France, a new voyage of diſcovery round the world. Unfortunately for the progreſs of knowledge, the war with the Ottoman Porte occaſioned the miſcarriage of this uſeful project.

But Forſter could not long remain in obſcurity. The different publications with which he occaſionally enriched natural hiſtory and literature, encreaſed his reputation. The Elector of Mentz accordingly appointed him preſident of the univerſity of the ſame name; and he was diſcharging the functions of his new office when the French troops took poſſeſſion of the capital. This philoſophical traveller, who had ſtudied ſociety under all the various aſpects ariſing from different degrees of civilization; who had viewed man ſimple and happy at Otaheite;—an eater of human fleſh in New Zealand, corrupted by commerce in England, depraved in France by luxury and atheiſm, in Brabant by ſuperſtition, and in Poland by anarchy;—beheld with wild enthuſiaſm the dawnings of the French revolution, and was the firſt, ſays M. Pougens, to promulgate republicaniſm in Germany.

The *Mayencois*, who had formed themſelves into a national convention, ſent him to Paris, in order to ſolicit their *reunion* with the French republic. But, in the courſe of his miſſion, the city of Mentz was beſieged and retaken by the Pruſſian troops. This event occaſioned the loſs of all his property; and what was ſtill more diſaſtrous, that of his numerous manuſcripts, which fell into the hands of the Prince of Pruſſia.

Our biographer, after conducting his hero through theſe ſcenes of public life, proceeds to give us a view of his domeſtic habits and private principles. He tells us, that he formed a connection (whether a marriage or not, the ſtudied ambiguity of his language leaves rather uncertain) with a young woman named *Thereſa Hayne*, who, by the illumination of French philoſophy, had diveſted herſelf of all the prejudices which, we truſt, the ladies of this country ſtill conſider as their honour, as they are certainly the guardians of domeſtic peace. Miſs Hayne was indignant at the very *name of duty*. With Eloiſa ſhe had taken it into her head that

> Love, free as air, at ſight of human ties,
> Spreads his light wings, and in a moment dies.

She was frank enough, however, ſays our author, to acknowledge the errors of her imagination; and from this expreſſion, and his calling her afterwards Forſter's wife, we are led to ſuppoſe that ſhe was actually married to him. But their union, of whatever kind, was of ſhort duration. Though the lady is ſaid to have been paſſionately attached to celebrated names, the *name* of George Forſter was not ſufficient to ſatisfy her. He ſoon ceaſed, we are informed, to *pleaſe* her; ſhe therefore transferred her affections to another; and, as was very natural for a woman who was indignant at the name of duty, ſhe proved falſe to her huſband's bed. Forſter, however, pretended to be ſuch a friend to the *modern* rights of men and women, that he defended the character of his Thereſa againſt crowds who condemned her conduct. Nay, we are told, that he conſidered himſelf, and every other huſband who ceaſes to pleaſe, as the *adulterer of nature*. He therefore laboured ſtrenuouſly to obtain a divorce, to enable Thereſa Hayne to eſpouſe the man whom ſhe preferred to himſelf. Strange, however, to tell, the prejudices even of this Coſmopolite were too ſtrong for his principles. While he was endeavouring to procure the divorce, he made preparations at the ſame time, by the ſtudy of the oriental languages, to undertake a journey to Thibet and Indoſtan, in order to remove from that part of the world, in which both his heart and his perſon had experienced ſo ſevere a ſhock. But the chagrin occaſioned by his misfortunes, joined to a ſcorbutic affection, to which he had been long ſubject, and which he had contracted at ſea during the voyage of circumnavigation, abridged his life, and prevented him from realiſing this double project. He died at Paris, at the age of 39, on the 13th of February 1792.

This is a ſtrange tale; but we truſt it will not prove uſeleſs. The latter part of it at leaſt ſhows, that when men diveſt themſelves of the principles of religion, they ſoon degenerate from the dignity of philoſophers to the level of mere ſenſualiſts; and that the woman who can, in defiance of decorum and honour, transfer her affections and her perſon from man to man, ranks no higher in the ſcale of being than a female brute of more than common ſagacity. It ſhews likewiſe, that the contempt of our modern ſages for thoſe partial attachments which unite individuals in one family, is a mere pretence; that the dictates of nature will be heard; and the laws of nature's God obeyed. George Forſter, though he was ſuch a zealous advocate for liberty and equality, as to vindicate the adultery of his wife; yet felt ſo ſenſibly the wound which her infidelity inflicted on his honour, that he could not ſurvive it, but periſhed, in conſequence, in the flower of his age.

Royal FORT, is one whoſe line of defence is at leaſt 26 fathoms long.

Star Fort, is a ſconce or redoubt, conſtituted by re-entering and ſaliant angles, having commonly from five to eight points, and the ſides flanking each other.

FOSSIL-Meal, otherwiſe called *lac lune*, mineral argaric,

argaric, and guhr, is, according to M. Fabbroni, a mixed earth, which exhales an argillaceous odour, and throws out a light whitiſh ſmoke when ſprinkled with water. It is abundant in Tuſcany, where it is employed for cleaning plate. It does not efferveſce with acids; is infuſible in the fire, in which it loſes an eighth part of its weight, though it becomes ſcarcely diminiſhed in bulk; and, according to the analyſis made by M. Fabbroni, conſiſts of the following component parts: Siliceous earth 55, magneſia 15, water 14, argil 12, lime 3, iron 1. With this earth, which is found near Caſteldelpiano in the territories of Sienna, M. Fabbroni compoſed bricks, which, either baked or unbaked, floated in water. Hence he infers, that the floating bricks, which Pliny mentions as peculiar to Maſſilua and Calento, two cities in Spain, muſt have been made of foſſil meal. Bricks made of that ſubſtance reſiſt water exceedingly well, and unite perfectly with lime; they are ſubject to no alteration either by heat or cold; and about a twentieth part of argil may be added with advantage to their compoſition, without depriving them of the property of floating. M. Fabbroni tried their reſiſtance, and found it very little inferior to that of common bricks; but it is much greater in proportion to their lightneſs. One of theſe bricks, ſeven inches in length, four and a half in breadth, and one inch eight lines in thickneſs, weighed only 14¼th ounces; whereas a common brick weighed 5 pounds 6¾ths ounces.

Bricks of foſſil-meal may be of important benefit in the conſtruction of reverberating furnaces; as they are ſuch bad conductors of heat, that a perſon may bring one half of them to a red heat, while the other is held in the hand. They may be employed alſo for buildings that require to be light; for conſtructing cooking places on board ſhips; and alſo floating batteries, the parapets of which, if made of theſe bricks, would be proof againſt red hot bullets; and, laſtly, for conſtructing powder magazines.

FOULAHS, or Foolahs, a people in Africa, inhabiting a country on the confines of the great deſert (ſee Sahara in this *Suppl.*), along the parallel of nine degrees north. They partake much of the negro form and complexion; but have neither the *jetty* colour, *thick* lips, nor *criſped* hair of the negroes. They have alſo a language diſtinct from the Mandinga, which is the prevailing one in this quarter. The Foulahs occupy, at leaſt as ſovereigns, ſeveral provinces or kingdoms, interſperſed throughout the tract comprehended between the mountainous border of the country of Sierra Leona on the weſt, and that of Tombuctoo on the eaſt; as alſo a large tract on the lower part of the Senegal river; and theſe provinces are inſulated from each other in a very remarkable manner. Their religion is Mahomedaniſm; but with a great mixture of Paganiſm, and with leſs intolerance than is practiſed by the Moors.

The principal of the Foulah ſtates is that within Sierra Leona; and of which Teemboo is the capital. The next in order appears to be that bordering on the ſouth of the Senegal river, and on the Jaloffs; this is properly named Siratik. Others of leſs note are Bondou, with Foota-Torra adjacent to it, lying between the rivers Gambia and Falemé; Foola-doo and Brooko along the upper part of the Senegal river; Waſſela beyond the upper part of the Niger; and Maſſina lower down on the ſame river, and joining to Tombuctoo on the weſt.

The kingdom of the Foulahs, ſituated between the upper part of the Gambia river and the coaſt of Sierra Leona, and along the Rio Grande, is governed by a Mahometan ſovereign; but the bulk of the people appear to be Pagans. From the circumſtances of their long hair, their lips, and comparatively light colour, Major Rennel is decidedly of opinion, that the Foulah's are the Leucæthiops of Ptolemy and Pliny. The former, as he obſerves, places the Leucæthiops in the ſituation occupied by the Foulahs; and by the name which he gave them, he evidently meant to deſcribe a people *leſs* black than the generality of the Ethiopians. Hence it may be gathered that this nation had been traded with, and that ſome notices reſpecting it had been communicated to Ptolemy. It may alſo be remarked, that the navigation of Hanno terminated on this coaſt; and as this was alſo the term of Ptolemy's knowledge, it may juſtly be ſuſpected that this part of the coaſt was deſcribed from Carthaginian materials.

Thoſe who have peruſed the Journal of Meſſrs Watt and Winterbottom through the Foulah country in 1794, and recollect how flattering a picture they give of the urbanity and hoſpitality of the Foulah's, will be gratified on finding that this nation was known and diſtinguiſhed from the reſt of the Ethiopians at a remote period of antiquity.

The contraſt between the Mooriſh and Negro characters is as great as that between the nature of their reſpective countries, or between their form and complexion. The Moors appear to poſſeſs the vices of the Arabs without their virtues; and to avail themſelves of an intolerant religion, to oppreſs ſtrangers: whilſt the Negroes, and eſpecially the Mandingas, unable to comprehend a doctrine that ſubſtitutes opinion or belief for the ſocial duties, are content to remain in their humble ſtate of ignorance. The hoſpitality ſhewn by theſe good people to Mr Park, a deſtitute and forlorn ſtranger, raiſes them very high in the ſcale of humanity: and I know of no fitter title, ſays Mr Rennel, to confer on them than that of the *Hindoos of Africa*; at the ſame time, by no means intending to degrade the Mahomedans of India by a compariſon with the African Moors.—See *Major Rennels Geographical Illuſtrations of Mr Park's Journey, and of North Africa at large*, printed for the African Aſſociation.

FRANCAIS (Port des), the name given by Perouſe to a bay, or rather harbour, which he undoubtedly diſcovered on the north-weſt coaſt of America. It is ſituated, according to him, in 58° 37′ N. Lat. and in 139° 50′ W. Long. from Paris. When the two frigates which he commanded approached it, as they were ſtretching along the coaſt from ſouth to north, he perceived from his ſhip a great reef of rocks, behind which the ſea was very calm. This reef appeared to be about three or four hundred toiſes in length from eaſt to weſt, and to be terminated, at about two cables length, by the point of the continent, leaving a pretty large opening; ſo that Nature ſeemed to have made, at the extremity of America, a harbour like that of Toulon, only more vaſt in her deſigns and in her means: this new harbour was three or four leagues deep.

Some officers, who had been diſpatched in boats to reconnoitre this harbour, gave a report of it extremely favourable;

Francais.

favourable; and on the 3d of July 1786, the two frigates entered it, and anchored near its mouth in three fathoms and a half, rocky bottom. The bay, however, was quickly ſounded, and much better anchoring ground diſcovered at an iſland in the middle of it, where the ſhips might ride in 20 fathoms water with muddy bottom. This ground was taken poſſeſſion of, an obſervatory erected on the iſland, which was only a muſket ſhot from the ſhips, and a ſettlement formed for their ſtay in the harbour. From a report made by one of the officers who had penetrated towards the bottom of the bay, Perouſe had conceived the idea of finding perhaps a channel by which he might proceed into the interior of America; but he was diſappointed. The bottom of the bay, indeed, according to him, is one of the moſt extraordinary places in the world. It is a baſon of water, of a depth in the middle that could not be fathomed, bordered by peaked mountains of an exceſſive height, covered with ſnow, without a blade of graſs upon this immenſe collection of rocks, condemned by Nature to perpetual ſterility. "I never (ſays he) ſaw a breath of air ruffle the ſurface of this water; it is never troubled but by the fall of enormous pieces of ice, which continually detach themſelves from five different glaciers, and which in falling make a noiſe that reſounds far in the mountains. The air is in this place ſo very calm, and the ſilence ſo profound, that the mere voice of a man may be heard half a league off, as well as the noiſe of ſome ſea birds which lay their eggs in the cavities of theſe rocks."

It was at the extremity of this bay that he was in hopes of finding a paſſage into the interior of America. He imagined that it might terminate in a great river, of which the courſe might lie between two mountains; and that this river might take its ſource in the great lakes to the northward of Canada. Two channels were indeed found, ſtretching, the one to the eaſt, and the other to the weſt; but both were very ſoon terminated by immenſe glaciers.

In Port des Français the variation of the compaſs is 28° eaſt, and the dip of the needle 74°. The ſea riſes there ſeven feet and a half at full and change of the moon, when it is high water at one o'clock. The ſea breezes, or perhaps other cauſes, act ſo powerfully upon the current of the channel, that M. Perouſe ſaw the flood come in there like the moſt rapid river; while, in other circumſtances, at the ſame period of the moon, it may be ſtemmed by a boat. In this channel he loſt two ſhallops and twenty men. In his different excurſions, he found the high water mark to be about 15 feet above the ſurface of the ſea. Theſe tides are probably incident to the bad ſeaſon. When the winds blow with violence from the ſouthward, the channel muſt be impracticable, and at all times the currents render the entrance difficult; the going out of it alſo requires a combination of circumſtances, which may retard the departure of a veſſel many weeks; there is no getting under way but at the top of high water; the breeze from the weſt to the north-weſt does not often riſe till toward eleven o'clock, which does not permit the taking advantage of the morning tide; finally, the eaſterly winds, which are contrary, appeared to him to be more frequent than thoſe from the weſt, and the vaſt height of the ſurrounding mountains never permits the land breezes, or thoſe from the north, to penetrate into the road.

Francais

As this port poſſeſſes great advantages, M. Perouſe thought it a duty incumbent on him to make its inconveniences alſo known. It ſeemed to him that this anchorage is not convenient for thoſe ſhips which are ſent out at a venture for trafficking in ſkins; ſuch ſhips ought to anchor in a great many bays, and always make the ſhorteſt ſtay poſſible in any of them; becauſe the Indians have always diſpoſed of their whole ſtock in the firſt week, and all loſt time is prejudicial to the intereſts of the owners: but a nation which ſhould form the project of eſtabliſhing factories ſimilar to thoſe of the Engliſh in Hudſon's Bay, could not make choice of a place more proper for ſuch a ſettlement. A ſimple battery of four heavy cannon, placed upon the point of the continent, would be fully adequate to the defence of ſo narrow an entrance, which is alſo made ſo difficult by the currents. This battery could not be turned or taken by land, becauſe the ſea always breaks with ſuch violence upon the coaſt, that to diſembark is impoſſible. The fort, the magazines, and all the ſettlements for commerce, ſhould be raiſed upon Cenotaph Iſland (A), the circumference of which is nearly a league: it is capable of being cultivated, and there is plenty of wood and water. The ſhips not having their cargo to ſeek, but being certain of having it collected to a ſingle point, would not be expoſed to any delay: ſome buoys, placed for the internal navigation of the bay, would make it extremely ſafe and eaſy. The ſettlement would form pilots, who, better verſed than we are in the ſet and ſtrength of the current at particular times of tide, would enſure the entrance and departure of the ſhips. Finally, continues the author, our traffic for otters ſkins has been ſo very conſiderable, that I may fairly preſume there could not, in any part of America, be a greater quantity of them collected.

The climate of this coaſt ſeemed to Perouſe much milder than that of Hudſon's Bay in the ſame latitude. Pines were meaſured of ſix feet diameter, and 140 high; while thoſe of the ſame ſpecies at Prince of Wales's Fort and Fort York, are of a dimenſion ſcarce ſufficient for ſtudding ſail-booms. Vegetation is alſo very vigorous during three or four months of the year; and our author thinks, that Ruſſian corn, as well as many common plants, might thrive exceedingly at Port des Français, where was found great abundance of celery, lupine, the wild pea, yarrow, and andive. Among theſe pot herbs were ſeen almoſt all thoſe of the meadows and mountains of France; ſuch as the angelica, the butter cup, the violet, and many ſpecies of graſs proper for fodder. The woods abound in gooſeberries, raſpberries, and ſtrawberries; cluſters of elder trees, the dwarf willow, different ſpecies of briar which grow in the ſhade, the gum poplar tree, the poplar, the ſallow, the horn-beam; and, finally, ſuperb pines, fit for the maſts.

(A) This name was given to the iſland in the bay from the monument erected on it to the memory of their unfortunate companions.

moſts of our largeſt ſhips. Not any of the vegetable productions of this country are unknown in Europe. M. de Martinière, in his different excurſions, met with only three plants which he thought new; and it is well known, that a botaniſt might do the ſame in the vicinity of Paris.

The rivers were filled with trout and ſalmon; and as the Indians ſold theſe fiſh to the French in greater quantities than they could conſume, they had very little fiſhing in the bay, and that only with the line. They caught ſome ling, a ſingle thornback, ſome plaice, *fletans* or *faitans*, of which ſome were more than 100 pounds in weight (b), and a fiſh reſembling the whiting, but a little larger, which abounds on the coaſt of Provence, where it is known by the name of *poor prieſt*. Perouſe calls theſe fiſh *capelans*. In the woods they met with bears, martens, and ſquirrels; but they ſaw no great variety of birds, though the individuals were very numerous.

" If the animal and vegetable productions of this country reſemble thoſe of a great many others, its appearance (ſays our author) can be compared to nothing. The views which it preſents are more frightful than thoſe of the Alps and the Pyrenees; but at the ſame time ſo pictureſque, that they would deſerve the viſits of the curious, were they not at the extremity of the world. The primitive mountains of granite or ſchiſtus, perpetually covered with ſnow, upon which are neither trees nor plants, have their foundation in the ſea, and form upon the ſhore a kind of quay; their ſlope is ſo rapid, that after the firſt two or three hundred toiſes, the wild goats cannot climb them; and all the gullies which ſeparate them are immenſe glaciers, of which the tops cannot be diſcerned, while the baſe is waſhed by the ſea. At a cable's length from the land there is no bottom at leſs than 160 fathoms. The ſides of the harbour are formed by ſecondary mountains, the elevation of which does not exceed from 800 to 900 toiſes; they are covered with pines, and overſpread with verdure, and the ſnow is only ſeen on their ſummits: they appeared to be entirely formed of ſchiſtus, which is in the commencement of a ſtate of decompoſition; they are extremely difficult to climb, but not altogether inacceſſible.

" Nature aſſigns inhabitants to ſo frightful a country, who as widely differ from the people of civilized countries as the ſcene which has juſt been deſcribed differs from our cultivated plains; as rude and barbarous as their ſoil is rocky and barren, they inhabit this land only to deſtroy its population: at war with all the animals, they deſpiſe the vegetable ſubſtances that grow around them. I have ſeen (ſays our author) women and children eat ſome raſpberries and ſtrawberries; but theſe are undoubtedly viands far too inſipid for men, who live upon the earth like vultures in the air, or wolves and tigers in the foreſts.

" Their arts are ſomewhat advanced, and in this reſpect civilization has made conſiderable progreſs; but that which ſoftens their ferocity, and poliſhes their manners, is yet in its infancy. The mode of life they purſue excluding all kind of ſubordination, they are continually agitated by fear or revenge; prone to anger, and eaſily irritated, they are continually attacking each other dagger in hand. Expoſed in the winter to periſh for want, becauſe the chaſe cannot be ſucceſsful, they live during the ſummer in the greateſt abundance, as they can catch in leſs than an hour a ſufficient quantity of fiſh for the ſupport of their family; they remain idle during the reſt of the day, which they paſs at play, to which they are as much addicted as ſome of the inhabitants in our great cities. This gaming is the great ſource of their quarrels. If to all theſe deſtructive vices they ſhould unfortunately add a knowledge of the uſe of any inebriating liquor, M. Perouſe does not heſitate to pronounce, that this colony would be entirely annihilated."

Like all other ſavages, they are incorrigible thieves; and when they aſſumed a mild and placid appearance, the Frenchmen were ſure that they had ſtolen ſomething. Iron, of which they appeared to know the uſe, and of courſe the value, moſt excited their cupidity; and when our navigators were engaged in careſſing a child, the father was ſure to ſeize the opportunity of taking up, and concealing under his ſkin-garment, every thing of that metal which lay within his reach, and was not too heavy to be carried off.

M. Rollin, ſurgeon major of one of the frigates, thus deſcribes theſe people. " They have very little ſimilarity to the Californians; they are taller, ſtouter, of a more agreeable figure, and greater vivacity of expreſſion: they are alſo much their ſuperiors in courage and ſenſe. They have rather a low forehead, but more open than that of the Southern Americans; their eyes are black and very animated; their eyebrows much fuller; their noſe of the uſual ſize, and well formed, except being a little widened at the extremity; their lips thinner; their mouth moderately large; their teeth fine and very even; their chin and ears very regular.

" The women alſo have an equal advantage over thoſe of the preceding tribes; they have much more mildneſs in their features and grace in their limbs.—Their countenance would be even very agreeable, if, in order to ſet it off, they did not make uſe of a ſtrange cuſtom of wearing in the lower lip an elliptical piece of wood, lightly grooved on its circumference and both its ſides, and which is commonly half an inch thick, two in diameter, and three in length.

" This ſingular ornament, beſides being a great deformity, is the cauſe of a very troubleſome as well as diſguſting involuntary flow of ſaliva. This appendage is peculiar to the women; and female children are made to undergo the preparatory operations from the time of their birth. For this purpoſe, the lower lip is pierced with a kind of pin of copper or gold, which is either left in the opening, or its place ſupplied with a ring of the ſame material, till the period of puberty. The aperture is then gradually enlarged, by ſubſtituting firſt a ſmall piece of wood of the form mentioned above, then a larger one; and ſo on, increaſing its ſize by degrees till it reaches the dimenſions juſt ſtated.

" This extraordinary cuſtom ſhews the great power of dilatation in the lip, and may encourage medical prac-

---

(b) This is a flat fiſh, longer and not ſo ſquare as the turbet. Its back is covered with ſmall ſcales; and thoſe which are taken in Europe are much leſs than the fletans of Port des Français.

titioners in their attempts to remedy deformities of this part by the uſe of the knife.

“ The general colour of theſe people is olive, a fainter tinge of which is apparent in their nails, which they ſuffer to grow very long; the hue of the ſkin, however, varies in different individuals, and in various parts of the ſame individual, according to their expoſure to the action of the air and ſun.

“ Their hair is, in general, neither ſo coarſe nor black as that of the South Americans. Cheſnut coloured hair is by no means unfrequent among them. Their beard is alſo fuller, and their armpits and parts of ſex better provided with hair.

“ The perfect evenneſs of their teeth led me at firſt to ſuſpect that it was the effect of art; but after an attentive and minute examination, I could perceive no wearing away of the enamel, and I ſaw that this regularity is natural. They tattoo and paint their face and body, and bore their ears and the cartilage of their noſe.

“ Some writers have imagined, that the cuſtom of painting the face and body, ſo generally adopted by the Africans, Americans, and Weſt Indians, is only intended as a preſervative againſt noxious inſects. I think, however, that I am warranted in aſſerting its ſole end to be ornament. I found it to prevail among the inhabitants of Eaſter Iſland and the natives of *Port des Français*, without obſerving among them either venomous inſects or reptiles. Beſides, I remarked that they wore paint only when they paid us a viſit; for they made no uſe of it when in their own houſes.”

M. Perouſe himſelf ſpeaks not ſo favourably of the women as M. Rollin. “ They are (he ſays) the moſt diſguſting of any on the earth, covered with ſtinking ſkins, which are frequently untanned; and yet they failed not to excite deſires in ſome perſons, in fact of no ſmall conſequence: they at firſt ſtarted many difficulties, giving aſſurances by their geſtures that they ran the riſk of their lives; but being overcome by preſents, they had no objection to the ſun being a witneſs, and abſolutely refuſed to retire into the wood.” There can be no doubt that this planet is the god of theſe people, ſince they frequently addreſſed themſelves to it in their prayers; but our voyagers ſaw neither temple nor prieſt, nor the leaſt trace of public worſhip at ſtated times. They burn their dead.

FRE'GATES FRANÇAISE *Baſſe de*, the name given by La Perouſe to a dangerous reef of ſunken rocks which he diſcovered in the Pacific ocean. On the north-weſt extremity of this reef they perceived an iſlet or ſplit rock from 20 to 25 fathoms in height and about 50 toiſes in diameter. From this iſlet the reef extends more than four leagues to the ſouth-eaſt; and upon the extremity of the point in that direction, the frigates had almoſt ſtruck before the breakers were obſerved. This was during a fine clear night and ſmooth ſea. With great propriety, the Commodore returned in the morning to aſcertain the geographical ſituation of this unknown rock; and he eſtimated the iſlet to be in 23° 45′ N. Lat. and 168° 10′ W. Long. from Paris.

FRICTION, in mechanics, is a ſubject of great importance both to the practical engineer and to the ſpeculative philoſopher. It is therefore our duty to correct, in this Supplement, the miſtakes into which we fell when treating of that ſubject in the *Encyclopædia*. What we have there taught of friction (ſee MECHANICS, Sect. II. § 8.) is taken from Ferguſon; but it has been ſhewn by Mr Vince, that the experiments from which his concluſions were drawn were not properly inſtituted. That eminent mathematician and philoſopher therefore entered upon the inveſtigation of the ſubject anew, and endeavoured, by a ſet of experiments, to determine the following queſtions:

1. Whether friction be a uniformly retarding force?
2. The quantity of friction?
3. Whether the friction varies in proportion to the preſſure or weight?
4. Whether the friction be the ſame on whichever of its ſurfaces a body moves?

1. With reſpect to the firſt of theſe queſtions, the author truly obſerves, that if friction be a uniform force, the difference between it and the given force of the moving power employed to overcome it muſt alſo be uniform; and that therefore the moving power, if it be a body deſcending by its own weight, muſt deſcend with a uniformly accelerated velocity, juſt as when there was no friction. The ſpaces deſcribed from the beginning of the motion will indeed be diminiſhed in any given time on account of the friction; but ſtill they muſt be to each other as the ſquares of the times employed. See DYNAMICS in this *Supplement*.

2. A plane was therefore adjuſted parallel to the horizon, at the extremity of which was placed a pulley, which could be elevated or depreſſed, in order to render the ſtring which connected the body and the moving force parallel to the plane. A ſcale accurately divided was placed by the ſide of the pulley perpendicular to the horizon, by the ſide of which the moving force deſcended; upon the ſcale was placed a moveable ſtage, which could be adjuſted to the ſpace through which the moving force deſcended in any given time; which time was meaſured by a well-regulated pendulum clock vibrating ſeconds. Every thing being thus prepared, the following experiments were made to aſcertain the law of friction.

3. *Exp.* 1. A body was placed upon the horizontal plane, and a moving force applied, which, from repeated trials, was found to deſcend 52¼ inches in 4″; for by the beat of the clock, and the ſound of the moving force when it arrived at the ſtage, the ſpace could be very accurately adjuſted to the time: The ſtage was then removed to that point to which the moving force would deſcend in 3″, upon ſuppoſition that the ſpaces deſcribed by the moving power were as the ſquares of the times; and the ſpace was found to agree very accurately with the time: the ſtage was then removed to that point to which the moving force ought to deſcend in 2″, upon the ſame ſuppoſition, and the deſcent was found to agree exactly with the time: laſtly, the ſtage was adjuſted to that point to which the moving force ought to deſcend in 1″, upon the ſame ſuppoſition, and the ſpace was obſerved to agree with the time. Now, in order to find whether a difference in the time of deſcent could be obſerved by removing the ſtage a little above and below the poſitions which correſponded to the above times, the experiment was tried, and the deſcent was always found too ſoon in the former, and too late in the latter caſe; by which the author was aſſured, that the ſpaces firſt mentioned correſponded exactly to the times. And, for the greater certainty, each deſcent was repeated eight or ten times;

and

and every caution uſed in this experiment was alſo made uſe of in all the following.

Exp. 2. A ſecond body was laid upon the horizontal plane, and a moving force applied which deſcended $41\frac{3}{4}$ inches in 3″; the ſtage was then adjuſted to the ſpace correſponding to 2″, upon ſuppoſition that the ſpaces deſcended through were as the ſquares of the times, and it was found to agree accurately with the time; the ſtage was then adjuſted to the ſpace correſponding to 1″, upon the ſame ſuppoſition, and it was found to agree with the time.

Exp. 3. A third body was laid upon the horizontal plane, and a moving force applied, which deſcended $59\frac{5}{8}$ inches in 4″; the ſtage was then adjuſted to the ſpace correſponding to 3″, upon ſuppoſition that the ſpaces deſcended through were as the ſquares of the times, and it was found to agree with the time; the ſtage was then adjuſted to the ſpace correſponding to 2″, upon the ſame ſuppoſition, and it was found to agree with the time; the ſtage was then adjuſted to the ſpace correſponding to 1″, and was found to agree with the time.

Exp. 4. A fourth body was then taken and laid upon the horizontal plane, and a moving force applied, which deſcended 55 inches in 4″; the ſtage was then adjuſted to the ſpace through which it ought to deſcend in 3″, upon ſuppoſition that the ſpaces deſcended through were as the ſquares of the times, and it was found to agree with the time; the ſtage was then adjuſted to the ſpace correſponding to 2″, upon the ſame ſuppoſition, and was found to agree with the time; laſtly, the ſtage was adjuſted to the ſpace correſponding to 1″, and it was found to agree exactly with the time.

Beſides theſe experiments, a great number of others were made with hard bodies, or thoſe whoſe parts ſo firmly cohered as not to be moved *inter ſe* by the friction; and, in each experiment, bodies of very different degrees of friction were choſen, and the reſults all agreed with thoſe related above; we may therefore conclude, that the *friction of hard bodies in motion is a uniformly retarding force.*

But to determine whether the ſame was true for bodies when covered with cloth, woollen, &c. experiments were made in order to aſcertain it; when it was found, in all caſes, that the retarding force increaſed with the velocity; but, upon covering bodies with paper, the conſequences were found to agree with thoſe related above.

4. Having proved that the retarding force of all hard bodies ariſing from friction is uniform, the quantity of friction, conſidered as equivalent to a weight without inertia drawing the body on the horizontal plane backwards, or acting contrary to the moving force, may be immediately deduced from the foregoing experiments. For let M = the moving force expreſſed by its weight; F = the friction; W = the weight of the body upon the horizontal plane; S = the ſpace through which the moving force deſcended in the time t expreſſed in ſeconds; $r = 16\frac{1}{12}$ feet; then the whole accelerative force (the force of gravity being unity) will be $\frac{M-F}{M+W}$; hence, by the laws of uniformly accelerated motions, $\frac{M-F}{M+W} \times r t^2 = S$, conſequently $F = M - \frac{\overline{M \times W} \times S}{r t^2}$. To exemplify this, let us take the caſe of the laſt experiment, where $M = 7$, $W = 25\frac{3}{4}$, $S = 4\frac{7}{12}$ feet, $t = 4''$; hence $F = 7 - \frac{32\frac{3}{4} \times 4\frac{7}{12}}{16\frac{1}{12} \times 16} = 6.417$; conſequently the friction was to the weight of the rubbing body as 6.4167 to 25.75. And the great accuracy of determining the friction by this method is manifeſt from hence, that if an error of one inch had been made in the deſcent (and experiments carefully made may always determine the ſpace to a much greater exactneſs), it would not have affected the concluſion $\frac{1}{800}$dth part of the whole.

5. We come, in the next place, to determine whether friction, *cæteris paribus*, varies in proportion to the weight or preſſure. Now if the whole quantity of the friction of a body, meaſured by a weight without inertia equivalent to the friction drawing the body backwards, increaſes in proportion to its weight, it is manifeſt that the retardation of the velocity of the body ariſing from the friction will not be altered; for the retardation varies as $\frac{\text{Quantity of friction}}{\text{Quantity of matter}}$; hence, if a body be put in motion upon the horizontal plane by any moving force, if both the weight of the body and the moving force be increaſed in the ſame ratio, the acceleration ariſing from that moving force will remain the ſame, becauſe the accelerative force varies as the moving force divided by the whole quantity of matter, and both are increaſed in the ſame ratio; and if the quantity of friction increaſes alſo as the weight, then the retardation ariſing from the friction will, from what has been ſaid, remain the ſame, and therefore the whole acceleration of the body will not be altered; conſequently the body ought, upon this ſuppoſition, ſtill to deſcribe the ſame ſpace in the ſame time. Hence, by obſerving the ſpaces deſcribed in the ſame time, when both the body and the moving force are increaſed in the ſame ratio, we may determine whether the friction increaſes in proportion to the weight. The following experiments were therefore made in order to aſcertain this matter:

Exp. 1. A body weighing 10 oz. by a moving force of 4 oz. deſcribed in 2″ a ſpace of 51 inches; by loading the body with 10 oz. and the moving force with 4 oz. it deſcribed 56 inches in 2″; and by loading the body again with 10 oz. and the moving force with 4 oz. it deſcribed 63 inches in 2″.

Exp. 2. A body, whoſe weight was 16 oz. by a moving force of 5 oz. deſcribed a ſpace of 49 inches in 3″; and by loading the body with 64 oz. and the moving force with 20 oz. the ſpace deſcribed in the ſame time was 64 inches.

Exp. 3. A body weighing 6 oz. by a moving force of $2\frac{1}{2}$ oz. deſcribed 28 inches in 2″; and by loading the body with 24 oz. and the moving force with 10 oz. the ſpace deſcribed in the ſame time was 54 inches.

Exp. 4. A body weighing 8 oz. by a moving force of 4 oz. deſcribed $33\frac{1}{2}$ inches in 2″; and by loading the body with 8 oz. and the moving force with 4 oz. the ſpace deſcribed in the ſame time was 47 inches.

Exp. 5. A body whoſe weight was 9 oz. by a moving force of $4\frac{1}{2}$ oz. deſcribed 48 inches in 2″; and by loading the body with 9 oz. and the moving force with $4\frac{1}{2}$ oz. the ſpace deſcribed in the ſame time was 60 inches.

Exp. 6. A body weighing 10 oz. by a moving force of

3 oz.

3 oz. deſcribed 20 inches in 2″; by loading the body with 10 oz. and the moving force with 3 oz. the ſpace deſcribed in the ſame time was 31 inches; and by loading the body again with 30 oz. and the moving force with 9 oz. the ſpace deſcribed was 34 inches in 2″.

From theſe experiments, and many others which it is not neceſſary here to relate, it appears, that the ſpace deſcribed is always increaſed by increaſing the weight of the body and the accelerative force in the ſame ratio; and as the acceleration ariſing from the moving force continued the ſame, it is manifeſt, that the retardation ariſing from the friction muſt have been diminiſhed, for the whole accelerative force muſt have been increaſed on account of the increaſe of the ſpace deſcribed in the ſame time; and hence (as the retardation from friction varies as $\frac{\text{Quantity of friction}}{\text{Quantity of matter}}$) *the quantity of friction increaſes in a leſs ratio than the quantity of matter or weight of the body.*

6. We come now to the laſt thing which it was propoſed to determine, that is, whether the friction varies by varying the ſurface on which the body moves. Let us call two of the ſurfaces A and *a*, the former being the greater, and the latter the leſs. Now the weight on every given part of *a* is as much greater than the weight on an equal part of A, as A is greater than *a*; if therefore the friction was in proportion to the weight, *cæteris paribus*, it is manifeſt, that the friction on *a* would be equal to the friction on A, the whole friction being, upon ſuch a ſuppoſition, as the weight on any given part of each ſurface multiplied into the number of ſuch parts or into the whole area, which products, from the proportion above, are equal. But from the laſt experiments it has been proved, that the friction on any given ſurface increaſes in a leſs ratio than the weight; conſequently the friction on any given part of *a* has a leſs ratio to the friction on an equal part of A than A has to *a*, and hence the friction on *a* is leſs than the friction on A, that is, the ſmalleſt ſurface has always the leaſt friction.

As this concluſion is contrary to the generally received opinion, Mr Vince thought it proper to confirm it by a ſet of experiments made with different bodies of exactly the ſame degree of roughneſs on their two ſurfaces.

Exp. 1. A body was taken whoſe flat ſurface was to its edge as 22 : 9, and with the ſame moving force the body deſcribed on its flat ſide $33\frac{1}{2}$ inches in 2″, and on its edge 47 inches in the ſame time.

Exp. 2. A ſecond body was taken whoſe flat ſurface was to its edge as 32 : 3, and with the ſame moving force it deſcribed on its flat ſide 32 inches in 2″, and on its edge it deſcribed $37\frac{1}{2}$ inches in the ſame time.

Exp. 3. He took another body and covered one of its ſurfaces, whoſe length was 9 inches, with a fine rough paper, and by applying a moving force, it deſcribed 25 inches in 2″; he then took off ſome paper from the middle, leaving only $\frac{3}{8}$ths of an inch at the two ends, and with the ſame moving force it deſcribed 40 inches in the ſame time.

Exp. 4. Another body was taken which had one of its ſurfaces, whoſe length was 9 inches, covered with a fine rough paper, and by applying a moving force it deſcribed 42 inches in 2″; ſome of the paper was then taken off from the middle, leaving only $1\frac{3}{8}$ inches at the two ends, and with the ſame moving force it deſcribed 54 inches in 2″; he then took off more paper, leaving only $\frac{1}{4}$ of an inch at the two ends, and the body then deſcribed, by the ſame moving force, 60 inches in the ſame time.

In the two laſt experiments the paper which was taken off the ſurface was laid on the body, that its weight might not be altered.

Exp. 5. A body was taken whoſe flat ſurface was to its edge as 30 : 17; the *flat* ſide was laid upon the horizontal plane, a moving force was applied, and the ſtage was fixed in order to ſtop the moving force, in conſequence of which the body would then go on with the velocity acquired until the friction had deſtroyed all its motion; when it appeared from a mean of 12 trials that the body moved, after its acceleration ceaſed, $5\frac{2}{7}$ inches before it ſtopped. The *edge* was then applied, and the moving force deſcended through the ſame ſpace; and it was found, from a mean of the ſame number of trials, that the ſpace deſcribed was $7\frac{1}{7}$ inches before the body loſt all its motion, after it ceaſed to be accelerated.

Exp. 6. Another body was then taken whoſe flat ſurface was to its edge as 60 : 19, and by proceeding as before, on the flat ſurface it deſcribed, at a mean of 12 trials, $5\frac{1}{8}$ inches, and on the edge $6\frac{11}{24}$ inches, before it ſtopped, after the acceleration ceaſed.

Exp. 7. Another body was taken whoſe flat ſurface was to its edge as 26 : 3, and the ſpaces deſcribed on theſe two ſurfaces, after the acceleration ended, were, at a mean of ten trials, $4\frac{3}{7}$ and $7\frac{7}{10}$ inches reſpectively.

From all theſe different experiments it appears, that the ſmalleſt ſurface had always the leaſt friction, which agrees with the conſequence deduced from the conſideration that the friction does not increaſe in ſo great a ratio as the weight; we may therefore conclude, that *the friction of a body does not continue the ſame when it has different ſurfaces applied to the plane on which it moves, but that the ſmalleſt ſurface will have the leaſt friction.*

To the experiments inſtituted by Mr Ferguſon and others, from which concluſions have been drawn ſo different from theſe, our author makes the following objections: It was their object to find what moving force would *juſt* put a body at reſt in motion; and having, as they thought, found it, they thence concluded, that the accelerative force was then equal to the friction. But it is manifeſt, as Mr Vince obſerves, that any force which will put a body in motion muſt be *greater* than the force which oppoſes its motion, otherwiſe it could not overcome it; and hence, if there were no other objection than this, it is evident, that the friction could not be very accurately obtained: but there is another objection which totally deſtroys the experiment ſo far as it tends to ſhew the quantity of friction, which is the ſtrong coheſion of the body to the plane when it lies at reſt; and this is confirmed by the following experiments. *1ſt*, A body of $12\frac{3}{4}$ oz. was laid upon an horizontal plane, and then loaded with a weight of 8 lb. and ſuch a moving force was applied as would, when the body was juſt *put* in motion, continue that motion without any acceleration; in which caſe the friction muſt be juſt equal to the accelerative force. The body was then ſtopped, when it appeared that the ſame moving force which had *kept* the body in motion before,

fore, would not *put* it in motion, and it was found neceſſary to take off 4½ oz. from the body before the ſame moving force *would* put it in motion; it appears therefore, that this body, when laid upon the plane, at reſt, acquired a very ſtrong coheſion to it. 2*dly*, A body whoſe weight was 16 oz. was laid at reſt upon the horizontal plane, and it was found that a moving force of 6 oz. would juſt *put* it in motion; but that a moving force of 4 oz. *would*, when it was juſt put in motion, *continue* that motion without any acceleration, and therefore the accelerative force muſt *then* have been equal to the friction, and not when the moving force of 6 oz. was applied.

From theſe experiments, therefore, it appears how very conſiderable the coheſion was in proportion to the friction when the body was in motion; it being, in the latter caſe, almoſt ⅓d, and in the former it was found to be very nearly equal to the whole friction. All the concluſions therefore deduced from the experiments, which have been inſtituted to determine the friction from the force neceſſary to *put* a body in motion, have manifeſtly been totally falſe; as ſuch experiments only ſhew the reſiſtance which ariſes from the coheſion and friction conjointly.

Our author concludes this part of his ſubject with the following remark upon n° 5: "It appears from all the experiments (ſays he) which I have made, that the proportion of the increaſe of the friction to the increaſe of the weight was different in all the different bodies which were made uſe of; no general rule therefore can be eſtabliſhed to determine this for *all* bodies, and the experiments which I have hitherto made have not been ſufficient to determine it for the *ſame* body."

He then proceeds to eſtabliſh a theory upon the principles which he has deduced from his experiments. That theory is comprehended in five propoſitions, of which the object of the firſt is "to find the time of deſcent, and the number of revolutions made by a cylinder rolling down an inclined plane in conſequence of its friction.

II. "To determine the ſpace through which a body, projected on an horizontal plane with a given velocity, will move before it ſtops, or before its motion becomes uniform.

III. "To find the centre of friction.

IV. "To determine, from the given velocity with which a body begins to revolve about the centre of its baſe, the number of revolutions which that body will make before all its motion be deſtroyed.

V. "To find the nature of the curve deſcribed by any point of a body affected by friction when it deſcends down any inclined plane."

To give the ſolutions of theſe problems, with the corollaries deduced from them, would ſwell this article to very little purpoſe; for they would be unintelligible to the mere mechanic, and the mathematician will either ſolve them for himſelf, or have recourſe to the original memoir, where he will find ſolutions at once elegant and perſpicuous.

FRIGORIFIC Mixtures, are thoſe which experience has taught philoſophers to employ for the purpoſe of producing artificial cold. Some of theſe mixtures are enumerated, under the title Cold (*Encycl.*), and a much more accurate liſt of them is given, together with the principle upon which they produce their effect, in the article Chemistry, n° 282. (*Suppl.*). There is one mixture, however, not mentioned in that liſt, which was employed by Seguin, and ſeems, on many accounts, to be the moſt eligible that has yet been propoſed. Conſidering the muriats (ſee Chemistry-*Index, Suppl.*) as a claſs of ſalts beſt ſuited for the purpoſe, he gave the decided preference to muriat of lime in cryſtals; and his method was to mix the cryſtals, previouſly pulveriſed, with an equal weight of uncompreſſed ſnow.

By means of this mixture Mr W. H. Pepys junior, of the London Philoſophical Society, with the aſſiſtance of ſome friends, froze, on the 8th of February 1799, 56 lbs. averdupoiſe of mercury into a ſolid maſs. The mercury was put into a ſtrong bladder and well ſecured at the mouth, the temperature of the laboratory at the time being + 33°. A mixture conſiſting of muriat of lime 2 lb. at + 33°, and the ſame weight of ſnow at + 32° gave — 42° (a). The mercury was put as gently as poſſible into this mixture (to prevent a rupture of the bladder), by means of a cloth held at the four corners. When the cold mixture had robbed the mercury of ſo much of its heat as to have its own temperature thereby raiſed from — 42° to + 5, another mixture, the ſame in every reſpect as the laſt, was made, which gave, on trial with the thermometer, — 43°. The mercury was now received into the cloth, and put gently into this new mixture, where it was left to be cooled ſtill lower than before.

In the mean time five pounds of muriat of lime, in a large pail made of tinned iron, and japanned inſide and outſide, was placed in a cooling mixture in an earthenware pan. The mixture in the pan, which conſiſted of 4 lb. of muriat of lime and a like quantity of ſnow, of the ſame temperature as the former, in one hour reduced the 5 lb. of muriat in the pail to — 15°. The mixture was then emptied out of the earthen pan, and four large corks, at proper diſtances, placed on its bottom, to ſerve as reſts for the japanned pail which was now put into the pan. The corks anſwered the purpoſe of inſulating the inner veſſel, while the exterior one kept off the ſurrounding atmoſphere, and preſerved the air between the two at a low temperature.

To the 5 lb. of muriat of lime which had been cooled, as already noticed, to — 15°, and which ſtill remained in the metallic veſſel, was now added ſnow, uncompreſſed and free from moiſture, at the uſual temperature of + 32°. In leſs than three minutes the mixture gave a temperature of — 62°: a degree of cold which perhaps was never before produced in this country, being 94° below the freezing point of water.

The mercury, which, by immerſion in the ſecond cooling mixture to which it was expoſed, was by this time reduced to — 30°, was now, by the means employed before, cautiouſly put into the laſt-made mixture of the temperature of — 62°. A hoop with net-work faſtened to its upper edge, and of ſuch a breadth in the rim

---

(a) The thermometer made uſe of in this experiment was filled with tinged alcohol, and accurately divided according to Fahrenheit's ſcale.

Frigorific.

rim that the net-work, when loaded with the bladder of mercury, could not reach its lower edge, was at the bottom of the mixture, to prevent the bladder from coming in contact with the veſſel; by which means the mercury was ſuſpended in the middle of the mixture. As ſoon as the bladder was ſafely depoſited on the net-work, the veſſels were carefully covered over with a cloth, to impede the paſſage of heat from the ſurrounding atmoſphere into the freezing materials. The condenſation of moiſture from the atmoſphere by the agency of ſo low a temperature was greater than could have been expected: it floated like ſteam over the veſſels, and, but for the interpoſed covering, would have given the mixture more temperature than was deſirable.

After one hour and forty minutes they found, by means of a ſearcher introduced for the purpoſe, that the mercury was ſolid and fixed. The temperature of the mixture at this time was — 46, that is, 16° higher than when the mercury was put into it.

Our young philoſophers having neglected to fling the hoop and net-work in ſuch a manner as might have enabled them to lift it out of the mixture at once, with the bladder and its contents, were obliged to turn out the whole contents of the pail into a large evaporating capſule made of iron. This was not effected without the mercury ſtriking againſt its bottom and being fractured, though it received a conſiderable increaſe of temperature from the capſule. The fracture was ſimilar to that of zinc, but with parts more cubical. The larger pieces were kept for ſome minutes before fuſion took place, while others were twiſted and bent into various forms, to the no ſmall gratification and ſurpriſe of thoſe who never witneſſed or expected to ſee ſuch an effect produced on ſo fuſible a metal.

In experiments of the kind here deſcribed, all the exterior veſſels ſhould be of earthen-ware or wood, which being bad conductors of heat, prevent the ingredients from receiving heat from the atmoſphere and ſurrounding objects with the ſame facility that they would through metals; and, for a ſimilar reaſon, the interior veſſels are beſt of metal, that they may allow the heat to paſs more readily from the ſubſtance to be cooled into the frigorific mixture employed for that purpoſe.

Muriat of lime is certainly the moſt powerful, and at the ſame time the moſt economical ſubſtance that can be employed for producing artificial cold; for its firſt coſt is a mere trifle, being a reſiduum from many chemical proceſſes, as the diſtillation of pure ammonia, &c. and often thrown away: beſides, it may be repeatedly uſed for ſimilar experiments, nothing being neceſſary for this purpoſe but filtration and evaporation to bring it to its firſt ſtate. The evaporation ſhould be carried on till the ſolution becomes as thick as a ſtrong ſyrup, and upon cooling the whole will be cryſtalliſed: it muſt then be powdered, put up in dry bottles, well corked, and covered with bladder or cement to prevent liquefaction; which otherwiſe would ſoon take place, owing to the great affinity the muriat has for moiſture.

The powerful effects produced by the frigorific mixture of muriat of lime and ſnow, preſent a wide field for experiments to determine the poſſibility of fixing ſome of the gaſes by intenſe cold. And we are happy to be informed by Mr Pepys, that, as ſoon as an opportunity offers, he and his friends mean to make ſome experiments with that view, and to communicate the reſult of them to the editor of the valuable miſcellany * from which we have taken this account of his experiment on mercury.

Frio
‖
Fuel

* The Philoſophical Magazine.

FRIO, a ſmall iſland on the coaſt of the Brazils, ſituated in 32° 2′ ſouth lat. and 41° 31′ 45″ weſt lon. The land of Frio is high, with a hollow in the middle, which gives it, at a diſtance, the reſemblance of two ſeparate iſlands. The paſſage between the iſland and the continent is about a mile broad, and ſeemed to Sir Eraſmus Gower to be clear from ſhoals.

FROST, as is well known in Scotland, is particularly deſtructive to the bloſſom of fruit trees; and the following method of ſecuring ſuch trees from being damaged by early froſts may be acceptable to many of our readers. A rope is to be interwoven among the branches of the tree, and one end of it brought down ſo as to be immerſed in a bucket of water. The rope, it is ſaid, will act as a conductor, and convey the effects of the froſt from the tree to the water. This idea is not new; for the following paſſage may be found in Colerus: "If you dig a trench around the root of a tree, and fill it with water, or keep the roots moiſt till it has bloomed, it will not be injured by the froſt. Or, in ſpring, ſuſpend a veſſel filled with water from the tree. If you wiſh to preſerve the bloom from being hurt by the froſt, place a veſſel of water below it, and the froſt will fall into it." *Philoſophical Magazine*, n° 11.

FUEL, whatever is proper to burn, or make a fire, either for warming a room or dreſſing victuals. The fuel moſt generally uſed in Great Britain is pit-coal, which is a very expenſive article; and that expence is greatly increaſed by the waſte of coal occaſioned by the injudicious manner in which fires in open chimneys are commonly managed. The enormous waſte of fuel in London, for inſtance, may be eſtimated by the vaſt dark cloud which continually hangs over that great metropolis, and frequently overſhadows the whole country far and wide; for this denſe cloud is certainly compoſed almoſt entirely of unconſumed coal, which has eſcaped by the chimneys, and continues to ſail about in the air, till, having loſt the heat which gave it volatility, it falls in a dry ſhower of extremely fine black duſt to the ground, obſcuring the atmoſphere in its deſcent, and frequently changing the brighteſt day into more than Egyptian darkneſs.

"I never (ſays Court Rumford) view from a diſtance, as I come into town, this black cloud which hangs over London, without wiſhing to be able to compute the immenſe number of chaldrons of coals of which it is compoſed; for could this be aſcertained, I am perſuaded ſo ſtriking a fact would awaken the curioſity, and excite the aſtoniſhment of all ranks of the inhabitants; and perhaps turn their minds to an object of economy to which they have hitherto paid little attention."

The object to which the benevolent author more particularly wiſhes to direct the public attention, is the lighting of a coal fire, in which more wood ſhould be employed than is commonly uſed, and fewer coals; and as ſoon as the fire burns bright, and the coals are well lighted, and not before, more coals ſhould be added to increaſe the fire to its proper ſize.

Kindling balls, compoſed of equal parts of coal,—charcoal,—and clay, the two former reduced to a fine powder,

powder, well mixed and kneaded together, with the clay moiſtened with water, and then formed into balls of the ſize of hens eggs, and thoroughly dried, might be uſed with great advantage inſtead of wood for kindling fires. Theſe kindling balls may be made ſo inflammable as to take fire in an inſtant and with the ſmalleſt ſpark, by dipping them in a ſtrong ſolution of nitre, and then drying them again; and they would neither be expenſive nor liable to be ſpoiled by long keeping. Perhaps a quantity of pure charcoal, reduced to a very fine powder, and mixed with the ſolution of nitre in which they are dipped, would render them ſtill more inflammable.

The Count thinks that the fires which are made in the open chimneys of elegant apartments might be greatly improved by preparing the fuel; for nothing (ſays he) was ever more dirty, inelegant, and diſguſting, than a common coal fire.

Fire balls, of the ſize of gooſe eggs, compoſed of coal and charcoal in powder, mixed up with a due proportion of wet clay, and well dried, would make a much more cleanly, and in all reſpects a pleaſanter fire, than can be made with crude coals; and, he believes, would not be more expenſive fuel. In Flanders, and in ſeveral parts of Germany, and particularly in the duchies of Juliers and Bergen, where coals are uſed as fuel, the coals are always prepared before they are uſed, by pounding them to a powder, and mixing them up with an equal weight of clay, and a ſufficient quantity of water to form the whole into a maſs, which is kneaded together and formed into cakes; which cakes are afterwards well dried and kept in a dry place for uſe. And it has been found, by long experience, that the expence attending this preparation is amply repaid by the improvement of the fuel. The coals, thus mixed with clay, not only burn longer, but give much more heat than when they are burnt in their crude ſtate.

It will doubtleſs appear extraordinary to thoſe who have not conſidered the ſubject with ſome attention, that the quantity of heat produced in the combuſtion of any given quantity of coals ſhould be increaſed by mixing the coals with clay, which is certainly an incombuſtible body; but the phenomenon may be explained in a ſatisfactory manner.

The heat generated in the combuſtion of any ſmall particle of coal exiſting under two diſtinct forms, namely, in that which is combined with the flame and ſmoke which riſe from the fire, and which, if means are not found to ſtop it, goes off immediately by the chimney and is loſt—and the radiant heat which is ſent off from the fire in all directions in right lines:—It is therefore reaſonable to conclude, that the particles of clay, which are ſurrounded on all ſides by the flame, arreſt a part at leaſt of the combined heat, and prevent its eſcape; and this combined heat, ſo arreſted, heating the clay red hot, is retained in it, and being changed by this operation to radiant heat, is afterwards emitted, and may be directed and employed to uſeful purpoſes. In the compoſition of fire-balls, the Count thinks it probable that a certain proportion of chaff, of ſtraw cut very fine, or even of ſaw-duſt, might be employed with great advantage.

FULLING of woollen cloths (ſee the method of performing the operation under the article Fulling, *Encycl.*) depends, like Felting, ſo entirely upon the ſtructure of wool and hair, that the following obſervations, which are not unimportant, will be intelligible to every reader who has peruſed that article in this *Supplement*.

The aſperities with which the ſurface of wool is every where ſurrounded, and the diſpoſition which it has to aſſume a progreſſive motion towards the root, render the ſpinning of wool, and making it into cloth, difficult operations. In order to ſpin wool, and afterwards to weave it, we are obliged to cover its fibres with a coating of oil, which, filling the cavities, renders the aſperities leſs ſenſible; in the ſame way as oil, when rubbed over the ſurface of a very fine file, renders it ſtill leſs rough. When the piece of cloth is finiſhed, it muſt be cleanſed from this oil; which, beſides giving it a diſagreeable ſmell, would cauſe it to ſoil whatever it came in contact with, and would prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil, it is carried to the fulling-mill, where it is beat with hammers in a trough full of water, in which ſome clay has been mixed; the clay combines with the oil, which it ſeparates from the cloth, and both together are waſhed away by the freſh water which is brought to it by the machine; thus, after a certain time, the oil is entirely waſhed out of the cloth.

But the ſcouring of the cloth is not the only object in fulling it; the alternate preſſure given by the mallets to the piece of cloth, occaſions, eſpecially when the ſcouring is pretty far advanced, an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compoſe one of the threads, whether of the warp or the woof, aſſume a progreſſive movement, introduce themſelves among thoſe of the threads neareſt to them, then into thoſe which follow; and thus, by degrees, all the threads, both of the warp and the woof, become felted together. The cloth, after having, by the above means, become ſhortened in all its dimenſions, partakes both of the nature of cloth and of that of felt; it may be cut without being ſubject to ravel, and, on that account, we are not obliged to hem the edges of the pieces of which clothes are made. Laſtly, As the threads of the warp and thoſe of the woof are no longer ſo diſtinct and ſeparated from each other, the cloth, which has acquired a greater degree of thickneſs, forms a warmer clothing. Knit worſted alſo is, by fulling, rendered leſs apt to run, in caſe a ſtitch ſhould drop in it.

FULMINATING Gold. } See Chemistry, *Suppl.*
Fulminating Silver. } nos 849 and 850.

Mr Berthollet, the inventor of fulminating ſilver, having contented himſelf with a general and conciſe deſcription of this ſubject, many practical chemiſts have failed in their attempts to prepare it; and others, forming their opinions from the ſpecimens which they had made, have been expoſed to great danger; as will appear from the following relation:

An ounce of fine ſilver was diſſolved in the courſe of eight hours in an ounce of pure nitrous acid, of the London Pharmacopœia, diluted previouſly with three ounces of diſtilled water in a glaſs matraſs. The ſolution being poured off, the reſiduary black powder and the matraſs were waſhed with ſeven or eight ounces of warm diſtilled water, and this was added to the ſolution. The black powder, being gold, was rejected; ſome gold being thus ſeparable from any ſilver of commerce.

To the foregoing diluted ſolution, pure lime-water prepared with diſtilled water was added gradually; for the ſolution ought not to be poured into the lime water. When about thirty pints of lime-water had been expended, and the precipitate had ſubſided, more lime-water was added, by ſucceſſive pints, as long as it cauſed any precipitation. For it was deemed fitter that the precipitation ſhould not be perfected, than that an exceſs of lime-water ſhould be uſed; the earthy pellicle of the exceſſive lime-water being apt to mix with the precipitate. The clear liquor being poured away, the precipitate was poured off, and waſhed into a filter.

When the ſaline liquor had drained from it, two ounces of diſtilled water were poured on the magma; and when this water had paſſed, freſh portions were ſucceſſively added and paſſed, until the whole quantity of water thus expended in waſhing away the nitrous calcareous ſalt amounted to a quart.

The filter being then unfolded, to let the magma of oxide of ſilver ſpread on the flattened paper, it was placed on a chalk-ſtone to accelerate the exſiccation, and was gradually dried in the open air; a cap of paper being placed looſely over it to exclude the duſt.

When the weather ſerved, the cap was removed, to expoſe the oxide to the rays of the ſun; although this was not deemed neceſſary; and exſiccation was promoted by cutting the oxide into thin ſlices. When perfectly dry it weighed 1 oz. 4 dwts. and about one-fifth of it was conſidered as oxygen.

When aqua ammoniæ puræ of any pharmacopœia is uſed with this oxide, either in the ſmall quantity which blackens it completely, or in a greater quantity, the black matter which ſubſides, and which has been repreſented by ſyſtematic writers as the fulminating compound, has no ſuch property, any farther than may be owing to the matter depoſited from the alkaline ſolution during the exſiccation.

The alkaline liquor containing the fulminating ſilver ought to be poured off from the inſoluble powder, and expoſed in a ſhallow veſſel to the air. In conſequence of the exhalation, black ſhining cryſtals form on the ſurface only, and ſoon join to form a pellicle. As this pellicle adheres a little to the ſides of the veſſel, or maintains its figure, the liquor may be poured off by a gentle inclination of the veſſel.

This liquor will yield another pellicle in the ſame way; but the third or fourth pellicle will be paler than the former, and weaker in the exploſion. The firſt pellicles, when ſlowly dried, explode by the touch of a feather, or by their being heated to about 96°.

The quantity of water in the ordinary aqua ammoniæ puræ renders it leſs active in the ſolution of the oxide, and is an impediment to the ſpeedy formation and ſeparation of the fulminating ſilver; and an experimenter who has often uſed twenty grains of the oxide to produce ſucceſſive pellicles of fulminating ſilver, which may be ſeparately exploded with ſafety, and who has perceived that the pellicles never explode whilſt wet, if they be not heated, would, in all probability, reſolve on the following improvement, and expoſe himſelf to the unforeſeen danger of it.

Diſtilled water was impregnated with as much pure ammoniac as it could eaſily retain under the ordinary temperature of the air. A quantity of this ſtrong ammoniacal liquor, equal in bulk to a quarter of an ounce of water, was placed in a ſmall bottle, and 24 grains of the oxide of ſilver, ground to fine powder, were added. The bottle, being almoſt filled, was corked, to prevent the formation of that film which uſually appeared in conſequence of the exhalation of the ammoniac in other experiments.

During the ſolution of the oxide, bubbles of the gaſeous kind aroſe from it, and the ſolution acquired a blue colour. As no film appeared, the bottle was agitated three or four times in the courſe of as many hours, in order to promote the ſolution of a ſmall quantity of blackened oxide which remained at the bottom. The experimenter conſidering this as an ample proviſion for twenty different charges, to be exploded in different circumſtances, in the preſence of the ſociety, intended to pour off the ſolution into as many ſmall veſſels, and to weigh the reſiduary black powder, after allowing two hours more for the ſolution.

On the ſixth hour he took his uſual precaution of wearing ſpectacles; and obſerving that a ſmall quantity of black powder ſtill remained undiſſolved, and that no film was yet formed at the ſurface, he took the bottle by the neck to ſhake it; knowing that it might explode by the heat of his hand, if he were to graſp it, and that the exploſion in this circumſtance might wound him dangerouſly.

In the inſtant of ſhaking, it exploded with a report that ſtunned him. The bottle was blown into fragments ſo ſmall as to appear like glaſs coarſely powdered. The hand which held it was impreſſed as by the blow of a great hammer, and loſt the ſenſe of feeling for ſome ſeconds; and about 52 ſmall grains of glaſs were lodged, many of them deeply, in the ſkin of the palm and fingers. The liquor ſtained his whole dreſs, and every part of the ſkin that it touched. Thus it appeared that fulminating ſilver may be made which will explode even when cold and wet, by the mere diſturbance of the arrangement of its parts, in the aqueous fluid.

In ſubſequent experiments, privately and carefully conducted, it ſeemed that the property of exploding in the cold liquor, by mere commotion, depended on the unuſual quantity or poximity of the exploſive molecules in a given bulk of the liquor. And the flat bottoms, as well as the ſides, of the thick veſſels of glaſs or potters-ware, whether they ſtood on boards or iron plates, were always beaten to ſmall fragments.

This afforded a curious inſtance of the poſſible equilibrium between the powers tending to retain the caloric and thoſe which effect the expulſion of it; and experiments and conſiderations of this kind ſeemed to promiſe a true ſolution of the phenomena of Rupert's drops.

FUNCTION, a term uſed in analytics for an algebraical expreſſion, anyhow compounded of a certain letter or quantity with other quantities or numbers; and the expreſſion is ſaid to be a function of that letter or quantity. Thus $a - 4x$, or $ax + 3x^2$, or $2x - a\sqrt{a^2 - x^2}$, or x^c, or c^x, is each of them a function of the quantity x.

FURD-Y-HUCKEECUT, in Bengal, ſignifies a paper of deſcription.

Furd-y-Sowal, paper of requeſt.

FUST, in architecture, the ſhaft of a column, or the part comprehended between the baſe and the capital, called alſo the naked.

G.

Gaguedi.

GAGUEDI, a tree peculiar to Lamalmon, in Abyſſinia, is thus deſcribed by Mr Bruce. The leaves are long, and broader as they approach the end. The point is obtuſe; they are of a dead green, not unlike the willow, and placed alternately one above the other on the ſtalk. The calyx is compoſed of many broad ſcales lying one above the other, which operates by the preſſure upon one another, and keeps the calyx ſhut before the flower arrives at perfection. The flower is monopetalous, or made of one leaf; it is divided at the top into four ſegments; where theſe end, it is covered with a tuft of down, reſembling hair, and this is the caſe at the top alſo. When the flower is young and unripe, they are laid regularly ſo as to incloſe one another in a circle. As they grow old and expand, they ſeem to loſe their regular form, and become more confuſed, till at laſt, when arrived at its full perfection, they range themſelves parallel to the lips of the calyx, and perpendicular to the ſtamina, in the ſame order as a roſe. The common receptacle of the flower is oblong, and very capacious, of a yellow colour, and covered with ſmall leaves like hair. The ſtile is plain, ſimple, and upright, and covered at the bottom with a tuft of down, and is below the common receptacle of the flower.

Our author ſays that he has obſerved, in the middle of a very hot day, that the flowers unbend themſelves more, the calyx ſeems to expand, and the whole flower to turn itſelf towards the ſun in the ſame manner as does the ſunflower. When the branch is cut, the flower dries as it were inſtantaneouſly, ſo that it ſeems to contain very little humidity.

GALVANISM.

1
Galvaniſm improperly called *animal electricity*.

GALVANISM is the name now commonly given to the influence diſcovered nearly eight years ago by the celebrated Galvani, profeſſor of anatomy at Bologna, and which, by him and ſome other authors, has been called *animal electricity*. We prefer the former name, becauſe we think it by no means proved that the phenomena diſcovered by Galvani depend either upon the electric fluid, or upon any law of animal life. While that is the caſe, it is ſurely better to diſtinguiſh a new branch of ſcience by the name of the inventor, than to give it an appellation which probably may, and in our opinion certainy does, lead to an erroneous theory.

2
Diſcovery of galvaniſm.

M. Galvani was engaged in a ſet of experiments, the object of which was to demonſtrate, if poſſible, the dependence of muſcular motion upon electricity. In the courſe of this inveſtigation, he had met with ſeveral new and ſtriking appearances which were certainly electrical; ſoon after which, a fortunate accident led to the diſcovery of the phenomena which conſtitute the chief ſubject of this article. The ſtrong reſemblance which theſe bore to the electrical facts which he had before obſerved, led almoſt irreſiſtibly to the concluſion that they all depended upon the ſame cauſe. This opinion he immediately adopted; and his ſubſequent experiments and reaſonings were naturally directed to ſupport it. The ſplendor of his diſcovery dazzled the imaginations of thoſe who proſecuted the enquiry; and for ſome time his theory, in ſo far at leaſt as it attributed the whole to the agency of the electric fluid, was ſanctioned by univerſal approbation. Of late, however, this opinion has rather loſt ground; and there are now many philoſophers who conſider the phenomena as totally unconnected with electricity.

3
Object of this article.

We propoſe, in the *firſt* place, to enumerate the chief facts which have been aſcertained on the ſubject; we ſhall then enquire, whether or not the cauſe of the appearances be the electric fluid; and, *thirdly*, we ſhall examine how far it has been proved that this cauſe is neceſſarily connected with animal life.

Whilſt Galvani was one day employed in diſſecting a frog, in a room where ſome of his friends were amuſing themſelves with electrical experiments, one of them having happened to draw a ſpark from the conductor at the ſame time that the profeſſor touched one of the nerves of the animal, its whole body was inſtantly ſhaken by a violent convulſion. Aſtoniſhed at the phenomenon, and at firſt imagining that it might be owing to his having wounded the nerve, he pricked it with the point of his knife, to aſſure himſelf whether or not this was the caſe, but no motion of the frog's body was produced. He now touched the nerve with the inſtrument as at firſt, and directed a ſpark to be taken at the ſame time from the machine, on which the contractions were renewed. Upon a third trial, the animal remained motionleſs; but obſerving that he held his knife by the handle, which was made of ivory, he changed it for a metallic one, and immediately the movements took place, which never was the caſe when he uſed an electric ſubſtance.

After having made a great many ſimilar experiments with the electrical machine, he reſolved to proſecute the ſubject with atmoſpheric electricity. With this view he raiſed a conductor on the roof of his houſe, from which he brought an iron wire into his room. To this he attached metal conductors, connected with the nerves of the animals deſtined to be the ſubjects of his experiments; and to their legs he faſtened wires which reached the floor. Theſe experiments were not confined to frogs alone. Different animals, both of cold and warm blood, were ſubjected to them; and in all of them conſiderable movements were excited whenever it lightned. Theſe preceded thunder, and correſponded with its intenſity and repetition; and even when no lightning appeared, the movements took place when any ſtormy cloud paſſed over the apparatus. That all theſe appearances were produced by the electric fluid was obvious.

Having ſoon after this ſuſpended ſome frogs from the iron paliſades which ſurrounded his garden, by means of metallic hooks fixed in the ſpines of their backs, he obſerved that their muſcles contracted frequently and involuntarily as if from a ſhock of electricity. Not doubting that the contractions depended on the electric fluid, he at firſt ſuſpected that they were connected with changes in the ſtate of the atmoſphere. He ſoon found, however, that this was not the caſe; and having varied, in many different ways, the circumſtances in which the frogs were placed, he at length diſcovered that he could produce the movements at pleaſure by touching the animals with two different metals, which, at the ſame time, touched one another either immediately or by the intervention of ſome other ſubſtance capable of conducting electricity.

All the experiments that have yet been made may be reduced to the following, which will give the otherwiſe uninformed reader a preciſe notion of the ſubject.

Lay bare about an inch of a great nerve, leading to any limb or muſcle. Let that end of the bared part which is fartheſt from the limb be in cloſe contact with a bit of zinc. Touch the zinc with a bit of ſilver, while another part of the ſilver touches, either the naked nerve, if not dry, or, whether it be dry or not, the limb or muſcle to which it leads. Violent contractions are produced in the limb or muſcle, but not in any muſcle on the other ſide of the zinc.

Or, touch the bared nerve with a piece of zinc, and touch, with a piece of ſilver, either the bared nerve, or the limb; no convulſion is obſerved, till the zinc and ſilver are alſo made to touch each other.

4 Has engaged much ſcientific attention.

A fact ſo new, illuſtrated by many experiments and much ingenious reaſoning, which Profeſſor Galvani ſoon publiſhed, could not fail to attract the attention of phyſiologiſts all over Europe; and the reſult of a vaſt number of experiments, equally cruel and ſurpriſing, has been from time to time laid before the public by Valli, Fowler, Monro, Volta, Humboldt, and others.

Frogs, unhappily for themſelves, have been found the moſt convenient ſubjects for theſe experiments, as they retain their muſcular irritability and ſuſceptibility of the galvanic influence very long. Many hours after they have been decapitated, or have had their brain and ſpinal marrow deſtroyed, ſtrong convulſions can be produced in them by the application of the metals. A leg ſeparated from the body will often continue capable of excitement for ſeveral days. Nay, very diſtinct movements have been produced in frogs pretty far advanced in the proceſs of putrefaction. Different kinds of fiſhes, and many other animals both of cold and warm blood, have been ſubjected to ſimilar experiments, and have exhibited the ſame phenomena; but the warm blooded animals loſe their ſuſceptibility of galvaniſm, as of every other ſtimulus, very ſoon after death.

5 The metals.

Almoſt any two metals will produce the movements; but, it is believed, the moſt powerful are the following, in the order in which they are here placed: 1. Zinc; 2. Tin; 3. Lead; in conjunction with, 1. Gold; 2. Silver; 3. Molybdena; 4. Steel; 5. Copper. Upon this point, however, authors are not perfectly agreed.

The proceſs by which theſe ſingular phenomena are produced, conſiſts in effecting, by the uſe of the exciting apparatus, a mutual communication between any two points of contact, more or leſs diſtant from one another, in a ſyſtem of nervous and muſcular organs. The ſphere of this mutual communication may be regarded as a complete circle, divided into two parts.

6 Animal and excitatory arcs.

That part of it which conſiſts of the organs of the animal under the experiment, has been called *the animal arc*; that which is formed by the galvanic inſtruments has been called *the excitatory arc*. The latter uſually conſiſts of more pieces than one; of which ſome are named *ſtays*, *braces*, &c. others *communicators*, from their reſpective uſes.

7 Experiments of the French inſtitute.

A very numerous train of experiments on galvaniſm has been made by a committee of the Phyſical and Mathematical Claſs of the National Inſtitute of France; and as their report comprehends a vaſt number of the moſt important facts which are yet known on the ſubject, we ſhall preſent our readers with the ſubſtance of it (A).

The immenſe maſs of matter which reſulted from the experiments of the committee, is, in their report, preſented, not in the order in which the experiments were made, but in a ſort of claſſification, by means of which a more diſtinct knowledge of the ſubject is obtained at one view. The facts are arranged under theſe ſix heads. *1ſt*, Reſults of the different combinations and diſpoſitions of the parts of the *animal arc*. *2d*, Account of what has been obſerved of the nature and the different diſpoſitions of the *excitatory arc*. *3d*, Circumſtances not entering into the compoſition of the galvanic circle, which, nevertheleſs, by their influence, modify, alter, or entirely prevent the ſucceſs of the experiments. *4th*, Means propoſed for varying, diminiſhing, or reſtoring the ſenſibility to galvaniſm. *5th*, Attempts to compare the phenomena of galvaniſm with thoſe of electricity. *6th*, Additional experiments, performed by M. Humboldt, in the preſence of the members of the committee; which have a reference to ſeveral of the proofs ſtated in the foregoing articles.

8 On the animal arc.

I. To the number of twenty experiments were made on the *animal arc*. The firſt ſeven of theſe were directed to aſcertain the relations between the nerves and thoſe muſcles over which they are diſtributed. In the laſt thirteen, the nerves were cut aſunder, or ſubjected to ligatures; the ſection or ligature being always between the extremities of the arc. Nerves taken from different animals, or from different parts of the ſame animal, and joined in one and the ſame arc, were among the particular ſubjects of theſe experiments; as were alſo the ſolitary nerve, and the ſolitary muſcle, included between the extremities of the *excitatory arc*. There were interpoſed, too, in the courſe of theſe experiments, portions of nerves, and of muſcles, diſtinct from thoſe parts. And, in ſome of the experiments, the animal was without the ſkin and the epidermis.

The following are inferences which have been deduced from theſe experiments:

9 Inferences.

1. The animal arc may conſiſt either of nerves and muſcles together, or of nerves alone, without muſcles (B).

2. Nerves are, therefore, the eſſential part of the animal

(A) The members of the committee were, M. M. Coulomb, Sabbatier, Pelletan, Charles, Fourcroy, Vauquelin, Guyton, *alias* Morveau, and Hallé. M. M. Venturi, De Modene, and M. Humboldt, aſſiſted in the experiment.

(B) We are ſtrongly inclined to doubt the truth of this propoſition. Dr Fowler was at firſt led to think that contractions could be excited in a limb without the metals having any communication with it, except through the medium of the nerve. Recollecting, however, that a very ſmall quantity of moiſture ſerves as a conductor of galvaniſm, he ſuſpected, and our opinion perfectly coincides with his, that in every caſe where contractions are nimal arc; for the muſcles are always more or leſs interſected by the nerves; and are, conſequently, in part, a nervous organ.

3. All the parts of the animal arc muſt be either mutually continuous, or at leaſt contiguous to one another. But even contiguity is ſufficient to enable the galvanic phænomena to take place.

4. The ſection or ligature of a nerve interrupts not the galvanic phenomena, if the parts which are cut aſunder or bound up ſtill remain in cloſe contiguity to one another.

5. No diverſity of the parts forming the animal arc, though theſe be taken from different parts of the ſame animal, or even from different animals, will have power to impair its galvanic ſuſceptibility, provided only that theſe parts be ſtill mutually contiguous.

6. If the *integrity* or galvanic ſuſceptibility of the animal arc be ſuſpended by the ſeparation of any of its parts to ſome diſtance from one another, it may be reſtored by the interpoſition of ſome ſubſtances, not of an animal nature, between the divided parts. Metallic ſubſtances are in particular fit for this uſe. But the mutual contiguity of all the ſubſtances entering into the compoſition of the arc muſt ever be carefully preſerved. Mr Humboldt diſcovered that a bit of freſh morelle (*Helvella mitra Linn.*) will ſupply the place of a part of the nerve.

7. The muſcular organs which indicate, by contraction, the preſence of the galvanic influence, are always thoſe in which the nerves of a complete animal arc have their ultimate termination.

From this it follows, that the muſcles affected by galvaniſm are always thoſe correſponding to that extremity of the arc which is the moſt remote from the origin of the nerves of which it is compoſed.

8. When all the nerves of the animal arc originate towards one of its extremities, then only thoſe muſcles which correſpond with the oppoſite extremity are ſuſceptible of galvanic convulſions.

9. When an animal arc conſiſts of more than one ſyſtem of different nerves, which have all their origin about the middle of the arc, then will the muſcles of theſe ſeveral ſyſtems of nerves be moved alike at both the extremities of the arc.

10. It ſeems likewiſe to appear, from a variety of theſe experiments, that the opinion of thoſe is inadmiſſible, who aſcribe the phænomena of galvaniſm to the concurrence of two different and reciprocally correſponding influences, one belonging to the nerve, the other to the muſcle, and who compare the relations between the nerve and the muſcle, in theſe phænomena, to thoſe between the interior and the exterior coating of the Leyden phial.

11. It appears, laſtly, that the covering of the epidermis, in the entire animal body, acts as an obſtacle to the deciſive diſplay of the effects of galvaniſm; and that,

---

are produced in a limb without any apparent communication between the metals and the muſcles, except through the medium of a nerve, the communication is in fact completed by the moiſture upon the ſurface of the nerve. In this caſe, the animal arc may be conſidered as conſiſting of three pieces, diſpoſed in the following order; the nerve, the muſcle, and the water adhering to the ſurface of the nerve. The latter, indeed, ought rather to be conſidered as a part of the excitatory arc. "When a nerve (ſays Dr Fowler), which for ſome time has been detached from ſurrounding parts, is either carefully wiped quite dry with a piece of fine muſlin, or (leſt this ſhould be thought to injure its ſtructure) ſuffered to remain ſuſpended till its moiſture has evaporated, no contractions can be excited in the muſcles, to which it is diſtributed, by touching it alone with any two metals in contact with each other; but if it be again moiſtened with a few drops of water, contractions inſtantly take place. And, in this way, by alternately drying and moiſtening the nerve, contractions may at pleaſure be alternately ſuſpended and renewed for a conſiderable time. It may, indeed, be contended, that the moiſture ſoftened, and thus reſtored elaſticity and free expanſion to the dried cellular membrane ſurrounding the fibres, of which the trunk of a nerve is compoſed; and thus, by removing conſtraint, gave free play to their organization.

"But from obſerving, that in every other inſtance where contractions are produced by the mutual contact of the metals, a conducting ſubſtance is interpoſed between them and the muſcles as well as between them and the nerve; I think it would be unphiloſophical not to allow, that, in the inſtance in queſtion, the moiſture, adhering to the ſurface of the nerve, formed that requiſite communication between the metals and the muſcles." We know of no accurate experiment by which it has ever been ſhewn, that contractions can be produced in a limb without a communication being eſtabliſhed between the metals and nerve, and again between the muſcles and the metals, either directly, or through ſome medium capable of conducting galvaniſm.

To remove the only objection which can be made to Dr Fowler's experiment, and of which we have ſeen that he was himſelf aware, namely, that the nerve while dry is incapable of performing its functions, we repeated it in the following manner: A ſmall, but vigorous and lively, male frog was decapitated, and the ſciatic nerve being laid bare from the knee upwards, was cut through where it paſſes out of the pelvis. Fifteen minutes after the head was cut off, the nerve having been cautiouſly ſeparated from the ſurrounding parts, and coated with tinfoil in the uſual manner, a ſilver probe was applied to it and its coating, without any other communication with the muſcles, and ſtrong contractions took place in the leg. The nerve was now very carefully dried with a piece of fine linen, and the probe was applied as before to the tinfoil and the nerve; no movement whatever took place. Things remaining preciſely in this ſituation, one end of the probe being ſtill in contact with the nerve and its coating, the other end was applied to the muſcles of the thigh, and the leg immediately contracted as ſtrongly as ever. Upon moiſtening the nerve, the contractions were again produced by applying the probe to the nerve and tinfoil alone. We find from this experiment, which we have ſeveral times repeated with the utmoſt care, and with the ſame reſult, that the dry nerve retained its functions completely. This appears to us perfectly deciſive of the queſtion.

that, though from its extreme tenuity, it may not altogether prevent theſe effects, yet it cannot but very materially diminiſh them.

10 Experiments on the excitatory arc. II. The *Excitatory Arc* is uſually formed of three different pieces, made of different metals. Of theſe, one muſt be in contact with the nerve; the other muſt touch the muſcle; and the third muſt form the mean of communication between theſe two. This arrangement, though not indiſpenſably neceſſary, is at leaſt the moſt convenient.

In reſpect to the excitatory arc, the committee examined, 1ſt, The application of metallic ſubſtances to form it: in reſpect to which they endeavoured to aſcertain the number and the diverſity of the pieces of metal of which this arc may be compoſed; the metallic mixtures or alloys which are capable of being employed for this uſe; the particular degree of the friction of one metal upon another, which is favourable to the exhibition of the phenomena; the different ſtates, in reſpect to galvaniſm, of metals differently mineralized. 2dly, The effects of the uſe of carbonic ſubſtances in forming the excitatory arc. 3dly, The effects in the ſame formation, of bodies, which are either non-conductors, or elſe very imperfect conductors of electricity, ſuch as jet, aſphaltus, ſulphur, amber, ſealing-wax, diamond, &c. 4thly, The conſequences of the interpoſition of water, and of ſubſtances moiſtened with water, between the different parts of the excitatory arc. In forming their excitatory arcs, too, they made themſelves the chord of the arc; they introduced into it animal ſubſtances which had loſt their vitality; they rubbed the ſupporters with the dry fingers, ſo as to mark them with nothing but the traces of the perſpiration from the ſkin. They made, likewiſe, ſome experiments for the purpoſe of aſcertaining the relations between, on the one hand, the extent and magnitude of the ſurfaces of the parts compoſing the arc, and, on the other, the effects produced by its energy. From their experiments they have alſo drawn ſome inferences concerning the relative efficiencies of the ſeveral conſtituent parts of the exciting arc. It is impoſſible for us here to relate in detail all this train of experiments. The following corollaries expreſs the ſubſtance of thoſe general truths, which their authors were led to infer from them.

11 Inferences. 1. The excitatory arc poſſeſſes the greateſt power of galvaniſm, when it is compoſed of at leaſt three diſtinct pieces; each of a peculiar nature: the metals, water, and humid ſubſtances, carbonaceous matters, and animal ſubſtances, ſtripped of the epidermis, being the only materials out of which theſe pieces may be formed.

2. Nevertheleſs the excitatory arc appears to be not deſtitute of exciting energy, even when it conſiſts but of one piece or of ſeveral pieces, all of one proper ſubſtance (c). In general it muſt be owned, identity of nature in the conſtituent pieces, and particularly in the ſupports forming the extremities of the arc, diminiſhes, in a very ſenſible manner, its galvanic energy.

3. The ſlighteſt difference of nature induced upon the parts, whether by any feeble alloy, or by friction with extraneous ſubſtances, is at any time ſufficient to communicate to the excitatory arc that full power in which the identity of its compoſition may have made it defective.

4. As the animal arc is ſuſceptible of being in part made up of metallic ſubſtances, or ſuch others as are adapted to enter into the compoſition of the excitatory arc; ſo, on the other hand, the excitatory arc admits of being in part formed of thoſe ſubſtances which are the proper components of the animal arc.

5. The energies of both the excitatory and the animal arcs are alike ſuſpended by the ſeparation of their component parts, or at leaſt by the ſeparation of theſe parts to a certain diſtance.

6. Even the ſmalleſt degree of moiſture is ſufficient to

(c) We do not think it has ever been proved, that one piece of metal, or ſeveral pieces of the ſame metal, are capable of forming the excitatory arc. It is admitted on all hands, that the ſlighteſt alloy communicates galvanic energy to a piece of metal; that is, renders it capable of forming the excitatory arc. It is alſo known, that the metallic oxides are much leſs perfect conductors of galvaniſm than their correſponding reguli, to make uſe of an antiquated expreſſion. It appears to us, that in all caſes where one metal appears to act, more eſpecially where friction with the fingers, or breathing on a piece of metal formerly inert, give it galvanic powers; in all theſe caſes, we think it probable that a ſlight degree of oxidation, produced in ſome part of the ſurface of the metal, gives it activity by deſtroying the homogeneity of its nature. We do not find that this circumſtance has been in general ſufficiently attended to. Dr Wells having diſcovered that charcoal acts powerfully as an exciter when applied along with a metal, found that by friction it alſo can be rendered capable of acting ſingly. What change is thus produced in it we can only conjecture; but that it is ſomething which deſtroys the identity of its ſtructure, rendering it in ſome meaſure a heterogeneous ſubſtance, muſt be admitted.

Candour forces us to acknowledge, that in one of Mr Humboldt's experiments, it ſeems very difficult to point out any want of homogeneity in the exciting arc. He put into a china cup ſome mercury exactly purified; he placed the whole near a warm ſtove, in order that the entire maſs might aſſume an equal temperature: the ſurface was clear without the appearance of oxidation, humidity, or duſt. A thigh of a frog, prepared in ſuch a manner that a crural nerve and a bundle of muſcular fibres of the ſame length hung down ſeparately, was ſuſpended by two ſilken threads above the mercury. When the nerve alone touched the ſurface of the metal, no irritation was manifeſted; but as ſoon as the muſcular bundle and the nerve touched the mercury together, they fell into convulſions ſo briſk, that the ſkin was extended as in an attack of tetanus. This is by far the moſt deciſive experiment which has been tried on the ſame ſide of the queſtion; but as it muſt be admitted, that in moſt caſes two metals are abſolutely neceſſary, and that a ſingle metal often derives activity from circumſtances ſo ſlight, that we could not *a priori* have expected that they were capable of producing any change; we feel ourſelves compelled to conclude, that in M. Humboldt's experiment ſome ſimilar very ſlight circumſtance had eſcaped unobſerved; perhaps ſome gilding, or ornaments with metallic colours, in a ſtate of oxidation.

to join the parts of the excitatory arc, and to determine their effects upon the animal arc.

7. The influence upon the ſtate of the atmoſphere, and of ſurrounding circumſtances, upon the ſucceſs of the experiments of galvaniſm, is, conſequently, very great. In order, therefore, to perform theſe experiments with due accuracy, the ſtate of the hygrometer, and of other meteorological inſtruments, muſt be vigilantly inſpected during their progreſs; and the influence of the perſons making the experiment upon the ſphere within which it is made, muſt likewiſe be carefully attended to.

8. The experiments which were made to aſcertain the nature of the animal arc, together with thoſe made upon the excitatory arc, with a view to the compariſon of the effects of the fleſh of animals, with or without the epidermis, and of the different effects of this epidermis, when it is wet and when it is dry, appear to ſuggeſt to us, that the epidermis is one of thoſe ſubſtances which diminiſh or interrupt the efficacy of the excitatory arc. The epidermis is, as well as the hairs and briſtles of animal bodies, among the number of thoſe ſubſtances which deſerve the appellation of *idio-electrics*.

9. Examine the ſubſtances which are fit for the formation of the excitatory arc, and you will find that the greater part of thoſe which have been ſucceſsfully put to this uſe are ſubſtances capable of acting as conductors of the electrical fluid; but that the ſubſtances which interrupt the operation of galvaniſm are generally ſuch as are well known alſo to reſiſt the tranſmiſſion of electricity.

10. Laſtly, it appears, that the galvanic energy depends, not only upon the nature and arrangement of the component parts of the excitatory arc, but on their extent too, and on the magnitudes of their tranſmitting ſurfaces.

12
Experiments relating to circumſtances different from the arcs.

III. The committee appear to have uſed no leſs care and diſcernment in experiments upon thoſe circumſtances which, though different from the ſtructure of the galvanic circle and its two conſtituent arcs, have, however, *a deciſive influence upon the exhibition of the phænomena of galvaniſm.* Some curious obſervations were made on the differences in the ſtate of the parts expoſed to the galvanic action. It was aſcertained, that frogs freſh from the ditches did by no means exhibit the ſame phænomena as thoſe which had been during ſome days preſerved in the houſe; nor did the limbs of animals, when recently ſtripped of the ſkin, preſent the ſame appearances as after they had been ſubjected to a variety of galvanic experiments; nor were the ſame effects to be produced upon the parts of animal bodies which, after a certain number of trials, had been left for a while at reſt, and then taken up again, as upon thoſe which had been ſubjected to one continued train of experiments. The committee next examined the variations in the ſucceſs of the experiments upon a ſtrong lively frog, which may be produced by varying the mode in which the *communicator* is carried from the one *ſupporter* to the other: when the communicator is brought into contact with the ſupporter, or is withdrawn from actual contact with it; when the *communicator* is brought ſlowly, or when it is brought rapidly, into contact with the *ſupporter;* the effects are nearly the ſame: and a ſmart convulſion is, in all theſe caſes, produced at the moment of the commencement of the mutual contact, or of its ceſſation. But when the frog is fatigued, the effects are different. Theſe ſucceſſive experiments likewiſe affect the reſults of one another, by means even of their ſucceſſion ſolely. And they are alſo naturally ſubject to be influenced by the nature of the media amidſt which they are performed; ſuch as common air, water, an electrical atmoſphere. The following are the inferences which have been deduced from this claſs of theſe experiments.

13
Inferences.

1. In many caſes the galvanic energy is excited by exerciſe, is exhauſted by continued motion, is renovated by reſt.

2. The multiplicity of the cauſes by which the experiments of galvaniſm are liable to be influenced to ſucceſs or failure, is ſo great, that we cannot, as yet, be too cautious in either rejecting or believing theſe accounts which we hear of the ſucceſs of any ſuch experiments; unleſs when we are able accurately to appreciate all the influencing circumſtances.

3. This is remarkably confirmed by a fact, which the committee have related in their paper, and which reſpects the continuation of the galvanic ſpaſm.

The communicator being ſupported by the hand, and reſting, ſeemingly, without change of poſition, ſtill upon the ſame point of contact, there is known to take place a real change in the galvanic contact, although the communicator have remained thus apparently motionleſs.

From this, it may be farther inferred, that the ſmalleſt poſſible change in the relative ſituations of the parts of the galvanic circle and the excitatory arc, is capable of producing an effect upon the ſuſceptible animal, and of occaſioning miſtakes in regard to the ſucceſs of the experiment, if the utmoſt care be not taken to notice and eſtimate every variation that can happen.

4. The truth of the foregoing propoſition is farther confirmed by the experiments upon the manner in which the galvanic movements are affected by the advancing or the withdrawing of the communicator. For theſe experiments fully evince the neceſſity for the moſt vigilant obſervation of every movement in the proceſs of an experiment, not only collectively, but in their ſucceſſion, and at the different periods of the operation.

5. It ſhould ſeem that there are, in the formation of the excitatory arc, independently of its modes of acting in the galvanic operations, certain enervating, and certain exciting diſpoſitions; of which ſome not only augment or diminiſh the energy in the preſent inſtance, but, beſides, diſpoſe the animal to a greater or a ſmaller ſuſceptibility, under ſubſequent experiments.

6. In order to accuracy of experiment, and to the correct aſcertaining of the effects of an experiment. it is of great importance to know the preciſe ſtate of the animal, the manner in which it has been preſerved and ſuſtained to the preſent moment, the ſtate of the atmoſphere, particularly as it is indicated by the hygrometer, by the barometer, the thermometer, and the electrometer.

7. It were to be wiſhed, that in making a ſtatement of experiments of different ſorts, theſe ſhould be arranged in the order of their efficacy, and that there might thus be formed a *galvanic ſcale,* which ſhould help us to determine the preciſe degree of the galvanic

ſuſceptibility of any animal in this or that particular ſtate or poſition, ſhould direct us in ſubjecting every ſuch animal only to experiments ſuitable to its particular ſuſceptibility; ſhould enable us to eſtimate, from the *efficacy* or *inefficacy* of our experiments, the galvanic value of the circumſtances in which we every day find ourſelves, and ſhould enable us to judge when the ſucceſs or miſcarriage of an experiment can afford room for certain concluſions abſolutely negative or affirmative.

14
Experiments on the galvanic ſuſceptibility of animal bodies, &c.

IV. In their experiments upon *the means of varying, diminiſhing, and renewing the ſuſceptibility of animal bodies* to the influence of galvaniſm, the committee examined, 1ſt, the influence of electricity upon that ſuſceptibility; 2d, the effects of the muſcular organs, and of certain liquors, ſuch as alcohol, the oxygenated muriatic acid, the ſolutions of potaſh and opium, upon the galvanic properties; 3d, and at the medical ſchool of Paris they made a number of experiments, in order to aſcertain what new modifications the galvanic energy undergoes in various caſes of ſuffocation or aſphyxia. Theſe laſt-mentioned experiments were made upon hot-blooded animals, of which ſome were reduced into the ſtate of aſphyxia by ſubmerſion, ſome by ſtrangulation, ſome by the action of gaſes, while others were killed *in vacuo* by the diſcharge of the electric ſpark. In that ſuffocation which was produced by ſulphurated hydrogenous gas, by carbonic vapours, and by ſubmerſion, in which the animal was ſuſpended by the hinder feet, the galvanic ſuſceptibility was entirely deſtroyed. The galvanic ſuſceptibility was only ſuſpended by ſuffocation produced by the pure carbonic acid confined under mercury. It was diminiſhed, but not deſtroyed, in thoſe caſes of ſuffocation, which were occaſioned by ſulphurated hydrogenous gas that had loſt a portion of its ſulphur, by gas ammoniac, gas azote, or ſuch gaſes as had been exhauſted of their pure air by reſpiration; and the ſame thing was found to take place in animals which had periſhed by total ſubmerſion. But the galvanic ſuſceptibility ſurvived unaltered in ſuffocations brought on by ſubmerſion in mercury, by pure hydrogenous gas, by carbonated hydrogenous gas, by oxygenated muriatic acid, by ſulphureous acid; as alſo when the ſuffocation was occaſioned by ſtrangulation, by the abſtraction of the air in the air-pump, or by diſcharges from an electrical battery. The reſults of the experiments at the medical ſchool ſuggeſted the following reflections:

15
Reflections.

1. Though it be true that all caſes of ſuffocation reſemble one another in the privation of reſpirable air, and in the ſuſpenſion of the functions of reſpiration, and of the circulation of the blood; yet, in their other circumſtances, they are ſubject to great differences, ariſing from diverſity of nature in the ſubſtances by which they are occaſioned.

2. Of theſe cauſes, ſome appear to act with a more thorough efficacy, penetrating at once all parts of the nervous and muſcular ſyſtems. Others again ſeem to act but ſuperficially, producing only pulmonary aſphyxia, with its immediate effects.

3. One of the moſt remarkable changes not confined to the organs of reſpiration, conſiſts in the alterations produced on the galvanic ſuſceptibility. In that reſpect the various caſes of aſphyxia differ greatly one from another.

4. The ſtate of the irritability of the muſcles, when examined by means of bodies, the mechanical action of which cauſes the muſcles to contract by irritating them, is far from always correſponding to the ſtate of their galvanic ſuſceptibility.

5. Laſtly, the cauſes of ſuffocation or aſphyxia, do not act upon all parts of the muſcular ſyſtem in the ſame manner; but the heart is very often found in a ſtate extremely different from that of the other muſcles.

16
Compariſon of the phenomena of galvaniſm with thoſe of electricity.

V. *The compariſon between the phenomena of galvaniſm and thoſe of electricity* is perhaps one of the moſt intereſting objects of attention in the whole body of animal phyſiology. It is well known that Galvani was accidentally led to his diſcovery by obſerving the motions of ſome frogs, at a certain diſtance from an electrical machine diſcharging ſparks. The committee from the inſtitute made, therefore, ſome attempts to aſcertain the relations between electricity and galvaniſm. Having firſt paid due attention to the ſuſceptibility of animals toward the influence of electricity, they then ſought to diſcover to what preciſe degree animals diveſted of the natural covering of the epidermis were liable to be affected by the variations of the electrical fluid in the atmoſphere around them. Next, comparing the ſuſceptibility of electricity with the ſuſceptibility of galvaniſm, they perceived that quantities of the electrical fluid, ſuch as are ſtill capable of being very accurately meaſured by the electrometer, are, however, often too weak to act upon a frog that retains the moſt perfect ſenſibility to all the energy of galvaniſm. The members of the committee purpoſe to proſecute farther their experiments upon this part of the ſubject.

17
Reſults of ſome experiments by Humboldt.

VI. The following are the general reſults of the experiments made by M. Humboldt in the preſence of the committee:

1. There is no truth in the aſſertion of certain phyſiologiſts, that the experiments of galvaniſm fail when tried upon the heart and thoſe other muſcles of which the contractions depend not upon volition; for theſe organs have been found to be actually ſubject to the influence of galvaniſm (D).

2. The effects of galvaniſm are liable to be interrupted by the conſtriction of a nerve, whenever both the nerve and the conſtricting ligature are enveloped in the fleſh of the animal body (E).

3. The powers of the exciting arc may be renovated or deſtroyed, even though its ſupporters remain the ſame, and although the extremities of the arc be unchanged. Only the relations of the intermediate matters require to be altered.

4. There are atmoſpheres of galvaniſm.

5. There are ſubſtances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvaniſm.

M. Humboldt had performed alſo other experiments which,

(D) This was demonſtrated ſix years ago by Dr Fowler.

(E) Dr Valli made this obſervation ſoon after the diſcovery of galvaniſm.

which, when he attempted to repeat them before the committee, could not be brought to ſucceed, on account, as was ſuppoſed, of the ſeaſon of the year.

Such are the principal reſults of this valuable train of experiments upon galvaniſm. From them our readers will perceive that this intereſting ſubject is ſtill very imperfectly underſtood, and will form ſome idea of the importance of the diſcoveries which a diligent proſecution of it promiſes to the philoſopher and the phyſician.

18 Effects of galvaniſm upon ſome of the organs of ſenſe.

The effects of galvaniſm upon ſome of the organs of ſenſe are no leſs ſtriking than thoſe which we have ſeen it capable of producing upon the muſcles.

If the upper and under ſurfaces of the tongue be coated with two different metals, and theſe be brought into contact with each other, a peculiar ſenſation, reſembling taſte, is produced in the tongue the moment that the metals touch each other. With the greater number of metals this ſenſation is ſcarcely perceptible; but with zinc and gold, zinc and ſilver, or zinc and molybdena, it is very ſtrong and diſagreeable. Dr Fowler thinks it is ſtrongeſt with zinc and gold; to us it appears a good deal ſtronger with zinc and ſilver. It is ſenſibly ſtronger when the zinc is applied to the upper, and the ſilver to the under ſurface of the tongue, than when this order is inverted. The ſenſation is moſt diſtinct when the tongue is of the ordinary temperature, and the metals of the ſame temperature with the tongue. Any conſiderable increaſe or diminution of heat in either greatly leſſens the effect. Mr Subſir of Berlin, in his *Theorie des Plaiſers*, p. 155, (publiſhed in 1767) takes notice of the diſagreeable taſte produced by ſilver and lead in contact upon the tongue. This is the firſt inſtance of galvaniſm that had been made public.

To enſure complete ſucceſs to the experiment, the metals ought to be allowed to remain ſome time in contact with the tongue before they are made to touch each other, that the taſte of the metals themſelves may not be confounded with the ſenſation produced by their mere contact. Whatever has a tendency to blunt the ſenſibility of the tongue, as opium, alcohol, acids, and the like, diminiſhes the effect of the metals.

It is difficult to deſcribe the ſenſation thus produced accurately. It has been called *ſubacid;* but we think it more nearly reſembles the effect produced by allowing a grain or two of nitre to lie upon the tongue for ſome time, than any other taſte with which we are acquainted. Joined to this, there is evidently a metallic taſte, which varies with the metal employed; but we are inclined to conſider this as the ordinary effect of the metals upon the tongue, which cannot be perfectly diſtinguiſhed from that occaſioned by their mutual contact.

This taſte can alſo be produced by applying one of the metals to the tongue, and the other to any part of the Schneiderian membrane. Profeſſor Robiſon has made many experiments of this kind, the reſult of which is contained in a letter to Dr Fowler. "I find (ſays he), that if a piece of zinc be applied to the tongue, and be in contact with a piece of ſilver which touches any part of the lining of the mouth, noſtrils, ear, urethra, or anus, the ſenſation reſembling taſte is felt on the tongue. If the experiment be inverted, by applying the ſilver to the tongue, the irritation produced by the zinc is not ſenſible, except in the mouth and the urethra, and is very ſlight. I find the irritation by the zinc ſtrongeſt when the contact is very ſlight, and confined to a narrow ſpace, and when the contact of the ſilver is very extenſive, as when the tongue is applied to the cavity of a ſilver ſpoon. When the zinc touches in an extenſive ſurface, the irritation produced by a narrow contact of the ſilver is very diſtinct, eſpecially on the upper ſide of the tongue, and along its margin. This irritation ſeems to be mere pungency, without any reſemblance to taſte, and it leaves a laſting impreſſion like that made by cauſtic alkali.

"When a rod of zinc, and one of ſilver, are applied to the roof of the mouth, as far back as poſſible, the irritations produced by bringing their outer ends into contact are very ſtrong, and that by the zinc reſembles taſte in the ſame manner as when applied to the tongue."

M. Volta found, that when a tin cup, filled with an alkaline liquor, is held in one or both hands previouſly moiſtened with water, if the point of the tongue is dipped in the liquor, an acid taſte is perceived. This is at firſt diſtinct and pretty ſtrong, but gradually yields to the alkaline taſte of the liquor. The acid taſte is ſtill more remarkable, when, inſtead of an alkaline liquor, an inſipid mucilage is made uſe of. The ſame philoſopher found, that when a cup made of tin, or, what is better, of zinc, was filled with water, and placed upon a ſilver ſupport, if the point of the tongue was applied to the water, it was found quite inſipid, till he laid hold of the ſilver ſupport, with the hand well moiſtened, when a very diſtinct and very ſtrong acid taſte was immediately perceived.

If one of the metals be applied to the tongue, and the other to the ball of the eye, a pale luminous flaſh is perceived when they are brought into contact with each other, and the ſenſation reſembling taſte is at the ſame time produced in the tongue. A flaſh is, in like manner, produced when one of the metals is applied to the eye, and the other to any part of the palate, fauces, or inſide of the cheek. This experiment requires a good deal of attention in the performance; care muſt be taken not to preſs the piece of metal againſt the ball of the eye, leſt a flaſh ſhould be produced by the mere mechanical preſſure. It ſhould be cautiouſly introduced between the eye-lids, till it juſt touch any part of the ball; and it ſhould be allowed to remain in that ſituation for ſome time before it is brought into contact with the other piece of metal, that the parts may be ſo far accuſtomed to it as to admit of the ſenſations produced being properly attended to. The experiment ſucceeds very well with tin and ſilver; but the flaſh is more bright when zinc and gold are uſed. The piece of metal which is applied to the ball of the eye muſt be finely poliſhed, otherwiſe the mechanical irritation is ſometimes ſo great as to prevent the flaſh from being perceived. Dr Robiſon has obſerved, that the brightneſs of the flaſh correſponds with the extent of contact of the metal with the tongue, palate, fauces, or cheek.

If a piece of one of the metals be placed as high up as poſſible between the gums and the upper lip, and the other in a ſimilar ſituation with reſpect to the under lip, a very vivid flaſh of light is obſerved at the moment that they are brought into contact, and another at the inſtant of their ſeparation. While they remain in contact, no flaſh is obſerved.

When a rod of ſilver is thruſt as far as poſſible up one of the noſtrils, and then brought into contact with a piece of zinc placed upon the tongue, a very ſtrong flaſh of light is produced in the correſponding eye at the inſtant of contact. We have ſometimes imagined that the flaſh in this experiment was produced before the metals actually touched ; but in this we may have been deceived.

The following curious experiment was firſt made by Profeſſor Robiſon : " Put a plate of zinc into one cheek, and a plate of ſilver (a crown piece) into the other, at a little diſtance from each other. Apply the cheeks to them as extenſively as poſſible. Thruſt in a rod of zinc between the zinc and the cheek, and a rod of ſilver between the ſilver and the other cheek. Bring their outer ends ſlowly into contact, and a ſmart convulſive twitch will be felt in the parts of the gums ſituated between them, accompanied by bright flaſhes in the eyes. And theſe will be diſtinctly perceived before contact, and a ſecond time on ſeparating the ends of the rods, or when they have again attained what may be called *the ſtriking diſtance*. If the rods be alternated, no effect whatever is produced."—The flaſhes produced in this laſt experiment are rather more vivid than any which we have been able to excite by the other methods. The convulſive twitches are very diſtinct, and ſomewhat painful, but quite different from the ſenſation produced by an electric ſhock. If the edges of the tongue be allowed to touch the plates of metal in the cheeks, the ſenſation reſembling taſte is felt very ſtrongly ; but this does not in the leaſt impair the other effects of the experiment.

No method has yet, we believe, been diſcovered of applying the galvanic influence ſo as to affect the ſenſes of ſmelling or hearing. We have tried many experiments with this view, chiefly on the organs of ſmelling, but hitherto without any ſucceſs (F). Neither has the ſenſe of touch been affected by it, unleſs, indeed, the following experiment be conſidered in that view : Let a ſmall portion of the cuticle be removed from any part of the body by a ſharp knife, and carry the inciſion to ſuch a depth that the blood ſhall juſt begin to ooze from the cutis vera. Let a piece of zinc be applied here, and a piece of ſilver to the tongue ; when they are brought into contact, a very ſmart irritation will be felt at the wound.

Some very ſingular facts of this kind have been diſcovered by M. Humboldt, who had the reſolution to make himſelf the ſubject of many well-deviſed experiments. One of the moſt remarkable of theſe is the following : He cauſed two bliſtering plaſters to be applied on the deltoid muſcle of both his own ſhoulders. When the left bliſter was opened, a liquor flowed out, which left no other appearance on the ſkin than a ſlight varniſh, which diſappeared by waſhing. The wound was afterwards left to dry up : this precaution was neceſſary, in order that the acrid humour which the galvanic irritation would produce, might not be attributed to the idioſyncriſis of the veſſels. This painful operation was ſcarcely commenced on the wound, by the application of zinc and ſilver, before the ſerous humour was diſcharged in abundance ; its colour became viſibly dark in a few ſeconds, and left on the parts of the ſkin where it paſſed traces of a brown inflamed red. This humour having deſcended towards the pit of the ſtomach, and ſtopped there, cauſed a redneſs of more than an inch in ſurface. The humour, when traced along the epidermis, left ſtains, which, after having been waſhed, appeared of a bluiſh red. The inflamed places having been imprudently waſhed with cold water, increaſed ſo much in colour and extent, that M. Humboldt, as well as his phyſician Dr Schalleru, who aſſiſted at theſe experiments, entertained ſome apprehenſion for the conſequences.

Having now taken notice of the principal facts that are hitherto known in galvaniſm, we proceed to conſider ſome of the leading opinions on the ſubject.

19
Phenomena of galvaniſm ſuppoſed to reſult from electricity;

The firſt writers upon the diſcovery of Galvani ſeem almoſt univerſally to have taken it for granted, that the phenomena depend on the electric fluid ; and leaving this very important queſtion behind them, proceeded to explain how this fluid produces ſuch effects. The celebrated diſcoverer of this influence himſelf conſiders a muſcle as the perfect prototype of a Leyden phial. When a muſcle contracts upon a connection being formed, by means of one or more metals between its external ſurface and the nerve which penetrates it, M. Galvani contends, that, previouſly to this effect, the inner and outer parts of the muſcle contain different quantities of the electric fluid ; that the nerve is conſequently in the ſame ſtate, with reſpect to that fluid, as the internal ſubſtance of the muſcle ; and that, upon the application of one or more metals between its outer ſurface and the nerve, an electrical diſcharge takes place, which is the cauſe of the contraction of the muſcle. Thus the nerve is ſuppoſed to perform the office of the wire connected with the internal ſurface of the phial ; and the excitatory arc is conſidered merely as a conductor.

This theory appears to us juſt as incapable of explaining the phenomena of galvaniſm as it is inconſiſtent with the known laws which regulate the motions of the electric fluid. We ſhall not conſider it minutely ; for we hope it will ſoon appear highly probable, if not certain, that the electric fluid has no ſhare in the production of the phenomena in queſtion. If this be the caſe, all the different modifications of that theory muſt of courſe fall to the ground. At preſent we ſhall content ourſelves with aſking the following queſtions :

20
This ſuppoſition ill founded.

1. How is it poſſible for the electric fluid to be condenſed in a muſcle, which is wholly ſurrounded by ſubſtances capable of conducting that fluid ?

2. If we ſuppoſe there is ſome non-deſcript non-conducting ſubſtance placed between the external and internal

---

(F) Profeſſor Robiſon has long ago obſerved, that the flavour of a pinch of ſnuff taken from a box made of tin-plate, which has been long in uſe, ſo that the tin coating is removed in many places, is extremely different from that of ſnuff when taken from a new box, or a box lined with tin-foil. The ſame difference is obſerved when we rub a piece of pure tin, or of pure iron and a half worn tinned plate, with the finger. Alſo, if we rub a caſt ſteel razor, and a common table knife conſiſting of iron and ſteel welded together. This is ſurely owing to a cauſe of the ſame kind.

ternal parts of a muſcle, which may admit of the one being poſitively, and the other negatively electrified at the ſame time—how comes it to paſs that a diſcharge does not take place, and a conſequent contraction enſue, when any ſubſtance whatever, capable of conducting the electric fluid, is interpoſed between the nerve and the external ſurface of the muſcle? For example, when the nerve and muſcle are laid bare, and the animal thrown into water; or when the nerve is cut through, and the end applied to the external ſurface of the muſcles.

3. How does it happen, when one diſcharge actually takes place, in conſequence of the application of the excitatory arc, that the balance is not inſtantly reſtored? That this does not happen, appears by the ſame muſcle and nerve being capable of producing many hundreds of ſimilar, and equally ſtrong diſcharges, without any apparent means of the equilibrium being again diſturbed.

We have never ſeen any anſwers to theſe queſtions which appeared to us at all ſatisfactory; and till we have ſeen them anſwered, we muſt be excuſed for diſbelieving M. Galvani's theory.

One of the earlieſt writers, and one of the moſt aſſiduous inveſtigators of the phenomena of galvaniſm, is Dr Valli. He differs in opinion from Galvani upon ſeveral points; but agrees with him in thinking electricity and galvaniſm the ſame. Let us conſider the proofs by which he ſupports this doctrine.

" I have aſſerted (ſays he), that the nervous fluid is the ſame with electricity, and with good reaſon; for

21
roofs by
hich Valli
ideavou:s
ſupport

" Subſtances which conduct electricity are conductors likewiſe of the nervous fluid.

" Subſtances which are not conductors of electricity do not conduct the nervous fluid.

" Non-conducting bodies, which acquire by heat the property of conducting electricity, preſerve it likewiſe for the nervous fluid.

" Cold, at a certain degree, renders water a non-conductor of electricity as well as of the nervous fluid.

" The velocity of the nervous fluid is, as far as we can calculate, the ſame with that of electricity.

" The obſtacles which the nerves, under certain circumſtances, oppoſe to electricity, they preſent likewiſe to the nervous fluid.

" Attraction is a property of the electric fluid, and this attraction has been diſcovered in the nervous fluid.

" We here ſee the greateſt analogy between theſe fluids; nay, I may even add, the characters of their identity."

That there is a conſiderable analogy between ſome of the effects of the electric fluid and ſome of the phenomena of galvaniſm, we readily admit; but that " the characters of their identity" are anywhere to be found, we abſolutely deny. In the above paſſage, Dr Valli conſiders it as certain that the nervous fluid is the cauſe of the phenomena diſcovered by Galvani. But it has never been demonſtrated irrefragably, that any ſuch thing as a nervous fluid exiſts, and ſtill leſs that this is the ſame with the influence diſcovered by Galvani.

22
nclu-
and

That bodies are, in general, conductors or non-conductors of galvaniſm, according as they are conductors or non-conductors of electricity, we believe to be true; but this rule is by no means without exception, as it certainly would be, if galvaniſm and electricity were the ſame. There is an experiment of Dr Fowler's, which ſeems to ſhew that water is a more powerful conductor of galvaniſm than mercury; though the reverſe is generally allowed as to electricity.

If the abdomen of a frog be filled with water, and a ſilver probe paſſed through it ſo as to touch the ſciatic nerves, no contractions are produced; neither do they appear when the probe is touched above the ſurface of the water with a piece of zinc. But if the zinc be applied to the probe at the ſurface of the water, contractions are produced as vigorous as if both the metals touched the nerve. Here the water ſerves as a conducting medium between the nerves and the point where the metals touch each other: but if the abdomen be filled with mercury inſtead of water, no contractions are produced by applying the ſilver probe to the nerves, and touching the probe with the zinc at the ſurface of the mercury. We do not ſee how this experiment can be accounted for, except by allowing that water is a more powerful conductor of galvaniſm than mercury.

If this experiment ſhould be thought inconcluſive, we have the authority of M. Humboldt, and of the committee of the National Inſtitute of France, for ſaying that there are ſubſtances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvaniſm. This is certainly ſufficient to take away all weight from Dr Valli's two firſt reaſons for conſidering theſe two fluids as the ſame, viz. that all conductors of electricity are likewiſe conductors of galvaniſm; and that all bodies which do not conduct the former are alſo non-conductors of the latter. Theſe two are by far the moſt important of his reaſons; and if they were true in their full extent, they would certainly ſhew a very ſtriking analogy, though they would by no means deſerve the appellation of " characters of identity."

As to the Doctor's two next propoſitions, which regard the effects of heat and cold in rendering bodies conductors or non-conductors, they are, in fact, only branches of the two firſt; and as we have ſeen that theſe are not univerſally true, we might admit that they are correct in this particular, without weakening our argument. For this reaſon we ſhall not conſider them minutely; but we may obſerve that Dr Fowler's experiments ſhew that boiling water, and water cooled down to the freezing point, both conduct this influence as well as water at the ordinary temperature of the atmoſphere. If any change in the conducting power takes place beyond theſe points, it may with greater probability be aſcribed to the changes of form which the water undergoes, than to the increaſe or diminution of its temperature.

We confeſs ourſelves perfectly ignorant of any data upon which Dr Valli could found a calculation, the reſult of which could ſhew that the velocity of the nervous fluid is the ſame with that of electricity. Suppoſe we ſhould take it into our heads to aſſert that the velocity of galvaniſm is the ſame with that of light, we apprehend our author could not eaſily demonſtrate the contrary. Neither, in all probability, would he conſider this aſſertion of ours as a ſufficient proof that galvaniſm and light are the ſame.

With regard to the next propoſition, that " the obſtacles which the nerves, under certain circumſtances, oppoſe to electricity, they preſent likewiſe to the nervous fluid;" we may remark, that any obſtacle which deſtroys the functions of a nerve completely, will prevent the muſcles which are ſupplied by that nerve from contracting upon the application of any ſtimulus whatever (G). It does not, however, by any means follow, that the paſſage of either the galvanic or the electric fluid is prevented. The nerves may ſtill be very good conductors of both, though the muſcle is deprived of all power of contracting. That there are obſtacles, however, which the nerves, under certain circumſtances, preſent to the paſſage of electricity, but which they do not under the ſame circumſtances preſent to galvaniſm, we think abundantly demonſtrated by Dr Valli's own experiments.

23 Inconſiſtent with his own experiments,

"I have frequently obſerved (ſays he) that the legs, of which the nerves had been tied at a certain diſtance from the muſcles, did not feel the action of a certain quantity of artificial electricity, although they were violently convulſed by exciting that which was inherent and peculiar to them." What then was the cauſe of the difference obſerved in theſe caſes between the effects of galvaniſm and electricity? Was it, that the quantity or degree of the former exceeded that of the latter? Be it ſo.

Dr Valli informs us, that in his experiments, an electric charge which could flaſh through a thickneſs of air equal to .035 of an inch, produced no movement in the leg of a frog of which the crural nerve was tied, while the other leg, of which the nerve was left free, underwent conſiderable movements.

That the influence diſcovered by Galvani can paſs through an exceeding thin plate of air, is certain, as it is tranſmitted from link to link of a chain, where no conſiderable force is uſed to bring the links into contact. Dr Robiſon's experiment, too, in which the flaſhes of light are diſtinctly obſerved before the rods of ſilver and zinc touch each other, is another proof of the ſame fact; and, if we be not deceived, the ſame thing takes place when a rod of ſilver thruſt up the noſtril is applied to a piece of zinc in contact with the tongue. But that it will only paſs through an exceeding thin plate of air, any man may convince himſelf by an experiment firſt tried by Dr Fowler, which is eaſily repeated. If a ſtick of ſealing-wax be coated with tinfoil, it will be found a very good conductor; but if, with a ſharp pen-knife, an almoſt imperceptible diviſion be made acroſs the tinfoil, even this interruption of continuity in the conductor will be found ſufficient effectually to bar the paſſage of galvaniſm.

We find, then, that a quantity of the electric fluid which can paſs through a plate of air of the thickneſs of .035 of an inch, is obſtructed by a ligature upon a nerve, while the galvanic influence paſſes readily along a nerve included in a ligature, but is obſtructed completely by making an almoſt imperceptible diviſion in a good conductor. The plate of air in this caſe ſurely is not near .035 of an inch in thickneſs. It reſults inconteſtibly, from a compariſon of theſe two experiments, that there is, between theſe two agents, ſome other difference beſides the mere degree of intenſity.

We come now to the laſt reaſon which our author aſſigns for his belief that galvaniſm, or, as he chooſes to call it, the *nervous fluid*, is the ſame with electricity. It will be found a very important one. That property by which bodies charged with the electric fluid attract or repel other bodies, according as they are in the ſame or the oppoſite ſtate of electricity from themſelves, is ſo ſtriking, and at the ſame time ſo univerſal, that it has been very properly adopted as the meaſure of this fluid. If it were true, then, that the galvanic influence poſſeſſed the ſame properties of attraction and repulſion as the electric fluid, this circumſtance would certainly increaſe the analogy between them very much. As we have already ſeen, however, that they differ in other eſſential points, even if it were true that they agreed in this, it could conſtitute no proof of their identity. But if, on the other hand, we ſhould find that this aſſertion of our author is founded on error, and that the galvanic influence poſſeſſes in no degree whatever thoſe properties of attraction and repulſion which have always been juſtly conſidered as eſſential characteriſtics of the electric fluid, we ſhall then be fully juſtified in aſſerting, that theſe two agents, however much they may reſemble each other in ſome leſs important particulars, are in their nature totally diſtinct and unconnected.

24 And with the knowledge of electricity.

Let us examine the proofs by which Dr Valli's aſſertion is ſupported. He tells us, that he obſerved the hairs of a mouſe, attached to the nerves of frogs, by the tinfoil with which he ſurrounded them, alternately attracted and repelled by each other, whenever another metal was ſo applied as to excite contractions in the frogs. We are very far from meaning to inſinuate that Dr Valli did not ſee, or think he ſaw, what he thus deſcribes; but that the motion of the hairs muſt have ariſen from ſome cauſe, different from that to which he aſcribed it, cannot admit of a doubt; for hairs, in ſuch a ſtate of electricity as he ſuppoſes, never attract, but always repel each other.

Dr Fowler, who has paid particular attention to this part of his ſubject, has many times repeated this experiment, both in the manner deſcribed by Dr Valli and with every variation in the diſpoſition of the hairs which he could deviſe: but whether they were placed on the metals, the nerves, or the muſcles, or upon all at the ſame time, he has never in any inſtance been able to obſerve them agitated in the ſlighteſt degree. He has made ſimilar experiments upon a dog, and upon a large and lively ſkate, by diſpoſing, in the ſame way that Valli did the hairs of a mouſe, flakes of the fineſt flax, ſwan-down, and gold leaf: but although the contractions produced in the ſkate, by the contact of the metals, were ſo ſtrong as to make the animal bound from the table, not the leaſt appearance of electricity was indicated. He next ſuſpended from a ſtick of glaſs, fixed in the ceiling of a cloſe room, ſome threads, five feet in length, of the flax uſed in the former experiment; and brought ſome frogs recently killed, and inſulated upon glaſs, as near to them as poſſible without touching: but the threads were in nowiſe affected by the contractions produced in the frogs.

In a very ingenious paper upon galvaniſm by Dr Wells,

(G) We do not here mean that contraction which muſcles are ſuſceptible of long after death, upon having their fibres mechanically irritated, which is produced by what phyſiologiſts have called the *vis inſita*, and which is perfectly known to our cooks, as it was to their predeceſſors in the Roman kitchens, as the foundation of the art of crimping. We at preſent confine ourſelves to contraction produced through the medium of the nerves.

25 eaſoning 'Dr Wells n the me ſub- ct,

Wells, which is publiſhed in the London Philoſophical Tranſactions for 1795, that gentleman maintains the opinion, that the influence diſcovered by Galvani is electrical. He admits, that it is not attended with thoſe appearances of attraction and repulſion which are held to be the teſts of the preſence of electricity; but he contends, that "neither ought ſigns of attraction and repulſion to be in this caſe preſented on the ſuppoſition that the influence is electrical; ſince it is neceſſary, for the exhibition of ſuch appearances, that bodies, after becoming electrical, ſhould remain ſo during ſome ſenſible portion of time; it being well known, for example, that the paſſage of the charge of a Leyden phial, from one of its ſurfaces to the other, does not affect the moſt delicate electrometer, ſuſpended from a wire, or other ſubſtance, which forms the communication between them."

26 nconclu- ve like- iſe.

That the charge of a Leyden phial does not, in paſſing along a wire, affect an electrometer, is certain; and it is equally true, that we have no means of applying an electrometer to a quantity of galvaniſm in a ſtate of reſt in a body. If this influence ever exiſts in ſuch a ſtate, we have no teſt by which we can diſcover its preſence; and it is only from the effects which it produces *in tranſitu* that we know of its exiſtence. But the electric fluid, in paſſing from link to link of a chain, ſenſibly affects an electrometer; and in Dr Fowler's experiment with the ſkate, for example, as more than one piece of metal is employed as an exciter, the fluid, in paſſing from one piece to another, ſhould have affected the light ſubſtances which were placed upon them. This appears to us a ſufficient anſwer to the objection ſtarted by Dr Wells: but the ſame objection having been lately made to us by a gentleman from whom we ſhall always receive every ſuggeſtion with uncommon deference, we thought it worth while to try the following experiment:

Three hours after a frog had been decapitated, it ſhewed ſtrong ſigns of galvanic ſuſceptibility. One of the ſciatic nerves being coated with tinfoil in the uſual manner, the leg was laid upon a plate of zinc. A gentleman was deſired to lay hold of the nerve and its coating with the fingers of one hand, which had been previouſly dipped in water, while with the other hand, alſo wet, he held the end of a ſmall braſs chain about two inches in length. Another gentleman now took hold of the other end of the chain, and, with a ſilver probe, held in his other hand, touched the plate of zinc. The influence being thus made to paſs through the chain, the leg contracted vigorouſly; but a very ſenſible electrometer, held ſo near to the chain as almoſt to touch it, was neither attracted nor repelled. In performing this experiment, it was neceſſary to have the hands wet, as the dry cuticle tends much to obſtruct the paſſage of galvaniſm; but the utmoſt care was taken that the chain ſhould be perfectly dry, otherwiſe the influence might have been tranſmitted by the moiſture upon its ſurface without paſſing through the chain itſelf.

To avoid the poſſibility of this happening, the experiment was varied in the following manner: The frog's leg was laid upon a plate of zinc, and the nerve upon a plate of ſilver. A gentleman now took a ſilver probe, and one end of the braſs chain in contact with it, in one hand; and in the other hand he held the other end of the chain in contact with a rod of zinc. He now touched the ſilver plate with the rod of ſilver, and the zinc plate with the rod of zinc. As the influence was not now to be made to paſs through his body, there was no neceſſity for his hands being wet; the whole excitatory arc was therefore made completely dry. In this way very ſtrong contractions were excited in the leg, and ſtill the electrometer was not affected in the ſmalleſt degree when brought near the chain.

It is proper to obſerve, that Dr Valli, in his aſſertion that attraction is a property of galvaniſm, does not reſt entirely upon his own obſervation: a committee of the Academy of Sciences at Paris performed the following experiment along with him: "They placed a prepared frog in a veſſel which contained the electrometer of M. Coulomb, charged negatively and poſitively by turns. In both caſes, in exciting the animal in the common way, the ball of the electrometer was attracted." It appears to us that Dr Valli and the committee have been deceived by the friction produced by the motion of the animals under their experiments having excited ſo much electricity as to affect the electrometer. The firſt time we tried the experiment abovementioned with the braſs chain, we were almoſt miſled by a ſimilar circumſtance. Inſtead of an artificial electrometer, which we happened not to have at hand, we made uſe of a very long and ſlender human hair; and we found that it was ſtrongly attracted by the chain. Upon an attentive examination, however, we found that this did not ariſe from the action of the influence paſſing thro' the chain, but from the ſtate of the hair itſelf, which was ſo highly electrical as to be ſtrongly attracted by every conducting ſubſtance which it approached. Upon ſubſtituting another hair, which ſhewed no mark of being either poſitively or negatively electrified, it was neither attracted nor repelled by the chain. From the above, or ſome ſimilar circumſtance, it is probable that Dr Valli's miſtake has originated; but we are confident, that whoever will repeat the experiment with ſufficient attention, will find the reſult preciſely as we have deſcribed it.

Perhaps it may ſtill be ſaid, that although we have never been able to diſcover attraction and repulſion as properties of galvaniſm, this may ariſe from our not being able to accumulate this influence in ſufficient quantity. To this reaſoning, if reaſoning it can be called, we oppoſe the following conſiderations, which ſtate a diſſimilarity in the phenomena of electricity and galvaniſm, that ſeems abſolutely irreconcileable with the identity of the cauſe.

27 Demonſtration, that the phenomena of galvaniſm and of electricity reſult not from the ſame cauſe.

Nothing is more completely eſtabliſhed in the ſcience of electricity than this, that all thoſe appearances which we call *attractions*, *repulſions*, *abſtractions*, *and accumulation of electric fluid*, are preciſely ſimilar to what would be the appearances, if electricity were a fluid, whoſe particles repel each other, and attract the particles of other matter, according to a certain law (See Electricity, *Suppl.*). Of all thoſe phenomena, the moſt remarkable is the accumulation of electric energy (to give it no more definite name), by means of thin idioelectrics, coated with non-electrics; ſuch, namely, as are exhibited by the Leyden phial, the condenſer, the doubler, &c.

If the phenomena of galvaniſm are produced by the paſſage of electric fluid from one extremity of the excitatory arc to the other, this paſſage will be regulated by the known laws of electricity. It may therefore be accumulated

accumulated *(in tranſitu)* by means of an apparatus ſimilar to the coated pane, or to the condenſer. Profeſſor Robiſon, with this view, made the following experiments :

1. He made a part of the conductor to his condenſer, or collector of atmoſpheric electricity, conſiſt of a long glaſs rod, on one ſide of which was faſtened (with varniſh) a very narrow ſlip of tinfoil; there was a fine point at one end of this rod, and a gold leaf electrometer at the other. This apparatus was inſulated at one end of a room 19 feet long, having a window in the middle of each ſide. A ſmall electric machine was placed at the other end. On a dry day, with a gentle breeze in a direction acroſs the room, both windows were opened a little way, ſo that there was a continual ſtream of air acroſs the room. The machine was worked; and after a ſhort time had elapſed, the electrometer began to diverge, gradually opened, and at laſt ſtruck the conducting ſlips on each ſide, and then collapſed, and again began to diverge. The windows were ſhut; and immediately, without working the machine, the electrometer diverged rapidly, and touched the ſides of the phial every minute and half. This continued ſo long, that there ſeemed to be no end to it. The Profeſſor now made a cut acroſs the tinfoil with a very ſharp knife; the electrometer now diverged very feebly, and 7½ minutes elapſed before it touched the ſides. He paſſed the knife a ſecond time through the cut. This widened it (though ſcarcely ſenſible to the eye), becauſe the knife had been blunted by the glaſs in the firſt operation. All divergency of the electrometer was now at an end; and although the machine was worked till the electric ſmell was ſenſible at the door to a perſon who happened to come in at this time, no tendency to divergence was obſerved. (*N. B.* the top of the electrometer had no conducting ſubſtance about it, except the ſlip of tinfoil).

The cut, being examined with a microſcope furniſhed with a micrometer, was $\frac{31}{1000}$th of an inch. It was now filled up, by binding over it another ſlip of tinfoil. A plate of talc, whoſe thickneſs did not exceed the 900th of an inch, was coated on one ſide in a circle of 1½ inch diameter. The electrometer was removed, and the coated ſide of the talc was put into cloſe contact with the ſlip of tinfoil on the glaſs rod. A ſtand of tin, whoſe top was a plate of 1½ inch diameter, ſmeared over with mercury, was placed in contact with the other ſide of the talc, and they were preſſed into very cloſe and continuous contact.

The machine being now worked, the coated talc received a charge in about 5 minutes ſufficient to give a very ſmart ſhock: and this was repeated with great regularity every five or ſix minutes. The windows were now thrown open, and the room cleared of its former contents of air, till none of thoſe preſent could perceive any electric ſmell. The machine was now worked again. But after half an hour, only a very faint twitch was felt; but enough to ſhew that an accumulation was taking place. The windows were now half ſhut. After working the machine about five minutes, a faint twitch was obtained; after a quarter of an hour more, there was a moderate ſhock.

In this ſtate of things, the apparatus was examined as a condenſer, by firſt taking out the ſharp point by an inſulating handle, and then removing the tin ſtand. Examined in this way, it appeared plainly that, even when all the windows were open, the accumulation began almoſt as ſoon as the machine was worked. Nay, it was found, on another day equally favourable, that a plate of talc $\frac{47}{1000}$ or $\frac{50}{1000}$ of an inch thick, took a charge, although a cut of $\frac{31}{1000}$ wide did not allow the electricity to fly acroſs it. This is perfectly ſimilar to all our experiments on coated glaſs. The thickneſs which admits an accumulation is almoſt incomparably greater than the diſtance to which a ſpark will fly, or a concuſſion is producible, in the ſame intenſity of electricity.

2. The above deſcribed apparatus was inſulated, and a wire connected with each end. To one wire was joined a thin plate of lac, coated on the ſide next the wire; and to the other a piece of moiſt leather covered with tin-foil. Theſe plates were rubbed together by means of inſulating handles. The plate of coated talc quickly took a charge.

The ſame plate of talc, and afterwards another plate not more than half as thick, was now made part of the excitatory arc, and ſometimes part of the animal arc. Sometimes plates of varniſh, incomparably thinner than either of theſe, were employed. But all Profeſſor Robiſon's attempts to produce an accumulation of galvanic energy in this way were fruitleſs. The ſecond form of the electrical experiment was adopted, as having a ſomewhat greater reſemblance to the ſuppoſed procedure of galvaniſm; but the well-informed electrician will eaſily perceive, that the firſt form is far more delicate and deciſive.

The internal procedure in the electric and galvanic convulſions is therefore ſo different, nay, oppoſite, that we cannot bring ourſelves to think that the appearances are operations of the ſame agent (H).

We have now gone over all the points of reſemblance which, in Dr Valli's opinion, conſtitute the characters of the identity of galvaniſm and electricity. We think that, without going farther, we might ſafely reſt our aſſertion, that theſe two agents are perfectly diſtinct and unconnected with each other. But there are ſeveral other circumſtances which merit attention.

28
Farther conſiderations on electricity and galvaniſm.

No electrical phenomenon can take place between two bodies, unleſs theſe bodies be in oppoſite ſtates of electricity with regard to each other. Now, how are we to account for the accumulation of electricity in any body, or part of a body, ſurrounded on all hands by conducting ſubſtances? The experiments of Galvani ſucceed equally well, whether the ſubjects of them be inſulated or ſurrounded by conductors; whether performed in the drieſt air or under water (I); whether, by

---

(H) What if it were called *metallorgaſm*, which tranſlates exactly metallic irritation, or metallegerſiſm, from μεταλλον, and εγερσις *excitatio*.

(I) Dr Fowler mentions an exception to this. "When the ſeparated leg of a frog was held under water, and formed part of the circuit through which this influence had to paſs in order to excite another leg, it never contracted; although it did, and ſtrongly, when held above the ſurface." In this caſe it is plain, that the frog's leg by means of an electrical machine, we charge the animal and the metals till every part of them ſtrongly affect the electrometer, or whether we reverſe the experiment and electrify them negatively, ſtill no change is produced in the force or frequency of the actions excited by the application of the metals. Is there any electrical experiment which could continue to give the ſame reſult in ſuch oppoſite circumſtances? or is there any poſſibility of accounting for it conſiſtently with the known laws of the electric fluid?

The writers on this ſubject who adopt the electric theory, inſtead of attempting to explain how the electric fluid can be condenſed in a body ſurrounded by conducting ſubſtances, have recourſe to the analogy of the gymnotus, torpedo, and other fiſhes of the ſame kind. Here, ſay they, we have in fact the electric fluid accumulated in ſuch a ſituation, and there is no reaſoning againſt facts. We anſwer, that theſe animals are all furniſhed with organs of a very peculiar ſtructure, which may poſſibly be fitted for the purpoſe of ſuch a condenſation. Beſides, we apprehend it has never been inconteſtibly proved that theſe ſingular animals derive their powers from the electric fluid. Without wiſhing to enter into this queſtion, which is foreign to our preſent ſubject, we may remark that Mr Walſh diſcovered, that the ſhock of the torpedo would not paſs through a ſmall braſs chain; a circumſtance in which it differs remarkably both from electricity and from the influence diſcovered by Galvani.

It were worth while to try Profeſſor Robiſon's methods of accumulation in the examination of the convulſions occaſioned by the torpedo. The Profeſſor ſuſpects that the popular horror at the lamprey, and the accounts of cramps and pains produced by it, have their ſource in ſome ſimilar powers of that animal.

Dr Valli's reaſoning on this part of the ſubject is very curious. He takes it for granted that the gymnotus owes its influence to the electric fluid. Then, though the gymnotus gives ſhocks and emits ſparks, while the torpedo only gives ſhocks without emitting ſparks, he ſays it would be abſurd to aſſert that the torpedo derives its influence from a cauſe different from the gymnotus. Again, though the influence diſcovered by Galvani neither gives ſhocks nor emits ſparks, it would ſtill be abſurd to maintain that it is not the ſame as the electric fluid, and as the influence of the gymnotus and torpedo. To diſſent from any part of this very logical deduction, he declares would be contrary to the laws of philoſophiſing! *Riſum teneatis?*

Afraid, probably, that his readers might be tempted to offend againſt theſe new laws, he proceeds to ſtrengthen them by the analogy of animals and vegetables retaining an uniform temperature *in media*, warmer or colder than their own bodies; from which he argues that they may alſo have a power of accumulating electricity, and retaining it in a particular part, though their whole bodies are conductors. But the caſes are in no reſpect ſimilar. Neither animals nor vegetables accumulate caloric in any particular part of their bodies in preference to any other part. They have no power of *retaining* caloric in their bodies more ſtrongly than any other bodies do; for if they are placed in a medium colder than themſelves, they are continually imparting caloric to that medium. Neither is there the ſmalleſt proof, from any experiments yet publiſhed, that when placed in a medium warmer than themſelves, they do not continually abſorb caloric from it. The exiſtence of a frigorific power in animals appears to us exceedingly problematical; but if it were proved to exiſt, it would by no means demonſtrate that animals or vegetables have a faculty of declining to abſorb caloric from bodies warmer than themſelves. It is readily admitted, that animals and vegetables have a power, within certain limits, of preſerving their temperature higher than that of the ſurrounding medium; nor is there any thing ſurpriſing in this, as the caloric, which they are continually receiving by the decompoſition of oxygenous gas, is diſſipated ſlowly. But if we ſhould allow that animals have a ſimilar faculty of generating the electric fluid; from the nature of that fluid it muſt be continually communicated, not only to every part of the bodies of the animals themſelves, the whole of which are conductors, but to every conducting ſubſtance contiguous to them: and this muſt take place, not ſlowly, like the diſſipation of caloric, but inſtantaneouſly, ſo as to render any ſenſible accumulation impoſſible.

29
Difference in their mode of excitement,

Galvaniſm differs from electricity in nothing more remarkably than in the mode of its excitement and diſcharge. To produce the phenomena diſcovered by Galvani, no operation at all ſimilar to the friction of an electric upon a conducting ſubſtance is neceſſary (K). The nerves and muſcles have only to be laid bare, and a communication formed between them by means of the excitatory arc, when the contractions immediately enſue. In the caſe of electricity, a ſingle diſcharge having reſtored the equilibrium, no farther effects can be produced till this has been again deſtroyed by ſome means capable of producing a condenſation in one quarter and a comparative rarefaction in another. The fact is very different with regard to galvaniſm; for with it the number of ſhocks which may be given appears to be infinite. Nay, they frequently become ſtronger in proportion as they have been longer continued: this influence differing extremely in this particular, too, from the electric fluid, which, beſides being itſelf exhauſted, never fails in a remarkable manner to exhauſt the contractile power of the muſcles.

30
And in the duration of their effects.

The permanence of the effects of galvaniſm is ſtill more ſtriking in the experiments upon the organ of taſte. When the metals are applied to the tongue, the ſenſation

---

leg had in fact formed no part of the circuit through which the influence paſſed; the influence had been tranſmitted by the water in which the leg was held.

(K) It is true, as we have noticed above, that galvanic energy is ſometimes communicated to a conducting ſubſtance by rubbing it upon ſome other ſubſtance; but this has no reſemblance to the excitement of electricity by friction. The galvanic energy is communicated in this caſe to a *conducting* ſubſtance, and it ſucceeds as readily when both the bodies are of this claſs as when one of them is an idio-electric. But no electric phenomenon has ever been produced by the friction of two conducting bodies upon each other; one of them muſt be an idio-electric, and it is in this one that the excitement takes place.

ſenſation produced is not ſudden and tranſient ; but ſo long as the metals are in contact with the tongue and with each other, ſo long does the taſte continue ; and, after ſome time, it becomes inſufferably diſagreeable. M. Volta, who adopts the electric theory with various modifications, ſenſible of the permanence of the effect, in his curious experiments abovementioned ſuppoſes, that a ſtream of electricity paſſes from the tin cup to the liquor, from this to the tongue of the perſon making the experiment, then through his body, and returns through the water upon his hands to the cup ; and thus he ſuppoſes the fluid to move perpetually in a circle. It is ſurely unneceſſary for us to obſerve, that the ſuppoſition of a ſtream of electricity continually moving in a circle in this manner, is wholly inconſiſtent with the laws which appear in every caſe to regulate the motions of that fluid. The ſame obſervation applies to the manner in which he explains moſt of the other phenomena of galvaniſm.

The electric fluid cannot be put in motion but by deſtroying the equilibrium to which it perpetually tends ; but whenever this is deſtroyed, all that is required to produce a diſcharge is, that a ſingle conducting ſubſtance be placed between the two points in which it is unequally diſtributed. Here again there is a very wide diſtinction between this fluid and the influence diſcovered by Galvani. M. Volta divides all conductors of galvaniſm into two claſſes ; 1ſt, Dry conductors, comprehending metals, pyrites, ſome other minerals, and charcoal ; and, 2d, Moiſt conductors. He aſſerts, that it is abſolutely neceſſary, in order to the production of the phenomena, that two conductors of the firſt claſs touch each other immediately on one hand, while at their other extremities they touch conductors of the ſecond claſs. Whether this be admitted or not, we have already ſtated our opinion that the action of two different ſubſtances is abſolutely neceſſary in order to excite contractions : and although it is contended by ſome writers that a ſingle piece of metal has ſometimes been found ſufficient, yet even they muſt allow that, in by far the greater number of caſes, it has been found neceſſary to make uſe of two metals, and that the effect is even heighened in general by employing three. In the whole ſcience of electricity, we do not know a ſingle fact which bears the ſlighteſt analogy to this. Never in a ſingle inſtance has it been found, that the effects of a Leyden phial have been increaſed by uſing a conductor formed of two or more metals in procuring the diſcharge.

31
Some m
non-con
ductors
galvaniſ

Before leaving the ſubject of conductors, we may take notice of a very curious and important fact mentioned by Dr Valli. "Amongſt men," ſays he, "there are ſome individuals who are good conductors, others who are leſs ſo ; and ſome again who appear to be almoſt non-conductors. I was one day carrying on, with three of my friends, ſome experiments upon frogs. A frog was put in water, and we each by turn eſſayed its power. Two of us excited ſtrong convulſions, the third only feeble ones, and the fourth none at all. This experiment was repeated frequently with the ſame reſult. This is not the only example I could adduce of the reality of this fact, but I do not think it neceſſary to dwell any longer upon it." We have met with one individual who is not ſenſible of any peculiar ſenſation when the metals are applied to his tongue. This ſeems in ſome meaſure to corroborate Dr Valli's obſervation. It is apprehended, however, that all men are equally good conductors of electricity.

There is ſtill another very marked diſtinction between the effects of galvaniſm and electricity. No ſhock at all reſembling that produced by the electric fluid has ever been felt by any perſon whoſe body was made a part of the chain conducting the galvanic influence, while a very ſmall quantity of the electric fluid is immediately felt (L). In Dr Robiſon's experiment with the plates of zinc and ſilver in the cheeks, there is no doubt a convulſive twitch diſtinctly felt in the gums ; but, as we have already obſerved, the ſenſation thus produced is quite different from that which is felt from an electric ſhock (M)

There is an experiment related by Dr Valli, which ſeems to ſhew that nothing like an electric ſhock is felt, even when this influence is tranſmitted through a nerve, ſo as to excite convulſions. Having laid bare the nerves of a fowl's wing, without cutting them, and without killing the fowl, upon applying the metals very ſmart movements were produced, but the animal remained perfectly tranquil. Nor was this owing to the fowl

---

(L) There is an exception to this rule which ought to be taken notice of. M. Cotugno informs us, that when he was one day employed in diſſecting a live mouſe, he received a ſenſible ſhock from the animal. But as neither he nor any other perſon has ever been ſimilarly affected in any other inſtance, it ſeems pretty certain that he was deceived into the belief of a ſhock from the ſenſation produced by the ſtruggles of the animal he diſſected.

(M) "No one (ſays M. Humboldt) can ſpeak more decidedly on this ſubject than myſelf, having made ſeveral experiments on my own perſon, the ſeat of which, in ſome inſtances, was the ſocket of a tooth which I had cauſed to be extracted ; in others, certain wounds which I made in my hand ; and in others, the excoriations produced by four bliſtering plaſters." The following is the reſult of theſe painful experiments. The galvanic irritation is always painful, and the more ſo in proportion as the irritated part is more injured and the time of irritation more prolonged. The firſt ſtrokes are felt but ſlightly ; the five or ſix following are much more ſenſible, and even ſcarcely to be endured, until the irritated nerve becomes inſenſible from continued ſtimulus. The ſenſation does not at all reſemble that which is cauſed by the electric commotion and the electric bath ; it is a peculiar kind of pain, which is neither ſharp, pungent, penetrating, nor by intermiſſions, like that which is cauſed by the electric fluid. We may diſtinguiſh a violent ſtroke, a regular preſſure, accompanied by an unintermitting glow, which is incomparably more active when the wound is covered with a plate of ſilver and irritated by a rod of zinc, than when the plate of zinc is placed on the wound, and the ſilver pincers are uſed to eſtabliſh the communication.

fowl being in a ſtate of inſenſibility; for when the nerves were pricked or irritated it ſcreamed violently. But all animals ſhew ſigns of great uneaſineſs from an electric ſhock.

In general, it muſt be confeſſed, that animals under experiments of this kind ſeem reſtleſs and uneaſy. The great diſtinction of which we ſpeak at preſent, conſiſts in this, that the electric fluid produces a ſhock and uneaſy ſenſation when any part of the body is introduced into the conducting chain; while the influence diſcovered by Galvani, on the contary, when merely tranſmitted through the body in this manner, gives no ſhock, nor any ſenſation whatever, inſomuch that we are not ſenſible of its paſſage. If this influence be made to act directly on a nerve, there is, no doubt, ſome kind of irritation produced, as appears from the effect of the metals upon the tongue, the eye, and other nervous parts; but ſtill this action bears no analogy to that of the electric fluid. As the application of the metals to the organs of ſenſe, produces in each organ the peculiar ſenſation for which it is conſtructed, as taſte in the tongue, light in the eye, &c. ſo when nerves intended merely for muſcular motion are ſubjected to the action of galvaniſm, the effect produced is motion in the muſcles on which they are diſtributed.

If this view of the matter be juſt, it will explain why no ſhock is felt when the human body is made a part of the conducting chain. In that caſe the influence does not, in all probability, act directly upon any nerve; and we ſee that this influence poſſeſſes no power, like the electric fluid, of producing a convulſive ſhock, when merely paſſed through any part of the body; but it has this peculiar property, when paſſed directly through a nerve, it excites that nerve to perform the function for which it was intended by nature. To this it will no doubt be objected, that contractions may be excited in different parts of a frog without any diviſion being made in its ſkin; and here it may be ſuppoſed that the influence is not made to paſs directly through a nerve. But it ought to be recollected that the ſkin of theſe animals is abundantly ſupplied with nerves, whoſe trunks communicate at different places with thoſe which ſupply the muſcles; and that the contractions are always ſtrong and eaſily excited, in proportion as they are applied near to the courſe of any of the nerves which go to the muſcles. But though we had no doubt thac the influence might be tranſmitted through the bodies of theſe animals, as well as through the human body, without any contractions being produced, we have thought it worth while to aſcertain the fact by the following experiment.

A frog was prepared in the uſual manner by coating its ſciatic nerve with tinfoil, and laying the leg upon a plate of zinc. Another frog, in a very vigorous ſtate, had its fore legs and cheſt attached to a rod of ſilver, and its poſterior extremities to a rod of zinc. The ſilver rod was applied to the tinfoil and nerve of the prepared frog, and the zinc rod to the plate of zinc upon which the leg was laid. Immediately very ſtrong contractions took place in the leg; but no motion, nor the ſlighteſt mark of uneaſineſs, appeared in the other frog through the body of which the influence muſt have paſſed. It is neceſſary in this experiment to dry the body of the frog which is to ſerve as a conductor very carefully, otherwiſe the influence might be tranſmitted by the water upon its ſurface without paſſing through its body.

There is an experiment mentioned by Dr Fowler, which ſhews a ſtriking difference between electricity and galvaniſm. It was inſtituted with a view to aſcertain the effects of the latter upon the blood-veſſels. The Doctor relates it as follows: "Having laid bare and ſeparated from ſurrounding parts and from each other, the crural artery and nerve in the thigh of a full grown frog, I cut out the whole of the nerve between the pelvis and the knee: I then inſinuated beneath the artery a thin plate of ſealing wax, ſpread upon paper, and broad enough to keep a large portion of the artery completely apart from the reſt of the thigh. The blood ſtill continued to flow through the whole courſe of the artery in an undiminiſhed ſtream. The artery, thus partially inſulated, was touched with ſilver and zinc, which were then brought into contact with each other; but no contraction whatever was produced in any muſcle of the limb. This experiment was frequently repeated upon ſeveral different frogs, both in whom the nerve was, and in whom it was not divided. The reſult was uniformly the ſame. But vivid contractions were produced in the whole limb when an electric ſpark, or even a full ſtream of the aura was paſſed into the artery."

Before taking leave of this branch of our ſubject, it may be proper to take notice of one fact, which may be thought to militate againſt the doctrine we have endeavoured to eſtabliſh. It is ſaid that a frog, exhauſted and brought near to a charged electrophorus, has been found to reſume its ſuſceptibility. We think this fact may be accounted for without admitting any connection between galvaniſm and electricity, merely by ſuppoſing that the irritability of the muſcles, which had been exhauſted, was reſtored by the application of a moderate ſtimulus, (the electric fluid), of a kind different from thoſe by which it had been exhauſted. Such of our readers as are acquainted with the writings of modern phyſiologiſts on the ſubject of muſcular irritability, will know that facts of this kind are very common. Thus it has been found by M. Humboldt, that the oxygenated muriatic acid has often reſtored irritability. To this explanation it will no doubt be objected, that the application of other ſtimuli, as alcohol and a ſolution of potaſh, inſtead of reſtoring, totally deſtroy the ſuſceptibility of galvaniſm. Suſpecting, that although theſe ſubſtances in a concentrated ſtate deſtroy the ſuſceptibility, yet that when ſufficiently diluted, they might be found to have the oppoſite effect, we tried the following experiment, which confirmed our conjecture.

A frog, 57 hours after it had been decapitated, had ceaſed for above an hour to be capable of excitement by the application of the metals in any way that could be deviſed. A few drops of alcohol being diluted with about a tea-ſpoonful of water, the nerve and the muſcles which had been laid bare, as well as the whole ſkin of the animal, were wet with it. Upon the application of an excitatory arc, compoſed of four pieces, gold, zinc, ſilver, and tinfoil, a few very ſlight contractions of the toes were diſtinctly obſerved. After this, no means that we could think of produced the ſmalleſt excitement. Alcohol was now applied in a more concentrated ſtate, but without any effect. The ſame

four

four pieces of metal which produced the contractions of the toes, had been uſed before the diluted alcohol was applied, but without effect. We have not tried the application of potaſh much diluted.

From what has been ſaid, we think we are fully warranted in ſaying, that although ſome of the phenomena diſcovered by Galvani bear a ſtriking reſemblance to ſome of thoſe produced by the electric fluid ; yet there are others, and theſe not the leaſt important, which differ ſo widely from any effects which have ever been ſeen to ariſe from that fluid, that they muſt derive their origin from ſome other cauſe. Our readers may probably think that we have dedicated too much time to this queſtion ; but as we conceive it to be the moſt important point which can be diſcuſſed on this ſubject, we thought it worth while to conſider it at ſome length; and we were the more convinced of the neceſſity of doing ſo, from this conſideration, that there are ſtill ſome writers of high authority who maintain the hypotheſis, that galvaniſm and electricity are the ſame.

32 The galvanic influence probably foreign from animals.

The next queſtion that occurs to us with regard to the nature of galvaniſm is, whether or not it depends upon any law of animal life ? To us it appears rather more probable, that the influence which incites the muſcles of animals to contract in the experiments of Galvani, is ſomething quite foreign to the animals themſelves; as much ſo as the electric fluid of the Leyden phial is to the animal which receives a ſhock from it, in both caſes the body of the animal acting as a mere conductor. Upon this queſtion, however, we confeſs that we have neither facts nor arguments to adduce ſufficient to warrant our drawing any certain concluſion. It will doubtleſs be aſked, if this influence be ſomething foreign to the bodies of animals, why do we never find it acting anywhere but in their bodies ? why is it not, like the electric fluid, capable of being made evident to the ſenſes by its effects upon inanimate matter ? The only anſwer which we are in a condition to give to this queſtion is, that it may very poſſibly be capable of producing important effects upon inanimate matter, nay, theſe effects may be the ſubject of our daily obſervation ; but for want of our being ſufficiently acquainted with galvaniſm to point out the relation between theſe effects and their cauſe, the effects themſelves are either not explained at all, or aſcribed perhaps to ſome other power, with which they have no connection. In like manner, the electric fluid has doubtleſs been producing moſt important effects from the beginning of time ; but, prior to the diſcovery of that fluid, theſe were either not explained at all, or conſidered as originating from ſome cauſe which, in fact, had no ſhare in their production.

The great difficulty is to obtain ſome teſt by which we may detect the galvanic influence when actually preſent in inanimate matter. Hitherto we have no ſuch teſt ; nor ſhould we know that ſuch an influence exiſts, but for the effects which it produces upon the bodies of animals through the medium of their nerves. If we had any means of aſcertaining its exiſtence, either in a ſeparate ſtate, or conjoined with inanimate matter, the ſcience would make a rapid progreſs, as it would be eaſy to diverſify experiments ſo as to diſcover its nature and effects. To detect it in a ſeparate ſtate is, in all probability, impoſſible ; but that the zeal and ingenuity of philoſophers will one day be able to diſcover ſome teſt of its preſence in inanimate matter, there ſeems no reaſon to doubt.

We have made many experiments with a view to diſcover ſuch a teſt, but hitherto without the ſmalleſt ſucceſs. In the trials we have already made, our views have been chiefly confined to the diſcovery of ſome chemical effects of this influence upon inanimate matter. M. Volta and other writers, having conſidered the ſenſation produced by it upon the tongue as ſimilar to that occaſioned by acids, we were not without hopes that it would be found to reſemble that claſs of ſubſtances in ſome of its other properties. We have therefore tranſmitted it through liquids tinged with the moſt delicate vegetable colours ; but no change in theſe colours has been effected by the tranſmiſſion of many galvanic ſhocks. We have alſo tried, in the ſame way, alkaline liquors, without any effect. We next diſſolved in water different neutral ſalts, and other compound bodies, of which the parts are held together by the weakeſt affinities ; but no change has been obſerved to be produced in them by the tranſmiſſion of this influence. Our want of ſucceſs, however, ſhall not deter us from continuing our efforts ; we ſhall vary the nature of our experiments in every way that ſhall occur to us as likely to be attended with advantage ; and if we ſhould ultimately fail, we truſt that others will be more fortunate. Every new fact which is diſcovered upon the ſubject tends to facilitate this inveſtigation, by furniſhing us with new guides to direct the courſe of our experiments.

33 Dr Fowler heſitates on this point.

Dr Fowler is of opinion, that this influence, whatever it may be, is not derived from the metals alone, but that the animals at leaſt contribute to its production, as well as indicate its preſence ; and he ſeems to have been led to adopt this theory chiefly from two conſiderations, neither of which appears to us to have much weight. They are the following : The neceſſity of a communication between the metals and the muſcles, as well as between the metals and the nerves ; and the obſervation, that animals have a more complete controul over its effects than one would expect them to have over an influence wholly external to them. But the communication between the metals and the muſcles may be neceſſary to the contraction of the latter, tho' not to the production of galvaniſm ; which, however, for want of any obvious effect, is not obſerved. That animals have ſome controul over the effects of galvaniſm upon themſelves, may be very true ; but this circumſtance does not appear to us capable of proving any thing, as they have a controul over the effects of other ſtimuli in the ſame way. Thus, an animal of any reſolution can bear, without betraying any uneaſy ſenſation, a blow which, inflicted unexpectedly, would have produced a convulſive ſtart. The will does not in any degree controul the effects produced by galvaniſm upon our ſenſes of taſte, ſeeing &c.; that is, the ſenſations are produced, though we may have reſolution not to betray them. But, ſays Dr Fowler, the will is not able to controul the effects of electricity, when the electricity is otherwiſe ſufficiently ſtrong to excite muſcles to contraction. This argument may tend to ſhew, that galvaniſm differs from electricity ; but as it muſt be admitted, that we can reſiſt the contractions naturally produced by the application of other foreign ſtimuli, it by no means proves that animals have any power of preventing

preventing the excitement or tranſmiſſion of galvaniſm. Beſides, though we cannot prevent an involuntary contraction of our muſcles from taking place when an electric ſhock of conſiderable ſtrength is paſſed through them, yet any man may with his hand draw ſparks from the prime conductor of an electric machine without ſhrinking, though even theſe ſparks would, if he were off his guard, produce a convulſive ſtart.

34
We think without reaſon.

If the galvanic influence exiſted ready formed in the muſcles or nerves of animals, the only thing requiſite to the production of the contractions would be to make a communication between the nerves and muſcles, by means of any ſingle ſubſtance capable of conducting this influence; as water, for example: but the reverſe is known to be true. It may be ſaid, however, that, although there is no proof that any influence naturally reſides in the nerves or muſcles capable of producing the effects mentioned by M. Galvani, theſe ſubſtances may ſtill, by ſome power, independent of the properties they poſſeſs in common with dead matter, *contribute* to the excitement of the influence, which is ſo well known to exiſt in them after a certain application of metals. Upon this part of the ſubject, the obſervations of Dr Wells will be found to merit conſiderable attention.

" It is known (ſays that gentleman), that if a muſcle and its nerve be covered with two pieces of the ſame metal, no motion will take place upon connecting thoſe pieces by means of one or more different metals. After making this experiment one day, I accidentally applied the metal I had uſed as the connector, and which I ſtill held in one hand, to the coating of the muſcle only, while with the other hand I touched the ſimilar coating of the nerve, and was ſurpriſed to find that the muſcle was immediately thrown into contraction. Having produced motions in this way ſufficiently often to place the fact beyond doubt, I next began to conſider its relations to other facts formerly known. I very ſoon perceived, that the immediate exciting cauſe of theſe motions could not be derived from the action of the metals upon the muſcle and nerve to which they were applied; otherwiſe it muſt have been admitted, that my body and a metal formed together a better conductor of the exciting influence than a metal alone; the contrary of which I had known, from many experiments, to be the caſe. The only ſource, therefore, to which it could poſſibly be referred, was the action of the metals upon my own body. It then occurred to me, that a proper opportunity now offered itſelf of determining whether animals contribute to the production of this influence by means of any other property than their moiſture. With this view I employed various moiſt ſubſtances, in which there could be no ſuſpicion of life to conſtitute, with one or more metals, different from that of the coatings of the muſcle and nerve, a connecting medium between theſe coatings, and found that they produced the ſame effect as my body. A ſingle drop of water was even ſufficient for this purpoſe; though, in general, the greater the quantity of the moiſture which was uſed, the more readily and powerfully were contractions of the muſcle excited. But if the mutual operation of metals and moiſture be fully adequate to the excitement of an influence capable of occaſioning muſcles to contract, it follows, as an immediate conſequence, that animals act by their moiſture alone in giving origin to the ſame influence in M. Galvani's experiments, unleſs we are to admit more cauſes of an effect than what are ſufficient for its production." We do not quote the above reaſoning as perfectly concluſive, for it by no means appears to us to be ſo; but it certainly gives ſome probability to the opinion, that galvaniſm is, as M. Volta ſuppoſes, the reſult of the action of two dry conductors, which touch each other immediately on one hand, while at their other extremities they touch conductors of what he calls the ſecond claſs, (that is, moiſture, for all the conductors of the ſecond claſs contain water), and that the bodies of animals act merely as moiſture.

One of M. Humboldt's experiments related above, appears to us to ſtrengthen the concluſion, that the influence diſcovered by Galvani is ſomething perfectly foreign to the bodies of animals. Can it be ſuppoſed that any ſubſtance which naturally reſides in our bodies, ſhould, in a few ſeconds after it is put in motion, convert the ſimple ſerous diſcharge of a bliſter into a dark coloured fluid, of a nature ſo acrid as to irritate and violently inflame the ſkin wherever it touches it? We do not ſay that this is impoſſible, for we are too little acquainted with the laws of ſecretion to ſay with certainty what may, or what may not, produce ſuch a change; but we know no ſimilar alteration produced, *in a few ſeconds*, by a mere change of action in the veſſels themſelves.

35
The cauſe which produces the galvanic effects unknown.

We ſhall not undertake to determine the nature of the cauſe which produces ſuch aſtoniſhing effects. We think it is certainly not the electric fluid, and probably ſomething which reſides or is formed in the excitatory arc; but we conſider our knowledge of galvaniſm as ſtill in its infancy, and our ſtock of facts as infinitely too ſmall to admit of our forming a juſt theory on the ſubject. Fortunately, however, the diſcovery of Galvani has attracted ſo much the attention of philoſophers in every part of Europe, that new facts may be expected to come to light every day; and we hope the time is not very diſtant, when theſe may be ſo claſſed, as to entitle the ſubject to be ranked among the ſciences. See Torpedo in this *Suppl.*

While this article was in the preſs, we were favoured by a friend with an account of ſome German diſſertations on the ſubject, which we are obliged to inſert in this irregular manner.

Mr Creve, ſurgeon in Wurtzburg, had an opportunity of obſerving the galvanic irritation on the leg of a boy, which had been amputated far above the knee in the hoſpital of that city. Immediately after the amputation, Mr Creve laid bare the crural nerve (kniekehlnerven), and ſurrounded it with a ſlip of tinfoil. He touched at once the tinfoil and the nerve with a French crownpiece. In that inſtant the moſt violent convulſions took place in the leg both above and below the knee. The remainder of the thighbone bent with force toward the calf; the foot was more bent than extended. All theſe motions were made with much force and rapidity. None were produced when the tinfoil was taken away, or when a ſteel pincer was uſed in place of a piece of ſilver, or when the tin or ſilver was covered with blood: but they were renewed when theſe obſtacles were removed. Theſe phenomena continued till 38 minutes after the amputation, when the limb became cold.

Dr Chriſtopher Heinrich Pfaff (*in Diſſertatione de Electricitate Animali*, Stutgardt, 1793: ſee alſo Gren's *Journal der Phyſik*, T. viii. p. 196, &c.) has claſſed the phenomena in a very orderly and perſpicuous manner; and the reſult of the numerous experiments made by himſelf and others, correſponds very nearly with our inferences in the preceding pages.

I. *Phenomena of muſcular contraction.*

The general form of his experiments is the ſame with that which we have placed at the beginning of this article; but the following varieties were obſerved:

The nerve being coated with tinfoil, it was always obſerved that the contractions were ſtronger when the ſilver firſt touched the muſcle, and then the coating. If it touched the coating firſt, the effects were always, and very ſenſibly, weaker.

They were ſtill ſtronger when the ſilver did not touch the muſcle at all, but only the nerve and its coating.

When the contractions were weaker at the beginning, they alſo ceaſed ſooner.

No contraction enſued from touching the coating only, or the nerve only, or the muſcle only, with the ſilver.

Continuing the contact did not occaſion any repetition of the contractions, except in ſome caſes, where the ſilver was drawn along different parts of the coating, while its other end remained in contact with the nerve.

The contractions took place only in the muſcles to which the nerve led.

Their ſtrength and duration were greater when the ſurfaces of contact were greater, and when the two metals touched each other in points or ſharp edges.

A ligature, with a ſilk thread below the coating (that is, between the coating and the muſcle, or part of the nerve touched by the ſilver), prevented all contraction; but not if the ligature was between the coating and the brain. If the nerve was cut through below the coating, and the parts ſeparated a quarter of an inch, no contraction followed by touching the coating and the nerve or muſcle: but it took place, if the parts were brought into contact; or even if a piece of any other nerve was put between the parts.

If a conſiderable part of a bared nerve was inſulated and coated, partly with tinfoil and partly with ſilver, contractions were produced in the muſcle to which it led whenever the two metals were brought into contact.

If one crural nerve be coated with tin, and the other with ſilver, contractions are produced in both legs by bringing the metals into contact.

If the nerve be dry under the coating, or when the ſilver touches it, or in both places, we have no contractions; but they begin as ſoon as we moiſten the nerve.

Dr Pfaff infers from theſe phenomena, that the nerve alone is ſubject to the irritation produced by the two metals.

If the prepared frog be immerſed in water, ſo that the coating touches the water, contractions are produced by touching the coating above water with the ſilver, while another part of the ſilver touches the nerve, or the muſcle, or even dips pretty deep in the water.

No ſuch thing happens in oil; or, at beſt, the contractions are very ſlight.

Dr Pfaff could not produce contractions without employing two metals, or a metal and charcoal.

A very thin covering of muſcular fleſh on the nerve did not altogether prevent the contractions, and in many caſes did not ſenſibly diminiſh them.

If a piece of ſilver be laid on the muſcles of the breaſt or belly, and be brought into contact with the tin-coating on the lumbal region, only the muſcles of the breaſt or belly are affected, but not thoſe of the legs.

Dr Pfaff ſays, that the involuntary muſcles are not affected by galvaniſm; and refers for convincing proofs to a diſſertation by Dr Ludwig, ſhewing that the heart is not furniſhed with nerves, (*Scriptor. neurolog. minor. ſelect.* vol. 2.).

II. *Irritation of the Organs of Senſe.*

Here Dr Pfaff's diſſertation contains nothing remarkable.

III. *Conjectures as to the Cauſe.*

Dr Pfaff uſes the ſame arguments that we have employed to refute the opinion of a ſimilarity between the animal organs and the Leyden phial, and the opinion that electricity is the agent. He mentions the opinion of thoſe who maintain that the agent is a fluid put into motion by means of its relation to the metals only, in their action on each other, and who conſider the animal as merely ſerving as a conductor; and alſo ſerving, by its irritability, to give us the information of the preſence of ſuch a fluid, in the ſame manner as another kind of irritation, ſomewhat analogous to it, indicates the preſence and agency of the electric fluid. It may therefore be called the METALLIC IRRITATION; a term which will ſufficiently diſtinguiſh it.

But Dr Pfaff ſeems rather to think that the agent reſides in the animal, and that the metals are the conductors (See a diſſertation, entitled, *Farther Contributions to the Knowledge of Animal Electricity*, in *Gren's Journal der Phyſik*, T. viii. p. 377.). This fluid he conceives to be intimately blended with the *principle of life*; nay, perhaps, to be the ſame. He mentions a thought of Profeſſor Kielmayer, "that it may reſemble the magnetic fluid in its manner of acting, giving connection to the diſtant particles of a nerve, as we obſerve a magnet give an inſtantaneous connection to each of a parcel of iron filings; all of which it would arrange in a certain preciſe manner, if they were ſufficiently moveable, by giving momentary polarity to each." This ſomewhat reſembles Newton's hypothetical whim read to the Royal Society, deſcribing what may be done by means of an æther (See *Birche's Hiſtory of the Royal Society*).

But all this is vague conjecture, and merits little attention. This will be better beſtowed on an obſervation of M. Humboldt of Jena, "that a bit of freſh morelle (the *Helvella mitra* of Linnæus) may be ſubſtituted for a bit of nerve in the animal arc in theſe experiments." This is the only vegetable ſubſtance yet diſcovered to have this property. If the nerve be laid on the morelle, we have only to touch the morelle with the zinc, and the muſcular contractions immediately follow.

GARDECAUT, or GUARD DU CORD, in a watch, is that which ſtops the fuſee when wound up, and for that end is driven up by the ſpring. Some call it Guard-cock; others Guard du Gut.

GARDEN (Francis), better known to the public by the title of *Lord Gardenſtone*, was born at Edinburgh June 24th, in the year 1721. His father was Alexander Garden of Troup; an opulent landholder in Aberdeenſhire; his mother was Jane, daughter of Sir Francis Grant of Cullen, S.C.I.

After paſſing through the uſual courſe of liberal education at the ſchool and the univerſity, he betook himſelf to the ſtudy of law for his profeſſion. In the year 1744 he was admitted a member of the Faculty of Advocates, and called to the Scottiſh bar.

In his practice as an advocate he ſoon began to be diſtinguiſhed, by a ſtrong, native rectitude of underſtanding; by that vivacity of apprehenſion and imagination which is commonly denominated *Genius*; by manly candour in argument, often more perſuaſive than ſubtlety and ſophiſtical artifice; by powers which, with diligence, might eaſily attain to the higheſt eminence of the profeſſion. But the ſame ſtrength, openneſs, and ardour of mind, which diſtinguiſhed him ſo advantageouſly among the pleaders at the bar, tended to give him a fondneſs for the gay enjoyments of convivial intercourſe, which was unfavourable to his progreſs in juridical erudition. Shining in the ſocial and convivial circle, he became leſs ſolicitouſly ambitious than he might otherwiſe have been, of the character of an eloquent advocate, or of a profound and learned lawyer. The vivacity of his genius was averſe from auſtere and plodding ſtudy, while it was captivated by the faſcinations of polite learning and of the fine arts. Nor did he always eſcape thoſe exceſſes in the purſuit of pleaſure into which the temptations of opening life are apt occaſionally to ſeduce the moſt liberal and ingenuous youth. But his cheerful conviviality, his wit, humour, taſte, good-nature, and benevolence of heart, rendered him the delight of all his acquaintance. He became his Majeſty's Solicitor July 3d, 1764.

At length the worth of his character, and his abilities as a lawyer, recommended him to the office of a Judge in the Courts of Seſſion and Juſticiary, the ſupreme judicature, civil and criminal, for Scotland. His place in the Court of Seſſion he continued to occupy till his death; but had, ſome years before, reſigned the office of a Commiſſioner of Juſticiary, and in recompence got a penſion of 200l. per annum. Clear diſcernment, ſtrong good ſenſe, conſcientious honeſty, and amiable benevolence, remarkably diſtinguiſhed all his opinions and conduct as a judge.

We not unfrequently ſee the gay young men of the preſent age, to turn, as they advance towards middle life, from the headlong purſuit of pleaſure to a ſordid and contracted ſelfiſhneſs, which excludes even thoſe few good qualities that ſeemed to accompany their firſt thoughtleſs days. Their life is divided between ſenſuality and that anxious *inhumane* avarice and ambition whoſe ultimate object is, to provide gratifications to ſenſuality and pride. The kindling light of rectitude, and the firſt ſparks of generous humanity, are extinguiſhed in their breaſts as ſoon as thoſe ebullitions of youthful paſſion and inexperience are over, by which the uſeful efficiency of their early good qualities was prevented. Hardly have they become tolerably well acquainted with mankind, when the milk of human kindneſs is turned into gall and venom in their hearts.

It was far otherwiſe with Lord Gardenſtone. As he advanced in years, humanity, taſte, public ſpirit, became ſtill more and more eminently the predominant principles in his mind.—He pitied the condition of the peaſantry, depreſſed rather by their ignorance of the moſt ſkilful modes of labour, and by their remoteneſs from the ſphere of improvement, than by any tyranny or extortion of their landlords. He admired, protected, and cultivated the polite arts He was the ardent votary of political liberty, and friendly to every thing that promiſed a feaſible amelioration of public economy, and the principles of government.

In the year 1762 he purchaſed the eſtate of Johnſton, in the county of Kincardine. Within a few years after he began to attempt a plan of the moſt liberal improvement of the value of this eſtate, by an extenſion of the village of Laurencekirk, adjoining. He offered leaſes of ſmall farms, and of ground for building upon, which were to laſt for the term of one hundred years; and of which the conditions were extremely inviting to the labourers and tradeſmen of the ſurrounding country. Theſe offers were eagerly liſtened to. More deſirous to make the attempt beneficial to the country than to derive profit from it to himſelf, he was induced, within a few years, to reduce his ground-rents to one-half of the original rate.—Weavers, joiners, ſhoemakers, and other artiſans in a conſiderable number, reſorted to ſettle in the riſing village. His Lordſhip's earneſtneſs for the ſucceſs of his project, and to promote the proſperity of the good people whom he had received under his protection, led him to engage in ſeveral undertakings; by the failure of which he incurred conſiderable loſſes. Projects of a printfield, and of manufactures of linen and of ſtockings, attempted with ſanguine hopes in the new village, and chiefly at his Lordſhip's riſk and expence, miſgave in ſuch a manner as might well have finally diſguſted a man of leſs ſteady and ardent philanthropy with every ſuch engagement. But the village ſtill continued to advance. It grew up under his Lordſhip's eye, and was the favourite object of his care. In the year 1779 he procured it to be erected into a burgh of barony; having a magiſtracy, an annual fair, and a weekly market. He provived in it a good inn for the reception of travellers; and with an uncommon attention to the entertainment of the gueſts who might reſort to it, furniſhed this inn with a library of books for their amuſement. He invited an artiſt for drawing, from the continent, to ſettle at Laurencekirk. He had the pleaſure of ſeeing a conſiderable linen manufacture at length fixed in it. A bleachfield was alſo eſtabliſhed as a natural counterpart to the linen manufacture. Before his Lordſhip's death, he ſaw his plan of improving the condition of the labourers, by the formation of a new village at Laurencekirk, crowned with ſucceſs beyond his moſt ſanguine hopes. He has acknowledged, with an amiable frankneſs, in a memoir concerning this village, "That he had tried, in ſome meaſure, a variety of the pleaſures which mankind purſue; but never reliſhed any ſo much as the pleaſure ariſing from the progreſs of his village."

In the year 1785, upon the death of his elder brother,

ther, Alexander Garden of Troup, M. P. for Aberdeenſhire, Lord Gardenſtone ſucceeded to the poſſeſſion of the family eſtates, which were very conſiderable. Until this time his Lordſhip's income had never been more than adequate to the liberal expence into which his rank, and the generoſity of his nature, unavoidably led him. But the addition of a fortune of about three thouſand pounds a-year to his former revenue, gave him the power of performing many acts of beneficence with which he could not before gratify his good heart. It was happy, likewiſe, that his ſucceſſion to this ample income, at a period when the vigour of his conſtitution was rapidly yielding to the infirmities of old age, enabled him to ſeek relief, by a partial ceſſation from buſineſs, by travel, and by other means, which could not have been eaſily compatible with the previous ſtate of his fortune.

In the month of Sept. 1786, he ſet out from London for Dover, and paſſed over into France. After viſiting Paris, he proceeded to Provence, and ſpent the winter months in the genial climate of Hieres. In the ſpring of 1787 he returned northwards, viſiting Geneva, Switzerland, the Netherlands, and the Dutch provinces, and paſſing through Germany into Italy. With a fond curioſity, attentive alike to the wonders of nature, to the noble monuments of the arts, and to the awful remains of ancient grandeur, with which Italy abounds, he viſited all its great cities, and ſurveyed almoſt every remarkable and famous ſcene that it exhibits.

His firſt object, in theſe travels, was to obtain the reſtoration of his declining health by the influence of a milder climate, by gentle, continued, and varied exerciſe; by that pleaſing exhilaration of the temper and ſpirits, which is the beſt medicine to health, and is moſt ſucceſsfully produced by frequent change of place, and of the objects of attention. But the curioſities of nature and art, in thoſe countries through which he travelled, could not fail to attract, in a powerful manner, the curioſity of a mind cultivated and ingenious as his. He, whoſe breaſt glowed with the moſt ardent philanthropy, could not view the varied works and manners of a diverſity of nations of his fellow men, without being deely intereſted by all thoſe circumſtances which might appear to mark their fortunes as happy or wretched. He eagerly collected ſpecimens of the ſpars, the ſhells, the ſtrata of rocks, and the veins of metals, in the ſeveral countries through which he paſſed. He amaſſed alſo cameos, medals, and paintings. He enquired into ſcience, literature, and local inſtitutions. He wrote down his obſervations, from time to time; not indeed with the minute care of a pedant, or the oſtentatious labour of a man travelling with a deſign to publiſh an account of his travels, but ſimply to aid memory and imagination in the future remembrance of objects uſeful or agreeable.

After an abſence of about three years he returned to his native country. The laſt years were ſpent in the diſcharge of the duties of his office as a judge; in ſocial intercourſe with his friends, among whom was the venerable Lord Monboddo, and others of the moſt reſpectable characters that our country has to boaſt of; in the performance of a thouſand generous offices of benevolence and humanity; in cheriſhing thoſe fine arts, of which he was an eminent admirer and judge; and above all, in promoting the comfort, and encouraging the induſtry of his dependants, and in lending his aid to every rational attempt at the improvement of public economy and public virtue.

St Bernard's Well, in the neighbourhood of Edinburgh, had been, long ſince, diſtinguiſhed for the medicinal virtues of its waters. But various circumſtances had alſo concurred of late to throw it into neglect. Yet its waters being ſtrongly mineralized by a ſulphurated hydrogenous gas, were, by this means, unqueſtionably qualified to operate, with highly beneficial effects, in the cure of various diſeaſes. The qualities of this mineral water falling under Lord Gardenſtone's notice, he was induced to purchaſe the property of the well, to direct it to be cleared from ſurrounding obſtacles, which contaminated the virtues of the water, or made it inacceſſible; to erect a beautiful and commodious edifice over it; and to appoint proper perſons to diſtribute the water, for a very trivial compenſation, to the public. The well lies at a diſtance from Edinbugh, which is very convenient for a ſummer morning's walk. Within the few years which have paſſed ſince Lord Gardenſtone's benevolent care brought it into notice, it has attracted many of the inhabitants of that city to viſit in the mornings of ſpring and ſummer. And, undoubtedly, the agreeable exerciſe to which they have thus been allured, and the ſalutary effects of the water, have contributed, in no mean degree, to diſpel diſeaſe, and to confirm, or re-eſtabliſh health. Such monuments are worthy to preſerve the memory of a patriotic and a good man!

As an amuſement for the laſt two or three years of his life, when his increaſing infirmities precluded him from more active exerciſe, and from mingling ſo frequently in the ſociety of his friends as was agreeable to his ſocial and convivial temper, he bethought himſelf of reviſing ſome of the *jeux d'eſprit*, and light fugitive pieces, in which he had indulged the gaiety of his fancy in his earlier days; and a ſmall volume of poems was publiſhed, in which the beſt pieces are, upon good authority, aſcribed to Lord Gardenſtone. He reviſed alſo the memorandums which he had made upon his travels, and permitted them to be ſent to preſs. The two former volumes were publiſhed one after another while his Lordſhip was yet alive; the third after his death. They met with a very favourable reception in the world, and were honoured with the high approbation of the moſt reſpectable writers of periodical criticiſm. They convey much agreeable information, and beſpeak an elegant, enlightened, and amiable mind. The laſt volume is filled chiefly with memorandums of his Lordſhip's travels in Italy; and contains many intereſting criticiſms upon ſome of the nobleſt productions of the fine arts of painting and ſculpture.

His Lordſhip's health had long been declining; and he died a bachelor on the 22d of July 1793, lamented by his relations and friends, by his tenants and humble dependants, and by all true patriots and good men to whom his merits and virtues were known.

Such is the account of Lord Gardenſtone's life, which was prefixed to the third volume of his travelling memorandums; and though it was no doubt an effuſion of fond friendſhip, we believe that the praiſe which it beſtows on his Lordſhip is not much exaggerated. In the latter years of his life, it muſt indeed be confeſſed, that he contracted intimacies with men unworthy

worthy of his regard; and that his attachment to liberty made him form expectations from the French revolution, which even the events which he ſaw ought to have repreſſed. But his mind was by that time weakened by diſeaſe; and it would be very unjuſt to balance the imprudencies of one or two years againſt the meritorious actions of a whole life. Beſides his travelling memorandums and his poems, his Lordſhip publiſhed *A Letter to the Inhabitants of Laurencekirk*, the moſt valuable, in our opinion, of all his publications; for it contains perhaps the moſt ſalutary advices which were ever offered to the inhabitants of a manufacturing town, for the regulation of their conduct towards each other. That the people of Laurencekirk have followed theſe advices, it would give us pleaſure to learn on good authority.

GAS. See that article, *Encycl.* and CHEMISTRY-*Index* in this *Supplement.* We have introduced the word here, to notice ſome experiments made by Profeſſor Jacquin of Vienna, at the deſire of Dr Chladni, on the different gaſes as the vehicle of ſounds. A glaſs bell was furniſhed with a metallic ſtopper cemented to a neck at the top; and in the bore of this cock, within the glaſs, a ſmall flute or pewter (etain) about ſix inches in length was fixed. The glaſs being then placed on the ſhelf of the pneumatic veſſel, and filled with any particular kind of gas, a bladder alſo filled with the ſame gas, and provided with a cock, was adapted to the external aperture of the cock belonging to the bell-glaſs. In this diſpoſition of the apparatus, the flute was made to ſound by gently preſſing the bladder. Comparative experiments were made with atmoſpheric air, oxygen, hydrogen, carbonic acid, and nitrous gas. The intenſity of the ſound did not vary; but when compared with that produced by atmoſpheric air, the oxygen gas gave a ſound half a tone lower; azotic gas, prepared by different methods, conſtantly gave a ſound half a tone lower; hydrogen gas gave nine or eleven tones higher; carbonic acid gas gave one-third lower, and nitrous gas alſo very nearly a third lower. A mixture of oxygen gas and azot, in the proportions of the atmoſpheric air, afforded the tone of this laſt; that is to ſay, it was half a tone higher than each of the component parts alone. When the two gaſes were not uniformly mixed, the ſound was abominably harſh. Chladni intends to give a fuller account of theſe intereſting experiments.—*Journal de Phyſique*, Vol. IV. N. S. p. 57.

GAZONS, in fortification, turfs, or pieces of freſh earth covered with graſs, cut in form of a wedge, about a foot long, and half a foot thick, to line or face the outſide of works made of earth, to keep them up, and prevent their mouldering.

GEOCENTRIC PLACE OF A PLANET, is the place where it appears to us from the earth; or it is a point in the ecliptic, to which a planet, ſeen from the earth, is referred.

GEOCENTRIC Latitude of a Planet, is its latitude as ſeen from the earth, or the inclination of a line connecting the planet and the earth to the plane of the earth's (or true) ecliptic: Or it is the angle which the ſaid line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic.

GEOCENTRIC Longitude of a Planet, is the diſtance meaſured on the ecliptic, in the order of the ſigns, between the geocentric place and the firſt point of Aries.

GEOMETRICAL METHOD OF THE ANCIENTS. The ancients eſtabliſhed the higher parts of their geometry on the ſame principles as the elements of that ſcience, by demonſtrations of the ſame kind: and they were careful not to ſuppoſe any thing done, till by a previous problem they had ſhewn that it could be done by actually performing it. Much leſs did they ſuppoſe any thing to be done that cannot be conceived; ſuch as a line or ſeries to be actually continued to infinity, or a magnitude diminiſhed till it become infinitely leſs than what it is. The elements into which they reſolved magnitudes were finite, and ſuch as might be conceived to be real. Unbounded liberties have of late been introduced; by which geometry, which ought to be perfectly clear, is filled with myſteries.

GEOMETRICAL Solution of a problem, is when the problem is directly reſolved according to the ſtrict rules and principles of geometry, and by lines that are truly geometrical. This expreſſion is uſed in contradiſtinction to an arithmetical, or a mechanical, or inſtrumental ſolution, the problem being reſolved only by a ruler and compaſſes.

The ſame term is likewiſe uſed in oppoſition to all indirect and inadequate kinds of ſolutions, as by approximation, infinite ſeries, &c. So we have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals, though there are mechanical ways, and others, by infinite ſeries, &c.

GEORGIUM SIDUS (ſee ASTRONOMY-*Index*, *Encycl.*) has no fewer than ſix ſatellites revolving round it, all diſcovered by Dr Herſchel. Of the two which he firſt diſcovered, one was found to revolve in 8 days 17 h. 1 m. 17 ſec. at the diſtance of 33″ from its primary; and the other in 13 d. 11 h. 5 m. 1,5 ſec. at the diſtance of 44″,23. The planes of their orbits form ſuch large angles with that of the planet itſelf, and conſequently of the ecliptic, as to be almoſt perpendicular to it. To this remarkable departure from the analogy of the old planets, another ſtill more ſingular has been lately announced. They move in a retrograde direction! The new ſatellites revolve as follows, the periodical times being inferred from their greateſt elongations: The interior ſatellite in 5 d. 21 h. 25 m. at the diſtance of 25′,5. A ſatellite intermediate between the two old ones in 10 d. 23 h. 4 m. at the diſtance of 38″,57. The neareſt exterior ſatellite at about double the diſtance of the fartheſt old one, and conſequently its periodical time 38 d. 1 h. 49 m. And the moſt diſtant ſatellite full four times as far from its primary as the old ſecond ſatellite. Whence it will take at leaſt 107 d. 16 h. 40 m. to complete its revolution. Whether the motions of theſe four be direct or retrograde, is, we ſuppoſe, not yet determined.

From ſome obſervations of the Doctor, with an excellent ſeven-feet teleſcope, certain appearances, reſembling that of two rings ſurrounding the planet, and croſſing each other at right angles, were ſeen on ſeveral different days. They were not altered in poſition by turning the ſpeculum in its cell; but (ſays Mr Nicholſon) there is little doubt that they were optical deceptions, becauſe they kept their poſition with reſpect to the tube, after the relative poſition of the parallel had been

been much changed by the earth's rotation, and becauſe they did not appear with larger teleſcopes applied during the courſe of ten years. The diſk of the Georgium Sidus is flattened. It therefore revolves with conſiderable rapidity on its axis. From the very faint light of the ſatellites, they are obſerved to diſappear in thoſe parts of their orbits which bring them apparently neareſt the planet. This does not ariſe from an atmoſphere; for the effect is the ſame, whether the ſatellite be within or beyond the planet.

GERARD (Alexander, D. D.), was the eldeſt ſon of the reverend Gilbert Gerard miniſter of Chapel-Garioch, in the county of Aberdeen. He was born on the 22d of February 1728, and received the firſt rudiments of his education at the pariſh ſchool of Foveran in the ſame county.

It may perhaps be proper to inform our Engliſh readers, that in every pariſh in Scotland there is a ſchool where, for very ſmall fees, the youth of the pariſh are not only taught to read the Engliſh language, to write, and to perform the elementary operations of arithmetic, but are alſo inſtructed in the Greek and Latin languages. Of theſe ſchools, many of the maſters were, about ſixty years ago, eminent for claſſical learning; and it ſeems that Mr Forbes, the maſter of the ſchool of Foveran, poſſeſſed ſuch fame as a teacher, that Mr Gerard judged it more expedient to commit his ſon to his care than to have him educated at the ſchool of his own pariſh, and under his own immediate inſpection. The attainments which that ſon afterwards made in literature, evince that his judgment was correct, and that the ſchoolmaſter of Foveran deſerved the fame which he enjoyed.

Young Gerard, however, did not remain long at Foveran. His father died when he was but ten years old; and his mother removing ſoon afterwards with her family to Aberdeen, he was of courſe put to the grammar ſchool in that city: but ſo ſolid was the foundation which had been already laid, that in two years time he was deemed fit for the univerſity, and was accordingly entered a ſtudent in Mariſchal college. Such rapid progreſs ſupplies the place of that teſtimony which we have not been able to procure, reſpecting his early attachment to literature.

After completing the uſual academical courſe of four years in the ſtudy of Greek, Latin, mathematics, and philoſophy, he was admitted to the degree of maſter of arts; and immediately afterwards commenced the ſtudy of theology, which he proſecuted in the univerſities of Aberdeen and Edinburgh. In 1748, when he had little more than completed his 20th year, he was licenſed to preach in the church of Scotland, and two years afterwards was choſen aſſiſtant to Mr David Fordyce profeſſor of philoſophy in the Mariſchal college and univerſity of Aberdeen. In this capacity he performed the duties of the abſent profeſſor till the 7th of July 1752, when he was appointed ſucceſſor to Mr Fordyce, who had been drowned on the coaſt of Holland, as has been already related in the Encyclopædia.

At that period it was the practice in the Mariſchal college, as it continued to be in the King's, for the ſame profeſſor to carry forward a claſs of ſtudents for three ſucceſſive years through all the different branches of philoſophy which were taught in the college. Theſe were, LOGIC, ONTOLOGY, PNEUMATICS, MORALS, POLITICS, and NATURAL PHILOSOPHY; and Mr Gerard carried one claſs through this extenſive courſe. MATHEMATICS and the GREEK language were taught by ſeparate profeſſors.

About the year 1754, a very material alteration was made in the *order* of teaching philoſophy in the univerſity of Aberdeen; and in the Mariſchal college each profeſſor was reſtricted to one department of ſcience. The principal and profeſſors in that college, juſtly obſerving that the public is intereſted in every thing which relates to education, thought it incumbent upon them to lay before that public the reaſons which had determined them to deviate from the arrangement which they had hitherto obſerved; and they employed Profeſſor Gerard to draw up theſe reaſons. This taſk he performed in a ſmall pamphlet, which, being printed by the appointment of the college, appears to have given very general ſatisfaction.

This, indeed, it could hardly fail to do; for the judicious author points out very clearly the inconveniences of the old, and the advantages of the new plan of academical ſtudy. Having obſerved that the philoſophy which had ſo long kept poſſeſſion of the ſchools, conſiſted, in a great meaſure, of verbal ſubtleties and theories ill-grounded, though ingeniouſly deviſed, he proceeds to contraſt it with the philoſophy of Bacon and Locke, and to ſhow of how little value the former is when compared with the latter. He then enters on a brief examination of the ſcholaſtic logic, and proves, to the conviction of every impartial judge, that the art of ſyllogiſing, though a proper enough introduction to a philoſophy which was built on general principles, either taken for granted, or founded on very narrow and inadequate obſervation, is by no means fitted to aſſiſt the mind in the cultivation of that ſcience which is deduced by induction from particular facts. "The only baſis of philoſophy (ſays he) is now acknowledged to be an accurate and extenſive hiſtory of nature, exhibiting an exact view of the various phenomena, for which philoſophy is to account, and on which it is to found its reaſonings. This being the reformed ſtate of philoſophy, great inconveniences muſt be found in proſecuting the ſcholaſtic order of the ſciences. The ſtudent muſt make a tranſition at once from words and languages to philoſophy, without being previouſly introduced to the knowledge of facts, the ſole foundation of, and preparation for it; he muſt be hurried at the firſt into the moſt abſtruſe, difficult, and ſubtle parts of it; he muſt be put upon examining the nature, foundation, and different kinds of evidence and reaſoning, before he is acquainted with any ſpecimens of theſe kinds by which they may be illuſtrated. And in proportion as philoſophy is more improved, and more thoroughly reformed, theſe inconveniences muſt become more ſenſible.

"The view of theſe (continues he) induced the maſters of the Mariſchal college to think of altering the hitherto received order; and after the moſt mature deliberation, made them at laſt reſolve, that their ſtudents ſhould, after being inſtructed in languages and claſſical learning, be made acquainted with the elements of hiſtory, natural and civil, of geography and chronology, accompanied with the elements of mathematics; that they ſhould then proceed to natural philoſophy; and, laſt of all, to morals, politics, logic, and metaphyſics."

In vindicating this arrangement, he labours with great

great earneſtneſs, and we think with complete ſucceſs, to ſhew the propriety of making logic the laſt branch of academical ſtudy. "All ſciences (ſays he), all departments of knowledge whatever, muſt be premiſed as a ground-work to genuine logic. Hiſtory has one kind of evidence, mathematics another, natural philoſophy one ſtill different, the philoſophy of human nature another diſtinct from all theſe; the ſubordinate branches of theſe ſeveral parts have ſtill minuter peculiarities in the evidence appropriated to them. An unprejudiced mind will in each of theſe be convinced by that ſpecies of argument which is peculiar to it, though it does not reflect *how* it comes to be convinced. By being converſant in *them*, one is prepared for the ſtudy of *logic*; for *they* ſupply him with a fund of materials; in *them* the different kinds of evidence and argument are exemplified; from *them* only thoſe illuſtrations can be taken, without which *its* rules and precepts muſt be unintelligible.

"All juſt concluſions concerning the works of nature muſt be founded on an induction of particulars. And as in *natural philoſophy* theſe particulars are ſupplied by obſervations and experiments on *natural bodies*; ſo in *logic*, the particulars, of which an induction muſt be made, are to be learned only from the body of *arts and ſciences*. Theſe are the ſubjects on which obſervations muſt be made, in order to lay down rules for inveſtigating and proving the truths of which they are made; juſt as the genuine performances of any art are what muſt be conſidered and obſerved in laying down the rules of that art. No ſolid precept can be formed in logic, except by examining arts and ſciences, and attending to the method of reaſoning uſed in them, and to the evidence that accompanies it. In proportion as they are cultivated, and no farther, logic may be improved. And what is true of the invention of logic, is true likewiſe of the ſtudy of it. It can be underſtood no farther, than the ſeveral ſciences which it reviews and criticiſes are previouſly underſtood. Accordingly we find, that all the ſyſtems of logic which have not been compiled from a careful review and examination of the ſeveral ſciences, conſiſt more of ingenious ſubtleties than of uſeful precepts aſſiſting to the mind in the various parts of knowledge. And when logic has been learned before the other ſciences, the ſubſtantial parts of it have been ſcarce attended to, or made any uſe of, in the proſecution of them; nor ſo much as underſtood, but in as far as the mind was gradually opened, and brought to recollect them in its progreſs through the ſciences.

"Logic is preciſely the ſame to *philoſophy* that works of criticiſm are to *poetry*. The rules of criticiſm are formed by an accurate ſcrutiny and examination of the beſt works of poetry. To one who had never read a poem, theſe rules would be obſcure and uſeleſs; he could not comprehend them, far leſs would he be able to form a judgment of their juſtneſs, and of the reaſons on which they are founded. If one peruſes the beſt poetical performances, he will acquire ſome degree of taſte, though he has never profeſſedly ſtudied the rules of criticiſm; and he will, at the ſame time, lay in materials, and obtain a ſtock of examples, which may render theſe rules intelligible to him, and enable him to judge whether they are juſt or not. And by afterwards ſtudying theſe rules, he improves, refines, and corrects his taſte, perceives the principles on which he has founded all his judgments, though he did not in the mean time think of them, and gains additional ſecurity againſt his judging wrong. This may illuſtrate what has been ſaid of the place which logic ought to hold among the ſciences. The obſervations made in it, both concerning the methods of invention and of probation, are founded on, and deduced from, the ſeveral ſciences in which theſe methods are uſed. Neither the obſervations themſelves, nor the reaſons on which they are built, can be fully comprehended by one abſolutely ignorant of theſe ſciences. In ſtudying the particular ſciences, reaſon will ſpontaneouſly exert itſelf: if the proper and natural method of reaſoning is uſed, the mind will, by the native force of its faculties, perceive the evidence, and be convinced by it, though it does not reflect *how* this comes to paſs, nor explicitly conſider according to what general rules the underſtanding is exerted. By afterwards ſtudying theſe rules, one will be farther fitted for proſecuting the ſeveral ſciences; the knowledge of the grounds and laws of evidence will give him the ſecurity of *reflection*, againſt employing wrong methods of proof and improper kinds of evidence, additional to that of *inſtinct* and *natural genius*. And thus logic will greatly contribute to improvement in knowledge; and more ſo, when it is uſed as a *review* of the method taken in the proſecution of ſcience, of the foundations gone upon, and of the general rules that have been obſerved, than when it is applied as an *introduction* to the elements of ſcience; for in the former caſe, its rules can be perfectly underſtood, ſufficiently illuſtrated, and put in practice as they are learned, which in the latter is quite impoſſible."

Having thus vindicated the new arrangement with reſpect to the place which it aſſigns to the ſtudy of logic, he proceeds to inquire in what order the other ſciences ſhould ſucceed each other. "Ethics (ſays he) or moral philoſophy is founded as well as logic on pneumatics, and muſt therefore come after it. The conſtitution of man, and his ſeveral active powers, muſt be explained, before his buſineſs, his duty, and his happineſs, can be diſcovered. Juriſprudence and politics, taking a more complex view of man than morals, by conſidering his various ſtates, as well as his nature and powers, cannot, with any propriety, be introduced till morals have firſt been ſtudied.

"It only remains then to determine whether natural philoſophy or pneumatology ought, in the order of teaching, to have the preference. And many conſiderations ſeem to require that the former ſhould be ſtudied firſt. If it were not, pneumatology would be too far disjoined from the practical ſciences founded on it; one of which, logic, ought, as we have ſeen, to be taught laſt of all. Beſides, we ought always to begin with the eaſieſt and moſt obvious ſubjects, and to proceed gradually to the moſt difficult; and in order to this, we ought to comply as much as poſſible with the natural openings and progreſs of the human mind. Now it is evident, that the mind receives firſt of all impreſſions and ideas of thoſe ſenſible things with which it is ſurrounded. It is not till after it has exerciſed its faculties about them that it reflects on its own operations, or acquires perceptions of them. We are from our earlieſt infancy accuſtomed to obſerve external things, though often tranſiently and inattentively; they lie always in our view, they force themſelves upon us, and we cannot avoid regarding them more or leſs. But we ſeldom attend to the operations of our minds in our earlier years; it is late before we acquire diſtinct notions of them, or can eaſily and readily make them the objects of our contemplation. Farther, external ſenſation, by which bodies are perceived, is a more palpable kind of evidence than internal, from which all our knowledge of ſpirits is derived; it ſtrikes and affects us more. The philoſophy of ſpirits, as well as that of bodies, is founded ſolely on experiments and obſervations; but in the latter it is much eaſier to make theſe than in the former: we can put *bodies* in any ſituation that we pleaſe, and obſerve at leiſure their effects on one another: but the phenomena of the *mind* are of a leſs conſtant nature; we muſt catch them in an inſtant, and be content to glean them up, by obſerving their effects as they accidentally diſcover themſelves in the ſeveral circumſtances of life. The reaſonings alſo by which concluſions are deduced concerning mind are of a more abſtruſe and difficult nature than thoſe employed in the ſcience of bodies; the ideas about which they are converſant are apter to be confounded with one another, and are with greater difficulty kept diſtinct. On all theſe accounts, natural philoſophy muſt be to young minds eaſier than pneumatology, and conſequently ſhould be taught firſt."

For this long digreſſion, if ſuch it ſhall be deemed, we are perſuaded that thoſe who retain any attachment to the place where their minds were firſt imbued with the principles of ſcience, will think no apology requiſite, when they are informed, that the plan of education, which is here ſo ably defended, was about the ſame period adopted by both colleges in the univerſity of Aberdeen; that the writer of this article had his own education in the King's college; and that in the proſperity of that college he ſtill feels himſelf deeply intereſted. Let it be remembered, too, that the publication from which this extract has been made, furniſhes a proof of profeſſor Gerard's abilities, and of the eſtimation in which he was held by his colleagues at a very early period of life; and then ſurely the digreſſion will not be thought impertinent.

He was now profeſſor of moral philoſophy and logic, and of theſe ſciences alone: but though his *plan of education in the Mariſchal College* ſhews the order in which his lectures were arranged, we have not been able to learn on what foundation he built his ſyſtem of ethics. As Hutcheſon's Moral Philoſophy was then much read and admired, it will not detract from Mr Gerard's merits to ſuppoſe, that, with his predeceſſor Mr Fordyce, he was an advocate for the *moral ſenſe* of that author; for there are but three or four foundations on which a ſyſtem of ethics can be raiſed; and it may be doubted whether there be one of them which is not as old as the age of Plato. ' It would indeed be ridiculous in any modern (A) to aim at giving a *new* foundation to moral virtue; for virtue muſt have been practiſed upon ſome ſteady principle from the earlieſt period of human ſociety; and the moſt eminent profeſſor will find ſufficient room for the diſplay of all his learning and ingenuity in illuſtrating the principle which his own judgment has led him to adopt.

Of this profeſſor Gerard was fully ſenſible; and whilſt he was conſcientiouſly diſcharging his duty to his pupils, he neglected no opportunity of improving himſelf. He was member of a literary ſociety at Aberdeen, of which the reſpectability will not be queſtioned, when it is known that it conſiſted of ſuch men as the late Doctors Blackwel, Gregory, Reid, and Campbell, with Dr Beattie, and many others of perhaps equal talents, though not known to the world as authors (B). This ſociety met regularly during the winter, we believe once every fortnight; the members communicated their ſentiments with the utmoſt freedom; every novel opinion was ſure to be canvaſſed on all ſides with impartiality; the underſtandings of the members were thus mutually whetted; and hence originated Reid's *Inquiry into the Human Mind*, Gregory's *Comparative View*, Gerard's *Eſſay on Genius*, Beattie's *Eſſay on Truth*, and Campbell's *Philoſophy of Rhetoric.*

On the 5th of September 1759, Mr Gerard was ordained a miniſter of the Church of Scotland; on the 11th of June 1760, he was appointed profeſſor of divinity in the Mariſchal College, and miniſter of the Grayfriars church in Aberdeen; and at the ſame time, as we ſuppoſe, created doctor in divinity.

On the 18th of June 1771 he reſigned his profeſſorſhip in Mariſchal College, together with his church-living, and was preferred to the theological chair in the univerſity of King's College, then become vacant by the death of profeſſor Lumiſden. In that ſtation he continued, proſecuting his ſtudies, beloved by his colleagues, and revered by his pupils, till his birth-day 1795; when, having juſt completed his 67th year, he died without a groan. His death was occaſioned by a ſchirrous tumor, which began to appear on his face in the year 1794, but without confining him to the houſe, or, except for a very few weeks, interrupting his uſual purſuits. It impaired, however, his health, and gradually undermined his conſtitution. Of this he was very ſoon ſenſible; but he ſaw his diſſolution approaching with the utmoſt compoſure and reſignation, and preſerved to all about him ſo much of that equanimity and placidneſs of temper which had marked the whole courſe of his life, that of him may truly be ſaid,

Multis illi multos annos precantibus
Diri carcinomatis veneno contabuit,
Nexibuſque vitæ paulatim reſolutis,
E terris, meliora ſperans, emigravit.

Were we to hazard an opinion of Dr Gerard's intellectual powers, from having attentively peruſed his works,

---

(A) The friends of Mr Godwin, who affect to call his Political Juſtice the *new* philoſophy, will, of courſe, think this a raſh aſſertion; but were it worth while, it would be no very difficult taſk to produce, from the atheiſtical writers of antient Greece, ſomething ſimilar even to his wildeſt paradoxes. Dr Gerard was too well acquainted with the ſubject, and too warm a friend to genuine virtue, to pretend to *novelty* in moral ſcience.

(B) Such as Profeſſor Thomas Gordon, who read lectures in the King's College for 63 or 64 years, and whoſe learning was equalled only by his virtues.

works, we would ſay that he poſſeſſed great rectitude of judgment, rather than any remarkable vigour of mind; that he was capable, by intenſe ſtudy, of becoming maſter of almoſt any ſubject, though perhaps he had not the imagination requiſite for making diſcoveries in ſcience; and that his attainments were ſolid rather than brilliant. What he knew, he knew thoroughly; but to us his knowledge ſeems to have been the reward of labour.

By one, to whom he was well known, and who himſelf ſtands high in the republic of letters *, we are aſſured that he had improved his memory to ſuch a degree, that, in little more than an hour, he could get by heart any ſermon of ordinary length; though far from availing himſelf of this talent, as many would have done, he compoſed with care all the ſermons that he preached. In early life he made it a rule not to ſtudy after ſupper; and from that rule he never deviated, but amuſed himſelf after that time, either with the converſation of his family, or with any light reading that came in his way; and he was generally in bed by half paſt eleven. He ſeems not to have approved of early more than of late ſtudy; for though, for a few years, when as profeſſor of philoſophy he had various ſciences to teach, he roſe regularly, during winter, at five in the morning, he diſcontinued that practice as ſoon as he had it in his power, and did not enter upon ſerious ſtudy till after breakfaſt, generally about ten o'clock. He was indeed very laborious through the day, and could with difficulty be perſuaded to take any bodily exerciſe; but being remarkably temperate in eating and drinking, he enjoyed very good health, which was only occaſionally interrupted by thoſe ſtomach complaints, to which men of ſedentary lives are often ſubject.

The fruits of this inceſſant ſtudy were, beſides the lectures which he read to his different claſſes, 1ſt, *An Eſſay on Taſte*, to which, in 1756, was adjudged the gold medal by the Philoſophical Society of Edinburgh (See SOCIETIES, *Encycl.*), which had propoſed taſte as the ſubject for a prize. Of this eſſay there has been a ſecond, and a third edition; of which the laſt, which was publiſhed in 1780, is conſiderably enlarged and improved. 2d, *Diſſertations on the Genius and Evidences of Chriſtianity*, publiſhed in 1766. 3d, *An Eſſay on Genius*, publiſhed in 1774. 4th, Two volumes of *Sermons*; of which the firſt was publiſhed in 1780, and the ſecond in 1782. 5th, A part of his theological courſe, entitled *The Paſtoral Care*, which was publiſhed in 1799 by his ſon Dr Gilbert Gerard, who ſucceeded him as profeſſor of divinity in the King's college and univerſity of Aberdeen. Beſides theſe works Dr Gerard publiſhed many ſingle ſermons, which were preached on occaſional ſubjects.

Of this amiable and reſpectable inſtructor of youth, we have been favoured with the following character, drawn by a man of talents and virtue †, who was firſt his pupil and afterwards his friend; and though it made part of a funeral ſermon, we believe that, by thoſe who were moſt intimately acquainted with Dr Gerard, the panegyric which it contains will not be deemed extravagant.

" In domeſtic life, his conduct was amiable and exemplary. He poſſeſſed, in a high degree, that kindneſs of heart and affability of manner which intereſted him at all times in the happineſs of his dependants, preſerved good humour in his houſe, and endeared him to his family. He knew how to check improprieties without harſhneſs, and when and how to indulge without impairing his authority. His natural good ſenſe, ſteadineſs, and prudence, prevented him from being thrown into confuſion by the adverſe incidents of life; and enabled him, in preſſing emergencies, to adopt wiſe meaſures, and to adminiſter ſalutary counſel. His tender ſympathy ſoothed the troubled hour of ſorrow; his rational and friendly advice guided his family thro' the perplexities of life, and he feelingly rejoiced in all their innocent enjoyments. His attachments were not confined to his family or his relatives; he was ſuſceptible of warm friendſhip. In ſelecting the objects of it he was cautious, always preferring thoſe whoſe merits entitled them to confidence and regard. His attachment, ſlowly formed, was not to be ſhaken by every oblique inſinuation, or by every idle report to the prejudice of his friend. Steady in his profeſſions of regard, he was capable of conſiderable and diſintereſted exertions to ſerve thoſe whom he really eſteemed. To his judicious advice they had ready acceſs; and his beſt efforts to promote their good they could always command. As a member of ſociety, his houſe was ever the ſeat of hoſpitality, and his door was always open to the ſtranger. In entertaining his friends, he equally avoided the extravagance and oſtentation which did not become his character or ſuit his fortune, and the rigid economy which marks the conduct of thoſe who give with a reluctant and ſparing hand. He neither anxiouſly courted, nor affectedly ſhunned learned converſation. While he never obtruded upon company ſubjects which, by the diſplay of ſuperior knowledge or abilities, were calculated to gratify his own vanity at the expence of hurting others, he always ſtudied, as far as propriety would admit, to adapt his converſation to the temper and inclinations of his aſſociates. To pleaſe the young, and to promote their harmleſs feſtivity, was ever his delight; with cheerfulneſs he deſcended to their trivial amuſements, and in his preſence they felt no reſtraints but thoſe which virtue and decency impoſe. Though he often left for a little ſtudies in which he was keenly engaged, to enjoy the converſation of a friend, he never ſuffered his love of ſociety, one of his ſtrongeſt paſſions, to induce him to ſacrifice any important literary purſuit, or to neglect any neceſſary buſineſs.

" As a clergyman, the office which he held for ſeveral years in Mariſchal college rendered it his duty to be a daily preacher, and gave him a ſeat in the eccleſiaſtical courts. But the unavoidable labour of preparing prelections for his theological pupils, did not prevent his unremitting attention to his public exhibitions in the pulpit. Theſe were marked by that diſtinctneſs of arrangement, that juſtneſs of reaſoning, and that accuracy of compoſition, which effectually ſecured the approbation of the ableſt judges; while by their plainneſs and ſimplicity, they failed not of promoting the edification of the meaneſt capacities. To the low arts of acquiring popularity he never ſtooped: But his prudence, his good ſenſe, his exemplary conduct, and his miniſterial diligence, eſtabliſhed his reſpectability and uſefulneſs, and procured him the full confidence and eſteem of his colleagues. Poſſeſſing more than ordinary

een.

dinary excellence, envy never led him to depreciate the merits of other preachers. Though one of the beſt of judges, he was always one of the moſt candid hearers. When by his tranſlation to the univerſity of King's college he was releaſed from the labour of conſtant preaching, far from ſhewing any averſion to diſcharge the moſt public miniſterial duties, he was always obedient to preſbyterial appointments; and while health and ſtrength remained, willing to oblige his clerical friends by appearing in their pulpits. Nor in private life did he ever loſe ſight of the character of a clergyman. Having in a publication ably defended its reſpectability, in oppoſition to the ſcoffs and ſneers and ſophiſms of modern ſceptics; he conſidered it as his honour, in his life and converſation, to diſplay its dignity and importance; and to ſhew that the gravity of a Chriſtian paſtor is perfectly conſiſtent with the good breeding of a gentleman, and with the cheerfulneſs, affability, and eaſe of an agreeable companion.

"As a man of letters, his attainments were far above thoſe at which the generality of ſtudents arrive. In his literary purſuits, he had all the advantages of a judgment uncommonly clear and diſtinct; aided, from his earlieſt years, by the moſt indefatigable and perſevering ſtudy. The well-earned reputation with which, before he was promoted to the theological chair, he taught in Mariſchal college different ſciences, inconteſtibly proves that his powers, not confined to one ſubject, juſtly entitled him to eminence in ſeveral branches of literature. His publications, ſeveral of which have been tranſlated into other languages, promiſe fair to extend his fame, and to hand it down to generations yet unborn; and his unremitting labours promiſed ſtill a farther contribution to the general ſtock of learning.

"As a profeſſor of divinity, he will be long and gratefully remembered by his numerous pupils. This was his peculiar department, and in this he ſhone. Poſſeſſing large ſtores of theological knowledge, he was judicious in ſelecting his ſubjects, happy and ſucceſsful in his manner of communicating inſtruction. He had the merit of introducing a new, and in many reſpects a better plan of theological education, than thoſe on which it had been formerly conducted. Liberal, but not looſe, in his ſentiments, his great aim was, not to impoſe by his authority upon his pupils any favourite ſyſtem of opinions; but to impreſs them with a ſenſe of the importance of the miniſterial office, to teach them the proper manner of diſcharging all its duties, and to enable them, by the knowledge of Scripture, to form a juſt and impartial judgment on controverted ſubjects. Solicitous for their improvement, he was ever ready to encourage riſing merit by his warmeſt approbation; and reluctant to damp even unſucceſsful efforts of genius by deſerved cenſure. Having a conſtant eye to what is practically uſeful, rather than to unedifying ſpeculation, he enjoined no duty which he was unwilling to exemplify in his own conduct. Hence that ſtrict regard to the miniſterial character which he uniformly diſplayed, and hence his uncommon punctuality in attending the public ordinances of religion."

GERMINATION, among botaniſts, is a very intereſting ſubject, on which the late diſcoveries in chemiſtry have thrown much light ſince the article GERMINATION was publiſhed in the *Encyclopædia*. In the year 1793, Mr Humboldt diſcovered that ſimple metallic ſubſtances are unfavourable to the germination of plants, and that metallic oxides favour it in proportion to their degree of oxidation. This diſcovery induced him to ſearch for a ſubſtance with which oxygen might be ſo weakly combined as to be eaſily ſeparated, and he made choice of oxigenated muriatic acid gas mixed with water. Creſſes (*lepidium ſativum*) in the oxygenated muriatic acid ſhewed germs at the end of ſix hours, and in common water at the end of 32 hours. The action of the firſt fluid on the vegetable fibres is announced by an enormous quantity of air bubbles which cover the ſeeds, a phenomenon not exhibited by water till at the end of from 30 to 45 minutes. Theſe experiments, announced in Humboldt's *Flora Subterranea Fribergenſis*, and in his Aphoriſms on the chemical phyſiology of Plants, have been repeated by others (A). They were made at a temperature of from 12 to 15 Reaumur. In the ſummer of 1796, Humboldt began a new ſeries of experiments, and found that by joining the ſtimulus of caloric to that of oxygen he was enabled ſtill more to accelerate the progreſs of vegetation. He took the ſeeds of garden creſſes (*lepidium ſativum*), peas (*piſum ſativum*), French beans (*phaſeolis vulgaris*), garden lettuce (*lactuca ſativa*), mignonette (*reſeda odorata*); equal quantities of which were thrown into pure water and the oxygenated muriatic acid at a temperature of 88° F. Creſſes exhibited germs in three hours in the oxigenated muriatic acid, while none were ſeen in water till the end of 26 hours. In the muriatic, nitric (B), or ſulphuric acid, pure or mixed with water, there was no germ at all: the oxygen ſeemed there to be too intimately united with baſes of azot or ſulphur, to be diſengaged by the affinities preſented by the fibres of the vegetable. The author announces, that his diſcoveries may one day be of great benefit in the cultivation of plants. His experiments have been repeated with great induſtry and zeal by ſeveral diſtinguiſhed philoſophers. Profeſſor Pohl at Dreſden cauſed to germinate in oxygenated muriatic acid the ſeed of a new kind of *euphorbia* taken from Bocconi's collection of dried plants, 110 or 120 years old. Jacquin and Vander Schott at Vienna threw into oxygenated muriatic acid all the old ſeeds which had been kept 20 or 30 years at the botanical garden, every attempt to produce vegetation in which had

---

(A) See Uſlar's Fragments of Phytology, Plenck's Phyſiology, Villdenow's Dendrology, and *Dictionnaire de Phyſique* par Gehler.

(B) The nitric acid, however, diluted with a great deal of water, accelerates germination alſo, according to the experiments of Candolle, a young naturaliſt, who has applied with great ſucceſs to vegetable phyſiology. This phenomena is the more intereſting, as chemiſtry affords other analogies of the oxygenated muriatic acid and the nitric acid. Profeſſor Pfaſs at Kiel, by purſuing Humboldt's experiments, has found that frogs ſuffocated in oxygenated muriatic acid gas increaſe in irritability, while thoſe which periſh in carbonic acid gas are leſs ſenſible of galvaniſm.

had been fruitleſs, and the greater part of them were ſtimulated with ſucceſs. Even the hardeſt ſeeds yielded to this agent. Among thoſe which germinated were the yellow bonduc or nickar tree (*guilandina bonduc*), the pigeon cytiſus or pigeon pea (*cytiſus cajan*), the *dodonea anguſtifolia*, the climbing mimoſa (*mimoſa ſcandens*), and new kinds of the *homea*.—There are now ſhewn at Vienna very valuable plants which are entirely owing to the oxygenated muriatic acid, and which are at preſent from five to eight inches in height. Humboldt cauſed to germinate the *cluſia roſea*, the ſeeds of which had been brought from the Bahama iſlands by Booſe, and which before had reſiſted every effort to make them vegetate. For this purpoſe he employed a new proceſs, which ſeems likely to be much eaſier for gardeners who have not an opportunity of procuring oxigenated muriatic acid: He formed a paſte by mixing the ſeeds with the black oxide of manganeſe, and then poured over it the muriatic acid diluted with water. Three cubic inches of water were mixed with half a cubic inch of the muriatic acid. The veſſel which contains this mixture muſt be covered, but not cloſely ſhut; elſe it might readily burſt. At the temperature of 95° the muriatic acid becomes ſtrongly oxidated; the oxigenated muriatic gas which is diſengaged paſſes through the ſeeds; and it is during this paſſage that irritation of the vegetable fibres takes place.—*Philoſophical Magazine.*

GESCHE EL AUBE, or GIR GIR, a ſpecies of graſs growing plentifully near *Ras el Feel* on the borders of Abyſſinia. It begins, ſays Mr Bruce, to ſhoot in the end of April, when it firſt feels the humidity of the air. It advances then ſpeedily to its full height, which is about 3 feet 4 inches. It is ripe in the beginning of May, and decays, if not deſtroyed by fire, very ſoon afterwards.

The leaf is long, pointed, narrow, and of a feeble texture. The ſtock from which it ſhoots produces leaves in great abundance, which ſoon turn yellow and fall to the ground. The goats, the only cattle theſe miſerable people have, are very fond of it, and for it abandon all other food while it is within their reach. On the leaves of ſome plants our author ſaw a very ſmall glutinous juice, like to what we ſee upon the leaves of the lime or the plane, but in much leſs quantity; this is of the taſte of ſugar.

From the root of the branch ariſes a number of ſtalks, ſometimes two, but never, as far as he had ſeen, more than three. The flower and ſeed are defended by a wonderful perfection and quantity of ſmall parts. The head, when in its maturity, is of a purpliſh brown.

This ſpecies of graſs was one of the acquiſitions of our author's travels. It was not before known in Europe, nor when he publiſhed his book had the ſeed produced a plant any where but in the garden of the French king.

GHEYSSIQUAS, a nation of Hottentots which inhabits a diſtrict of South Africa bordering on the country of Caffraria. M. Vaillant viſited a horde of this people at no great diſtance from Orange river, as he was returning from his laſt African excurſion to the Cape, and was ſhewn by them a chain of mountains to the eaſt, which extending to a diſtance was loſt in the north, and which, inhabited by their principal tribes, ſeparated them from the Caffies, or at leaſt from the Briquas and Bremas, whom they conſider as tribes of Caffres.

With reſpect to ſuch characteriſtics as are not original and derived from nature, as the form of their dreſs, weapons, inſtruments of muſic, fondneſs for hunting and dancing, and the like, the Gheyſſiquas do not differ from the ſurrounding nations, except in having adopted a particular colour for their ornaments. All the ornaments of the Gheyſſiquas are white, and compoſed of the bones of a ſheep's leg or foot, to which they give a dazzling whiteneſs by proceſſes peculiar to themſelves. Thus, as they fabricate their own necklaces and other articles of luxury, and have no occaſion to purchaſe the materials, they have no dependence on the colonies with reſpect to trade, except for a few neceſſary articles, which they want in common with other ſavages. Accordingly this nation is leſs known and leſs viſited than any other.

The women are well made, lively, and always ready to laugh or dance: yet, with all the gaiety of their diſpoſition, they have the reſervedneſs of manners to which poliſhed nations give the names of modeſty and decorum, and which, in ſo warm a climate, and with ſuch ardent conſtitutions, appears to be a virtue of no eaſy attainment.

Our author ſays that he no where met with a nation ſo truly generous. Though he had nothing to give in exchange, yet during two days that he ſtaid with them, he had bowls of milk brought to him as preſents, night and morning, from every hut. The chief even obliged him to accept a lamb; and though our traveller's attendants were not deſtitute of proviſions, he would give them alſo ſeveral ſheep with which to regale themſelves; a degree of generoſity of which a proper eſtimate can be formed only by thoſe who know ſomething of ſavage manners and ſavage penury.

The practice of ſemi-caſtration prevails among the Gheyſſiquas, and among them only of all the Hottentot tribes; and it prevails in all their hordes without exception. Our author convinced himſelf of this fact by his own eyes; for the men were ſo complaiſant, that, if he had choſen, he might have inſpected the whole horde. Many travellers have written upon the ſubject of this whimſical operation; but they do not agree either as to its origin, the motives that lead to its invention, or the nations by whom it is practiſed. Kolben, who ſays that it commonly conſiſts in the extraction of the left teſticle, repreſents it as a religious ceremony, a general and ſacred law, with all the Hottentots indiſcriminately; but this is unqueſtionably falſe. (See HOTTENTOTS, *Encycl.*) Others attribute it to the deſire of the Gheyſſiquas to render themſelves more fleet in running, an effect which it ſurely is not calculated to produce; and ſome have ſaid that its intention is to prevent the too abundant propagation of the ſpecies. Yet Kolben, though he ſeems inclined to this laſt opinion, affirms that twins are not the leſs common on account of the operation. According to thoſe whom M. Vaillant queſtioned on the ſubject, it is merely a mark of diſtinction, which their anceſtors, being at war with the neighbouring nations, invented for the purpoſe of knowing one another; but, as he himſelf admits, this is a very improbable account of the matter, as they would ſurely have adopted, like the Loangoes, Pomboes, and Cormantins, marks of diſtinction more eaſily diſcerned. Be this as it may, the operation among the Gheyſſiquas is performed by the father, commonly at the birth of the child, though ſometimes not till he has completed his third year.

GHIRGONG, the capital of *Aſam* in Hindoſtan, is, according to Mr Pennant, ſituated in latitude 26° 30′ north. He does not ſtate its longitude. It has four gates, and the city is encompaſſed with a bound hedge of bamboos. The Rajah's palace is ſurrounded by a cauſey, planted on each ſide with a cloſe hedge of bamboos, which ſerves inſtead of a wall. On the outſide there is a ditch, which is always full of water. The Rajah's ſeat is adorned with lattice work and carving. Within and without have been placed plates of braſs, ſo well poliſhed, that when the rays of the ſun ſtrike upon them they ſhine like mirrors. It is an aſcertained fact, that 3000 carpenters and 12,000 labourers were conſtantly employed in this work during two years before it was finiſhed.

Pennant's View of Hindoſtan.

The Aſiatic Reſearches ſpeak much of the wealth of Aſam, and of the plenty and excellency of its natural productions, and that it abounds in all metals but tin. Gold is found in every part of the country by waſhing the ſand of the rivers, and is one of the ſources of revenue ; 12,000, ſome ſay 20,000 people, are employed in that work, each of whom has from the Rajah certain wages. Its gum lac is excellent, and it is very productive of ſilk.

Among the fruits which this country produces are mangoes, plantains, jacks, oranges, citrons, limes, pine apples, and puniala, a ſpecies of tamarind, which has ſuch an excellent flavour, that every perſon who taſtes it prefers it to the plum. There are alſo cocoa nut trees, pepper vines, and areca trees. The ſugar cane excels in ſoftneſs and ſweetneſs, and is of three colours, red, black, and white. There is ginger free from fibres, and betel vines. The ſtrength of vegetation and fertility of the ſoil are ſuch, that whatever ſeed is ſown or ſlips planted they always thrive. The environs of Ghirgong furniſh ſmall apricots, yams, and pomegranates ; but as theſe articles are wild, and not aſſiſted by cultivation and engraftment, they are very indifferent. The principal crop in this country conſiſts in rice and lentiles. Wheat and barley are never ſown ; lignum aloes is alſo a production of this country. The ſilks are excellent, and reſemble thoſe of China, but they manufacture very few more than are required for uſe. They are ſucceſsful in embroidering with flowers and in weaving velvet.—One of their great foreſts is inhabited by abundance of elephants : 6 or 700 may be taken in a year, but they are neglected by the natives, who have neither horſes, camels, nor aſſes, ſuch as are brought from other countries.

According to our author, " the people of Aſam are a baſe unprincipled nation, and have no fixed religion. They follow no rule but that of their own inclination, and make their own vicious minds the teſt of the propriety of their actions. They do not adopt any mode of worſhip practiſed either by heathens or Mahomedans, nor do they concur with any of the known ſects which prevail among mankind ; unlike the pagans of Hindoſtan, they do not reject victuals which have been dreſſed by Moſlems, and they abſtain from no fleſh except human. They even eat animals that have died a natural death."

On this paſſage, one of the ableſt of our literary journaliſts obſerves, that in juſtice to the people of Aſam, we muſt remark, that the above account, extracted from the memoirs of Mir Jumla's expedition into that country, was compoſed by a rigid Mahomedan, at the court of that fanatical tyrant Aurengzebe. The author and his maſter ſaw, in the Aſameſe, only idolaters ; and, in idolaters, the meaneſt of mankind. Their diet, though leſs reſtricted than that of the Hindoos of Bengal, is by no means promiſcuous ; and their religion does not in any way differ from that of Hindoſtan,—as might eaſily be proved by their coins, inſcribed with the names of Hindoo deities.

GIBBON (Edward, Eſq.), the celebrated hiſtorian of the Decline and Fall of the Roman Empire, was born at Putney in the county of Surrey on the 27th of April 1737. He was the firſt child of the marriage of Edward Gibbon, Eſq; and Judith Porten, the youngeſt daughter of a merchant of London.

The family of Gibbon appears to be ancient and honourable ; and our author delights to trace his pedigree from John Gibbon architect to King Edward III. who poſſeſſed lands in the hundred and pariſh of Rolvenden, in the diſtrict which is now called the *Weald* of Kent. In that diſtrict the elder branch of the family ſtill adheres to its native ſoil, without much increaſe or diminution of property ; but the fortunes of the younger branch, from which ſprung the ſubject of this memoir, were fluctuating. It is not, however, with his family, but with himſelf, that we are concerned.

So feeble was his conſtitution, and ſo precarious his life during his childiſh years, that at the baptiſm of each of his brothers (and they were five in number) his father's prudence ſucceſſively repeated the name of Edward, that, in caſe of the death of the eldeſt ſon, this patronymick appellation might ſtill be perpetuated in the family. His brothers and a ſiſter were all ſnatched away in their infancy; and, in terms of affectionate gratitude, he attributes his own preſervation to the more than maternal care of a maiden aunt, his mother's eldeſt ſiſter. " Many anxious and ſolitary days (ſays he) did that dear and excellent woman conſume in the patient trial of every mode of relief and amuſement. Many wakeful nights did ſhe ſit by my bed-ſide in trembling expectation that each hour would be my laſt. Suffice it to ſay, that while every practitioner from Sloane and Ward to the Chevalier Taylor was ſucceſſively ſummoned to torture or relieve me, the care of my mind was too frequently neglected for that of my health. Compaſſion always ſuggeſted an excuſe for the indulgence of the maſter, or the idleneſs of the pupil ; and the chain of my education was broken as often as I was called from the ſchool of learning to the bed of ſickneſs."

His education ſeems indeed to have been far from ſyſtematical. At the age of ſeven he was delivered into the hands of Mr John Kirby, who exerciſed about eighteen months the office of his domeſtic tutor, and of whom he writes in terms of reſpect. This man had been an indigent curate in Cumberland, and when forced by diſtreſs to leave his native country, he was introduced by his learning and his virtue to the family of Mr Gibbon, from whom he might have found at leaſt a temporary ſhelter, had not an act of indiſcretion again driven him into the world. One day reading prayers in the pariſh church, he moſt unluckily forgot the name of of King George; and his patron, a loyal ſubject, diſmiſſed him with ſome reluctance and a decent reward. As our author deſcribes his anceſtors as hereditary Tories, and ſome of them as Jacobites, we think it not improbable that Mr Kirby may have been accuſtomed to omit the name of the King when reading prayers in the family; for otherwiſe he would have pronounced it mechanically in the church.

Be this as it may, our author, upon the diſmiſſion of his tutor, was ſent to Kingſton upon Thames, to a ſchool of ſeventy boys kept by Dr Wooddeſon and his aſſiſtants. He does not repreſent himſelf either as happy or as having made great progreſs at that ſchool. The want of ſtrength and activity diſqualified him for the ſports of the field; his companions reviled him for the ſins of his Tory anceſtors; and his ſtudies were frequently interrupted by ſickneſs. After a real or nominal reſidence of near two years at Kingſton, he was finally recalled (Dec. 1747) by the death of his mother. By this time he was well acquainted with Pope's Homer, the Arabian Nights Entertainments, Dryden's Virgil, and a tranſlation of Ovid's Metamorphoſes; and the entertainment which he received from theſe books gave him a taſte for deſultory reading.

After living a year with his maternal aunt, during which period he read many books on religious ſubjects too deep for the comprehenſion of a boy, he was in January 1749 entered in Weſtminſter ſchool, of which Dr John Nicholl was at that time head maſter. "There (ſays he) in the ſpace of two years, interrupted by danger and debility, I painfully climbed into the third form; and my riper age was left to acquire the beauties of the Latin and the rudiments of the Greek tongue. Inſtead of audaciouſly mingling in the ſports, the quarrels, and the connections of our little world, I was ſtill cheriſhed at home under the maternal wing of my aunt, who now lived in College-ſtreet; and my removal from Weſtminſter long preceded the approach of manhood."

He was firſt carried to Bath for the recovery of his health; then to Wincheſter, where he lived in the houſe of a phyſician; then to Bath again, where he read with a clergyman ſome odes of Horace and ſome epiſodes of Virgil; after which an unſucceſsful trial was made to renew his attendance at Weſtminſter ſchool. "It might now be apprehended (ſays he) that I ſhould continue for life an illiterate cripple; but as I approached my ſixteenth year, Nature diſplayed in my favour her myſterious energies: my conſtitution was fortified and fixed; and my diſorders inſtead of growing with my growth, and ſtrengthening with my ſtrength, moſt wonderfully vaniſhed." In conſequence of this he was carried to Oxford; and before he had accompliſhed his fifteenth year, was, on April 3. 1752, matriculated a gentleman commoner of Magdalen college.

For the honour of that celebrated univerſity, we would fain hope that the account which Mr Gibbon gives of Magdalen college is greatly exaggerated. He repreſents his tutors as totally regardleſs of his morals or his ſtudies. Speaking of the firſt and beſt of them, for he had two, he ſays, "No plan of ſtudy was recommended for my uſe; no exerciſes were preſcribed for his inſpection; and, at the moſt precious ſeaſon of youth, whole days and weeks were ſuffered to elapſe without labour or amuſement, without advice or account." We ſhall make no other remark on this paſſage, than that from gentlemen, who muſt have been contemporary with Mr Gibbon at Magdalen, we have received different accounts of the college; and it is ſurely a very ſingular circumſtance, that at this period of idleneſs, our author ſhould have become enamoured of Sir John Marſham's *Canon Chronicus*, and have conceived the idea of writing an *Eſſay on the age of Seſoſtris*. Such, however, was the caſe. Not only was the eſſay planned, but part of it was written; and though he never finiſhed it, he declares, that his ſolution of ſome difficulties in chronology was not devoid of ingenuity; but he goes on to vilify Oxford. "It might at leaſt be expected (ſays he), that an eccleſiaſtical ſchool ſhould inculcate the orthodox principles of religion. But our venerable mother had contrived to unite the oppoſite extremes of bigotry and indifference: an heretic, or unbeliever, was a monſter in her eyes; but ſhe was *always*, or *often*, or *ſometimes* (A), remiſs in the ſpiritual education of her own children. Without a ſingle lecture, either public or private, either Chriſtian or Proteſtant, without any academical ſubſcription, without any Epiſcopal confirmation, I was led by the dim light of my catechiſm to grope my way to the chapel and communion table, where I was admitted without a queſtion, how far, or by what means, I might be qualified to receive the ſacrament. Such almoſt incredible neglect was productive of the worſt miſchiefs. From my childhood I had been fond of religious diſputation; nor had the elaſtic ſpring been totally broken by the weight of the atmoſphere of Oxford. The blind activity of idleneſs urged me to advance without armour into the dangerous mazes of controverſy; and, at the age of ſixteen, I bewildered myſelf in the errors of the church of Rome."

Thus anxious is our author to account for his reconciliation to the Romiſh church by the negligence of the tutors of his college. This event took place on the 8th of June 1753, when, at the feet of a prieſt in London, he ſolemnly, though privately, abjured the errors of hereſy. An elaborate controverſial epiſtle, approved by his director, and addreſſed to his father, announced and juſtified the ſtep he had taken; and the old gentleman, in the firſt ſally of paſſion, divulging the ſecret, the gates of Magdalen college were ſhut againſt the convert. It was neceſſary therefore to form a new plan of education; and our young Catholic, by the advice of Mr Eliot (afterwards Lord Eliot), was ſettled, on the 30th of June, under the roof and tuition of Mr Pavilliard, a Calviniſt miniſter at Lauſanne in Switzerland.

He repreſents his ſituation there as at firſt extremely uncomfortable. He could not avoid contraſting a ſmall chamber, ill contrived and ill-furniſhed, with his elegant apartment in Magdalen college; and M. Pavilliard being entruſted with the management of his expences, he felt himſelf degraded from the rank of gentleman commoner to that of a ſchool-boy. He began, however, gradually to be reconciled to his fate; and his love of reading returned, which, he ſays, had been chilled by the air of Oxford. He rapidly acquired the French language; and of his tutor he ſays, "My obligations to

---

(A) Surely *always* and *ſometimes* are words of very different import: why are they uſed then, in this ſentence, as ſynonymous?

to the leſſons of Mr Pavilliard gratitude will not ſuffer me to forget. He was endued with a clear head and a warm heart; his innate benevolence had aſſuaged the ſpirit of the church; he was rational, becauſe he was moderate: in the courſe of his ſtudies, he had acquired a juſt, though ſuperficial knowledge of moſt branches of literature; by long practice he was ſkilled in the arts of teaching; and he laboured with aſſiduous patience to know the character, gain the affection, and open the mind of his Engliſh pupil."

Under the tuition of this amiable preceptor he deſcribes his progreſs in the French and Latin claſſics, in hiſtory, geography, logic, and metaphyſics, as uncommonly rapid; and he allows to the ſame man a handſome ſhare of the honour of reclaiming him from the errors of popery. The various diſcriminating articles of the Romiſh creed diſappeared like a dream; and, after a full conviction, on Chriſtmas-day 1754, he received the ſacrament in the church of Lauſanne. Thus had our author communicated with three different ſocieties of Chriſtians before the completion of his eighteenth year; and as ſuch changes from church to church are always dangerous, we need not wonder that, in a mind ſo ill-furniſhed as Mr Gibbon's then was for theological inveſtigations, they paved the way for his laſt change to Deiſm. At preſent, however, he ſuſpended his religious inquiries, acquieſcing (as he ſays) with implicit belief in the tenets and myſteries which are adopted by the general conſent of Catholics and Proteſtants.

He continued to proſecute his ſtudies with ardour. Under Mr Pavilliard he learned the Greek alphabet, the grammar, and the pronunciation of the language according to the French accent, and ſoon made himſelf maſter of the works of Homer, Herodotus, and Xenophon. During two winters he attended the private lectures of M. de Traytorrens, who explained the elements of algebra and geometry as far as the conic ſections of the Marquis de l'Hôpital; but in mathematics he was content (he ſays) to receive the paſſive impreſſion of his profeſſor's lectures, without any active exerciſe of his own powers. In the writings of Grotius and Puffendorf he ſtudied the duties of a man, the rights of a citizen, the theory of juſtice, and the laws of peace and war, which have had ſome influence on the practice of modern Europe. "Locke's treatiſe on government (ſays he) inſtructed me in whig principles, which are founded rather in reaſon than experience; but my delight was in the frequent peruſal of Monteſquieu, whoſe energy of ſtyle and boldneſs of hypotheſis were powerful to awaken and ſtimulate the genius of the age"

We have been thus minute in our account of Mr Gibbon's ſtudies, becauſe it furniſhes perhaps the moſt uſeful leſſon which can be drawn from the whole hiſtory of his life. His education had been rendered irregular, and had been often interrupted by ill-health and a feeble conſtitution; but as ſoon as he was able, and had an opportunity, he applied with ardour to the cultivation of letters, and his works bear witneſs that his labour was crowned with ſucceſs. "This part of his ſtory therefore (to uſe the words of Johnſon) well deſerves to be remembered. It may afford uſeful admonition and powerful encouragement to men whoſe abilities have been made, for a time, uſeleſs, and who, having loſt one part of life in idleneſs, are tempted to throw away the remainder in deſpair."

In the year 1757 Voltaire arrived at Lauſanne, and our young ſtudent's deſire to ſee the man who was at once a poet, an hiſtorian, and, as he deemed himſelf, the prince of philoſophers, was ardent, and eaſily gratified. He was received by the vain and arrogant Frenchman with civility as an Engliſh youth, but could not boaſt of any peculiar notice or diſtinction. "The higheſt gratification (ſays he) which I received from Voltaire's reſidence at Lauſanne, was the uncommon circumſtance of hearing a great poet declaim his own productions on the ſtage. His declamation was faſhioned to the pomp and cadence of the old ſtage; and he expreſſed the enthuſiaſm of poetry rather than the feelings of Nature."

About this time Mr Gibbon became enamoured of Mademoiſelle Suſan Curchod, the daughter of the miniſter of Craſſe, in the mountains which ſeparate the Pays de Vaud from the county of Burgundy. In terms of rapture he deſcribes this lady as poſſeſſed of every accompliſhment which could adorn her ſex. She liſtened to the voice of truth and paſſion; her parents honourably encouraged the connection; and our author indulged in the dream of felicity: but on his return to England, he diſcovered that his father would not hear of this ſtrange connection, and that without his conſent he was deſtitute and helpleſs. "After a painful ſtruggle (ſays he) I yielded to my fate. I ſighed as a lover, I obeyed as a ſon, and my wound was inſenſibly healed by time, abſence, and the habits of a new life." The lady conſoled herſelf by giving her hand to M. Neckar, then a rich banker of Paris, afterwards the miniſter, and at laſt one of the deſtroyers of the French monarchy.

In the ſpring of the year 1758 our author was recalled to England. On his arrival in London he haſtened to the houſe of his aunt, Mrs Porten, who had been the guardian of his tender years; for though his father was in town awaiting his arrival, he knew not how he ſhould be received by a parent who had parted with him in anger, and given him a ſtepmother in his abſence. His reception was more agreeable than he expected. His father received him as a man and a friend; and the manners of Mrs Gibbon were ſuch, that, after ſome reſerve on his ſide, ſhe and he eaſily adopted the tender names and genuine characters of mother and ſon; and, by the indulgence of theſe parents, he was left at liberty to conſult his own taſte or reaſon in the choice of place, of company, and of amuſements. In London he had few acquaintances, and hardly any friends; and being accuſtomed to a very ſmall ſociety at Lauſanne, he preferred the retirement of the country to the buſtle of that over-grown metropolis, where he found hardly any entertainment but in the theatres.

Before he left Lauſanne he had begun a work on the ſtudy of ancient literature, which was ſuggeſted by the deſire of juſtifying and praiſing the object of a favourite purſuit. "In France (ſays he), to which my ideas were confined, the learning and language of Greece and Rome were neglected by a philoſophic age. The guardian of thoſe ſtudies, the Academy of Inſcriptions, was degraded to the loweſt rank among the three royal ſocieties of Paris: The new appellation of *Erudits* was contemptuouſly applied to the ſucceſſors of Lipſius and Caſaubon; and I was provoked to hear *, that the exerciſe of the memory, their ſole merit, had been ſuperſeded by the nobler faculties of the imagination and the judgment

* *See Le Diſcours Preliminai par D'Alembert à l'Encyclop die.*

judgment. I was ambitious of proving by my own example, as well as by my precepts, that all the faculties of the mind may be exerciſed and diſplayed by the ſtudy of ancient literature." This laudable ambition continued; and in his father's houſe at Beriton in Hampſhire he finiſhed his *Eſſai ſur l' Etude de la Literature;* which, after being reviſed by Mallet the poet and Dr Maty of the Britiſh muſeum, was, in 1761, publiſhed in a ſmall 12mo volume.

The ſubjects of taſte, criticiſm, and philoſophy, which in this work came under our young author's conſideration, could hardly promiſe much novelty of remark. Some former obſervations, however, he appears to have placed in a new and pleaſing point of view; advancing, moreover, ſome ingenious conjectures, and diſplaying no inconſiderable erudition. Yet, by his own account, he was at this time almoſt a ſtranger to the writers of Greece; and when he quotes them, it is probable that the quotations are given at ſecond hand. To this eſſay was prefixed a dedication to his father in the Engliſh language, which exhibits the author himſelf in a very amiable light; but if his reputation had depended ſolely upon this youthful attempt, the name of Gibbon would have been loſt in oblivion. Yet he ſeems, even in his riper years, to have been delighted with it himſelf, and to have conſidered its merits as equal to thoſe of his later productions; but Milton, it is ſaid, preferred the Paradiſe Regained to the Paradiſe Loſt.

Before the publication of this eſſay, the author, at his own deſire, had been appointed a captain in the South Hampſhire militia, in which he ſerved upwards of two years. At firſt, the company of ruſtic and illiterate officers, and the buſtle of a military life, were extremely diſagreeable to him, as they interrupted his ſtudies; but he admits, that his military ſervices, his bloodleſs and inglorious campaigns, as he calls them, were, on the whole, beneficial, as they brought him acquainted with Engliſh manners, Engliſh parties, and Engliſh principles, to which his foreign education and reſerved temper had hitherto kept him an entire ſtranger. In the camp and in quarters he had even found leiſure, after the firſt ſeven or eight months of his ſervice, to read a great deal of Greek, and to plan different hiſtorical works, to the compoſition of which he ſeems to have thought that he was born with an innate propenſity. He always talks of himſelf as a philoſopher; but ſurely a more unphiloſophical perſuaſion than this has ſeldom been admitted.

At the end of the war he went again abroad, and reached Paris on the 28th of January 1763, only 36 days after the diſbanding of the militia in which he had borne the commiſſion of a captain. In that metropolis he ſtaid not long. He viſited palaces, churches, gardens, and theatres, and was introduced to D'Alembert and Diderot, then conſidered as at the head of French ſcience. From Paris he proceeded to Switzerland, and once more took up his reſidence at his favourite Lauſanne. Voltaire's impieties had forced him from that town to his own caſtle at Ferney, where our author once viſited him, without (he ſays) courting his more intimate acquaintance.

The ſociety in which Mr Gibbon moſt delighted during his ſecond reſidence at Lauſanne was a very ſingular one. "It conſiſted of fifteen or twenty unmarried ladies of genteel families; the eldeſt perhaps about twenty, all agreeable, ſeveral handſome, and two or three of exquiſite beauty. At each other's houſes they aſſembled almoſt every day, without the controul, or even the preſence of a mother or an aunt; they were truſted to their own prudence, among a crowd of young men of every nation in Europe. They laughed, they ſung, they danced, they played at cards, they acted comedies; but in the midſt of this careleſs gaiety, they reſpected themſelves, and were reſpected by the men; the inviſible line between liberty and licentiouſneſs was never tranſgreſſed by a geſture, a word, or a look, and their virgin chaſtity was never ſullied by the breath of ſcandal or ſuſpicion."

We readily agree with our author that this ſingular inſtitution was expreſſive of the innocent ſimplicity of Swiſs manners; and we only regret that he had not the ſame reſpect for the ladies of his own country as for thoſe frolic females of Switzerland. He would not, in that caſe, have ſtained ſome of his moſt brilliant pages with obſcene ribaldry.

We ſhall not follow him in his ramble through Italy, or repeat his remarks on the towns which he viſited. It is ſufficient, in ſuch a ſketch as this, to inform our readers, that it was at Rome on the 15th of October 1764, as he ſat muſing amidſt the ruins of the Capitol, that the idea of his great work firſt ſtarted into his mind. But his original plan was circumſcribed to the decay of the city rather than of the empire.

From carrying even this contracted plan into execution he was for ſome years diverted. On the 25th of June 1765 he arrived from Italy at his father's houſe in Hampſhire, and found that he had filial duties to perform which interrupted his ſtudies and diſturbed his quiet. His father had involved himſelf in difficulties from which he could be extricated only by ſelling or mortgaging part of his eſtate; and to ſuch ſale or mortgage our author cheerfully conſented. He regrets on this occaſion that he had not "embraced the lucrative purſuits of the law or of trade, the chances of civil office or India adventure, or even the fat ſlumbers of the church;" and it is to be hoped that, when he thought even of *ſlumbering* in the church, he had ſtill ſome faith in revealed religion. He waſted ſome time in planning a hiſtory of the revolutions of Switzerland, and even wrote part of it in the French language, which, by the advice of friends, he however ſuppreſſed. We next find him engaged with a friend in a Journal entitled *Memoires Literaires de la Grande Bretagne*, of which two volumes for the years 1767 and 1768 were publiſhed, and a third almoſt completed, when his friend, a native of Switzerland, was engaged, through his intereſt, as travelling governor to Sir Richard Worſley, and the Journal was, of courſe, abandoned. He then entered the liſts with Warburton; whoſe interpretation of the ſixth book of the Æneid he attacked with great petulance and with much ſucceſs. The biſhop of Gloceſter was by this time in a ſtate of great mental decay, which was peculiarly unfortunate for our author; for had his Lordſhip enjoyed his priſtine vigour, he would probably have given Mr Gibbon ſuch a chaſtiſement as might have made him more modeſt afterwards when writing the hiſtory of the Decline and Fall of the Roman Empire.

To that great work he now ſat down ſeriouſly; and the hiſtory which he gives of his preparatory ſtudies ſufficiently accounts for the inaccuracy of his quotations. Through the darkneſs of the middle ages he explored his way in the annals and antiquities of Italy by the learned Muratori and other moderns; and ſeems to acknowledge that, from the beginning to the end of his work, he frequently contented himſelf with authorities furniſhed at ſecond hand.

At laſt, in 1776, the firſt volume of his hiſtory was publiſhed by Cadell the bookſeller and Strahan the printer; and the ſucceſs of it far ſurpaſſed his expectation. The encomiums laviſhed on it by Dr Robertſon and Mr Hume in letters to the author, and the fulſome compliments which thoſe three eminent hiſtorians paid to each other, are melancholy ſpecimens of lettered littleneſs and vanity. The ſecond and third volumes appeared in 1781; the fourth, fifth, and ſixth in 1787; and Mr Gibbon's fame was eſtabliſhed as a hiſtorian. The work was admired both by natives and by foreigners, and tranſlated into ſeveral of the languages of Europe. Dr Zimmerman repreſents the author as excelling perhaps Hume and Robertſon, who were hiſtorians of the firſt rank. All the dignity (he adds), all the charms of hiſtoric ſtyle, are united in Gibbon: his periods are melody itſelf, and all his thoughts have nerve and vigour." This praiſe, however, muſt not be admitted without exception. Few writers, indeed, were poſſeſſed of ſuch popular talents as our hiſtorian. The acuteneſs of his penetration, and the fertility of his genius, have been ſeldom equalled, and ſcarcely ever ſurpaſſed. He ſeizes, with ſingular felicity, on all the moſt intereſting facts and ſituations; and theſe he embelliſhes with the utmoſt luxuriance of fancy and elegance of ſtyle. His periods are full and harmonious; his language is always well choſen, and is frequently diſtinguiſhed by a new and peculiarly happy adaptation. His epithets, too, are in general beautiful and happy; but he is rather too fond of them. The uniform ſtatelineſs of his diction ſometimes imparts to his narrative a degree of obſcurity, unleſs he deſcends to the miſerable expedient of a note, to explain the minuter circumſtances. His ſtyle, on the whole, is much too artificial; and this gives a degree of monotony to his periods, which extends, we had almoſt ſaid, to the turn of his thoughts.

A more ſerious objection is his attack upon Chriſtianity; the looſe and diſreſpectful manner in which he mentions many points of morality regarded as important on the principles of natural religon; and the indecent alluſions and expreſſions which too often occur in the work. .

An attack upon Chriſtianity is not cenſurable merely as ſuch; it may proceed from the pureſt and moſt virtuous motives: but, in that caſe, the attack will never be carried on in an inſidious manner, and with improper weapons, and Chriſtianity itſelf, ſo far from dreading, will invite every mode of fair and candid diſcuſſion. Our hiſtorian, it muſt be confeſſed, often makes, when he cannot readily find, an opportunity to inſult the Chriſtian religion. Such, indeed, is his eagerneſs in the cauſe, that he ſtoops to the moſt deſpicable pun, or to the moſt awkward perverſion of language, for the pleaſure of turning the ſcripture into ribaldry, or calling Jeſus an impoſtor.

Yet of the Chriſtian religion has Mr Gibbon himſelf obſerved, that it "contains a pure, benevolent, and univerſal ſyſtem of ethics, adapted to every duty and every condition of life." Such an acknowledgment, and from ſuch a writer, too, ought to have due weight with a certain claſs of readers, and of authors likewiſe, and lead them ſeriouſly to conſider, how far it is conſiſtent with the character of good citizens, to endeavour, by ſly inſinuations, oblique hints, indecent ſneer, and profane ridicule, to weaken the influence of ſo *pure* and *benevolent* a ſyſtem as that of Chriſtianity, acknowledgd to be admirably calculated for promoting the happineſs of individuals, and the welfare of ſociety.

Mr Hayley, in his poetical Eſſay on Hiſtory, after a ſplendid panegyric on the arduous labours of his friend, laments the irreligious ſpirit by which he was actuated.

> Think not my verſe means blindly to engage
> In raſh defence of thy profaner page!
> Though keen her ſpirit, her attachment fond,
> Baſe ſervice cannot ſuit with Friendſhip's bond;
> Too firm from Duty's ſacred path to turn,
> She breathes an honeſt ſigh of deep concern,
> And pities Genius, when his wild career
> Gives Faith a wound, or Innocence a tear.
> Humility herſelf divinely mild,
> Sublime religion's meek and modeſt child,
> Like the dumb ſon of Crœſus, in the ſtriſe,
> Where force aſſail'd his father's ſacred life,
> Breaks ſilence, and with filial duty warm,
> Bids thee revere her parent's hallowed form (B)!

The part of the hiſtory which gave ſuch offence to his own friend, as well as to the friends of the Chriſtian religion in general, was the account which our hiſtorian has given of the progreſs and eſtabliſhment of Chriſtianity in the two laſt chapters of his firſt volume; in which he endeavours to prove, that the wonderful triumph of that religion over all the eſtabliſhed religions of the earth, was not owing to any miraculous atteſtations to its truth, but to five ſecondary cauſes which he enumerates; and that Chriſtianity, of courſe, could not be of divine origin. Several anſwers appeared on this occaſion, written, as we may naturally ſuppoſe, with different degrees of temper and ability (C).

One of them only, Mr Davis, who had undertaken to point out various inſtances of miſrepreſentation, inaccuracy, and even plagiariſm in his account, did our hiſtorian condeſcend particularly to anſwer, and that in a tone of proud contempt and confident ſuperiority. To this

---

(B) Herodotus relates, that a Perſian ſoldier, at the ſtorming of Sardis, was preparing to kill Crœſus, whoſe perſon he did not know, and who, giving up all as loſt, neglected to defend his own life. A ſon of the unfortunate monarch, who had been dumb from his infancy, and who never ſpoke afterward, found utterance in that trying moment, and preſerved his father by exclaiming, 'O kill not Crœſus!'

(C) Dr Chelſum, Dr Randolph, Dr Watſon (biſhop of Llandaff), Lord Hailes, Dr White, Mr Apthorpe, Mr Davis, and Mr Taylor, the author of 'The Letters of Ben Mordecai.'

this Mr Davis replied ; and it is but juſtice to obſerve, that his reply bears evident marks of learning, judgment, and critical acumen, and that he has convicted our author of ſometimes quoting inaccurately to ſerve a purpoſe. At his other anſwerers Mr Gibbon merely glanced, treating Dr Watſon, however, with particular reſpect ; but his poſthumous memoirs ſhew how much he felt the attacks made on him by Lord Hailes, Dr White of Oxford, and Mr Taylor. To Dr Prieſtley, who, in his *Hiſtory of the Corruptions of Chriſtianity*, threw down his gauntlets at once to Biſhop Hurd and the hiſtorian of the Roman empire, and who preſented the latter with a copy of his book, declaring at the ſame time, that he ſent it not as a gift but as a *challenge ;* he wrote in ſuch terms as produced a correſpondence, which certainly added not to the honour of the diſſenting divine.

At the beginning of the memorable conteſt between Great Britain and America, our author was returned, by the intereſt of Mr Eliot (now Lord Eliot), for the borough of Liſkeard, and ſupported, with many a ſincere and ſilent vote, the rights, though not, perhaps, the intereſt, of the mother country. " After a fleeting illuſive hope, prudence condemned me (ſays he) to acquieſce in the humble ſtation of a mute. I was not armed by Nature and education with the intrepid energy of mind and voice.

Vincentem ſtrepitus, et natum rebus agendis.

Timidity was fortified by pride ; and even the ſucceſs of my pen diſcouraged the trial of my voice."

That pen, however, was uſeful to the miniſtry whom he could not ſupport by his eloquence in the houſe. At the requeſt of the Lord Chancellor and Viſcount Weymouth, then ſecretary of ſtate, he vindicated, in a very able manner, againſt the French manifeſto, the juſtice of the Britiſh arms ; and his *Memoire Juſtificatif* was delivered as a ſtate paper to the courts of Europe. He was rewarded for this ſervice with the place of one of the lords commiſſioners of trade and plantations; and kept it, till the board was aboliſhed by Mr Burke's reform bill. For accepting this place he was ſeverely, but moſt unjuſtly, blamed by ſome of the leaders of the oppoſition, as if he had deſerted a party in which he had never enliſted, and to the principles of which he was rendered inimical both by family prepoſſeſſion and by his own judgment.

On the downfal of Lord North's adminiſtration, Mr Gibbon was of courſe in the oppoſition deprived of an office, without the ſalary of which he could not conveniently ſupport the expence of living in London. The coalition was indeed ſoon formed, and his friends were again in power ; but having nothing to give him immediately, they could not detain him in parliament or even in England. He was tired of the buſtle of the metropolis, and ſighed once more for the retirement of Lauſanne, at which he arrived before the overthrow of the coalition miniſtry, and where he lived happily till the laſt years of his life. It was in this retreat that he wrote the fourth, fifth, and ſixth volumes of his hiſtory; and he left it only for a year to ſuperintend the publication of theſe volumes in London. This great work being concluded, he returned to the banks of the Leman lake, but found his enjoyments damped by the diſtreſs, and ſoon afterwards by the death, of his oldeſt and deareſt Swiſs friend. Lauſanne had now loſt much of its attraction ; the French revolution had crowded it with unfortunate emigrants, who could not be cheerful themſelves or excite the cheerfulneſs of others ; and the demons of democracy had begun to poiſon the minds of the ſober citizens with principles which Mr Gibbon had always held in abhorrence. Speaking of theſe principles and their effects in Switzerland, he adds, " I beg leave to ſubſcribe my aſſent to Mr Burke's creed on the revolution of France. I admire his eloquence, I approve his politics, I adore his chivalry, and I can almoſt excuſe his reverence for church eſtabliſhments. While the ariſtocracy of Berne protects the *happineſs*, it is ſuperfluous to inquire whether it be founded in the *rights* of men : the economy of the ſtate is liberally ſupplied without the aid of taxes ; and the magiſtrates *muſt* reign with prudence and equity, ſince they are unarmed in the midſt of an armed nation."

It was againſt the beneficent and mild government of Berne that the emiſſaries of France contrived to excite the diſcontents of the people, by inſtilling into their ſimple and untutored minds their own wild notions of liberty and equality. From the effects of this Gallic frenzy, which began to be very viſible ſo early as the beginning of the year 1792, Mr Gibbon reſolved to take ſhelter in England, and to abandon, for ſome time at leaſt, what he called his paradiſe at Lauſanne. Difficulties intervened, and forced him to poſtpone his journey from week to week, and from month to month ; but on receiving the accounts of Lady Sheffield's death, he haſtened to adminiſter conſolation to his friend, and arrived ſafe in London in the beginning of June 1793.

He continued in good health and ſpirits through the whole of the ſummer ; but his conſtitution had ſuffered much from repeated attacks of the gout, and from an incipient dropſy in his ancles. The ſwelling of his ancles, however, ſubſided ; but it was only in conſequence of the water flowing to another place : and being repeatedly tapped for a *hydrocele*, he at laſt ſunk under it, and died at his lodgings in St James's ſtreet, London, on the 16th of January 1794.

To draw a character at once general and juſt of this extraordinary man, would be difficult perhaps to one who had enjoyed the pleaſure of his acquaintance, and muſt be impoſſible to thoſe to whom his perſon was a ſtranger. Of the extent of his erudition there can be but one opinion ; but various opinions may be held reſpecting the accuracy of his knowledge. Lord Sheffield, who knew him well, and loved him much, aſſures us, that his converſation was ſtill more captivating than his writings : but this could not reſult from the brilliancy of his wit ; for of wit he declares himſelf that he had none. His memory was capacious and retentive, his penetration uncommon, and his colloquial eloquence ready and elegant ; ſo that he could illuſtrate almoſt any topic of converſation from the copious ſtores of his own mind. From his private correſpondence, and a journal not written for the public eye, he appears to have been a dutiful ſon, a loyal ſubject, and an affectionate and ſteady friend ; but it is difficult to reconcile with ſo much moral and political worth his unfair and unmanly ſneers at the religion of his country.

GIBRALTAR is a fortreſs of immenſe ſtrength, of which a very full account has been given in the *Encyclopædia.*

cyclopædia. Nothing, however, is in that article ſaid of the natural hiſtory of the mountain on which the fortreſs is built, though, to men of ſcience, that ſubject muſt be as intereſting as a detail of ſieges. This defect we are enabled to ſupply by means of Major Imrie's mineralogical deſcription of Gibraltar, which is publiſhed in the fourth volume of the Tranſactions of the Royal Society of Edinburgh; and, we are perſuaded, the following abſtract of that elegant memoir will afford rational entertainment to many of our readers.

"The form of this mountain is oblong; its ſummit a ſharp craggy ridge; its direction is nearly from north to ſouth; and its greateſt length, in that direction, falls very little ſhort of three miles. Its breadth varies with the indentations of the ſhore, but it nowhere exceeds three quarters of a mile. The line of its ridge is undulated, and the two extremes are ſomewhat higher than its centre.

"The ſummit of the Sugar Loaf, which is the point of its greateſt elevation towards the ſouth, is 1439 feet; the Rock Mortar, which is the higheſt point to the north, is 1350; and the Signal Houſe, which is nearly the central point between theſe two, is 1276 feet above the level of the ſea. The weſtern ſide of the mountain is a ſeries of rugged ſlopes, interſperſed with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the north-weſt, where what are called the Lines intervene, and a narrow paſſage of flat ground that leads to the iſthmus, and is entirely covered with fortification. The eaſtern ſide of the mountain moſtly conſiſts of a range of precipices; but a bank of ſand, riſing from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its ſouthern extremity falls, in a rapid ſlope from the ſummit of the Sugar Loaf, into a rocky flat of conſiderable extent, called Windmill Hill.

"The principal maſs of the mountain rock conſiſts of a grey, denſe (what is generally called primary) marble; the different beds of which are to be examined in a face of 1350 feet of perpendicular height, which it preſents to Spain in a conical form. Theſe beds, or ſtrata, are of various thickneſs, from 20 to upwards of 40 feet, dipping in a direction from eaſt to weſt, nearly at an angle of 35 degrees. In ſome parts of the ſolid maſs of this rock are found teſtaceous bodies entirely tranſmuted into the conſtituent matter of the rock, and their interior hollows filled up with calcareous ſpar; but theſe do not occur often in its compoſition, and its beds are not ſeparated by any intermediate ſtrata.

"The caves of Gibraltar are many, and ſome of them of great extent. That which moſt deſerves attention and examinatinn is called St Michael's Cave, which is ſituated upon the ſouthern part of the mountain, almoſt equally diſtant from the Signal Tower and the Sugar Loaf. Its entrance is 1000 feet above the level of the ſea: This entrance is formed by a rapid ſlope of earth, which has fallen into it at various periods, and which leads to a ſpacious hall, incruſted with ſpar, and apparently ſupported in the centre by a large maſſy ſtalactitical pillar. To this ſucceeds a long ſeries of caves of difficult acceſs. In theſe cavernous receſſes, the formation and proceſs of ſtalactites is to be traced, from the flimſy quilt-like cone, ſuſpended from the roof, to the robuſt trunk of a pillar, three feet in dimeter, which riſes from the floor, and ſeems intended by Nature to ſupport the roof from which it originated.

"The only inhabitants of theſe caves are bats, ſome of which are of a large ſize. The ſoil, in general, upon the mountain of Gibraltar is but thinly ſown; and in many parts that thin covering has been waſhed off by the heavy autumnal rains, which have left the ſuperficies of the rock, for a conſiderable extent, bare and open to inſpection. In thoſe ſituations, an obſerving eye may trace the effects of the ſlow, but conſtant, decompoſition of the rock, cauſed by its expoſure to the air, and the corroſion of ſea-ſalts, which, in the heavy gales of eaſterly winds, are depoſited with the ſpray on every part of the mountain. Thoſe uncovered parts of the mountain rock alſo expoſe to the eye a phenomenon worthy of ſome attention, as it tends clearly to demonſtrate, that, however high the ſurface of this rock may now be elevated above the level of the ſea, it has once been the bed of agitated waters. This phenomenon is to be obſerved in many parts of the rock, and is conſtantly found in the beds of torrents. It conſiſts of potlike holes, of various ſizes, hollowed out of the ſolid rock, and formed apparently by the attrition of gravel or pebbles, ſet in motion by the rapidity of rivers or currents in the ſea.

"Upon the weſt ſide of the mountain, towards its baſe, ſome ſtrata occur, which are heterogenial to the mountain rock: the firſt, or higheſt, forms the ſegment of a circle; its convex ſide is towards the mountain, and it ſlopes alſo in that direction. This ſtratum conſiſts of a number of thin beds; the outward one, being the thinneſt, is in a ſtate of decompoſition, and is mouldering down into a blackiſh brown or ferruginous coloured earth. The beds, inferior to this, progreſſively increaſe in breadth to 17 inches, where the ſtratification reſts upon a rock of an argillaceous nature.

"This laſt bed, which is 17 inches thick, conſiſts of quartz of a blackiſh blue colour, in the ſepta or cracks of which are found fine quartz cryſtals, colourleſs, and perfectly tranſparent. Theſe cryſtals are compoſed of 18 planes, diſpoſed in hexangular columns, terminated at both extremities by hexangular pyramids. The largeſt of thoſe that Major Imrie ſaw did not exceed one-fourth of an inch in length: They, in general, adhere to the rock by the ſides of the column, but are detached without difficulty. Their great degree of tranſparency has obtained them the name of *Gibraltar diamonds*."

Much has been ſaid of the foſſil bones found in the rock of Gibraltar; and the general idea which exiſts concerning them is, that they are found in a petrified ſtate, and encloſed in the ſolid calcareous rock; but this, ſays Major Imrie, is a miſtake, which could ariſe only from inaccurate obſervation and falſe deſcription.

"In the perpendicular fiſſures of the rock, and in ſome of the caverns of the mountain (all of which afford evident proofs of their former communication with the ſurface), a calcareous concretion is found, of a reddiſh brown ferruginous colour, with an earthy fracture, and conſiderable induration, encloſing the bones of various animals, ſome of which have the appearance of being human. Theſe bones are of various ſizes, and lie in all directions, intermixed with ſhells of ſnails, fragments of the calcareous rock, and particles of ſpar; all of which materials are ſtill to be ſeen in their natural uncombined ſtates,

ſtates, partially ſcattered over the ſurface of the mountain. Theſe having been ſwept, by heavy rains at different periods, from the ſurface into the ſituations above deſcribed, and having remained for a long ſeries of years in thoſe places of reſt, expoſed to the permeating action of water, have become inveloped in, and cemented by, the calcareous matter which it depoſits.

“ The bones, in this compoſition, have not the ſmalleſt appearance of being petrified; and if they have undergone any change, it is more like that of calcination than that of petrifaction, as the moſt ſolid parts of them generally admit of being cut and ſcraped down with the ſame eaſe as chalk,

“ Bones combined in ſuch concretions are not peculiar to Gibraltar: they are found in ſuch large quantities in the country of Dalmatia, and upon its coaſts in the iſlands of Cherſo and Oſero, that ſome naturaliſts have been induced to go ſo far as to aſſert, that there has been a regular ſtratum of ſuch matter in that country, and that its preſent broken and interrupted appearance has been cauſed by earthquakes, or other convulſions, experienced in that part of the globe. But, of late years, a traveller (Abbé Alberto Fortis) has given a minute deſcription of the concretion in which the bones are found in that country: And by his account it appears, that with regard to ſituation, compoſition, and colour, it is perfectly ſimilar to that found at Gibraltar. By his deſcription, it alſo appears that the two mountain rocks of Gibraltar and Dalmatia conſiſt of the ſame ſpecies of calcareous ſtone; from which it is to be preſumed, that the concretions in both have been formed in the ſame manner and about the ſame periods.

“ Perhaps if the fiſſures and caves of the rock of Dalmatia were ſtill more minutely examined, their former communications with the ſurface might yet be traced, as in thoſe deſcribed above; and, in that caſe, there would be at leaſt a ſtrong probability, that the materials of the concretions of that country have been brought together by the ſame accidental cauſe which has probably collected thoſe found in the caverns of Gibraltar. Major Imrie traced, in Gibraltar, this concretion, from the loweſt part of a deep perpendicular fiſſure, up to the ſurface of the mountain. As it approached to the ſurface, the concretion became leſs firmly combined, and, when it had no covering of the calcareous rock, a ſmall degree of adheſion only remained, which was evidently produced by the argillaceous earth, in its compoſition, having been moiſtened by rain and baked by the ſun.

“ The depth at which theſe materials had been penetrated by that proportion of ſtalactitical matter, capable of giving to the concretion its greateſt adheſion and ſolidity, he found to vary according to its ſituation, and to the quantity of matter to be combined. In fiſſures, narrow and contracted, he found the concretion poſſeſſing a great degree of hardneſs at ſix feet from the ſurface; but in other ſituations more extended: and where a larger quantity of the materials had been accumulated, he found it had not gained its greateſt degree of adheſion at double that depth. In one of the caves, where the maſs of concretion is of conſiderable ſize, he perceived it to be divided into different beds, each bed being covered with a cruſt of the ſtalactitical ſpar, from one inch to an inch and a half in thickneſs; which ſeems to indicate, that the materials have been carried in at various periods, and that thoſe periods have been very remote from each other.

“ At Roſia Bay, upon the weſt ſide of Gibraltar, this concretion is found in what has evidently been a cavern, originally formed by huge unſhapely maſſes of the rock which have tumbled in together. The fiſſure, or cavern formed by the diſruption and ſubſidence of thoſe maſſes, has been entirely filled up with the concretion, and is now expoſed to full view by the outward maſs having dropped down in conſequence of the encroachments of the ſea. It is to this ſpot that ſtrangers are generally led to examine the phenomenon; and the compoſition, having here attained to its greateſt degree of hardneſs and ſolidity, the haſty obſerver, ſeeing the bones incloſed in what has ſo little the appearance of having been a vacuity, examines no further, but immediately adopts the idea of their being incaſed in the ſolid rock. The communication from this former chaſm to the ſurface from which it has received the materials of the concretion, is ſtill to be traced in the face of the rock, but its opening is at preſent covered by the baſe of the line wall of the garriſon. Here bones are found that are apparently human; and thoſe of them that appear to be of the legs, arms, and vertebræ of the back, are ſcattered among others of various kinds and ſizes, even down to the ſmalleſt bones of ſmall birds. Major Imrie found here the complete jaw-bone of a ſheep; it contained its full complement of teeth, the enamel of which was perfect, and its whiteneſs and luſtre in no degree impaired. In the hollow parts of ſome of the large bones was contained a minute cryſtallization of pure and colourleſs calcareous ſpar; but, in moſt, the interior part conſiſted of a ſpary cruſt of a reddiſh colour, ſcarcely in any degree tranſparent.

“At the northern extremity of the mountain, the concretion is generally found in perpendicular fiſſures. The miners there, employed upon the fortifications in excavating one of thoſe fiſſures, found, at a great depth from the ſurface, two ſkulls, which were ſuppoſed to be human; but, to the Major, one of them, if not both, appeared to be too ſmall for the human ſpecies. The bone of each was perfectly firm and ſolid; from which it is to be preſumed, that they were in a ſtate of maturity before they were incloſed in the concretion. Had they appertained to very young children, perhaps the bone would have been more porous, and of a leſs firm texture. The probability is, that they belonged to a ſpecies of monkey, which ſtill continues to inhabit, in conſiderable numbers, thoſe parts of the rock which are to us inacceſſible.

“This concretion varies, in its compoſition, according to the ſituation in which it is found. At the extremity of Princes Lines, high in the rock which looks towards Spain, it is found to conſiſt only of a reddiſh calcareous earth, and the bones of ſmall birds cemented thereby. The rock around this ſpot is inhabited by a number of hawks, that, in the breeding ſeaſon, neſtle here and rear their young; the bones in this concretion are probably the remains of the food of thoſe birds. At the baſe of the rock, below King's Lines, the concretion conſiſts of pebbles of the prevailing calcareous rock. In this concretion, at a very conſiderable depth under the ſurface, was found the under parts of a glaſs bottle, uncommonly ſhaped, and of great thickneſs; the colour of the glaſs was of a dark green.”

Major Imrie makes an apology for giving ſo minute a deſcription of theſe foſſil bones; but, in our opinion, the public is indebted to him for beſtowing ſo much attention on a ſubject which all muſt admit to be curious, and which, from the ſtrange inferences drawn from ſimilar phenomena by modern philoſophers, has become important as well as curious.

We cannot diſmiſs this article without noticing the ſubterraneous galleries conſtructed in the rock not only for the protection of the men during a ſiege, but alſo for placing cannon, to annoy the enemy, in ſituations inacceſſible but by ſuch means. The idea of forming theſe galleries was conceived by the late Lord Heathfield when governor, and by him, in ſome meaſure, carried into execution; though the plan was not completed till lately by General O'Hara. Of theſe galleries we have in the *Monthly Magazine* for April 1798 an animated account, which we ſhall inſert in the writer's own words.

“ The ſubterraneous galleries are very extenſive, pierce the rock in ſeveral places and in various directions, and at various degrees of elevation; all of them have a communication with each other, either by flights of ſteps cut in the rock, or by wooden ſtairs where the paſſages are required to be very perpendicular.

“ The centinels may now be relieved during a ſiege from one poſt to another in perfect ſafety; whereas, previouſly to the conſtructing of theſe galleries, a vaſt number of men were killed by the Spaniards while marching to their ſeveral ſtations. The width of theſe galleries is about twelve feet, their height about fourteen. The rock is broken through in various places, both for the purpoſe of giving light and for placing the guns to bear on the enemy. In different parts there are ſpacious receſſes, capable of accommodating a conſiderable number of men. To theſe receſſes they give names, ſuch as St Patrick's Chamber, St George's Hall, &c. The whole of theſe ſingular ſtructures have been formed out of the ſolid rock by blaſting with gunpowder. Through the politeneſs of an officer on duty, a place called Smart's Reſervoir was opened for our inſpection, which is a great curioſity, and not generally permitted to be ſhewn. It is a ſpring at a conſiderable depth in the body of the rock, and is above 700 feet above the level of the ſea; we deſcended into the cavern that contains it by a rope ladder, and with the aid of lighted candles proceeded through a narrow paſſage over cryſtallized protuberances of the rock till we came to a hollow, which appears to have been opened by ſome convulſion of Nature. Here, from a bed of gems, ariſes the ſalutary fount, clear as the brilliant of the eaſt, and cold as the icicle. We hailed the nymph of the grot, and, proſtrating ourſelves, quaffed hygean nectar from her ſparry urn. When reſtored to the light of day, we obtained, through the medium of the ſame gentleman, the key of St George's Hall, at which we arrived by a very intricate and gloomy path to the ſpacious excavation, which is upwards of an hundred feet in length, its height nearly the ſame. It is formed in a ſemicircular part of the rock; ſpacious apertures are broken through, where cannons of a very large calibre command the iſthmus, the Spaniſh lines, and a great part of the bay. The top of the rock is pierced through, ſo as to introduce ſufficient light to enable you to view every part of it. It appears almoſt incredible that ſo large an excavation could be formed by gunpowder, without blowing up the whole of that part of the rock, and ſtill more ſo, that they ſhould be able to direct the operations of ſuch an inſtrument, ſo as to render it ſubſervient to the purpoſe of elegance. We found in the hall a table, placed, I ſuppoſe, for the conveniency of thoſe who are traverſing the rock. The cloth was ſpread, the wine went round, and we made the vaulted roof reſound with the accents of mirth and the ſongs of conviviality.”

Theſe excavations are indeed very extraordinary works; but as the whole rock abounds with caverns, we wiſh that our author had inquired more particularly than he ſeems to have done, whether St George's Hall be wholly the work of art. From one of the paſſages which we have extracted from Major Imrie's memoir, we are led to think that it is not, or at leaſt, that the concretion removed had not acquired the conſiſtence of the more ſolid parts of the rock. If this was the caſe, much of the wonder will vaniſh, ſince the pick-axe and chiſel were probably employed to give elegance to the vault, and even, in ſome degree, to direct the operation of the gunpowder.

GIMBOLS, are the braſs rings by which a ſea-compaſs is ſuſpended in its box that uſually ſtands in the binacle.

GIRT, in timber-meaſuring, is the circumference of a tree, though ſome uſe this word for the quarter or 4th part of the circumference only, on account of the great uſe that is made of it; for the ſquare of this 4th part is eſteemed and uſed as equal to the area of the ſection of the tree; which ſquare therefore multiplied by the length of the tree, is accounted the ſolid content. This content, however, is always about one-fourth part leſs than the true quantity; being nearly equal to what this will be after the tree is hewed ſquare in the uſual way: ſo that it ſeems intended to make an allowance for the ſquaring of the tree.

GIRT *Line*, is a line on the common or carpenter's ſliding rule, employed in caſting up the contents of trees by means of their girt.

GLASS ETCHING, or *Engraving upon*, is in the article CHEMISTRY (*Encycl.*) ſaid to be a new art; and as that acid which diſſolves ſiliceous earth, and alſo glaſs, was firſt diſcovered in the year 1771 by Scheele, one might naturally imagine that the art of etching with it upon glaſs could not be older. By many others, as well as by us, it has indeed been noticed as a new invention; yet Profeſſor Beckmann, whoſe laborious reſearches have brought many things to light, has proved, that ſo early as the year 1670 the art of etching upon glaſs was diſcovered by Henry Schwanhard, ſon of George Schwanhard, who was a celebrated glaſs cutter, patronized by the Emperor Ferdinand III. about the middle of the laſt century. At the time of his death, 1667, the father practiſed his art at Prague and Ratiſbon. Whether the ſon followed the ſame buſineſs at the ſame towns, or removed to Nuremberg, is not very evident from the profeſſor's hiſtory; but in the year above-mentioned, ſome *aqua regia (nitro muriatic acid)* having accidentally fallen on his ſpectacles, he was ſurpriſed to find the glaſs corroded by it, and become quite ſoft. He thus found himſelf in poſſeſſion of a liquid by which he could etch writing and figures upon plates of glaſs.

Such is our information; but if it be admitted (and it would diſplay unreaſonable ſcepticiſm to queſtion it), Schwanhard muſt either have improved the nitro-muriatic acid by ſome means or other unknown to us, or have confined his etchings to ſome particular kinds of glaſs; for the *fluoric* is the only acid, with which we are acquainted, that corrodes all glaſs. (See CHEMISTRY-*Index* in this *Supplement*). M. Beckmann indeed ſeems to think that he had diſcovered the fluoric acid itſelf; for in the year 1725 there appeared in a periodical work the following receipt for making a powerful acid, by which figures of every kind can be etched upon glaſs.

“When the *ſpiritus nitri per diſtillationem* has paſſed into the recipient, ply it with a ſtrong fire, and when well dephlegmated, pour it, as it corrodes ordinary glaſs, into a Weldenburg flaſk. Then throw into it a pulveriſed green Bohemian emerald, otherwiſe called *heſphorus* (which, when reduced to powder, and heated, emits in the dark a green light), and place it in warm ſand for 24 hours. Take a piece of glaſs well cleaned, and freed from all greaſe by means of a ley; put a border of wax round it, about an inch in height, and cover it all over with the above acid. The longer you let it ſtand ſo much the better; and at the end of ſome time the glaſs will be corroded, and the figures which have been traced out with ſulphur and varniſh will appear as if raiſed above the pane of glaſs.”

That the Bohemian emerald or *heſphorus* mentioned in this receipt is green ſparry fluor, cannot, ſays the profeſſor, be doubted; and he ſeems to have as little doubt of the receipt itſelf having paſſed from Schwanhard and his ſcholars to the periodical work of 1725, from which it has been lately inſerted in the Œkonomiſche Encyclopedie of Krunitz. This ſuppoſition certainly acquires a conſiderable degree of probability from the ſimilarity of Schwanhard's method of etching to that which is here recommended, and which is ſo different from what is now followed. At preſent, the glaſs is covered with a varniſh either of iſinglaſs diſſolved in water, or of turpentine oil mixed with a little white lead, through which the figures to be etched are traced as on copper; but Schwanhard, when he had drawn his figures, covered them with varniſh, and then by his liquid corroded the glaſs around them. His figures, therefore, when the varniſh was removed, remained ſmooth and clear, appearing raiſed from a dim or dark ground; and M. Beckmann, who perſuaded ſome ingenious artiſts to make trial of this antient method of etching, declares, that ſuch figures have a much better effect than thoſe which are cut into the glaſs.

Before concluding this article, it may be worth while juſt to mention a propoſal which has been lately made to employ glaſs inſtead of copper for throwing off prints in the rolling preſs. That it is poſſible to uſe glaſs plates of great thickneſs for this purpoſe, it would be raſh to deny; but the ſuperiority of ſuch plates to thoſe of copper we cannot conceive. If not broken in pieces in the rolling preſs, they would doubtleſs laſt longer; but the expence of them at firſt would probably be greater, and the engraving on them could not be ſo fine.

GLOSSOCOMMON, in mechanics, is a name given by Heron to a machine compoſed of divers dented wheels with pinions, ſerving to raiſe huge weights.

GLUCINA (A), a peculiar earth diſcovered by Vauquelin in the beryl and the emerald. Its general properties are as follows: 1. It is white; 2. Inſipid; 3. Inſoluble in water; 4. Adheſive to the tongue; 5. Infuſible; 6. Soluble in the fixed alkalis; 7. Inſoluble in ammoniac; 8. Soluble in the carbonat of ammoniac; 9. Soluble in almoſt every one of the acids (except the carbonic and phoſphoric acids), and forming ſalts of a ſaccharine taſte; 10. Fuſible with borax into a tranſparent glaſs; 11. Abſorbs one fourth of its weight of carbonic acid; 12. Decompoſes the aluminous ſalts; 13. Is not precipitable by well ſaturated hydro-ſulphurets.

The ſpecific characters of glucina, which are united in none of the other known earths, are: 1. Its ſalts are ſaccharine, and ſlightly aſtringent; 2. It is very ſoluble in the ſulphuric acid by exceſs; 3. It decompoſes the aluminous ſalts; 4. It is ſoluble in the carbonat of ammoniac; 5. Is completely precipitated from its ſolutions by ammoniac; 6. Its affinity for the acids is intermediate between magneſia and alumine.

One hundred parts of beryl contain 16 of glucina; but for the beſt method of analyzing the beryl, and of courſe obtaining the earth, we muſt refer our readers to the article MINERALOGY in this *Supplement;* and ſhall conclude this ſhort article with a valuable and judicious remark of Vauquelin's.

“It almoſt always happens (ſays this able chemiſt), in the ſciences of obſervation, and even in the ſpeculative ſciences, that a body, a principle, or a property, formerly unknown, though it may often have been uſed, or even held in the hands, and referred to other ſimple ſpecies, may, when once diſcovered, be afterwards found in a great variety of ſituations, and be applied to many uſeful purpoſes. Chemiſtry affords many recent examples of this truth. Klaproth had no ſooner diſcovered the different ſubſtances with which he has enriched the ſcience, but they were found in various other bodies; and if I may refer to my own proceſſes, it will be ſeen, that after I had determined the characters of chrome, firſt found in the native red lead, I eaſily recognized it in the emerald and the ruby. The ſame has happened with regard to the earth of the beryl. I have likewiſe detected it in the emerald; in which, nevertheleſs, it was overlooked both by Klaproth and myſelf in our firſt analyſis: ſo difficult it is to be aware of the preſence of a new ſubſtance, particularly when it poſſeſſes ſome properties reſembling thoſe already known!”

GOLD, the moſt perfect of all the metals. See CHEMISTRY-*Index* in this *Supplement.*

It has been a very common opinion among metallurgiſts, that tin has the property of deſtroying the ductility of gold, on being melted with it even in very ſmall quantities; and Dr Lewis adds, that even the vapours which ariſe from tin in the fire, make gold ſo brittle, that it flies in pieces under the hammer. This opinion was controverted by Staneſby Alchorne, Eſq; of his Majeſty's mint, who made a ſet of experiments, which, in his opinion, authoriſe a very different concluſion, viz. that though tin, like other inferior metals,

will

(A) This name was given to the earth of beryl by the editors of the *Annales de Chimie.* Its moſt characteriſtic property being that it forms ſalts of a ſaccharine taſte, they gave it a name derived from γλυκαινω, *to render ſweet.* According to this etymology, ſhould not the name be *Glycina?*

will contaminate gold in proportion to the quantity mixed with it, yet there does not appear in tin any thing ſpecifically inimical to that precious metal.

As we have elſewhere (ſee CHEMISTRY, nº 1091, &c. *Encycl.*) enumerated theſe experiments, and admitted the concluſion drawn from them, it becomes our duty, in this place, to ſtate what has been urged againſt that concluſion.

M. Tillet, being in his own mind perſuaded that tin renders gold ſo brittle that it cannot be reduced to thin leaves, and far leſs be made to paſs through the wire-plate but by virtue of repeated annealing, and peculiar treatment, which gold of the uſual ductility does not require, determined, from reſpect to M. Alchorne, to repeat his experiments.

His firſt experiment* conſiſted in mixing 24 grains of fine gold with one of tin which contained no arſenic. He wrapped the grain of tin in the 24 grains of gold reduced to a very thin leaf, and placed the whole upon a piece of charcoal, ſo hollowed out as to ſupport the mixed metal during fuſion. He even ſprinkled a ſmall quantity of calcined borax upon the metal, in order that the fuſion might be more ſudden, that the metal might flow together, and the tin unite with the gold, without allowing time for it to become calcined. This alloy was ſpeedily fuſed by the enameller's lamp, and reduced into a ſmall button without any loſs of weight. It was then flattened carefully beneath the hammer; but, notwithſtanding his utmoſt precaution in this reſpect, it cracked, and at laſt broke into three pieces, its thickneſs then being a quarter of a line or thereabouts. He repeated this experiment with a double quantity as well of pure gold as of tin, and the reſult was the ſame.

He next alloyed 4 ounces of gold, of the fineneſs of 22 carats, with 1 gros 24 grains of tin deprived of arſenic, or, in other words, with 4 pennyweights of tin; and theſe two metals being reduced into ſmall pieces, were mixed together, put into a crucible, and urged by the ſtrong heat of a forge with two pair of bellows. When their fuſion appeared to be complete, he poured the metal into a ſmall ingot mould proportioned to the quantity.

The ingot thus obtained had loſt ſcarcely any thing of the weight of the two metals that compoſed it; which was a proof that the tin had united and incorporated with the four ounces of gold. But on attempting to bend the ingot, which was about ſix inches long, and not more than two or three lines thick, he remarked, contrary to the nature of gold of 22 carats, that it was rigid, and would have required a conſiderable effort to give it any degree of curvature, or bring it to the flexibility it would have poſſeſſed if no tin had entered into its compoſition. Not ſatisfied, however, with the inference naturally flowing from this circumſtance, he proceeded to the proper teſt by hammering, particularly with the edge of the hammer, in order that the bar might be lengthened, and by that means ſubmitted to the moſt deciſive proof. He did not obſerve, during the continuation of this proceſs, till the bar was reduced to about two-thirds of its firſt thickneſs, that its edges were cracked, or exhibited much of the appearance of brittleneſs; but as he was apprehenſive that this accident might happen by too long hammering, he divided the bar by cutting off the part which had been hammered out. This part was placed in the midſt of lighted charcoal, in order that, by a moderate annealing, it might recover the ſtate of malleability it poſſeſſed before it was hammered. But when he went to take it out of the fire, where it had undergone no greater heat than a cherry-red, he found it divided into two parts. After having ſuffered theſe to cool, he forged them again. They were extended with conſiderable eaſe, though with ſome cracks at the edges; but they did not yet ſatisfy the whole of his enquiries. He therefore annealed one of the two laſt mentioned pieces a ſecond time, and reſerved the other in its hard-hammered ſtate to be paſſed between the laminating rollers. The annealed part, which might have the thickneſs of about a ſhilling, broke in the fire, though the heat was very gentle, into four or five portions. The longeſt of theſe portions, which beſt reſiſted the action of the fire, bent and twiſted itſelf, and ſhewed, by this ſtate of ſtrong contraction in different directions, that it had tended to break and become divided into ſmall portions, ſimilar to thoſe which had already ſeparated from it.

Satisfied by this experiment that the piece of the mixed ingot which he had kept in its hammer-hardened ſtate would not bear annealing, he determined to extend it ſtill more between the rollers, ſetting them up very gradually, in order that the fracture, if it ſhould take place, might be principally owing to the brittleneſs of the material, and not to the force of compreſſion to which it was ſubjected. By this management he ſucceeded in extending the metal to double its length notwithſtanding its hardneſs, and rendering it as thin as ſtrong paper; though the edges were cracked through their whole length like the teeth of a ſaw. But this accident is not at all ſurpriſing, when it is conſidered that gold, though alloyed ſimply with copper, whatever may be the cauſe, does not poſſeſs its uſual ductility, particularly when it is laminated very thin, without repeated annealing as the metal becomes hard.

Aware that the fracture of the pieces of gold might be attributed to an incomplete fuſion, or unequal mixture of the two metals, he melted the whole ingot over again with the utmoſt precaution; but in vain. The metal was as brittle as formerly, and would not bear annealing.

He next fuſed ſix ounces of pure gold of 24 carats with 2 gros, or 6 penny-weights of tin, taking every poſſible precaution to have the metals completely mixed. When the whole was in perfect fuſion, he poured the mixture into an ingot mould, and obtained an ingot rather longer and cleaner than the two former. As ſoon as it was cold he forged one of its extremities with the edge of the hammer. It was lengthened without any perceptible crack; and when it was reduced to the thickneſs of one line, or thereabouts, he cut it off for ſeparate treatment. By moderate annealing it maintained its integrity; and, with the exception of a few cracks, it paſſed the laminating rollers without breaking. As he was fearful, nevertheleſs, that it might break in ſome part if he continued to laminate it, he gave it a ſlight annealing. It had ſcarcely acquired a cherry-redneſs between the charcoal, before it broke into five or ſix parts, ſome of which were ſimply bended or twiſted, and others flat as they quitted the rollers. Among the annealed pieces of this extremity

---

* *Memoirs of the Academy of Sciences at Paris for the year* 1790.

extremity of the ingot, there was one ſufficiently long, though a little curled, which he laminated a ſecond time, with the determination of rendering it very thin without the leaſt annealing. It acquired at leaſt double the length it had at firſt without breaking; and, if we except the two ſides of this plate which were cracked, the body, or main piece, was entire. It was ſpongy, and might be conſidered as if formed out of an ingot of common gold containing no tin, but not poſſeſſing the whole of its natural ductility.

" It follows, ſays M. Tillet, from theſe experiments, that gold, whether fine or alloyed, when perfectly fuſed with a ſmall portion of the fineſt tin, acquires rigidity and hardneſs by the mixture; that it loſes ſomewhat of its diſtinguiſhing colour; and that it may, indeed, by careful management, be extended to a certain degree by the hammer, or ſtill better by the rollers; but that, as it cannot be annealed without danger of breaking, it is by this defect deprived of the eſſential advantage of recovering its original ſoftneſs after it has been ſtrongly hammer-hardened. It is not but by careful management in the uſe of the hammer, and by frequent annealing, that artiſts employed on works of gold and ſilver ſucceed in obtaining them without cracks, and bringing them to a ſtate of perfection, without being obliged to have recourſe to ſolder to repair the defects which exceſſive hardneſs under the hammer would occaſion. How much, therefore, ought gold-workers, who continually have this metal in their hands, to be attentive to prevent the introduction of tin in their workſhops, and never to employ ſuch compounds of gold as are ſubject to break, or even to warp, while annealing? The expence of refining, which they would pay for depurating ſuch compounds, would be of leſs conſequence to them than the loſs of time required for the careful management of ſuch gold contaminated by tin, even if they did ſucceed in uſing it, and were not often forced to abandon, after much labour, a work nearly finiſhed.

" If it be allowable (continues our author) to form conjectures on the cauſe of the fracture of plates of gold containing tin, when ſubjected to the annealing heat, it may be preſumed, ſince tin very ſpeedily melts, while gold requires a ſtrong heat for its fuſion, that the parts of the tin intermixed in a ſort of proportional equality with thoſe of the gold, tend to ſeparate by a ſpeedy fuſion and at a very gentle degree of heat; that they remain without conſiſtence between the parts of the gold, while the latter preſerve the whole of their ſolidity, and do not loſe it even by the annealing heat: whence it ſeems, that the parts of the precious metal, when ignited among the coals, having no longer the ſolid connection formed by the tin, but, on the contrary, having an infinite number of ſmall cavities occupied by particles of that metal in fuſion, muſt tend to diſunion; whereas the ſame accident does not take place in the pieces which have reſiſted the annealing, and have been laminated after cooling, becauſe the particles of tin have become ſolid by cooling, and have recovered their original ſtate of union with the gold.

" This fracture of the compound does not take place with an alloy of gold and copper, for an oppoſite reaſon to that which has here been explained; namely, becauſe theſe two metals require nearly the ſame heat for their fuſion. The effect of annealing being there- fore equal upon both, the metals, notwithſtanding this treatment, preſerve their natural conſiſtence, even tho' the heat be carried near the point of fuſion."

Gold-Leaf. See *Gold-Leaf* (*Encycl.*), where a full account is given from Dr Lewis of the proceſs of gold-beating. In that article we have ſaid that gold-leaf ought to be prepared from the fineſt gold; but Mr Nicholſon, who in all probability knows much more of the matter than the author from whom our account was copied, aſſures us that this is a miſtake, and that pure gold is too ductile to be worked between the gold-beater's ſkin. The neweſt ſkins will work the fineſt gold, and make the thinneſt leaf, becauſe they are the ſmootheſt. Old ſkins, being rough or foul, require coarſer gold. The finer the gold, the more ductile; inſomuch that pure gold, when driven out by the hammer, is too ſoft to force itſelf over the irregularities, but would paſs round them, and by that means become divided into narrow ſlips. The fineſt gold for this purpoſe has three grains of alloy in the ounce, and the coarſeſt twelve grains. In general, the alloy is ſix grains, or one-eightieth part. That which is called pale-gold contains three pennyweights of ſilver in the ounce. The alloy of leaf-gold is ſilver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold is delivered by the maſter to the workman, who, if extraordinary ſkilful, returns two thouſand leaves, or eighty books of gold, together with one ounce and ſix pennyweights of waſte cuttings. Hence one book weighs 4.8 grains; and as the leaves meaſure 3.3 inches in the ſide, the thickneſs of the leaf is one two hundred and eighty-two thouſandth part of an inch.

The yellow metal called Dutch gold is fine braſs. It is ſaid to be made from copperplates, by cementation with calamine, without ſubſequent fuſion. Its thickneſs, compared with that of leaf gold, proved as 19 to 4, and under equal ſurfaces it is conſiderably more than twice as heavy as the gold. *Nicholſon's Journal*, vol. 1ſt.

GOLDONI (Charles), was born at Venice in the year 1707. He gave early indications of his humourous character, as well as his invincible propenſity to thoſe ſtudies which have rendered his name immortal. His father, perceiving that the darling amuſement of his ſon was dramatic performances, had a ſmall theatre erected in his own houſe, in which Goldoni, while yet an infant, amuſed himſelf with three or four of his companions, by acting comedies. Before he was ſent to ſchool, his genius prompted him to become an author. In the ſeventh and eighth years of his age, ere he had ſcarcely learned to read correctly, all his time was devoted to the peruſing comic writers, among whom was *Cicognini*, a Florentine, little known in the dramatic commonwealth. After having well ſtudied theſe, he ventured to ſketch out the plan of a comedy, which needed more than one eye-witneſs of the greateſt probity to verify its being the production of a child.

After having finiſhed his grammatical ſtudies at Venice, and his rhetorical ſtudies at the Jeſuit's college in Perugia, he was ſent to a boarding-ſchool at Rimini to ſtudy philoſophy. The impulſe of nature, however, ſuperſeded with him the ſtudy of Ariſtotle's works, ſo much in vogue in thoſe times. He frequented the theatres with uncommon curioſity; and paſſing gradually from the pit to the ſtage, entered into a familiar acquaintance with the actors. When the ſeaſon of comic performances was over, and the actors were to remove to Chiozza, young Goldoni made his eſcape in their company. This was the firſt fault he committed, which, according to his own confeſſion, drew a great many others after it. His father had intended him to be a phyſician, like himſelf: the young man, however, was wholly averſe to the ſtudy. He propoſed afterwards to make him an advocate, and ſent him to be a practitioner in Modena. An horrid ceremony of eccleſiaſtical juriſdiction, at which he was preſent, inſpired him with a melancholy turn, and he determined to become a capuchin.

His father, perceiving the whimſical, inconſtant humour of his ſon, feigned to ſecond this propoſal, and promiſed to go and preſent him to the guardian of the capuchins in Venice, in the hope that, after ſome ſtay in that extenſive and merry city, his melancholy fit would ceaſe. The ſcheme ſucceeded; for the young man, indulging in all the faſhionable diſſipation of the place, was cured of his fooliſh reſolution. It was however neceſſary for him to be ſettled in ſome employment; and he was prevailed upon by his mother, after the death of his father, to exerciſe the profeſſion of a lawyer in Venice. By a ſudden reverſe of fortune he was compelled to quit at once both the bar and Venice. He then went to Milan, where he was employed by the reſident of Venice in the capacity of ſecretary; where becoming acquainted with the manager of the theatre, he wrote a farce, entitled *Il Gondoliere Veneziano*, the Venetian Gondolier; which was the firſt comic production of his that was performed and printed. Some time after, Goldoni broke with the Venetian reſident, and removed to Verona.

There was in this place, at that time, the company of comedians of the theatre of St Samuel of Venice, and among them the famous actor *Coſali*, an old acquaintance of Goldoni, who introduced him to the manager. He began therefore to work for the theatre, and became inſenſibly united to the company, for which he compoſed ſeveral pieces. Having removed along with them to Genoa, he was for the firſt time ſeized with an ardent paſſion for a lady, who ſoon afterwards became his wife. He returned with the company to Venice, where he diſplayed, for the firſt time, the powers of his genius, and executed his plan of reforming the Italian ſtage. He wrote the *Momolo*, *Courtiſan*, the *Squanderer*, and other pieces, which obtained univerſal admiration.

Feeling a ſtrong inclination to reſide ſome time in Tuſcany, he repaired to Florence and Piſa, where he wrote *The Footman of Two Maſters*, and *The Son of Harlequin loſt and found again*. He returned to Venice, and ſet about executing more and more his favourite ſcheme of reform. He was now attached to the theatre of St Angelo, and employed himſelf in writing both for the company and for his own purpoſes. The conſtant toils he underwent in theſe engagements impaired his health. He wrote, in the courſe of twelve months, ſixteen new comedies, beſides forty-two pieces for the theatre; among theſe many are conſidered as the beſt of his productions. The firſt edition of his works was publiſhed in 1753, in 10 vols. 8vo. As he wrote afterwards a great number of new pieces for the theatre of St Luca, a ſeparate edition of theſe was publiſhed, under the title of *The New Comic Theatre*: among theſe was the *Terence*, called by the author his *favourite*, and judged to be the maſter-piece of his works. He made another journey to Parma, on the invitation of Duke Philip, and from thence he paſſed to Rome. He had compoſed 59 other pieces ſo late as the year 1761, five of which were deſigned for the particular uſe of Marque Albergati Capacelli, and conſequently adapted to the theatre of a private company. Here ends the literary life of Goldoni in Italy.

Through the channel of the French Ambaſſador in Venice, he had received a letter from Mr Zenuzzi, the firſt actor in the Italian theatre at Paris, containing a propoſal for an engagement of two years in that city. He accordingly repaired to Paris, where he found a ſelect and numerous company of excellent performers in the Italian theatre. They were, however, chargeable with the ſame faults which he had corrected in Italy; and the French ſupported, and even applauded in the Italians, what they would have reprobated on their own ſtage. Goldoni wiſhed to extend even to that country his plan of reformation, without conſidering the extreme difficulty of the undertaking. Scurrilities and jeſts, which are ever accompanied by actions, geſtures, and motions, are the ſame in all countries, and almoſt perfectly underſtood even in a foreign tongue: while the beauties of ſentiment and dialogue, and other things which lead to the underſtanding of characters and intrigues, require a familiar acquaintance with the tongue of the writer.

The firſt attempt of Goldoni towards his wiſhed-for reform, was the piece called *The Father for Love*; and its bad ſucceſs was a ſufficient warning to him to deſiſt from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general taſte, and publiſhed twenty-four comedies; among which *The Love of Zelinda and Lindor* is reputed the beſt.

The term of two years being expired, Goldoni was preparing to return to Italy, when a lady, reader to the dauphineſs, mother to the late king, introduced him at court, in the capacity of Italian maſter to the princeſſes, aunts to the king. He did not live in the court, but reſorted there at each ſummons, in a poſt-chaiſe ſent to him for the purpoſe. Theſe journeys were the cauſe of a diſorder in the eyes, which afflicted him the reſt of his life; for being accuſtomed to read while in the chaiſe, he loſt his ſight on a ſudden, and in ſpite of the moſt potent remedies, he could never afterwards recover it entirely. For about ſix months lodgings were provided him in the chateau of Verſailles. The death, however, of the dauphin, changed the face of affairs. Goldoni loſt his lodgings, and only, at the end of three years, received a bounty of 100 louis in a gold box, and the grant of a penſion of four thouſand livres a-year. This ſettlement would not have been ſufficient for him, if he had not gained, by other means, farther ſums. He wrote now and then comedies for the theatres of Italy and Portugal; and, during theſe occupations, was deſirous to ſhew to the French that he merited a high rank among their dramatic writers. For this purpoſe, he neglected nothing which could be of uſe to render himſelf maſter of the French language.

Goldoni, Good Hope

He heard, ſpoke, and converſed ſo much in it, that, in his 62d year, he ventured to write a comedy in French, and to have it repreſented in the court theatre, on the occaſion of the marriage of the king.

This piece was the *Bourru Bienfaiſant* ; and it met with ſo great ſucceſs, that the author received a bounty of 150 louis from the king, another gratification from the performers, and conſiderable ſums from the bookſellers who publiſhed it. He publiſhed, ſoon after, another comedy in French, called *L'Avare Faſtueux*. After the death of Louis XV. Goldoni was appointed Italian teacher to the Princeſs Clotilde, the preſent princeſs of Piedmont ; and after her marriage he attended the late unfortunate Princeſs Elizabeth in the ſame capacity.

The approach of old age obliged him to quit Verſailles, and to live in Paris, the air of which, leſs ſharp, was better adapted to his conſtitution. The laſt work of Goldoni was *The Volponi*, written after his retirement from court ; from which time he bade a laſting adieu to writing. Unfortunately for him, he lived to ſee his penſions cut off at the revolution, like others, and he ſpent his laſt days in poverty and diſtreſs. He died in 1792, at a criſis when, according to the expreſſion of a deputy in the Convention, the French nation was ready to repay him every debt of gratitude.

Goldoni is on a par with the greateſt comic poets of modern times, with regard to dramatic talents, and is thought ſuperior to them all with regard to the fertility of his genius. His works were printed at Leghorn in 1788—91, in 31 vols. 8vo. He has been generally called the Moliere of Italy ; and Voltaire, in one of his letters to Marquis Albergati, ſtyles him *The Painter of Nature*. Goldoni is one of thoſe authors whoſe writings will be reliſhed in the moſt remote countries, and by the lateſt poſterity.

GOOD-HOPE, or Cape of Good Hope, was taken by the Britiſh on 17th Auguſt 1796 with very little difficulty. At this we need not be much ſurpriſed, if to the diſcontent which muſt have prevailed among the planters and townſmen with the new order of things, be added the manners of the people. M. Vaillant, who was at the Cape during the laſt war, when the garriſon expected to be every day attacked by a Britiſh ſquadron, and when the people were not abſolutely diſguſted with their own government, repreſents them, however, as rendered ſo completely frivolous by imitating the manners of their French allies, that, though the place was ſtrongly fortified, it could hardly be expected to hold out long againſt a vigorous and well conducted ſiege.

"The females of the Cape (ſays he), when I ſaw them for the firſt time, had really excited my aſtoniſhment by their dreſs and their elegance ; but I admired in them, above all, that modeſty and reſerve peculiar to the Dutch manners, which nothing as yet had corrupted.

"In the courſe of ſix months, a great change had taken place. It was no longer the French modes that they copied ; it was a caricature of the French. Plumes, feathers, ribbons, and tawdry ornaments heaped together, without taſte, on every head, gave to the prettieſt figures a groteſque air, which often provoked a ſmile when they appeared. This mania had extended to the neighbouring plantations, where the women could ſcarcely be known. A mode of dreſs entirely new was everywhere introduced ; but ſo fantaſtical, that it would have been difficult to determine from what country it had been imported."

Good Hope

At that time a French and a Swiſs regiment were in the garriſon ; and though the town was occupied only with warlike preparations, and though an attack from the Britiſh fleet was every moment expected, the French officers had already introduced a taſte for pleaſure. Employed in the morning at their exerciſe, the French ſoldiers in the evening acted plays. A part of the barracks was transformed into a theatre ; and as women capable of performing female characters could not be found in the town, they aſſigned theſe parts to ſome of their comrades, whoſe youth, delicate features, and freſhneſs of complexion, ſeemed beſt calculated to favour the deception. Theſe heroines, of a new kind, heightened the curioſity of the ſpectators, and rendered the entertainment ſtill more lively and intereſting.

To add to the general pleaſure, ladies of the firſt rank conſidered it as incumbent on them to lend to the military actors and actreſſes, their laces, jewels, rich dreſſes, and moſt valuable ornaments. But ſome of them had cauſe to repent of their condeſcenſion ; for it happened more than once that the Counteſs of Almaviva having left in pledge at the ſuttling-houſe her borrowed decorations, the owner, to recover them, was obliged to diſcharge not only the bill due for brandy and tobacco, but all the other debts of the heroine.

During the intoxication and giddineſs occaſioned by theſe amuſements, Love alſo did not fail to act his part ; and certain little intrigues were, from time to time, brought to light, which gave employment to the tongue of ſcandal, and introduced unhappineſs into families. Hymen, it is true, amidſt theſe adventures, ſometimes intervened to repair the follies of his brother ; and many marriages, which reſtored every thing to order, were the reſult of his negotiations ; but the complaints, though ſtifled, did not leſs exiſt. The watchfulneſs of the mother was alert. The huſband, by ſo much the more ſecretly irritated as he ſaw himſelf obliged to conceal his jealouſy, curſed in his heart both actors and theatre ; while the matronly part of the community, leſs on the reſerve, declaimed with bitterneſs againſt the licentiouſneſs that prevailed, which they wholly imputed to this mode of theatrical entertainment. At laſt, to the great mortification of the young, but to the high ſatisfaction of the old women and huſbands, the theatre was on a ſudden ſhut up. The cauſe that affected this was altogether foreign to the complaints that were made, and of a nature that it was impoſſible to foreſee. Two of the French actors, who, it muſt be remembered, were officers in the army, thought proper to imitate the paper money of the company, and to put their forged notes in circulation. The forgery was detected, and traced to its authors ; the two theatrical heroes were baniſhed from the Cape ; and the company, aſhamed of the adventure, dared neither ſeek others to ſupply the vacant places, nor reſume their ſtage entertainments.

Intoxicating as were theſe pleaſures, government meanwhile had not been inattentive to the danger which threatened the colony. As they daily expected to be attacked by the Britiſh fleet, they had increaſed the means of defence, and ordered different works and new fortifications to be conſtructed.

At firſt, the buſineſs was carried on with activity and ardour; becauſe the inhabitants, inſtigated by their private intereſt, which was then conſidered as involved with that of the public, had voluntarily offered their ſervices, and mingled with the workmen. Young and old, ſoldiers and magiſtrates, ſailors and planters, all ſolicited the honour of co-operating for the general good and common ſafety. To behold this heterogeneous multitude—ſome loaded with pick-axes, and ſome with ſpades, or other ſimilar implements—marching out in the morning from the town, and proceeding in high ſpirits to the new fortifications, was a ſight truly admirable.

But this patriotic fervour was of no long continuance. Under pretence of ſparing their ſtrength, and that they might not weary themſelves to no purpoſe, they ſoon cauſed their ſlaves to follow them with the tools and inſtruments. In a little time they contented themſelves with ſending their ſlaves only; and at laſt theſe ſubſtitutes themſelves, in imitation of their maſters, or perhaps by their ſecret orders, gave over going alſo. Their enthuſiaſm, in ſhort, from the firſt moment of its breaking out till the period when it was thus entirely cooled, had been the affair of ſomething leſs than a fortnight.

This taſte for frivolity which, almoſt twenty years ago, was introduced among the Dutch in Cape-town by their good friends the French, ſpread rapidly thro' the planters, who are thus deſcribed by M. Vaillant, who certainly had the beſt opportunities of knowing them.

The planters of the Cape may be divided into three claſſes; thoſe who reſide in the vicinity of the Cape, within a diſtance of five or ſix leagues; thoſe who live farther off in the interior parts of the colony; and laſtly, thoſe who, more diſtant ſtill, are found at the extremity of the frontiers among the Hottentots.

The firſt, who are opulent proprietors, and have handſome country houſes, may be likened to what was formerly called in France *petits ſeigneurs terriers*, and differ extremely from the other planters in eaſe and luxury, and particularly in their manners, which are haughty and diſdainful. Such is the reſult of wealth. The ſecond, ſimple, kind, hoſpitable, are cultivators, who live upon the fruits of their labour. Here we have an example of the good effects of mediocrity. The laſt, poor enough, yet too indolent to derive ſubſiſtence from the ſoil, have no other reſource than the produce of ſome cattle, which they feed as they can. Like the Beduin Arabs, they think much of the trouble of driving them from canton to canton, and from one paſturage to another. This wandering life prevents them from building any ſettled habitations. When their flocks oblige them to ſojourn for a while in the ſame place, they conſtruct, in haſte, a rude kind of hut, which they cover with matts, after the manner of the Hottentots, whoſe cuſtoms they have adopted, and from whom they in no reſpect differ, but in their complexion and features. And here the evil is, that there is no preciſe ſituation in ſocial life to which theſe miſerable beings belong.

Theſe ſluggiſh tribes are held in horror by their induſtrious neighbours, who dread their approach, and remove as far from them as they can; becauſe, having no property of their own, they ſteal without ſcruple that of others, and, when in want of paſturage for their cattle, conduct them ſecretly to the firſt cultivated piece of ground that comes in their way. They flatter themſelves they ſhall not be diſcovered, and they remain till every thing is devoured. If detected in their thefts, ſquabbles and contentions enſue, and afterwards a ſuit at law, in which recourſe is had to the magiſtrate, and which commonly terminates in making three men enemies, the robber, the perſon robbed, and the judge.

Nothing can be ſo mean and cringing as the conduct of the firſt deſcription of planters, when they have any thing to tranſact with the principal officers of the company, who may have ſome influence over their lot; and nothing ſo abſurdly vain and ſo ſuperlatively inſolent as their behaviour to perſons from whom they have nothing to hope and nothing to fear. Proud of their wealth, ſpoiled by reſiding near a town, from whence they have imbibed only a luxury that has corrupted, and vices that have degraded them, it is particularly towards ſtrangers that they exerciſe their ſurly and pitiful arrogance. Though neighbours to the planters who inhabit the interior of the country, you muſt not ſuppoſe they regard them as brethren; on the contrary, in the true ſpirit of contempt, they have given them the name of Rauw-boer, a word anſwering to the loweſt deſcription of clown. Accordingly, when theſe honeſt cultivators come to the town upon any kind of buſineſs, they never ſtop by the way at the houſes of the gentry of whom we are ſpeaking; they know too well the inſulting manner in which they would be received. One might ſuppoſe them to be two inimical nations always at war, and of whom ſome individuals only met at diſtant intervals, upon buſineſs that related to their mutual intereſts.

What is the more diſguſting in the inſolence of theſe Africans is, that the majority of them are deſcended from that corrupt race of men, taken from priſons and hoſpitals, whom the Dutch company, deſirous of forming a ſettlement at the Cape, ſent thither to begin, at their riſk and pearl, the population of the country. This ſhameful emigration, of which the period is not ſo remote but that many circumſtances of it are remembered, ought to render particularly modeſt thoſe who are in the moſt diſtant manner related to it. On the contrary, it is this very idea that moſt contributes to their arrogance; as if they flattered themſelves that, under the guiſe of ſupercilious manners, they could hide the abjectneſs of their origin. If a ſtranger arrives at the Cape with the deſign of remaining and ſettling there, they conceive him to be driven from his country by the ſame wretched circumſtances which formerly baniſhed their fathers, and they treat him with the moſt ſovereign contempt.

This melancholy failing is the more to be lamented as the contagion has ſpread through almoſt every reſidence about the Cape, which is in reality a very charming canton. Embelliſhed by cultivation, by its numerous vineyards and pleaſant country houſes, it everywhere exhibits ſo varied and delicious a proſpect, that, were it occupied by other inhabitants, it would excite no ſenſations but thoſe of pleaſure.

As we advance into the country, the planters are a ſort of farmers; and conſtitute, by their manners, cuſtoms, and occupations, a claſs by themſelves, perfectly diſtinct from what we have been deſcribing. Situated farther from the Cape, and, of conſequence, not having the ſame opportunities for diſpoſing of their commodities, they are leſs rich than the firſt. We ſee among them none of thoſe agreeable country houſes, which, placed at different diſtances from the town, embelliſh the country as we paſs, and afford ſuch charming proſpects. Their habitation, which is about the ſize of a large coach-houſe, is covered with thatch, and divided into three rooms by means of two partitions, which reach only to a certain height. The middle apartment, in which is the entrance to the houſe, ſerves at once both as a parlour and eating-room. It is there that the family reſide during the day, and that they receive their tea and other viſitors. Of the two other rooms, one forms a chamber for the male children, and the other for the females, with the father and mother. At the back of the middle apartment is a farther room ſerving for a kitchen. The reſt of the building conſiſts of barns and ſtables.

Such is the diſtribution which is generally followed in the interior plantations of the colony; but nearer to the frontiers, where there does not prevail the ſame eaſe of circumſtances, the habitations are much leſs commodious. They are merely a barn, conſiſting of a ſingle room, without any diviſion, in which the whole family live together, without ſeparating either day or night. They ſleep upon ſheep ſkins, which ſerve them alſo for covering.

The dreſs of theſe planters is ſimple and ruſtic. That of the men conſiſts of a check ſhirt, a waiſtcoat with ſleeves, a large pair of trowſers, and a hat half unlooped. The women have a petticoat, a jacket fitted to their ſhape, and a little round bonnet of muſlin. Unleſs upon extraordinary occaſions, neither ſex wear ſtockings. During a part of the year, the women even walk with their feet quite naked. The occupations of the men require that theirs ſhould have ſome covering; and this covering they make from a piece of the hide of an ox, applied and ſhaped to the foot ſoon after the animal is killed, and while the hide is yet freſh. Theſe ſandals are the only article of their dreſs which they make themſelves; the reſt is the buſineſs of the women, who cut out and prepare their whole wardrobe. Though the equipment we have mentioned conſtitute the every-day dreſs of the planter, he has, however, a coat of handſome blue cloth, which he wears upon days of gala and ceremony. He has then alſo ſtockings and ſhoes, and is dreſſed exactly like an European. But this finery never makes its appearance but when he goes to the Cape; and then, indeed, is not put on till he arrives at the entrance of the town.

It is commonly in theſe journeys that they purchaſe ſuch things as they may want to refit their wardrobe. There is, at the Cape, as well as in Paris and London, a ſpecies of old-clothes-men, who deal in commodities of this ſort; and who, from their enormous profits, and the extortion they practiſe, they have obtained the name of *Capſe Smouſe*, or Cape Jews. Theſe traffickers contrive at all times to ſell their goods at a dear rate; but they vary their price in proportion as their ſtock is great or ſmall: of courſe they bear no fixed price; and the planter who comes from the deſert, and who can underſtand but little of this fluctuation, is ſure to be duped.

On the other hand, the regular ſhopkeeper, who knows the probity of theſe farmers, and how punctual they are in the payment of their debts, exerts every effort to prevail on them to open an account with him. He tempts them by the pretended cheap price and excellent quality of his ſtuffs, and offers to remit the payment till their next journey in the following year. It is ſeldom that theſe people, ſimple and unexperienced as they are, perceive the craft that is preſented to them under this guiſe of kindneſs and civility. If they ſuffer themſelves to be prevailed upon, they are ſhackled for life. Upon their return, there are new purchaſes to be made upon the ſame conditions; and thus, year after year, always in debt, always buying without prompt payment, they become the prey of an extortioner, who raiſes to himſelf a fortune out of their weakneſs.

It is true, theſe buyers, after being thus duped at the Cape, commonly return home only to make dupes of others. The cunning that has been employed to deceive them, they employ in their turn to tempt the Hottentots who are in their ſervice. The remnants of ſtuff, or the frippery garments which they bring back, are ſold to theſe unfortunate ſervants with ſo great a profit, that commonly the wages of a year are inadequate to the payment; and they find themſelves, like their maſters, in debt for the year that is to come. In the end, therefore, it is the poor Hottentot that pays for the extortion at the Cape.

Cuſtom has rendered the planters inſenſible to the want of fruit and pulſe, though the ſoil is admirably adapted to the cultivation of both. The facility with which they rear their cattle makes up for this privation, as their flocks afford them plenty of proviſion. The chief food is mutton; and their tables are loaded with ſuch profuſion as to diſguſt one at the ſight.

From this mode of living, cattle are in the colonies, as in other places, not only a uſeful object, but an article of the firſt neceſſity. The planter undertakes himſelf the care of watching over his flocks. Every evening, when they return from the field, he ſtands at his door, with a ſtick in his hand, and counts them over one by one, in order to be ſure that none of them are miſſing.

People who have no other employment than a little agriculture, and the ſuperintendance of a flock, muſt have long intervals of idleneſs. It is thus with the planters, particularly thoſe who live in the interior parts of the country, and who being unable, on account of their diſtance from the Cape, to diſpoſe of their corn, never raiſe more than is ſufficient for their own conſumption. From the profound inaction in which they live, one would ſuppoſe their ſupreme felicity to conſiſt in doing nothing. They ſometimes, however, viſit each other; and upon theſe occaſions the day is ſpent in ſmoking, and drinking tea, and in telling, or liſtening to tales of romance, that are equal neither in merit nor morality to the ſtory of Blue-beard.

As every man always carries with him, wherever he goes, both a pipe, and a tobacco-pouch made of the ſkin of the ſea-calf, he is ſure in theſe viſits to have one ſource of amuſement. When any one of the company is deſirous of lighting his pipe, he takes out his pouch, and, having filled, paſſes it to the reſt. This is a civility that is never omitted. However numerous may be the party, every body ſmokes: the conſequence of which is a cloud, that, riſing at firſt to the upper part of the room, increaſes, by degrees, till it fills the whole houſe, and becomes at laſt ſo thick that it is impoſſible for the ſmokers to ſee one another.

When a ſtranger travelling through the country is received by the maſter of a houſe, he inſtantly becomes a member of the family. Accuſtomed to a domeſtic life, the planters delight in the ties of affinity, and conſider in the light of a relative every perſon whom they love. Upon entering a houſe, the form of ſalutation is, to ſhake hands firſt with the maſter, and then with every male perſon in the company arrived at years of maturity. If there happens to be any one whom we do not like, the hand is refuſed to him; and this refuſal, of ſo common a teſtimony of friendſhip, is looked upon as a formal declaration that the viſitor conſiders him as his enemy. It is not the ſame with the females in the company. They are all embraced one after another; and to make an exception would be a ſignal affront. Old or young, all muſt be kiſſed. It is a benefice with the duties attached to it.

At whatever time of the day you enter the houſe of a planter, you are ſure to find the kettle and tea-things upon the table. This practice is univerſal. The inhabitants never drink pure water. If a ſtranger preſents himſelf, it is tea they offer him for refreſhment. This is their common liquor in the interval of meals, and in one ſeaſon of the year, when it often happens that they have neither beer nor wine, is their only beverage.

If a ſtranger arrives at dinner-time before the cloth is taken away, he ſhakes hands, embraces, and immediately ſeats himſelf at the table. If he wiſhes to paſs the night, he ſtays without ceremony, ſmokes, drinks tea, aſks the news, gives them all he knows in his turn; and the next day, the kiſſing and ſhaking hands being repeated, he goes on his way, to perform elſewhere the ſame ceremony.' To offer money on theſe occaſions would be regarded as an inſult.

Theſe particulars of a people, whoſe condition it is to be hoped that the generoſity of the Britiſh charac-
1799. ter, and the mildneſs of the Britiſh government, will
gradually meliorate, cannot but be acceptable to many of our readers. We ſhall, therefore, make no apology for the length of this article.

GOMASHTEH, in the language of Bengal, one cent.

GONIOMETRY, a method of meaſuring angles, ſo called by M. de Lagny, who gave ſeveral papers on this method in the Memoirs of the Royal Acad. anno 1724, 1725, 1729. M. de Lagny's method of goniometry conſiſts in meaſuring the angles with a pair of compaſſes, and that without any ſcale whatever, except an undivided ſemicircle. Thus, having any angle drawn upon paper to be meaſured, produce one of the ſides of the angle backwards behind the angular point; then with a pair of fine compaſſes deſcribe a pretty large ſemicircle from the angular point as a centre, cutting the ſides of the propoſed angle, which will intercept a part of the ſemicircle. Take then this intercepted part very exactly between the points of the compaſſes, and turn them ſucceſſively over upon the arc of the ſemicircle, to find how often it is contained in it, after which there is commonly ſome remainder: then take this remainder in the compaſſes, and, in like manner, find how often it is contained in the laſt of the integral parts of the firſt arc, with again ſome remainder: find, in like manner, how often this laſt remainder is contained in the former; and ſo on continually, till the remainder become too ſmall to be taken and applied as a meaſure. By this means he obtains a ſeries of quotients, or fractional parts, one of another, which being properly reduced into one fraction, give the ratio of the firſt arc to the ſemicircle, or of the propoſed angle to two right angles, or 180 degrees, and conſequently that angle itſelf in degrees and minutes.

We have given this account of goniometry from Dr Hutton, and frankly acknowledge that we had never thought of it till we peruſed his excellent Dictionary of Mathematics and Philoſophy. To have omitted the method when pointed out to us would have been wrong; though we miſtake much if mathematicians in general will not look upon it as a method of very little value.

GOTHIC ARCHITECTURE. See *Gothic* ARCHITECTURE in this *Suppl.* and ROOF, *Encycl.*

GOUVERNANTE, the Spaniſh name of a plant which the Indians of California uſe in decoction as a ſudorific drink for the cure of the venerial diſeaſe. It is thus deſcribed in the third volume (Engliſh tranſlation) of Perouſe's Voyage round the World.

Calyx quadrified, egg-ſhaped, of the ſame ſize with the corolla; placed beneath the fruit, deciduous. Corolla polypetalous; petals four, ſmall, entire, egg-ſhaped, fixed upon the receptacle. Stamina, eight, fixed to the receptacle, of the ſame length as the corolla: threads channelled, concave on the one ſide, and convex on the other; wings veiled, antheræ ſimple. Piſtil, germ oblong, covered, with five angles, and five cells; ſeeds oblong; pericarpium covered with fine hairs.

This plant is a ſhrub of middle ſize; the branches are angular and knotty, and covered with an adheſive varniſh; the lateral branches are alternate, and placed very near to each other: the leaves are ſmall, petiolated, bilobed, oppoſite, ſmooth on the upper ſide, the under ſide indiſtinctly veined; the bloſſoms are axillary, ſometimes terminating, pedunculated, ſolitary, but ſometimes in pairs.

From this deſcription, the gouvernante appears to be a new ſpecies of *daphne*.

GRAVIMETER, the name given by citizen Guyton (Morveau) to an inſtrument of glaſs, conſtructed in all reſpects on the principle of Nicholſon's Hydrometer, deſcribed in the article HYDROSTATICS, n° 18. *Encycl.* It is therefore needleſs to give a deſcription of this inſtrument here; as every artiſt in glaſs, who has ſeen Nicholſon's hydrometer, or underſtands our deſcription of it, may conſtruct the gravimeter of Morveau; and every man who has made himſelf maſter of our article SPECIFIC *Gravity*, may apply the gravimeter to every purpoſe to which it is applicable. It may juſt be proper to obſerve, that Morveau, having at firſt loaded the ſmall ſcale or baſon G (Plate 240, fig. 9. *Encycl.*) with a bulb of glaſs containing a ſufficient quantity of mercury, found it expedient afterwards to ſubſtitute in the place of this bulb a ſmall maſs of ſolid glaſs, brought to the proper form and weight by grinding. For a minute account of this inſtrument, if any of of our readers can be ſuppoſed to require a minute account of it, we muſt refer to the third number of Nicholſon's *Journal of Philoſophy, Chemiſtry, and the Arts.*

GREEN, though one of the ſeven original or priſmatic colours, is among dyers a compound of blue and yellow. Of the European methods of dyeing green, and of the principles on which theſe methods are founded, a ſufficient account will be found in the *Encyclopædia,* under the articles *Colour-Making* and Dyeing, and, in this *Supplement,* under *Animal and Vegetable Substances;* but it may be worth while, in this place, to inſert the method practiſed at Aſtracan, in giving to cotton yarn that beautiful green colour for which the oriental cotton is ſo juſtly admired.

The principal dye is the blue, which is employed both for cotton and ſilk. To prepare it, the indigo or blue dye-ſtuff is finely pounded, and diſſolved in water by a gentle heat in large earthen jars, ſeven of which ſtand in brick-work over the fire-place, at the diſtance of about an ell and a half from each other. About two pounds are put into each veſſel. Five pounds of ſoda finely pounded, together with two pounds of pure lime and one pound of clarified honey, are added to each; when theſe ingredients have been well mixed, the fire is ſtrengthened; and when the whole begins to boil, the dye is ſtirred carefully round in all the veſſels, that every thing may be completely diſſolved and mixed. After the firſt boiling the fire is ſlackened, and the dye is ſuffered to ſtand over a gentle heat, while it is continually ſtirred round: this is continued even after the furnace is cooled, till a thick ſcum ariſes in the neck of each jar, and ſoon after diſappears. The dye is then allowed to ſtand two days, until the whole is incorporated, and the dye thickens.

The dyers aſſert, that with this dye they can produce three ſhades of blue, and that, as the dyeing particles gradually diminiſh, they can dye alſo a green colour by the addition of yellow.

When a manufacturer gives cotton yarn to a blue dyer, he firſt boils it at home in a ley of ſoda (*kalakar*), then dries it, waſhes it, and dries it again. The blue dyer lays this yarn to ſteep in pure water, preſſes out the ſuperfluous water with the hands, and then immediately begins to dip it in the blue jar, often wringing it till it is completely penetrated by the dye. This firſt tint is generally given to yarn in ſuch jars as have had their colouring matter partly exhauſted. It is then dried, rinſed, and again dried; after which, it is put into the freſh blue dye, properly ſaturated; and, after the colour has been ſufficiently heightened, it is dried for the laſt time.

For a yellow dye, the dyers of Aſtracan employ partly ſaw-wort, brought from Ruſſia, and partly the leaves of the *kiſlar belge* or *ſumach.* The proceſs is as follows: The yarn is firſt boiled for an hour in a ſtrong ley of ſoda; it is then dried, afterwards rinſed and laid wet to ſteep for twelve hours in a ſolution of alum with warm water. When it has been dried in the air, it is laid to ſoak ſeveral times in troughs with the dye which has been boiled thick in kettles from the above-mentioned plants, till it has acquired the wiſhed-for colour, care being taken to dry it each time it is ſoaked. It is then rinſed in running water, and dried for the laſt time.

On this yellow colour a green is often dyed. After the yarn has been dyed yellow, it is given out to the blue dyer, who immediately dips it in the blue jars, the dye of which has been already partly exhauſted; and if the green colour is not then ſufficiently high, the operation is repeated, the yarn being dried each time. See *Neue Nordiſche Beytrage,* by Profeſſor Pallas; or *Philoſophical Magazine,* n° 2.

GREGORY (David), was a ſon of the Rev. John Gregory, miniſter of Drumoak, in the county of Aberdeen, and elder brother to Mr James Gregory, the inventor of the moſt common reflecting teleſcope. He was born about the year 1627 or 1628; and though he poſſeſſed all the genius of the other branches of his family, he was educated by his father for trade, and ſerved an apprenticeſhip to a mercantile houſe in Holland. Having a ſtronger paſſion, however, for knowledge than for money, he abandoned trade in 1655; and returning to his own country, he ſucceeded, upon the death of an elder brother, to the eſtate of Kinardie, ſituated about forty miles north from Aberdeen, where he lived many years, and where thirty-two children were born to him by two wives. Of theſe, three ſons made a conſpicuous figure in the republic of letters, being all profeſſors of mathematics at the ſame time in three of the Britiſh univerſities, viz. David at Oxford, James at Edinburgh, and Charles at St Andrews.

Mr Gregory, the ſubject of this memoir, while he lived at Kinardie, was a jeſt among the neighbouring gentlemen for his ignorance of what was doing about his own farm, but an oracle in matters of learning and philoſophy, and particularly in medicine, which he had ſtudied for his amuſement, and began to practiſe among his poor neighbours. He acquired ſuch a reputation in that ſcience, that he was employed by the nobility and gentlemen of that county, but took no fees. His hours of ſtudy were ſingular. Being much occupied through the day with thoſe who applied to him as a phyſician, he went early to bed, roſe about two or three in the morning, and, after applying to his ſtudies for ſome hours, went to bed again and ſlept an hour or two before breakfaſt.

He was the firſt man in that country who had a barometer; and having paid great attention to the changes in it, and the correſponding changes in the weather, he was once in danger of being tried by the preſbytery for witchcraft or conjuration. A deputation of that body waited upon him to enquire into the ground of certain reports that had come to their ears; but he ſatisfied them ſo far as to prevent the proſecution of a man known to be ſo extenſively uſeful by his knowledge of medicine.

About the beginning of this century he removed with his family to Aberdeen, and in the time of Queen Anne's war employed his thoughts upon an improvement in artillery, in order to make the ſhot of great guns more deſtructive to the enemy, and executed a model of the engine he had conceived. Dr Reid informs us, that he converſed with a clock-maker in Aberdeen who had been employed in making this model; but having made many different pieces by direction without knowing their intention, or how they were to be put together, he could give no account of the whole. After making ſome experiments with this model,

del, which ſatisfied him, the old gentleman was ſo ſanguine in the hope of being uſeful to the allies in the war againſt France, that he ſet about preparing a field equipage with a view to make a campaign in Flanders, and in the mean time ſent his model to his ſon the Savilian profeſſor, that he might have his and Sir Iſaac Newton's opinion of it. His ſon ſhewed it to Newton, without letting him know that his own father was the inventor. Sir Iſaac was much diſpleaſed with it, ſaying, that if it had tended as much to the preſervation of mankind as to their deſtruction, the inventor would have deſerved a great reward; but as it was contrived ſolely for deſtruction, and would ſoon be known by the enemy, he rather deſerved to be puniſhed, and urged the profeſſor very ſtrongly to deſtroy it, and if poſſible to ſuppreſs the invention. It is probable the profeſſor followed this advice. He died ſoon after, and the model was never found.

If this be a juſt account of the matter, and Dr Reid's veracity is unqueſtionable, we cannot help thinking that Newton's uſual ſagacity had, on that occaſion, forſaken him. Were the implements of war much more deſtructive than they are, it by no means follows that more men would be killed in battle than at preſent. Muſkets and cannons are ſurely more deſtructive weapons than javelines and bows and arrows; and yet it is a well known fact, that ſince the invention of gunpowder battles are not half ſo bloody as they were before that period. The oppoſite armies now ſeldom come to cloſe quarters, a few rounds of muſketry and artillery commonly decide the fate of the day; and had Mr Gregory's improvement been carried into effect, ſtill fewer rounds would have decided it than at preſent, and the carnage would conſequently have been leſs.

When the rebellion broke out in 1715, the old gentleman went a ſecond time to Holland, and returned when it was over to Aberdeen, where he died about 1720, aged 93, leaving behind him a hiſtory of his own time and country, which was never publiſhed.

GREGORY (Dr David). In addition to the account given in the *Encyclopædia* of this eminent mathematician, it may be proper to add, that he was a moſt intimate and confidential friend of Sir Iſaac Newton, and was intruſted with a manuſcript copy of the *Principia*, for the purpoſe of making obſervations on it. Of theſe Newton availed himſelf in the ſecond edition, they having come too late for his firſt publication, which was exceedingly hurried by Dr Halley, from fears that Newton's backwardneſs would not let it appear at all. There is a complete copy of theſe obſervations preſerved in the library of the univerſity of Edinburgh, preſented to it by Dr James Gregory, the preſent profeſſor of the practice of medicine. Theſe contain many ſublime mathematical diſcuſſions, many valuable commentaries on the *Principia*, and many intereſting anecdotes. There are in it ſome paragraphs in the hand-writing of Huyghens relative to his Theory of Light. It would appear that this work of confidential friendſhip was the foundation of that ſyſtem of phyſical and mathematical aſtronomy which has raiſed Dr Gregory to great eminence in the republic of letters.

GRINDING, in Cutlery, a well-known operation, by which edge-tools are ſharpened. As commonly practiſed, the grinding of tools is attended with great inconveniency, ariſing from the production or developement of heat by friction. The fact of ſparks flying from a dry grindſtone when a piece of iron or ſteel is applied to its ſurface during the rotation, has been ſeen by every one. The heat produced during this proceſs is ſuch that the ſteel very ſoon becomes ignited, and hard tools are very frequently ſoftened and ſpoiled, for want of care during the grinding. When a cylindrical ſtone is partly immerſed in a trough of water, the rotation muſt be moderate and the work ſlow, otherwiſe the water would ſoon be thrown off by the centrifugal force; and when this fluid is applied by a cock from above, the quantity is too ſmall to preſerve the requiſite low temperature. It is even found, that the point of a hard tool, ground under a conſiderable maſs of water, will be ſoftened, if it be not held ſo as to meet the ſtream; ſparks being frequently afforded even under the water.

To find a remedy for this, Mr Nicholſon was led, by ſome accounts which he received of German cutlery, to make the following experiment. He procured a Newcaſtle grindſtone of a fine grit and ten inches in diameter, and alſo a block of mahogany to be uſed with emery on its face. Both the ſtone and the wooden block were mounted on an axis, to be occaſionally applied between the centres of a ſtrong lathe. In this ſituation both were turned truly cylindrical, and of the ſame diameter. The face of the wood was grooved obliquely in oppoſite directions, to afford a lodgement for the emery. The face of the ſtone was left ſmooth, and there was a trough of proper ſize applied beneath the ſtone to hold water. The grindſtone was then uſed with water, and the wooden cylinder was faced with emery and oil. The inſtrument ground was a file, out of which it was propoſed to grind all the teeth. The rotation was produced by the mechaniſm of the lathe; the velocity being ſuch as to turn the grinding apparatus about five revolutions in a ſecond. The ſtone operated but ſlowly, and the water from the trough was ſoon exhauſted, with inconvenience to the workman, who could ſcarcely be defended from it but by ſlackening the velocity. The emery cylinder cut rather faſter. But notwithſtanding the friction was made to operate ſucceſſively and by quick changes on the whole ſurface of the file, it ſoon became too much heated to be held with any convenience; and when a cloth was uſed to defend the hand, the work not only became awkward, but the heat increaſed to ſuch a degree that the oil began to be decompoſed, and emitted an empyreumatic ſmell. The ſtone was then ſuffered to dry, and the file tried upon its face. It almoſt immediately became blue, and ſoon afterwards red-hot. Both the cylinders were then covered with tallow, by applying the end of a candle to each while revolving, and emery was ſprinkled upon the cylinder of wood. The ſame tool was then applied to the grindſtone in rapid motion. At the firſt inſtant the friction was ſcarcely perceptible; but very ſpeedily afterwards the zone of tallow preſſed by the tool became fuſed, and the ſtone cut very faſt. The tool was ſcarcely at all heated for a long time; and when it began to feel warm, its temperature was immediately lowered by removing

moving it to a new zone of the cylinder. The ſame effect took place when the experiment was repeated with the wooden cylinder.

It is not difficult to explain this by the modern doctrine of heat. When oil was uſed upon the wooden cylinder, the heat developed by the friction was employed in raiſing the temperature of the tool and of the fluid oil: but when tallow was ſubſtituted inſtead of the oil, the greateſt part of the heat was employed in fuſing this conſiſtent body. From the increaſed capacity of the tallow, when melted, this heat was abſorbed, and became latent, inſtead of being employed to raiſe the temperature: and whenever, by continuing the proceſs, the tallow already melted began to grow hot, together with the tool, it was eaſy to reduce the temperature again by employing the heat on another zone of conſiſtent tallow. He uſed theſe two cylinders, with much ſatisfaction, in a conſiderable quantity of work.

This promiſes to be a valuable diſcovery; and the public is obliged to the ingenious author of the Philoſophical Journal for being at ſo much pains on this, as well as on other occaſions, to render his ſcience ſubſervient to the uſeful arts.

GROSE (Francis, Eſq; F.A.S.) was born, we believe, in 1731. He was the ſon of Mr Francis Groſe of Richmond, jeweller, who filled up the coronation crown of George II. and died 1769. By his father he was left an independent fortune, which he was not of a diſpoſition to add to, or even to preſerve. He early entered into the Surrey militia, of which he became adjutant and paymaſter; but ſo much had diſſipation taken poſſeſſion of him, that in a ſituation which above all others required attention, he was ſo careleſs as to have for ſome time (as he uſed pleaſantly to tell) only two books of accounts, viz. his right and left hand pockets. In the one he received, and from the other paid; and this too with a want of circumſpection which may be readily ſuppoſed from ſuch a mode of book-keeping. His loſes on this occaſion rouſed his latent talents. With a good claſſical education he united a fine taſte for drawing; and encouraged by his friends, as well as prompted by his ſituation, he undertook the work from which he derived both profit and reputation; we mean, his Views of Antiquities in England and Wales, which he firſt began to publiſh in numbers in the year 1773, and finiſhed in the year 1776. The next year he added two more volumes to his Engliſh Views, in which he included the iſlands of Guernſey and Jerſey, which were completed in 1787. This work anſwered his moſt ſanguine expectations; and, from the time he began it to the end of his life, he continued without intermiſſion to publiſh various works (a liſt of which we ſubjoin), generally to the advantage of his literary reputation, and almoſt always to the benefit of his finances. His wit and good humour were the abundant ſource of ſatiſfaction to himſelf, and entertainment to his friends. He viſited almoſt every part of the kingdom, and was well received wherever he went. In the ſummer of 1789 he ſet out on a tour in Scotland; the reſult of which he began to communicate to the public in 1790 in numbers. Before he had concluded this work, he proceeded to Ireland, intending to furniſh that kingdom with views and deſcriptions of her antiquities, in the ſame manner he had executed thoſe of Great Britain; but ſoon after his arrival in Dublin, being at the houſe of Mr Horne there, he ſuddenly was ſeized at table with an apoplectic fit, on the 6th May 1791, and died immediately. He was interred in Dublin.

"His literary hiſtory (ſays a friend), reſpectable as it is, was exceeded by his good humour, conviviality, and friendſhip. Living much abroad, and in the beſt company at home, he had the eaſieſt habits of adapting himſelf to all tempers; and, being a man of general knowledge, perpetually drew out ſome converſation that was either uſeful to himſelf or agreeable to the party. He could obſerve upon moſt things with preciſion and judgment; but his natural tendency was to humour, in which he excelled both by the ſelection of anecdotes and his manner of telling them: it may be ſaid, too, that his figure rather aſſiſted him, which was in fact the very title-page to a joke. He had neither the pride nor malignity of authorſhip: he felt the independency of his own talents, and was ſatisfied with them, without degrading others. His friendſhips were of the ſame caſt; conſtant and ſincere, overlooking ſome faults, and ſeeking out greater virtues. He had a good heart; and, abating thoſe little indiſcretions natural to moſt men, could do no wrong."

He married at Canterbury, and reſided there ſome years, much beloved and reſpected for his wit and vivacity; "which (another friend obſerves), though he poſſeſſed in an extreme degree, was but little tinctured with the cauſtic ſpirit ſo prevalent among ſpirits of that claſs. His humour was of that nature which exhilarates and enlivens, without leaving behind it a ſting; and though perhaps none poſſeſſed more than himſelf the faculty of "ſetting the table in a roar," it was never at the expence of virtue or good manners. Of him indeed may be ſaid in the words of Shakeſpeare,

> ——— a merrier man,
> Within the limits of becoming mirth,
> I never ſpent an hour's talk withal:
> His eye begets occaſion for his wit;
> And every object that the one doth catch,
> The other turns to a mirth-moving jeſt.

"Of the moſt careleſs, open, and artleſs diſpoſition, he was often (particularly in the early part of his life) the prey of the deſigning; and has more than once (it is believed) embarraſſed himſelf by too implicit confidence in the probity of others. A tale of diſtreſs never failed to draw commiſeration from his heart; and often has the tear been diſcovered gliding down that cheek which a moment before was fluſhed with jocularity."

He was father of Daniel Groſe, Eſq; captain of the royal regiment of artillery (who, after ſeveral campaigns in America, was appointed in 1790 deputy governor of the new ſettlement at Botany Bay), and ſome other children.

His works are as follow:

1. The Antiquities of England and Wales, 8 vols. 4to and 8vo. 2. The Antiquities of Scotland, 2 vols. 4to and 8vo. 3. The Antiquities of Ireland, 2 vols. 4to and 8vo. 4. A Treatiſe on ancient Armour and Weapons, 4to, 1785. 5. A Claſſical Dictionary of the Vulgar Tongue, 8vo, 1785. 6. Military Antiquities; being a Hiſtory of the Engliſh Army from

the Conqueſt to the preſent time, 2 vols 4to, 1786, 1788. 7. The Hiſtory of Dover Caſtle, by the Rev. William Danell, 4to, 1786. 8. A Provincial Gloſſary, with a Collection of local Proverbs and popular Superſtitions, 8vo, 1788. 9. Rules for drawing Caricatures, 8vo, 1788. 10. Supplement to the Treatiſe on Ancient Armour and Weapons, 4to, 1789. 11. A Guide to Health, Beauty, Honour, and Riches; being a collection of humorous Advertiſements, pointing out the Means to obtain thoſe bleſſings; with a ſuitable introductory Preface, 8vo. 12. The Olio; being a Collection of Eſſays in 8vo, 1793.

GUERITE, in Fortification, a centry-box; being a ſmall tower of wood, or ſtone, uſually placed on the point of a baſtion, or on the angles of the ſhoulder, to hold a centinel, who is to take care of the ditch, and watch againſt a ſurpriſe.

GUILLOTINE, a new term introduced into the languages of Europe by the mournful effects of fanaticiſm in the holy cauſe of liberty. Our readers are not ignorant that this is the name given by the National Aſſembly of France to the engine of decapitation, which thoſe uſurpers of the legiſlative authority decreed to be the ſole puniſhment of thoſe condemned to death for their crimes. This decree was iſſued on March 20th 1792.

We do not imagine that the world will derive much uſeful inſtruction from a minute deſcription of this terrible inſtrument of public juſtice; and therefore content ourſelves with giving two figures of it, ſufficiently expreſſive of its conſtruction. It is only the revival of an inſtrument uſed in former times. The earlieſt accounts that we have of it is, that it was uſed in the barony of Halyfax in Yorkſhire. It was alſo ſet up in Scotland; but we have no certain information that it has ever been uſed; and it is ſtill ſhewn as a ſort of curioſity by the name of the *Mayden*. See MAIDEN, *Encycl.*

Plate XXIX.

Eratoſthenes could not think of a better way of handing down his name to future ages than by burning the temple of Diana at Epheſus; Dr Guillotin, phyſician at Lyons, and member of the ſelf-named National Aſſembly of France, thought himſelf honoured by the decree which aſſociated his name with this inſtrument of popular vengeance. It was indeed propoſed by him as an inſtrument of mercy, in a ſtudied harangue, filled with that ſentimental ſlang of philanthropy, which coſts ſo little, promiſes ſo much, and has now corrupted all the languages of Europe. His invention is indeed one of the moſt expenſive ſpecimens of Gallic philanthropy, whoſe tender mercies are cruel; and was accordingly received with loud applauſes, both from the houſe and from the galleries. To proceed, however, with impoſing dignity, it was referred to the conſideration of a committee, with injunctions to aſk the opinion of able ſurgeons of its efficiency. Mr Louis, a celebrated ſurgeon of Paris, declared it well fitted for the taſk, in a long pedantic diſſertation; in which he takes occaſion to deliver, with academic coldneſs, a theory of the operation of cutting inſtruments; and ſays that he had examined the edge of the guillotine, and other ſuch inſtruments, with a microſcope, and had diſcovered that the fineſt edges were toothed like a ſaw. M. Guillotin, he ſaid, had therefore with great judgment made the axe of his engine of death with a ſloping edge, by which means *il gliſſoit d'une façon infinitment plus douce.* This diſſertation was ſo much to the taſte of the humane legiſlature, that they rewarded Mr Louis with 2000 livres, and publiſhed it in the Paris Journals. As to the inventor, he reaped all the benefit from it which he ſo kindly intended for the nation, by the trial of it on his own perſon, when he fell under the diſpleaſure of Robeſpierre.

We acknowledge, that in as far as this inſtrument leſſens the duration of the horrid conflict with the king of terrors, and probably diminiſhes the corporeal ſufferance, it may be called merciful (alas! the day!); but we queſtion much, whether the dreadful agitation of ſoul is not rather increaſed by the long train of preparatory operations. The hands of the convict are tied behind his back: he is then ſtretched along on his face on a ſtrong plank, and his preciſe poſition adjuſted to the inſtrument. When faſtened to the plank, it is puſhed forward into its place under the fatal edge, his neck adjuſted to the block, and a baſket placed juſt before his eyes (for the face of Louis XVI. was not covered) to receive his head. This muſt employ a good deal of time, and every moment is terrible.

The conſtruction has received many alterations and refinements; and has at laſt been made ſo compendious and portable, as to become part of the travelling equipage of a commiſſioner from the National Aſſembly, ſent on a provincial or ſpecial viſitation. Thus did the ſovereign people become terrible in majeſty. So ſenſible was the aſſembly of the advantages of this awful impreſſion, or ſo intoxicated with the enjoyment of irreſiſtible power, that they have thought their coins ornamented by this attribute of their ſupremacy: and as Jupiter is diſtinguiſhed by his thunderbolt, ſo the majeſty of the people is diſtinguiſhed by the no leſs fatal axe. We have ſeen a piece of ten ſous, ſtruck at Mentz in 1793, and iſſued as current money, at the very time that they were planting the tree of liberty in that illuminated city by the hands of Cuſtine and his troops. The device is the faſces and axe of ancient Rome, crowned with a red cap, and ſurrounded by a laurel wreath. The inſcription is, *Republique Françoiſe*, 1793, *an.* 2d. Fully impreſſed with the ſame ſentiments, Lequinio, the ſentimental novelliſt of France, whom Mercier compares with the tender, the heart-touching Sterne—Lequinio, now commiſſioner, ſent by the National Aſſembly to regenerate Normandy and Brittany, writes to his maſters, that "he is very ſucceſsful in converſions from ſuperſtition to ſound reaſon." He oppoſes to the Bible and the relicts of the ſaints the conſtitution and the guillotine. "And you would wonder (ſays he) at my ſucceſs—The wiſe (but they are few) give up their prejudices at once; but the multitude, the ſtupid worſhippers of *Notre Dame*, look at our lady the guillotine; are ſilent, becomes ſerious, and their doubts vaniſh;—they are converted. This is your *labarum*—*in hoc ſigno vinces.*"

GULA, GUEULE, or GOLA, in Architecture, a wavy member whoſe contour reſembles the letter S, commonly called an Ogee.

GUNPOWDER, as we have obſerved in the *Encyclopædia* under the word GUN, has been known in the eaſt, and particularly in China, from a period of very remote antiquity. No man, however, ſeems to have ſuſpected that the knowledge of it was conveyed from the eaſt into Europe; but all have agreed to allow the merits of the invention both to friar Bacon and to Bartholomew Schwartz. This generally received opinion has been lately controverted by citizen Langles, who, in a memoir read in the French national inſtitute, contends, that the knowledge of gunpowder was conveyed to us from the Arabs, on the return of the Cruſaders to Europe. He aſſures us that the Arabs made uſe of it in 690 at the ſiege of Mecca; and he adds, that they derived it from the Indians, among whom it muſt have been known in the remoteſt ages, ſince their ſacred books (the Vedam) forbid the uſe of it in war.

It is indeed extremely probable, that the compoſition of gunpowder was known in India at a very early period; for in whatever country nature forms nitre in the greateſt plenty, there its deflagrating quality is moſt likely to be firſt obſerved; and a few experiments founded on that obſervation, will lead to the compoſition which produces ſuch ſudden and violent effects. "Nitre (ſays Sir George Staunton) is the natural and daily produce of China and India; and there accordingly the knowledge of gunpowder ſeems to be coeval with that of the moſt diſtant hiſtoric events. Among the Chineſe, it has been applied at all times to uſeful purpoſes; ſuch as blaſting rocks, and removing great obſtructions, and to thoſe of amuſement in making a vaſt variety of fire-works. It was alſo uſed as a defence by undermining the probable paſſage of the enemy, and blowing him up. But its force had not been directed through ſtrong metallic tubes as it was by Europeans ſoon after they had diſcovered it. And though, in imitation of Europe, it has been introduced into the armies of the Eaſt, other modes of warfare are ſometimes ſtill preferred to it."

Of gunpowder manufactured by thoſe who have manufactured it ſo long, it is deſirable to know the compoſition and the qualities. It was therefore natural for the Hon. George Napier, when ſuperintending the royal laboratory at Woolwich, and making experiments upon ſo neceſſary an implement of modern war, to procure ſome Chineſe powder from Canton.

This he did; and analyzing two ounces of it, he found, after repeating the operation ſix times, that the mean reſult gave the following proportions *. Nitre 1 oz. 10 dwts. charcoal 6 dwts. ſulphur 3 dwts. 14 grs. Here is a deficiency in weight of ten grains, which M. Napier ſuppoſes the conſequence of ſome defect in his proceſs; but as M. Baumé, a French chemiſt, made a variety of experiments to obtain a total ſeparation of the ſulphur from the charcoal of gunpowder, and was never able to effect it, one fourteenth part remaining united, three grains muſt be deducted from the charcoal and added to the ſulphur to give the accurate proportion of the ingredients; which by turning to the article GUNPOWDER, *Encycl.* the reader will perceive differs ſomewhat from the proportion of the ſame ingredients in the gunpowder of Europe. This Chineſe powder was uſually large-grained, and not ſtrong, but very durable. It had been made many years when our author got it; yet there was no viſible ſymptom of decay, the grain being hard, well coloured, and though angular, it was even-ſized, and in perfect preſervation.

When we conſider the operations in which gunpowder is employed, it is obvious that it muſt be an object of importance to aſcertain its exploſive force; and yet there is ſcarcely a ſubject concerning which the moſt approved writers have ſo much differed. Mr Robins, who has done more towards perfecting the art of gunnery than any other individual, ſtates the exploſive force of gunpowder to be 1000 times greater than the mean preſſure of the atmoſphere; while the celebrated Daniel Barnouilli determines it to be not leſs than 10,000 times this preſſure. Such a difference of opinion led Count Rumford to purſue a courſe of experiments, of which ſome were publiſhed in the Tranſactions of the Royal Society for the year 1781, and the remainder in the Tranſactions of the ſame Society for 1797; with the view principally of determining the initial expanſive force of gunpowder. By one of theſe experiments, it appeared, that calculating even on Mr Robins's own principles, the force of gunpowder, inſtead of being 1000 times, muſt at leaſt be 1308 times greater than the mean preſſure of the atmoſphere. From this experiment, the Count thought himſelf warranted in concluding that the principles aſſumed by Mr Robins were erroneous, and that his mode of aſcertaining the force of gunpowder could never ſatisfactorily determine it. Deſpairing of ſucceſs in that way, he reſolved to make an attempt for aſcertaining this force by actual meaſurement; and after many unſucceſsful experiments, he was at length led to conclude, that this force was at leaſt 50,000 times greater than the mean preſſure of the atmoſphere.

Mr Robins apprehends that the force of fired gunpowder conſiſts in the action of a permanently elaſtic fluid, ſimilar in many reſpects to common atmoſpherical air; and this opinion has been very generally received: but Count Rumford thinks, that though the permanently elaſtic fluids, generated in the combuſtion of gunpowder, aſſiſt in producing the effects which reſult from its exploſion, its enormous force, allowing it to be 50,000 times greater than the mean preſſure of the atmoſphere, cannot be explained, without ſuppoſing that it ariſes principally from the elaſticity of the aqueous vapour generated from the powder in its combuſtion.

"The brilliant diſcoveries of modern chemiſts (ſays he) have taught us, that both the conſtituent parts of which water is compoſed, and even water itſelf, exiſt in the materials which are combined to make gunpowder; and there is much reaſon to believe that water is actually formed, as well as diſengaged, in its combuſtion. M. Lavoiſier, I know, imagined that the force of fired gunpowder depends in a great meaſure upon the expanſive force of uncombined *caloric*, ſuppoſed to be let looſe in great abundance during the combuſtion or deflagration of the powder: but it is not only dangerous to admit the action of an agent whoſe exiſtence is not yet clearly demonſtrated; but it appears to me that this ſuppoſition is quite unneceſſary, the elaſtic force of the heated aqueous vapour, whoſe exiſtence can hardly be doubted, being quite ſufficient to account for all the phenomena. It is well known that the elaſticity of aqueous vapour is incomparably more augmented by any given augmentation of temperature than that of any permanently elaſtic fluid whatever; and thoſe who are acquainted with the amazing force of ſteam, when heated only to a few degrees above the boiling point, can eaſily perceive that its elaſticity muſt be almoſt infinite when greatly condenſed and heated to the

* *Tranſactions of the Royal Iriſh Academy.*

temperature of red-hot iron; and this heat it muſt certainly acquire in the exploſion of gunpowder. But if the force of fired gunpowder ariſes *principally* from the elaſtic force of heated aqueous vapour, a cannon is nothing more than a *ſteam engine* upon a peculiar conſtruction; and upon determining the ratio of the elaſticity of this vapour to its denſity, and to its temperature, a law will be found to obtain very different from that aſſumed by Mr Robins in his Treatiſe on Gunnery."

In order to meaſure the elaſtic force of fired gunpowder, Count Rumford adopted a new plan; and, inſtead of cauſing the generated elaſtic fluid to act on a moveable body through a determined ſpace, which he had found to be ineffectual to his purpoſe, he contrived an apparatus in which this fluid ſhould be made to act, "by a determined ſurface, againſt a weight, which, by being increaſed at pleaſure, ſhould at laſt be ſuch as would juſt be able to confine it, and which in that caſe would juſt counterbalance and conſequently *meaſure* the elaſtic force."

Having ſucceeded in ſetting fire to the powder, without any communication with the external air, "by cauſing the heat employed for that purpoſe to paſs through the ſolid ſubſtance of the barrel, it only remained to apply ſuch a weight to an opening made in the barrel, as the whole force of the generated elaſtic fluid ſhould not be able to lift, or diſplace." Many precautions were neceſſary. A ſolid block of very hard ſtone, four feet four inches ſquare, was placed upon a bed of ſolid maſonry, which deſcended ſix feet below the ſurface of the earth. Upon this block of ſtone, which ſerved as a baſe to the whole machinery, was placed the ſmall barrel, in which the exploſions were made, with its opening directly upwards. This opening was cloſed by a ſolid hemiſphere of hardened ſteel, on which the weight to be overcome by the exploſion was laid. Having charged the barrel with 10 grains of powder, its whole contents being about 28 grains, and a 24 pounder, weighing 8081 lbs. avoirdupois, being placed on its caſcabel ſo as by its weight to confine the generated elaſtic fluid, a heated iron ball was applied to the end of the vent tube (a ſmall ſolid projection from the centre of the bottom of the barrel). In a few moments the powder took fire, though the exploſion made a very feeble report; and when the weight was raiſed, the confined elaſtic vapour ruſhed out of the barrel. The ſlight effect produced by this exploſion induced ſome of the attendants on this occaſion to undervalue the importance of this experiment, and to form a very inadequate idea of the real force of the elaſtic fluid that had been thus almoſt inſenſibly diſcharged. In a ſecond experiment, the barrel was filled with powder, and the ſame weight laid on as before. The barrel was made of the beſt hammered iron, and uncommonly ſtrong. The charge of powder amounted to little more than $\frac{1}{16}$th of a cubic inch, which is not ſo much as would be required to load a ſmall pocket-piſtol, and not *one-tenth* part of the quantity frequently uſed for the charge of a common muſket. Yet this inconſiderable quantity of powder, when ſet on fire, exploded with a force that burſt the barrel, and with a loud report that alarmed the whole neighbourhood.

The author proceeds to make an eſtimate, from the known ſtrength of iron, and the area of the fracture of the barrel in the preceding experiment, of the real force employed by the elaſtic vapour to burſt it; and he computes that it muſt have been equal to the preſſure of a weight of 412529 lbs.; which, by another computation, he found to be 55024 times greater than the mean preſſure of the atmoſphere. By another proceſs, he inveſtigates the ſtrength of the iron of which the barrel was made; and he thence finds that the force required to burſt it was equal to the preſſure of a weight of 410624½ lbs. This weight, reduced into atmoſpheres, gives 54750 atmoſpheres for the meaſure of the force exerted by the elaſtic fluid in the preſent inſtance. This force muſt be conſiderably leſs than the initial force of the elaſtic fluid generated in the combuſtion of gunpowder, before it has begun to expand; "for it is more than probable (ſays Count Rumford) that the barrel was in fact burſt before the generated elaſtic fluid had exerted all its force, or that this fluid would have been able to have burſt a barrel ſtill ſtronger than that uſed in the experiment."

After having ſhewn the extreme force of fired gunpowder, the Count adverts to an objection which may be made againſt his deductions. How does it happen that fire-arms and artillery of all kinds, which certainly are not calculated to withſtand ſo enormous a force, are not always burſt when they are uſed? Inſtead of anſwering this queſtion, by aſking how it happened that the extremely ſtrong barrel uſed in his experiment could be burſt by the force of gunpowder, if this force be not in fact much greater than it has ever been ſuppoſed to be, he proceeds to ſhew that the combuſtion of gunpowder, inſtead of being inſtantaneous, as Mr Robins's theory ſuppoſes, is much leſs rapid than has hitherto been apprehended; an obſervation which, if eſtabliſhed, is certainly ſufficient to anſwer the objection.

He remarks, that it is a well-known fact that, on the diſcharge of fire-arms of all kinds, there is always a conſiderable quantity of unconſumed grains of gunpowder blown out of them; and what is very remarkable, as it leads directly to a diſcovery of the cauſe of this effect, theſe unconſumed grains are not merely blown out of the muzzles of fire-arms, but come out alſo by their vents or touch-holes, where the fire enters to inflame the charge, as many perſons who have had the misfortune to ſtand with their faces near the touch-hole of a muſket, when it has been diſcharged, have found to their coſt.

It appears extremely improbable to our author, if not abſolutely impoſſible, that a grain of gunpowder actually in the chamber of the piece, and completely ſurrounded by flame, ſhould, by the action of that very flame, be blown out of it without being at the ſame time ſet on fire. And, if this be true, he conſiders it as a moſt deciſive proof, not only that the combuſtion of gunpowder is leſs rapid than it has generally been thought to be, but that a grain of gunpowder actually on fire, and burning with the utmoſt violence over the whole of its ſurface, may be projected with ſuch a velocity into a cold atmoſphere, as to extinguiſh the fire, and ſuffer the remains of the grain to fall to the ground unchanged, and as inflammable as before.

This extraordinary fact was aſcertained beyond all poſſibility of doubt by the Count's experiments. Having procured from a powdermill in the neighbourhood of the city of Munich a quantity of gunpowder, all of the ſame maſs, but formed into grains of very different ſizes, ſome as ſmall as the grains of the fineſt Battel powder, he placed a number of vertical ſcreens of very thin paper, one behind another, at the diſtance of 12 inches from each other; and loading a common muſket repeatedly with this powder, ſometimes without and ſometimes with a wad, he fired it againſt the foremoſt ſcreen, and obſerved the quantity and effects of the unconſumed grains of powder which impinged againſt it. The ſcreens were ſo contrived, by means of double frames united by hinges, that the paper could be changed with very little trouble, and it was actually changed after every experiment.

The diſtance from the muzzle of the gun to the firſt ſcreen was not always the ſame; in ſome of the experiments it was only 8 feet, in others it was 10, and in ſome 12 feet.

The charge of powder was varied in a great number of different ways; but the moſt intereſting experiments were made with one ſingle large grain of powder, propelled by ſmaller and larger charges of very fine grained powder.

Theſe large grains never failed to reach the ſcreen; and though they ſometimes appeared to have been broken into ſeveral pieces by the force of the exploſion, yet they frequently reached the ſcreen entire; and ſometimes paſſed through all the ſcreens (five in number) without being broken.

When they were propelled by large charges, and conſequently with great velocity, they were ſeldom on fire when they arrived at the firſt ſcreen; which was evident, not only from their not ſetting fire to the paper (which they ſometimes did), but alſo from their being found ſticking in a ſoft board, againſt which they ſtruck, after having paſſed through all the five ſcreens; or leaving viſible marks of their having been impinged againſt it, and being broken to pieces and diſperſed by the blow. Theſe pieces were often found lying on the ground; and from their forms and dimenſions, as well as from other appearances, it was often quite evident that the little globe of powder had been on fire, and that its diameter had been diminiſhed by the combuſtion before the fire was put out, on the globe being projected into the cold atmoſphere.

That theſe globes or large grains of powder were always ſet on fire by the combuſtion of the charge, can hardly be doubted. This certainly happened in many of the experiments; for they arrived at the ſcreens on fire, and ſet fire to the paper; and in the experiments in which they were projected with ſmall velocities, they were often ſeen to paſs through the air on fire; and when this was the caſe, no veſtige was to be found. They ſometimes paſſed on fire through ſeveral of the foremoſt ſcreens without ſetting them on fire, and ſet fire to one or more of the hindmoſt, and then went on and impinged againſt the board which was placed at the diſtance of twelve inches behind the laſt ſcreen.

The Count then proceeds to mention another experiment, in which the progreſſive combuſtion of gunpowder was ſhewn in a manner ſtill more ſtriking, and not leſs concluſive.

A ſmall piece of red hot iron being dropped down into the chamber of a common horſe piſtol, and the piſtol being elevated to an angle of about 45 degrees, upon dropping down into its barrel one of the ſmall globes of powder (of the ſize of a pea), it took fire, and was projected into the atmoſphere by the elaſtic fluid generated in its own combuſtion, leaving a very beautiful train of light behind it, and diſappearing all at once like a falling ſtar. This amuſing experiment was repeated very often, and with globes of different ſizes. When very ſmall ones were uſed ſingly, they were commonly conſumed entirely before they came out of the barrel of the piſtol; but when ſeveral of them were uſed together, ſome, if not all of them, were commonly projected into the atmoſphere on fire.

As the ſlowneſs of the combuſtion of gunpowder is undoubtedly the cauſe which has prevented its enormous and almoſt incredible force from being diſcovered, our author deduces, as an evident conſequence, that the readieſt way to increaſe its effects, is to contrive matters ſo as to accelerate its inflammation and combuſtion. This may be done in various ways; but, in his opinion, the moſt ſimple and moſt effectual manner of doing it would be to ſet fire to the charge of powder, by ſhooting (through a ſmall opening) the flame of a ſmaller charge into the midſt of it.

He contrived an inſtrument on this principle for firing cannon three or four years ago; and it was found, on repeated trials, to be uſeful, convenient in practice, and not liable to accidents. It likewiſe ſuperſedes the neceſſity of uſing priming, of vent tubes, port-fires, and matches; and on that account he imagined it might be of uſe in the Britiſh navy, but it does not appear to have been received into practice.

Another infallible method of increaſing very conſiderably the effect of gunpowder in fire-arms of all ſorts and dimenſions, would be to cauſe the bullet to fit the bore exactly, or without windage, in that part of the bore at leaſt where the bullet reſts on the charge; for when the bullet does not completely cloſe the opening of the chamber, not only much of the elaſtic fluid, generated in the firſt moment of the combuſtion of the charge, eſcapes by the ſide of the bullet; but what is of ſtill greater importance, a conſiderable part of the unconſumed powder is blown out of the chamber along with it in a ſtate of actual combuſtion, and, getting before the bullet, continues to burn on as it paſſes through the whole length of the bore; by which the motion of the bullet is much impeded.

The loſs of force which ariſes from this cauſe, is in ſome caſes almoſt incredible; and it is by no means difficult to contrive matters ſo as to render it very apparent, and alſo to prevent it.

If a common horſe-piſtol be fired with a looſe ball, and ſo ſmall a charge of powder that the ball ſhall not be able to penetrate a deal board ſo deep as to ſtick in it when fired againſt it from the diſtance of ſix feet; the ſame ball, diſcharged from the ſame piſtol with the ſame charge of powder, may be made to paſs quite through one deal board, and bury itſelf in a ſecond placed behind it, merely by preventing the loſs of force which ariſes from what is called windage, as he found more than once by actual experiment.

The Count has in his poſſeſſion a muſket, from which, with a common charge of powder, he fires two bullets at once with the ſame velocity that a ſingle bullet is diſcharged from a muſket on the common conſtruction with the ſame quantity of powder. And, what renders the experiment ſtill more ſtriking, the diameter of the bore of his muſket is exactly the ſame as that of a common muſket, except only in that part of it where it joins the chamber, in which part it is juſt ſo much contracted, that the bullet, which is next to the powder, may ſtick faſt in it. He adds, that though the bullets are of the common ſize, and are conſequently conſiderably leſs in diameter than the bore, means are uſed which effectually prevent the loſs of force by windage; and to this laſt circumſtance he concludes, it is doubtleſs owing, in a great meaſure, that the charge appears to exert ſo great a force in propelling the bullets.

That the conical form of the lower part of the bore where it unites with the chamber has a conſiderable ſhare in producing this extraordinary effect, is, however, very certain, as he has found by experiments made with a view merely to aſcertain that fact.

At the cloſe of the Count's laſt memoir, we have a computation, deſigned to ſhew that the force of the elaſtic fluid generated in the combuſtion of gunpowder, enormous as it is, may be ſatisfactorily explained on the ſuppoſition that it depends *ſolely* on the elaſticity of watery vapour, or ſteam. From experiments made in France in the year 1790, it appears that the elaſticity of ſteam is doubled by every addition of temperature equal to 30° of Fahrenheit's thermometer. As the heat generated in the combuſtion of gunpowder cannot be leſs than that of red-hot iron, it may be ſuppoſed equal to 1000° of Fahrenheit's ſcale:—but the elaſtic force of ſteam is juſt equal to the mean preſſure of the atmoſphere, when its temperature is equal to that of boiling water, or to 212° of Fahrenheit's thermometer; conſequently $212^\circ + 30^\circ = 240^\circ$ will repreſent the temperature, when its elaſticity will be equal to the preſſure of two atmoſpheres; and, purſuing the calculation, at 602°, or 2° above the heat of boiling linſeed oil, its elaſticity will be equal to the preſſure of 8192 atmoſpheres, or above *eight times* greater than the utmoſt force of the fluid generated in the combuſtion of gunpowder, according to Mr Robins's computation: but the heat in this caſe is much greater than that of 602° of Fahrenheit; and therefore the elaſticity of the ſteam generated from the water contained in the powder muſt be much greater than the preſſure of 8192 atmoſpheres. At 722°, the elaſticity will be equal to the preſſure of 131,072 atmoſpheres; and this temperature is leſs than the heat of iron, which is viſibly red-hot in day-light, by 355°:—but the flame of gunpowder has been found to melt braſs, which requires a heat equal to that of 3807° of Fahrenheit; 2730° above the heat of red-hot iron, or 3805° higher than the temperature which gives to ſteam an elaſticity equal to the preſſure of 131,072 atmoſpheres. That there is in gunpowder water ſufficient for ſupplying the neceſſary quantity of ſteam, the author has very ſatisfactorily evinced; but we muſt not purſue his curious inveſtigations any farther. Thoſe who want a fuller account of them, will find it either in the original memoirs themſelves, or in a very accurate abridgment of theſe memoirs in the firſt volume of Nicholſon's *Journal of Natural Philoſophy*, &c.

We cannot conclude this article without mentioning a new kind of gunpowder, invented ſome years ago in France, in which the marine acid is ſubſtituted, in equal quantity, for nitre. Dr Hutton tried ſome of this new powder which was made at Woolwich, and found it of about double the ſtrength of the ordinary ſort; but it is not likely to come into common and general uſe, for the preparation of the acid is difficult and expenſive (See CHEMISTRY-*Index* in this *Suppl.*), and the powder which is made of it catches fire and explodes from the ſmalleſt degree of heat, and without the aid of a ſpark. It is to this circumſtance, however, that its ſuperior ſtrength ſeems to be in a great meaſure owing.

GUNTER's CHAIN. See GEOMETRY, *Encyclopædia*, Part II. chap. 1.

GUT-TIE, a dangerous diſeaſe to which oxen and male calves are rendered liable by an improper mode of caſtration. In ſome places, and particularly in Herefordſhire, the breeders of cattle, when they caſtrate their calves, open the *ſcrotum*, take hold of the teſticles with their teeth, and tear them out with violence; by which means all the veſſels thereto belonging are ruptured. The *vaſa deferentia*, entering by the holes of the tranſverſe and oblique muſcles into the abdomen, paſs over the ureters in acute angles; at which turning, by their great length and elaſtic force, the peritoneum is ruptured; the *vaſa deferentia* are ſevered from the teſticles, and, ſpringing back, form a kind of bow from the urethra, where they are united, over the ureters, to the tranſverſe and oblique muſcles, and there again unite, where they firſt entered the abdomen; the part of the gut that is tied is the jejunum, at its turning from the left ſide to the right, and again from the right to the left, forming right angles under the kidney, and attached to the duplicature of the peritoneum, to which it was united, where the rupture happened. There the bow of the gut hangs over the bow of the *vaſa deferentia*, which, by a ſudden motion, or turn of the beaſt, form a hitch or tie of the ſtring round the bow of the gut (filled with air), ſimilar to what a carter makes on his cart line. This cauſes a ſtoppage in the bowels, and brings on a mortification, which, in two days, or four at moſt, proves fatal: And to this accident is the beaſt, when caſtrated as above, liable from the day that he was caſtrated till the time of his being ſlaughtered.

The ſymptoms of the gut-tie are the ſame as theſe of an incurable colic, *volvulus*, or mortification of the bowels. The beaſt affected with this complaint will kick at its belly, lie down, and groan; it has alſo a total ſtoppage in its bowels (except blood and mucus, which it will void in large quantities), and a violent fever, &c. To diſtinguiſh with certainty the gut-tie from the colic, &c. the hand and arm of the operator muſt be oiled, and introduced into the anus, through the rectum, beyond the os pubis, turning the hand down to the tranſverſe and oblique muſcles, where the veſſels of the teſticles enter the abdomen. There the ſtring will be found united to the muſcles, and is eaſily traced to the ſtricture by the hand, without pain to the beaſt.

From the general view of the agriculture of the county of Hereford, drawn up by Mr Clark of Builth, Breconſhire, we learn that Mr Harris farmer at Wickton, near Leominſter, had been uncommonly ſucceſsful in the cure of the gut-tie. That gentleman informs us, that he had cut cattle for this diſeaſe from the age of three months to that of nine years; and as it is a matter of great importance, we ſhall ſtate his method of operating in his own words.

“ The only method of cure (ſays he) that can be ſafely ventured upon is, to make a perpendicular inciſion, four inches under the third vertebra of the loins, on the left ſide, over the paunch or ſtomach, and introduce the arm to find the part affected ; if poſſible, keep the beaſt ſtanding by the help of proper aſſiſtants. The knife I make uſe of to ſevere the ſtring is in the form of a large fiſh-hook, with an edge on the concave ſide : it is fixed to a ring, which fits the middle finger, which finger crooks round the back of the knife, the end of the thumb being placed on its edge. The inſtrument, by being thus held in the hand, is ſecured from wounding the ſurrounding inteſtines ; with it I divide the ſtring or ſtrings, and bring out one or both, as circumſtances require. Here it is to be obſerved, that great care muſt be taken by the operator not to wound or divide the ureters, which would be certain death. I then ſew up the divided lips of the peritoneum very cloſe, with a ſurgeon's needle threaded with ſtrong thread, eight or ten double, ſufficiently waxed ; I alſo ſew up the ſkin, leaving a vacancy at the top and bottom of the wound ſufficiently wide to introduce a tent of ſurgeon's tow, ſpread with common digeſtive and traumatic balſam ; covering the inciſion with a plaſter made of the whites of eggs and wheat flour. The wound, thus treated, and dreſſed every day, will be well in a fortnight. The medicine I give to remove the ſtoppage in the three ſtomachs occaſioned by the tie, and to carry off the fever, is four ounces of Glauber's ſalt, two ounces of cream of tartar, and one ounce of ſenna, infuſed in two pounds of boiling water, adding half a pound of olive-oil, and working it off with plenty of gruel, mixed with a large quantity of infuſion of mallows and elder-bark. I adminiſter the gruel and infuſion for at leaſt two or three days ; by which time the beaſt will be well, will eat his provender, and chew the cud, and will forever be relieved, and remain ſafe from this fatal diſorder.

“ The following ſimple and eaſy method of caſtration will effectually prevent the gut-tie. Open the ſcrotum, looſen out the teſticles, and tie the ſeveral veſſels with a waxed thread or ſilk ; or ſear them with a hot iron, to prevent their bleeding, as in the common way of cutting colts. This method can never diſplace the veſſels of the teſticles, bladder, kidneys, or inteſtines ; all of which remain covered or attached to the peritoneum, or lining of the abdomen of the beaſt, which renders it impoſſible that there ſhould ever be a ſtricture or tie on the gut.”

GUZ, an Indian meaſure, varying in different places, but which may be reckoned about an Engliſh yard, The guz of Akbar was 41 fingers.

H.

HANCES, Hanches, Haunches, or *Hanſes*, in architecture, are certain ſmall intermediate parts of arches between the key or crown and the ſpring at the bottom, being perhaps about one-third of the arch, and ſituated nearer the bottom than the top or crown ; and are otherwiſe called the *ſpandrels*. See Arch in this *Supplement*.

HANSPIKE, or Handspec, a lever or piece of ſtrong wood, for raiſing by the hand great weights, &c. It is five or ſix feet long, cut thin and crooked at the lower end, that it may get the eaſier between things that are to be ſeparated, or under any thing that is to be raiſed. It is better than a crow of iron, becauſe its length allows a better poiſe.

HARRIOT (Thomas) was a very eminent mathematician of the 16th and 17th centuries, of whom ſome account has been given in the *Encyclopædia Britannica*. In that article it has been ſhewn, that Des Cartes had ſeen ſome improvements of Harriot's in algebra, and publiſhed them to the world as his own ; but this piece of plagiariſm has been more completely proved in the Aſtronomical Ephemeris for the year 1788, by Dr Zache, aſtronomer to the Duke of Saxe-Gotha ; who likewiſe ſhews that Harriot was an aſtronomer as well as an algebraiſt.

“ I here preſent to the world (ſays the Doctor) a ſhort account of ſome valuable and curious manuſcripts, which I found in the year 1784 at the ſeat of the earl of Egremont, at Petworth in Suſſex.

“ A predeceſſor of the family of lord Egremont, viz. that noble earl of Northumberland, named Henry Percy, was not only a generous favourer of all good learning, but alſo a patron and Mæcenas of the learned men of his age. Thomas Harriot, the author of the ſaid manuſcripts, Robert Hues (well known by his Treatiſe upon the Globes), and Walter Warner, all three eminent mathematicians, who were known to the earl, received from him yearly penſions ; ſo that when the earl was committed priſoner to the Tower of London in the year 1606, our author, with Hues and Warner, were his conſtant companions ; and were uſually called the earl of Northumberland's three Magi.

“ Thomas Harriot is a known and celebrated mathematician among the learned of all nations, by his excellent work, *Artis Analyticæ Praxis, ad æquationes algebraicas nova expeditata & generali methodo, reſolvendas, Tractatus poſthumus* ; London 1631 : dedicated to Henry earl of Northumberland ; publiſhed after his death by Walter Warner. It is remarkable, that the fame and the honour of this truly great man were conſtantly attacked by the French mathematicians, who could not endure that Harriot ſhould in any way diminiſh the fame of their Vieta and Des Cartes, eſpecially the latter, who was openly accuſed of plagiariſm from our author.

“ Des Cartes publiſhed his Geometry ſix years after Harriot's work appeared, viz. in the year 1637. Sir Charles Cavendiſh, then ambaſſador at the French court at Paris, obſerved to the famous geometrician Roverval, that theſe improvements in analyſis had been already made theſe ſix years in England, and ſhewed him afterwards Harriot's *Artis Analyticæ Proxis;* which, as Roverval was looking over, at every page he cried out, *Oui! oui! il l'a vu! Yes! yes! he has ſeen it!* Des Cartes had alſo been in England before Harriot's death, and had heard of his new improvements and inventions in analyſis.

“ Now all this relates to Harriot the celebrated analyſt; but it has not hitherto been known that Harriot was an eminent aſtronomer, both theoretical and practical, which firſt appears by theſe manuſcripts; among which, the moſt remarkable are 199 obſervations of the ſun's ſpots, with their drawings, calculations, and determination of the ſun's rotation about his axis. There is the greateſt probability that Harriot was the firſt diſcoverer of theſe ſpots, even before either Galileo or Scheiner. The earlieſt intelligence we have of the firſt diſcovered ſolar ſpots is of one Joh. Fabricius Phryſius, who in the year 1611 publiſhed at Wittemberg a ſmall treatiſe, intitled, *De Maculis in Sole obſervatis & apparente earum cum Sole converſione narratio.* Galileo, who is commonly accounted the firſt diſcoverer of the ſolar ſpots, publiſhed his book, *Iſtoria e Dimonſtrazioni intorne alle Machie Solare e loro accidente*, at Rome in the year 1613. His firſt obſervation in this work is dated June 2d 1612. Angelo de Filiis, the editor of Galileo's work, who wrote the dedication and preface to it, mentions, page 3. that Galileo had not only diſcovered theſe ſpots in the month of April in the year 1611, at Rome, in the Quirinal Garden, but had ſhewn them ſeveral months before (*molti meſi innanzi*) to his friends in Florence; and that the obſervations of the diſguiſed Apelles (the Jeſuit Scheiner, a pretender to this firſt diſcovery) were not later than the month of October in the ſame year; by which the epoch of this diſcovery was fixed to the beginning of the year 1611. But a paſſage in the firſt letter of Galileo's works, pa. 11. gives a more preciſe term to this diſcovery. Galileo there ſays in plain terms, that he had obſerved the ſpots in the ſun 18 months before. The date of this letter is May 24. 1612; which brings the true epoch of this diſcovery to the month of November 1610. However, Galileo's firſt produced obſervations are only from June 2. 1612, and thoſe of father Scheiner of the month of October in the ſame year. But now it appears from Harriot's manuſcripts, that his firſt obſervations of theſe ſpots are of Dec. 8. 1610. It is not likely that Harriot could have this notice from Galileo, for I do not find this mathematician's name ever quoted in Harriot's papers: But I find him quoting book i. chap. 2. of Joſeph a Coſta's *Natural and Moral Hiſtory of the Weſt Indies;* in which he relates, that in Peru there are ſpots to be ſeen in the ſun which are not ſeen in Europe: and hence it is probable, that Harriot took the hint of looking for ſuch ſpots. Beſides, it is not unlikely, that living with ſo munificent a patron, Harriot got from Holland the new invented teleſcopes much ſooner than they could reach Galileo, who at that time lived at Venice. Harriot's very careful and exact obſervations of theſe ſpots, ſhew alſo that he was in poſſeſſion of the beſt and moſt improved teleſcopes of that time; for it appears he had ſome with magnifying powers of 10, 20, and 30 times. At leaſt there are no earlier obſervations of the ſolar ſpots extant than his; they run from December 8. 1610, till January 18. 1613. I compared the correſponding ones with theſe obſerved by Galileo, between which I found an exact agreement. Had Harriot had any notion about Galileo's diſcoveries, he certainly would have alſo known ſomething about the phaſes of Venus and Mercury, and eſpecially about the ſingular ſhape of Saturn, firſt diſcovered by Galileo; but I find not a word in all his papers concerning the particular figure of that planet.

“ I found likewiſe (continues Dr Zach) among the papers of Harriot a large ſet of obſervations on the ſatellites of Jupiter, with drawings of them, their poſitions, and calculations of their revolutions and periods. His firſt obſervation of thoſe diſcovered ſatellites, I find to be of January 16. 1610; and they go till February 26. 1612. Galileo pretends to have diſcovered them January 7. 1610; ſo that it is not improbable that Harriot was likewiſe the firſt diſcoverer of theſe attendants of Jupiter.

“ Among his other obſervations of the moon, of eclipſes, of the planet Mars, of ſolſtices, of refraction, of the declination of the needle, &c. there are remarkable ones of the comet of 1607, and the latter comet (for there were two) of 1618. They were all obſerved with a croſs-ſtaff, by meaſuring their diſtances from fixed ſtars; whence theſe obſervations are the more valuable, as comets had before been but groſsly obſerved. Kepler himſelf obſerved the comet of 1607 only with the naked eye, pointing out its place by a coarſe eſtimation, without the aid of an inſtrument; and the elements of their orbits could, in defect of better obſervations, be only calculated by them. The obſervations of the comet of the year 1607 are of the more importance, even now for modern aſtronomy, as this is the ſame comet that fulfilled Dr Halley's prediction of its return in the year 1759. That prediction was only grounded upon the elements afforded him by theſe coarſe obſervations; for which reaſon he only aſſigned the term of its return to the ſpace of a year. The very intricate calculations of the perturbations of this comet, afterwards made by M. Clairaut, reduced the limits to a month's ſpace. But a greater light may now be thrown upon this matter by the more accurate obſervations on this comet by Mr Harriot. In the month of October 1785, when I converſed upon the ſubject of Harriot's papers, and eſpecially on this comet, with the celebrated mathematician M. de la Grange, director of the Royal Academy of Sciences at Berlin, he then ſuggeſted to me an idea, which, if brought into execution, will clear up an important point in aſtronomy. It is well known to aſtronomers how difficult a matter it is to determine the maſs, or quantity of matter, in the planet Saturn; and how little ſatisfactory the notions of it are that have hitherto been formed. The whole theory of the perturbations of comets depending upon this uncertain datum, ſeveral attempts and trials have been made towards a more exact determination of it by the moſt eminent geometricians of this age, and particularly by la Grange himſelf; but never having been ſatisfied with the few and uncertain data heretofore obtained for the reſolution of this problem, he thought that Harriot's obſervations on the comet of 1607, and the modern ones of the ſame comet in 1759, would ſuggeſt a way of reſolving the problem *à poſteriori;* that of determining by by them the elements of its ellipſis. The retardation of the comet, compared to its period, may clearly be laid to the account of the attraction and perturbation it has ſuffered in the region of Jupiter and Saturn; and as the part of it belonging to Jupiter is very well known, the remainder muſt be the ſhare which is due to Saturn; whence the maſs of the latter may be inferred. In conſequence of this conſideration, I have already begun to reduce moſt of Harriot's obſervations of this comet, in order to calculate by them the true elements of its orbit on an elliptical hypotheſis, to complete M. de la Grange's idea upon this matter.

"I forbear to mention here any more of Harriot's analytical papers, which I found in a very great number. They contain ſeveral elegant ſolutions of quadratic, cubic, and biquadratic equations; with ſome other ſolutions and *loca geometrica*, that ſhew his eminent qualifications, and will ſerve to vindicate them againſt the attacks of ſeveral French writers, who refuſe him the juſtice due to his ſkill and accompliſhments, merely to ſave Des Cartes's honour, who yet, by ſome impartial men of his own nation, was accuſed of public plagiariſm."

HASSELQUIST (Frederick) was born in the province of Eaſt Gothland in 1722, and ſtudied medicine and botany in the univerſity of Upſal. Linnæus had in his lectures repreſented the extraordinary merits and great celebrity which a young ſtudent might obtain by travelling through Paleſtine, and by inquiring into and deſcribing the natural hiſtory of that country, which was till then unknown, and had become of the greateſt importance to interpret the bible, and to underſtand eaſtern philology. Haſſelquiſt was fired with ambition to accompliſh an object ſo important in itſelf, and ſo warmly recommended by his beloved maſter. There being no fund ariſing from the liberality of the crown, private collections were made, which poured in very copiouſly, eſpecially from the native country of the young traveller. All the faculties of the univerſity of Upſal alſo granted him a ſtipend.

Thus protected, he commenced his journey in the ſummer of 1749. By the interference of Lagerſtroem, he had a free paſſage to Smyrna in one of the Swediſh Eaſt Indiamen. He arrived there at the concluſion of the year, and was received in the moſt friendly manner by Mr A. Rydel, the Swediſh conſul. In the beginning of 1750 he ſet out for Egypt, and remained nine months at Cairo the capital. Hence he ſent to Linnæus, and to the learned ſocieties of his country, ſome ſpecimens of his reſearches. They were publiſhed in the public papers, and met with the greateſt approbation; and upon the propoſition of Dean Baeck and Dr Wargentin, ſecretary of the Royal Academy of Sciences, a collection of upwards of 10,000 dollars in copper money was made for the continuance of the travels of young Haſſelquiſt. Counſellors Lagerſtroem and Nordencrantz were the moſt active in raiſing ſubſcriptions at Stockholm and Gothenburgh. In the ſpring of 1751, he repaired to his deſtination, and paſſed through Jaffa to Jeruſalem, Jericho, &c. He returned afterwards through Rhodus and Scio to Smyrna. Thus he fulfilled all the expectations of his country, but he was not to reap the reward of his toils. The burning heat of the ſandy deſerts of Arabia had affected his lungs; he reached Smyrna in a ſtate of illneſs, in which he languiſhed for ſome time, and died February 9. 1752, in the 30th year of his age.

The fruits of his travels were, however, preſerved through the liberality of a great princeſs. He had been obliged to contract debts. The Turks, therefore, ſeized upon all his collections, and threatened to expoſe them to public ſale. The Swediſh conſul prevented it. He ſent, with the intelligence of the unhappy exit of his countryman, an account of the diſtreſſes under which he died;—and at the repreſentation of Dean Baeck, Queen Louiſa Ulrica granted the ſum of 14,000 dollars in copper ſpecie to redeem all his collections. They arrived afterwards in good preſervation at Stockholm; conſiſting of a great quantity of antiques, Arabian manuſcripts, ſhells, birds, ſerpents, inſects, &c. and were kept in the cabinets at Ulrichſdale and Drottningholm. The ſpecimens of the natural curioſities of theſe muſeums being double or treble in number, Linnæus obtained ſome of them, and publiſhed the voyage of his ill-fated friend, and honoured his memory with a plant which he called from his name *Haſſelquiſtia*. HASSELQUISTA, *Encycl.*

HAT-MAKING is a mechanical proceſs, which is detailed in the *Encyclopædia* from the beſt information that could then be obtained. We have lately learned, however, that our detail is ſometimes defective, and ſometimes erroneous; and it is our duty to ſupply thoſe defects, and to correct thoſe errors. But, ſtrangers as we are to the buſineſs of hat-making, we ſhould not perhaps have ſuſpected, that we had been miſled by the perſons whom we conſulted, had we not been informed by a very intelligent writer in Nicholſon's Philoſophical Journal, that the account of the manufacturing of hats, which is given in the *Encyclopædia*, is far from the truth. This information induced us to look through the Journal itſelf for a more accurate account of the proceſs; well convinced, that the liberal-minded author of that work would not have pointed out our miſtakes without making us welcome to avail ourſelves of his aid to correct them. Our readers will therefore be indebted only to Mr Nicholſon and his correſpondent for whatever inſtruction they may derive from this article; and as we wiſh not to deck ourſelves in borrowed plumes, we ſhall communicate that inſtruction in the words of its author.

Having viſited the manufactory of Meſſrs Collinſons, hatters in Gravel-lane, Southwark, Mr Nicholſon gives the following account of their procedure:

"The materials for making hats are rabbits fur cut off from the ſkin, after the hairs have been plucked out, together with wool and beaver. The two former are mixed in various proportions, and of different qualities, according to the value of the article intended to be made; and the latter our author believes to be univerſally uſed for facing the finer articles, and never for the body or main ſtuff. Experience has ſhewn, that theſe materials cannot be evenly, and well felted together, unleſs all the fibres be firſt ſeparated, or put into the ſame ſtate with regard to each other. This is the object of the firſt proceſs, called *bowing*. The material, without any previous preparation (A), is laid upon a platform of wood,

---

(A) Some writers mention a partial wetting of the fur while on the ſkin, by lightly ſmearing it with a ſolution of nitrate of mercury to give it a curl. Meſſrs Collinſons do not uſe it, nor any other preparation.

or of wire, ſomewhat more than four feet ſquare, called a *hurdle*, which is fixed againſt the wall of the workſhop, and is enlightened by a ſmall window, and ſeparated by two ſide partitions from other hurdles which occupy the reſt of the ſpace along the wall. The hurdle, if of wood, is made of deal planks, not quite three inches wide, diſpoſed parallel to the wall, and at the diſtance of one-fortieth or one-fiftieth of an inch from each other, for the purpoſe of ſuffering the duſt, and other impurities of the ſtuff, to paſs through; a purpoſe ſtill more effectually anſwered by the hurdle of wire.

“ The workman is provided with a bow, a bow-pin, a baſket, and ſeveral cloths. The bow is a pole of yellow deal wood, between ſeven and eight feet long, to which are fixed two bridges, ſomewhat like that which receives the hair in the bow of the violin (B). Over theſe is ſtretched a catgut, about one-twelfth part of an inch in thickneſs. The bow-pin is a ſtick with a knob, and is uſed for plucking the bow-ſtring. The baſket is a ſquare piece of ozier work, conſiſting of open ſtrait bars with no croſſing or interweaving. Its length acroſs the bars may be about two feet, and its breadth eighteen inches. The ſides into which the bars are fixed are ſlightly bended into a circular curve, ſo that the baſket may be ſet upright on one of theſe edges near the right hand end of the hurdle, where it uſually ſtands. The cloths are linen. Beſides theſe implements, the workman is alſo provided with brown paper.

“ The *bowing* commences by ſhovelling the material towards the right hand partition with the baſket; upon which, the workman holding the bow horizontally in his left hand, and the bow-pin in his right, lightly places the bow-ſtring, and gives it a pluck with the pin. The ſtring, in its return, ſtrikes part of the fur, and cauſes it to riſe, and fly partly acroſs the hurdle in a light open form. By repeated ſtrokes, the whole is thus ſubjected to the bow; and this beating is repeated till all the original clots or maſſes of the filaments are perfectly opened and obliterated. The quantity thus treated at once is called a *batt*, and never exceeds half the quantity required to make one hat.

“ When the batt is ſufficiently bowed, it is ready for *hardening*; which term denotes the firſt commencement of felting. The prepared material being evenly diſpoſed on the hurdle, is firſt preſſed down by the convex ſide of the baſket, then covered with a cloth, and preſſed ſucceſſively in its various parts by the hands of the workman. The preſſure is gentle, and the hands are very ſlightly moved back and forwards at the ſame time through a ſpace of perhaps a quarter of an inch, to favour the hardening or entangling of the fibres (See FELTING in this *Suppl.*) In a very ſhort time, indeed, the ſtuff acquires ſufficient firmneſs to bear careful handling. The cloth is then taken off, and a ſheet of paper, with its corners doubled in, ſo as to give it a triangular outline, is laid upon the batt, which laſt is folded over the paper as it lies, and its edges, meeting one over the other, form a conical cap. The joining is ſoon made good by preſſure with the hands on the cloth. Another batt, ready hardened, is in the next place laid on the hurdle, and the cap here mentioned placed upon it, with the joining downwards. This laſt batt being alſo folded up, will conſequently have its place of junction diametrically oppoſite to that of the inner felt, which it muſt therefore greatly tend to ſtrengthen. The principal part of the hat is thus put together, and now requires to be worked with the hands a conſiderable time upon the hurdle, the cloth being alſo occaſionally ſprinkled with clear water. During the whole of this operation, which is called *baſoning* (C), the article becomes firmer and firmer, and contracts in its dimenſions. It may eaſily be underſtood, that the chief uſe of the paper is to prevent the ſides from felting together.

“ The baſoning is followed by a ſtill more effectual continuation of the felting, called *working* (D). This is done in another ſhop, at an apparatus called a *battery*, conſiſting of a *kettle* (containing water ſlightly acidulated with ſulphuric acid, to which, for beaver hats, a quantity of the grounds of beer is added, or elſe plain water for rinſing out), and eight *planks* of wood joined together in the form of a fruſtum of a pyramid, and meeting in the kettle at the middle. The outer or upper edge of each plank is about two feet broad, and riſes

---

(B) Mr Nicholſon's correſpondent, who is himſelf a hatter, ſays that the bow is beſt made of aſh; that it is compoſed of the *ſtang* or handle; that the bridge at the ſmaller end, or that which is neareſt the window in the act of bowing, is called the *cock*; and that the other bridge, which is nearer to the workman's hand, is called the *breech*.

(C) Mr Nicholſon's correſpondent ſays, that after bowing, and previous to the baſoning, a *hardening ſkin*, that is, a large piece of ſkin, about four feet long and three feet broad, of leather alumed or half tanned, is preſſed upon the bat, to bring it by an eaſier gradation to a compact appearance; after which it is baſoned, being ſtill kept upon the hurdle. This operation, the baſoning, derives its name from the proceſs or *mode of working*, being the ſame as that practiſed upon a wool hat after bowing; the laſt being done upon a piece of caſt metal, four feet acroſs, of a circular ſhape, called a *baſon*: the joining of each batt is made good here by ſhuffling the hand, that is, by rubbing the edge of each batt folded over the other to excite the progreſſive motion of each of the filaments in felting, and to join the two together. Many journeymen, to hurry this work, uſe a quantity of vitriol (ſulphuric acid), and then, to make the nap riſe and flow, they kill the vitriol, and open the body again by throwing in a handful or two of oatmeal; by this means they get a great many made, though, at the ſame time, they leave them quite grainy from the want of labour. This, in handling the dry grey hat when made, may be in part diſcovered; but in part only.

(D) The intelligent writer who has been ſo often quoted, ſays, that before this operation is begun, the hat is dipped into the boiling kettle, and allowed to lie upon the plank until cold again; this is called *ſoaking*, that is, being perfectly ſaturated with the hot liquor: if they are put in too haſtily in this ſtate, for they are then only bowed and baſoned, they would burſt from the edges, each batt not being ſufficiently felted into the other.

riſes a little more than two feet and a half above the ground; and the ſlope towards the kettle is conſiderably rapid, ſo that the whole battery is little more than ſix feet in diameter. The quantity of ſulphuric acid added to the liquor is not ſufficient to give a ſour taſte, but only renders it rough to the tongue. In this liquor, heated rather higher than unpractiſed hands could bear, the article is dipped from time to time, and then worked on the planks with a roller, and alſo by folding or rolling it up, and opening it again; in all which, a certain degree of care is at firſt neceſſary, to prevent the ſides from felting together; of which, in the more advanced ſtages of the operation, there is no danger. The imperfections of the work now preſent themſelves to the eye of the workman, who picks out knots and other hard ſubſtances with a bodkin, and adds more felt upon all ſuch parts as require ſtrengthening. This added felt is patted down with a wet bruſh, and ſoon incorporates with the reſt. The beaver is laid on towards the concluſion of this kind of working. Mr Nicholſon could not diſtinctly learn why the beer grounds were uſed with beaver-hats. Some workmen ſaid, that by rendering the liquor more tenacious, the hat was enabled to hold a greater quantity of it for a longer time; but others ſaid, that the mere acid and water would not adhere to the beaver facing, but would roll off immediately when the article was laid on the plank. It is probable, as he obſerves, that the manufacturers who now follow the eſtabliſhed practice, may not have tried what are the inconveniences this addition is calculated to remove."

Our author's correſpondent, however, aſſigns ſeveral reaſons for the addition of thoſe dregs, which, he ſays, ought to be thick, and the ſoureſt that can be got. 1. Vitriol (ſulphuric acid) would harden the hat too much, which is kept mellow by the dregs. 2. The dregs are ſaid by the workmen to hold or fill the body, whilſt a little vitriol cleanſes it of the dirt, &c. that may be on the rabbit or other wools. 3. Another advantage attending the uſe of dregs, whether of beer, porter, or wine, is, that as the boiling of the dyeing does not draw out much of the mucilage from each hat when it comes to be ſtiffened, the dregs form a body within the hat, ſufficiently ſtrong or retentive to keep the glue from coming through amongſt the nap. 4. Vitriol (ſulphuric acid) alone purges or weakens the goods too much; conſequently half of the quantity does better with the addition of dregs, as it allows the body to be made cloſer by more work.

Of theſe four reaſons for the uſe of dregs, the laſt alone appears to us perſpicuous or at all ſatisfactory. But be this as it may, acid of ſome kind gives a roughneſs to the ſurface of the hair, which facilitates the mechanical action of felting; and Mr Collinſon informed Mr Nicholſon, that in a proceſs, called *carotting*, they make uſe of nitrous acid. In this operation, the material is put into a mixture of the nitrous and ſulphuric acids in water, and kept in the digeſting heat of a ſtove all night; by which means the hair acquires a ruddy or yellow colour, and loſes part of its ſtrength.

" It muſt be remembered, that our hat ſtill poſſeſſes the form of a cone, and that the whole of the ſeveral actions it has undergone have only converted it into a ſoft flexible felt, capable of being extended, though with ſome difficulty, in every direction. The next thing to be done is to give it the form required by the wearer. For this purpoſe, the workman turns up the edge or rim to the dipth of about an inch and a half, and then returns the point back again through the centre or axis of the cap, ſo far as not to take out this fold, but to produce another inner fold of the ſame depth. The point being returned back again in the ſame manner, produces a third fold; and thus the workman proceeds, until the whole has acquired the appearance of a flat circular piece, conſiſting of a number of concentric undulations or folds, with the point in the centre. This is laid upon the plank, where the workman, keeping the piece wet with the liquor, pulls out the point with his fingers, and preſſes it down with his hand, at the ſame time turning it round on its centre in contact with the plank, till he has, by this means, rubbed out a flat portion equal to the intended crown of the hat. In the next place, he takes a block, to the crown of which he applies the flat central portion of the felt, and by forcing a ſtring down the ſides of the block, he cauſes the next part to aſſume the figure of the crown, which he continues to wet and work, until it has properly diſpoſed itſelf round the block. The rim now appears like a flounced or puckered appendage round the edge of the crown; but the block being ſet upright on the plank, the requiſite figure is ſoon given by working, rubbing, and extending this part. Water only is uſed in this operation of faſhioning or blocking; at the concluſion of which it is preſſed out by the blunt edge of a copper implement for that purpoſe.

" Previous to the dyeing, the nap of the hat is raiſed or looſened out with a wire bruſh, or carding inſtrument. The fibres are too rotten after the dyeing to bear this operation. The dyeing materials are logwood, and a mixture of the ſulphates of iron and of copper, known in the market by the names of green copperas and blue vitriol. As the time of Mr Collinſon was limited, and my attention, ſays Mr Nicholſon, was more particularly directed to the mechanical proceſſes, I did not go into the dye-houſe; but I have no doubt that the hats are boiled with the logwood, and afterwards immerſed in the ſaline ſolution. I particularly aſked whether galls were uſed, and was anſwered in the negative.

" The dyed hats are, in the next place, taken to the ſtiffening ſhop. One workman, aſſiſted by a boy, does this part of the buſineſs. He has two veſſels, or boilers, the one containing the grounds of ſtrong beer, which coſts ſeven ſhillings per barrel, and the other veſſel containing melted glue, a little thinner than it is uſed by carpenters. Our author particularly aſked, whether this laſt ſolution contained any other ingredient beſides glue, and was aſſured that it did not. The beer grounds are applied in the inſide of the crown to prevent the glue from coming through to the face, and alſo, as he ſuppoſes, to give the requiſite firmneſs at a leſs expence than could be produced by glue alone. If the glue were to paſs through the hat in different places, it might, he imagines, be more difficult to produce an even gloſs upon the face in the ſubſequent finiſhing. The glue ſtiffening is applied after the beer grounds are dried, and then only upon the lower face of the flap, and the inſide of the crown. For this purpoſe the hat is put into another hat, called a ſtiffening hat, the crown of which is notched, or ſlit open in various directions. Theſe are then placed in a hole in a deal board, which ſupports the flap, and the glue is applied with a bruſh.

" The dry hat, after this operation, is very rigid, and its figure irregular. The laſt dreſſing is given by the application of moiſture and heat, and the uſe of the bruſh and a hot iron, ſomewhat in the ſhape of that uſed by tailors, but ſhorter and broader on the face. The hat being ſoftened by expoſure to ſteam, is drawn upon a block, to which it is ſecurely applied by the former method of forcing a ſtring down from the crown to the commencement of the rim. The judgment of the workman is employed in moiſtening, bruſhing, and ironing the hat, in order to give and preſerve the proper figure. When the rim of the hat is not intended to be of an equal width throughout, it is cut by means of a wooden, or perhaps metallic pattern ; but as no ſuch hats are now in faſhion, Mr Nicholſon ſaw only the tool for cutting them round. The contrivance is very ingenious and ſimple. A number of notches are made in one edge of a flat piece of wood for the purpoſe of inſerting the point of a knife, and from one ſide or edge of this piece of wood there proceeds a ſtraight handle, which lies parallel to the notched ſide, forming an angle ſomewhat like that of a carpenter's ſquare. When the legs of this angle are applied to the outſide of the crown, and the board lies flat on the rim of the hat, the notched edge will lie nearly in the direction of the radius, or line pointing to the centre of the hat. A knife being therefore inſerted in one of the notches, it is eaſy to draw it round by leaning the tool againſt the crown, and it will cut the border very regular and true. This cut is made before the hat is quite finiſhed, and is not carried entirely through ; ſo that one of the laſt operations conſiſts in tearing off the redundant part, which by that means leaves an edging of beaver round the external face of the flap. When the hat is completely finiſhed, the crown is tied up in gauze paper, which is neatly ironed down. It is then ready for the ſubſequent operations of lining," &c.

Our author concludes his valuable memoir on the fabrication of hats, with ſome obſervations on the probable gain or loſs of employing machinery in the manufacture. Theſe obſervations, as they are ſtated in the original paper, we recommend to the ſerious attention of every judicious hat-maker, who carries on his buſineſs on a large ſcale ; for he will find them not the reveries of a raſh ſpeculatiſt, but the cool reflections of a real philoſopher, who is at the ſame time no ſtranger to the arts of life. They ſuggeſt the following ſubjects of inquiry : Whether carding, which is rapidly and mechanically done, be inferior to bowing, which does not promiſe much facility for mechanical operation ? Whether a ſucceſſion of batts or cardings might be thrown round a fluted cone, which rapidly revolving, in contact with three or more cylinders, might perform the hardening, and even the working, with much more preciſion and ſpeed than they are now done by hand ? Whether blocking or ſhaping be not an operation extremely well calculated for the operation of one or more machines ? Whether looſe weaving and ſubſequent felting might not produce a lighter, cheaper, and ſtronger article ? And how far the mechanical felting, which is not confined merely to the hairs of animals, might be applied to this art ?

Before we diſmiſs this ſubject, it may be worth while to ſtate Mr Dunnage's method of making *water-proof hats*, in imitation of beaver, for which, in November 1794, he obtained a patent. It is as follows : Let a ſhag be woven, of ſuch count in the reed, and cut over ſuch ſized wire, as will give the hats to be manufactured from it that degree of richneſs, or appearance of fur, which may be thought neceſſary. The materials of which this ſhag may be compoſed are various, and ſhould be accommodated to different kinds of hats, according to the degree of beauty and durability to be given them, and the price at which they are deſigned to be ſold ; that is to ſay, ſilk, mohair, or any other hair that is capable of being ſpun into an end fine enough for the purpoſe, cotton, inkle, wool, or a mixture of any, or all the above materials, as may ſuit the different purpoſes of the manufacturer. Thoſe anſwer beſt (ſays our author), which are made with two poles, either of Bergam, Piedmont, or Organzine ſilk, riſing alternately, in a reed of about nine hundred count to eighteen inches wide, with three ſhoots over each wire. This method of weaving diſtributes the ſilk (as it may be put ſingle into the harneſs), and prevents any ribby appearance which it might have if the ſilk were paſſed double, and the whole of the pole cut over each wire. This may be made either on a two or four thread ground of hard ſilk, ſhot with fine cotton, which he thinks preferable for ſhoot, to ſilk, inkle, or any other material, as it forms both a cloſe and fine texture. An inferior kind of hats may be made from any of the before-mentioned materials, and with cheaper ſilk. This ſhag ſhould be ſtretched on a frame, ſuch as dyers uſe to rack cloth ; then (having previouſly ſet the pile upright with a comb, to prevent its being injured or ſtuck together), go over the ground with thin ſize, laid on with a ſoft bruſh. For black, or dark colours, common ſize will do ; with white, or any light colour, uſe iſinglaſs, or a ſize made from white kid leather. Theſe, or gum, or any other mucilaginous matter, which, without altering the colour, will prevent oil from getting through the ground ſo as to injure the pile, will anſwer the purpoſe. Take care not to apply more of any material, as a preparation, than may be fully ſaturated with oil or varniſh, ſo that water will not diſcharge it from the ground. The ſize, or other glutinous matter, being dry, the pile muſt be teeſeled, or carded with a fine card, till the ſilk is completely taken out of the twiſt or throwing, when it will loſe its coarſe ſhaggy look, and aſſume the appearance of a very fine fur. It muſt now be once more ſet upright with a comb, and you may proceed to lay on your water-proof material ; this too may be varied according to circumſtances. For black, or any dark colour, linſeed oil well boiled with the uſual driers, and thickened with a ſmall quantity of any good drying colour, will do ; for white, or very fine colours, poppy or nut oil, or copal or other varniſhes, may be uſed. In this particular the manufacturer muſt judge what will beſt anſwer his purpoſe, taking care never to uſe any thing that will dry hard, or be ſubject to crack. Mr Dunnage has found good drying linſeed oil preferable to any other thing which he has uſed, and, with the precaution of laying on very little the firſt time, it will not injure the fineſt colours. When the firſt coat of oil is dry, go over it a ſecond and a third time, if neceſſary, till you are convinced the pores of the ground are fully cloſed up, and the ſtuff rendered impervious to water. It ſhould now ſtand ſeveral days, till the ſmell is ſufficiently gone off; and before it is taken from the frame, ſhould be gone over with ſome ox-gall or lime-water, to take off the greaſineſs, which would otherwiſe prevent the ſtiffening from adhering to the oil. The material being now ready to be formed into hats, ſhould be cut into proper ſhapes for that purpoſe. The crown ſhould be made up over a block, with needle and ſilk, the oiled ſide outwards. The ſeams ſhould then be rubbed with a piece of hard wood, bone, or ivory, to make them lie flat, and the edges of the ſtuff pared off very near the ſtitches, that no joint may appear on the right ſide. The ſeams ſhould then be carefully gone over with the prepared oil, till every crevice or hole made by the needle is completely filled up, and the crown rendered perfectly water-proof. The crown may then be turned and ſtiffened, by ſticking linen, leather, paper, or any other material that may be found to anſwer the purpoſe, to the inner or painted ſide, till it acquires about the ſame degree of ſtiffneſs, or reſiſtance to the touch, as a good beaver. The mucilaginous matter which he uſed to attach the ſtiffening to the crown, and the upper and under parts of the brim to each other, was compoſed of one pound of gum-arabic or ſenega, one pound of ſtarch, and a half a pound of glue, boiled up with as much water as reduced the whole to the conſiſtence of a thick paſte. A greater or leſs proportion of any of theſe ingredients may be uſed, and other glutinous and adheſive ſubſtances may anſwer the ſame purpoſes; or drying-oils may be made uſe of, inſtead of this or other mucilage; or any of the reſinous gums diſſolved in oil or ſpirits; only it ſhould be obſerved, in this caſe, the hats will require more time in the preparation, as the oily matter, unleſs expoſed to the air, will not readily dry; but he found by experience that the above mentioned compoſition does not dry hard or brittle, but retains that pleaſant flexibility which is agreeable to the touch, while it communicates to the other materials a ſufficient degree of elaſticity. Before the brim is perfectly dry, care ſhould be taken to form a neck or riſing round the hole where it is to be attached to the crown, by notching it round with a pair of ſciſſars, and then forcing it over a block ſomething larger than you have made the hole, ſo that the uncut ſtuff may turn up, under the lower edge of the crown, about a quarter of an inch. Before you join the crown and brim together, go over the outſide of the neck of the brim, and the inſide of the crown, as high as the neck will come (which ſhould be about half an inch), with the prepared oil; and when they are nearly dry, ſo as to adhere to the finger on touching them, put the crown over the neck of the brim, and let them be ſewed ſtrongly together, taking care to ſew down as little of the pile as poſſible, and uſing the ſame precaution of oiling, where the needle has been through, as was obſerved in making up the crown. The hat is now ready for dreſſing; which operation may be performed over a block, with a hot iron, bruſh, &c. in the ſame manner as thoſe commonly called felts. When putting in the lining, be very careful to let the needle only take hold of the under ſurface of the brim; for ſhould it perforate the upper one, the water will find its way through, and the hat be of no value. Though we have already declared how little we are acquainted with the operation of hat-making, we cannot help ſuggeſting the inquiry, whether theſe water-proof hats might not be improved both in ſtrength and beauty, by a ſlight felting before the application of the ſize by the bruſh. Such of them as are compoſed of wool or hair, or contain a mixture of theſe materials, are unqueſtionably ſuſceptible of felting.

HAWKINS (Sir John), was the youngeſt ſon of a man who, though deſcended from Sir John Hawkins the memorable admiral and treaſurer of the navy in the reign of Queen Elizabeth, followed at firſt the occupation of a houſe-carpenter, which he afterwards exchanged for the profeſſion of a ſurveyor and builder. He was born in the city of London on the 30th day of March 1719; and after having been ſent firſt to one ſchool, and afterwards to a ſecond, where he acquired a tolerable knowledge of Latin, he went through a regular courſe of architecture and perſpective, in order to fit him for his father's profeſſion of a ſurveyor. He was, however, perſuaded, by a near relation, to abandon the profeſſion of his firſt choice, and to embrace that of the law; and was accordingly articled to Mr John Scott an attorney and ſolicitor in great practice. In this ſituation his time was too fully employed in the actual diſpatch of buſineſs to permit him, without ſome extraordinary means, to acquire the neceſſary knowledge of his profeſſion by reading and ſtudy; beſides that, his maſter is ſaid to have been more anxious to render him a good copying clerk, by ſcrupulous attention to his hand-writing, than to qualify him by inſtruction to conduct buſineſs. To remedy this inconvenience, therefore, he abridged himſelf of his reſt, and riſing at four in the morning, found opportunity of reading all the neceſſary and moſt eminent law writers, and the works of our moſt celebrated authors on the ſubjects of verſe and proſe. By theſe means, before the expiration of his clerkſhip, he had rendered himſelf a very able lawyer, and had acquired a love for literature in general, but particularly for poetry and the polite arts; and the better to facilitate his improvement, he occaſionally furniſhed to the Univerſal Spectator, the Weſtminſter Journal, the Gentleman's Magazine, and other periodical publications of the time, eſſays and diſquiſitions on ſeveral ſubjects. The firſt of theſe is believed to have been an Eſſay on *Swearing*; but the exact time of its appearance, and the paper in which it was inſerted, are both unknown. It was, however, re-publiſhed ſome years before his death (without his knowledge till he ſaw it in print) in one of the newſpapers. His next production was an Eſſay on *Honeſty*, inſerted in the Gentleman's Magazine for March 1739; and which occaſioned a controverſy, continued through the Magazines for ſeveral ſucceeding months, between him and a Mr Calamy, a deſcendant of the celebrated Dr Edmund Calamy, then a fellow-clerk with him.

About the year 1741, a club having been inſtituted by ſeveral amateurs of muſic, under the name of the Madrigal Society, to meet every Wedneſday evening, and his clerkſhip being now out, he became a member of it, and continued ſo many years. Purſuing his inclination for muſic ſtill farther, he became alſo a member of the Academy of Ancient Muſic, which uſed to meet every Thurſday evening at the Crown and Anchor in the Strand, but ſince removed to Freemaſons Hall; and

and of this he continued a member till a few years before its removal.

Impelled by his own taſte for poetry, and excited to it by his friend Foſter Webb's example, who had contributed to the Gentleman's Magazine many very elegant poetical compoſitions, he had, before this time, himſelf become an occaſional contributor in the ſame kind, as well to that as to ſome other publications. The earlieſt of his productions of this ſpecies, now known, is ſuppoſed to be a copy of verſes "To Mr George Stanley, occaſioned by looking over ſome Compoſitions of his lately publiſhed," which bears date 19th February 1740, and was inſerted in the Daily Advertiſer for February 21. 1741; but, about the year 1742, he propoſed to Mr Stanley the project of publiſhing, in conjunction with him, ſix cantatas for a voice and inſtruments, the words to be furniſhed by himſelf, and the muſic by Mr Stanley. The propoſal was accepted, the publication was to be at their joint expence, and for their mutual benefit; and accordingly, in 1742, ſix cantatas were thus publiſhed, the five firſt written by Mr Hawkins, the ſixth and laſt by Foſter Webb; and theſe having ſucceeded beyond the moſt ſanguine expectations of their authors, a ſecond ſet of ſix more, written wholly by himſelf, was in like manner publiſhed a few months after, and ſucceeded equally well.

As theſe compoſitions, by being frequently performed at Vauxhall, Ranelagh, and other public places, and at many private concerts, had become favourite entertainments, many perſons, finding the author alſo a modeſt well-informed young man of unexceptionable morals, were become deſirous of his acquaintance. Among theſe was Mr Hare of Limehouſe, a brewer, who being himſelf a muſical man, and having met him at Mr Stanley's at muſical parties, gave him an invitation to his houſe; and, to forward him in his profeſſion, introduced him to a friend of his, Peter Storer of Highgate, Eſq; which proved the means of making his fortune.

In the winter of the year 1749, Doctor, then Mr Johnſon, was induced to inſtitute a club to meet every Tueſday evening at the King's Head, in Ivy lane, near St Paul's. It conſiſted only of nine perſons; and Mr Hawkins was one of the firſt members About this time, as it is ſuppoſed, finding his father's houſe, where he had hitherto reſided, too ſmall for the diſpatch of his buſineſs, now very much increaſing, he, in conjunction with Dr Munckley, a phyſician with whom he had contracted an intimacy, took a houſe in Clements-lane, Lombard-ſtreet. The ground-floor was occupied by him as an office, and the firſt floor by the Doctor as his apartment. Here he continued till the beginning of 1753, when, on occaſion of his marriage with Sidney, the youngeſt of Mr Storer's daughters, who brought him a conſiderable fortune, he took a houſe in Auſtin Friars, near Broad-ſtreet, ſtill continuing to follow his profeſſion of an attorney.

Having received, on the death of Peter Storer, Eſq; his wife's brother, in 1759, a very large addition to her fortune, he quitted buſineſs to Mr Clark, afterwards Alderman Clark, who had a ſhort time before completed his clerkſhip under him, diſpoſed of his houſe in Auſtin Friars, and purchaſed a houſe at Twickenham. Soon afterwards he bought the leaſe of one in Hatton-ſtreet, London, for a town reſidence.

From a very early period of his life he had entertained a ſtrong love for the amuſement of angling; and his affection for it, together with the vicinity of the river Thames, was undoubtedly his motive to a reſidence at this village. He had been long acquainted with Walton's Complete Angler; and had, by obſervation and experience, become himſelf a very able proficient in the art. Hearing, about this time, that Mr Moſes Browne propoſed to publiſh a new edition of that work, and being himſelf in poſſeſſion of ſome material particulars reſpecting Walton, he, by letter, made Mr Browne an offer of writing, for his intended edition, Walton's Life. To this propoſal no anſwer was returned, at leaſt for ſome time; from which circumſtance Mr Hawkins concluded, as any one reaſonably would, that his offer was not accepted; and, therefore, having alſo learnt that Mr Browne meant not to publiſh the text as the author left it, but to modernize it, in order to file off the ruſt, as he called it, he wrote again to tell Mr Browne that he underſtood his intention was to ſophiſticate the text, and that therefore he, Mr Hawkins, would himſelf publiſh a correct edition. Such an edition, in 1760, he accordingly publiſhed in octavo with notes, adding to it a Life of Walton by himſelf, a Life of Cotton, the author of the ſecond part, by the well-known Mr Oldys; and a ſet of cuts deſigned by Wale, and engraved by Ryland.

His propenſity to muſic, manifeſted by his becoming a member and frequenter of the ſeveral muſical ſocieties before mentioned, and alſo by a regular concert at his houſe in Auſtin Friars, had led him, at the time that he was endeavouring to get together a good library of books, to be particularly ſolicitous for collecting the works of ſome of the beſt muſical compoſers; and, among other acquiſitions, it was his ſingular good fortune to become poſſeſſed by purchaſe of ſeveral of the moſt ſcarce and valuable theoretical treatiſes on the ſcience any where extant, which had formerly been collected by Dr Pepuſch. With this ſtock of erudition, therefore, he, about this time, at the inſtance of ſome friends, ſet about procuring materials for a work then very much wanted, a Hiſtory of the Science and Practice of Muſic, which he afterwards publiſhed.

At the recommendation of the well-known Paul Whitehead, to the Duke of Newcaſtle, then Lord-lieutenant for Middleſex, his name was, in 1761, inſerted in the commiſſion of the peace for that county; and having, by the proper ſtudies, and a ſedulous attendance at the ſeſſions, qualified himſelf for the office, he became an active and uſeful magiſtrate in the county (A). Obſerving, as he had frequent occaſion to do in the courſe of his duty, the bad ſtate of highways, and

---

(A) When he firſt began to act, he formed a reſolution of taking no fees, not even the legal and authoriſed ones, and purſued this method for ſome time, till he found that it was a temptation to litigation, and that every trifling ale-houſe quarrel produced an application for a warrant. To check this, therefore, he altered his mode, and received his due fees, but kept them ſeparately in a purſe; and at the end of every ſummer, before he left the country for the winter, delivered the whole amount to the clergyman of the pariſh, to be by him diſtributed among ſuch of the poor as he judged fit.

and the great defect in the laws for amending and keeping them in repair, he ſet himſelf to reviſe the former ſtatutes, and drew an act of parliament conſolidating all the former ones, and adding ſuch other regulations as were neceſſary. His ſentiments on this ſubject he publiſhed in octavo, in 1763, under the title of "Obſervations on the State of Highways, and on the Laws for amending and keeping them in Repair;" ſubjoining to them the draught of the act before mentioned; which bill being afterwards introduced into parliament, paſſed into a law, and is that under which all the highways in England are at this time kept repaired. Of this bill, it is but juſtice to add, that, in the experience of more than thirty years, it has never required a ſingle amendment.

Johnſon, and Sir Joſhua, then Mr Reynolds, had, in the winter of this year (1763) projected the eſtabliſhment of a club to meet every Monday evening at the Turk's Head, in Gerard-ſtreet; and, at Johnſon's ſolicitation, Mr Hawkins became one of the firſt members.

An event of conſiderable importance engaged him, in the year 1764, to ſtand forth as the champion of the county of Middleſex, againſt a claim then for the firſt time ſet up, and ſo enormous in its amount as juſtly to excite reſiſtance. The city of London finding it neceſſary to rebuild the gaol of Newgate, the expence of which, according to their own eſtimates, would amount to L.40,000, had this year applied to parliament, by a bill brought into the Houſe of Commons, in which, on a ſuggeſtion that the county priſoners removed to Newgate for a few days previous to their trials at the Old Bailey, were as two to one to the London priſoners conſtantly confined there, they endeavoured to throw the burthen of two-thirds of the expence on the county, while they themſelves propoſed to contribute one-third only. This attempt the magiſtrates for Middleſex thought it their duty to oppoſe; and accordingly a vigorous oppoſition to it was commenced and ſupported under the conduct of Mr Hawkins, who drew a petition againſt the bill, and a caſe of the county, which was printed and diſtributed amongſt the members of both houſes of parliament. It was the ſubject of a day's converſation in the Houſe of Lords; and produced ſuch an effect in the Houſe of Commons, that the city, by its own members, moved for leave to withdraw the bill. The ſucceſs of this oppoſition, and the abilities and ſpirit with which it was conducted, naturally attracted towards Mr Hawkins the attention of his fellow-magiſtrates; and the chairman of the quarter ſeſſions dying not long after, he was, on the 19th day of September 1765, elected his ſucceſſor.

In the year 1771 he quitted Twickenham, and ſold his houſe there to Mr Vaillant; and in the ſummer of the next year, for the purpoſe of obtaining, by ſearches in the Bodleian and other libraries, farther materials for his hiſtory of muſic, he made a journey to Oxford, carrying with him an engraver from London, to make drawings from the portraits in the muſic ſchool.

On occaſion of actual tumults or expected diſturbances, he had more than once been called into ſervice of great perſonal danger. When the riots at Brentford had ariſen, during the time of the Middleſex election in the year 1768, he and ſome of his brethren attended to ſuppreſs them; and, in conſequence of an expected riotous aſſembly of the journeymen Spitalfield weavers in Moorfields in 1769, the magiſtrates of Middleſex, and he at their head, with a party of guards, attended to oppoſe them; but the mob, on ſeeing them prepared, thought it prudent to diſperſe. In theſe and other inſtances, and particularly in his conduct as chairman, having given ſufficient proof of his activity, reſolution, abilities, integrity, and loyalty, he, on the 23d of October 1772, received from his majeſty the honour of knighthood.

In 1773, Dr Johnſon and Mr Stevens publiſhed, in 10 vols 8vo, their firſt joint edition of Shakeſpeare, to which Sir John Hawkins contributed ſuch notes as are diſtinguiſhed by his name, as he afterwards did a few more on the republication of it in 1778. An addreſs to the king from the county of Middleſex, on occaſion of the American war, having, in 1774, been judged expedient, and at his inſtance voted, he drew up ſuch an addreſs, and, together with two of his brethren, had, in the month of October in that year, the honour of preſenting it.

After ſixteen years labour, he, in 1776, publiſhed, in five volumes quarto, his General Hiſtory of the Science and Practice of Muſic; which, in conſequence of permiſſion obtained in 1773, he dedicated to the king, and preſented it to him at Buckingham Houſe on the 14th of November 1776, when he was honoured with an audience of conſiderable length both from the king and queen.

Not long after this publication, that is to ſay in November 1777, he was induced, by an attempt to rob his houſe, which, though unſucceſsful, was made three different nights with the interval of one or two only between each attempt, to quit his houſe in Hatton-ſtreet; and, after a temporary reſidence for a ſhort time in St James's Place, he took a leaſe of one, formerly inhabited by the famous Admiral Vernon, in the ſtreet leading up to Queen Square, Weſtminſter, and removed thither.

By this removal he became a conſtant attendant on divine worſhip at the pariſh-church of St Margaret, Weſtminſter; and having learnt, in December 1778, that the ſurveyor to the board of ordnance was, in defiance of a proviſo in the leaſe under which they claimed, carrying up a building at the eaſt end of the church, which was likely to obſcure the beautiful painted glaſs window over the altar there, Sir John Hawkins, with the concurrence of ſome of the principal inhabitants, wrote to the ſurveyor, and compelled him to take down two feet of the wall, which he had already carried up above the ſill of the window, and to ſlope off the roof of his building in ſuch a manner, as that it is not only no injury, but, on the contrary, a defence to the window.

In the month of December 1783, Dr Johnſon having diſcovered in himſelf ſymptoms of a dropſy, ſent for Sir John Hawkins, and telling him the precarious ſtate of his health, declared his deſire of making a will, and requeſted him to be one of his executors. Sir John accepted the office; inſtructed the Doctor how to make his will; and on his death undertook to be his biographer, and the guardian of his fame, by publiſhing a complete edition of his works.

Not three months after the commencement of this undertaking, he met with the ſevereſt loſs of almoſt any that a literary man can ſuſtain, ſhort of that of his friends or relations, in the deſtruction, by fire, of his library; conſiſting of a numerous and well-choſen collection

lection of books, ancient and modern, in many languages, and on moſt ſubjects, which it had been the buſineſs of above 30 years at intervals to get together. Of this loſs, great as it was in pecuniary value, and compriſing in books, prints, and drawings, many articles that could never be replaced, he was never heard in the ſmalleſt degree to complain; but having found a temporary reception in a large houſe in Orchard-ſtreet, Weſtminſter, he continued there a ſhort time, and then took a houſe in the Broad Sanctuary, Weſtminſter.

This event, for a ſhort time, put a ſtop to the progreſs of his literary purſuits. As ſoon, however, as he could ſufficiently collect his thoughts, he recommenced his office of biographer of Johnſon; and completed his intention by publiſhing, in 1787, the life and works, in eleven volumes octavo, which he dedicated to the king.

With this production he terminated his literary labours; and having for many years been more particularly ſedulous in his attention to the duties of religion, and accuſtomed to ſpend all his leiſure from other neceſſary concerns in theological and devotional ſtudies, he now more cloſely addicted himſelf to them, and ſet himſelf to prepare for that event, which he ſaw could be at no great diſtance; and the better to accompliſh this end, in the month of May 1788, he, by a will and other proper inſtruments, made ſuch an arrangement of his affairs as he meant ſhould take place after his deceaſe.

In this manner he ſpent his time till about the beginning of May 1789, when, finding his appetite fail him in a greater degree than uſual, he had recourſe, as he had ſometimes had before on the ſame occaſion, to the waters of the Iſlington Spa. Theſe he drank for a few mornings; but on the 14th of that month, while he was there, he was, it is ſuppoſed, ſeized with a paralytic affection, as, on his returning to the carriage which waited for him, his ſervants perceived a viſible alteration in his face. On his arrival at home, he went to bed, but got up a few hours after, intending to receive an old friend, from whom he expected a viſit in the evening. At dinner, however, his diſorder returning, he was led up to bed, from which he never roſe, on the 21ſt of the ſame month, about two in the morning, dying of an apoplexy. He was interred on the 28th in the cloiſters of Weſtminſter Abbey, in the north walk near the eaſtern door into the church, under a ſtone, containing, by his expreſs injunctions, no more than the initials of his name, the date of his death, and his age; leaving behind him a high reputation for abilities and integrity, united with the well-earnt character of an active and reſolute magiſtrate, an affectionate huſband and father, a firm and zealous friend, a loyal ſubject, and a ſincere Chriſtian.

Such is the character of him in the Biographical Dictionary, which we have neither right no inclination to controvert. With none of his works are we acquainted but his edition of *Walton's Complete Angler*, and his *Life of Johnſon*. The former is a very pleaſing book; and in the latter are collected many intereſting anecdotes of literature and literary men; but they are not well arranged, and the ſtyle of the compoſition is coarſe and ſlovenly. Sir John, we doubt not, was a man of worth, and his reflections on the ſentimental ſlang of Sterne and others, ſhew that he had ſucceſsfully ſtudied human nature; but he certainly was not a man of general taſte.

HEAT. See in this Supplement, CHEMISTRY, Part I. chap. v. where we have endeavoured to eſtabliſh the modern doctrine reſpecting *Caloric* or latent heat. In n°·309, &c. of that article, we have given an account of Count Rumford's ingenious experiments, inſtituted with a view to determine whether or not caloric be a ſubſtance, and have ſtated our reaſons for diſſenting from his opinion. It has been ſuggeſted to us, however, by a friend, to whoſe judgment we are inclined to pay great deference, that it would be proper, in this place, to give the Count's arguments at full length, and in his own words; and the propriety of this is the more apparent, that in the ſupplementary article ELECTRICITY, we have hinted our own ſuſpicions of the non-exiſtence of an *electrical fluid*. The Count then reaſons from his experiments in the following words:

"By meditating on the reſults of all theſe experiments, we are naturally brought to that great queſtion which has ſo often been the ſubject of ſpeculation among philoſophers, namely, What is heat?—Is there any ſuch thing as an *igneous fluid?*—Is there any thing that can with propriety be called caloric?

"We have ſeen that a very conſiderable quantity of heat may be excited in the friction of two metallic ſurfaces, and given off in a conſtant ſtream or flux *in all directions*, without interruption or intermiſſion, and without any ſigns of diminution or exhauſtion.

"From whence came the heat which was continually given off in this manner in the foregoing experiments? Was it furniſhed by the ſmall particles of metal detached from the larger ſolid maſſes on their being rubbed together? This, as we have already ſeen, could not poſſibly have been the caſe.

"Was it furniſhed by the air? This could not have been the caſe; for in three of theſe experiments, the machinery being kept immerſed in water, the acceſs of the air of the atmoſphere was completely prevented.

"Was it furniſhed by the water which ſurrounded the machinery? That this could not have been the caſe is evident; *firſt*, becauſe this water was continually *receiving heat* from the machinery, and could not at the ſame time be *giving to* and *receiving heat from* the ſame body; and, *ſecondly*, becauſe there was no chemical decompoſition of any part of this water. Had any ſuch decompoſition taken place (which indeed could not reaſonably have been expected), one of its compound elaſtic fluids (moſt probably inflammable air) muſt at the ſame time have been ſet at liberty, and, in making its eſcape into the atmoſphere, would have been detected; but though I frequently examined the water to ſee if any air bubbles roſe up through it, and had even made preparations for catching them, in order to examine them if any ſhould appear, I could perceive none; nor was there any ſign of decompoſition of any kind whatever, or other chemical proceſs going on in the water.

"Is it poſſible the heat could have been ſupplied by means of the iron bar to the end of which the blunt ſteel borer was fixed? or by the ſmall neck of gun-metal by which the hollow cylinder was united to the cannon? Theſe ſuppoſitions appear more improbable even than either of thoſe before mentioned; for heat was continually going off or *out of the machinery*, by both theſe laſt paſſages, during the whole time the experiment laſted.

"And, in reaſoning on this ſubject, we muſt not forget to conſider that moſt remarkable circumſtance, that the ſource of the heat generated by friction in theſe experiments appeared evidently to be inexhauſtible.

"It is hardly neceſſary to add, that any thing which any *inſulated* body or ſyſtem of bodies can continue to furniſh *without limitation*, cannot poſſibly be a *material ſubſtance*; and it appears to me to be extremely difficult, if not quite impoſſible, to form any diſtinct idea of any thing capable of being excited and communicated in the manner the heat was excited and communicated in theſe experiments, except it be motion.

"But although the mechaniſm of heat ſhould in fact be one of thoſe myſteries of nature which are beyond the reach of human intelligence, this ought by no means to diſcourage us, or even leſſen our ardour, in our attempts to inveſtigate the laws of its operations. How far can we advance in any of the paths which ſcience has opened to us, before we find ourſelves enveloped in thoſe thick miſts which on every ſide bound the horizon of the human intellect? But how ample and intereſting is the field that is given us to explore!

"Nobody, ſurely, in his ſober ſenſes has ever pretended to underſtand the mechaniſm of gravitation; and yet what ſublime diſcoveries was our immortal Newton enabled to make, merely by the inveſtigation of the laws of its action! The effects produced in the world by the agency of heat are probably *juſt as extenſive* and quite as important, as thoſe which are owing to the tendency of the particles of matter towards each other; and there is no doubt but its operations are in all caſes determined by laws equally immutable."

HELENA, or St Helena. In addition to the account of this iſland in the *Encyclopædia*, the following particulars from Sir George Staunton deſerve a place in this *Supplement*, becauſe ſome of them are important in themſelves, while others correct one or two miſtakes into which we had fallen, by adopting, implicitly, the narrative of Forſter.

The circumference of St Helena meaſures ſomewhat leſs than twenty-eight miles. Along the whole coaſt to leeward, or to the northward, ſhips may anchor in perfect ſecurity in all ſeaſons of the year, but the bank ſhelves ſo abruptly afterwards, that the anchorage, being in deep water, is inſecure. The tide ſeldom riſes above three feet and a half; but the ſurge of the ſea is ſometimes tremendous; and ſeveral accidents happened in approaching or quitting the ſhore, until a wharf was erected lately, which renders the arrival there, and departure from it, perfectly ſafe. In the immediate neighbourhood of the iſland, ſtorms are little known, thunder is rarely heard, and lightning is ſeldom perceived.

The ſteep eminences which intervene between the valleys, that are the chief ſeats of population, render the communication from one part of this little ſpot to another ſlow and difficult. Planters on the windward ſide of the iſland conſider a journey to the leeward, or ſeat of government, as a ſerious undertaking. Several of them take that opportunity of paying their reſpects to the governor, which is called there ſometimes "going to court." There are St Helena planters who have not travelled ſo far. At preſent, by order of the governor, there are ſignals ſo placed all over the iſland, as to give inſtant notice of the approach of veſſels to any part of it.

In the *Encyclopædia*, it is ſaid that peaches are the only European fruits which thrive in St Helena; but this appears to be a miſtake Several ſorts of fruit trees imported into the iſland had been deſtroyed by a particular inſect; but encouragement has been given for the cultivation of thoſe which that miſchievous animal is known to ſpare, ſuch as the apple, for example, with all the varieties of which it is ſuſceptible. The plantain and banana, or the two ſpecies of the *muſa*, thrive alſo remarkably well. The ground is fertile, and in favourable ſeaſons produces, in ſome inſtances, double crops within the year. Plantations, however, of cotton, indigo, or canes, were not found to anſwer; though ſome good coffee has been produced in it. A botanic garden has been eſtabliſhed near the governor's country houſe. An intelligent gardener has been ſent to take care of it by the company; and a vaſt variety of trees, plants, and flowers of different, and ſometimes oppoſite climates, are already collected in it. The ſurrounding ſea abounds in eſculent fiſh; and ſeventy different ſpecies, including turtle, have been caught upon the coaſts. Whales are ſeen in great numbers playing round the iſland, where it is ſuppoſed the ſouthern whale fiſhery might be carried on to great national advantage.

The country is chiefly cultivated by blacks. Perſons of that colour were brought in a ſtate of ſlavery to it by its firſt European ſettlers; and it ſeldom happens that white men will ſubmit to common work where there are black ſlaves to whom it may be transferred. Theſe were for a long time under the unlimited dominion of their owners, until a repreſentation of the abuſes made of that power induced the India Company to place them under the immediate protection of the magiſtracy, and to enact various regulations in their favour; which have contributed to render them, in a great degree, confortable and ſecure. Theſe regulations may have hurt, at firſt, the feelings of the owners of ſlaves, but not their real intereſt; for it appears, that before their introduction there was a loſs, upon an average, of about ten in a hundred ſlaves every year, to be ſupplied at a very heavy expence; whereas, under the preſent ſyſtem, they naturally increaſe. All future importation of ſlaves into the iſland is prohibited.

Beſides the blacks in a ſtate of ſlavery, there are ſome who are free. The labour of theſe tending to diminiſh the value of that of ſlaves, the free blacks became once obnoxious to ſome ſlave owners; who had ſufficient influence, in a grand jury, to preſent them as without viſible means of gaining a livelihood, and liable to become burdenſome to the community; but upon examination, it appeared that all free blacks of age to work were actually employed; that not one of them had been tried for a crime for ſeveral years, nor had any of them been upon the pariſh. They are now by the humane interpoſition of the company placed under the immediate protection of the government, and put nearly upon a footing with the other free inhabitants, who, when accuſed of crimes, have the privilege of a jury, as well as in civil cauſes.

The principal ſettlement of St Helena has the peculiar advantage of uniting the ſhelter of a leeward ſituation with the coolneſs of windward gales. The ſouth-eaſt wind blows conſtantly down the valley, rendering a reſidence in it pleaſant as well as healthy.

The country is ſo fertile, and the climate ſo congenial to the human feelings, that perhaps it would be difficult to find out a ſpot where perſons, not having acquired a reliſh for the enjoyments of the world, or already advanced in life, and ſurfeited with them, could have a better chance of protracting their days in eaſe, health, and comfort.

HELICOID Parabola, or the *Parabolic Spiral*, is a curve ariſing from the ſuppoſition that the common or Apollonian parabola is bent or twiſted, till the axis come into the periphery of a circle, the ordinates ſtill retaining their places and perpendicular poſitions with reſpect to the circle, all theſe lines ſtill remaining in the ſame plane.

HELISPHERICAL Line, is the Rhumb line in Navigation; being ſo called, becauſe on the globe it winds round the pole helically or ſpirally, coming ſtill nearer and nearer to it.

HENIOCHAS, or Heniochus, a northern conſtellation, the ſame as Auriga, which ſee *Encycl.*

HERSCHEL, the name by which the French, and moſt other European nations, call the new planet diſcovered by Dr Herſchel in the year 1781. Its mark or character is ♅. The Italians call it Ouranos, or Urania; but the Engliſh, the Georgian Planet, or Georgium Sidus.

HETERODROMUS Vectis, or Lever, in Mechanics, a lever in which the fulcrum, or point of ſuſpenſion, is between the weight and the power; being the ſame as what is otherwiſe called a lever of the firſt kind.

HINZUAN, the proper name of one of the Comora iſlands, which by different writers of different nations has been called *Anzuame*, *Anjuan*, *Juanny*, and *Johanna*, and which is deſcribed in the *Encyclopædia* under the name of St Joanna. In that article, it is obſerved, that an anonymous writer has cenſured the deſcriptions of this iſland given by the Abbé Reynal and Major Rooke, as being not only exaggerated, but erroneous; neither the country being ſo pictureſque as the former repreſents it, nor the inhabitants meriting the reſpectable character given of them by the latter.

There was not perhaps much propriety in admitting into ſuch a work as the *Encyclopædia Britannica*, the anonymous cenſure of deſcriptions, authenticated by the names of reſpectable authors; but the beſt reparation which we can make to thoſe authors is, to inform our readers, that their deſcriptions of Hinzuan are confirmed by Sir William Jones, whoſe teſtimony, we believe, no man will controvert. That accompliſhed ſcholar, who viſited the iſland on his voyage to India, thus deſcribes its appearance from the bay in which the ſhip rode at anchor.

"Before us was a vaſt amphitheatre, of which you may form a general notion by picturing in your minds a multitude of hills infinitely varied in ſize and figure, and then ſuppoſing them to be thrown together, with a kind of artleſs ſymmetry, in all imaginable poſitions. The back ground was a ſeries of mountains, one of which is pointed, near half a mile perpendicularly high from the level of the ſea, and little more than three miles from the ſhore: all of them richly clothed with wood, chiefly fruit trees, of an exquiſite verdure. I had ſeen many a mountain of ſtupendous height in Wales and Swiſſerland, but never ſaw one before, round the boſom of which the clouds were almoſt continually rolling, whiles it green ſummit roſe flouriſhing above them, and received from them an additional brightneſs. Next to this diſtant range of hills was another tier, part of which appeared charmingly verdant, and part rather barren; but the contraſt of colours changed even this nakedneſs into a beauty: nearer ſtill were innumerable mountains, or rather cliffs, which brought down their verdure and fertility quite to the beach; ſo that every ſhade of green, the ſweeteſt of colours, was diſplayed at one view by land and by water. But nothing conduced more to the variety of this enchanting proſpect, than the many rows of palm trees, eſpecially the tall and graceful *Arecas*, on the ſhores, in the valleys, and on the ridges of hills, where one might almoſt ſuppoſe them to have been planted regularly by deſign. A more beautiful appearance can ſcarce be conceived, than ſuch a number of elegant palms in ſuch a ſituation, with luxuriant tops, like verdant plumes, placed at juſt intervals, and ſhowing between them part of the remoter landſcape, while they left the reſt to be ſupplied by the beholder's imagination. The town of *Matſamúdò* lay on our left, remarkable at a diſtance for the tower of the principal moſque, which was built by Halímah, a queen of the iſland, from whom the preſent king is deſcended: a little on our right was a ſmall town, called *Bantáni*. Neither the territory of *Nice*, with its olives, date trees, and cypreſſes, nor the iſles of *Hieres*, with their delightful orange groves, appeared ſo charming to me as the view from the road of *Hinzúàn*."

Sir William Jones, ſpeaking of the inhabitants, takes notice of the *Lords*, *Dukes*, and *Princes*, of whom we have made mention after Major Rooke. "The frigate, (ſays he) was preſently ſurrounded with canoes, and the deck ſoon crowded with natives of all ranks, from the high born chief, who waſhed linen, to the half-naked ſlave, who only paddled. Moſt of them had letters of recommendation from Engliſhmen, which none of them were able to read, though they ſpoke Engliſh intelligibly; and ſome appeared vain of titles, which our countrymen gave them in play, according to their ſuppoſed ſtations: we had *Lords*, *Dukes*, and *Princes*, on board, ſoliciting our cuſtom, and importuning us for preſents. In fact, they were too ſenſible to be proud of empty ſounds, but juſtly imagined, that thoſe ridiculous titles would ſerve as marks of diſtinction, and, by attracting notice, procure for them ſomething ſubſtantial." He ſpeaks with great reſpect of the king, whoſe name was *Ahmed*, as well as of ſeveral chiefs whom he ſaw, and ſeems to have met with no man of rank on the iſland whoſe character was contemptible, but Selim the king's eldeſt ſon. For the behaviour of that prince, the old ſovereign made the beſt apology that he could, while he privately aſſured the interpreter, that he was much diſpleaſed with it, and would not fail to expreſs his diſpleaſure. He concluded his converſation with a long harangue on the advantage which the Engliſh might derive from ſending a ſhip every year from Bombay to trade with his ſubjects, and on the wonderful cheapneſs of their commodities, eſpecially of their cowries. Ridiculous as this idea might ſeem, it ſhowed (ſays Sir William) an enlargement of mind, a deſire of promoting the intereſt of his people, and a ſenſe of the benefits ariſing from trade, which could hardly have been expected from a petty African chief, and which, if he had been ſovereign of Yemen, might have been expanded into rational projects proportioned to the extent of his dominions.

The maſter of the frigate learned from one of the chiefs a few curious circumſtances concerning the government of *Hinzuan;* which he found to be a monarchy limited by an ariſtocracy. The king, he was told, had no power of making war by his own authority; but if the aſſembly of nobles, who were from time to time convened by him, reſolved on a war with any of the neighbouring iſlands, they defrayed the charges of it by voluntary contributions; in return for which, they claimed as their own all the booty and captives that might be taken. The hope of gain or the want of ſlaves is uſually the real motive for ſuch enterpriſes, and oſtenſible pretexts are eaſily found: at that very time, he underſtood they meditated a war, becauſe they wanted hands for the following harveſt. Their fleet conſiſted of ſixteen or ſeventeen ſmall veſſels, which they manned with about two thouſand five hundred iſlanders, armed with muſkets and cutlaſſes, or with bows and arrows. Near two years before they had poſſeſſed themſelves of two towns in *Mayáta*, which they ſtill kept and garriſoned. The ordinary expences of the government were defrayed by a tax from two hundred villages; but the three principal towns were exempt from all taxes, except that they paid annually to the chief *Mufti* a fortieth part of the value of all their moveable property; and from that payment neither the king nor the nobles claimed an exemption. The kingly authority, by the principles of their conſtitution, was conſidered as elective, though the line of ſucceſſion had not in fact been altered ſince the firſt election of a ſultan.

Sir William Jones concludes his remarks on this iſland with ſome reflections; of which, though they may be conſidered as digreſſive, we are perſuaded our readers will approve of our extending the circulation.

"We have lately heard of civil commotions in *Hinzuan*, which, we may venture to pronounce, were not excited by any cruelty or violence of Ahmed, but were probably occaſioned by the inſolence of an oligarchy naturally hoſtile to king and people. That the mountains in the *Comara* iſlands contain diamonds, and the precious metals, which are ſtudiouſly concealed by the policy of the ſeveral governments, may be true, though I have no reaſon to believe it, and have only heard it aſſerted without evidence; but I hope, that neither an expectation of ſuch treaſures, nor of any other advantage, will ever induce an European power to violate the firſt principles of juſtice by aſſuming the ſovereignty of *Hinzuan*, which cannot anſwer a better purpoſe than that of ſupplying our fleets with ſeaſonable refreſhment; and although the natives have an intereſt in receiving us with apparent cordiality, yet if we wiſh their attachment to be unfeigned and their dealings juſt, we muſt ſet them an example of ſtrict honeſty in the performance of our engagements. In truth, our nation is not cordially loved by the inhabitants of *Hinzuan*, who, as it commonly happens, form a general opinion from a few inſtances of violence or breach of faith. Not many years ago an European, who had been hoſpitably received and liberally ſupported at *Matſamudo*, behaved rudely to a young married woman, who, being of low degree, was walking veiled through a ſtreet in the evening; her huſband ran to protect her, and reſented the rudeneſs, probably with menaces, poſſibly with actual force; and the European is ſaid to have given him a mortal wound with a knife or bayonet, which he brought, after the ſcuffle, from his lodging. This foul murder, which the law of nature would have juſtified the magiſtrate in puniſhing with death, was reported to the king, who told the governor (I uſe the very words of Alwi, a couſin of the king's), that "it would be wiſer to huſh it up." Alwi mentioned a civil caſe of his own, which ought not to be concealed. When he was on the coaſt of Africa in the dominions of a very ſavage prince, a ſmall European veſſel was wrecked; and the prince not only ſeized all that could be ſaved from the wreck, but claimed the captain and the crew as his ſlaves, and treated them with ferocious inſolence. Alwi aſſured me, that, when he heard of the accident, he haſtened to the prince, fell proſtrate before him, and by tears and importunity prevailed on him to give the Europeans their liberty; that he ſupported them at his own expence, enabled them to build another veſſel, in which they ſailed to *Hinzuan*, and departed thence for Europe or India: he ſhewed me the captain's promiſſory notes for ſums, which to an African trader muſt be a conſiderable object, but which were no price for liberty, ſafety, and, perhaps, life, which his good, though diſintereſted, offices had procured. I lamented that, in my ſituation, it was wholly out of my power to aſſiſt Alwi in obtaining juſtice; but he urged me to deliver an *Arabic* letter from him, incloſing the notes, to the governor general, who, as he ſaid, knew him well; and I complied with his requeſt. Since it is poſſible, that a ſubſtantial defence may be made by the perſon thus accuſed of injuſtice, I will not name either him or the veſſel which he had commanded; but, if he be living, and if this paper ſhould fall into his hands, he may be induced to reflect how highly it imports our national honour, that a people, whom we call ſavage, but who adminiſter to our convenience, may have no juſt cauſe to reproach us with a violation of our contracts."

HIPS, in architecture, are thoſe pieces of timber placed at the corners of a roof. Theſe are much longer than the rafters, becauſe of their oblique poſition. Hip means alſo the angle formed by two parts of the roof, when it riſes outwards.

Hip-Roof, called alſo Italian roof, is one in which two parts of the roof meet in an angle, riſing outwards: the ſame angle being called a valley, when it ſinks inwards.

HIRCUS, in aſtronomy, a fixed ſtar of the firſt magnitude, the ſame with capella.

HIRCUS is alſo uſed by ſome writers for a comet, encompaſſed as it were with a mane, ſeemingly rough and hairy.

HIRUDO. See *Encycl.* A new ſpecies of this inſect was diſcovered in the South Sea by Le Martiniere, naturaliſt in Perouſe's voyage of diſcovery. He found it buried about half an inch in a ſhark's liver, but could not conceive how it had got thither. It was ſomething more than an inch long, of a whitiſh colour, and compoſed of ſeveral rings ſimilar to thoſe of the tænia. The ſuperior part of its head was furniſhed with four ſmall ciliated mamillæ, by which it took its food; under each mamilla on both ſides was a ſmall oblong pouch, in the form of a cup; and in the form of its *inſtrumenta cibaria*, it very nearly reſembles the animal which has been ſuppoſed to be the cauſe of meaſles in ſwine. Both theſe ſpecies are referable to the genus *hirudo*, the characters of which, as given by Linnæus, ſtand (ſays Martiniere) in need of reformation.

HIRUNDO Esculenta (ſee Hirundo, *Encycl.* nº 3.), is thus deſcribed in the *Tranſactions of the Batavian Society in the Iſland of Java*, vol. iii. ; and the deſcription confirms the ſagacious conjecture of Mr Latham reſpecting the ſize of the bird, which the reader will find in our article referred to.

“ The hirundo eſculenta is of a blackiſh grey colour, inclining a little to green ; but on the back to the tail, as well as on the belly, this blackiſh colour gradually changes into a mouſe colour. The whole length of the bird from the bill to the tail is about four inches and a half, and its height from the bill to the extremity of the middle toe three inches and a quarter. The diſtance from the tip of the one wing to that of the other, when extended, is ten inches and a quarter. The largeſt feathers of the wings are about four inches in length. The head is flat ; but, on account of the thickneſs of the feathers, appears round, and to be of a large ſize in proportion to the reſt of the body. The bill is broad, and ends in a ſharp extremity, bent downwards in the form of an awl. The width of it is increaſed by a naked piece of ſkin, ſomewhat like parchment, which, when the bill is ſhut, lies folded together ; but which, when the bill opens, is conſiderably extended, and enables the bird to catch with greater eaſe, while on wing, the inſects that ſerve it for food. The eyes are black, and of a conſiderable ſize. The tongue, which is not forked, is ſhaped like an arrow. The ears are flat, round, naked ſpots, with ſmall oblong openings, and are entirely concealed under the feathers of the head. The neck is very ſhort, as well as the legs and the bones of the wings. The thighs are wholly covered with feathers ; and the very tender lower parts of the legs, and the feet themſelves, are covered with a ſkin like black parchment. Each foot has four toes, three of which are before and one turned backwards. They are all detached from each other to the roots ; and the middle one, together with the claw, is fully as long as the lower part of the leg. Each toe is furniſhed with a black, ſharp, crooked claw of a conſiderable length, by which the animal can with great facility attach itſelf to crags and rocks. The tail is fully as long as the body together with the neck and the head. When expanded it has the form of a wedge, and conſiſts of ten large feathers. The four firſt on each ſide are long ; and, when the tail is cloſed, extend almoſt an inch beyond the reſt. The other feathers decreaſe towards the middle of the tail, and are equal to about the length of the body.”

There is a variety of this ſpecies of hirundo, with a ſpeckled breaſt, and white ſpots on the tail feathers ; and this, though leſs numerous than the other, and indeed not found at all in Java, appears to have been the only hirundo eſculenta known to Linnæus. For an account of the eatable neſts of theſe birds, and the manner of collecting them, ſee Cap and Button in this *Supplement*.

HISPANIOLA, or St Domingo, the largeſt of the Antilles or Caribbee iſlands, has been deſcribed, as it exiſted prior to the French revolution, in the *Encyclopædia*. Previous to the year 1789 the government of the French part of the iſland was adminiſtered by an officer called the Intendant, and a Governor-General, both nominated by the crown, and inveſted with authority for three years. Their powers were in ſome caſes diſtinct, and in others united; but though theſe powers were extenſive and almoſt abſolute, the attention which the old government of France paid to the character and rank of thoſe perſons whom it had placed over its foreign ſettlements, ſecured to the inhabitants of Hiſpaniola a very conſiderable ſhare of happineſs. In ſpite of what our reſtleſs innovators call political evils, ſigns of proſperity were everywhere viſible; their towns were opulent, their markets plentiful, their commerce extenſive, and their cultivation increaſing.

Such was, in 1788, the ſtate of the French colony, in the iſland of St Domingo; but in that eventful year, the flame, which had burſt forth in Europe, ſpread itſelf to the Weſt Indies. An aſſociation had been formed in France upon principles ſomewhat ſimilar to thoſe of our ſociety for the abolition of the ſlave trade ; but that aſſociation, which called itſelf *Amis des Noirs*, had much more dangerous deſigns than ours. Avowing its deteſtation of every kind of ſlavery, as well as of the African trade, and condemning thoſe abettors of liberty who dared to declare themſelves poſſeſſors of men, its members kept up an intimate and clandeſtine connection with thoſe rich mulattoes who reſided in France for their education, and laboured to convince them that neither their colour nor their *ſpurious birth* ſhould make any civil or political diſtinction between them and the whites who were born in *wedlock*. To co-operate, as it were, with theſe factious and falſe doctrines, the National Aſſembly iſſued its famous declaration, in which it was maintained that all mankind are born, and continue free, and equal in their rights. The conſequence of this was ſuch as might have been expected. The mulattoes of Hiſpaniola, inſtructed in the French philoſophy of the rights of man, broke out into rebellion; but not acting in concert, they were quickly overpowered.

The ſpirit, however, which had been excited among them, ſtill continued to ferment ; and the National Aſſembly of France, taking the ſtate of the iſland into ſolemn conſideration, decreed, by a great majority, that its intention had never been to intermeddle with the internal affairs of the colony ; that their internal legiſlation was entirely their own ; and that the legiſlature of the mother country would make no innovation, directly or indirectly, in the ſyſtem of commerce in which the colonies were already concerned. However grateful this declaration might be to the whites of St Domingo, and in the then ſtate of things however wiſe in itſelf, it occaſioned diſcontent and remonſtrances on the part of the factious friends of the negroes. They regarded it as an unwarrantable ſanction of the African traffic, and a confeſſion that the planters of Hiſpaniola were not coloniſts, but an independent people.

The coloniſts themſelves, indeed, or rather their repreſentatives, ſeem to have thought that by this decree they were rendered independent ; for in their general aſſembly they paſſed an act debarring the king's delegate, the governor-general, from negativing any of their future acts. This violent meaſure was far from giving univerſal ſatisfaction. The weſtern pariſhes recalled their delegates, while thoſe of Cape François renounced their obedience to the whole aſſembly, and petitioned the governor to diſſolve it.

During theſe diſſenſions, the commander of a ſhip of the line, which lay in the harbour of Port-au-Prince, gave a ſumptuous entertainment to the friends of the governor ; on which account the ſeamen, who declared themſelves in the intereſt of the aſſembly, thought fit to mutiny; and the aſſembly, in return, voted their thanks to the mutineers. Some of their partizans, ſeizing at the ſame time a powder magazine, the governor declared them adherents to traitors, and called on all officers, civil and military, to bring them to puniſhment. This was the ſignal for civil inſurrection; armed troops took the field on both ſides; and war ſeemed inevitable, when the aſſembly reſolved to repair in a body to France, and juſtify their paſt conduct.

In the mean time the *Amis des Noirs* contrived to excite the people of colour to rebellion. They initiated in the doctrine of equality and the rights of man one James Oge, then reſiding in Paris in ſome degree of affluence. They perſuaded him to go to St Domingo, put himſelf at the head of his people, and deliver them from the oppreſſion of the whites; and in order to evade the notice of government, they undertook to procure for him arms and ammunition in America. He embarked accordingly, July 1790, for New England with money and letters of credit; but notwithſtanding the caution of the *Amis des Noirs*, his deſigns were diſcovered by the French government, and his portrait was ſent out before him to St Domingo. He landed on the iſland in October, and ſix weeks afterwards publiſhed a manifeſto, declaring his intention of taking up arms, if the privileges of whites were not granted to *all perſons without diſtinction*. He was joined by about 200 men of colour; and this little army of ruffians not only maſſacred the whites wherever they fell in with them in ſmall numbers, but, by a ſtill more unjuſtifiable mode of conduct, took vengeance on thoſe of their own colour who refuſed to join their rebellious ſtandard. They were, however, ſoon overpowered by the regular troops; and their leader, after diſcloſing, it is ſaid, ſome important ſecrets, ſuffered the puniſhment due to his treaſon.

While theſe things were going on in the iſland, the members of the Colonial Aſſembly arrived at Paris, where they were received by the repreſentatives of the French people with marked ſymptoms of averſion. The reſolutions compoſing their famous decree were pronounced improper; their vote of thanks to the mutineers was declared criminal; they were themſelves perſonally arreſted; orders were given for a new aſſembly to be called; and the king was requeſted to augment the naval and military force then at St Domingo.

The National Aſſembly of France having decreed that every perſon twenty-five years old and upwards, poſſeſſing property, or having reſided two years in the colony and paid taxes, ſhould be permitted to vote in the formation of the colonial aſſembly, the people of colour very naturally concluded that this privilege was conferred upon them. Such, however, we believe, was not the meaning of the National Aſſembly; but Gregoire, with the other friends of the negroes, at laſt prevailed, and mulattoes born of free parents were pronounced to be not only worthy of chooſing their repreſentatives, but alſo eligible themſelves to ſeats in the colonial aſſemblies. This decree ſacrificed at once all the whites in the iſland to the people of colour; and the indignation which filled the minds of both the royal and the republican parties ſeemed to have united them in one common cauſe. They reſolved to reject the civic oath; to confiſcate the French property in the harbour, on which they actually laid an embargo; to pull down the national colours, and to hoiſt the Britiſh ſtandard in their ſtead. The mulattoes in the mean time collected in armed bodies, and waited with anxious expectation to ſee what meaſures the colonial aſſembly would adopt.

During theſe diſſenſions, the negro ſlaves, into whoſe minds had been ſedulouſly inſtilled an opinion that their rights were equal to thoſe of their maſters, reſolved to recover their freedom. On the morning of the 23d of Auguſt 1791, the town of the Cape was alarmed by a confuſed report that the ſlaves in the adjoining pariſhes had revolted; and the tidings were ſoon confirmed by the arrival of thoſe who had narrowly eſcaped the maſſacre. The rebellion had broken out in the pariſh of Acul, nine miles from the city, where the whites had been butchered without diſtinction; and now the rebels proceeded from pariſh to pariſh, murdering the men, and raviſhing the unfortunate women who fell into their hands. In a ſhort time the ſword was accompanied with fire, and the cane-fields blazed in every direction. The citizens now flew to arms, and the command of the national troops was given to the governor, whilſt the women and children were put aboard the ſhips in the harbour for ſafety. In the firſt action the rebels were repulſed; but their numbers rapidly increaſing, the governor judged it expedient to act ſolely on the defenſive. In the ſpace of two months it was computed that upwards of 2000 white perſons periſhed; and of the inſurgents, who conſiſted as well of mulattoes as of negroes, not fewer than 10,000 died by famine and the ſword, and hundreds by the hands of the executioner.

When intelligence of theſe dreadful proceedings reached Paris, the Aſſembly began to be convinced that its equaliſing principles had been carried too far; and the famous decree, which put the people of colour on the ſame footing with the whites, was repealed. Three commiſſioners were likewiſe ſent to the colony to reſtore peace between the whites and the mulattoes; but two of them being men of bad character, and none of them poſſeſſing abilities for the arduous taſk of extinguiſhing the flames of a civil war, they returned to France without accompliſhing in any degree the object of their miſſion.

In the mean time the *Amis des Noirs* in the mother country had once more gained the aſcendant in the National Aſſembly; and three new commiſſioners, Santhonax, Polverel, and Ailhaud, with 6000 choſen men from the national guards, were embarked for St Domingo. It was ſtrongly ſuſpected that the object of theſe commiſſioners was to procure unqualified freedom for all the blacks in the iſland; but they ſolemnly ſwore that their ſole purpoſe was to eſtabliſh the rights of the mulattoes, as decreed by the law which had been lately repealed. The whites therefore expected that a colonial aſſembly would be convoked; but inſtead of this the commiſſioners nominated twelve perſons, of whom ſix had been members of the laſt aſſembly, and ſix were mulattoes, *Une Commiſſion Intermediaire*, with authority to raiſe contributions on the inhabitants, the application of which, however, they reſerved to themſelves. The governor finding that the commiſſioners uſurped all authority, complained that he was but a cypher in public affairs; his complaint was anſwered by an arreſt upon his perſon, and he was ſent a ſtate priſoner to France.

The tyranny of the commiſſioners did not ſtop here. They overawed the members of the commiſſion *intermediaire*, by arreſting four of their number; and diſagreeing among themſelves, Santhonax and Polverel diſmiſſed Ailhaud from their councils. War was by this time declared.

declared between the mother country and Great Britain, and prudence compelled the government of France to take ſome care of the injured colony. Galbaud, therefore, a man of fair character, was appointed governor, and ordered to put the iſland in a ſtate of defence againſt foreign invaſion; but poſſeſſing Weſt India property, which it ſeems was a legal diſqualification for the office of governor, the commiſſioners diſregarded his authority, and took up arms againſt him. Finding themſelves likely to be worſted, they offered to purchaſe the aid of the rebel negroes, by the offer of a pardon for their paſt conduct, freedom in future, and the plunder of the capital. Two of the negro chiefs, more honourable than the French commiſſioners, ſpurned at the baſe propoſal; but a third, after the governor had fled to the ſhips, entered the town with 3000 revolted negroes, and began an indiſcriminate maſſacre. The miſerable inhabitants fled to the ſhore, but their retreat was ſtopped by a party of mulattoes; and for two days the ſlaughter was inceſſant. The town was half conſumed by fire; and the commiſſioners, terrified at the work of their own hands, fled for protection to a ſhip of the line, and thence iſſued a manifeſto, which, while it tried to extenuate, evinced a conſciouſneſs of their guilt.

Thus was loſt the fineſt iſland in the Weſt Indies; an iſland which produced alone as much ſugar as all the Britiſh Weſt India poſſeſſions united; not to mention the coffee and indigo, which were in immenſe quantities cultivated in Hiſpaniola. Had it not been for the reſtleſs machinations of the *Amis des Noirs*, it does not appear that ſo general a revolt would have taken place among the ſlaves; for though the ſpirit of republicaniſm had found its way into the iſland, the republicans joined with the royaliſts to keep the negroes in proper ſubjection. The unſucceſsful attempt which, at the requeſt of the more reſpectable part of the inhabitants, the Britiſh government made to ſubdue the execrable commiſſioners and their adherents, is freſh in the memory of all our readers, and need not here be detailed at length. Suffice it to ſay, that after prodigies of valour, our troops were compelled, rather by diſeaſe than by the ſwords of the enemy, to abandon the iſland. Touſſaint L'Ouverture, a black chief, converted it into an independent republic, and continued to govern it undiſturbed, till the preliminaries of peace were ſigned between Britain and France in 1801. Immediately after that event, Bonaparte diſpatched a fleet from Breſt, with the permiſſion of our government, carrying a conſiderable army under the command of general Le Clerc. Touſſaint at firſt refuſed to ſubmit. Several bloody actions were fought between the French troops and the blacks, in which the former were uniformly ſucceſsful. The open country was ſoon abandoned by the negroes: ſeveral of Touſſaint's generals ſubmitted; and at laſt he himſelf was prevailed upon, by the addreſs and the magnificent promiſes of Le Clerc, not only to throw down his arms, but to put himſelf into the power of the French general. For ſome days theſe promiſes were religiouſly obſerved; but a pretence was ſoon found for breaking them. Touſſaint was ſtript of his immenſe property, and ſent priſoner to France. Thus was the colony recovered to France in a ſtill ſhorter time than it had been loſt. Since that event, nothing has tranſpired concerning the ſtate of the iſland, or the regulations which the French find it neceſſary to make. But it is obvious, that a conſiderable period muſt elapſe before it can be reſtored to that ſtate of proſperity which it formerly enjoyed.

HOLLOW, in architecture, a concave moulding, about a quarter of a circle, by ſome called a caſement, by others an abacus.

Hollow-Tower, in fortification, is a rounding made of the remainder of two briſures, to join the curtain to the orillon, where the ſmall ſhot are played, that they may not be ſo much expoſed to the view of the enemy.

HOMODROMUS Vectis, or *Lever*, in mechanics, is a lever in which the weight and power are both on the ſame ſide of the fulcrum as in the lever of the 2d and 3d kind; being ſo called, becauſe here the weight and power move both in the ſame direction, whereas in the heterodromus they move in oppoſite directions.

HOOKE (Dr Robert) is ſaid, in the account of him which is publiſhed in the *Encyclopædia*, to have laid claim to the inventions of others, and to have boaſted of many of his own, which he never communicated. We will not preſume to ſay that this charge is entirely groundleſs; but we know that it has been greatly exaggerated, and that many diſcoveries undoubtedly made by him have been claimed by others. Of this the reader will find one conſpicuous proof under the article Watch (*Encycl.*); and perhaps the following hiſtory of the inventions to which he laid claim may furniſh another. It would be harſh to charge him with falſity in any of them; that is to ſay, to imagine that he either ſtole them from others, or did not *think*, at leaſt, that he was *an* inventor. And, with reſpect to many of them, the priority of his claim is beyond diſpute.

1656, Barometer, a weather glaſs.

1657, A ſcapement, for maintaining the vibration of a pendulum.—And not long after, the regulating or balance ſpring for watches.

1658, The double barrelled air-pump.——The conical pendulum.—His firſt employment of the conical pendulum was no leſs ingenious and ſcientific than it was original. He employed it to repreſent the mutual gravitation of the planets; a fact which he had moſt ſyſtematically announced. He had ſhewn that a force, perfectly analogous to gravity on this earth, operated on the ſurface of the moon and of Jupiter. Conſidering the numerous round pits on the ſurface of the moon, ſurrounded with a ſort of wall, and having a little eminence in the middle, as the production of volcanoes, he inferred, that the ejected matter fell back again to the moon, as ſuch matter falls back again to the earth. He ſaw Jupiter ſurrounded with an atmoſphere, which accompanied him; and therefore preſſed on him, as our air preſſes on the earth:—He inferred, that it was the ſame kind of power that maintained the ſun and other planets in a round form. He inferred a force to the ſun from the circulation round him, and he called it a *gravitation*; and ſaid that it was not the earth which deſcribed the ellipſe, but the centre of gravity of the earth and moon. He therefore made a conical pendulum, whoſe tendency to a vertical poſition repreſented the gravitation to the ſun, and which was projected at right angles to the vertical plane; and ſhewed experimentally, how the different proportions of the projectile and centripetal tendencies produced various degrees of eccentricity in the orbit. He then added another pendulum, deſcribing a cone round the firſt, while this deſcribed a cone round the vertical line, in order to ſee what point between them deſcribed the ellipſe.

ellipſe. The reſults of the experiment were intricate and unſatisfactory ; but the thought was ingenious. He candidly acknowledged, that he had not diſcovered the true law of gravitation which would produce the deſcription of an ellipſe *round the focus*, owing to his want of due mathematical knowledge ; and therefore left this inveſtigation to his ſuperiors. Sir Iſaac Newton was the happy man who made the diſcovery, after having entertained the ſame notions of the forces which connected the bodies of the ſolar ſyſtem, before he had any acquaintance with Dr Hooke, or knew of his ſpeculations.

1660, The engine for cutting clock and watch wheels. —The chief phenomena of capillary attraction.—The freezing of water at a fixed temperature.

1663, The method of ſupplying air to a diving bell. —The number of vibrations made by a muſical chord.

1664, His Micrographia was, by the council of the Royal Society, ordered to be printed; but in that work are many juſt notions reſpecting reſpiration, the compoſition of the atmoſphere, and the nature of light, which were afterwards attributed as diſcoveries to Mayow and others, who, though we are far from ſuppoſing that they ſtole their diſcoveries from Dr Hooke, were certainly anticipated by him.

1666, A quadrant by reflection.

1667, The marine barometer.—The gage for ſounding unfathomable depths.

1668, The meaſurement of a degree of the meridian, with a view to determine the figure of the earth, by means of a zenith ſector.

1669, The fact of the *conſervatio virium vivarum*, and that in all the productions and extinctions of motion, the accumulated forces were as the ſquares of the final or initial velocities. This doctrine he announces in all its generality and importance, deducing from it all the conſequences which John Bernoulli values himſelf ſo highly upon, and which are the chief facts adduced by Leibnitz in ſupport of his doctrine of the forces of bodies in motion. But Hooke was perfectly aware of their entire correſpondence with the Carteſian, or common doctrine, and was one of the firſt in applying the celebrated 39th propoſition of Newton's Principia to his former poſitions on this ſubject, as a mathematical demonſtration of them.

1673, That the catenaria was the beſt form of an arch.

1674, Steam engine on Newcomen's principle.

1679, That the air was the ſole ſource of heat in burning: That combuſtion is the ſolution of the inflammable vapour in air ; and that in this ſolution the air gives out its heat and light. That nitre explodes and cauſes bodies to burn without air, becauſe it conſiſts of this air, accompanied by its heat and light in a condenſed or ſolid ſtate ; and air ſupports flame, becauſe it contains the ſame ingredients that gunpowder doth, that is, a nitrous ſpirit : That this air diſſolves ſomething in the blood while it is expoſed to it in the lungs in a very expanded ſurface, and when ſaturated with it, can no longer ſupport life nor flame ; but in the act of ſolution, it produces animal heat : That the arterial and venal blood differ on account of this ſomething being wanting in one of them. In ſhort, the fundamental doctrines of modern chemiſtry are ſyſtematically delivered by Dr Hooke in his Micrographia, publiſhed in 1664, and his Lampas, publiſhed in 1677.

1680, He firſt obſerved the ſecondary vibrations of elaſtic bodies, and their connection with harmonic ſounds. A glaſs containing water, and excited by a fiddleſtick, threw the water into undulations, which were ſquare, hexagonal, octagonal, &c. ſhewing that it made vibrations ſubordinate to the total vibration ; and that the fundamental ſound was accompanied by its octave, its twelfth, &c.

1681, He exhibited muſical tones by means of toothed wheels, whirled round and rubbed with a quill, which dropped from tooth to tooth, and produced tones proportioned to the frequency of the cracks or ſnaps.

1684, He read a paper before the Royal Society, in which he affirms, that ſome years before that period, he had propoſed a method of diſcourſing at a diſtance, not by ſound, but by ſight. He then proceeds to deſcribe a very accurate and complete telegraph, equal, perhaps, in all reſpects to thoſe now in uſe. But ſome years previous to 1684, M. Amontans had not invented his telegraph ; ſo that, though the Marquis of Worceſter unqueſtionably gave the firſt hint of this inſtrument, Dr Hooke appears to have firſt brought it to perfection. See Telegraph, *Encycl.* ; and a book, publiſhed 1726, entitled *Philoſophical Experiments and Obſervations* of the late eminent Dr Robert Hooke.

We are indebted to him for many other diſcoveries of leſſer note ; ſuch as the wheel barometer, the univerſal joint, the manometer, ſcrew divided quadrant, teleſcopic ſights for aſtronomical inſtruments, repreſentation of a muſcular fibre by a chain of bladders, experiments ſhewing the inflection of light, and its attraction for ſolid bodies, the curvilineal path of light thro' the atmoſphere.

HORNE (George, D. D.), late Lord Biſhop of Norwich, was a man of ſuch amiable diſpoſitions, primitive piety, and exemplary morals, that we wiſh it were in our power to do juſtice to his character. His life, it is true, has been already written, at conſiderable length, by two authors, poſſeſſed of erudition and of unqueſtionable integrity ; but mere erudition is by no means ſufficient to fit a man for diſcharging the duties of a biographer. It was not the learning of Johnſon, but his ſagacity, and intimate acquaintance with human nature, that placed him ſo far above his contemporaries in this department of literature.

Of Biſhop Horne's biographers, one poſſeſſed, indeed, the great advantage of having lived in habits of intimacy with him from his boyiſh years. In the authenticity of his narrative, therefore, the fulleſt confidence may be placed : and that narrative we ſhall faithfully follow ; reſerving, however, to ourſelves the liberty of ſometimes making reflections on the various incidents recorded, widely different from thoſe of the author.

George Horne was, in 1730, born at Otham in Kent, a village near Maidſtone, giving the name to a pariſh, of which his father was the rector. He was the ſecond of four ſons ; of whom the eldeſt died in very early life, and the youngeſt, who is ſtill alive, ſucceeded his father both in the rectory of Otham and in that of Breda in the county of Suſſex. He had likewiſe three ſiſters, of whoſe fortunes we know nothing.

Mr Horne, the father of the family, was of a temper ſo remarkably averſe from giving pain or trouble upon any occaſion, that he uſed to awake his ſon George, when an infant, by playing upon a flute, that the change from ſleeping to awaking might be gradual and pleaſant. Having been for ſome years a tutor at Oxford, he took upon himſelf the early part of the claſſical education of this favourite ſon; an office of which he was well qualified to diſcharge the duties. Uunder ſuch an inſtructor, the ſubject of this memoir led a very pleaſant life, and made a rapid progreſs in the Greek and Latin languages. By the perſuaſion of a friend, however, he was, at the age of thirteen, placed in the ſchool of Maidſtone, then under the care of a Mr Bye, eminent for his knowledge of ancient literature. And remaining with this gentleman two years, he added much to his ſtock of learning; and, among other things, a little elementary knowledge of the Hebrew tongue, which Mr Bye taught on the plan of Buxtorf. Though Dr Horne afterwards rejected that plan, he readily admitted, that the knowledge of it was of great advantage to him.

At the age of fifteen, he was removed from Maidſtone ſchool to Univerſity college Oxford, where his father had happily obtained for him a ſcholarſhip. At college his ſtudies were, in general, the ſame with thoſe of other virtuous and ingenious youths; while the vivacity of his converſation, and the propriety of his conduct, endeared him to all whoſe regard was creditable. About the time of his taking his bachelor's degree, he was choſen a fellow of Magdalen College; and ſoon afterwards, if not before, commenced author.

The hiſtory of his authorſhip is curious, and we ſhall give it at ſome length. While he was deeply engaged in the ſtudy of oratory, poetry, and every branch of polite literature, he was initiated by his faithful friend Mr Jones in the myſteries of Hutchinſonianiſm; but Mr Jones was not his preceptor. Indeed that gentleman informs us, that when he firſt communicated to Mr Horne the novelties with which his own mind was filled, he found his friend very little inclined to conſider them; and had the mortification to ſee, that he was himſelf loſing ground in Mr Horne's eſteem, even for making the attempt to convert him. At this we are not to be much ſurpriſed. Mr Horne, though, by his biographer's account, no deep Newtonian, ſaw, or thought he ſaw, the neceſſity of a *vacuum* to the poſſibility of *motion*; and as we believe that every man, who knows the meaning of the words *motion* and *vacuum*, and whoſe mind is not biaſſed in favour of a ſyſtem, ſees the ſame thing, it was not to be ſuppoſed, that a youth of ſound judgment would haſtily relinquiſh ſo natural a notion. By Mr Horne, however, it was at length relinquiſhed. Mr Jones introduced him to Mr George Watſon, a fellow of Univerſity college, whom he repreſents as a man of very ſuperior accompliſhments; and by Mr Watſon Mr Horne was made a Hutchinſonian of ſuch zeal, that at the age of nineteen, he implicitly adopted the wild opinion of the author of that ſyſtem, that Newton and Clarke had formed the deſign of bringing the Heathen *Jupiter*, or Stoical *anima mundi*, into the place of the God of the univerſe. With ſuch a conviction impreſſed upon his mind, it is not wonderful that he ſhould endeavour to diſcredit the ſyſtem of Newton. This he attempted, by publiſhing a parallel between that ſyſtem and the Heathen doctrines in the *Somnium Scipionis* of Cicero. That publication, which was anonymous, we have never ſeen; but Mr Jones himſelf admits it to have been exceptionable; and the amiable author ſeems to have been of the ſame opinion, for he never republiſhed it, nor, we believe, replied to the anſwers which it provoked.

He did not, however, deſert the cauſe, but publiſhed, ſoon afterwards, a mild and ſerious pamphlet, which he called *A Fair, Candid, and Impartial State of the Caſe between Sir Iſaac Newton and Mr Hutchinſon*. Even of this pamphlet we have not been able to procure a ſight; but Mr Jones aſſures us, that the author allows to Sir Iſaac the great merit of having ſettled laws and rules in natural philoſophy, and of having meaſured *forces* as a mathematician with ſovereign ſkill; whilſt he claims for Mr Hutchinſon the diſcovery of the true phyſiological cauſes, by which, under the power of the Creator, the natural world is moved and directed.

If this be a fair view of *the ſtate of the caſe*, it allows to Newton more than ever Newton claimed, or has been claimed for him by his fondeſt admirers; for the laws and rules, which he ſo faithfully followed in the ſtudy of philoſophy, were not ſettled by him, but by the illuſtrious Bacon. With reſpect to the *true* cauſes here mentioned, we have repeatedly had occaſion, during the courſe of this Work, to declare our opinion, that all men are equally ignorant of them, if they be conſidered as any thing diſtinct from the general *laws* by which the operations of nature are carried on. To the diſcovery of other phyſiological cauſes, Newton, in his greateſt work, made indeed no pretenſion; but it may be worth while, and can hardly be conſidered as a digreſſion, to conſider what are the pretenſions of Huchinſon, to which Meſſrs Horne and Jones gave ſo decided a preference.

Mr Hutchinſon himſelf writes ſo obſcurely, that we dare not venture to tranſlate his language into common Engliſh, leſt we ſhould undeſignedly miſrepreſent his meaning; but according to Mr Jones, who has ſtudied his works with care, his diſtinguiſhing doctrine in philoſophy is, that "The forces, of which the Newtonians treat, are not the forces of nature; but that the world is carried on by the action of the elements on one another, and all under God." What is here meant by the elements, we are taught by another eminent diſciple of that ſchool. "The great agents in nature, which carry on all its operations, are certainly (ſays Mr Parkhurſt) the *fluid* of the heavens; or, in other words, the fire at the orb of the ſun, the light iſſuing from it, and the ſpirit or groſs air conſtantly ſupporting, and concurring to the actions of the other two." (See CHERUBIM in this *Supplement*). Mr Horne adopted this ſyſtem in preference to the Newtonian; becauſe, ſays his biographer, "It appeared to him nothing better than raving, to give active powers to matter, ſuppoſing it capable of acting where it is not; and to affirm, at the ſame time, that all matter is inert, that is, inactive; and that the *Deity* cannot act but where he is *preſent*, becauſe his *power* cannot be but where his *ſubſtance* is."

That much impious arrogance has been betrayed, not by Newtonians only, but by philoſophers of every ſchool, when treating of the *modus operandi* of the Deity, we feel not ourſelves inclined to controvert; but we never knew a well-informed Newtonian, who ſpoke of the active powers of matter but in a metaphorical ſenſe; and ſuch language is uſed, and muſt be uſed, by the

the followers of Hutchinſon. Mr Jones ſpeaks of the *action* of the elements; and Mr Parkhurſt calls the fluid of the heavens, which, according to him, conſiſts of fire, light, and air, *agents*; but it would ſurely be uncandid to accuſe theſe two pious men of *animating* the elements, though we know that *action* and *activity*, in the literal ſenſe of the words, can be predicated only of living beings. With reſpect to giving active powers to matter, therefore, the followers of Hutchinſon rave juſt as much as thoſe of Newton; and we ſee not the raving of either in any other light than as the neceſſary conſequence of the poverty of language.

But the Newtonian makes matter act upon matter at a diſtance! No; the genuine Newtonian does not make matter *act* (in the proper ſenſe of the word) at all; but he believes, that God has ſo conſtituted matter, that the motions of different maſſes of it are affected by each other at a diſtance; and the Hutchinſonian holds the very ſame thing. As this celeſtial fluid of Mr Parkhurſt's conſiſts partly of air, we know, by the teſt of experiment, that it is elaſtic. The particles of which it is compoſed are therefore diſtant from each other; and yet they reſiſt compreſſion. How does the Hutchinſonian account for this fact? Perhaps he will ſay, that as matter is in itſelf equally indifferent to motion and reſt, God has ſo conſtituted the particles of this fluid, that though they poſſeſs no innate power or activity of their own, they are affected by each other at a diſtance, in conſequence of his fiat at the creation. This we believe to be the only ſolution of the difficulty which can be given by man; but it is the very anſwer given by the Newtonians to thoſe who object to them the abſurdity of ſuppoſing matter to be affected by matter at a diſtance. That the motions of the heavenly bodies are affected by the preſence of each other is a fact, ſay they, which appears incontrovertible. "We have aſcertained with preciſion the laws by which theſe motions are regulated; and without troubling ourſelves with the true phyſiological cauſes, have demonſtrated the agreement of the phenomena with the laws. The interpoſition of this celeſtial fluid removes not a ſingle difficulty with which our doctrine is ſuppoſed to be clogged. To have recourſe to it can therefore ſerve no purpoſe, even were the phenomena conſiſtent with the nature of an elaſtic fluid conſidered as a phyſical cauſe; but this is not the caſe. It is demonſtrable (ſee ASTRONOMY and DYNAMICS in this *Suppl.*) that the motions of the heavenly bodies are not conſiſtent with the mechaniſm of an elaſtic fluid, conſidered as the cauſe of theſe motions; and therefore, whether there be ſuch a fluid or not diffuſed through the ſolar ſyſtem, we cannot allow that it is the great agent in nature by which all its operations are carried on."

Such might be the reaſoning of a well-informed Newtonian in this controverſy; and it appears ſo concluſive againſt the objections of Hutchinſon to the Newtonian forces, as well as againſt the agents which he has ſubſtituted in their ſtead, that ſome of our readers may be diſpoſed to call in queſtion the ſoundneſs of that man's underſtanding who could become a Hutchinſonian ſo zealous as Mr Horne. But to theſe gentlemen we beg leave to reply, that the ſoundeſt and moſt upright mind is not proof againſt the influence of a ſyſtem, eſpecially if that ſyſtem has novelty to recommend it, and at the ſame time conſiſts of parts, of which, when taken ſeparately, many are valuable. Such was the ſyſtem of Hutchinſon when adopted by Mr Horne. It was then but very little known; it could be ſtudied only through the medium of Hebrew literature, not generally cultivated; and that literature, to the cultivation of which Mr Hutchinſon had given a new and a better turn, is in itſelf of the utmoſt importance. Let it be obſerved, too, that the Hutchinſonians have, for the moſt part, been men of devout minds, zealous in the cauſe of Chriſtianity, and untainted by Arianiſm, Socinianiſm, and the other hereſies which have ſo often divided the church of Chriſt:—and when all theſe circumſtances are taken into conſideration, it will not be deemed a proof of any defect in Mr Horne's underſtanding, that in early life he adopted the *whole* of a ſyſtem, of which ſome of the parts contain ſo much that is good; eſpecially when it is remembered, that at *firſt view* the agency of the celeſtial fluid appears ſo plauſible, that for a time it ſeems to have impoſed upon the mind of Newton himſelf.

But the truth is, that Mr Horne was at no period of his life a thorough-paced Hutchinſonian. It is confeſſed by Mr Jones, "that Mr Hutchinſon and his admirers laid too great a ſtreſs on the evidence of Hebrew etymology; and that ſome of them carried the matter ſo far, as to adopt a mode of ſpeaking, which had a nearer reſemblance to cant and jargon than to ſound ſenſe and ſober learning. Of this (continues he) Mr Horne was very ſoon aware; and he was in ſo little danger of following the example, that he uſed to diſplay the foibles of ſuch perſons with that mirth and good humour," which he poſſeſſed in a more exquiſite degree than moſt men. This ſeems to be complete evidence that he was never a friend to the etymological part of the ſyſtem; and the preſent writer can atteſt, that, in the year 1786, he ſeemed by his converſation to have loſt much of his conviction of the agency of the celeſtial fluid. He continued, indeed, to ſtudy the Hebrew Scriptures on the plan of Mr Hutchinſon, unincumbered with the Maſoretic points, or with rabbinical interpretations; and the fruits of his ſtudies are in the hands of the religious public, in works which, by *that* public, will be eſteemed as long as their language is underſtood.

Hitherto Mr Horne was a layman, but he intereſted himſelf in every thing connected with religion, as much as the moſt zealous dignitary of the church; and conſidering the *naturalization* of the Jews as a meaſure at leaſt indecent in a Chriſtian country, he publiſhed, in an evening paper, a ſeries of letters on that ſubject, both when the Jew-bill was depending, and after it had paſſed the houſe. The letters were anonymous; but they attracted much notice, and many groundleſs conjectures were made reſpecting their author. To the real author, the meaſure which they oppoſed was ſo very obnoxious, that he refuſed to dine at the table of a friend, only becauſe the ſon-in-law of Mr Pelham was to be there. And he was not much more friendly to the marriage-act than to the Jew-bill. If he conſidered the one as diſgraceful to religion, he probably thought that the other, with its numerous clauſes, might be made a ſnare for virtue.

The time now approached when he was to take holy orders, which to him was a very ſerious affair; and when he gave an account of his ordination to an intimate friend, he concluded the letter with the following reflections, which, even in an abſtract like this, it would be unpardonable to omit :

“ May he, who ordered Peter three times to *feed his lambs*, give me grace, knowledge, and ſkill, to watch and attend to the flock which he purchaſed upon the croſs, and to give reſt to thoſe who are under the burden of ſin and ſorrow. It hath pleaſed God to call me to the miniſtry in very troubleſome times indeed, when a lion and a bear have broken into the fold, and are making havoc among the ſheep. With a firm, though humble confidence, do I purpoſe to go forth ; not in my own ſtrength, but in the ſtrength of the Lord God ; and may he proſper the work of my hands !” This was in the year 1753, when the pious author was hardly 23 years of age ; and he had not been many months in orders, when one of the moſt celebrated preachers in the metropolis pronounced, that “ George Horne was, without exception, the beſt preacher in England.”

In the year 1756, he was again involved in controverſy. A pamphlet had been publiſhed at Oxford, ſuppoſed by Mr Kennicott, who afterwards gained ſuch fame as a collector of Hebrew manuſcripts, entitled *A Word to the Hutchinſonians*, in which Mr Horne was perſonally ſtruck at. To this work our author replied in a ſmall tract, called *An Apology for certain Gentlemen in the Univerſity of Oxford, Aſperſed in a late Anonymous Pamphlet* ; and whatever may be thought of the queſtion at iſſue, all men muſt admire the temper with which the apologiſt conducted himſelf under very great provocation.

But it was not about Hutchinſonianiſm alone that theſe two illuſtrious men were doomed to differ. Mr Horne took a decided part againſt Mr Kennicott's propoſal for collating the text of the Hebrew bible, with ſuch manuſcripts as could be found, for the purpoſe of *reforming the text*, and preparing it for a new tranſlation into the Engliſh language ; and in the year 1760, he publiſhed *A View of Mr Kennicott's Method of Correcting the Hebrew Text, with three Queries formed thereon, and humbly ſubmitted to the Chriſtian world.* That his alarm was on this occaſion too great, experience has ſhewn ; but that it was not groundleſs, is evident from the *View*, in which the reader will find above 20 inſtances from Mr Kennicott's diſſertations (ſee KENNICOTT, *Encycl.*), to ſhew what an inundation of licentious criticiſm was breaking in upon the ſacred text. Indeed there is reaſon to believe, that this tract, together with another on the ſame ſide of the queſtion by Dr Rutherford of Cambridge, contributed to repreſs the collector's raſhneſs, and to make the Bible of Dr Kennicott the valuable work which we find it. Be this as it may, ſuch was the moderation of the Drs Kennicott and Horne, that though their acquaintance commenced in hoſtility, they at length contracted for each other a friendſhip, which laſted to the end of their lives, and ſtill ſubſiſts between their families.

In what year Mr Horne was admitted to the degree of D. D. and when he was choſen preſident of his college, Mr Jones has not informed us ; but, if our memory does not deceive us, he had obtained both theſe preferments when, in the year 1772, he gave to the public a ſmall work, 8vo, entitled *Conſiderations on the Life and Death of St John the Baptiſt.* This tract was the ſubſtance of a courſe of ſermons, which he had many years before, in conformity to an eſtabliſhed cuſtom at Magdalen College, preached before the univerſity of Oxford. Mr Jones, ſpeaking of it, ſays, that “ he is perſuaded there was no other man of his time, whoſe fancy as a writer was bright enough, whoſe ſkill as an interpreter was deep enough, and whoſe heart as a moraliſt was *pure* enough, to have made him the author of that little work.” By moſt readers this ſtrain of panegyric will be thought extravagant, and of courſe it will defeat its own purpoſe ; but the work is certainly a work of merit.

In the year 1776, when the author was vice-chancellor, was publiſhed, in two volumes 4to, Dr Horne's Commentary on the Pſalms. It is a work of which very different opinions have been formed, though it was the reſult of the labour of twenty years. That it will always be a favourite companion of the devout Chriſtian, we are as much inclined to believe as Mr Jones ; but we cannot, without belying our own judgment, ſay that it appears to us calculated to produce much general good in an age like the preſent. Granting it to be true, which we believe will not be granted without ſome exceptions, that Clarke, and Hoadley, and Hare, and Middleton, and Warburton, and SHERLOCK, and SOUTH, and WILLIAM LAW, and Edmund Law, had turned the public attention, of which they had got the entire command, too much to the *letter* of the Bible to the neglect of the *ſpirit* of it ; ſhould not Dr Horne, after the example of St Paul, have let in the light gradually upon ſuch weak organs as thoſe of the public thus diſeaſed, rather than pour it upon them at once in a flood of ſplendor. The apoſtle “ fed his Corinthian converts with milk and not with meat” when he found them unable to bear the latter food ; and there is reaſon to ſuſpect that the carnal followers of Warburton, and Sherlock, and South, were unable to bear, at once, ſuch ſtrong meat, as that which makes the fifteenth pſalm a portrait of our Saviour. Indeed, we think it not improbable that the mind of Sherlock would have recoiled with horror from the very conception of the *poſſibility* of Jeſus Chriſt “ ſwearing to his neighbour and diſappointing him,” though that conception muſt have paſſed through a mind which was certainly as pure as his. The commentary, however, though truth thus compels us to ſay that, in our opinion, it is far from perfect, is certainly a work of great learning, great genius, and fervent piety, and ſuch as the devout Chriſtian will peruſe again and again with much advantage.

Dr Horne's next work was of a different kind, and, we think, of a ſuperior order. In the year 1776 was publiſhed a letter of Dr Adam Smith's, giving an account of the death of Mr David Hume. The object of the author was to ſhew that Mr Hume, notwithſtanding his ſceptical principles, had died with the utmoſt compoſure, and that in his life, as well as at his death, he had conducted himſelf as became one of the wiſeſt and beſt men that ever exiſted. The letter is very much laboured, and yet does no honour either to the author or his friend. It could not repreſent Mr Hume as ſupporting himſelf under the gradual decay of nature with the hopes of a happy immortality ; but it might have repreſented him as taking refuge, with other infidels, in the eternal ſleep of death. This, though but a gloomy proſpect, would not have been childiſh; but the hero of the tale is exhibited as talking like a ſchool-boy of his conferences with Charon, and his reluctance to go into the Stygian ferry-boat, and as conſoling himſelf with the thought of leaving all his friends, and his brother's family in particular, in great proſperity!!! The abſurdities of this letter did not eſcape the watchful and penetrating eye of Dr Horne; and as he could not miſtake its object, he held it up to the contempt and ſcorn of the religious world in *A Letter to Adam Smith, L. L. D. on the Life, Death, and Philoſophy of his Friend David Hume, Eſq; by one of the People called Chriſtians.* The reaſoning of this little tract is clear and concluſive, while its keen, though good humoured wit is inimitable; and it was, ſome years afterwards, followed by a ſeries of *Letters on Infidelity*, compoſed on the ſame plan, and with much of the ſame ſpirit. This ſmall volume, to the ſecond edition of which the letter to Dr Smith was prefixed, is better calculated than almoſt any other with which we are acquainted, to guard the minds of youth againſt the inſidious ſtrokes of infidel ridicule, the only dangerous weapon which infidelity has to wield.

When the letters on infidelity were publiſhed, their author had for ſome time been Dean of Canterbury, where he was beloved by the chapter and almoſt adored by the citizens. He was a very frequent preacher in the cathedral and metropolitical church, where the writer of this ſhort ſketch has liſtened to him with delight, and ſeen thouſands of people of very various deſcriptions hang with rapture on his lips. As a preacher indeed he excelled; and notwithſtanding the ſhortneſs of his ſight, which deprived him of ſome of the graces of a pulpit orator, ſuch were the excellence of his matter, the ſimple elegance of his ſtyle, and the ſweetneſs of his voice, that, when at the primary viſitation of the preſent archbiſhop, he preached his admirable ſermon *on the Duty of Contending for the Faith*, the attention of more than 2000 people was ſo completely fixed, that the ſmalleſt noiſe was not to be heard through the whole crowded choir. Of the importance of preaching, and of the proper mode of performing that duty, he had very juſt notions; and though he never had himſelf a parochial cure of ſouls, it was the deſire and pleaſure of his life to make himſelf uſeful in the pulpit wherever he was, whether in town or in the moſt obſcure corner of the country. Four or five volumes of his ſermons have been publiſhed ſince his death.

In the year 1787 he publiſhed, under the name of an undergraduate of the univerſity of Oxford, *a letter to Dr Prieſtley*, in which he made that oracle of Socinianiſm almoſt as ridiculous as, in the letter to Dr Smith, he had formerly made the hero of modern ſcepticiſm.

The merits of Dr Horne, which had made him preſident of Magdalen College, a king's chaplain, and dean of Canterbury, raiſed him, we think, in the year 1790, to the ſee of Norwich; and he had ſoon an opportunity of ſhewing that he had not loſt ſight of his ſpiritual character in the ſplendour of the peer of parliament. The Scotch Epiſcopalians had for ſome time been ſoliciting the legiſlature to repeal certain penal laws of uncommon ſeverity, under which they had groaned for upwards of forty years; but they found it a work of no little difficulty to make the equity of their claim generally underſtood*. In removing this difficulty no man was more aſſiſting to them than the Dean of Canterbury, to whom their religious and political principles were well known; and he continued his aſſiſtance after he was biſhop of Norwich. Indeed the whole bench ſhewed, on this occaſion, a zeal for the intereſts of true religion every way becoming their character of Chriſtian biſhops; and after Dr Horne was removed to a better world, the Scotch Epiſcopalians found among his ſurviving brethren friends as zealous and active as he.

Dr Horne, though a very handſome man, was not naturally of a ſtrong conſtitution; and from the diſadvantage of being uncommonly near-ſighted, he had not been able to increaſe its ſtrength by the practice of any athletic exerciſe. The only amuſement in which he took delight was agreeable converſation; and his life was therefore what is called ſedentary. The conſequence of this was, that the infirmities of age came faſt upon him; and when the deſign was formed of making him a biſhop, he felt himſelf little inclined to undertake the charge of ſo weighty an office. He was, however, prevailed upon to accept of the ſee of Norwich; but he enjoyed his new dignity for a very ſhort period, if he can with truth be ſaid to have *enjoyed* it at all. His health declined rapidly; and, in the autumn of 1791, he ſuffered, while on the road from Norwich to Bath, a paralytic ſtroke, the effects of which he never recovered. He lingered a month or two, with ſuch apparent changes in the ſtate of his health as ſometimes gave deluſive hopes to his family, till the 17th of January 1792, when he died in the 62d year of his age, with thoſe hopes which can be excited only by the conſciouſneſs of a well ſpent life, and by a firm truſt in the promiſes of the goſpel.

In this ſhort ſketch of the life of biſhop Horne we have taken the liberty to expreſs our diſſent from ſome of his opinions, and to ſtate the reaſons on which that diſſent reſts. By himſelf we know that this part of our conduct would have been applauded; but it is poſſible that by ſome of his friends it may be deemed diſreſpectful to his memory. To theſe gentlemen we beg leave to obſerve, that if Johnſon made the praiſe of *Kyrl*, Pope's Man of Roſs, really more ſolid by making it more credible, it will be difficult to perſuade us that we have done any injury to Dr Horne's fame by avoiding the extravagant panegyric of thoſe who ſeem to have conſidered him as a man exempted from error. He was firſt induced to favour the Hutchinſonians becauſe he thought he perceived danger to religion in the Newtonian doctrines of attraction and repulſion; and we very readily admit that many Newtonians, not underſtanding the doctrines of their maſter, have expreſſed themſelves in ſuch a manner as could not render a religious man partial to their ſyſtem. But from the dangers of miſtake, no ſyſtem, whether religious or philoſophical, was ever free; and the atheiſtical purpoſes which the agency of ethers and celeſtial fluids has lately been made to ſerve, muſt induce every man of piety to pauſe before he admit ſuch agency. Dr Horne lived to witneſs ſome of its pernicious effects; and we have reaſon to believe that they made a due impreſſion on his mind; but he ſpent his latter years, as indeed he had ſpent the greater part of his life, in nobler purſuits than the ſtudy of human ſcience; he ſpent them in the proper employments of a Chriſtian, a clergyman, and a biſhop. His faith was founded on a rock; and it was that genuine faith which worketh by love; for though his preferments

---

* See Scotch Episcopalians in this *Supplement*.

were rich, his charity kept pace with them; and it has been proved that, notwithſtanding his proper economy, he hoarded not one ſhilling of his annual income. This was an elevation of character above all literary, above all philoſophical fame. The author of this article had the honour to be known to Dr Horne, to enjoy, if he miſtook not, a ſhare in his friendſhip, and to correſpond with him regularly for many years; and there is not one of his rational admirers who more fully admits the truth of the character given of him by Dr Thurlow late biſhop of Durham when ſucceeding him in the office of proctor in the Univerſity. "As to the laſt proctor (ſaid he) I ſhall ſpeak of him but in few words, for the truth of which I can appeal to all that are here preſent. If ever virtue itſelf was viſible and dwelt upon earth, it was in the perſon who this day lays down his office."

Soon after he was advanced to the preſidentſhip of Magdalen college, this great and good man married the only daughter of Philip Burton, Eſq; a gentleman of conſiderable fortune. By this lady he had three daughters, of whom the eldeſt was married to a clergyman a ſhort time before the death of her father, and the two younger were, in 1796, reſiding with Mrs Horne in Hertfordſhire.

HOROGRAPHY, the art of making or conſtructing dials; called alſo dialing, horologiography, gnomonica, ſciatherica, photoſciatherica, &c.

HOROPTER, in optics, is a right line drawn through the point where the two optic axes meet, parallel to that which joins the centres of the two eyes, or the two pupils.

HORSE-Shoe, in fortification, is a work ſometimes of a round, ſometimes of an oval figure, incloſed with a parapet, raiſed in the ditch of a marſhy place, or in low grounds; ſometimes alſo to cover a gate; or to ſerve as a lodgment for ſoldiers, to prevent ſurpriſes, or relieve an over-tedious defence.

HOVEN is a word of the ſame import with *raiſed, ſwelled, tumefied*. It is particularly applied to black cattle and ſheep, when from eating too voraciouſly of clover, or any other ſucculent food, they become ſwollen. Such cattle are, in the language of the farmer, called

Hoven-Cattle; and the beaſt, whether bullock or ſheep, which is hoven, when left without relief, dies in half an hour. The cauſe of the diſeaſe is the extra quantity of air taken down with that kind of food, which, in its paſſage from the paunch upwards, forces the broad leaves of the clover before it, till they cloſe up the paſſage at the entrance of the paunch, and prevent the wind from going upwards in its regular courſe. The uſual method of relief is to ſtab the animal in the paunch; an operation which is always dangerous, and has often proved fatal. It was therefore, with good reaſon, that the Society for the Encouragement of Arts, Manufactures, and Commerce, voted a bounty of fifty guineas to Mr Richard Eagar of Graſſham farm, near Guildford, for making public a very ſimple method practiſed by him for the cure of hoven-cattle. It is this; "let the grazier or farmer have always ready ſmooth knobs of wood, of different ſizes, fixed to the end of a flexible cane, which for oxen ſhould be at leaſt ſix feet long, and for ſheep three feet. When a beaſt is hoven, let one perſon take hold of him by the noſtril and one horn; let another hold his tongue faſt in one hand, putting the cane down his throat with the other. Be careful not to let the animal get the knob of the cane between his grinders: obſerve alſo to put the cane far enough down; the whole length will not injure. You will find the obſtacle at the entrance of the paunch: puſh the cane hard, and when you perceive a ſmell to come from the paunch, and the animal's body to ſink, the cure is performed, and Nature will act for itſelf."

This method, we doubt not, will prove ſucceſsful; but might not the purpoſe be as well, if not better, effected, by uſing, inſtead of the cane and knob, a piece of thick ſtiff rope, which, in many places of Scotland, is employed to force down turnips or potatoes when they ſtick in the throat of a bullock?

HOUGHTON (——) is a man to whom the ſcience of geography is ſo much indebted, that we are almoſt aſhamed to confeſs that we know not his Chriſtian name, the place where he was born, or the age at which he died. He had been a captain in the 69th regiment, and in the year 1779 had acted under General Rooke as fort-major in the iſland of Goree. Hearing, ſome time in the year 1789, or perhaps earlier, that the African aſſociation wiſhed to penetrate to the Niger by the way of Gambia, he expreſſed his willingneſs to undertake the execution of their plan. For this taſk he was peculiarly fitted. A natural intrepidity of character which ſeemed inacceſſible to fear, and an eaſy flow of conſtitutional good humour, which even the rougheſt accidents of life were not able to ſubdue, formed him for exploring the country of relentleſs ſavages; whilſt the darkneſs of his complexion was ſuch, that he ſcarcely differed in appearance from the Moors of Barbary, whoſe dreſs in travelling he intended to aſſume.

His inſtructions from the aſſociation were, to aſcertain the courſe, and, if poſſible, the riſe and termination of the Niger; and after viſiting the cities of Tombuctoo and Houssa (ſee theſe articles in this *Supplement*), to return by the way of the deſart, or by any other route which the circumſtances of his ſituation at the time might recommend to his choice.

Having left England on the 16th of October 1790, he arrived at the entrance of the Gambia on the 10th of November, and was kindly received by the king of Barra, who remembered the viſit which the major had formerly paid him from the iſland of Goree; and who now, in return for a ſmall preſent of the value of 20s. cheerfully tendered protection and aſſiſtance as far as his dominion or influence extended.

Proceedings of the African Aſſociation.

An offer from the maſter of an Engliſh veſſel employed in the trade of the river, enabled the Major, and the interpreter he had engaged on the coaſt, to proceed to Junkiconda; where he purchaſed from the natives a horſe and five aſſes, and prepared to paſs with the merchandiſe which conſtituted his travelling fund, to Medina, the capital of the ſmall kingdom of Woolli.

Fortunately for him, a few words, accidentally dropped by a negro woman in the Mandingo language, of which he had haſtily acquired a ſuperficial knowledge, excited ſuſpicions of danger; and gave him intimation of a conſpiracy which the negro miſtreſſes of the traders, who feared that the Major's expedition portended the ruin of their commerce, had formed againſt his life. Afraid, therefore, of travelling by the cuſtomary route, he availed himſelf of the opportunity which the dry ſea-

Houghton.

ſon and the tide of ebb afforded of ſwimming his horſe and his aſſes acroſs the ſtream; and having by thoſe means avoided the parties who were ſent for his deſtruction, he proceeded with much difficulty on the ſouthern ſide of the river, to that diſtrict of Cantor which is oppoſite to the kingdom of Woolli. There he repaſſed the Gambia, and ſet a meſſenger to inform the king of his arrival, and to requeſt a guard for his protection.

An eſcort, commanded by the king's ſon, was immediately diſpatched; and the Major, whoſe intended preſent had been announced, was kindly received, and hoſpitably entertained at Medina.

The town is ſituated at the diſtance of about 900 miles by water from the entrance of the Gambia; and the country adjacent abounds in corn and cattle, and, generally ſpeaking, in all things that are requiſite for the ſupport, or eſſential to the comfort of life. Two different ſects of religion diſtinguiſh rather than divide the people; the one is compoſed of the profeſſors of the Mahomedan faith, who are called Buſhreens; the other, and, it is ſaid, the more numerous, conſiſts of thoſe who, denying the miſſion of the prophet, avow themſelves deiſts, and from their cuſtom of drinking with freedom the liquors of which he prohibited the uſe, are denominated Sonikees or drinking men.

In a letter from Major Houghton to his wife, which a ſeaman preſerved from the wreck of a veſſel in which the diſpatches to the ſociety were loſt, the Major indulged the reflections that naturally aroſe from his paſt and preſent ſituations. A bilious fever had attacked him ſoon after his arrival in the Gambia; but his health was now unimpaired—a conſpiracy had aſſailed his life; but the danger was paſſed—the journey from Junkiconda had expoſed him to innumerable hardſhips; but he was now in poſſeſſion of every gratification which the kindneſs of the king or the hoſpitality of the people could enable him to enjoy. Delighted with the healthineſs of the country, the abundance of the game, the ſecurity with which he made his excurſions on horſeback, and, above all, with the advantages that would attend the erection of a fort on the ſalubrious and beautiful hill of Fatetenda, where the Engliſh once had a factory, he expreſſes his earneſt hope that his wife will hereafter accompany him to a place in which an income of ten pounds a-year will ſupport them in affluence; and that ſhe will participate with him in the pleaſure of rapidly acquiring that vaſt wealth which he imagines its commerce will afford.

While, in this manner, he indulged the dream of future proſperity, and with ſtill more ample ſatisfaction contemplated the eclat of the diſcoveries for which he was preparing, but in the purſuit of which he was retarded by the abſence of the native merchant, for whoſe company he had engaged, he found himſelf ſuddenly involved in unexpected and irreſiſtible misfortune. A fire, the progreſs of which was accelerated by the bamboo roofs of the buildings, conſumed with ſuch rapidity the houſe in which he lived, and with it the greateſt part of Medina, that ſeveral of the articles of merchandize, to which he truſted for the expences of his journey, were deſtroyed; and to add to his affliction, his faithleſs interpreter, who had made an ineffectual attempt on his goods, diſappeared with his horſe and three of his aſſes; a trade gun which he had purchaſed on the river ſoon afterwards burſt in his hands, and wounded him in the face and arm: and though the hoſpitable kindneſs of the people of the neighbouring town of Barraconda, who cheerfully opened their houſes to more than a thouſand families, whoſe tenements the flames had conſumed, was anxiouſly exerted for his relief; yet the loſs of his goods, and the conſequent diminution of his travelling fund, were evils which no kindneſs could remove.

It was in this ſituation that, wearied with the fruitleſs hope of the return of the native trader, with whom he had contracted for his journey, he reſolved to avail himſelf of the company of another ſlave merchant, who was lately arrived from the ſouth, and was now on his way to his farm on the frontier of the kingdom of Bambouk. Accordingly, on the evening of the 8th of May, he proceeded by moon light and on foot, with his two aſſes, which the ſervants of the ſlave merchant offered to drive with their own, and which carried the wreck of his fortune; and journeying by a north-eaſt courſe, arrived on the fifth day at the uninhabited frontier which ſeparates the kingdoms of Woolli and Bondou.

He had now paſſed the former limit of European diſcovery; and while he remarked with pleaſure the numerous and extenſive population of this unviſited country, he obſerved, that the long black hair and copper complexion of the inhabitants announced their Arab original. They are a branch of that numerous tribe which, under the appellation of Foolies, have overſpread a conſiderable part of Senegambia; and their religious diſtinctions are ſimilar to thoſe which prevail in the kingdom of Woolli.

A journey of 150 miles, which was often interrupted by the engagements of his companion who traded in every town, conducted him to the banks of the Falemé, the ſouth-weſtern boundary of the kingdom of Bambouk. Its ſtream was exhauſted by the advanced ſtate of the dry ſeaſon, and its bed exhibited an appearance of ſlate intermixed with gravel.

Bambouk is inhabited by a nation, whoſe woolly hair and ſable complexions beſpeak them of the negro race, but whoſe character ſeems to be varied in proportion as the country riſes from the plains of its weſtern diviſion to the highlands of the eaſt. Diſtinguiſhed into ſects, like the people of Woolli and Bondou, by the different tenets of Mahomedans and Deiſts, they are equally at peace with each other, and mutually tolerate the reſpective opinions they condemn.

Agriculture and paſturage, as in the negro ſtates on the coaſt of the Atlantic, are their chief occupations; but the progreſs which they have made in the manufacturing arts, is ſuch as enables them to ſmelt their iron ore, and to furniſh the ſeveral inſtruments of huſbandry and war. Cloth of cotton, on the other hand, which in this part of Africa ſeems to be the univerſal wear, they appear to weave by a difficult and laborious proceſs; and to theſe two circumſtances it is probably owing, that with them the meaſure of value is not, as on the coaſt, a bar of iron, but a piece of cloth.

The common vegetable food of the inhabitants appears to conſiſt of rice; their animal, of beef or mutton. A liquor, prepared from fomented honey, ſupplies the want of wine, and furniſhes the means of thoſe feſtive entertainments that conſtitute the luxury of the court of Bambouk.

On the Major's arrival at the banks of the river Falemé, he found that the war which had lately ſubſiſted between the kings of Bondou and Bambouk was terminated by the ceſſion to the former of the conqueſts he had made in the low land part of the dominions of the latter; and that the king of Bondou had taken up his reſidence in the territory which he had thus obtained.

The Major haſtened to pay his reſpects to the victorious prince, and to offer a ſimilar preſent to that which the kings of Barra and Woolli had cheerfully accepted; but to his great diſappointment an ungracious reception, a ſullen permiſſion to leave the preſent, and a ſtern command to repair to the frontier town from which he came, were followed by an intimation that he ſhould hear again from the king. Accordingly, on the next day, the king's ſon, accompanied by an armed attendance, entered the houſe in which the Major had taken up his temporary dwelling, and demanded a ſight of all the articles he had brought. From theſe the prince ſelected whatever commodities were beſt calculated to gratify his avarice, or pleaſe his eye; and, to the Major's great diſappointment, took from him the blue coat in which he hoped to make his appearance on the day of his introduction to the Sultan of Tombuctoo. Happily, however, a variety of articles were ſucceſsfully concealed, and others of inferior value were not conſidered as ſufficiently attractive.

The Major now waited with impatience for the performance of the promiſe which the ſlave merchant, with whom he had travelled from the Gambia, had made of proceeding with him to Tombuctoo; but as the merchant was obliged to ſpend a few days at his rice farm on the banks of the Falemé, the Major accepted an invitation to the hoſpitality of his roof. There he obſerved, with extreme regret, that the apprehenſion of a ſcarcity of grain had alarmed his friend; and that, dreading the conſequences of leaving his family in ſo perilous a ſeaſon to the chances of the market, he had determined on collecting, before his departure, a ſufficient ſupply for their ſupport. This argument for delay was too forcible to be oppoſed; and therefore the Major reſolved to employ the interval in viſiting the king of Bambouk, who reſided in the town of Ferbanna, on the eaſtern ſide of the Serra Coles, or river of Gold. Unfortunately, however, by a miſtake of his guide, he loſt his way in one of the vaſt woods of the country; and as the rainy ſeaſon, which commenced with the new moon on the 4th of July, and was introduced with a weſterly wind, was now ſet in, the ground on which he paſſed the night was deluged with rain, while all the ſky exhibited that continued blaze of lightning, which in thoſe latitudes often accompanies the tornado. Diſtreſſed by the fever, which began to aſſail him, the Major continued his route at the break of day, and waded with difficulty through the river Serra Coles, which was ſwelled by the floods, and on the banks of which the alligators were baſking in the temporary ſun-ſhine.

Scarcely had he reached Ferbanna when his fever roſe to a height that rendered him delirious; but the ſtrength of his conſtitution, and the kindneſs of the negro family to which his guide had conducted him, ſurmounted the dangerous diſeaſe; and in the friendly reception which was given him by the king of Bambouk he ſoon forgot the hardſhips of his journey. The king informed him, that the loſſes he had lately ſuſtained in the conteſt with the armies of Bondou, aroſe from his having exhauſted his ammunition; for, as the French traders, who formerly ſupplied his troops, had abandoned the fort of St Joſeph, and, either from the dryneſs of the laſt ſeaſon, or from other cauſes, had deſerted the navigation of the upper part of the Senegal, he had no means of repleniſhing his ſtores; whereas his enemy, the king of Bondou, continued to receive from the Britiſh, through the channel of his agents on the Gambia, a conſtant and adequate ſupply.

Major Houghton availed himſelf of the opportunity which this converſation afforded, to ſuggeſt to the king the advantage of encouraging the Britiſh to open a trade by the way of his dominions to the populous cities on the banks of the Niger.

Such was the ſtate of the negociation, when all buſineſs was ſuſpended by the arrival of the annual preſents of Mead, which the people of Bambouk, at that ſeaſon of the year, are accuſtomed to ſend to their king; and which are always followed by an intemperate feſtival of ſeveral ſucceſſive days.

In the interim, the Major received, and gladly accepted, the propoſal of an old and reſpectable merchant of Bambouk; who offered to conduct him on horſeback to Tombuctoo, and to attend him back to the Gambia. A premium of L. 125, to be paid on the Major's return to the Britiſh factory at Junkiconda, was fixed by agreement as the merchant's future reward. It was further determined that the Major ſhould be furniſhed with a horſe in exchange for his two aſſes; and ſhould convert into gold duſt, as the moſt portable fund, the ſcanty remains of the goods he had brought from Great Britain.

This plan was much approved by the king, to whom the merchant was perſonally known; and who gave to the Major at parting, as a mark of his eſteem, and a pledge of his future friendſhip, a preſent of a purſe of gold. With an account of theſe preparations the Major cloſed his laſt diſpatch, of the 24th July 1791; and the African aſſociation entertained for ſome time ſanguine hopes of his reaching Tombuctoo. Alas! theſe hopes were blaſted. Mr Park, who ſucceeded him in the arduous taſk of exploring that ſavage country, learned, that having reached JARRA (See that article in this *Supplement*), he there met with ſome Moors who were travelling to Tiſheet (a place by the ſalt pits in the Great Deſart, ten days journey to the northward) to purchaſe ſalt; and that the Major, at the expence of ſome tobacco and a muſket, engaged them to convey him hither. It is impoſſible (ſays Mr Park) to form any other opinion on this determination, than that the Moors intentionally deceived him with a view to rob, and leave him in the Deſart. At the end of two days he ſuſpected their treachery, and inſiſted on returning to Jarra. Finding him perſiſt in this determination, the Moors robbed him of every thing which he poſſeſſed, and went off with their camels. Being thus deſerted, he returned to a watering place, in poſſeſſion of the Moors, called Farra; and being by theſe unfeeling wretches refuſed food, which he had not taſted for ſome days, he ſunk at laſt under his misfortunes. Whether he actually died of hunger, or was murdered outright by the ſavage Mahometans, Mr Park could not learn;

but he was ſhewn at a diſtance the ſpot in the woods to which his body was dragged, and where it was left a prey to corruption.

Thus periſhed, in the prime of life, Major Houghton, a man whoſe travels enlarged the limits of European diſcovery, and whoſe accounts of the places which he viſited were ſtrongly confirmed by the intelligence which the Britiſh conſul at Tunis collected from the Barbary merchants.

HOUSSA, the capital of an African empire, on the banks of the Niger, is a city which has excited much curioſity among men of ſcience, ſince it was firſt mentioned to a committee of the African Aſſociation about the year 1790. The perſon from whom they received their information was an Arab, of the name of Shabeni; who ſaid that the population of Houſſa, where he had reſided two years, was equalled only (ſo far as his knowledge extended) by that of London and Cairo: and, in his rude unlettered way, he deſcribed the government as monarchical, yet not unlimited; its juſtice as ſevere, but directed by written laws; and the rights of landed property as guarded by the inſtitutions of certain hereditary officers, whoſe functions appear to be ſimilar to thoſe of the Canongoes of Hindoſtan (ſee CANONGOES in this *Suppl.*); and whoſe important and complicated duties imply an unuſual degree of civilization and refinement. For the probity of the merchants of Houſſa, the Arab expreſſed the higheſt reſpect; but remarked, with indignation, that the women were admitted to ſociety, and that the honour of the huſband was often inſecure. Of their written alphabet, he knew no more than that it is perfectly different from the Arabic and the Hebrew characters; but he repreſented the art of writing as common in Houſſa. And when he deſcribed the manner in which their pottery is made, he gave, unknowingly to himſelf, a repreſentation of the ancient Grecian wheel. In paſſing to Houſſa from Tombuctoo, in which laſt city he had reſided ſeven years, he found the banks of the Niger more numerouſly peopled than thoſe of the Nile, from Alexandria to Cairo; and his mind was obviouſly impreſſed with higher ideas of the wealth and grandeur of the empire of Houſſa, than of thoſe of any kingdom which he had ſeen, England alone excepted.

The exiſtence of the city of Houſſa, and of the empire thus deſcribed by Shabeni, was ſtrongly confirmed by letters which the committee received from his Majeſty's conſuls at Tunis and Morocco; and it has been put beyond all poſſibility of doubt by Mr Park, who received from various perſons ſuch concurring accounts of it, as could not be the offspring of deliberate falſehood. From a well-informed ſhereeff, who had viſited Houſſa, and lived ſome years at Tombuctoo, he learned that the former of theſe cities was the largeſt that the ſhereeff had ever ſeen; and by comparing this man's account of its population with that of various other cities, of which Mr Park had ſeen one or two, we can hardly eſtimate the inhabitants of Houſſa at a leſs number than 100,000. Many merchants, with whom our traveller converſed, repreſented Houſſa as larger, and more populous, than Tombuctoo, and the trade, police, and government, as nearly the ſame in both. In that caſe, the king of Houſſa and chief officers of ſtate muſt be Moors, and zealots for the Mahometan religion; but they cannot be ſo intolerant as the ſovereign of Tombuctoo and his miniſters; for in Houſſa, Mr Park was told that the Negroes are in greater proportion to the Moors than in Tombuctoo, and that they have likewiſe ſome ſhare in the government. According to accounts derived from Barbary merchants, the people of Houſſa have the art of tempering their iron with more than European ſkill; and their files, in particular, are much ſuperior to thoſe of Great Britain and France. The conſuls at Tunis and Morocco aſſured the committee of the African Aſſociation, that at both theſe courts the eunuchs of the ſeraglio are brought from Houſſa.

To thoſe who may ſtill entertain doubts of ſo much refinement being to be found in the interior parts of a country, conſidered as peculiarly ſavage, we ſhall only obſerve, in the words of the committee of aſſociation, that it is by no means "impoſſible that the Carthaginians, who do not appear to have periſhed with their cities, may have retired to the ſouthern parts of Africa; and though loſt to the Deſart, may have carried with them to the new regions which they occupy ſome portion of thoſe arts and ſciences, and of that commercial knowledge, for which the inhabitants of Carthage were once ſo eminently famed. In Major Rennel's laſt map of North Africa, Houſſa is placed in 16° and about 20′ N. Lat. and 4° 30′ E. Long.

HOUZOUANAS, are a wandering people, who inhabit that part of Africa, which, in a direction from eaſt to weſt, extends from Caffraria to the country of the Greater Nimiquas (See NIMIQUAS in this *Suppl.*) According to the map prefixed to Vaillant's new travels, the diſtrict occupied by the Houzouanas lies between 16° and 29° eaſt longitude. Of its breadth from ſouth to north we are ignorant, but it begins at the 23d parallel, and ſtretches northward probably a great way.

M. Vaillant is inclined to believe, that the Houzouanas are the original ſtem of the various nations, inhabiting at preſent the ſouthern part of Africa, and that from them all the tribes of the eaſtern and weſtern Hottentots are deſcended. The people themſelves know nothing of their origin; but to the queſtions that are put to them on the ſubject, they always reply, that they inhabit the country which was inhabited by their anceſtors. At the Cape M. Vaillant received the following account of them, which, though he does not warrant its authenticity, has much the appearance of being authentic.

When the Europeans firſt eſtabliſhed themſelves at the Cape, the Houzouanas inhabited the country of Camdebo, the ſnowy mountains, and the diſtrict that ſeparates theſe mountains from Caffraria. Become neighbours to the colony, in conſequence of its extending itſelf towards them, they at firſt lived on peaceable terms with the planters; and, as they diſplayed more intelligence and greater activity than the Hottentots, they were even employed in preference to aſſiſt in cultivating the land and in forming the ſettlement. This good underſtanding and harmony were, however, ſoon interrupted by that multitude of lawleſs banditti ſent from Holland to people the country.

Thoſe worthleſs profligates wiſhed to enjoy the fruits of the land without the trouble of tilling it. Educated, beſides, with all the prejudices of the whites, they imagined that men of a different colour were born only to be their ſlaves. They accordingly ſubjected them to bondage, condemned them to the moſt laborious ſervices, and repaid thoſe ſervices with harſh and ſevere treatment. The Houzouanas, incenſed at ſuch arbitrary and tyrannical conduct, refuſed any longer to work for them, and retired to the defiles of their mountains. The planters took up arms and purſued them; they maſſacred them without pity, and ſeized on their cattle and their country. Thoſe who eſcaped their atrocities betook themſelves to flight, and removed to the land which they now occupy; but, on quitting their former poſſeſſions, they ſwore, in their own name and that of their poſterity, to exterminate thoſe European monſters, to be revenged againſt whom they had ſo many incitements. And thus, if tradition be true, was a peaceful and induſtrious nation rendered warlike, vindictive, and ferocious.

This hatred has been perpetuated from generation to generation, though the Houzouanas of the preſent day are ignorant of the original cauſe of it. Bred up with an invincible averſion to the planters, they know only that they are animated to plunder and deſtroy them; but it is only by a vague ſentiment of deteſtation, with the ſource of which they are unacquainted; and which, though it renders them cruel towards the planters, does not prevent them from being good, kind, and humane, towards each other.

The Houzouanas, being known only by their incurſions and plundering, are in the colonies often confounded with the Boſhmen, and diſtinguiſhed by the ſame appellation. Sometimes, however, from their tawny colour, they are called Chineſe Hottentots; and, by means of this double denomination, ill-informed travellers may eaſily be led into an error, of which the conſequence muſt be, that their narratives will be replete with abſurdity and falſehoods.

Their real name, and the only one which they give themſelves, is that of Houzouana; and they have nothing in common with the Boſhmen, who are not a diſtinct people, but a mere collection of fugitives and free-booters. The Houzouanas form no alliances but among themſelves. Being almoſt always at war with the ſurrounding nations, they never mix with them; and, if they conſent at any time to admit a ſtranger into their hordes, it is only after a long acquaintance, a ſort of apprenticeſhip, during which he has given proofs of his fidelity, and eſtabliſhed his courage. Such indeed are their courage and predatory habits, that they are the dread of all the ſurrounding tribes; and the Hottentots who accompanied M. Vaillant trembled at the very thought of entering the Houzouana territories. Nay, after they had lived many days among them, and had experienced their fidelity, they continued under the daily apprehenſion of being maſſacred by them. Yet one of their own countrymen, who had lived long among the Houzouanas, gave ſuch a character of that people as ſhould have baniſhed thoſe idle fears.

" The Houzouanas (ſaid he), are by no means what you ſuppoſe them to be, murderers by profeſſion. If they ſometimes ſhed blood, it is not from a thirſt of carnage, but to make juſt repriſals that they take up arms. Attacked and perſecuted by ſurrounding nations, they have found themſelves reduced to the neceſſity of flying to inacceſſible places among the barren mountains, where no other people could exiſt.

" If they find antelopes and damans to kill; if the nymphs of ants are abundant; or if their good fortune brings them plenty of locuſts—they remain within the precincts of their rocks; but if the proviſions neceſſary to ſubſiſtence fail, the nations in their neighbourhood muſt ſuffer. From the ſummits of their mountains, they ſurvey at a diſtance the countries around; and if they obſerve cattle, they make an incurſion to carry them off, or ſlaughter them upon the ſpot, according to circumſtances; but though they rob, they never kill, except to defend their lives, or by way of retaliation to revenge an ancient injury.

" It happens ſometimes, however, that after very fatiguing expeditions they return without booty; either becauſe the objects of their attack have diſappeared, or becauſe they have been repulſed and beaten. In ſuch caſes, the women, exaſperated by hunger and the lamentation of their children crying for food, become almoſt furious with paſſion. Reproaches, inſult, and threats, are employed; they wiſh to ſeparate from ſuch daſtardly men, to quit huſbands deſtitute of courage, and to ſeek others who will be more anxious to procure proviſion for them and their children. In ſhort, having exhauſted whatever rage and deſpair could ſuggeſt, they pull off their ſmall apron of modeſty, and beat their huſbands about the head with it till their arms are weary of the exerciſe.

" Of all the affronts which they can offer, this is the moſt inſulting. Unable to withſtand it, the men in their turn become furious. They put on their war-cap, a ſort of helmet made with the ſkin that covers the neck of the hyæna, the long hair of which forms a creſt that floats over the head, and ſetting out like madmen, never return till they have ſucceeded in carrying off ſome cattle.

" When they come back, their wives go to meet them, and extol their courage amidſt the fondeſt careſſes. In a word, nothing is then thought of but mirth and jollity; and, till ſimilar ſcenes are recalled by ſimilar wants, paſt evils are forgotten."

Such was the character given of this formidable people to M. Vaillant at his firſt interview with them; and during the long excurſions which he made in their company, they did not belie it in a ſingle inſtance. In many reſpects they appeared to reſemble the Arabs, who, being alſo wanderers, and like them brave and addicted to rapine, adhere with unalterable fidelity to their engagements, and defend, even to the laſt drop of their blood, the traveller who civilly purchaſes their ſervices, and puts himſelf under their protection. In our author's opinion, if it be at all practicable to traverſe from ſouth to north the whole of Africa, it could only be under the conduct of the Houzouanas; and he really thinks that fifty men of their temperate, brave, and indefatigable nation, would be ſufficient to protect an enterpriſing European through that long and hazardous journey.

Yet theſe people, ſo ſuperior both in body and mind to the other natives of South Africa, are but of low ſtature; and a perſon five feet four inches in height is accounted among them very tall; but in their little bodies, perfectly well proportioned, are united, with ſurpriſing

priſing ſtrength and agility, a certain air of aſſurance, boldneſs, and haughtineſs, which awes the beholder, and with which our author was greatly pleaſed. Of all the ſavage races, he ſaw none that appeared to be endowed with ſo active a mind, and ſo hardy a conſtitution.

Their head, though it exhibits the principal characteriſtics of that of the Hottentot, is, however, rounder towards the chin. They are alſo not ſo black in complexion; but have the lead colour of the Malays, diſtinguiſhed at the Cape by the name of *bouguinée*. Their hair, more woolly, is ſo ſhort, that he imagined at firſt their heads to have been ſhaved. The noſe too is ſtill flatter than that of the Hottentots; or, rather, they ſeem altogether deſtitute of a noſe; what they have conſiſting only of two broad noſtrils which project at moſt but five or ſix lines. From this confirmation of the noſe, a Houzouana, when ſeen in profile, is the reverſe of handſome, and conſiderably reſembles an ape. When beheld in front, he preſents, on the firſt view, an extraordinary appearance, as half the face ſeems to be forehead. The features, however, are ſo expreſſive, and the eyes ſo large and lively, that, notwithſtanding this ſingularity of look, the countenance is tolerably agreeable.

As the heat of the climate in which he lives renders clothing unneceſſary, he continues during the whole year almoſt entirely naked, having no other covering than a very ſmall jackal ſkin faſtened round his loins by two thongs, the extremities of which hang down to his knees. Hardened by this conſtant habit of nakedneſs, he becomes ſo inſenſible to the variations of the atmoſphere, that when he removes from the burning ſands of the level country to the ſnow and hoar-froſt of his mountains, he ſeems indifferent to and not even to feel the cold.

His hut in nowiſe reſembles that of the Hottentot. It appears as if cut vertically through the middle; ſo that the hut of a Hottentot would make two of thoſe of the Houzouanas. During their emigrations, they leave them ſtanding, in order that, if any other horde of the ſame nation paſs that way, they may make uſe of them. When on a journey, they have nothing to repoſe on but a mat ſuſpended from two ſticks, and placed in an inclined poſition. They often even ſleep on the bare ground. A projecting rock is then ſufficient to ſhelter them; for every thing is ſuited to a people whoſe conſtitutions are proof againſt the ſevereſt fatigue. If, however, they ſtop anywhere to ſojourn for a while, and find materials proper for conſtructing huts, they then form a kraal; but they abandon it on their departure, as is the caſe with all the huts which they erect.

This cuſtom of labouring for others of their tribe announces a ſocial character and a benevolent diſpoſition. They are indeed not only affectionate huſbands and good fathers, but excellent companions. When they inhabit a kraal, there is no ſuch thing among them as private property; whatever they poſſeſs is in common. If two hordes of the ſame nation meet, the reception is on both ſides friendly; they afford each other mutual protection, and confer reciprocal obligations. In ſhort, they treat one another as brethren, though perhaps they are perfect ſtrangers, and have never ſeen each other before.

Active and nimble by nature, the Houzouanas conſider it as amuſement to climb mountains, and the moſt elevated peaks; and they conducted M. Vaillant, his ſervants and cattle, over precipices, and through defiles, which he and his Hottentots would have deemed abſolutely impaſſable. The only arms of this people are bows and arrows, in the uſe of which they are very expert. The arrows, which are uncommonly ſhort, are carried on the ſhoulder in a quiver, about 18 inches in length, and four in diameter, made of the bark of the aloe, and covered with the ſkin of a large ſpecies of lizard, which theſe wanderers find in all their rivers, particularly on the banks of Orange and Fiſh River.

Nocturnal fires are a peculiar language underſtood and employed by almoſt all ſavage nations. None, however, have carried this art ſo far as the Houzouanas, becauſe none have ſo much need of underſtanding and bringing it to perfection. If it be neceſſary to announce a defeat or a victory, an arrival or departure, a ſucceſsful plundering expedition, or the want of aſſiſtance, in a word, any intelligence whatever, they are able, either by the number of their fires or the manner in which they arrange them, to make it known in an inſtant. They are even ſo ſagacious as to vary their fires from time to time, leſt their enemies ſhould become acquainted with their ſignals, and treacherouſly employ them in their turn to ſurpriſe them.

Our author ſays, that he is unacquainted with the principles of theſe ſignals, invented with ſo much ingenuity. He did not requeſt information; becauſe he very rationally inferred that his requeſt would not have been granted; but he obſerved, that three fires kindled at the diſtance of twenty paces from each other, ſo as to form an equilateral triangle, were the ſignal for rallying.

Among the phyſical qualities which, in M. Vaillant's opinion, prove that the Houzouanas are a diſtinct nation, he mentions the enormous natural rump of the women, as a deformity which diſtinguiſhes them from every other people, ſavage or poliſhed, which he had ever known. “I have ſeveral times (ſays he) had occaſion to remark, that, among the female Hottentots in general, as they advance in age, the inferior part of the back ſwells out, and acquires a ſize which it greatly exceeds the proportion it bore in infancy with the other parts of the body. The Houzouana women, having in their figure ſome reſemblance to the Hottentots, and appearing therefore to be of the ſame race, one might be induced to believe that their projection behind is only the Hottentot rump more ſwelled and extended. I obſerved, however, that among the former this ſingularity was an excreſcence of ſlow growth, and in ſome meaſure an infirmity of old age; whereas among the latter it is a natural deformity, an original characteriſtic of their race. The Houzouana mothers wear on their reins, like our miners, a ſkin which covers this protuberance of the poſteriors; but which, being thin and pliable, yields to the quivering of the fleſh, and becomes agitated in the ſame manner. When on a journey, or when they have children too young to follow them, they place them upon their rump. I ſaw one of theſe women run in this manner with a child, about three years of age, that ſtood erect on its feet at her back, like a footboy behind a carriage.”

If one half of what our traveller ſays of the activity and enterpriſing ſpirit of this ſingular people be true, might not the African Aſſociation ſend a ſecond Houghton, or ſecond Park, to make diſcoveries in that unexplored country, under the protection of the Houzouanas? We do not indeed think that it would be poſſible to traverſe the whole extent of Africa from ſouth to north, but Vaillant penetrated farther in that direction than any one had done before him; and it appears that with his intrepid Houzouanas he might have penetrated much farther.

HUNGARY-WATER, is ſpirit of wine diſtilled upon roſemary, and which therefore contains its oily and ſtrong-ſcented eſſence (ſee PHARMACY, nº 365. *Encycl.*) To be really good, ſays Profeſſor Beckmann, the ſpirit of wine ought to be very ſtrong, and the roſemary freſh; and if that be the caſe, the leaves are as proper as the flowers, which, according to the preſcription of ſome, ſhould only be taken. It is likewiſe neceſſary that the ſpirit of wine be diſtilled ſeveral times upon the roſemary; but that proceſs is too troubleſome and expenſive to admit of this water being diſpoſed of at the low price it is uſually ſold for; and it is certain that the greater part of it is nothing elſe than common brandy united with the eſſence of roſemary in the ſimpleſt manner. In general, it is only mixed with a few drops of the oil. For a long time paſt, this article has been brought to us principally from France, where it is prepared, particularly at Beaucaire, Montpelier, and other places in Languedoc, in which that plant grows in great abundance.

Hiſt. of Inventions.

The name *Hungary water* ſeems to ſignify, that this water, ſo celebrated for its medicinal virtues, is an Hungarian invention; and we read in many books, that the receipt for preparing it was given to a queen of Hungary by a hermit; or, as others ſay, by an angel, who appeared to her in a garden, all entrance to which was ſhut, in the form of a hermit or a youth. Some call the queen St Iſabella; but thoſe who pretend to be beſt acquainted with the circumſtance affirm, that Elizabeth, wife of Charles Robert king of Hungary, and daughter of Uladiſlaus II. king of Poland, who died in 1380 or 1381, was the inventreſs. By often waſhing with this ſpirit of roſemary, when in the 70th year of her age, ſhe was cured, as we are told, of the gout and an univerſal lameneſs; ſo that ſhe not only lived to paſs 80, but became ſo lively and beautiful, that ſhe was courted by the king of Poland, who was then a widower, and who wiſhed to make her his ſecond wife.

The Profeſſor juſtly conſiders this ſtory as a ridiculous fable (A). "It appears to me (ſays he) moſt probable, that the French name *l'eau de la reine d'Hongrie*, was choſen by thoſe who, in latter times, prepared ſpirit of roſemary for ſale, in order to give greater conſequence and credit to their commodity; as various medicines, ſome years ago, were extolled in the gazettes under the title of Pompadour, though the celebrated lady, from whoſe name they derived their importance, certainly neither ever ſaw them nor uſed them."

HUNTER (John), the celebrated ſurgeon, was the youngeſt child of John Hunter of Kilbride, in the county of Lanark. He was born on the 14th of July 1728, at Long Calderwood, a ſmall eſtate belonging to the family; and loſing his father when he was about ten years of age, he was perhaps too much indulged by his mother. One conſequence of this was, that at the grammar-ſchool he made no progreſs in learning; and he may be ſaid to have been almoſt totally illiterate when, in September 1748, he arrived in London. His brother, Dr William Hunter, of whom an account is given in the *Encyclopædia*, was then the moſt celebrated teacher of anatomy, and John had expreſſed a deſire to aſſiſt him in his reſearches. The Doctor, who was very deſirous to ſerve him, and anxious to form ſome opinion of his talents for anatomy, gave him an arm to diſſect for the muſcles, with the neceſſary directions how it was to be done; and he found the performance ſuch as greatly exceeded his expectation.

His firſt eſſay in anatomy having thus gained him ſome credit, Mr Hunter was now employed in a diſſection of a more difficult nature; this was an arm in which all the arteries were injected, and theſe, as well as the muſcles, were to be expoſed and preſerved. The manner in which this was performed, gave Dr Hunter ſo much ſatiſfaction, that he did not ſcruple to ſay that his brother would become a good anatomiſt, and that he ſhould not want for employment. From this period we may conſider Mr Hunter as having ſeriouſly engaged in anatomy; and under the inſtructions of Dr Hunter, and his aſſiſtant Mr Symonds, he had every opportunity of improvement, as all the diſſections at this time carried on in London were confined to that ſchool.

(A) It was firſt publiſhed to the world in 1659 in a poſthumous work of John Prevot, who ſays, that in the beginning of a very old breviary, he ſaw a remedy for the gout, written by the queen's own hand, in the following words:

"I Elizabeth, queen of Hungary, being very infirm and much troubled with the gout in the 72d year of my age, uſed for a year this receipt, given to me by an ancient hermit, whom I never ſaw before nor ſince; and was not only cured, but recovered my ſtrength, and appeared to all ſo remarkably beautiful, that the king of Poland aſked me in marriage, he being a widower and I a widow. I, however, refuſed him for the love of my Lord Jeſus Chriſt, from one of whoſe angels, I believe, I received the remedy. The receipt is as follows:

> "℞. Take of aqua vitæ, four times diſtilled, three parts, and of the tops and flowers of roſemary two parts: put theſe together in a cloſe veſſel, let them ſtand in a gentle heat 50 hours, and then diſtil them. Take one dram of this in the morning once every week, either in your food or drink, and let your face and the diſeaſed limb be waſhed with it every morning.

"It renovates the ſtrength, brightens the ſpirits, purifies the marrow and nerves, reſtores and preſerves the ſight, and prolongs life." Thus far from the Breviary. Then follows a confirmation which Prevot gives from his own experience.

In the ſummer 1749, Mr Cheſelden, at the requeſt of Dr Hunter, permitted him to attend at Chelſea Hoſpital; and he there learned the firſt rudiments of ſurgery.

The following winter he was ſo far advanced in the knowledge of human anatomy, as to inſtruct the pupils in diſſection, to whom Dr Hunter had very little time to pay attention. This office, therefore, fell almoſt entirely upon him, and was his conſtant employment during the winter ſeaſon.

In the ſummer months of 1750, Mr Hunter attended the hoſpital at Chelſea; in 1751, he became a pupil at St Bartholomew's, and in the winter was preſent at operations occaſionally, whenever any thing extraordinary occurred. The following ſummer he went to Scotland; and in 1753 entered, it is difficult to conceive for what reaſon, as a gentleman commoner at St Mary-hall, Oxford. In 1754 he became a ſurgeon's pupil at St George's hoſpital, where he continued during the ſummer months; and in 1756 was appointed houſe-ſurgeon.

In the winter 1755, Dr Hunter admitted him to a partnerſhip in his lectures, and a certain portion of the courſe was allotted to him; beſides which, he gave lectures when the Doctor was called away to attend his patients. Making anatomical preparations was at this time a new art, and very little known; every preparation, therefore, that was ſkilfully made, became an object of admiration; many were wanting for the uſe of the lectures; and the Doctor being himſelf an enthuſiaſt for the art, left no means untried to infuſe into his brother a love for his favourite purſuits. How well he ſucceeded, the collection afterwards made by Mr Hunter will ſufficiently evince.

Anatomy ſeems to have been a purſuit for which Mr Hunter's mind was peculiarly fitted, and he applied to it with an ardour and perſeverance of which there is hardly an example. His labours were ſo uſeful to his brother's collection, and ſo gratifying to his diſpoſition, that although in many other reſpects they did not agree, this ſimple tie kept them together for many years.

Mr Hunter worked for ten years on human anatomy; during which period he made himſelf maſter of what was already known, as well as made ſome addition to that knowledge. He traced the ramifications of the olfactory nerves upon the membranes of the noſe, and diſcovered the courſe of ſome of the branches of the fifth pair of nerves. In the gravid uterus, he traced the arteries of the uterus to their termination in the placenta. He was alſo the firſt who diſcovered the exiſtence of the lymphatic veſſels in birds.

Many parts of the human body being ſo complex, that their ſtructure could not be underſtood, nor their uſes aſcertained, Mr Hunter was led to examine ſimilar parts in other animals, in which the ſtructure was more ſimple, and more within the reach of inveſtigation; this carried him into a wide field, and laid the foundation of his collection in comparative anatomy.

In this new line of purſuit, this active inquirer began with the more common animals, and preſerved ſuch parts as appeared by their analogy, or in ſome other way, to elucidate the human economy. It was not his intention to make diſſections of particular animals, but to inſtitute an inquiry into the various organizations by which the functions of life are performed, that he might thereby acquire ſome knowledge of general principles.

So eagerly did Mr Hunter attach himſelf to comparative anatomy, that he ſought by every means in his power the opportunities of proſecuting it with advantage. He applied to the keeper of wild beaſts in the Tower for the bodies of thoſe which died there; and he made ſimilar applications to the men who ſhowed wild beaſts. He purchaſed all rare animals which came in his way; and theſe, with ſuch others as were preſented to him by his friends, he entruſted to the ſhowmen to keep till they died, the better to encourage them to aſſiſt him in his labours.

His health was ſo much impaired by exceſſive attention to his purſuits, that in the year 1760 he was adviſed to go abroad, having complaints in his breaſt which threatened to be conſumptive. In October of that year, Mr Adair, inſpector-general of hoſpitals, appointed him a ſurgeon on the ſtaff; and in the following ſpring he went with the army to Belliſle, leaving Mr Hewſon to aſſiſt his brother during his abſence.

Mr Hunter ſerved, while the war continued, as ſenior ſurgeon on the ſtaff, both in Belliſle and Portugal, till the year 1763; and in that period acquired his knowledge of gun-ſhot wounds. On his return to England he ſettled in London; where, not finding the emoluments from his half-pay and private practice ſufficient to ſupport him, he taught practical anatomy and operative ſurgery for ſeveral winters. He returned alſo, with unabated ardour, to comparative anatomy; and as his experiments could not be carried on in a large town, he purchaſed for that purpoſe, about two miles from London, a piece of ground near Brompton, at a place called Earl's Court, on which he built a houſe. In the courſe of his inquiries, this excellent anatomiſt aſcertained the changes which animal and vegetable ſubſtances undergo in the ſtomach when acted on by the gaſtric juice; he diſcovered, by means of feeding young animals with madder (which tinges growing bones red), the mode in which a bone retains its ſhape during its growth; and explained the proceſs of exfoliation, by which a dead piece of bone is ſeparated from the living.

His fondneſs for animals made him keep ſeveral of different kinds in his houſe, which, by attention, he rendered familiar with him, and amuſed himſelf by obſerving their peculiar habits and inſtincts; but this familiarity was attended with conſiderable riſk, and ſometimes led him into ſituations of danger, of which the following is a remarkable inſtance:

Two leopards, which were kept chained in an outhouſe, had broken from their confinement, and got into the yard among ſome dogs, which they immediately attacked; the howling this produced alarmed the whole neighbourhood; Mr Hunter ran into the yard to ſee what was the matter, and found one of them getting up the wall to make his eſcape, the other ſurrounded by the dogs; he immediately laid hold of them both, and carried them back to their den; but as ſoon as they were ſecured, and he had time to reflect upon the riſk of his own ſituation, he was ſo much agitated, that he was in danger of fainting.

On the fifth of February 1767, he was choſen a fellow of the Royal Society. His deſire for improvement in thoſe branches of knowledge which might aſſiſt in his reſearches, led him at this time to propoſe to Dr George Fordyce and Mr Cumming, an eminent mechanic, that they ſhould adjourn from the meetings of the Royal Society to ſome coffee-houſe, and diſcuſs ſuch ſubjects as were connected with ſcience. This plan was no ſooner eſtabliſhed, than they found their numbers increaſed; they were joined by Sir Joſeph Banks, Dr Solander, Dr Maſkelyne, Sir George Shuckburgh, Sir Harry Engleſield, Sir Charles Blagden, Dr Noothe, Mr Ramſden, Mr Watt of Birmingham, and many others. At theſe meetings diſcoveries and improvements in different branches of philoſophy were the objects of their conſideration; and the works of the members were read over and criticiſed before they were given to the public. It was in this year that, by an exertion in dancing, after the muſcles of the leg were fatigued, he broke his tendo achillis. This accident, and the confinement in conſequence of it, led him to pay attention to the ſubject of broken tendons, and to make a ſeries of experiments to aſcertain the mode of their union.

In the year 1768 Mr Hunter became a member of the corporation of ſurgeons; and in the year following, through his brother's intereſt, he was elected one of the ſurgeon's of St George's hoſpital. In May 1771, his Treatiſe on the Natural Hiſtory of the Teeth was publiſhed; and in July of the ſame year he married Miſs Home, the eldeſt daughter of Mr Home, ſurgeon to Burgoyne's regiment of light horſe. The expence of his purſuits had been ſo great, that it was not till ſeveral years after his firſt engagement with this lady that his affairs could be ſufficiently arranged to admit of his marrying.

Though after his marriage his private practice and profeſſional character advanced rapidly, and though his family began to increaſe, he ſtill devoted much of his time to the forming of his collection, which, as it daily became larger, was alſo attended with greater expence. The whole ſuit of the beſt rooms in his houſe were occupied by his preparations; and he dedicated his mornings, from ſunriſe to eight o'clock (the hour for breakfaſt), entirely to his purſuits. To theſe he added ſuch parts of the day as were not engaged in attending his patients.

The knowledge he derived from his favourite ſtudies he conſtantly applied to the improvement of the art of ſurgery, and omitted no opportunity of examining morbid bodies; from which he made a collection of facts which are invaluable, as they tend to explain the real cauſes of ſymptoms, which, during life, could not be exactly aſcertained, the judgment of the practitioner being too frequently miſled by theoretical opinions, and deluſive ſenſations of the patients.

In the practice of ſurgery, where caſes occurred in which the operations proved inadequate to their intention, he always inveſtigated, with uncommon care, the cauſes of that want of ſucceſs; and in this way detected many fallacies, as well as made ſome important diſcoveries, in the healing art. He detected the cauſe of failure, common to all the operations in uſe for the radical cure of the hydrocele, and was enabled to propoſe a mode of operating, in which that event can with certainty be avoided. He aſcertained, by experiments and obſervations, that expoſure to atmoſpherical air ſimply, can neither produce nor increaſe inflammation. He diſcovered in the blood ſo many phenomena connected with life, and not to be referred to any other cauſe, that he conſidered it as alive in its fluid ſtate. He improved the operation for the fiſtula lachrymalis, by removing a circular portion of the os unguis inſtead of breaking it down with the point of a trochar. He alſo diſcovered that the gaſtric juice had a power when the ſtomach was dead of diſſolving it; and gave to the Royal Society a paper on this ſubject, which is publiſhed in the Philoſophical Tranſactions.

In the winter 1773, he formed a plan of giving a courſe of lectures on the theory and principles of ſurgery, with a view of laying before the public his own opinions upon that ſubject. For two winters he read his lectures *gratis* to the pupils of St George's Hoſpital; and in 1775, gave a courſe for money upon the ſame terms as the other teachers in the different branches of medicine and ſurgery. But giving lectures was always particularly unpleaſant to him; ſo that the deſire of ſubmitting his opinions to the world, and learning their general eſtimation, were ſcarcely ſufficient to overcome his natural diſlike to ſpeaking in public. He never gave the firſt lecture of his courſe without taking 30 drops of laudanum to take off the effects of his uneaſineſs.

Comparative anatomy may be conſidered as the purſuit in which Mr Hunter was conſtantly employed. No opportunity eſcaped him. In the year 1773, at the requeſt of his friend Mr Walſh, he diſſected the torpedo, and laid before the Royal Society an account of its electrical organs. A young elephant, which had been preſented to the Queen by Sir Robert Barker, died, and the body was given to Dr Hunter, which afforded Mr Hunter an opportunity of examining the ſtructure of that animal by aſſiſting his brother in the diſſection; ſince that time two other elephants died in the Queen's menagerie, both of which came under Mr Hunter's examination. In 1774, he publiſhed in the Philoſophical Tranſactions an account of certain receptacles of air in birds, which communicate with the lungs, and are lodged both among the fleſhy parts and hollow bones of theſe animals; and a paper on the Gillaroo trout, commonly called in Ireland the *Gizzard-trout*.

In 1775, ſeveral animals of that ſpecies, called the *gymnotus electricus of Surinam*, were brought alive to this country, and by their electrical properties excited very much the public attention. Mr Walſh, deſirous of purſuing his inveſtigations of animal electricity, made a number of experiments on the living animals; and to give his friend Mr Hunter an opportunity of examining them, purchaſed thoſe that died. An anatomical account of their electrical organs was drawn up by Mr Hunter, and publiſhed in the Philoſophical Tranſactions. In the ſame volume there is a paper of his, containing experiments on animals and vegetables reſpecting their power of producing heat.

In the courſe of his purſuits, Mr Hunter met with many parts of animals where natural appearances could not be preſerved, and others, in which the minuter veſſels could not be diſtinctly ſeen when kept in ſpirits; it was therefore neceſſary to have them drawn, either at the moment, or before they were put into bottles.

The expence of employing profeſſed draughtſmen, the difficulty of procuring them, and the diſadvantage which they laboured under in being ignorant of the ſubject they were to repreſent, made him deſirous of having an able perſon in his houſe entirely for that purpoſe.

With this view he engaged an ingenious young artiſt to live with him for ten years; his time to be wholly employed as a draughtſman, and in making anatomical preparations. This gentleman, whoſe name was Bell, ſoon became a very good practical anatomiſt, and from that knowledge was enabled to give a ſpirited and accurate reſemblance of the ſubjects he drew, ſuch as is rarely to be met with in repreſentations of anatomical ſubjects. By his labours Mr Hunter's collection is enriched with a conſiderable number of very valuable drawings, and a great variety of curious and delicate anatomical preparations.

In January 1776, Mr Hunter was appointed ſurgeon extraordinary to his Majeſty; and in the ſpring he gave to the Royal Society a paper on the beſt mode of recovering drowned perſons.

In the autumn he was taken extremely ill; and the nature of his complaints made his friends, as well as himſelf, conſider his life to be in danger. When he reflected upon his own ſituation, that all his fortune had been expended in his purſuits, and that his family had no proviſion but what ſhould ariſe from the ſale of his collection, he became very ſolicitous to give it its full value, by leaving it in a ſtate of arrangement. This he accompliſhed with the aſſiſtance of Mr Bell and his brother-in-law Mr Home.

In 1778, he publiſhed the ſecond part of his Treatiſe on the Teeth, in which their diſeaſes, and the mode of treatment are conſidered. This rendered his work upon that ſubject complete. He publiſhed alſo in the Philoſophical Tranſactions a paper on the Heat of Animals and Vegetables. In 1779, he publiſhed his account of the Free Martin in the Philoſophical Tranſactions; and in 1780, he laid before the Royal Society an account of a woman who had the ſmall pox during pregnancy, where the diſeaſe ſeemed to have been communicated to the fœtus.

In 1781, he was elected a fellow of the Royal Society of Sciences and Belles Lettres at Gottenburg. And in 1782, he gave the Royal Society a paper on the Organ of Hearing in Fiſh. Beſides the papers which he preſented to that learned body, he read ſix Croonion lectures upon the ſubject of Muſcular Action, for the years 1776, 1778, 1779, 1780, 1781, and 1782. In theſe lectures he collected all his obſervations, upon muſcles, reſpecting their powers and effects, and the ſtimuli by which they are affected; and to theſe he added Comparative Obſervations upon the moving Powers of Plants.

Theſe lectures were not publiſhed in the Philoſophical Tranſactions, for they were withdrawn as ſoon as read, not being conſidered by the author as complete diſſertations, but rather as materials for ſome future publication.

It is much to be regretted (ſays Mr Home) that Mr Hunter was ſo tardy in giving his obſervations to the public; but ſuch was his turn for inveſtigation, and ſo extenſive the ſcale upon which he inſtituted his inquiries, that he always found ſomething more to be accompliſhed, and was unwilling to publiſh any thing which appeared to himſelf unfiniſhed. His obſervations on the Muſcular Action of the Blood-veſſels were laid before the Royal Society in 1780, and yet he delayed publiſhing them till his Obſervations on the Blood and Inflammation were arranged; and they make part of the volume which was publiſhed after his death.

In 1783, he was choſen into the Royal Society of Medicine and the Royal Academy of Surgery in Paris; and the ſame year the leaſe of the houſe which he occupied in Jermyn-ſtreet having expired, he purchaſed the leaſe of a large houſe on the eaſt-ſide of Leiceſter-ſquare, and the whole lot of ground adjoining to Caſtle-ſtreet, on which there was another houſe. In the middle ſpace between the two houſes, he erected, at the expence of L. 3000, a building for his collection; though, unfortunately for his family, the leaſe did not extend beyond 24 years.

In the building formed for the collection there was a room fifty-two feet long by twenty-eight feet wide, lighted from the top, and having a gallery all round, for containing his preparations. Under this were two apartments; one for his lectures, and the other, with no particular deſtination at firſt, but afterwards made uſe of for weekly meetings of medical friends during the winter. To this building the houſe in Caſtle-ſtreet was entirely ſubſervient; and the rooms in it were uſed for the different branches of human and comparative anatomy.

About this period Mr Hunter may be conſidered as at the height of his chirurgical career; his mind and body were both in their full vigour. His hands were capable of performing whatever was ſuggeſted by his mind; and his judgment was matured by former experience. Some inſtances of his extraordinary ſkill may very properly be mentioned.

He removed a tumor from the ſide of the head and neck of a patient at St George's Hoſpital, as large as the head to which it was attached; and by bringing the cut edges of the ſkin together, the whole was nearly healed by the firſt intention.

He diſſected out a tumor on the neck, which one of the beſt operating ſurgeons in this country had declared, rather too ſtrongly, that no one but a fool or a madman would attempt; and the patient got perfectly well.

He diſcovered a new mode of performing the operation for the popliteal aneuriſm, by taking up the femoral artery on the anterior part of the thigh, without doing any thing to the tumor in the ham. The ſafety and efficacy of this mode have been confirmed by many ſubſequent trials; and it muſt be allowed to ſtand very high among the modern improvements in ſurgery.

If we conſider Mr Hunter at this period of his life, it will afford us a ſtrong picture of the turn of his mind, of his deſire to acquire knowledge, and his unremitting aſſiduity in proſecuting whatever was the object of his attention.

He was engaged in a very extenſive private practice; he was ſurgeon to St George's Hoſpital; he was giving a very long courſe of lectures in the winter; he was carrying on his inquiries in comparative anatomy; had a ſchool of practical human anatomy in his houſe; and was always employed in ſome experiments reſpecting the animal economy.

He was always ſolicious for ſome improvement in

medical

medical education; and, with the aſſiſtance of Dr Fordyce, inſtituted a medical ſociety, which he allowed to meet in his lecture rooms, and of which he was choſen one of the patrons. This ſociety, called the *Lyceum Medicum Londinenſe*, under his auſpices and thoſe of Dr Fordyce, has acquired conſiderable reputation, both from the numbers and merits of its members.

In the year 1786, in conſequence of the death of Mr Middleton, Mr Hunter was appointed deputy ſurgeon-general to the army. He now publiſhed his work upon the Venereal Diſeaſe, which had been long expected by the public; and, if we may judge from the rapid ſale of the firſt edition, theſe expectations have not been diſappointed. He alſo publiſhed a work entitled, Obſervations on certain Parts of the Animal Economy. In this work he has collected ſeveral of his papers inſerted in the Philoſophical Tranſactions, which related to that ſubject, having permiſſion from the preſident and council of the Royal Society to reprint them; there are alſo Obſervations upon ſome other parts of the Animal Economy, which had not before been publiſhed. This work met with a very ready ſale.

In the year 1787, he gave a paper to the Royal Society, containing an Experiment to determine the Effect of extirpating one Ovarium on the Number of Young; a paper in which the wolf, jackall, and dog, are proved to be of the ſame ſpecies; and a third upon the Anatomy of the Whale Tribe. Theſe papers procured him the honour of receiving Sir John Copley's annual gold medal, given as a mark of diſtinguiſhed abilities.

His collection, which had been the great object of his life, both as a purſuit and an amuſement, was now brought into a ſtate of arrangement; and gave him at length the ſatisfaction of ſhewing to the public a ſeries of anatomical facts formed into a ſyſtem, by which the economy of animal life was illuſtrated. He ſhewed it to his friends and acquaintances twice a-year, in October to medical gentlemen, and in May to noblemen and gentlemen, who were only in town during the ſpring. This cuſtom he continued to his death.

Upon the death of Mr Adair, which happened in the year 1792, Mr Hunter was appointed inſpector-general of hoſpitals, and ſurgeon-general to the army. He was alſo elected a member of the Royal College of Surgeons in Ireland. In the year 1791, he was ſo much engaged in the duties of his office, as ſurgeon-general to the army, and his private practice, that he had little time to beſtow upon his ſcientifical objects; but his leiſure time, ſmall as it was, he wholly devoted to them.

In 1792, he was elected an honorary member of the Chirurgo-Phyſical Society of Edinburgh, and was choſen one of the vice-preſidents of the Veterinary College, then firſt eſtabliſhed in London. He publiſhed in the Tranſactions of the Society for the Improvement of medical and chirurgical Knowledge, of which ſociety he was one of the original members and a zealous promoter, three papers on the following ſubjects: Upon the Treatment of Inflamed Veins, on Introſuſception, and on a Mode of conveying Food into the Stomach in Caſes of Paralyſis of the Œſophagus.

He finiſhed his Obſervations on the Economy of Bees, and preſented them to the Royal Society. Theſe obſervations were made at Earl's Court, and had engaged his attention for many years; every inquiry into the economy of theſe inſects had been attended by almoſt unſurmountable difficulties; but theſe proved to him only an incitement, and the contrivances he made uſe of to bring the different operations of theſe indefatigable animals to view were almoſt without end.

Earl's Court to Mr Hunter was a retirement from the fatigues of his profeſſion; but in no reſpect a retreat from his labours; there, on the contrary, they were carried on with leſs interruption, and with an unwearied perſeverance. From the year 1772 till his death, he made it his cuſtom to ſleep there during the autumn months, coming to town only during the hours of buſineſs in the forenoon, and returning to dinner.

It was there he carried on his experiments on digeſtion, on exfoliation, on the tranſplanting of teeth into the combs of cocks, and all his other inveſtigations on the animal economy, as well in health as in diſeaſe. The common bee was not alone the ſubject of his obſervation, but the waſp, hornet, and the leſs known kinds of bees, were alſo objects of his attention. It was there he made the ſeries of preparations of the external and internal changes of the ſilk worm; alſo a ſeries of the incubation of the egg, with a very valuable ſet of drawings of the whole ſeries. The growth of vegetables was alſo a favourite ſubject of inquiry, and one on which he was always engaged in making experiments.

The collection of comparative anatomy which Mr Hunter has left, and which may be conſidered as the great object of his life, muſt be allowed to be a proof of talents, aſſiduity, and labour, which cannot be contemplated without ſurpriſe and admiration. It remains an unequivocal teſt of his perſeverance and abilities, and an honour to the country in whoſe ſchools he was educated, and by the patronage of which he was enabled on ſo extenſive a ſcale to carry on his purſuits. In this collection we find an attempt to expoſe to view the gradations of Nature, from the moſt ſimple ſtate in which life is found to exiſt, up to the moſt perfect and moſt complex of the animal creation—man himſelf.

By the powers of his art, this collector has been enabled ſo to expoſe, and preſerve in ſpirits or in a dried ſtate, the different parts of animal bodies intended for ſimilar uſes, that the various links of the chain of perfection are readily followed and may be clearly underſtood.

This collection of anatomical facts is arranged according to the ſubjects they are intended to illuſtrate, which are placed in the following order: *Firſt*, Parts conſtructed for motion. *Secondly*, Parts eſſential to animals reſpecting their own internal economy. *Thirdly*, Parts ſuperadded for purpoſes connected with external objects. *Fourthly*, Parts for the propagation of the ſpecies and maintenance or ſupport of the young.

Mr Hunter was a very healthy man for the firſt forty years of his life; and, if we except an inflammation of his lungs in the year 1759, occaſioned moſt probably by his attention to anatomical purſuits, he had no complaint of any conſequence during that period. In the ſpring of 1769, in his forty-firſt year, he had a regular fit of the gout, which returned the three following ſprings, but not the fourth; and in the ſpring of 1773, having met with ſomething which very forcibly affected his mind, he was attacked at ten o'clock in the forenoon with a pain in the ſtomach, attended with all the ſymptoms of *angina pectoris*. In the life of him prefixed to his *Treatiſe on the Blood, Inflammation, and Gun-Shot Wounds*,

Wounds, the reader will find one of the moſt complete hiſtories of that diſeaſe upon record. Suffice it, in this place, to ſay, that for twenty years he was ſubject to frequent and ſevere attacks of it, which however did not, till a ſhort time before his death, either impair his judgment or render him incapable of performing operations in ſurgery. "In autumn 1790 (ſays Mr Home), and in the ſpring and autumn 1791, he had more ſevere attacks than during the other periods of the year, but of not more than a few hours duration: in the beginning of October 1792, one, at which I was preſent, was ſo violent that I thought he would have died. On October the 16th, 1793, when in his uſual ſtate of health, he went to St George's Hoſpital, and meeting with ſome things which irritated his mind, and not being perfectly maſter of the circumſtances, he withheld his ſentiments; in which ſtate of reſtraint he went into the next room, and turning round to Dr Robertſon, one of the phyſicians of the hoſpital, he gave a deep groan and dropt down dead; being then in his 65th year, the ſame age at which his brother Dr Hunter had died."

It is a curious circumſtance, that the firſt attack of theſe complaints was produced by an affection of the mind, and every future return of any conſequence aroſe from the ſame cauſe; and although bodily exerciſe, or diſtention of the ſtomach, brought on ſlighter affections, it ſtill required the mind to be affected to render them ſevere; and as his mind was irritated by trifles, theſe produced the moſt violent effects on the diſeaſe. His coachman being beyond his time, or a ſervant not attending to his directions, brought on the ſpaſms, while a real misfortune produced no effect.

Mr Hunter was of a ſhort ſtature, uncommonly ſtrong and active, very compactly made, and capable of great bodily exertion. His countenance was animated, open, and in the latter part of his life deeply impreſſed with thoughtfulneſs. When his print was ſhewn to Lavater, he ſaid, "That man thinks for himſelf." In his youth he was cheerful in his diſpoſition, and entered into youthful follies like others of the ſame age; but wine never agreed with his ſtomach; ſo that after ſome time he left it off altogether, and for the laſt twenty years drank nothing but water.

His temper was very warm and impatient, readily provoked, and, when irritated, not eaſily ſoothed. His diſpoſition was candid, and free from reſerve, even to a fault. He hated deceit; and as he was above every kind of artifice, he deteſted it in others, and too openly avowed his ſentiments. His mind was uncommonly active; it was naturally formed for inveſtigation, and that turn diſplayed itſelf on the moſt trivial occaſions, and always with mathematical exactneſs. What is curious, it fatigued him to be long in a mixed company which did not admit of connected converſation; more particularly during the laſt ten years of his life.

He required leſs relaxation than moſt other men; ſeldom ſleeping more than four hours in the night, but almoſt always nearly an hour after dinner; this, probably, aroſe from the natural turn of his mind being ſo much adapted to his own occupations, that they were in reality his amuſement, and therefore did not fatigue.

In private practice he was liberal, ſcrupulouſly honeſt in ſaying what was really his opinion of the caſe, and ready upon all occaſions to acknowledge his ignorance, whenever there was any thing which he did not underſtand.

In converſation, he ſpoke too freely, and ſometimes harſhly, of his contemporaries; but if he did not do juſtice to their undoubted merits, it aroſe not from envy, but from his thorough conviction that ſurgery was as yet in its infancy, and he himſelf a novice in his own art; and his anxiety to have it carried to perfection, made him think meanly and ill of every one whoſe exertions in that reſpect did not equal his own.

HUNTERS, in fortification, denote pieces of timber, about ſix inches ſquare, placed at the lower end of the platform, next to the parapet, to prevent the wheels of the gun-carriages from damaging the parapet.

HYDROGRAPHICAL Charts or Maps, more uſually called ſea-charts, are projections of ſome part of the ſea, or coaſt, for the uſe of navigation. In theſe are laid down all the rhumbs or points of the compaſs, the meridians, parallels, &c. with the coaſts, capes, iſlands, rocks, ſhoals, ſhallows, &c. in their proper places, and proportions.

HYDROMETER, is an inſtrument, of which ſo much has been ſaid in the *Encycl.* under that title, and in the article *Specific Gravity*, that we certainly ſhould not again introduce it in this place, but to guard our readers againſt error, when ſtudying the works of the French chemiſts. Theſe gentlemen, who are ſo ſtrongly attached to every thing which is new, as to believe that their anceſtors have for ages been wandering in the mazes of ignorance, refer very frequently to the *peſe-liqueur* of Baumé; and as that inſtrument has never been generally uſed in this country, it becomes our duty to deſcribe its conſtruction.

Inſtead of adopting the ſimpler method of immediate numerical reference to the denſity of water expreſſed by unity, as is done in all modern tables of ſpecific gravity, he had recourſe to a proceſs ſimilar to that of graduating the ſtems of thermometers from two fixed points. The firſt of theſe points was obtained by immerſing his inſtrument, which is the common areometer, conſiſting of a ball, ſtem, and counterpoiſe, in pure water. At that point of the ſtem which was interſected by the ſurface of the fluid, he marked *zero*, or the commencement of his graduations. In the next place, he provided a number of ſolutions of pure dry common ſalt in water: theſe ſolutions contained reſpectively one, two, three, four, &c. pounds of the ſalt; and in each ſolution the quantity of water was ſuch, as to make up the weight equal to one hundred pounds in the whole; ſo that in the ſolution containing one pound of ſalt, there were ninety-nine pounds of water; in the ſolution containing two pounds of ſalt, there were ninety-eight pounds of water, and ſo of the reſt. The inſtrument was then plunged in the firſt ſolution, in which of courſe it floated with a larger portion of the ſtem above the fluid, than when pure water was uſed. The fluid, by the interſection of its ſurface upon the ſtem, indicated the place for making his firſt degree; the ſame operation repeated, with the fluid containing two pounds of ſalt, indicated the mark for the ſecond degree; the ſolution of three pounds afforded the third degree; and in this manner his enumeration was carried as far as fifteen degrees. The firſt fifteen degrees afterwards, applied with the compaſſes repeatedly along the ſtem, ſerving to extend the graduation as far as eighty degrees, if required.

This inſtrument, which is applicable to the admeaſurement of denſities exceeding that of pure water, is commonly diſtinguiſhed by the name of the *Hydrometer for ſalts*.

The hydrometer for ſpirits is conſtructed upon the ſame principle; but in this the counterpoiſe is ſo adjuſted, that moſt part of the ſtem riſes above the fluid when immerſed in pure water, and the graduations to expreſs inferior denſities are continued upwards. A ſolution of ten parts by weight of ſalt in ninety parts of pure water, affords the firſt point, or zero, upon the ſtem; and the mark indicated by pure water is called the tenth degree; whence, by equal diviſions, the remaining degrees are continued upwards upon the ſtem as far as the fiftieth degree.

Theſe experiments, in both caſes, are made at the tenth degree of Reaumur, which anſwers very nearly to fifty-five of Fahrenheit.

HYDRUS, or WATER SERPENT, one of the new ſouthern conſtellations, including only ten ſtars.

HYGROMETER, is an inſtrument of ſo much importance to the meteorologiſt, that it becomes us to give ſome account of every improvement of it which has fallen under our notice. In the *Encyclopædia*, the principles upon which hygrometers are conſtructed have been clearly ſtated, and the defects of each kind of hygrometer pointed out.

Inſtead of hairs or cat-gut, of which hygrometers of the firſt kind are commonly made, Caſſebois, a Benedictine monk at Mentz, propoſed to make ſuch hygrometers of the gut of a ſilk-worm. When that inſect is ready to ſpin, there are found in it two veſſels proceeding from the head to the ſtomach, to which they adhere, and then bend towards the back, where they form a great many folds. The part of theſe veſſels next the ſtomach is of a cylindric form, and about a line in diameter. Theſe veſſels contain a gummy ſort of matter from which the worm ſpins its ſilk; and, though they are exceedingly tender, means have been deviſed to extract them from the inſect, and to prepare them for the above purpoſe. When the worm is about to ſpin, it is thrown into vinegar, and ſuffered to remain there twenty-four hours; during which time the vinegar is abſorbed into the body of the inſect, and coagulates its juices. The worm being then opened, both the veſſels, which have now acquired ſtrength, are extracted; and, on account of their pliability, are capable of conſiderable extenſion. That they may not, however, become too weak, they are ſtretched only to the length of about fifteen or twenty inches. It is obvious that they muſt be kept ſufficiently extended till they are completely dry. Before they attain to that ſtate, they muſt be freed, by means of the nail of the finger, from a ſlimy ſubſtance which adheres to them. Such a thread will ſuſtain a weight of ſix pounds without breaking, and may be uſed for an hygrometer in the ſame manner as cat-gut; but we confeſs that we do not clearly perceive its ſuperiority.

To an improvement of the hygrometer conſtructed on the third principle, ſtated in the *Encyclopædia*, M. Hochheimer was led in the following manner:

Mr Lowitz found at Dmitriewſk in Aſtracan, on the banks of the Wolga, a thin bluiſh kind of ſlate which attracted moiſture remarkably ſoon, but again ſuffered it as ſoon to eſcape. A plate of this ſlate weighed, when brought to a red heat, 175 grains, and, when ſaturated with water, 247: it had therefore imbibed, between complete dryneſs and the point of complete moiſture, 72 grains of water. Lowitz ſuſpended a round thin plate of this ſlate at the end of a very delicate balance, faſtened within a wooden frame, and ſuſpended at the other arm a chain of ſilver wire, the end of which was made faſt to a ſliding nut that moved up and down in a ſmall groove on the edge of one ſide of the frame. He determined, by trial, the poſition of the nut when the balance was in equilibrio and when it had ten degrees of over-weight, and divided the ſpace between theſe two points into ten equal parts, adding ſuch a number more of theſe parts as might be neceſſary. When the ſtone was ſuſpended from the one arm of the balance, and at the other a weight equal to 175 grains, or the weight of the ſtone when perfectly dry, the nut in the groove ſhewed the exceſs of weight in grains when it and the chain were ſo adjuſted that the balance ſtood in equilibrio. A particular apparatus on the ſame principles as a vernier, applied to the nut, ſhewed the exceſs of weight to ten parts of a grain. Lowitz remarked that this hygrometer in continued wet weather gave a moiſture of more than 55 grains, and in a continued heat of 113 degrees of Fahrenheit only 1½ degree of moiſture.

The hygrometer thus invented by Lowitz was, however, attended with this fault, that it never threw off the moiſture in the ſame degree as the atmoſphere became drier. It was alſo ſometimes very deceitful, and announced moiſture when it ought to have indicated that dryneſs had again begun to take place in the atmoſphere. To avoid theſe inconveniences, M. Hochheimer propoſes the following method:

1. Take a ſquare bar of ſteel about two lines in thickneſs, and from ten to twelve inches in length, and form it into a kind of balance, one arm of which ends in a ſcrew. On this ſcrew let there be ſcrewed a leaden bullet of a proper weight, inſtead of the common weights that are ſuſpended. 2. Take a glaſs plate about ten inches long, and ſeven inches in breadth, deſtroy its poliſh on both ſides, free it from all moiſture by rubbing it over with warm aſhes, ſuſpend it at the other end of the balance, and bring the balance into equilibrium by ſcrewing up or down the leaden bullet. 3. Mark now the place to which the leaden bullet is brought by the ſcrew, as accurately as poſſible, for the point of the greateſt dryneſs. 4. Then take away the glaſs plate from the balance, dip it completely in water, give it a ſhake that the drops may run off from it, and wipe them carefully from the edge. 5. Apply the glaſs-plate thus moiſtened again to the balance, and bring the latter into equilibrium by ſcrewing the leaden bullet. Mark then the place at which the bullet ſtands as the higheſt degree of moiſture. 6. This apparatus is to be ſuſpended in a ſmall box of well dried wood, ſufficiently large to ſuffer the glaſs-plate to move up and down. An opening muſt be made in the lid, exactly of ſuch a ſize as to allow the tongue of the balance to move freely. Parallel to the tongue apply a graduated circle, divided into a number of degrees at pleaſure from the higheſt point of dryneſs to the higheſt degree of moiſture. The box muſt be pierced with ſmall holes on all the four ſides, to give a free paſſage to the air; and to prevent moiſture from penetrating into

into the wood by rain, when it may be requiſite to expoſe it at a window, it muſt either be lackered or painted. To ſave it at all times from rain, it may be covered, however, with a ſort of roof fitted to it in the moſt convenient manner. But all theſe external appendages may be improved or altered as may be found neceſſary.

HYPERBOLA Deficient, is a curve having only one aſymptote, though two hyperbolic legs running out infinitely by the ſide of the aſymptote, but contrary ways.

HYPOTRACHELION, in Architecture, is uſed for a little frize in the Tuſcan and Doric capital, between the aſtragal and annulets; called alſo the colerin and gorgerin. The word is applied by ſome authors in a more general ſenſe, to the neck of any column, or that part of its capital below the aſtragal.

I.

JACOBINS, in the language of the preſent day, is the name aſſumed, at the beginning of the French revolution, by a party in Paris, which was outrageouſly democratical, and fanatically impious. This party, which conſiſted of members of the National Aſſembly, and of others maintaining the ſame opinions and purſuing the ſame objects, formed itſelf into a club, and held its meetings in the hall belonging to the Jacobin friars, where meaſures were ſecretly concerted for exciting inſurrections, and over-awing at once the legiſlature and the king. The name of *Jacobin*, though it was derived from the hall where the club firſt met, has ſince been extended to all who are enemies to monarchy, ariſtocracy, and the Chriſtian religion; and who would have every man to be his own prieſt and his own lawgiver. Hence it is, that we have Jacobins in Great Britain and Ireland, as well as in France.

Of the proceedings of the French Jacobins, ſome account has been given in the *Encyclopædia*, under the title Revolution; and the ſubject will be reſumed in this *Supplement* under the ſame title. The purpoſe of the preſent article is to trace the principles of the ſect from their ſource; for theſe principles are not of yeſterday.

"At its very firſt appearance (ſays the Abbé Barruel), this ſect counted 300,000 adepts; and it was ſupported by two millions of men, ſcattered through France, armed with torches and pikes, and all the firebrands of the revolution." Such a wide ſpread conſpiracy could not be formed in an inſtant; and indeed this able writer has completely proved, that this ſect, with all its conſpiracies, is in itſelf no other than "the coalition of a triple ſect, of a triple conſpiracy, in which, long before the revolution, the overthrow of the altar, the ruin of the throne, and the diſſolution of all civil ſociety, had been debated and determined."

It is known to every ſcholar, that there have been in all ages and countries men of letters and pretenders to letters, who have endeavoured to ſignalize themſelves individually by writing againſt the religion of their country; but it was reſerved for the philoſophiſts (A) of France to enter into a combination for the expreſs purpoſe of eradicating from the human heart every religious ſentiment. The man to whom this idea firſt ocurred was Voltaire; who, daring to be jealous of his God, and being weary, as he ſaid himſelf, of hearing people repeat that twelve men were ſufficient to eſtabliſh Chriſtianity, reſolved to prove that one might be ſufficient to overthrow it. Full of this project, he ſwore, before the year 1730, to dedicate his life to its accompliſhment; and for ſome time he flattered himſelf that he ſhould enjoy alone the glory of deſtroying the Chriſtian religion. He found, however, that aſſociates would be neceſſary; and from the numerous tribe of his admirers and diſciples, he choſe D'Alembert and Diderot as the moſt proper perſons to co-operate with him in his deſigns. How admirably they were qualified to act the part aſſigned them, may be conceived from the life of Diderot in this *Supplement*. But Voltaire was not ſatisfied with their aid alone.

He contrived to embark in the ſame cauſe Frederic II. of Pruſſia, who wiſhed to be thought a philoſopher, and who of courſe deemed it expedient to talk and write againſt a religion which he had never ſtudied, and into the evidence of which he had probably never deigned to inquire. This royal adept was one of the moſt zealous of Voltaire's coadjutors, till he diſcovered that the philoſophiſts were waging war with the throne as well as with the altar. This indeed was not originally Voltaire's intention. He was vain; he loved to be careſſed by the great; and, in one word, he was, from natural diſpoſition, an ariſtocrate and admirer of royalty: But when he found that almoſt every ſovereign but Frederic, diſapproved of his impious projects as ſoon *as he perceived their iſſue*, he determined to oppoſe all the governments on earth, rather than forfeit the glory, with which he had flattered himſelf, of vanquiſhing Chriſt and his apoſtles in the field of controverſy.

He now ſet himſelf, with D'Alembert and Diderot, to excite univerſal diſcontent with the eſtabliſhed order of things. This was an employment entirely ſuited to their diſpoſition; for not being in any ſenſe *great* themſelves (B), they wiſhed to pull all men down to their own level. How effectually they contrived to convert the *Encyclopedie* into an engine to ſerve their purpoſes, has been ſhewn already; but it was not their only nor their moſt powerful engine; they formed ſecret ſocie-

---

(A) This term was invented by Abbé Barruel, and we have adopted it, as denoting ſomething very different from the meaning of the word *philoſopher*.

(B) We do not by this mean to inſinuate that D'Alembert was not a man of ſcience. He was perhaps the only man of ſcience in that gang; but he was a maſter of no ſcience but mathematics; and his birth being ob-

Jacobins.

ties, aſſumed new names, and employed an enigmatical language. Thus, Frederic is called *Luc*: D'Alembert, *Protagoras*, and ſometimes *Bertrand*; Voltaire, *Raton*; and Diderot, *Platon*, or its anagram *Tonpla*; while the general term for the conſpirators is *Cacouac*. In their ſecret meetings they profeſſed to celebrate the myſteries of *Mythra*; and their great object, as they profeſſed to one another, was to confound the *wretch*, meaning J— C—. Voltaire propoſed to eſtabliſh a colony of philoſophiſts at Cleves, who. protected by the king of Pruſſia, might publiſh their opinions without dread or danger; and Frederic was diſpoſed to take them under his protection, till he diſcovered that their opinions were anarchical, as well as impious, when he threw them off, and even wrote againſt them.

They contrived, however, to engage the miniſters of the court of France in their favour, by pretending to have nothing in view but the enlargement of ſcience, in works which ſpoke indeed reſpectfully of revelation, while every diſcovery which they brought forward was meant to undermine its very foundation. When the throne was to be attacked, and even when barefaced atheiſm was to be promulgated, a number of impious and licentious pamphlets were diſperſed, for ſome time none knew how, from a ſecret ſociety formed at the Hotel d'Holbach at Paris. Theſe were ſold for trifles, or diſtributed *gratis* to ſchoolmaſters, and others who were likely to circulate their contents. D'Alembert, Diderot, and Condorcet, who was now aſſociated with the other conſpirators, flattered the ambition of every man among the great, and eſpecially of the Duke d'Orleans, the richeſt ſubject in Europe, and a prince of the blood of France. The firſt and the laſt of theſe three adepts had, by their mathematical knowledge, got ſuch an aſcendancy in the Royal Academy of Sciences, that they could admit or exclude candidates as they knew them to be friendly or inimical to the projects of the conſpirators; and they had contrived, by matchleſs addreſs and unwearied perſeverance, to fill almoſt all the ſeminaries of education with men of their own principles.

Thus was the public mind in France completely corrupted, when the maſon lodges, over which the infamous Orleans preſided, were viſited by a delegation from the German illuminati; and nothing more was neceſſary to produce the ſect of *Jacobins*, by whoſe intrigues and influence, France, as M. Barruel expreſſes himſelf, has become a prey to every crime. It was by the machinations of this ſect that its ſoil was ſtained with the blood of its pontiffs and prieſts, its rich men and nobles; with the blood of every claſs of its citizens, without regard to rank, age, or ſex. Theſe diſciples of Voltaire were the men who, after having made the unfortunate Louis, his queen, and ſiſter, drink, to the very dregs, the cup of outrage and ignominy during a long confinement, ſolemnly murdered them on a ſcaffold, proudly menacing all the ſovereigns of the earth with a ſimilar fate. Yet think not, indignant reader, that the ways of Providence are unequal. The nations of Europe were ripe for chaſtiſement; and that chaſtiſement theſe villains were employed to inflict: but their own puniſhment did not linger. Voltaire died in agonies of deſponding remorſe, which can be exceeded only by the torments of the damned. There is reaſon to believe that the end of D'Alembert and Diderot very much reſembled that of their leader; while the more hardened adept, Condorcet, became his own executioner; and the other chiefs of the rebellion have regularly inflicted vengeance on each other, every alteration of the French conſtitution (and theſe alterations have been many) being followed by the execution of thoſe by whom the government was previouſly adminiſtered.

Jaghire || Jago.

JAGHIRE, aſſignment made in Bengal by an Imperial grant upon the revenue of any diſtrict, to defray civil or military charges, penſions, gratuities, &c.

JAGHIREDER, the holder of a Jaghire.

St JAGO, the largeſt and moſt populous of the Cape de Verde Iſlands, of which ſome account has been given in the *Encyclopædia*, is repreſented by Sir George Staunton as liable to long and exceſſive droughts, for which no philoſophical cauſe can be aſſigned. When the embaſſy to China touched at it in the latter end of 1792, it was in a ſtate of abſolute famine. Little or no rain had fallen for about three years before. The rivers were almoſt all entirely dry. The ſurface of the earth was, in general, naked of any herbage. The greateſt part of the cattle had periſhed, not leſs through drought than want of food. Of the inhabitants many had migrated, and many were famiſhed to death. Nor was this calamity peculiar to St Jago. All the iſlands of Cape de Verde were ſaid to have experienced the ſame long drought, and to be conſequently in a ſtate of ſimilar deſolation. Yet the frequent ſhowers which were obſerved by the firſt navigators who touched at St Jago, induced them to give to the iſland the name of *Pluvialis*; and no change had been obſerved in the ſteady current of wind, blowing from the eaſt, which is common to tropical climates.

"What were the uncommon circumſtances (ſays Sir George) that took place in the atmoſphere of that part of Africa to which the Cape de Verde iſlands lie contiguous, or in the vaſt expanſe of continent extending to the eaſt behind it, and from which this direful effect muſt have proceeded, as they happened where no man of ſcience exiſted to obſerve or to record them, will therefore remain unknown; nor is theory bold enough to ſupply the place of obſervation. Whatever was the cauſe which thus arreſted the bountiful hand of Nature, by drawing away the ſources of fertility, it was obſervable, that ſome few trees and plants perſevered to flouriſh with a luxuriance, indicating that they ſtill could extract from the arid earth whatever portion of humidity it was neceſſary to derive from thence for the purpoſe of vegetable life, though it was denied to others."

Beſide the trees of the palm kind, which are often found verdant amidſt burning ſands, nothing, for example, could be more rich in flavour, or abound more with milky, though corroſive juice, than the aſclepias gigantea (ſee Asclepias, *Encycl.*), growing plentifully, about ſeveral feet high, without culture, indeed, but undiſturbed, it being of no avail to cut it down in favour of plants that would be uſeful, but required the aid of more moiſture from the atmoſphere. The jatropha

---

ſcure, if not ſpurious, and abſtract mathematics not furniſhing ready acceſs to the great, his ideas, when compared with Voltaire's, were grovelling, and (as M. Barruel ſays) he was afraid to be ſeen.

pha curcas, or phyſic nut tree, which the French Weſt Indians, with ſome propriety, call *bois immortel*, and plant, on that account, in the boundaries of their eſtates, appeared as if its perpetuity was not to be affected by any drought. Some indigo plants were ſtill cultivated with ſucceſs in ſhaded vales, together with a few cotton ſhrubs. Throughout the country ſome of thoſe ſpecies of the mimoſa, or ſenſitive plant, which grow into the ſize of trees, were moſt common, and did not appear to languiſh. In particular ſpots the annona, or ſugar apple tree, was in perfect verdure. The boraſſus, or great fan palm, lifted, in a few places, its lofty head and ſpreading leaves with undiminiſhed beauty. In a bottom, about a mile and a half behind the town of Praya, was ſtill growing, in a healthy ſtate, what may be called for ſize a phenomenon in vegetation, a tree known to botaniſts by the name of adanſonia, and in Engliſh called *monkey bread tree*. The natives of St Jago call it *kaliſera*; others, baobab. Its trunk meaſured at the baſe no leſs than 56 feet in girth; but it ſoon divided into two great branches, one riſing perpendicularly, and meaſuring 42 feet in circumference; that of the other was about 26. By it ſtood another of the ſame ſpecies, whoſe ſingle trunk, of 38 feet girth, attracted little notice from the vicinity of its huge companion.

But the annual produce of agriculture was ſcarcely to be found. The plains and fields, formerly productive of corn, ſugar-canes, or plaintains, nouriſhed by regular falls of rain, now bore little ſemblance of vegetation. Yet in the ſmall number of plants which ſurvived the drought, were ſome which, from the ſpecimens ſent to Europe, were found to have been hitherto unknown. Vegetation quickly, indeed, revived wherever, through the ſoil, any moiſture could be conveyed.

Sir George repreſents Praya, the reſidence of the Portugueſe Viceroy, as a hamlet rather than a town. It conſiſts of about 100 very ſmall dwellings, one ſtory high, ſcattered on each ſide of the plain, which extended near a mile in length, and about the third of a mile in breadth; and fell off, all around, to the neighbouring valleys and to the ſea. Not being commanded by any neighbouring eminence, it was a ſituation capable of defence; the fort, however, or battery, was almoſt in ruins; and the few guns mounted on it were moſtly honey-combed, and placed on carriages which ſcarcely held together.

A party belonging to the embaſſy croſſed the country to the ruins of St Jago, the former capital of the iſland, ſituated in the bottom of a vale, through which ran a ſtream, then both ſmall and ſluggiſh. On each ſide of that ſtream are the remains of dwellings of conſiderable ſolidity and ſize; and the fragments of glaſs luſtres, ſtill hanging from the ceilings of ſome of the principal apartments, denote the elegance or riches that were once diſplayed in this now deſerted place. Not above half a dozen families remain in it at preſent; the reſt abandoned it, or periſhed. Here was ſtill, however, an attempt at a ſlight manufactory of ſtripped cotton ſlips, the ſame as are made in the other parts of the iſland, for the uſe of the Africans on the main, who pay for them in ſlaves, elephants teeth, and that gum which is generally called arabic.

Amidſt the ruins of St Jago, the party found a Portugueſe, to whom one of them was recommended, and who received them with the moſt cordial hoſpitality in his houſe, and treated them with every ſpecies of tropical fruits from his garden, lying on each ſide the river.

He had been a navigator; and informed them that the iſle of Brava, one of the Cape de Verde's, was a fitter and ſafer place for ſhips to call at for water and proviſions than the iſland of St Jago; that it had three harbours: one called Puerto Furno on the eaſt ſide of the iſland, from which veſſels muſt warp, or be towed out by boats; the Puerto Fajendago to the weſt; and the Puerto Ferreo to the ſouth, which was the beſt for large ſhips, and into which runs a ſmall river. In another of the Cape de Verde iſlands, called San Vicente, he obſerved that there was alſo a large harbour on the north end, but that freſh water was at ſome diſtance from it: and there was likewiſe a good port at Bonaviſta. This information of the harbours in the iſle of Brava was confirmed by accounts given by others to Sir Eraſmus Gower, who recommends to make a trial of them.

JALOFFS, or YALOFFS, are an active, powerful, and warlike people, inhabiting great part of that tract of Africa which lies between the Senegal and the Mandingo ſtates on the Gambia (See MANDINGOES in this *Supplement*). Their noſes, ſays Mr Park, are not ſo much depreſſed, nor their lips ſo protuberant, as thoſe of the generality of Africans; and though their ſkin is of the deepeſt black, they are conſidered by the white traders as the moſt ſightly negroes in that part of the continent where they live. They are divided into ſeveral independent ſtates or kingdoms, which are frequently at war with their neighbours or with each other. In their manners, ſuperſtitions, and government, they have a greater reſemblance to the Mandingoes than to any other nation; but excel them in the manufacture of cotton cloth, ſpinning the wool to a finer thread, weaving it in a broader loom, and dyeing it of a better colour. They make very good ſoap, by boiling ground nuts in water, and then adding a ley of wood aſhes. They likewiſe manufacture excellent iron, which they carry to Bondou to barter for ſalt. Their language is ſaid to be copious and ſignificant, and is often learned by Europeans trading to Senegal. From the names of their numerals, as given by Mr Park, it would appear that their numeration proceeds by *fives*, as ours does by *tens*.

Our author relates the event of a religious war, which, as it diſplays a generoſity of character very uncommon among ſavages, will afford pleaſure to the minds of many of our readers. Almami Abdulkader, ſovereign of a Mahomedan kingdom called Foota Torra, ſent to Damel, a king of the Jaloffs, an imperious meſſage, commanding him and his ſubjects to embrace inſtantly the faith of the prophet. The ambaſſador having got admiſſion to the preſence of Damel, ordered ſome Buſhreens (*i. e.* Mahomedan negroes) who accompanied him, to preſent the emblems of his miſſion. Two knives were accordingly laid before the Jaloff prince, and the ambaſſador explained himſelf as follows:

"With this knife (ſaid he) Abdulkader will condeſcend to ſhave the head of Damel, if Damel will embrace the Mahomedan faith; and with this other knife Abdulkader will cut the throat of Damel, if Damel refuſes to embrace it: Take your choice."—Damel coolly told the ambaſſador that he had no choice to make:

he neither choſe to have his head ſhaved, nor his throat cut. And with this anſwer the ambaſſador was civilly diſmiſſed.

Abdulkader took his meaſures accordingly; and with a powerful army invaded Damel's country. The inhabitants of the towns and villages filled up their wells, deſtroyed their proviſions, carried off their effects, and abandoned their dwellings, as he approached. By this means he was led on from place to place, until he had advanced three days journey into the country of the Jaloffs. He had, indeed, met with no oppoſition; but his army had ſuffered ſo much from the ſcarcity of water, that ſeveral of his men died by the way. This induced him to direct his march towards a watering place in the woods, where his men, having quenched their thirſt, and being overcome with fatigue, lay down careleſsly to ſleep among the buſhes. In this ſituation they were attacked by Damel before day-break, and completely routed. Many of them were trampled to death as they lay aſleep by the Jaloffs horſes; others were killed in attempting to make their eſcape; and a ſtill greater number were taken priſoners. Among the latter was Abdulkader himſelf. This ambitious, or rather frantic prince, who, but a month before, had ſent the threatening meſſage to Damel, was now himſelf led into his preſence as a miſerable captive. The behaviour of Damel, on this occaſion, is never mentioned by the ſinging men* but in terms of the higheſt approbation; and it was, indeed, ſo extraordinary in an African prince, that the reader may find it difficult to give credit to the recital. When his royal priſoner was brought before him in irons, and thrown upon the ground, the magnanimous Damel, inſtead of ſetting his foot upon his neck, and ſtabbing him with his ſpear, according to the cuſtom in ſuch caſes, addreſſed him as follows: "Abdulkader, anſwer me this queſtion. If the chance of war had placed me in your ſituation, and you in mine, how would you have treated me?" "I would have thruſt my ſpear into your heart (returned Abdulkader with great firmneſs); and I know that a ſimilar fate awaits me." "Not ſo (ſaid Damel); my ſpear is indeed red with the blood of your ſubjects killed in battle, and I could now give it a deeper ſtain, by dipping it in your own; but this would not build up my towns, nor bring to life the thouſands who fell in the woods. I will not therefore kill you in cold blood, but I will retain you as my ſlave, until I perceive that your preſence in your own kingdom will be no longer dangerous to your neighbours; and then I will conſider of the proper way of diſpoſing of you." Abdulkader was accordingly retained, and worked as a ſlave for three months; at the end of which period, Damel liſtened to the ſolicitations of the inhabitants of Foota Torra, and reſtored to them their king. Strange as this ſtory may appear, Mr Park has no doubt of the truth of it. It was told to him at Malacotta by the negroes; it was afterwards related to him by the Europeans on the Gambia; by ſome of the French at Goree; and confirmed by nine ſlaves, who were taken priſoners along with Abdulkader by the watering place in the woods, and carried in the ſame ſhip with him to the Weſt Indies.—Such generoſity as this reflects honour on human nature.

JARRA, is a town of conſiderable extent in the Mooriſh kingdom of Ludamar in Africa. The houſes are built of clay and ſtone intermixed, a kind of wall very common in many parts of Scotland, where clay is made to ſupply the place of mortar. The greater part of the inhabitants of Jarra are Negroes from the borders of the ſouthern ſtates, who prefer, ſays Mr Park, a precarious protection under the Moors, which they purchaſe by a tribute, to the being continually expoſed to their predatory hoſtilities. The tribute which they pay is conſiderable; and they manifeſt the moſt unlimited obedience and ſubmiſſion to their Mooriſh ſuperiors: by whom they are, in return, treated with the utmoſt indignity and contempt. The Moors in this, and the other ſtates adjoining the country of the Negroes, reſemble in their perſons the Mulattoes of the Weſt Indies, and ſeem to be a mixed race between the Moors, properly ſo called, of the north, and the Negroes of the ſouth; poſſeſſing many of the worſt qualities of both nations. Jarra is ſituated in 15° 5′ N. Lat. and 6° 48′ E. Long.

IBIS. Under the generic name TANTALUS *(Encycl.)*, we have deſcribed, after Mr Bruce, a bird which he found in Abyſſinia, and concluded to be the ſacred ibis of ancient Egypt. M. Vaillant, during his laſt travels in Africa, found, in ſome lakes near the elephants river, a bird very different from Mr Bruce's, which he conſidered as belonging to the ſame ſpecies; and which he deſcribes thus: It is three feet in height. Its head and throat, which are extremely bare, are covered with a ſkin of the brighteſt red, terminated by a band of a beautiful orange, which ſeparates the naked part from that covered with feathers. The upper part of the wings, having broad ſtripes of a fine violet colour, agreeably ſhaded, is bordered by a white band of feathers, the thick and ſilky beards of which, ſeparated from each other, have a perfect reſemblance to a rich fringe. The quills of the wings and tail are of a greeniſh black, which, as it receives the light in a more or leſs oblique direction, aſſumes the appearance of violet or purple. The reſt of the plumage is of a beautiful white. The bill, which is long and ſomewhat crooked, is yellow; as are the feet. This bird belongs to the genus of the ibis, of which we are already acquainted with ſeveral ſpecies.

ICE-HOUSE. See that article, *Encyclopædia*. Profeſſor Beckmann, in the third volume of his Hiſtory of Inventions, has proved clearly that the ancients were well acquainted with what ſerved the purpoſe of ice-houſes.

"The art (ſays he) of preſerving ſnow for cooling liquors during the ſummer, in warm countries, was known in the earlieſt ages. This practice is mentioned by Solomon *, and proofs of it are ſo numerous in the works of the Greeks and the Romans, that it is unneceſſary for me to quote them, eſpecially as they have been collected by others. How the repoſitories for keeping it were conſtructed, we are not expreſsly told; but it is probable that the ſnow was preſerved in pits or trenches.

"When Alexander the Great beſieged the city of Petra, he cauſed 30 trenches to be dug, and filled with ſnow, which was covered with oak branches; and which kept in that manner for a long time. Plutarch ſays, that a covering of chaff and coarſe cloth is ſufficient; and at preſent a like method is purſued in Portugal. Where the ſnow has been collected in a deep gulph,

---

* *The hiſtorians of the country.*

* *Proverbs*, xxv. 15.

ſome graſs or green ſods, covered with dung from the ſheep pens, is thrown over it; and under theſe it is ſo well preſerved, that the whole ſummer through it is ſent the diſtance of 60 Spaniſh miles to Liſbon.

"When the ancients, therefore, wiſhed to have cooling liquors, they either drank the melted ſnow, or put ſome of it in their wine, or they placed jars filled with wine in the ſnow, and ſuffered it to cool there as long as they thought proper. That ice was alſo preſerved for the like purpoſe, is probable from the teſtimony of various authors; but it appears not to have been uſed ſo much in warm countries as in the northern. Even at preſent ſnow is employed in Italy, Spain, and Portugal; but in Perſia ice. I have never any where found an account of Grecian or Roman ice-houſes. By the writers on agriculture they are not mentioned."

ICHNOGRAPHY, in architecture, is a tranſverſe or horizontal ſection of a building, exhibiting the plot of the whole edifice, and of the ſeveral rooms and apartments in any ſtory; together with the thickneſs of the walls and partitions; the dimenſions of the doors, windows, and chimneys; the projectures of the columns and piers, with every thing viſible in ſuch a ſection.

JEBB (John), was born in Southampton-ſtreet, Covent Garden, London, on the 16th of February 1736. He was the eldeſt ſon of the Rev. John Jebb, dean of Caſhel, in the kingdom of Ireland. He received the elements of his education in different ſchools, and was admitted, July 7. 1753, penſioner in the univerſity of Dublin, whence he removed, November the 9th 1754, to St Peter's college in Cambridge, where he was likewiſe a penſioner. In January 1757 he proceeded to the degree of B. A. and his place in the diſtribution of academical honours was, on that occaſion, ſecond wrangler, the late eminent mathematician Dr Waring being the firſt. In 1758 he obtained the ſecond prize of fifteen guineas, annually given by the univerſity to the authors of the beſt compoſitions in Latin proſe, being ſenior or middle bachelors of arts. Dr Roberts, afterwards provoſt of Eton college, obtained the firſt.

In the month of June 1760, Mr Jebb was admitted probationer fellow of St Peter's college, and proceeded to the degree of Maſter of Arts at the commencement in the ſame year; and on the firſt of July 1761, was confirmed fellow by Dr Mawſon, biſhop of Ely.

On the 6th of June 1762, he was ordained deacon at Bugden by Dr John Green, biſhop of Lincoln; and on the 25th of September, 1763, he was admitted by the ſame biſhop into prieſt's orders.

On the 22d of Auguſt, 1764, Mr Jebb was collated by Dr Matthias Mawſon, biſhop of Ely, to the ſmall vicarage of Gamlingay, near Potton, in Bedfordſhire, upon the recommendation of Dr Law, maſter of Peterhouſe. On the 17th of the following October, he was elected by the univerſity into the rectory of Ovington, near Watton, in Norfolk, after a competition with the Rev. Henry Turner, then fellow of St John's college, afterwards vicar of Burwell, in Cambridgeſhire. Upon caſting up the votes, there appeared to be for Mr Jebb 91, for Mr Turner 73; and accordingly he was inſtituted into the ſame the 15th of December following.

On the 29th of the ſame month, (December 1764). Mr Jebb married Anne, eldeſt daughter of the Rev. James Torkington, rector of Little Stukeley, in Huntingdonſhire, and of lady Dorothy Sherard, daughter of Philip, ſecond earl of Harborough.

Early in the year 1765, Mr Jebb, together with the Rev. Robert Thorpe, fellow of Peterhouſe, and the Rev. George Woolſton, fellow of Sidney college, publiſhed, in a ſmall quarto, a comment on thoſe parts of Sir Iſaac Newton's *Principia* which more immediately relate to the ſyſtem of the world. The title of the joint work of theſe able and judicious philoſophers was, "Excerpta quædam e Newtoni principiis philoſophiæ naturalis, cum notis variorum." A work, of which the univerſity of Cambridge continues to bear teſtimony to the excellence, by the general uſe of it in the courſe of academical education.

Mr Chappelow profeſſor of Arabic, dying on the 14th of January 1768, Mr Jebb offered himſelf a candidate for the vacant chair; but it was given to Dr Hallifax, afterwards biſhop of Glouceſter; a man of deſerved celebrity, of whom we regret that it was not in our power to give a biographical ſketch.

On July 10. 1769, Mr Jebb was inſtituted to the vicarage of Flixton, near Bungay, in Suffolk, on the preſentation of William Adair, Eſq. of Flixton-hall; and on the 4th of April 1770, was inſtituted to the united rectories of Homersfield and St Croſs, pariſhes contiguous to Flixton, upon the ſame preſentation: being alſo, in the ſummer of the ſame year, nominated chaplain to Robert earl of Harborough. In conſequence of the acceſſion of theſe preferments, though not conſiderable in themſelves, he reſigned, ſome time in the month of October 1771, the rectory of Ovington, which he had received from the univerſity; and Mr Sheepſhanks, fellow of St John's college, was elected in his place.

Dr Hallifax ſucceeding to the profeſſorſhip of civil law, in the month of October 1770, upon the death of Dr Ridlington, Mr Jebb once more ſolicited that of Arabic, which Dr Hallifax then vacated: but he had by this time diſplayed ſuch an innovating ſpirit in religion, that the univerſity gave the vacant profeſſorſhip to Mr Craven, a man reſpected even by Mr Jebb and his friends.

Early in the year 1771, a deſign was formed of applying to parliament for relief in the matter of ſubſcription to the liturgy, and thirty-nine articles of the Church of England; and in the proſecution of this deſign Mr Jebb took a very active part. He attended different meetings of the diſcontented clergy, held at the Feathers tavern, London, aſſiſted in the drawing up of their petition, and wrote their circular letter, which gave to the public an account of their aims. He buſied himſelf at the ſame time in making various attempts to bring about what he called a reformation of the univerſity of Cambridge: but finding them fruitleſs, he retired, on the 25th of June 1772, to Bungay, where he ſtudied French and Italian, and proceeded in a plan of ſome *political* or *conſtitutional lectures*.

He had by this time ceaſed to read the prayers of the church, though he ſtill continued to preach occaſionally; and the Archdeacon of Suffolk, holding, this year, his uſual viſitation of ſome neighbouring pariſhes in the church of Flixton, Mr Jebb preached ſuch a ſermon againſt ſubſcription, as drew upon himſelf a public rebuke from the Archdeacon, in the preſence of the clergy. "Much altercation, (ſays he) enſued;

and for ſome days I expected a ſummons to Norwich; but have heard no more of it. *I acted thus, with a view to call the attention of the Norwich clergy to our cauſe;* and have in part ſucceeded."

He acted much more honourably than this, when, in 1775, he reſigned all his preferments in the church; which ſurely he ought not to have retained one day after his conſcience would not permit him to read the prayers of the liturgy. He now reſolved to become a phyſician; and after attending St Bartholomew's hoſpital in London for ſix months, as the pupil of Dr William Pitcairn, he received, on the 18th of March 1777, a diploma of Doctor of Phyſic from the univerſity of St Andrews!! He did not, however, commence practice till the 5th of February 1778; and even then he continued to attend the lectures of Dr Hunter, Mr John Hunter, and Dr Higgins. On the 18th of February 1779 he was elected a fellow of the Royal Society.

Dr Jebb, at the breaking out of the American war, had ſhewn himſelf at Cambridge a warm partizan of the revolting colonies; and of courſe a keen advocate for what he called, and, we doubt not, thought, the civil liberties of mankind. He now ſignalized himſelf by "An addreſs to the Freeholders of Middleſex," aſſembled at Free maſon's tavern in Great Queen-ſtreet, on Monday, December the 20th 1779, for the purpoſe of eſtabliſhing meetings to maintain and ſupport the freedom of election. Upun this occaſion, he communicated to James Townſend, Eſq. chairman of that meeting, the above addreſs, under the ſignature of "Salus Publica;" preſuming, that if the ſentiments appeared to be founded in reaſon, they would not be the leſs regarded on account of their being ſuggeſted by an unknown individual."

This addreſs was immediately printed, and very ſoon paſſed through three editions, each being enlarged by the addition of freſh matter; and in 1782, followed the fourth edition corrected, which alſo bore our author's name in the title page.

About the end of February 1780, Dr Jebb was appointed by the committee of the county of Huntingdon, one of their deputies, to attend a meeting in London of repreſentatives from certain other petitioning counties, in order to concert meaſures for the more effectual reform of the preſent conſtitution of the houſe of commons. Soon afterwards he became one of the moſt active members of "the ſociety for conſtitutional information;" of which the object, according to their own account, was to diffuſe throghout the kingdom, as univerſally as poſſible, a knowledge of the great principles of conſtitutional freedom, particularly ſuch as reſpect the election and duration of the repreſentative body. "With this view (ſay they), conſtitutional tracts, intended for the extenſion of this knowledge, and to communicate it to perſons of all ranks, are printed and diſtributed gratis, at the expence of the ſociety. Eſſays, and extracts from various authors, calculated to promote the ſame deſign, are alſo publiſhed under the direction of the ſociety, in ſeveral of the newſpapers; and it is the wiſh of the ſociety to extend this knowledge throughout every part of the united kingdoms, and to convince men of all ranks, that it is their intereſt, as well as their duty, to ſupport a free conſtitution, and to maintain and aſſert thoſe common rights, which are eſſential to the dignity and to the happineſs of human nature." Could Dr Jebb have foreſeen all the miſchiefs which have flowed from this inſtitution; could he have foreſeen the wonderful ſpawn of factious ſocieties which have ſprung from it as from a parent ſtock, our veneration for genius and learning will not permit us to believe, that he would have neglected the ſtudies of his profeſſion for the ſake of taking the lead in party politics.

Dr Petit, one of the phyſicians of St Bartholomew's hoſpital, dying the 26th of May, Dr Jebb offered himſelf a candidate to ſucceed to that appointment. The election came on the 23d of June; when Dr Budd, his antagoniſt, ſucceeded by a great majority.

The oppoſition which was made to his election at St Bartholomew's, followed him in the winter, when he offered himſelf at St Thomas's hoſpital in the borough. Indeed he relinquiſhed his pretenſions there ſooner than in the former place; but for no other reaſon than becauſe he found that all his political principles were likely to be again objected to him, and to hazard his ſucceſs.

In the year 1783 he concurred with others in forming "the ſociety for promoting the knowledg of the ſcriptures," which met firſt on the 20th of September in that year, and whoſe meetings continued to be held, and, for ought we know to the contrary, are ſtill held at Eſſex-houſe. The ſketch of their plan was chiefly written by Dr Jebb; and their object was to propagate the doctrines of Unitarianiſm, for which he was as great a zealot as for civil liberty.

His health now began to decline; but during his confinement, he ſtudied the Saxon language, the Anglo Saxon laws, Engliſh hiſtory and antiquities, with a view to examine into our criminal code, and particular points of liberty. The vigour of his mind was ſtill equal to the furniſhing himſelf with this freſh ſtore of knowledge; he foreſaw the advantage of ſuch an acquiſition in the inveſtigation of the legal rights of Engliſhmen, and had deſigned to have employed it in the ſupport of ſome great conſtitutional queſtions, which he conſidered as eſſential to the freedom of his country.

But as the year began to dawn, it was very obſervable to many of his friends that, according to every appearance, and without ſome very great and ſingular effort of nature, his increaſed debility would defeat every exertion of the moſt judicious medical aſſiſtance, and terminate the remaining ſparks of human life.

In this enfeebled ſtate, his mind was active. His "Thoughts on Priſons" were printed and circulated in the county of Suffolk in 1785, by his much valued friend Mr Lofft; and there is ſufficient reaſon for concluding that this little tract had effect on the deliberations of the juſtices at Ipſwich and Bury, then engaged in erecting a new gaol for the diviſion of Ipſwich, and a new houſe of correction for that of Bury.

The good effects of this very excellent tract, it was apprehended, would be extended by a more general publication. In this hope Dr Jebb reviſed and corrected it with his dying hand: and his ſurviving friend publiſhed it ſoon after his death, adding thereto "an abſtract of felonies created by ſtatute and other articles relative to the penal law.

He continued to linger till May the 2d 1786, when, about 8 o'clock in the evening, he breathed his laſt,
leaving

Jefferſonia
Jerboa

Jerboa,
Jillifree.

leaving behind him, among men of different perſuaſions, very different characters. By the diſſenters he is ſeldom mentioned but as the *Great Jebb*; by churchmen, his abilities are univerſally allowed, whilſt regret is expreſſed that they were ſo often employed in ſupport of faction and hereſy. His moral character has never been aſperſed.

JEFFERSONIA, a new plant lately diſcovered in Georgia by Dr Brickel of Savannah, and ſo named by him in compliment to the vice preſident of the United States. In the *Monthly Magazine* for July 1798 we have the following deſcription of it;

JEFFERSONIA pentendria monogynia.

Calyx, below, compoſed of five ſhort oval imbricated leaves; *corolla*, monophyllous, funnel-ſhaped on the receptacle, ſub-pentangular, bearing the filaments near the baſe, its margin hypocrateriform, divided into five round ducts nearly equal; *ſtyle*, pitiform, ſhorter than the petal, but longer than the ſtamens; *ſtigma*, quadripid; *anthers*, erect, linear, ſagittated; *fruit*, two univalved, carinated, polyſpermous capſules, united at the baſe, opening on their tops and contiguous ſides, having flat ſeeds, with a marginal wing.

Only one ſpecies is as yet diſcovered, *Jefferſonia ſempervireus*. It is a ſhrub with round poliſhed twining ſtems, which climb up on buſhes and ſmall trees; the petioles ſhort, oppoſite; leaves oblong, narrow, entire, evergreen, acute; flowers axillary, yellow, having a ſweet odour. The woods are full of this delightful ſhrub, which is covered with bloſſoms for many months in the year.

JERBOA, ſee Mus, *Encycl*, where deſcriptions are given of the jaculus or common jerboa, and of the Arabian, Egyptian, and Siberian jerboas. A variety of this animal has lately been found in Canada by Major-general Davies, F. R. S. and L. S. who ſays it belongs to Schreber's genus of Dipus, and may be thus characteriſed: DIPUS CANADENSIS *palmis tetradactylis, plantis pentadactylis, caudâ annulatâ undique ſetoſâ, corpore longiore*. The truth, however, ſeems to be, that it is only a variety, if indeed a variety, of the Siberian jerboa. The beautiful figure indeed given by General Davies of the Canadian jerboa differs in ſome reſpects from our figure of the Sibericus. Its ears lie flat and farther down the neck; its belly is not ſo large; its toes are longer; and it has no bruſh at the end of the tale; but the habits of the two animals ſeem to be the ſame. This will be apparent from the following extracts of the General's letter to the Linnean Society:

"The firſt I was ſo fortunate to catch was taken in a large field near the falls of Montmorenci, and by its having ſtrayed too far from the ſkirts of the wood, allowed myſelf, with the aſſiſtance of three other gentlemen, to ſurround it, and after an hour's hard chaſe to get it unhurt, though not before it was thoroughly fatigued; which might in a great meaſure accelerate its death.

"During the time the animal remained in its uſual vigour, its agility was incredible for ſo ſmall a creature. It always took progreſſive leaps of from three to four, and ſometimes of five yards, although ſeldom above 12 or 14 inches from the ſurface of the graſs; but I have frequently obſerved others in ſhrubby places and in the woods, amongſt plants, where they chiefly reſide, leap conſiderably higher. When found in ſuch places, it is impoſſible to take them, from their wonderful agility, and their evading all purſuit by bounding into the thickeſt cover they can find."

That the Canadian, as well as the Siberian Jerboa, ſleeps through the winter, ſeems evident from a ſpecimen having been found, towards the end of May, incloſed in a ball of clay, about the ſize of a cricket ball, nearly an inch in thickneſs, perfectly ſmooth within, and about twenty inches under ground. It was given to the General; who proceeds thus:

"How long it had been under ground it is impoſſible to ſay; but as I never could obſerve theſe animals in any parts of the country after the beginning of September, I conceive they lay themſelves up ſome time in that month, or beginning of October, when the froſt becomes ſharp: nor did I ever ſee them again before the laſt week in May, or beginning of June. From their being enveloped in balls of clay, without any appearance of food, I conceive they ſleep during the winter, and remain for that term without ſuſtenance. As ſoon as I conveyed this ſpecimen to my houſe, I depoſited it, as it was, in a ſmall chip box, in ſome cotton, waiting with great anxiety for its waking; but that not taking place at the ſeaſon they generally appear, I kept it until I found it begin to ſmell: I then ſtuffed it, and preſerved it in its torpid poſition. I am led to believe, its not recovering from that ſtate aroſe from the heat of my room during the time it was in the box, a fire having been conſtantly burning in the ſtove, and which, in all probability, was too great for reſpiration. I am led to this conception from my experience of the ſnow bird of that country, which always expires in a few days (after being caught, although it feeds perfectly well) if expoſed to the heat of a room with a fire or ſtove; but being nouriſhed with ſnow, and kept in a cold room or paſſage, will live to the middle of ſummer."

JETTE, the border made round the ſtilts under a pier, in certain old bridges, being the ſame with ſtarling; conſiſting of a ſtrong framing of timber filled with ſtones, chalk, &c. to preſerve the foundations of the piers from injury.

JILLIFREE is a town on the northern bank of the river Gambia, oppoſite to James's iſland, where the Engliſh had formerly a ſmall fort. The kingdom of Barra, in which it is ſituated, produces great plenty of the neceſſaries of life; but the chief trade of the inhabitants is in ſalt, which they carry up the river in canoes; and, in return, bring down Indian corn, cotton cloths, elephants teeth, ſmall quantities of Gold duſt, &c. "The number of canoes and people conſtantly employed in this trade, make the king of Barra (ſays Mr Park) more formidable to Europeans than any other chieftain on the river, and have encouraged him to eſtabliſh thoſe exorbitant duties, which traders of all nations are obliged to pay at entry, amounting nearly to L. 20 on every veſſel, great and ſmall. Theſe duties, or cuſtoms, are generally collected in perſon by the alkaid or governor of Jillifree, who is attended by a numerous train of noiſy and troubleſome dependants, who, by their frequent intercourſe with the Engliſh, have acquired a ſmattering of our language, and beg for every thing which they fancy with ſuch earneſtneſs, that traders, in order to get quit of them, are frequently obliged to grant their requeſts. Lat. 13° 16′. Long. 16° 10′ weſt from Greenwich.

1 Object of the Illuminati.

ILLUMINATI is the name which was aſſumed by a ſecret ſociety or order, founded, on the firſt of May 1776, by Dr Adam Weiſhaupt profeſſor of canon law in the univerſity of Ingolſtadt. The real object of this order was, by clandeſtine arts, to overturn every government and every religion; to bring the ſciences of civil life into contempt; and to reduce mankind to that imaginary ſtate of Nature when they lived independent of each other on the ſpontaneous productions of the earth. Its avowed object, however, was very different. It profeſſed to diffuſe from ſecret ſocieties, as from ſo many centres, the light of ſcience over the world; to propagate the pureſt principles of virtue; and to re-inſtate mankind in the happineſs which they enjoyed during the golden age fabled by the poets. Such an object was well adapted to make a deep impreſſion on the ingenuous minds of youth; and to young men alone Weiſhaupt at firſt addreſſed himſelf.

It will naturally occur to the reader, that the means of attaining this glorious object ſhould have been made as public as poſſible; and that the veil of ſecrecy thrown over the proceedings of the order was calculated to excite ſuſpicion, and to keep even *young* men of virtue and ſagacity at a diſtance. In any other country than Germany ſecrecy might perhaps have had this effect; but various circumſtances conſpired there to make it operate with a powerful attraction.

Ever ſince free-maſonry had acquired ſuch reputation throughout Europe, a multitude of petty ſecret ſocieties had been formed in the univerſities of Germany, each having its lodge, its maſter, its myſteries, all modelled on thoſe founded by maſons coming from England and Scotland (A). Before the foundation of Weiſhaupt's order, theſe lodges, we believe, were in general harmleſs; or if they were productive of any evil, it was only by giving the youth of the univerſities a taſte for ſecrecy and miſticiſm. Of this Weiſhaupt availed himſelf; and as ſoon as he had conceived the outlines of his plan, and digeſted part of his ſyſtem, he initiated two of his own pupils, to whom he gave the names of AJAX and TIBERIUS, aſſuming that of SPARTACUS to himſelf. Theſe two diſciples ſoon vying with their maſter in impiety (for it will be ſeen by and bye that he was moſt impious), he judged them worthy of being admitted to his myſteries, and conferred on them the higheſt degree which he had as yet invented. He called them *Areopagites*, denominated this monſtrous aſſociation, THE ORDER OF ILLUMINATI, OR ILLUMINEES, and inſtalled himſelf GENERAL of the order.

When public report ſpread the news in Germany of this new order having been founded in the univerſity of Ingolſtadt by Weiſhaupt, it was generally ſuppoſed to be one of thoſe little college-lodges which could not intereſt the adepts after they had finiſhed their ſtudies. Many even thought that Weiſhaupt, who was at that time a ſworn enemy to the Jeſuits, had founded this lodge with no other view than to form a party for himſelf againſt theſe fathers, who after the ſuppreſſion of their order had been continued in their offices of public teachers at the univerſity of Ingolſtadt; and this opinion the illuminees were at pains to propagate. His character, too, was at this time ſuch as to remove every ſuſpicion from the public mind. A ſeeming aſſiduity in his duty, and a great ſhew of zeal and erudition in expounding the laws, eaſily miſled people to believe that his whole time and talents were engroſſed with the ſtudy of them; and if we are to credit his own account, Ingolſtadt had never witneſſed a profeſſor ſo well calculated to add new luſtre to its univerſity.

2 Art of the founder.

This ſeems, indeed, to have been the general opinion as well as his own; for, ſome time after the foundation of his order, he applied himſelf with ſuch diligence and apparent candour to the duties of his office, that he was choſen what Abbé Barruel's tranſlator calls SUPERIOR of the univerſity. This new dignity only added to his hypocriſy, and furniſhed him with freſh means of carrying on his dark deſigns. He converted his houſe into one of thoſe boarding houſes where young men, perpetually under the eye of their maſters, are ſuppoſed to be better preſerved than anywhere elſe from the dangers which threaten them at that age. He ſolicited fathers and mothers to entruſt their children to his care; and, counterbalancing in ſecret the leſſons which he was obliged to give in public, he ſent home his pupils well diſpoſed to continue the ſame career of ſeduction which he himſelf carried on at Ingolſtadt. Atrociouſly impious, we ſee him (ſays M. Barruel), in the firſt year of his illuminiſm, aping the God of Chriſtianity, and ordering *Ajax*, in the following terms, to propagate the doctrines of his new goſpel: "Did not Chriſt ſend his apoſtles to preach his goſpel to the univerſe? You that are my Peter, why ſhould you remain idle at home? Go then and preach."

Theſe preachers had yet received no particular deſignation; for when his firſt adepts were initiated, he was far from having completed the code of his order. He knew that years and experience were neceſſary to perfect that gradual ſyſtem of initiations and trials which, according to the plan he had conceived, his novices were to undergo; but he could not endure the idea of ſacrificing years to mere theoretic projects; and he flattered himſelf with the hopes of ſupplying the deficiencies of his incomplete code by proviſional regulations and private inſtructions, and of acquiring aſſociates who would receive his new goſpel implicitly, and cooperate with him in all his views.

3 The ſect divided into claſſes of

At length, however, the code was completed, and the ſect divided into two grand claſſes; and each of theſe again ſubdivided into leſſer degrees, proportionate to the progreſs of the adepts.

The

(A) Such, we are ſorry to ſay, is the caſe ſtill. In a letter, dated the 10th of May 1799, which we received from a gentleman of learning and honour then reſiding in Upper Saxony, is the following account of the univerſity of Jena: "This univerſity contains from two to three thouſand ſtudents, who are almoſt all republicans, and go about the country in republican uniforms. They are all formed into clubs or *ſecret ſocieties*; and the quarrel of one member of a club is taken up by all. The conſequence is, that the number of duels among the different clubs is inconceivable. The weapon is generally the ſabre, and the duel often ends in the death of one of the combatants." Yet gentlemen of Great Britain ſend their ſons to Germany to be educated!

Illuminati.

4
Preparation and

“ The *firſt* claſs is that of Preparation. It contains four degrees, *viz.* thoſe of *Novice*, of *Minerval*, of *Minor Illuminee*, or *Illuminatus Minor*, and of *Major Illuminee*, or *Illuminatus Major*. To this claſs belong likewiſe ſome intermediary degrees, borrowed from free-maſonry, as means of propagation. Of the maſonic degrees, the code of the illuminati admits the firſt three without *any alteration;* but it adapts more particularly to the views of the ſect the degree of *Scotch Knight*, and ſtyles it the degree of *Directing Illuminee*, or *Illuminatus dirigens*.

5
The Myſteries.

The *ſecond* claſs is that of the Mysteries, which are ſubdivided into the *leſſer* and *greater myſteries*. The leſſer comprehend the prieſthood, and adminiſtration of the ſect, or the degrees of *prieſts*, and of *regents* or *princes*.

In the *greater myſteries* are comprehended the two degrees of *Magus* or philoſopher, and of the *Man-king*. The *elect* of the latter compoſe *the council and degree of Areopagites*.

6
The recruiter,

“ In all theſe claſſes, and in every degree (ſays the Abbé Barruel), there is an office of the utmoſt conſequence, and which is common to all the brethren. It is that which is occupied by him who is known in the code by the appellation of *Recruiter*, or *Brother Inſinuator*. This (continues our author) is not a term of my invention: it is really to be found in the code, and is the denomination of that illuminee, whoſe employment is to entice members into the ſect.”

As the whole ſtrength of the order depended upon the vigilant and ſucceſsful exerciſe of this office, ſome brethren were carefully inſtructed for it, who might afterwards viſit the different towns, provinces, and kingdoms, in order to propagate the doctrines of illuminiſm. Weiſhaupt propoſed to ſelect as his apoſtles either weak men, who would implicitly obey his orders, or men of abilities, who would improve the office by artifices of their own. It was, however, a duty which every brother was obliged to exerciſe once or twice in his life, under the penalty of being for ever condemned to the lower degrees.

To ſtimulate the ardour of the brother inſinuator, he was appointed ſuperior over every novice whom he ſhould convert. To aſſiſt his judgment, he was inſtructed in three important points concerning the deſcription of men whom he ought to ſelect for converſion, the means which he ought to employ for enticing them to enter the order, and the arts which he ought to ſtudy to form their character.

7
To pry into the characters of all men.

To enable the recruiter to determine whom he ought to ſelect for converſion, he was to inſinuate himſelf into all companies; he was to pry into the character of all whom he ſhould meet with, whether friends, relations, ſtrangers, or enemies; he was to write down all his remarks regularly every day; to point out their ſtrong and weak ſides, their paſſions and prejudices, their intimacies, their intereſts, and their fortune. This journal was to be tranſmitted twice every month to the ſuperiors; by which means the order would learn who were friendly or hoſtile to their views, and who were the individuals to whom they ought to direct their arts of ſeduction (B).

Illuminati.

The perſons to be excluded were all ſuch as would expoſe the order to ſuſpicion or reproach. All indiſcreet talkers, all who were proved violent, and difficult to be managed, all addicted to drunkenneſs, and all Pagans, Jews, and Jeſuits, were to be rejected. As the patronage of princes would tend much to enrich and ſtrengthen the ſociety, it was agreed to admit them to the inferior degrees, but they were never to be initiated into the grand myſteries; they were never to riſe beyond the degree of Scotch knight.

8
Perſons proper for the order,

The perſons to be ſelected were young men of all ſtations, from eighteen to thirty; but particularly thoſe whoſe education was not completed, and conſequently whoſe habits were not formed. “ Seek me out (ſays Weiſhaupt in his directions to the inſinuator) the dexterous and daſhing youths. We muſt have adepts who are inſinuating, intriguing, full of reſource, bold and enterpriſing; they muſt alſo be flexible and tractable, obedient, docile, and ſociable ” In another place he ſays, “ Above all things pay attention to the figure, and ſelect the well made men and handſome young fellows. They are generally of engaging manners and nice feelings. When properly formed, they are the beſt adapted for negociations; for firſt appearances prepoſſeſs in their favour. It is true, they have not the depth that men of more gloomy countenances often have. *They are not the perſons to be entruſted with a revolt, or the care of ſtirring up the people;* but it is for that very reaſon we muſt know how to chooſe our agents. I am particularly fond of thoſe men whoſe very ſoul is painted in their eyes, whoſe foreheads are high, and whoſe countenances are open. Above all, examine well the eyes, for they are the very mirrors of the heart and ſoul. Obſerve the look, the gait, the voice. Every external appearance leads us to diſtinguiſh thoſe who are fit for our ſchool.”

9
To be ſeduced by whatever means;

Though young men were preferred, yet perſons of all ages were to be admitted if their character accorded with the principles of the order. The inſinuator was deſired to ſeek out thoſe who were diſtinguiſhed by their power, riches, or learning. “ Spare no pains (ſays Weiſhaupt), ſpare nothing in the acquiſition of ſuch adepts. If heaven refuſe its ſuccour, conjure hell.

Flectere ſi nequeas ſuperos, Acheronta moveta.”

Perſons were to be ſingled out from thoſe profeſſions which give men influence over others, or put them in the moſt favourable ſituation for diſſeminating any peculiar opinions. With this view, ſchoolmaſters, and ſuperintendants of eccleſiaſtic ſeminaries, were to be ſought after with much care. Bookſellers, poſt-maſters, and the ſecretaries of poſt-offices, were alſo to be ſelected. Thoſe profeſſions which accuſtomed men to ſpeak and argue, as that of counſellors and attorneys, and even phyſicians, were alſo to be courted. “ They are worth having (ſays Weiſhaupt), but they are ſometimes real devils, ſo difficult are they to be led; they are, however, worth having when they can be gained over.” Every exertion was to be made to gain the officers of a prince, whether preſiding over provinces or attending him in his councils. “ He that has done this, has done more than if he had engaged the prince himſelf.”

(B) As a ſpecimen of the journals kept by the inſinuators, and of the characters which the illuminees ſelected

There was alſo another deſcription of men of whom Weiſhaupt very wiſely judged that they would be admirably fitted for the diffuſſion of his doctrines. Theſe were the diſappointed and diſſatisfied. "Select thoſe in particular (ſays he) who have met with misfortunes, not from accidents, but from ſome injuſtice; that is to ſay, in other words, the diſcontented; for ſuch men are to be called into the boſom of illuminiſm as into their proper aſylum."

10 And their characters tranſmitted to the ſuperiors.

When the inſinuator has made choice of his victim, he is required to draw from his diary a view of his character, opinions, principles, and connections. This he is to tranſmit to the ſuperiors for their examination, and that they may compare it with the diaries which they have already received, perhaps from different inſinuators. When the choice of this inſinuator is approved, the ſuperiors determine which of the inſinuators will be beſt qualified to perform the taſk of ſeducing their candidate.

Two different methods were recommended; one of which was to be employed in enticing men who were ſomewhat advanced in life or diſtinguiſhed by ſcience; the other was to be uſed in ſeducing young men whoſe character was not formed.

11 Proper methods of ſeducing men of knowledge,

With men of knowledge, who had already imbibed the principles of modern philoſophiſm (for no true philoſophers were to be attempted), the inſinuator was to aſſume the character of a philoſopher well acquainted with the myſteries of ancient times. He was to deſcant upon the importance of the ſecret doctrines tranſmitted by tradition, to quote the gymnoſophiſts of India, the prieſts of Iſis in Egypt, and thoſe of Eleuſis, with the Pythagorean ſchool in Greece. He was to learn by heart certain paſſages from Iſocrates, Cicero, and Seneca, that he might have them ready upon all occaſions. He was to throw out hints, that theſe ſecret doctrines explained the difficult queſtions concerning the origin and order of the univerſe, the Providence of God, the nature of the ſoul, its immortality and future deſtination; he was to inſpire them with the belief that the knowledge of theſe things would render life more agreeable and pain more ſupportable, and would enlarge their ideas of the majeſty of God: he was then to declare that he had been initiated into theſe myſteries. If the candidate expreſſed any curioſity to be made acquainted with them, the inſinuator was firſt to aſcertain his opinions upon ſome leading points, by propoſing to him to write a diſſertation upon certain queſtions. Should the anſwers not pleaſe the inſinuator, he was to relinquiſh his prey; but ſhould they be ſatisfactory, the candidate was to be admitted to the firſt degree.

12 And young men,

When the ſelected victim was young, and had not imbibed any of thoſe opinions which correſponded with the principles of the ſect, a different method was to be followed. "Let your firſt care (ſays the legiſlator to his inſinuators) be to gain the affection, the confidence, and the eſteem of thoſe whom you are to entice into the order. Let your whole conduct be ſuch, that they ſhall ſurmiſe ſomething more in you than you wiſh to ſhew; hint that you belong to ſome ſecret and powerful ſociety; excite by degrees, and not at once, a wiſh in your candidate to belong to a ſimilar ſociety. Certain arguments and certain books, which the inſinuator muſt have, will greatly contribute to raiſe ſuch a wiſh; ſuch, for example, are thoſe which treat of the union and ſtrength of aſſociations."

Every inſinuator muſt be provided with books of this ſort. But that their ſucceſs might not depend ſolely upon books, Weiſhaupt gave to his diſciples a ſpecimen of the artifices which they might employ. The inſinuator might begin by obſerving, that a child in the cradle, abandoned to itſelf, is entirely helpleſs; and that it is by the aſſiſtance of others that it acquires ſtrength; and that princes owe their greatneſs and their power to the union of their ſubjects. Then the inſinuator might touch on the importance of knowing mankind, and the arts of governing them; that one man of parts might eaſily lead hundreds, even thouſands, if he but knew his advantages. He was next to dwell upon the defects of civil ſociety; to mention how little relief a man can obtain even from his beſt friends; and how very neceſſary it is for individuals to ſupport one another in theſe days: to add, that men would triumph even over heaven were they but united. He was to adduce as examples, the influence of the freemaſons and of the Jeſuits. He was to aſſert, that all the great events which take place in the world depend upon hidden cauſes, which theſe ſocieties powerfully influence. He was to awake in the breaſt of his pupil the deſire of reigning in ſecret; of prepa-
ring

---

for propagating their principles, we ſhall give the character of Zwack, denominated *Cato*, as it is deſcribed in the tablet of his inſinuator Ajax (Maſſenhauſen).

"Francis Xaverius Zwack was ſon of Philip Zwack, commiſſary of the *Chambre de Comptes*, and was born at Ratiſbon; at the time of his initiation (29th May 1776) he was twenty years of age, and had finiſhed his college education.

"He was then about five feet high; his perſon emaciated with debauchery; his conſtitution bordering on melancholy; his eyes of a dirty grey, weak and languiſhing; his complexion pale and ſallow; his health weak, and much hurt by frequent diſorders; his noſe long, crooked and hooked; his hair light brown; gait precipitate; his eyes always caſt towards the ground; under the noſe, and on each ſide of the mouth, a mole.

"His heart tender and philanthropic in an extaordinary degree; but ſtoic when in a melancholy mood; otherwiſe a true friend, circumſpect, reſerved, extremely ſecret; often ſpeaking advantageouſly of himſelf; envious of other people's perfections; voluptuous; endeavouring to improve himſelf; little calculated for numerous aſſemblies; choleric and violent, but eaſily appeaſed; willingly giving his private opinions when one has the precaution to praiſe him, though contradicting him; a lover of novelties. On religion and conſcience widely differing from the received ideas; and thinking preciſely as he ought, to become a good member of the order.

"His predominant paſſions are, pride, love of glory, probity; he is eaſily provoked; has an extraordinary propenſity for myſteries; a perpetual cuſtom of ſpeaking of himſelf and of his own perfections; he is alſo a perfect maſter in the arts of diſſimulation; a proper perſon to be received into the order, as applying himſelf particularly to the ſtudy of the human heart." Such is the character of the beloved diſciple of Weiſhaupt, the incomparable Cato, and a leader of the ſect of the illuminees!

ring in his cloſet a new conſtitution for the world; and of governing thoſe who think they govern others.

13 Into the noviciate.

After theſe, or other artifices of the ſame kind, have been employed, if the candidate be inſpired with an ardour to be initiated, and give ſatisfactory anſwers to the queſtions propoſed to him, he is immediately admitted a novice. But ſhould he reject all means of ſeduction, let him take heed to imſelf; "for the vengeance of ſecret ſocieties is not a common vengeance; it is the hidden fire of wrath. It is irreconcileable; and ſcarcely ever does it ceaſe the purſuit of its victims until it has ſeen them immolated."

14 Period of the noviciate.

The period of the noviciate varied according to the age of the new convert to illuminiſm. At firſt it continued three years for thoſe under 18 years of age, two years for thoſe between 18 and 24, and one year for thoſe who were near 30; but it was afterwards ſhortened,

The novice was not acquainted with any of the order except his inſinuator, under whoſe direction he remained during his noviciate. The firſt leſſons which he was taught reſpected the inviolable nature of the ſecrecy which every illuminee was obliged to obſerve. He was told that ſilence and ſecrecy were the very ſoul of the order; that ingenuouſneſs was a virtue only with reſpect to his ſuperiors; and that diſtruſt and reſerve were fundamental principles. He was enjoined never to ſpeak of any circumſtance relating to the order, concerning his own admiſſion, or the degree which he had received, not even before brethren, without the ſtrongeſt neceſſity; and was required to ſign a declaration to this purpoſe.

15 Dictionary, geography, calendar, and cypher of the order.

The novice was next taught the dictionary of the order, its geography, calendar, and cypher. To prevent the poſſibility of diſcovery, every illuminee received a new name, which was characteriſtic of his diſpoſitions, or of the ſervices which were expected of him. Thus Weiſhaupt, as we have obſerved, was called *Spartacus*, becauſe he pretended to wage war againſt thoſe oppreſſors who had reduced mankind to ſlavery; and Zwack, as we have ſeen, was named *Cato*, becauſe he had written a diſſertation in favour of ſuicide, and had once determined to commit that crime.

According to the new geography of the order, Bavaria was called *Achaia*; Munich was called *Athens*; Vienna was named *Rome*; Wurtzburg was denominated *Carthage*; and Ingolſtadt, the fountain of the order, was called *Epheſus*, and by the profound adepts *Eleuſis*. The novice had alſo to learn the Perſian calendar, which the order had adopted. Their era began A. D. 630. The months received new names: May was called *Adarpahaſcht*; June, *Chardad*; July, *Thermeh*; Auguſt, *Merdedmeh*; and ſo on. The cypher conſiſted of numbers which correſponded to the letters of the alphabet, in this order *a*, *b*, *c*, *d*, anſwering to the numbers 12, 11, 10, 9.

The novice had next to ſtudy *the ſtatutes of the illuminees*, which he was aſſured contained nothing injurious to the ſtate, to religion, or to good morals. He was next deſired to apply himſelf to acquire the morality of the order; which he was to do, not by reading the goſpels, but by peruſing Epictetus, Seneca, and Antoninus, and by ſtudying the works of the modern ſophiſts Weiland, Meiners, and Helvetius, &c. The ſtudy of man was alſo recommended as the moſt intereſting of all the ſciences. He was taught this ſtudy not merely as a ſcience, but as an art. A model of a journal was given him, and he was required to inſert in it obſervations upon the character of every perſon that he happened to meet with. To quicken his diligence, the inſinuator occaſionally examined his journal. In the mean time, the inſinuator was watching him as a centinel, and noting down regularly obſervations upon the defects and merits of his pupil, which he always ſent to his ſuperiors.

16 Novice obliged to draw his own character.

The great object of the inſinuator was to entangle the novice, and to bind him indiſſolubly to the order. With this view he required the novice to draw a faithful picture of himſelf, under the pretence that he would thus know himſelf better. He deſired him to write down his name, his age, his country, his reſidence, and his employment; to give a liſt of the books in his library; to ſtate his revenue; to enumerate his friends and enemies, and the cauſe of his enmities. He was alſo to give a ſimilar account of his father and mother, his brothers and ſiſters, and to be very careful in pointing out their paſſions and prejudices, their ſtrong and weak ſides.

In the mean time, the inſinuator was occupied in drawing up a new ſtatement of every thing he had been able to diſcover of the character and conduct of the novice. This ſtatement was tranſmitted to the ſuperiors, compared with the former. If the novice was approved, he was then admitted to the ſecond degree, upon his anſwering, in a ſatisfactory manner, 24 grand queſtions, which might enable the order to judge of his principles and the credit to which he was entitled, and would fix him down by ſtronger ties to the authority of the ſuperiors. The deteſtable principles of the illuminees now begin to appear, as will be evident from the following queſtions which we have ſelected:

17 Power of life and death claimed by the ſociety.

Have you ſeriouſly reflected on the importance of the ſtep you take, in binding yourſelf by engagements that are unknown to you? Should you ever diſcover in the order any thing wicked or unjuſt to be done, what part would you take? Do you, moreover, grant the power of life and death to our order or ſociety? Are you diſpoſed, upon all occaſions, to give the preference to men of our order over all other men? Do you ſubject yourſelf *to a blind obedience, without any reſtriction whatſoever?*

The novice having thus ſurrendered his conſcience, his will, and his life, to the devotion of the conſpirators, and thus ſubſcribed, with his own hand, and confirmed by his oath, a reſolution to become the moſt abject ſlave, was now deemed qualified to aſcend to the ſecond degree, called *Minerval*.

18 Admiſſion to the degree of Minerval.

In the dead hour of midnight he was conducted to a retired apartment, where two of the order were waiting to receive him. The ſuperior, or his delegate, appeared ſtanding in a ſevere and threatening poſture; he held a glimmering lamp in his hand, and a naked ſword lay before him. The novice was aſked, whether he ſtill perſiſted in his intention of adhering to the order? Upon anſwering in the affirmative, he was ordered into a dark room, there to meditate in ſilence on his reſolution. On his return, he was ſtrictly and repeatedly queſtioned if he was determined to give implicit obedience to all the laws of the order? The inſinuator became ſecurity for his pupil, and then requeſted for him the protection of the order, which the ſuperior granted with great ſolemnity, proteſting that nothing would be found there hurtful to religion, to morals, or to the ſtate. Having thus ſaid, the ſuperior takes up the naked ſword, and pointing it at the heart of the novice, threatens him with the fatal conſequences of betraying the ſecrets of the order. The novice again takes an oath, by which he binds himſelf, in the moſt unlimited manner, to ſerve the order with his life, honour, and eſtate, and to obſerve an inviolable obedience and fidelity to all his ſuperiors. He is then admitted a Minerval, and henceforth is allowed to attend the academy of the ſect.

19 Minerval academy; The Minerval academy was compoſed of 10, 12, or 15 Minervals, and placed under the direction of a major Illuminee. It met twice every month in an inner apartment, ſeparated from the other rooms of the manſion by an antichamber; the door of which was to be ſhut with care during the meeting, and ſtrongly ſecured by bolts. At the commencement of every meeting, the preſident read and commented upon ſome ſelect paſſages of the Bible, Seneca, Epictetus, Marcus Aurelius, or Confucius; evidently with a view of diminiſhing the reverence for the ſacred writings, by thus placing them on a level with the heathen moraliſts. Then each brother was aſked what books he had read ſince laſt meeting, what obſervations he had made, and what ſervices he had performed for promoting the ſucceſs of the order?

20 Its library. To each Minerval academy a library belonged. This was formed by the contributions of the brethren, by preſents of books, and by another method very extraordinary. All Illuminees acting as librarians, or keepers of archives, were admoniſhed to *ſteal* ſuch books or manuſcripts as might be uſeful to the order. At one time, ſending a liſt of the books which he wiſhed to be embezzled from the library of the Carmes, Weiſhaupt ſays, "All theſe would be of much greater uſe if they were in our hands. What do thoſe raſcals do with all theſe books?

Every brother at his admiſſion was required to declare to what art or ſcience he meant chiefly to apply; and it was expected that he ſhould afterwards every year give an account of the diſcoveries or improvements which he had made. All the other brethren who were occupied in the ſame ſtudies, were deſired to give him every poſſible aſſiſtance. Thus a kind of academy was formed, to which thoſe who could not ſerve it by their talents might give pecuniary contributions. That this academy might have the appearance of a literary ſociety, prizes were annually diſtributed; the beſt diſcourſe was publiſhed, and the profits ſent to the coffers of the order.

Every month the preſident was to take a review of the faults which he had obſerved in his pupils, and examine them concerning thoſe which they might have been conſcious of in themſelves; and it would be an unpardonable neglect, ſay the ſtatutes, ſhould any pupil pretend that, during the ſpace of a whole month, he had remarked nothing reprehenſible.

It is impoſſible to read theſe rules without admiring them. Were men but half as anxious, attentive, and careful, to render themſelves good citizens and good men, as theſe men were to render themſelves ſucceſsful conſpirators, what a bleſſed world ſhould we ſee!

21 Admiſſio to the degree of minor illuminee. The Minerval was rigorouſly ſcrutinized, whether he was ready to ſubmit to every torture, or even to commit ſuicide, rather than give any information againſt the order. Suicide was reckoned not only innocent, but honourable, and was alſo repreſented as a peculiar ſpecies of voluptuouſneſs. In order to diſcover the ſentiments of the Minervals upon this ſubject, they were required to write a diſſertation upon the character and death of Cato, or any ſimilar ſubject. They were alſo deſired to diſcuſs the favourite doctrine of Weiſhaupt, that *the end ſanctifies the means;* a principle of the moſt pernicious tendency, which would render calumny, aſſaſſination, ſedition, and treaſon, laudable and excellent. Next, they were called upon to compoſe a diſſertation, by which their opinions concerning kings and prieſts might be aſcertained. If they performed all theſe taſks with the ſpirit of an infidel, and the deſperate firmneſs of a conſpirator, they were then judged worthy of being promoted to the degree of minor illuminee.

22 Minor illuminees trained for the degree of

The minor illuminees held meetings ſimilar to thoſe of the Minerval academy. It was neceſſary that the preſident ſhould be one who was raiſed to the degree of prieſt, and initiated in the myſteries; but he was required to perſuade his pupils, that beyond the degree which he had attained there were no myſteries to be diſcloſed. The minor illuminees were to be ſo trained, that they might look upon themſelves as the founders of the order; that by this powerful motive they might be animated to diligence and exertion. With this view, hints were ſcattered rather than precepts enjoined. It was inſinuated, that the world was not ſo delightful as it ought; that the happineſs for which man was made is prevented by the misfortunes of ſome, and the crimes of others; that the wicked have power over the good; that partial inſurrection is uſeleſs; and that peace, contentment, and ſafety, might be eaſily obtained by means drawn from the greateſt degree of force of which human nature is capable. Such views, it is added, actuating a ſecret ſociety, would not only be innocent, but moſt worthy of the wiſe and well-diſpoſed.

Weiſhaupt had formed, with peculiar care, a code for this degree, which was intitled, *Inſtructions for forming uſeful Labourers in Illuminiſm.* Theſe inſtructions diſcover an aſtoniſhing knowledge of human nature, and are drawn up with a degree of ſyſtematic coolneſs which perhaps no conſpirator before him ever exhibited. He lays down rules, by which the character of almoſt any perſon may be aſcertained. He recommends to the minor illuminees, to attend to the conduct of any perſon entruſted to their care, at two periods; when he is tempted to be what he ought not to be, and when, removed from the influence of every external temptation, he follows the dictates of his inclination. They were to ſtudy the peculiar habits and ruling paſſions of each; to kindle his ardour by deſcanting on the dignity of the order, and the utility of its labours; to infuſe a ſpirit of obſervation, by aſking queſtions, and applauding the wiſdom of the anſwers; to correct the failings of their pupil, by ſpeaking of them as if they were not his, and thus making him judge in his own cauſe; to inſtruct and adviſe, not by tedious declamation, but by ſometimes dropping a few words to the purpoſe, when the mind ſhould be in a proper ſtate to receive them. Above all, they were directed to avail themſelves of thoſe moments when they obſerved a pupil diſcontented with the world. "It is then (ſays Weiſhaupt) you muſt preſs the ſwelling heart, ſtimulate the ſenſibility, and demonſtrate how neceſſary ſecret ſocieties are for the attainment of a better order of things."

23
Scotch novice.

Having paſſed with applauſe through the ſtates of probation already deſcribed, the minor illuminee is promoted to the rank of major illuminee, or Scotch novice. As major illuminee, he is encompaſſed with more rigid chains; and as Scotch novice, he is diſpatched as a miſſionary into maſonic lodges, to convert the brethren to illuminiſm.

The candidate for this degree is ſtrictly examined, in order to diſcover what opinions he now entertains concerning the object of the ſociety; the motives that prompted him to join it; whether he is diſpoſed ſtill to co-operate with the reſt of the brethren in accompliſhing the grand object; and whether he be a member of any other ſociety; and what are the duties which it requires.

24
Candidates for higher degrees ſubmit to new trials.

The fertile genius of Weiſhaupt is not exhauſted; he has ſtill in reſerve artifices more profound, and bonds more powerful; his reſources keep pace with the progreſs of his ſchemes. He now lays a ſnare for his pupils, from which he hopes none can eſcape, and therefore he flatters himſelf they are his for ever. He demands of every candidate for higher degrees, to write, as a proof of confidence, a minute and faithful account of his whole life, without any reſerve or diſſimulation. Reſerve or diſſimulation would indeed be vain; for the moſt ſecret circumſtances of his life are already well known to the adepts, by means of innumerable ſpies, who, by the appointment of the ſuperiors, have, unknown to him, been watching and ſcrutinizing all his actions and words, his temper, paſſions, and opinions.

Now is preſented to the candidate the code of the brother ſcrutator, called by the order the *noſce te ipſum* (know thyſelf). This is a catechiſm, containing from a thouſand to fifteen hundred queſtions, concerning his perſon, his health, his education, his opinions, his inclinations, his habits, his paſſions, his prejudices, and even his weakneſſes. Queſtions are alſo propoſed reſpecting his acquaintances, his relations, friends, and enemies. The candidate is required to enumerate his favourite colours, to deſcribe his language, the nature of his converſation, his gait and geſtures. Nothing, in ſhort, is omitted that can tend to diſtinguiſh his character as an individual, or as a member of ſociety. Upon many qualities in his character, thirty, forty, or ſometimes near a hundred queſtions are propoſed. The following ſpecimen will enable the reader to judge what aſtoniſhing care Weiſhaupt employed to diſcriminate characters.

Is his *gait* ſlow, quick, or firm? Are his ſteps long, ſhort, dragging, lazy, or ſkipping? Is his *language* regular, diſorderly, or interrupted? In ſpeaking, does he agitate his hands, his head, or his body with vivacity? Does he cloſe upon the perſon he is ſpeaking to? Does he hold him by the arm, clothes, or button-hole? Is he a great talker, or is he taciturn? If ſo, why? Is it through prudence, ignorance, reſpect, or ſloth? &c. Concerning his *education*, he is queſtioned to whom does he owe it? Has he always been under the eyes of his parents? How has he been brought up? Has he any eſteem for his maſters? Has he travelled, and in what countries?

By theſe queſtions his temper and diſpoſitions might be accurately known. His leading paſſions would be diſcovered by the following queries: "When he finds himſelf with different parties, which does he adopt; the ſtrongeſt or the weakeſt; the wittieſt or the moſt ſtupid? Or does he form a third? Is he conſtant and firm in ſpite of all obſtacles? How is he to be gained? by praiſe, by flattery, or low courtſhip; by women, money, or the entreaties of his friends? Does he love ſatire; and on what does he exerciſe that talent; on religion, hypocriſy, intolerance, government, miniſters, monks?" &c.

All theſe queſtions are to be anſwered and illuſtrated by facts. It is neceſſary to obſerve that the ſcrutators alſo give in written anſwers to all theſe queſtions. When the candidate has thus given a minute hiſtory of his life, and revealed all his ſecrets, his foibles, his errors, his vices, and his crimes, Weiſhaupt triumphantly exclaims, "Now I hold him; I defy him to hurt us; if he ſhould wiſh to betray us, we have alſo his ſecrets."

The adept is next introduced into a dark apartment, where he ſolemnly ſwears to keep ſecret whatever he may learn from the order. He then delivers up the hiſtory of his life, ſealed, when it is read to the lodge, and compared with the character drawn of him by the brother ſcrutators. A corner of the veil is now lifted up, ſtill, however, with extreme caution. Nothing appears palpable but the pureſt principles and moſt generous deſigns. At the ſame time many things are darkly ſuggeſted, which are incompatible with purity and generoſity; for while the utmoſt care is employed to deceive the underſtanding, nothing is neglected that can tend ſecretly to corrupt the heart. A number of queſtions are aſked; the evident intention of which is to make the adept diſcontented with the preſent moral government of the world, and to excite the deſire of attempting a great revolution. After anſwering theſe queſtions, the ſecretary opens the code of the lodge; and having informed the young illuminee that the object of the order is to diffuſe the pure truth, and to make virtue triumph, he proceeds to ſhow that this is to be accompliſhed by freeing men from their prejudices, and enlightening their underſtandings. "To attain this, (continues the ſecretary), we muſt trace the origin of all ſciences, we muſt reward oppreſſed talents, we muſt undertake the education of youth; and, forming an indiſſoluble league among the moſt powerful geniuſes, we muſt boldly, though with prudence, combate ſuperſtition, incredulity ,and folly; and at length form our people to true, juſt, and uniform principles on all ſubjects." The ſecretary adds, that in attempting to diveſt vice of its power, that the virtuous may be rewarded even in this world, the order is counteracted by *princes and prieſts, and the political conſtitutions of nations*; that, however, it was not intended to excite revolutions and oppoſe force by force, but merely to bind the hands of the protectors of diſorder, and to govern without appearing to command; that the powers of the earth muſt be encompaſſed with a legion of indefatigable men, all directing their labours towards the improvement of human nature. Were there but a certain number of ſuch men in every country, each might form two others. "Let theſe (ſays he) only be united, and nothing will be impoſſible to our order." All this is very ſpecious; it is well contrived to faſcinate the imagination of the young, and the heart of the

the

the generous and benevolent, while, under all this pretended regard to virtue and to the happineſs of mankind, is concealed a moſt formidable conſpiracy againſt the peace of the world.

After this addreſs is delivered, the major illuminee is preſented with the codes of the inſinuator and ſcrutator; for he muſt now inſpect the pupils of the inſinuators, and muſt exerciſe the office of ſcrutator while preſiding over the Minerval academies.

25
The degree of Scotch knight.

The next degree, which is that of Scotch knight, is both intermediate and ſtationary. It is ſtationary for thoſe who are not ſufficiently imbued with the principles of the order, and intermediate for thoſe who have imbibed the true ſpirit of illuminiſm. The Scotch knights were appointed the directors of all the preparatory degrees, and to watch over the intereſts of the order within their diſtrict. They were to ſtudy plans for increaſing the revenues of the order, and to endeavour to promote to public offices of confidence, of power and wealth, as many of the adepts as poſſible; and to ſtrive to acquire an abſolute ſway in the maſonic lodges. They were to procure the management of the maſonic funds; and while they were to perſuade the brethren that theſe were expended according to their own orders, they were to employ them for promoting the views of the order. Thus one office of the Scotch knights was to embezzle the money that was entruſted to them, in order to diffuſe truth, and to make virtue triumph.

After paſſing with applauſe through this long and tedious probation, the adept is introduced to the claſs of the myſteries. He is not yet, however, made acquainted with the whole ſecrets of the ſociety; he muſt ſtill ſubmit to new trials; his curioſity muſt be farther excited, his imagination muſt be kept longer upon the ſtretch, and his principles of depravity be rendered more violent and inveterate before the vail be entirely withdrawn, which will diſcover to him Weiſhaupt and his infernal crew, plotting the deſtruction of the laws, ſciences, and religion of mankind. The degree of epopt or prieſt, to which the adept was next raiſed, opened to view, however, ſo great a part of the myſteries, that the reader will be fully prepared to expect the ſecrets which remain to be unfolded in the other degrees.

26
Preparations for the prieſthood.

Before being admitted to the degree of epopt, the adept was required to give a written anſwer to ten preliminary queſtions. The inſinuations againſt the eſtabliſhed order of the world, which had formerly been ſlightly mentioned, increaſe now to an indirect propoſal to attempt a complete revolution. The candidate is aſked, whether he thinks the world has arrived at that happy ſtate which was intended by nature? Whether civil aſſociations and religion attain the ends for which they were deſigned? Whether the ſciences are conducive to real happineſs? or whether they are not merely the offspring of the unnatural ſtate in which men live, and the crude inventions of crazy brains? It is then propoſed as a queſtion, whether there did not in antient times exiſt an order of things more ſimple and happy? What are the beſt means for reſtoring mankind to that ſtate of felicity? Should it be by public meaſures, by violent revolutions, *or by any means that would enſure ſucceſs?* Would it not be proper, with this view, to preach to mankind a religion more perfect, and a philoſophy more elevated? And, in the mean time, is it not adviſable to diſſeminate the truth in ſecret ſocieties?

Should the anſwers given to theſe queſtions accord with the ſentiments of the order, on the day fixed for the initiation, the candidate is blindfolded, and, along with his introducer, is put into a carriage, the windows of which are darkened. After many windings and turnings, which it would be impoſſible for the adept to trace back, he is conducted to the porch of the temple of the myſteries. His guide ſtrips him of the maſonic inſignia which he wore as a knight, removes the bandage from his eyes, and preſents him with a drawn ſword; and then having ſtrictly enjoined him not to advance a ſtep till he is called, leaves him to his meditations. At length he hears a voice exclaiming, "Come, enter, unhappy fugitive; the fathers wait for you; enter, and ſhut the door after you." He advances into the temple, where he ſees a throne with a rich canopy riſing above it, and before it, lying upon a table, a crown, a ſceptre, a ſword, ſome pieces of gold, and precious jewels, interlaid with chains. At the foot of the table, on a ſcarlet cuſhion, lie a white robe, a girdle, and the ſimple ornaments of the ſacerdotal order. The candidate is required to make his choice of the attributes of royalty, or of the white robe. If he chooſe the white robe, which he knows it is expected he ſhould do, the hierophant, or inſtructor, thus addreſſes him: "Health and happineſs to your great and noble ſoul. Such was the choice we expected from you. But ſtop; it is not permitted you to inveſt yourſelf with that robe, until you have heard to what we now deſtine you." The candidate is then ordered to ſit down; the book of the myſteries is opened, and the whole brethren liſten in ſilence to the voice of the hierophant.

27
Inſtructions previous to admiſſion.

The exordium is long and pompous; much artifice is concealed in it, and much eloquence diſplayed. It expatiates on the ſublime and generous views of the ſociety; evidently with the deſire of lulling aſleep the ſuſpicion of the candidate, of exciting him to admiration, and of inſpiring him with enthuſiaſm. The hierophant then proceeds to unveil the myſteries. He launches out into a ſplendid deſcription of the original ſtate of mankind; when health was their ordinary ſtate, when meat, and drink, and ſhelter, were their only wants. At that period (ſays he) men enjoyed the moſt ineſtimable bleſſings, *equality and liberty*; they enjoyed them to their utmoſt extent: but when the wandering life ceaſed, and property ſtarted into exiſtence; when arts and ſciences began to flouriſh; when a diſtinction of ranks and civil aſſociations were eſtabliſhed, "liberty was ruined in its foundation, and equality diſappeared. The world then ceaſed to be a great family, to be a ſingle empire; the great bond of nature was rent aſunder." Wants now increaſed, and the weak imprudently ſubmitted to the wiſe or the ſtrong, that they might be protected. As the ſubmiſſion of one perſon to another ariſes from wants, it ceaſes when the wants no longer exiſt. Thus the power of a father is at an end when the child has acquired his ſtrength. Every man, having attained to years of diſcretion, may govern himſelf; when a whole nation, therefore, is arrived at that period, there can exiſt no farther plea for keeping it in wardſhip.

Such a ſtate as that of civil ſociety, is then repreſented as incompatible with the practice of virtue. "With the diviſion of the globe, and of its ſtates, benevolence (ſays the hierophant) was reſtrained within certain limits, beyond which it could no longer be extended. Patriotiſm was deemed a virtue; and he was ſtyled a patriot who, partial towards his countrymen, and unjuſt to others, was blind to the merits of ſtrangers, and believed the very vices of his own country to be perfections. We really beheld (continues he) patriotiſm generating localiſm, the confined ſpirit of families, and even egoiſm. Diminiſh, reject that love of country, and mankind will once more learn to know and love each other as men. Partiality being caſt aſide, a union of hearts will once more appear, which will expand itſelf over the globe."

Theſe unphiloſophical declamations, enthuſiaſtically pronounced, at length make the proſylete exclaim, in uniſon with his maſter, "Are ſuch then the conſequences of the inſtitution of ſtates, and of civil ſociety? O folly! Oh people! that you did not foreſee the fate that awaited you; that you ſhould yourſelves have ſeconded your deſpots in degrading human nature to ſervitude, and even to the condition of the brute!"

Having wrought up the proſelyte to this pitch of frenzy, and enumerated all the evils which, according to Weiſhaupt, ariſe from political aſſociation, the hierophant comes to reveal the means by which the grievances of the human race may be redreſſed. "Providence (he ſays) has tranſmitted the means to us of ſecretly meditating, and at length operating, the ſalvation of human kind. Theſe means are the ſecret ſchools of philoſophy. Theſe ſchools have been in all ages the archives of nature, and *of the rights of man.* Theſe ſchools ſhall one day retrieve the fall of human nature, and PRINCES AND NATIONS SHALL DISAPPEAR FROM THE FACE OF THE EARTH; and that without any violence. Human nature ſhall form one great family, and the earth ſhall become the habitation of the man of reaſon. *Reaſon ſhall be the only book of laws, the ſole code of man.* This is one of our *grand myſteries.* Attend to the demonſtration of it; and learn how it has been tranſmitted down to us."

This pretended demonſtration makes part of the ſame ſophiſtical harangue; and conſiſts in panegyrics on the dignity of human nature; in a baſeleſs morality; and in a ſcandalous perverſion of the Chriſtian Scriptures, with a blaſphemous account of the miniſtry of the Saviour of the world.

"What ſtrange blindneſs (continues the hierophant) can have induced men to imagine, that human nature was always to be governed as it has hitherto been? Where is the being who has condemned men, the beſt, the wiſeſt, and the moſt enlightened men, to perpetual ſlavery? Why ſhould human nature be bereft of its moſt perfect attribute, that of governing itſelf? Why are thoſe perſons to be always led who are capable of conducting themſelves? Is it then impoſſible for mankind, or at leaſt the greater part of them, to come to majority? Are we then fallen ſo low as not even to feel our chains, as to hug them, and not cheriſh the flattering hope of being able to break them, and recover our liberty? No; let us own that it is not impoſſible to attain UNIVERSAL INDEPENDENCE."

28
The illuminees enemies to commerce.

The principal means which Weiſhaupt offers to his adepts for the conqueſt of this land of promiſe, is to diminiſh the wants of the people; and accordingly the code denounces eternal war with every ſpecies of commerce. Hence the hierophant proceeds to inform the candidate, that he who wiſhes to ſubject nations to his yoke, need but to create wants, which he alone can ſatiſfy. "Confer (ſays he) upon the *mercantile tribe* ſome rank or ſome authority in the government, and you will have created perhaps the moſt formidable, the moſt deſpotic of all powers. He, on the contrary, who wiſhes to render mankind free, teaches them how to refrain from the acquiſition of things which they cannot afford: he enlightens them, he infuſes into them bold and inflexible manners. If you cannot diffuſe, at the ſame inſtant, this degree of light among all men, at leaſt begin by enlightening yourſelf, and by rendering yourſelf better. The mode of diffuſing univerſal light is, not to proclaim it at once to the whole world, but to begin with yourſelf; then turn to your next neighbour: you too can enlighten a third and a fourth: let theſe in the ſame manner extend and multiply the number of the children of light, until *numbers and force ſhall throw power into your hands.* You will ſoon acquire ſufficient force to *bind the hands of your opponents, to ſubjugate them,* and to ſtifle wickedneſs in the embryo;" *i. e.* you will ſoon be able to ſtifle every principle of law, of government, of civil or political ſociety, whoſe very inſtitution, in the eyes of an illuminee, is the germ of all the vices and misfortunes of human nature.

29
Their morality;

The hierophant, continuing to inſiſt on the neceſſity of enlightening the people to operate the grand revolution, ſeems to be apprehenſive that the candidate may not yet clearly conceive the real plan of this revolution, which is in future to be the ſole object of all his inſtructions. Let your inſtructions and lights be univerſally diffuſed; ſo ſhall you render mutual ſecurity univerſal; *and ſecurity and inſtruction will enable us to live without prince or government.* The inſtruction which is to accompliſh this great end, is inſtruction in *morality,* and *morality alone;* for "*true morality* is nothing elſe than the art of teaching men to *ſhake off their wardſhip,* to attain the age of manhood; and thus to need neither princes nor governments. The morality which is to perform this miracle, is not a morality of vain ſubtleties. It is not that morality which, degrading man, renders him careleſs of the goods of this world, forbids him the enjoyment of the innocent pleaſures of life, and inſpires him with the hatred of his neighbour. *Above all,* it muſt *not* be that morality which, adding to the miſeries of the miſerable, throws them into a ſtate of puſillanimity and deſpair, *by the threats of hell and the fear of devils.* It muſt be a divine doctrine, ſuch as Jeſus taught to his diſciples, and of which he gave the real interpretation in his ſecret conferences."

30
And blaſphemies of Chriſt.

The impious hierophant then proceeds, with matchleſs blaſphemy, to repreſent the Redeemer of mankind as teaching, like the Grecian ſophiſts, an exoteric and an eſoteric doctrine. He deſcribes him as the grand maſter of the illuminees; and affirms, that the object of his *ſecret,* which is loſt to the world in general, has been preſerved in their myſteries. It was "to reinſtate mankind in their ORIGINAL EQUALITY and LIBERTY, and to prepare the means. This explains in

what

what ſenſe Chriſt was the *Saviour and Redeemer of the world*. The doctrine of original ſin, of the fall of man, and of his regeneration, can now be underſtood. The ſtate of pure nature, of fallen or corrupt nature, and the ſtate of grace, will no longer be a problem. Mankind, in quitting their ſtate of *original liberty*, *fell* from the ſtate of nature, and *loſt their dignity*. In their civil ſociety, under their governments, they no longer live in the ſtate of *pure* nature, but in that of *fallen* and *corrupt* nature. If the moderating of their paſſions, and the diminution of their wants, reinſtate them in their primitive dignity, that will really conſtitute their *redemption* and their *ſtate of grace*. It is to this point that morality, and the moſt perfect of all morality, that of Jeſus, leads mankind. When at length this doctrine ſhall prevail throughout the world, the reign of the good and of the elect ſhall be eſtabliſhed."

31 Preparatory rites to

This language (as M. Barruel obſerves) is ſurely not enigmatical; and the proſelyte who has heard it without ſhuddering, may flatter himſelf with being worthy of this Antichriſtian prieſthood. He is led back to the porch, where he is inveſted with a white tunic and broad ſcarlet belt of ſilk. The ſleeves of the tunic, which are wide, are tied in the middle and at the extremities with ribbons likewiſe of ſcarlet; and the candidate is recalled into the temple of myſteries. He is met by one of the brethren, who does not permit him to advance till he has declared "whether he perfectly underſtands the diſcourſe which has been read to him; whether he has any doubts concerning the doctrines taught in it; whether his heart is penetrated with the ſanctity of the principles of the order; whether he is ſenſible of the call, feels the ſtrength of mind, the fervent will, and all the diſintereſtedneſs requiſite to labour at the *grand undertaking*; whether he is ready to make a ſacrifice of *his will*, and to ſuffer himſelf to be *led* by the moſt *excellent ſuperiors of the order*."

32 Initiation to the prieſthood.

The rites of the preceding degree were in impious deriſion of the ſacrament of the Lord's ſupper; thoſe of the preſent are an atrocious mimicry of ſacerdotal ordination; at which, as every one knows, the Lord's ſupper is likewiſe celebrated. A curtain is drawn, and an altar appears with a crucifix upon it. On the altar is a bible; and the ritual of the order lies on a reading deſk, with a cenſer and a phial full of oil beſide it. The dean, or preſident, who acts the part of a biſhop, bleſſes the candidate, cuts hair from the crown of his head, anoints him, clothes him in the veſtments of the prieſthood, and pronounces prayers after the faſhion of the order. He preſents him with a cap, ſaying, "Cover thyſelf with this cap; it is more precious than the royal diadem." The mock communion is then diſtributed; and it conſiſts of milk and honey, which the dean gives to the proſelyte, ſaying, "This is that which nature gives to man. Reflect how happy he would ſtill have been, if the deſire of ſuperfluities had not, by depriving him of a taſte for ſuch ſimple food, multiplied his wants, and poiſoned the balm of life." The ceremonies are terminated by delivering to the epopt that part of the code which relates to his new degree.

33 Duties of the prieſt or epopt.

Among the inſtructions which it contains, the following are more particularly worthy of notice. The epopt, ſays the code, "will take care that the writings of the members of the order ſhall be cried up, and that the trumpet of fame ſhall be ſounded in their honour. He will alſo find means of *hindering the reviewers from caſting any ſuſpicions* on the writers of the ſect." He is likewiſe inſtructed to *bribe* the common people into the intereſts of the order, and to corrupt their minds, by getting poſſeſſion of ſchools and other ſeminaries of learning. But "if it be neceſſary for us to be maſters of the ordinary ſchools (ſays the impious legiſlator), of how much more importance will it be to gain over the *Eccleſiaſtic ſeminaries and their ſuperiors!* With them we gain over the chief part of the country; we acquire *the ſupport of the greateſt enemies to innovation*; and the grand point of all is, that through *the clergy* we become *maſters of the middle and lower claſſes of the people*."

34 Qualifications for the degree of regent.

From the degree of epopt or prieſt are choſen the *regents* or *prince-illuminees*. On making this choice, ſays the code, three things of the utmoſt conſequence are to be obſerved. "1*ſt*, The greateſt reſerve is neceſſary with reſpect to this degree: 2*dly*, Thoſe who are admitted into it, muſt be as much as poſſible *free men*, and *independent of princes*: 3*dly*, They muſt have clearly manifeſted their *hatred of the general conſtitution*, or the *actual ſtate* of mankind; and have ſhewn how evidently they wiſh for a *change in the government of the world*." If theſe requiſites be found in an epopt who aſpires to the degree of regent, ſix preliminary queſtions are put to him; of which the obvious meaning is to diſcover, whether he deems it lawful and proper to teach ſubjects to throw off the authority of their ſovereigns, or, in other words, to deſtroy every king, miniſter, law, magiſtrate, and public authority on earth.

35 Admiſſion to this degree.

When theſe queſtions are anſwered to the ſatisfaction of his examiner, he is informed, "that as, in future, he is to be entruſted with papers belonging to the order of far greater importance than any which he has yet had in his poſſeſſion, it is neceſſary that the order ſhould have farther ſecurities. He is therefore commanded to make his *will*, and inſert a clauſe with reſpect to any private papers which he may leave, in caſe of ſudden death. He is to get a formal or juridical receipt for that part of his will from his family, or from the public magiſtrate; and he is to take their promiſes in writing, that they are to fulfil his intentions." This precaution being taken, and the day fixed for his inauguration, he is admitted into an antechamber hung with black, where he ſees a ſkeleton, elevated two ſteps, with a crown and ſword lying at its feet. Having given up the written diſpoſitions, &c. reſpecting his papers, his hands are loaded with chains as if he were a ſlave, and he is left to his meditations. A dialogue then takes place between his introducer and the provincial, who is ſeated on a throne in a ſaloon adjoining. It is in a voice loud enough to be heard by the candidate, and conſiſts of various queſtions and anſwers; of which the following may ſerve for a ſpecimen:

Prov. Who has reduced him to this ſtate of ſlavery?

Anſ. by the Introd. SOCIETY, GOVERNMENTS, the SCIENCES, and falſe RELIGION.

Prov. And he wiſhes to caſt off this yoke, to become a ſeditious man and a rebel?

Anſ. No; he wiſhes to unite with us, to JOIN IN

OUR

OUR FIGHTS AGAINST THE CONSTITUTION OF GOVERNMENTS, the corruption of morals, and the profanation of religion. He wiſhes, through our means, to become POWERFUL, that he may attain the GRAND ULTIMATUM.

Prov. Is he ſuperior to *prejudices?* Does he prefer the *general intereſt of the univerſe* to that of *more limited aſſociations?*

Anſ. Such have been his promiſes.

Prov. Aſk him, whether the ſkeleton which is before him be that of a *king*, a *nobleman*, or a *beggar?*

Anſ. He cannot tell; all that he ſees is, that this ſkeleton was a man like us; and the character of *man* is all that he attends to.

After a great deal of inſidious mummery like this, the epopt is admitted to the degree of prince; but before his inveſtiture with the inſignia of that order, he is exhorted to be *free*, *i. e.* to be a man, and a man who knows how to *govern himſelf*; a man who knows his duty, and his *impreſcriptible rights;* a man who ſerves the *univerſe alone;* whoſe actions are ſolely directed to the *general benefit* of the world and of human nature. "Every thing elſe (ſays the provincial) is INJUSTICE." A long panegyric is then made on the happineſs which will be experienced by mankind, when *every father* of a family ſhall be *ſovereign* in his tranquil cot! when he that wiſhes to invade theſe *ſacred rights* ſhall not find an aſylum on the face of the earth! when idleneſs ſhall be no longer ſuffered; and when *the clod of uſeful ſciences ſhall be caſt ſide* (c)!

36 Sign of the degree. The *ſign* of this degree conſiſted in extending out the arms to a brother with the hands open; the *gripe* was to ſeize the brother by the two elbows, as it were to prevent him from falling; and the *word* was REDEMPTION! The epopt was inveſted with his principality by receiving a buckler, boots, a cloak, and a hat; and on receiving the boots, he was deſired to *fear no road* which might lead to the propagation or diſcovery of *happineſs*. Thus decorated, the prince illuminee received the *fraternal embrace,* and heard the inſtructions for his new degree.

One would think that the adept had now arrived at the very acmé of profaneneſs and treaſonable conſpiracy. He has been initiated in myſteries which burleſque Chriſtianity and its Divine Author, and at the ſame time vow vengeance againſt all government, all law, and all ſcience: yet Weiſhaupt, in a letter to Cato Zwack, his incomparable man, ſays, that he has compoſed four degrees above that of regent, or prince-illuminee; with reſpect even to the *loweſt* of which, his degree of prieſt will be found no more than child's play. "The ritual of theſe degrees, (ſays he), I never ſuffer to go out of my hands. It is of too ſerious an import; it is the key of the ancient and modern, the religious and political, hiſtory of the univerſe."

This caution of the chief conſpirator has deprived us of the power to give ſo particular an account of theſe degrees as we have done of the preceding; but the Abbé Barruel aſſures us that they were reduced to two, viz. that of MAGUS, and that of the MAN-KING; and that theſe two conſtituted the GREATER MYSTERIES. When the adept was admitted to the degree of *magus*, he was illuminized only in philoſophy and religion; when to that of *man-king*, new lights were given him reſpecting property, and every ſpecies of political aſſociation. The Abbé quotes a paſſage from *the Critical hiſtory of all the degrees of illuminiſm,* written by a man of honour, who had paſſed through them all, which will give the reader a ſufficient idea of the object of theſe laſt degrees.

37 Objects of the degrees of magus and man-king. "With reſpect to the two degrees of *magus* and of *man-king* (ſays this writer), there is no reception, that is to ſay, there are no ceremonies of initiation. Even the elect are not permitted to tranſcribe theſe degrees; they only hear them read, and that is the reaſon why I do not publiſh them in this work. The firſt is that of Magus, called alſo philoſopher. It contains the fundamental principles of Spinoziſm. Here every thing is *material;* God and the world are but one and the ſame thing: all religions are inconſiſtent, chimerical, and the invention of ambitious men."

That this is the doctrine of Spinoza, and that Spinoza was an atheiſt, is moſt certain; but though nothing can be *eſſentially* worſe than atheiſm, we are ſtrongly inclined to ſuſpect that, at the initiation of the Magus, expreſſions muſt have been uſed more *ſhocking at leaſt to the ear* than the philoſophic jargon of the apoſtate Jew. It is long ſince the philoſophy of Spinoza was in Germany recommended from the preſs (ſee SPINOZA, *Encycl.*); it is but very lately that a profeſſor in the univerſity of Jena publiſhed a book, in which he teaches that there is *no God*, and that we abſurdly give that title to *the relations of Nature* (D); and ſomething approaching ſo near to atheiſm had been communicated to the adept when he was admitted to the prieſthood, that we are perſuaded Weiſhaupt muſt have alluded to *language* at leaſt different from that in which Spinoza taught his dark doctrines, and that language, accompanied perhaps with impious and audacious geſtures, when he ſaid that, compared with his higher myſteries, his degree of prieſt was but child's play.

What gives ſome degree of probability to this conjecture, if it be nothing more, is the following fact related by the Abbé Barruel. During the French revolution (ſays that able and well-informed writer), a comedian appeared

---

(C) This will naturally ſurpriſe our readers; but it could not ſurpriſe him to whom it was addreſſed; for when candidate for the prieſthood, he had been aſked, "Do the ſciences which men cultivate, furniſh them with real lights? Are they conducive to real happineſs? Are they not, on the contrary, the offspring of numberleſs wants, and of the unnatural ſtate in which men live? Are they not the crude inventions of crazy brains?" There were, however, to be academies for the cultivation of ſuch ſciences as ſuited the deſigns of the order. Each academy was to conſiſt of nine epopts, of whom ſeven were to preſide reſpectively over ſo many departments of ſcience, whilſt the other two were to officiate as ſecretaries. One of the departments included the occult ſciences, to which belonged the art of *raiſing the ſeals of the letters* of all who belonged not to the order, and of ſecuring their own letters againſt ſimilar practices!!

(D) We learned this from the letter already quoted in note (A).

38
Atheiſm and

appeared (E), dreſſed in the ſacerdotal robes of the illuminees, and perſonally defying Almighty God. "No! (ſaid the impious wretch) thou doſt not exiſt. If thou haſt power over the thunderbolts, graſp them; aim them at the man who dares ſet thee at defiance in the face of thy altars. But no! I blaſpheme thee, and I ſtill live. No! thou doſt not exiſt." It will be ſeen by and bye, that the chiefs of the revolution, and even numbers of their tools, were illuminized; and is it improbable that this blaſphemer, who was arrayed in the inſignia of the epopts, made uſe of the language and geſtures of the higher myſteries? Whether it be or not, M. Barruel has proved, even from the writings of Weiſhaupt himſelf, that the magi were at leaſt atheiſts of the ſchool of Spinoza.

"The ſecond degree of the grand myſteries, called the *Man-king*, teaches (according to the author of the Critical Hiſtory), that every inhabitant of the country or town, every father of a family, is ſovereign, as men formerly were in the times of the patriarchal life, to which mankind is once more to be carried back; that in conſequence all authority and all magiſtracy muſt be deſtroyed."

39
Savagiſm.

This may appear to be nothing more than what the adept has been already taught in the leſſer myſteries; and it is in fact nothing more than that to which he muſt have ſeen theſe myſteries tending; but the reader underſtands not the language of the illuminees, if he ſuppoſes that, by the patriarchal ſtate, they mean ſuch a ſtate as that of the patriarchs of the Old Teſtament. No! their patriarchal ſtate is the fancied ſavage ſtate of the atheiſtical philoſophers of Greece and Rome, when mankind had neither property nor fixed habitation. This is evident from one of the diſcourſes of the hierophant; in which he tells the adept, that it would have been happy for man "had he known how to preſerve himſelf in the primitive ſtate in which Nature had placed him! But ſoon the unhappy germ developed itſelf in his heart, and reſt and happineſs diſappeared. As families multiplied, the neceſſary means of ſubſiſtence began to fail. *The Nomade or roaming life ceaſed; property began; men choſe fixed habitations; agriculture brought them together;* LIBERTY WAS RUINED IN ITS FOUNDATIONS, AND EQUALITY DISAPPEARED."

To reſtore that liberty and equality, therefore, which is the ultimate object of the order, and conſtitutes the MAN-KING, all property muſt be aboliſhed, every houſe burnt, as well the cottage of the peaſant as the palace of the prince; and mankind muſt once more inhabit woods and caverns without clothes and without fire, and ſally out occaſionally to encounter their fellow-brutes, and to ſearch for food among the wild herbs of the deſart. According to Mochus the Phenician, and the Greek philoſophers of this hopeful ſchool, this was the original ſtate of man *; and to this ſtate it was the object of Weiſhaupt and his adepts to reduce man again. Hence we hear them laviſhing the moſt rapturous encomiums on the Goths and Vandals who over-ran the Roman empire, annihilated the arts, put a ſtop to agriculture, and burnt the towns and villages of civilized Europe! It was thus, according to the illuminees, that thoſe barbarians regenerated mankind: but the regeneration was not complete; for the Goths and Vandals could not preſerve themſelves from the contagion of civil life; and their fall from ſavagiſm to ſcience drew from Weiſhaupt's hierophants the moſt piteous lamentations!

40
The laſt ſecret of the order.

The laſt ſecret communicated to the moſt favoured adepts was the novelty of the order. Hitherto their zeal had been inflamed, and their reſpect demanded to an inſtitution pretended to be of the higheſt antiquity. The honour of inſtituting the myſteries had been ſucceſſively attributed to the children of the Patriarchs, to ancient philoſophers, even to Chriſt himſelf, and to the founders of the maſonic lodges (ſee MASONRY in this *Suppl.*). But now the time is come when the adept, initiated in the higher myſteries, is ſuppoſed to be ſufficiently enthuſiaſtic in his admiration of the order, to be entruſted with the hiſtory of its origin. Here then they inform him, that this ſecret ſociety, which has ſo artfully led him from myſtery to myſtery; which has, with ſuch perſevering induſtry, rooted from his heart every principle of religion, all love of his country, and affection for his family; all pretenſions to property, to the excluſive right to riches, or to the fruits of the earth;—this ſociety, which has taken ſo much pains to demonſtrate the tyranny and deſpotiſm of all laws human and divine, and of every government, whether monarchical, ariſtocratical, or republican; which has declared him free, and taught him that he has no ſovereign on earth or in heaven; no rights to reſpect in others, but thoſe of perfect equality, of ſavage liberty, and of the moſt abſolute independence; that this ſociety is not the offspring of an ignorant and ſuperſtitious antiquity, but of modern philoſophy; in one word, that the true father of illuminiſm is no other than Adam Weiſhaupt, known in the ſociety by the name of SPARTACUS! This *important* ſecret, however, remained a myſtery even to the greater part of the *magi* and the *man-kings*, being revealed only to the grand council of *areopagites*, and to a few other adepts of diſtinguiſhed merit.

41
Propoſal for a female order.

So zealouſly was the order bent upon propagating its execrable principles through the whole world, that ſome of the chiefs had planned an order of female adepts, in ſubſerviency to the deſigns of the men. "It will be of great ſervice, (ſays *Cato* Zwack), it will procure us both information and money, and will ſuit charmingly the taſte of ſome of our trueſt members, who are lovers of the ſex." An aſſeſſor of the Imperial chamber at Wetzlar, of the name of Dittfurt, but known among the illuminees by that of *Minos*, expreſſed even his deſpair of ever bringing men to the grand object of the order without the ſupport of female adepts; and he makes an offer of his own wife and his four daughters-in-law to be firſt initiated. This order was to be ſubdivided into two claſſes, each forming a ſeparate ſociety, and having different ſecrets. The firſt was to be compoſed of virtuous women; the ſecond of the wild, the giddy, and the voluptuous. The brethren were to conduct the firſt, by promoting the reading of good books; and to train the ſecond

* See Doig's *Letters on the Savage State.*

(E) He does not ſay where this appearance was made; but the circumſtances related lead us to ſuppoſe that it was in a church.

ſecond to the arts of *ſecretly gratifying their paſſions*. The wife of an adept named Ptolemy Magus was to preſide over one of the claſſes; which (ſays Minos) will become, under her management and his, a very pretty ſociety. "You muſt contrive pretty degrees, and dreſſes, and ornaments, and elegant and decent rituals. No man muſt be admitted. This will make them more keen, and they will go much farther than if we were preſent, or than if they thought that we knew of their proceedings. Leave them to the ſcope of their own fancies, and they will ſoon invent myſteries which will put us to the bluſh, and myſteries which we can never equal. They will be our great apoſtles. Reflect on the reſpect, nay, the awe and terror, inſpired by the female myſtics of antiquity. Ptolemy's wife muſt direct them, and ſhe will be inſtructed by Ptolemy; and my ſtep-daughters will conſult with me. We muſt always be at hand to prevent the introduction of any improper queſtion. We muſt prepare themes for their diſcuſſion: thus we ſhall confeſs them, and inſpire them with our ſentiments. No man, however, muſt come near them. This will fire their roving fancies, and we may expect rare myſteries!"

42
Rejected by Spartacus.

But notwithſtanding all the plans and zeal of this profligate wretch and others of the fraternity, it does not appear that the General *Spartacus* ever conſented to the eſtabliſhment of the ſiſterhood. He ſupplied, however, the want of ſuch an inſtitution, by ſecret inſtructions to the regents, on the means of making the influence of women over men ſubſervient to the order, without entruſting them with any of the ſecrets. "The fair ſex (ſays he) having the greateſt part of the world at their diſpoſal, no ſtudy is more worthy the adept than the *art of flattery*, in order to gain them. They are all more or leſs led by vanity, curioſity, pleaſure, or the love of novelty. It is on that ſide, therefore, they are to be attacked, and by that to be rendered ſubſervient to the order." That Weiſhaupt's ſagacity had not on this occaſion forſaken him, is very evident; ſince it has been proved that the German fair, who were the correſpondents of the illuminees, welcomed the French invaders of their native country *. Nay, ſo lately as the winter of 1798, our correſpondent in Saxony heard ſeveral of theſe illuminized ladies expreſs a wiſh that the French might invade and conquer England; for then, ſaid they, *tea and coffee would be cheaper!*

It is not enough for the founder of a ſect of conſpirators to have fixed the preciſe object of his plots. His accomplices muſt form but one body, animated by one ſpirit; its members muſt be moved by the ſame laws, under the inſpection and government of the ſame chiefs. A full account of the government of Weiſhaupt's order will be found in the valuable work of Abbé Barruel; our limits permit us to give only ſuch a general view of it as may put our readers on their guard againſt the ſecret machinations of theſe execrable villains, whoſe lodges are now recruiting, under different denominations, in every country in Europe.

43
Subordination of the illuminees.

Wherever illuminiſm has gained a footing, as the means of ſubordination, there is a general diviſion of command as well as of locality. The *candidates* and *novices* are each under the direction of his own inſinuator, who introduces him into the *Minerval lodges*; each *Minerval lodge* has a ſuperior from among the preparatory claſs, under the inſpection of the intermediary claſs. So many lodges conſtitute a diſtrict, under the direction of a ſuperior, whom the order calls *dean*. The dean is ſubjected to the *provincial*, who has the inſpection and command of all the lodges and deaneries of the province. Next in order comes the *national ſuperior*, who has full power over all within his nation, provincials, deans, lodges, &c. Then comes the ſupreme council of the order, or the *areopagites*, over which preſides the *general* of illuminiſm. Thus has the order formed within itſelf a ſupreme tribunal, to whoſe inquiſition all nations are to be ſubjected. The areopagites, conſiſting of twelve fathers of the order, with the general at their head, form the centre of communication with all the national ſuperiors on earth; each *national* is the centre of one particular nation; the *provincial*, of one province; the *dean*, of the lodges within his deanery; the *Minerval maſter*, of his academy; the *venerable*, of his maſonic lodge; and the *inſinuator* or *recruiter*, of his *novices* and *candidates*.

44
Their mode of correſpondence;

The higher degrees (ſays Weiſhaupt in one of his inſtructions to the regents) muſt always be hidden from the lower. The ſimple illuminee therefore correſponds with his immediate ſuperior, knowing perhaps no other member of the order; the latter, with his dean; and thus gradually aſcending to the national ſuperiors, who alone are acquainted with the reſidence of the areopagites, as they again are with the names and reſidence of the general. Any member, however, of the inferior degrees, may occaſionally correſpond with his unknown ſuperiors, by addreſſing his letters *Quibus licet*; and in theſe letters he may mention whatever he thinks conducive to the advancement of the order. If he be a novice, he may in theſe letters inform his ſuperiors how his inſtructor behaves to him, or may draw the character of any perſon whatever. When the letter of any adept contains ſecrets, or complaints which he chooſes to conceal from his immediate ſuperior, he directs it *Soli* or *Primo*; and then it can be opened only by the *provincial*, the *national ſuperior*, the *areopagites*, or the *general*, according to the rank of the writer, which is by ſome contrivance unknown to M. Barruel, indicated on the outſide of the letter. The *provincial* opens the letters of the *minor* and *major* illuminees which are directed *Soli*; the *Quibus licets* of the epopts; and the *Primos* of the novices; but he cannot open either the *Primo* of the minerval, the *Soli* of the Scotch knight, or the *Quibus licet* of the regent. He can only form a conjecture as to the perſons who open his own letters, and thoſe which he is not permitted to open himſelf.

45
And of giving importance to their order,

When it is conſidered, that by one of Weiſhaupt's ſtatutes, the provincial has in each chapter or diſtrict a confidential epopt, who is his *ſecret cenſor* or *ſpy*; that theſe ſpies are to inſinuate themſelves into all companies, and collect *anecdotes of ſecret hiſtory*; that the hiſtorian of the province is to inſert theſe anecdotes into a journal kept for that purpoſe; and that the provincials are obliged to forward the contents of theſe journals to the high ſuperiors of the order--ſome notion may be formed of the influence of the general and areopagites in every country into which illuminiſm has found its way. "The means of acquiring an aſcendency over men (ſays Weiſhaupt), are incalculable. Who could enumerate them all? They muſt vary with the diſpoſition of the times. At one period, it is a

---

* Dr Robiſon's *Proofs of a Conſpiracy*.

taſte for the marvellous that is to be wrought upon. At another, the lure of ſecret ſocieties is to be held out. For this reaſon, it is very proper to make your inferiors believe, without telling them the real ſtate of the caſe, that all other ſecret ſocieties, particularly that of *Freemaſonry*, *are ſecretly directed by us*. Or elſe, and IT IS REALLY THE FACT IN SOME STATES, THAT POTENT MONARCHS ARE GOVERNED BY OUR ORDER. When any thing remarkable or important comes to paſs, hint that it *originated with our* order. Should any perſon by his merit acquire a great reputation, let it be generally underſtood that *he is one of us*.

46
By every means, good or bad.

“ If our order cannot eſtabliſh itſelf in any particular place, with all the forms and regular progreſs of our degrees, *ſome other form muſt be aſſumed*. Always have *the object* in view; that is the eſſential point. No matter what *the cloak* be, provided you ſucceed; *a cloak*, however, *is always neceſſary*, for in *ſecrecy our ſtrength lies*. The INFERIOR LODGES OF FREEMASONRY ARE THE MOST CONVENIENT CLOAKS for our GRAND OBJECT; becauſe the world is already familiariſed with the idea, that *nothing of importance*, or *worthy of their attention, can ſpring from maſonry*.” No artifice, however, is to be left untried. “ You may attend large and commercial towns during the times of fairs in different characters; as *a merchant*, *an officer*, *an abbé*. Everywhere you will perſonate an extraordinary man, having important buſineſs on your hands; but all this muſt be done with a great deal of *art and caution*, leſt you ſhould have the appearance of an adventurer. You may write your orders with a *chymical preparation of ink*, *which diſappears after a certain time*. Never loſe ſight of the *military ſchools*, of the *academies*, *printing preſſes*, *libraries*, *cathedral chapters*, or *any public eſtabliſhments* that can influence *education*, or *government*. Let our regents perpetually attend to the various means, and form plans, for MAKING US MASTERS *of all theſe eſtabliſhments*. When an author ſets forth principles true in themſelves, but which do not as yet ſuit *our general plan of education for the world*, or principles, the publication of which is premature; every effort muſt be made to *gain over the author*; but ſhould all our attempts fail, and we ſhould prove unable to entice him into the order, *let him be diſcredited by every poſſible means*”

Of their methods of diſcrediting authors, one has come to our knowledge, which muſt be intereſting to ſome of our readers. Dr Robiſon's work, entitled *Proofs of a Conſpiracy*, &c. which firſt unmaſked theſe hypocrites in this country, found its way into Germany, and was tranſlated into the German language, and expoſed to ſale at the Leipſic fairs. The illuminees, under the diſguiſe of *merchants* and *abbes*, attended, and bought up the whole impreſſion, which they committed to the flames. A ſecond edition was publiſhed, and it ſhared the ſame fate (F). This was a more compendious way of anſwering the learned author than that which has been adopted by the Jacobin journaliſts in London; but perhaps it may convince the readers of theſe journals, that the Doctor has not ſo far miſtaken the ſenſe of the writings of *Philo* and *Spartacus*, as their illuminiſed maſters wiſh them to believe.

When theſe arts of diſſeminating the diſorganiſing and impious principles of the order are duly conſidered, and when it is remembered that its emiſſaries dare not diſobey a ſingle injunction of the high ſuperiors, without expoſing themſelves to poiſon, or to the daggers of a thouſand unſeen aſſaſſins, no man can be ſurpriſed to learn that the illuminees contributed greatly to the French revolution. 47 Illuminiſm of France. The philoſophers of France had indeed prepared the public mind for embracing readily the doctrines of illuminiſm; and ſo early as 1782, *Philo* and *Spartacus* had formed the plan of illuminizing that nation; but they were afraid of the vivacity and caprice of the people, and extended not their attempts, at that time, beyond Straſbourg. Already, however, there exiſted ſome adepts in the very heart of the kingdom; and the Marquis de Mirabeau, when ambaſſador at the court of Berlin, was initiated at Brunſwick by a diſciple of Philo Knigge's. On his return to France he began to introduce the new myſteries among his maſonic brethren.

48
By means of free maſonry.

The ſtate of free maſonry was at that time peculiarly adapted to the views of the conſpirators. The French had engrafted on the old and innocent Britiſh maſonry a number of degrees, gradually riſing above each other, to the very myſteries of illuminiſm itſelf (ſee MASONRY in this *Suppl.*) Theſe were called the *philoſophical* degrees, and comprehended the *knights of the ſun*, the higher *Roſicrucians*, and the *knights Kadeſh*. At the head of all theſe ſocieties, whether ancient or modern, were three lodges at Paris, remarkable for the authority which they exerciſed over the reſt of the order, and Philip of Orleans was the grand-maſter. So early as the year 1787, France contained 282 towns, in which were to be found regular lodges, under the direction of that execrable wretch. He increaſed their number by introducing to the *maſonic* myſteries the loweſt of the rabble, as well as thoſe French guards whom he deſtined to the ſubſequent attack of the baſtile, and to the ſtorming of the palace of his near relation and royal maſter. In every country town and village lodges were opened for aſſembling the workmen and peaſantry, in hopes of heating their imaginations with the ſophiſticated ideas of equality and liberty, and the rights of man; and it was then that Mirabeau invited a deputation from the order of Weiſhaupt, which very quickly diffuſed the light of illuminiſm through the whole kingdom. Inſtead of *Spartacus* Weiſhaupt, *Cato* Zwack, and *Philo* Knigge, we find wielding the firebrands of revolution in the capital of France, *Philip of Orleans*, *Mirabeau*, *Syeyes*, and *Condorcet*. The day of general inſurrection was fixed by theſe miſcreants for the 14th of July 1789. At the ſame hour, and in all parts of France, the cries of *equality* and *liberty* reſounded from the lodges. The Jacobin clubs were formed; and hence ſprung the revolution, with all its horrors of atheiſm, murder, and maſſacre!

In ſupport of this account of the illuminees we have not loaded our margin with authorities; becauſe our detail has been taken wholly from the valuable works of

---

(A) This information was communicated to us by a gentleman of character, who was at Leipſic when the two impreſſions of the book were thus diſpoſed of. The Abbé Barruel's work has no doubt been anſwered in the ſame way, though we cannot ſay ſo upon the ſame authority.

of Abbé Barruel and Dr Robiſon, to which we refer our readers for much curious information that our limits do not permit us to give. We cannot, however, conclude the article, without making ſome remarks on that ſpecious principle by which the conſpirators have deluded numbers, who abhor their impieties, and who would not go all their length even in rebellion; we mean the maxim, "that it is our duty to love all men with an equal degree of affection, and that any partial regard for our country, or our children, is unjuſt."

49 Reflections on the fundamental principles of illuminiſm;

That this maxim is falſe, every *Chriſtian* knows, becauſe he is enjoined to "do good indeed unto all men, but *more eſpecially* to them who are of the houſehold of faith;" becauſe he is told, that "if any man provide not for his *own*, and eſpecially for thoſe of his *own houſe*, he hath denied the faith, and is worſe than an infidel;" becauſe his divine maſter, immediately after reſolving all duty into the love of God and man, delivers a parable, to ſhew that we neither can nor ought to love all men *equally*; and becauſe the ſame Divine Perſon had one diſciple whom he loved more than the reſt. But we wiſh thoſe *philoſophers* who talk perpetually of *the mechaniſm* of the human mind, and at the ſame time affect to have no *partial* fondneſs for any individual, but to love all with the ſame degree of *rational* affection, to conſider well whether ſuch philanthropy be conſiſtent with what they call (very improperly indeed) *mechaniſm*. If this mechaniſm be (as one of them ſays it is) nothing more than *attraction* and *repulſion*, we know that it *cannot* extend with equal force over the whole world; becauſe the force of attraction and repulſion varies with the diſtance. If by this abſurd phraſe, they mean a ſet of *inſtinctive* propenſities, or feelings, we know that among ſavages, who are more governed by inſtinct than civilized men, philanthropy is a feeling or propenſity of a very limited range. If they believe all our paſſions to originate in ſelf love, then is it certain that our philanthropy muſt be progreſſive; embracing firſt, and with ſtrongeſt ardour, our relations, our friends, and our neighbours; then extending gradually through the ſociety to which we belong; then graſping our country; and laſt of all the whole human race. Perhaps they may ſay that reaſon teaches us to love all men equally, becauſe ſuch equal love would contribute moſt to the ſum of human happineſs. This ſome of them indeed have actually ſaid; but it is what no man of reflection can poſſibly believe. Would the ſum of human happineſs be increaſed, were a man to pay no greater attention to the education of his own children than to the education of the children of ſtrangers? were he to do nothing more for his aged and helpleſs parents than for any other old perſon whatever? or, were he to neglect the poor in his neighbourhood, that he might relieve thoſe at the diſtance of 1000 miles? Theſe queſtions are too abſurd to merit a ſerious anſwer.

When a man, therefore, boaſts of his univerſal benevolence, declaring himſelf ready, without fee or reward, to ſacrifice every thing dear to him for the benefit of ſtrangers whom he never ſaw; and when he condemns, in the cant phraſe of faction, that narrow policy which does not conſider the whole human race as one great family—we may ſafely conclude him to be either a conſummate hypocrite, who loves none but himſelf, or a philoſophical fanatic, who is at once a ſtranger to his duty and to the workings of his own heart.

50 Exemplified in the conduct of the illuminees.

If this concluſion require any farther proof, we have it in the conduct of Weiſhaupt and his areopagites. In the hand-writing of *Cato* his *incomparable man*, was found the deſcription of a ſtrong box, which, if forced open, would blow up and *deſtroy its contents*; ſeveral receipts for *procuring abortion*; a compoſition which *blinds or kills* when ſpurted in the face; *tea* for procuring abortion: *Herbæ quæ habent qualitatem delateream*; a method for filling a bed-chamber with *peſtilential vapours*; how to take off impreſſions of ſeals, ſo *as to uſe them afterwards as ſeals*; a receipt *ad excitandum furorem uterinum*; and a diſſertation on *ſuicide*. Would genuine philanthropiſts have occaſion for ſuch receipts as theſe? No! the order which uſed them was founded in the moſt conſummate villany, and by the moſt deteſtable hypocrite. The inceſtuous Weiſhaupt ſeduced the widow of his brother, and ſolicited poiſon and the dagger to murder the woman whom he had fondly preſſed in his arms. "Execrable hypocrite (ſays M. Barruel), he implored, he conjured both art and friendſhip, to deſtroy the innocent victim, the child, whoſe birth muſt betray the morals of his father. The ſcandal from which he ſhrinks, is not that of his crime: it is the ſcandal which, publiſhing the depravity of his heart, would deprive him of that authority by which, under the cloak of virtue, he plunged youth into vice and error. *I am on the eve,* (ſays he) *of loſing that reputation which gave me ſo great authority over our people: My ſiſter in-law is with child. I will hazard a deſperate blow, for I neither can nor will loſe my honour.*" Such is the benevolence of thoſe who, baniſhing from their minds all partial affection for their children and their country, profeſs themſelves to be members of one great family, the family of the world!

IMAGINARY Quantities, or *Impoſſible Quantities*, in algebra, are the even roots of negative quantities; which expreſſions are Imaginary, or impoſſible, or oppoſed to real quantities; as $\surd - aa$, or $^4\surd - a^4$, &c. For as every even power of any quantity whatever, whether poſitive or negative, is neceſſarily poſitive, or having the ſign +, becauſe + by +, or — by —, give equally +; hence it follows that every even power, as the ſquare for inſtance, which is negative, or having the ſign —, has no poſſible root; and therefore the even roots of ſuch powers or quantities are ſaid to be impoſſible or imaginary. The mixt expreſſions ariſing from imaginary quantities joined to real ones, are alſo imaginary; as $a - \surd - aa$, or $b + \surd - aa$.

Imaginary Roots of an equation, are thoſe roots or values of the unknown quantity, which contain ſome imaginary quantity. Thus the roots of the equation $xx + aa = 0$, are the two imaginary quantities $+ \surd - aa$ and $- \surd - aa$, or $+ a\surd - 1$ and $- a\surd - 1$.

IMPACT, the ſimple or ſingle action of one body upon another to put it in motion. Point of impact is the place or point where a body acts.

IMPERFECT Number, is that whoſe aliquot parts, taken all together, do not make a ſum that is equal to the number itſelf, but either exceed it, or fall ſhort of it; being an abundant number in the former caſe, and a defective number in the latter. Thus, 12 is an abundant imperfect number, becauſe the ſum of all its aliquot parts, 1, 2, 3, 4, 6, makes 16, which exceeds the

the number 12. And 10 is a defective imperfect number, becauſe its aliquot parts, 1, 2, 5, taken all together, make only 8, which is leſs than the number 10 itſelf?

IMPOST, in architecture, a capital or plinth, to a pillar, or pilaſter, or pier, that ſupports an arch, &c.

Doctrine of Impulſion.

IMPULSION, is the term employed in the language of mechanical philoſophy, for expreſſing a ſuppoſed peculiar exertion of the powers of body, by which a moving body changes the motion of another body by hitting or ſtriking it. The plaineſt caſe of this action is when a body in motion hits another body at reſt, and puts it in motion by the ſtroke. The body thus put in motion is ſaid to be IMPELLED by the other: and this way of producing motion is called IMPULSION, to diſtinguiſh it from PRESSION, THRUSTING, or PROTRUSION, by which we puſh a body from its place without ſtriking. The term has been gradually extended to every *change* of motion occaſioned by the colliſion of bodies.

1
Hiſtory of it.

When ſpeculative men began to collect into general claſſes, the obſervations made during the continual exertions of our own perſonal powers on external bodies, in order to gain the purpoſes we had in view, it could not be long before they remarked, that as we, by the ſtrength of our arm, can move a body, can ſtop or any how change its motion; ſo a body already in motion produces effects of the ſame kind in another body, by hitting it. Such obſervations were almoſt as early and as intereſting as the other; and the attention was very forcibly turned to the general facts which obtained in this way of producing motion; that is, to the expiſcation of the general laws of impulſion. We do not find, however, in what remains of the phyſical ſcience of the ancients, that they had proceeded far in this claſſification. While mechanics, or the ſcience of machines, had acquired ſome form, and had been the ſubject of ſucceſsful mathematical diſcuſſion, we do not find that any thing ſimilar had been done in the ſcience of impulſe. Yet the artillery of ancient times was very ingenious and powerful. But although Vegetius, and Ammianus Marcellinus, and Hero, deſcribe the mechaniſm of theſe engines with great care, and frequently with mathematical ſkill, we ſee no attempts to aſcertain with preciſion the force of the miſſile weapon, or to ſtate the efficacy of the battering ram, by meaſures of the momentum, and compariſon of it with the reſiſtance oppoſed to it. The engineers were contented with very vague notions on theſe points.

Ariſtotle, in his 20th Mechanical Queſtion, and Galen in ſome occaſional obſervations, are the only authors of antiquity whom we recollect as treating the force of impulſe as a quantity ſuſceptible of meaſure. Their obſervations are extremely vague and trivial, chiefly directed, however, to the diſcrimination of the force of impulſe from that of preſſure.

In more modern times, great additions had already been made to the aſſiſtance we had derived from the impulſive efficacy of bodies in motion. Water-mills and wind-mills had been invented, and had been applied to ſuch a variety of purpoſes, that the engineers were faſt acquiring more diſtinct notions of the force of impulſe. Naval conſtructions was changed in ſuch a manner, that there hardly remained any thing of the ancient rigging. The oblique action of wind and water were now found even more effective than the direct; and ſhips could now ſail with almoſt any wind. All theſe things fixed the attention of the engineers and of the ſpeculatiſt on the numberleſs modifications of the force of impulſe.

But it ſoon appeared that this was a refined branch of knowledge, and required a more profound ſtudy than any other department of the ſcience of motion. At the ſame time, it was equally clear, that it was alſo of ſuperior importance. Mills worked by cattle, or by mens hands, were everywhere giving place to wind and water mills; and a ſhip alone appeared to every intelligent mechanician to be the greateſt effort of human invention, and moſt deſerving his careful ſtudy. All theſe improvements in the arts of life derived their efficacy from the impulſe of bodies. The laws of impulſion, therefore, became the objects of ſtudy to all who pretended to philoſophical ſcience. But this is a branch of ſtudy wholly new, and derives little aſſiſtance from the mechanical ſcience already acquired; for that was confined to the determination of the circumſtances which regulated the equilibrium of forces, either in their combined action on bodies in free ſpace, or by the intervention of machines. But in the production of motion by impulſe, the equilibrium is not ſuppoſed to obtain; and therefore its rules will not ſolve the moſt important queſtion, "What will be the preciſe motion?"

Galileo, to whom we are indebted for the firſt diſcoveries in the doctrine of free motions, was alſo the firſt who attempted to bring impulſion within the pale of mathematical diſcuſſion. This he attempted, by endeavouring to ſtate what is the force or energy of a body in motion. The very obſcure reflections of Ariſtotle on this ſubject only ſerved to make the ſtudy more intricate and abſtruſe. Galileo's reflections on it are void of that luminous perſpicuity which is ſeen in all his other writings, and do not appear to have ſatiſfied his own mind. He has recourſe to an experiment, in order to diſcover what preſſure was excited by impulſion. A weight was made to fall on the ſcale of a balance, the other arm of which was loaded with a conſiderable weight; and the force of the blow was eſtimated by the weight which the blow could thus ſtart from the ground. The reſults had a certain regularity, by which ſome analogy was obſerved between the weights thus ſtarted and the velocity of the impulſe; but the anomalies were great, and the analogy was ſingular and puzzling; it led to many intricate diſcuſſions, and ſcience advanced but ſlowly.

2
Laws of impulſion diſcovered by Wallis, Wrenn, and Huyghens

At laſt the three eminent mathematicians, Dr Wallis, Sir Chriſtopher Wrenn, and Huyghens, about the ſame time, and unknown to each other, diſcovered the ſimple and beautiful laws of colliſion, and communicated them to the Royal Society of London in 1668 (Phil. Tranſ. n° 43—46.). Sir Chriſtopher Wrenn alſo invented a beautiful method of demonſtrating the doctrine by experiment. The bodies which were made to ſtrike each other were ſuſpended by threads of equal length, ſo as to touch each other when at reſt. When removed from this their vertical ſituation, and then let go, they ſtruck when arrived at the loweſt points of their reſpective circles, and their velocities were proportional to the chords of the arches through which they had deſcended. Their velocities, after the ſtroke, were meaſured,

meaſured, in like manner, by the chords of their arches of aſcent. The experiments correſponded preciſely with the theoretical doctrine.

In the mean time, this ſubject had keenly occupied the attention of philoſophers, who found it to be of a very abſtruſe nature; or, which is nearer the truth, they indulged in great refinement in proſecuting the ſtudy. The firſt attempts to meaſure the impulſive force of bodies, by ſetting it in oppoſition to preſſures, which had long been meaſured by weights, gave riſe to ſome very refined reflections on the nature of theſe two kinds of forces. Ariſtotle had ſaid that they were things altogether diſparate. If ſo, there can be no proportion between them. Yet the analogy obſerved in the experiments above mentioned of Galileo, ſhewed that impulſe could be gradually augmented, till it exceed any preſſure. This indicates ſameneſs in kind, according to Euclid himſelf. A curious experiment of Galileo's, in which the impulſe of a vein of water was ſet in equilibrio with a weight, ſeemed not only to eſtabliſh this identity beyond a doubt, but even to ſhew the origin of preſſure itſelf. The weight in one ſcale is ſuſtained as long as the ſtream of water continues to ſtrike the other ſcale. In this experiment, therefore, preſſure is equivalent to continual impulſe. But *continual* impulſe is not conceivable: we muſt conſider the impulſe of the ſtream as the *ſucceſſive* impulſe of the different particles of water, at intervals which are altogether indiſtinguiſhable.

From theſe conſiderations were deduced two very momentous doctrines: 1. That preſſure is nothing but repeated impulſe; 2. That although preſſure and impulſe are the ſame in kind, they are incomparable in magnitude. The impulſe is equal to the weight of a column of water, whoſe length is the height neceſſary for communicating the velocity. Now this is inceſſant; and the weight is ſuſtained during any the ſmalleſt moment of time, by the impulſe, not of the whole column, but of the inſenſible portion of it which is then making its ſtroke. Impulſe, therefore, is infinitely greater than preſſure.

3
Impulſe ſaid to be the only cauſe of motion.

Theſe abſtruſe ſpeculations have a charm for certain ingenious ſpeculative minds; and when indulged, will lead them very far. Accordingly, it was not long before ſome of the moſt ingenious philoſophers of Europe taught that impulſe was the ſole origin of preſſure. There is but one moving power (ſaid they) in mechanical nature: This is impulſe.—*Nihil movetur* (ſays Euler) *niſi a contiguo et moto.* Moreover, having been long and familiarly converſant with the actions of animals, and the actions of moving bodies, and conceiving, with ſufficient diſtinctneſs, that impenetrable bodies cannot move without moving thoſe with which they are ſurrounded and in contact, they imagined that they fully underſtood how all this diſplacement of bodies is carried on; and therefore they maintained, that any motion is fully explained when it is ſhewn to be a caſe of impulſion: But they ſaw many caſes of motion where this impulſion could not be exhibited to the ſenſes. Thus, the fall of heavy bodies, the mutual approach or receſs of magnetic and electric bodies, exhibited no ſuch operation. But even here their experience helped them to an explanation. Air is an inviſible ſubſtance, and its very exiſtence was for a long time known to us only by means of its impulſe. As we ſee that preſſures are generated by the impulſe of water and of air, may there not be fluids ſtill more ſubtle than air, by whoſe inviſible impulſe bodies are made to fall, and magnets are made to approach or avoid each other? The impoſſibility of this cannot be demonſtrated, and the laws of impulſe had not as yet been ſo far inveſtigated as to ſhew that they were incompatible with thoſe productions of motion. It was therefore an open field for diſcuſſion; and the philoſophers, without farther heſitation, adopted, as a firſt truth, that ALL MOTION WHATEVER IS PRODUCED BY IMPULSION. The buſineſs of the philoſopher, therefore (ſay they), is to inveſtigate what combination of inviſible impulſions is competent to the production of any obſerved motion; ſuch as the fall of a heavy body, the elliptical motion of a planet, or the polarity of a magnetic needle. The curious diſpoſition of iron-filings round a magnet encouraged this kind of ſpeculation: It looks ſo like a ſtream of fluid; but it is a number of quieſcent fragments of iron. This does not hinder us from *ſuppoſing* ſuch a ſtream, not of iron-filings, but of a magnetic fluid, which will arrange (ſay the atomiſts) thoſe fragments, juſt as we ſee the flote-graſs in a brook arranged by a ſtream of water. Fluids, therefore, moving in ſtreams, vortices, and a thouſand different ways, have been ſuppoſed, in order to *explain*, that is, to bring under a general known law of mechanical Nature, all thoſe caſes of the production of motion where impulſion is not obſerved by the ſenſes.

As we have gradually become better acquainted with the laws of the production of motion by impulſion, we have been able to explode many of thoſe proffered explanations, by ſhewing that the genuine reſults of the ſuppoſed inviſible motions, that is, the impulſions which they would produce, are very unlike the motions which we attempt to explain. It has been ſhewn that the vortices ſuppoſed by Des Cartes, or by Leibnitz, or by Huyghens, cannot exiſt; and they have been given up. But it is anſwered to all thoſe demonſtrations of futility, that ſtill the axiom remains. Motion is produced only by impulſe; but we have not yet diſcovered all the poſſibilities of impulſion; and we muſt not deſpair of diſcovering that preciſe ſet of inviſible motions, and conſequent impulſions, of which the phenomena before us is the neceſſary reſult.

4
The application of this principle is hazardous.

But this is by no means ſufficient authority for deſerting the rule of philoſophizing, ſo prudently and judiciouſly recommended by Sir Iſaac Newton; namely, not to admit as the cauſe of phenomenon any thing that is not *ſeen* to operate in its production. The prudence of this reſtriction is evident; and it has alſo been ſufficiently ſhewn (PHILOSOPHY, *Encycl.* n° 48. &c.), that true philoſophical explanation, or extenſion of knowledge, is unattainable, if this rule be not ſtrictly adhered to. We therefore require a cogent reaſon for a practice that opens the door to every abſurdity, and that cannot give us the knowledge which we are in queſt of. What, then, is the reaſon that always induces philoſophers to have recourſe to impulſion for the explanation of a phenomenon, and to reſt ſatisfied in every caſe where it can be clearly proved that the phenomenon is really a caſe of impulſion? We ſay that we inquire into the reaſon why a body falls, and that we will be ſatisfied if it can be ſhewn us that it has received a number of impulſions downward. Do we inquire why a body in motion puts another body in motion by hitting it? And if we do, have we diſcovered the reaſon? We believe that none of the philoſophers, who have recourſe to inviſible impelling fluids, ever aſk a reaſon for motion by impulſion. Indeed they ſhould not, otherwiſe it would ceaſe to be a firſt principle of explanation. Other philoſophers, indeed (namely, ſuch as aſk no reaſon for the weight of a body, but the FIAT of the ALMIGHTY), require an explanation of motion by impulſe, and think that, in almoſt every caſe, they have found it out.

If the philoſophers aſk no reaſon for this production of motion, they muſt (that it may ſerve as a principle of explanation) ſay that impulſiveneſs is an original property of matter, either contingent or eſſential. Accordingly, we believe that this, or ſomething like this, has been aſſumed as a principle by the greater part of mechanicians. It has been aſſumed, as we have obſerved in the article Dynamics, *Suppl.* that a *moving body* poſſeſſes the power of producing motion in another body by hitting it; and they call it the IMPULSIVE FORCE *of moving bodies*—the FORCE INHERENT *in a moving body*. The reader will have obſerved, in our manner of treating that article, and alſo in ſeveral paſſages of different articles of the *Encyclopædia Britannica*, that we do not conſider this aſſumption as very clearly authoriſed by obſervation, or deducible by abſtract reaſoning, from the firſt principles of philoſophy. There is no branch of natural philoſophy on which ſo many ingenious diſſertations have been written; and perhaps there is none that has been more ſucceſsfully proſecuted: Yet this is the only part of the ſcience of motion that has given riſe to a ſerious diſpute; a diſpute that has divided, and ſtill divides, the mechanicians of Europe.

Some may think it preſumptuous in us, in a Work of this kind, which only aims at collecting and exhibiting in one view the *exiſting ſcience* of Europe, to pretend to give new doctrines, or to decide a queſtion which has called forth all the powers of a Leibnitz, a Bernoulli, a Jurin, a M'Laurin, &c. But we make no ſuch pretenſions; we only hope that, by ſeparating the queſtion from others with which it has, in every inſtance, been complicated, and by conſidering it apart, ſuch notions may be formed, in perfect conformity to the principles adopted by all parties, that the myſtery, which has gradually gathered like a cloud, may be diſpelled, and all cauſe of difference taken away. We apprehend that this requires no very extenſive knowledge, but merely a ſtrict attention to the conceptions which we form of the actions of bodies on each other, and a preciſion in the uſe of the terms employed in the diſcuſſion.

5 Inquiry into its truth.

We truſt that our philoſophical readers perceive and approve of our anxiety to eſtabliſh (in the article Dynamics, *Suppl.*) the leading principles of mechanical philoſophy, from which we are to reaſon in future on acknowledged FACTS, or LAWS of human thought. It is not ſo much the queſtion, What is the eſſence of material Nature, from which all the appearances in the univerſe proceed? as it is, What do we know of it? how do we come by this knowledge? and what uſe can we make of it? The tænia knows nothing of the ſolar ſyſtem, and man is ignorant of the cauſe of impulſiveneſs. Other intelligent creatures may have ſenſes, of which this is the proper object; and others, of a ſtill more exalted rank, may perceive the operations of mind as clearly as we perceive thoſe of matter, while they are equally ignorant with ourſelves of the cauſes which connect the conjoined events in either of thoſe operations. But "known unto God, and to Him alone, are ALL His works!"

6 We learn the exiſtence of matter chiefly by means of touch.

To accompliſh this purpoſe, we directed the reader's attention to what paſſes in his own mind when he thinks on the mechanical phenomena of Nature; on what he calls body; on the perceptions which bring it into his view, and which give him all the notions that he can form of its diſtinguiſhing, its characteriſtic properties. How does he learn that there is matter in a particular place? He has more than one mean of information; and each of theſe informs him of peculiar qualities of the thing which he calls *matter*. Many appearances ſuggeſt to his mind the preſence of a body. Shew a monkey or a kitten (and even ſometimes a human infant) a mirror, and it will inſtantly grope round it to find a companion. Why does the creature grope about ſo? It is not contented with the firſt indication of matter, and nothing will ſatisfy it but touching or graſping what is behind the mirror. It is by our ſenſe of touch alone that we get the irreſiſtible conviction that matter or body is perceived by us, and it never fails to give us the perception; nay, we have the perception even in ſome caſes where the experienced philoſopher thinks himſelf obliged to doubt of its truth. Some ſenſations, ariſing from ſpaſm, cannot be diſtinguiſhed from the feeling of touch; and the patient inſiſts that ſomething preſſes on the diſeaſed part, while the phyſician knows that it is only a nervous affection. Every perſon will think that a cobweb touches his face when an electrified body is brought near it, and will try to wipe it off with his hand. But the modern philoſopher ſees good reaſon for aſſerting, that in this inſtance our feeling gives us very inaccurate, if not erroneous, information. He ſhews that the fact, of which our feeling truly informs us, is the bending of the ſmall hairs or down which grow on the face, and that theſe only have been touched; and the followers of Epinus deny that even this has been demonſtrated.

7 The excitement of touch is accompanied by the feeling of exerted preſſure.

The philoſopher adopts this mode of perception as unqueſtionable, and allows that, and that alone, to be matter, which invariably produces this ſenſation by contiguity. But engaged in ſpeculations which fix his attention on the external object, he neglects and overlooks the inſtrument of information, and its manner of producing the effect, juſt as the aſtronomer overlooks the teleſcope, and the union and decuſſation of the rays of light which form the picture by which he perceives the ſatellite of Jupiter travel acroſs his diſk. The philoſopher finds it convenient to generaliſe the immenſe variety of touches which he feels from external bodies, and to conſider them as the operations of one and the ſame diſcriminating quality, a PROPERTY inherent in the external ſubſtance BODY: and he gives it a name, by which he can excite the ſame notion in the minds of his hearers. It is worth while to attend to what has been done in this matter, becauſe it gives much information concerning the firſt principles of mechaniſm. An exquiſite painting has ſometimes ſuch an appearance of prominence, that one is diſpoſed to draw the finger along it, and we expect to feel ſome roughneſs, ſome *obſtruction*, ſomething that prevents the finger

ger from going over the place. Perhaps we doubt, and want to be aſſured. We preſs a little cloſer; but feel no obſtruction; and we deſiſt. The very firſt appearance, therefore, which this indicating quality, viewed as the *property* of external matter, has in our conceptions, is that of an obſtruction, an obſtacle, to the exertion of one of our natural powers. The power exerted on this occaſion is familiarly and *diſtinctively* known by the name of PRESSURE. This is the name of our own exertion, our own action; and, in this inſtance, and (we think, in this alone, the word is uſed purely, primitively, and without figure. When we ſay that a ſtone preſſes on the ground, we ſpeak figuratively, as truly as when we ſay that the candleſtick ſtands, and the ſnuffers lie, on the table. It is a perſonification, authoriſed by the ſimilarity of the effects and appearances. Further, when we ſpeak of our preſſure on any thing, with the intention of being preciſe in our communication, we ſpeak only of what obtains in the touching parts of the finger and the thing preſſed, paying no attention to the long train of intermediate exertions of the mind on the nerves, the nerves on the muſcular fibre, the fibre on the articulated machine, and the machine on the touching part of the finger. And thus the exertion of the ſentient and active being is attributed to the particles of lifeleſs inactive matter at the extremity of the finger, and theſe are ſaid to preſs immediately on the touching parts of the external body. And, laſtly, as this our exertion is unqueſtionably the perceived employment of a faculty in us, which we call *force*, *power*, *ſtrength*, diſtinguiſhing it from every other faculty by theſe names; we ſay (but figuratively), that force or power is exerted at the tips of the fingers, and we call it the FORCE OF PRESSURE.

8 And preſſure is conceived or ſuppoſed in almoſt every production of motion.

By far the greateſt part of our actions on external bodies is with the intention of putting them out of their preſent ſituations; and we can hardly ſeparate the thought of exerted preſſure from the thought of motion produced by it. Therefore, almoſt at its firſt appearance in the mind, preſſure comes before us as a MOVING POWER. Nay, we apprehend, that the more we ſpeculate, and the more we aim at preciſion in our conceptions, we ſhall be the more ready to grant that we have no clear *conception* of any other moving power. No man will contend that he has any conception at all of the power exerted by the mind in moving the body. It is of importance to reflect on the manner in which this notion is extended to all other productions of motion. We think that this will ſhew, that in every caſe we ſuppoſe preſſure to be exerted.

9 Examination of the inſtances of this perception.

The philoſopher proceeds in his ſpeculations, and obſerves that one man can preſs on another, and can puſh him out of his place, in the ſame way as he removes any other body; and he cannot obſerve any difference in his own exertions and ſenſations in the two caſes. But the man who is puſhed has the ſame feelings of touch and preſſure. By withdrawing from the preſſure, he alſo withdraws from the ſenſation; by withſtanding or reſiſting it, he feels the preſſure of the other man; and what he feels is the ſame with what he feels when he preſſes on the other perſon, or on any piece of matter. The ſame ſenſations of touch are excited. He attributes them to the preſſure of the other perſon. Therefore he attributes the ſame ſenſations to the counter preſſure of any other body that excites them. Farther, he can reſiſt to ſuch a degree that he is not puſhed from his place. In this caſe, the greateſt preſſure is exerted, and is felt by both. Each feels that the more he reſiſts, the greater is the mutual preſſure. And each feels that, unleſs he *not only do not reſiſt, but alſo withdraw himſelf* from the preſſure of the other, he will be preſſed, and the other will feel counter preſſure, the ſame in kind with what is produced by his reſiſtance, though leſs in degree.

10 They are generally figurative.

All theſe things are diſtinctly and invariably felt; but they require attention, in order to be ſubjects of recollection and after-conſideration. From this, and no other ſources, are derived all our notions of corporeal preſſure, of counter preſſure, of action, re-action, of *reſiſtance*, and of *inactivity* or *inertia*. Our notions of moving power, of the mobility of matter, and of the neceſſity of this power to produce motion in matter, have the ſame origin. Our notions alſo of the reſiſtance of inanimate matter, indicated by the expenditure of actual preſſure, are formed from the ſame premiſes: the counter-preſſure, or what at leaſt produces the ſame feelings in the perſon who is the mover, is conſidered as the property of dead matter; becauſe we feel, that if *we* do not exert real force, we are diſplaced by the ſame preſſure that would diſplace a lifeleſs body of the ſame bulk.

11 We obſerve many preſſures.

Theſe direct inferences are confirmed as we extend our acquaintance with things around us. We can exert our force in bending a ſpring, and we feel its counter-preſſure, preciſely ſimilar to that of another man. We feel that we muſt continue this preſſure, in order to keep it bent; and that as we withdraw our preſſure, the ſpring follows our hand, ſtill producing ſimilar feelings in our organs of touch, and requiring ſimilar exertions of our ſtrength to keep it in any ſtate of tenſion. Theſe phenomena are interpreted as indications of preſſures actually exerted by the ſpring, and quite different from what we ſhould feel from its mere reſiſtance to being moved. This action reſembles our own exertion in every particular; it produces all the effects of preſſure; it will ſqueeze in the ſoft flexible parts of our body with which we act on it; it will compreſs any ſoft body, juſt as we do ourſelves; it will put bodies in motion. Farther, we can ſet the action of one ſpring in oppoſition to that of another, and obſerve that each is bent by bending the other; and we ſee that their touching parts exert preſſure, for they will compreſs any ſoft body placed between them.

Thus, then, in all thoſe caſes, we have the ſame notion of the power immediately exerted between the two bodies, animated or inanimated. It is always preſſure. If indeed we begin to ſpeculate about the *modus operandi* in any one of theſe inſtances, we find that we muſt ſtop ſhort. How our preſſure excites the feeling of preſſure in the other perſon, or how it produces motion, eludes even conjecture—So it is—Nay, how our intention and volition cauſes our limb to exert this preſſure, or how the ſpringineſs of a ſpring produces ſimilar effects, remains equally hid from our ken. Unwearied ſtudy has greatly advanced our knowledge of theſe ſubjects in one reſpect. It has pointed out to us a train of operations, which go on in our animal frame before the oſtenſible preſſure is produced; we have diſcovered ſomething of their kind, and of the order in which they proceed; we have gone farther, and have diſcovered, in ſome of the preſſures exerted by lifeleſs matter, ſimilar trains of intervening operations. In the caſe of a ſpring, we have diſcovered that there is a certain combination of the properties of all its parts neceſſary for the viſible exertion. But what is the principle which thus makes them co-operate, we cannot tell, any more than in our own exertions of preſſure. Such being the origin of our notions on theſe ſubjects, it is no wonder that all our language is alſo derived from it. Force, power, preſſurre, action, re-action, reſiſtance, impulſion, are, without any exception, words immediately expreſſive of our own exertions, and applied metaphorically to the phenomena of matter and motion.

Laſtly, when we ſee a body in motion diſplace another body by hitting it, and endeavour to form a notion of the way in which this motion is immediately produced, fixing our attention on what paſſes in the very inſtant of the change, we find ourſelves ſtill obliged to ſuppoſe the thing we call preſſure. We can have no other conception of it; and there is no violence in this act of the imagination. For we know, that if we are joſtled from our place, and forcibly driven againſt another perſon, we put that perſon in motion without any intention or action of our own; and we experience, in doing this, that the very ſame feelings of touch and preſſure are excited as in the inſtances of the ſame motions produced by exerted preſſion. We alſo ſee, that when a body ſtrikes another, and puts it in motion, it makes an impreſſion or dimple in it if ſoft, or breaks it if brittle; and, in ſhort, produces every effect of preſſure. A ball of ſoft clay makes a dimple in the ball of ſoft clay which it diſplaces, and is dimpled by it. Springy bodies compreſs each other in their colliſions, and reſile from each other. In ſhort, in every caſe of this claſs, mutual preſſure, indicated by all its ordinary effects, appears to be the intermedium by which the changes of motion are immediately produced; and the previous motion of the ſtriking body ſeems to be only the method of producing this preſſure.

12
Preſſure is the only diſtinct notion of a moving power.

From this copious induction of particulars, and careful attention to the circumſtances of each, we think it plain, that preſſure is the only clear notion that a mind, not familiar with ſcrupulous diſcuſſion, forms of moving power; and therefore that it is very ſingular to think of excluding it from the liſt, and ſaying that impulſion is the only power in nature, and the ſource of all preſſure.

It may perhaps be ſaid, that the mutual immediate action to which the vulgar, and many philoſophers, have erroneouſly given the metaphorical name preſſure, is indeed the real cauſe of motion, or change of motion; but ſtill it is now properly called impulſion, becauſe it is occaſioned only by the previous motion of the impelling body. We conceive clearly (they may ſay) how this previous motion produces the impulſion. Since matter is impenetrable, we ſee clearly that a ſolid body, or a ſolid particle, cannot proceed without diſplacing the bodies with which it comes into contact; we have notions of this as clear as thoſe of geometry; whereas, how preſſure is produced, is inconceivable by us. If we preſs a ball ever ſo ſtrongly againſt another, and remove the obſtacle which prevented its motion, it will not move an inch, unleſs we *continue* to follow it, and preſs it forward; but we ſee a moving body produce compreſſion, bend ſprings, make pits in ſoft bodies, and produce all the effects of real animal preſſure. Impulſe, therefore, is the true cauſe of motion, and the ſolicitation of gravity is nothing but the repeated impulſe of an inviſible fluid.

But, in the firſt place, let it be obſerved, that both parties profeſs to *explain* the phenomena of mechanical nature, that is, to make them eaſier conceived by the mind. Now it may be granted, that could we have any previous conviction of a fluid continually flowing toward the centre of the earth, we could have ſome notion of the production of a downward motion of bodies, but not more explanation than we have without it, becauſe impulſiveneſs is as little underſtood by us as preſſure.

13
Many preſſures are inexplicable by impulſion.

But there are thouſands of inſtances of moving forces where we cannot conceive how they can be produced by the impulſe of a body already in motion. There appear to be many moving powers in nature, independent of, and inexplicable by, any previous motion; theſe may be brought into action, or occaſions may be afforded for their action, in a variety of ways. The mere will of an animal brings ſome of them into action in the internal procedure of muſcular motion; mere vicinity brings into action powers which are almoſt irreſiſtible, and which produce moſt violent motions. Thus a little aquafortis poured on powdered chalk contained in a bombſhell, will burſt it, throwing the fragments to a great diſtance. A ſpark of fire brings them into action in a maſs of gunpowder, or other combuſtibles. And here it deſerves remark, that the greater the maſs is to which the ſpark is applied, the more violent is the motion produced. It would be juſt the contrary, if the motion were produced by impulſe. For in all caſes of impulſion, the velocity is inverſely proportional to the matter that is moved. When a ſpring is bent, and the two ends are kept together by a thread, a preſſure is excited, which continues to act as long as the thread remains entire. What contrivance of impelling fluid will *explain* this, or give us any conception of the total ceſſation of this preſſure, when the thread is broken, and the ſpring regains its quieſcent form?

14
All preſſures do not produce a ſenſible motion.

We can explain, in a moſt intelligible manner, why the hardeſt preſſure produces no ſenſible motion in the caſe referred to above. We can conceive, with ſufficient diſtinctneſs, a tube filled with ſteel wires, coiled up like cork ſcrews, and compreſſed together into $\frac{1}{10}$th of their natural length. A tube of 10 inches long will contain 100 of them. While in this ſtate, compreſſed by a plug, we can ſuppoſe each of the ſprings to be tied with a thread. Suppoſe now that the thread of the ſpring next the piſton is burnt or cut; it will preſs on the piſton, and force it out, accelerating its motion till it has advanced one inch; after this, the piſton will proceed with a uniform motion. It is plain that the velocity will be moderate, perhaps hardly ſenſible, becauſe the preſſure acted on it during a very ſhort time. But if two ſprings have been ſet at liberty at the ſame inſtant, the preſſure on the piſton will be continued through a ſpace of two inches, and the final velocity will be greater, becauſe the ſame (not a double) preſſure will be exerted through a double ſpace. Unbending four ſprings at once, will give the piſton a double velocity (See Dynamics, *Suppl.* n° 95.) Now the effect of the motion of the ſecond ſpring is to keep the preſſure of the firſt

firſt in action during a longer time, by following it, and keeping it in a ſtate of compreſſion. There is nothing ſuppoſed of this kind in the caſe of ſtrong preſſure alluded to; and therefore no motion is produced when the obſtacle is removed, except what the inſenſible compreſſion produces by accelerating the body along an inſenſible ſpace. If all the 100 ſprings are diſengaged at once, the piſton will be accelerated through 100 inches, and will acquire ten times the velocity that one ſpring can communicate. (*N. B.* The force expended in moving the ſprings themſelves is not conſidered here).

It is in this way only that the previous motion of the impelling body acts in producing a conſiderable motion. The whole proceſs will be minutely conſidered by and bye.

15
Impulſion is no more clearly conceived than preſſure.

We may now aſk, how it is ſo clear a point, that a ſolid body in motion muſt diſplace other bodies? This ſeems to be the very point in queſtion, Is the affirmative deduced from our notion of ſolidity? What is our notion of ſolidity, and whence is it derived? We apprehend that even this primary notion is derived from preſſure. It is by handling a thing, and finding that we cannot put our hand into the place where it is without diſplacing it, that we know that it is material. All this is indicated to us by the feeling excited by our preſſure. We feel this property always as an obſtacle; and therefore ſay, that by this property it reſiſts our preſſure. Nay, there are caſes where even the philoſopher prefers this quality to impulſiveneſs as a teſt of matter. To convince another that the jar out of which he has poured the water that filled it is not empty, but full of matter, he dips the mouth of the jar into water, and ſhows, that although he preſs it down till the ſurrounding water is above the bottom of it, the water has hardly gotten half an inch into the jar; there is ſomething there which keeps it out; there is matter in it. He then opens a hole in the bottom of the jar; the water immediately riſes on the inſide of the jar, and fills it. He ſays that the preſſure of the water has driven the matter out by the hole; and he *confirms* the materiality of what is expelled by holding a feather above the hole. It is agitated, ſhewing that the expelled thing has impulſiveneſs, another property (he ſays) of matter: what filled the jar was air, and air in motion is wind. The philoſopher can exhibit ſome new caſes, where ſomething like impulſiveneſs appears. A ſlender magnet may be ſet on one end, the ſouth pole, for inſtance, and will ſtand in that tottering ſituation. If a perſon bring the north pole of a powerful magnet haſtily near the upper end, it will be thrown down, juſt as it may be blown down by a puff of wind; therefore (ſays the philoſopher) there may be appearances of impulſion, and I may imagine that there is impelling matter; but nothing but matter excludes all other matter from its place: this property, therefore, is the ſureſt teſt of its preſence.

Thus we ſee, that our notion of ſolidity or impenetrability (a name ſtill indicating an obſtacle to preſſure), gives us no clearer conception of the productions of motion by impulſion than preſſure does; for it is the ſame, or indicated by the ſame ſenſations.

16
Motion does not impel by transfuſing inherent force or inherent motion.

The queſtion now ſeems to be reduced to this—Since the ſtrongeſt preſſure of a quieſcent body does not produce motion, or excite that kind of preſſure which is the immediate cauſe of motion, while a body in motion, exciting but a very moderate preſſure (as may be ſeen by the trifling *compreſſion* or dimpling), produces a very conſiderable motion, how is the previous motion conducive to this purpoſe? The anſwer uſually given is this: A body in motion (by whatever cauſe) perſeveres in that motion by the *inherent force;* when it arrives at another body, it cannot proceed without diſplacing that body. The nature of the inherent force is ſuch, that none of it is loſt, and that a portion of it paſſes into the other body, and the two bodies inſtantly proceed with the ſame quantity of motion that was in the impelling body alone. This is an exact enough narrative of the general fact, but it gives no great *explanation* of it. If the impelling body perſeveres in its motion by means of its inherent force, that force is exerted in performing its office, and can do no more. The impelled body ſeems as much to poſſeſs an inherent force; for the ſame marks and evidences of preſſure on both ſides are obſerved in the colliſion. If both bodies are ſoft or compreſſible, both are dimpled or compreſſed. We are as much entitled, therefore, to ſay, that part of the force by which it perſeveres at reſt, paſſes into the other body. But the reſt, or quieſcence of a body, is always the ſame; yet what paſſes into the impelling body is different, according to its previous velocity. We can form no conception how the half of the inherent force of the impelling body is expended by every particle, paſſes through the points of contact, and is diſtributed among the particles of the impelled body; nay, we cannot conceive this halving, or any other partition of the force. Is it a thing *ſui generis*, made up of its parts, which can be detached from each other, as the particles of ſalt may be, and really are, when a quantity of freſh water is put into contact with a quantity of brine? We have no clear conception of this; and therefore this is no elucidation of the matter, although it may be an exact ſtatement of the viſible fact.

17
This involves abſurdities.

Let us take the ſimpleſt poſſible caſe, and ſuppoſe only two particles of matter, one of which is at reſt, and the other moves up to it at the rate of two feet per ſecond. The event is ſuppoſed to be as follows: in the inſtant of contact, the two particles proceed with half of the former velocity. Now this inſtant of time, and this preciſe point of ſpace, in which the contact is made, is not a part of either the time or ſpace before colliſion, or of thoſe after-colliſion; it is the boundary between both; it is the laſt inſtant of the former time, and the firſt inſtant of the latter time; it belongs to both, and may be ſaid to be in both. What is the ſtate or condition of the impelling particle in this inſtant? In virtue of the previous motion, it has the determination, or the force, or the power, to move at the rate of two feet per ſecond; but, in virtue of the motion after colliſion, it has the determination or power of moving at the rate of one foot per ſecond. In one and the ſame inſtant, therefore, it has two determinations, or only one of them, or neither of them. And it may, in like manner, be ſaid of the impelled body, that, in that inſtant, it was both at reſt, and moving at the rate of one foot per ſecond. This ſeems inconceivable or abſurd.

18
Impulſiveneſs is not an intuitive property of matter.

It is not perhaps very clear and demonſtrable, nor is it intuitively certain, that the moving body or particle muſt diſplace the other at all. All that we know is, that matter is moveable, and that cauſes of this motion exiſt in nature. When they have produced this motion, they have performed their taſk, and the motion is their complete effect: the particle continues in this condition for ever, unleſs it be changed by ſome cauſe; but we do not ſee any thing in this condition that enables us to ſay what cauſes are competent to this change, and what are not. Is it either intuitive or demonſtrable, that the *mere exiſtence* of another particle is not a ſufficient or adequate cauſe? Is it certain that the arrival at another particle is an adequate cauſe? or can we prove that this will not ſtop it altogether? The only concluſion that we can draw with any confidence is, that "two particles, or two equal bodies, meeting with equal velocities, in oppoſite directions, will ſtop." But our only reaſon for this concluſion is, that we cannot aſſign an adequate reaſon why either ſhould prevail. But this form of argument never carries luminous conviction, nor does it even give a deciſion at all, unleſs a number of caſes can be ſpecified which include *every poſſible reſult*. This can hardly be affirmed in the preſent caſe.

19
But an obſerved fact.

We apprehend that the next caſe, in point of ſimplicity, has ſtill leſs intuitive or deductive evidence; namely, when bodies meet in oppoſite directions with equal quantities of motion. It is by no means eaſy, if it be at all poſſible, to ſhew that they muſt ſtop. The proof proceeds on ſome notion of the manner in which the impulſion, exerted on one particle, or on a few of each body, namely, thoſe which come into contact, is diſtributed among all the particles. A material atom is moved only when a moving force acts on it, and each atom gets a motion preciſely commenſurate to the force which actuates it. Now, it is ſo far from being clear, how a force impreſſed on one particle of a ſolid body occaſions an equal portion of itſelf to paſs into every particle of that body, and impel it forward in the ſame direction, that the very authors who aſſume the preſent propoſition as an elementary truth, claim no ſmall honour for having determined with preciſion the moving forces that are exerted on each particle, and the circumſtances that are neceſſary for producing an equal progreſſive motion in each. It was by no means an eaſy problem to ſhew, that the motion of the body (eſtimated by an average taken of the motions of every particle) is preciſely that which is announced by this propoſition. We muſt alſo conſider how this inveſtigation is conducted. It is by aſſuming, that whatever force connects a particle a with a particle b, or whatever force a exerts on b, the particle b exerts an equal force on a in the oppoſite direction—Surely no logician will ſay that this is an intuitive truth. The contrary is moſt diſtinctly conceivable. It was a *diſcovery* of the aſtronomers, that every deflection toward the ſun is accompanied by an equal deflection of the ſun. It was a *diſcovery*, that a piece of iron attracts a loadſtone; and it was a *diſcovery* (and we dare not yet affirm it to be without exception), that every action of bodies is accompanied by an equal and contrary re-action. But this is by no means a firſt principle. It is the expreſſion of a moſt generally obſerved fact, a ſum total of knowledge. When received on this authority, it is fully competent to ſolve every caſe of impulſion, independent of all obſcure and illogical doctrines of force inherent in moving bodies, of force of inertia, of communication of motion, &c.

The impoſſibility of conceiving the detachment of part of the *force* inherent in A, and transferring *this* part into B, and the ſimilar impoſſibility of conceiving the imparting to B ſome of the *motion* that was in A, ſhould make us reject any propoſition involving ſuch conceptions, and refuſe its admiſſion as an elementary truth. Much more ſhould we reject a propoſition that obliges us to ſuppoſe that a particle of matter has two determinations, forces, motions, or call them by any other name, in one and the ſame inſtant. One of theſe neceſſarily excludes the other. Indeed this was ſo evident, even to the moſt eminent partizans of the doctrine of the transfuſion of inherent force, and others conſequent on it, that they found themſelves obliged to deny that there was ſuch a thing in the world as a perfectly hard body, in which the motion muſt be inſtantaneouſly changed into another, differing from it by any ſenſible quantity. The exiſtence of perfectly hard bodies is poſitively denied by the celebrated mathematician of Baſle, John Bernoulli, in his Diſſertation on the Communication of Motion, which contended for the prize given by the Academy of Sciences at Paris 1710. His reaſon for this rejection is ſingular, and ſomewhat amuſing. "In the colliſion of perfectly hard bodies, the *conſervatio virium vivarum*, demonſtrated by the moſt eminent mathematician (Mr Leibnitz), to be a law of nature, would be broken without any effect being produced. He does not obſerve, that it is as completely broken by elaſtic bodies in the inſtant of greateſt compreſſion. A Britiſh philoſopher, *nullius addictus jurare in verba magiſtri*, aſked, What will be the caſe of two encountering atoms of matter? Without calling them hard, we muſt conceive that they acquire their changes of motion in the inſtant of mutual contact, and that they acquire them *totally*, being ατομοι, indiviſible. No anſwer has been given, or indeed can be given, but what implies the ſame difficulty. From all that has been ſaid, we muſt conclude, that this branch of mechanical philoſophy is not put, by thoſe philoſophers, into the condition of an elementary foundation of clear and demonſtrative ſcience; that the transfuſion, or transference, either of force or motion, is not a thing of which we have a diſtinct conception; and that it neceſſarily leads us into very untenable doctrines. Far leſs does it ſeem ſafe for us to confide ſo much in its clearneſs and certainty, as to affirm, that impulſion is the ſole moving force in mechanical nature, and the ſource of what we call preſſure.

All this difficulty and obſcurity has ariſen from our arrogant notion, that we are competent judges of firſt *principles*; whereas we muſt acknowledge, that we can only perceive ſuch as are properly related or accommodated to our intellectual powers: theſe powers, being ſpecific and peculiar, cannot judge of principles of the firſt claſs, but of thoſe only that are *ſuitably* compounded. We can never know or comprehend any eſſential property of matter—we can only know the *relative* properties of *ſuch matter as we ſee*.

20
Therefore to be learned only by obſerving nature.

Therefore let us quit entirely the barren and trackleſs fields of abſtraction, and reſt ſatisfied with contemplating *what* the Author of Nature has exhibited to our view, and *ſuch* as he has been pleaſed in his wiſdom to exhibit it. We grant that there are no bodies open to our inſpection which are perfectly hard, receiving finite changes of motion in an inſtant. It has not pleaſed God

God to put any ſuch within our reach. When God created matter, it was with the purpoſe of forming a beautiful univerſe of this matter. He therefore gave it properties which fitted it for this purpoſe. It is this matter only that he has expoſed to the wondering view of man. Thanks to his bounty, he has alſo given us properties of mind, by which this adaptation, when perceived by us, becomes a ſource of dignified pleaſure to the obſerver.—A Newton, to whom "*Jovis omnia plena*," a Daniel Bernoulli, were rapt almoſt into ecſtacy by a ſingle atom, when they obſerved how its properties, and only ſuch properties, fitted it for making part of a world, which

> Unwearied, and from day to day,
> Should its CREATOR's power diſplay.

Let the unhappy La Place conſider theſe properties, which enſure the permanency of the ſolar ſyſtem through ages of ages, as proofs of fataliſm, as qualities eſſential to matter. But this Gallic torch effaces the bloom of life from the univerſe, the expreſſion of the Supreme Mind which ſhines from within; and it ſpreads over the countenance of Nature the ghaſtly paleneſs of univerſal death. But let us Britons rather follow the example of our illuſtrious countryman, and ſolace ourſelves with every diſcovery which tends to quicken our perception of Nature's *animated* charms. Let us liſten to the conjectures of him who had already diſcovered ſo many, and who endeavoured to remove the veil which concealed the reſt.

21 Moving powers are inherent in all matter. Newton's conjecture improved by Boſcovich.

Newton, in his maturity of judgment, after having collected much information from his unwearied experiments in magnetiſm, in chemiſtry, in optics, &c. ſaid, that "he ſtrongly ſuſpected, that, in the ſame manner as the bodies of the ſolar ſyſtem were connected by gravitation, ſo the particles of ſublunary bodies were connected together, and affected each other, by means of forces which acted at ſmall, and, in many caſes, inſenſible diſtances; producing the phenomena of coheſion, in all its forms of hardneſs, elaſticity, ductility, ſoftneſs, fluidity, by which their mechanical actions on each other were modified and regulated." Father Boſcovich, one of the firſt mathematicians of Europe, was the firſt who gave this conjecture of Newton's the attention that it ſo highly deſerved. Other writers indeed, ſuch as Keill, Freind, Boerhaave, &c. took occaſional notice of it, and even made ſome uſe of it in their attempts to explain ſome complicated phenomena of nature. But they were ſo careleſs in their employment of Newton's conjecture, ſo completely neglected his cautious manner of proceeding, indulged ſo wantonly in hypothetical aſſumptions, and reaſoned ſo falſely from them, that they brought his conjecture into diſcredit. Boſcovich, on the contrary, copied Newton with care, and ſecured his progreſs as he advanced by the aid of geometry; eſtabliſhing a ſet of uncontrovertible propoſitions, which muſt be the inevitable reſults of the premiſes adopted by him. He then proceeded to compare theſe with the phenomena of nature; and he ſhews that the coincidence is as complete as can be deſired. All this is done in his *Theoria Philoſophiæ Naturalis*, firſt publiſhed at Vienna in 1759. We have given a very ſhort account of it in the article BOSCOVICH, *Suppl.*; but it hardly goes beyond the enunciation of the general principles, and the indication of its applicability to the purpoſes intended. His application to the production of motion by the colliſion of bodies, is peculiarly ſatisfactory. But as the work is written chiefly with the view of gaining the approbation of perſons well inſtructed in natural philoſophy, it can hardly be called an elementary work, or be employed for the inſtruction of perſons entering on the ſtudy. We ſhall attempt to explain this important law of mechaniſm in a way that will give our readers a diſtinct notion (and, we apprehend, a juſt one) of the procedure of Nature in all the caſes of impulſion *that we can obſerve*. We hope to do this, by conſidering the changes of motion produced by moving bodies in a certain ſeries of familiar caſes, where the procedure of nature may be diſtinctly obſerved, and where it is uniformly conceived by every ſpectator; and which will gradually lead the mind to thoſe caſes where the procedure is not obſerved with diſtinctneſs; but the ſimilarity to the former caſe is concluded by ſo fair analogy, that we imagine no perſon will controvert it. We ſhall begin by attending to the manner in which two magnets in motion affect each other's motions; a phenomenon that is familiarly known in the general, although, perhaps, few perſons have attended to it minutely.

Plate xxix.

22 Examination of the mutual action of magnets.

Let us, therefore, ſuppoſe two magnets, A and B (fig. 1.) equal in weight (in the firſt inſtance). Let them be made to float on water, by placing them on pieces of cork. Let them be placed with their north poles touching each other. Let A be held faſt, and let B be at liberty to move. We know that it will gradually recede from A, with a motion that would continually accelerate, were it not for the reſiſtance of the water. What is the inference drawn from this appearance? Surely this, that either a moving power, inherent in A, repels B, or that B avoids A, by an evaſive power inherent in itſelf. It is immaterial for our purpoſe which opinion we adopt. Let us ſay that A repels B. This admits more conciſe language than the other If we prevent this motion of B by means of a very ſlender ſpring applied to its remote end, we ſhall obſerve that the ſpring is bent back a little, juſt as if we were puſhing away the magnet gently with the finger; and we obſerve, that the bending of the ſpring is ſo much the greater as B is nearer to A. We can judge of the intenſity of the force by which B is actuated, by the bending of the ſpring.—This force is equal to the *weight* of any body that will bend the ſpring to the ſame degree. This force is analogous, therefore, to the weight, the preſſure of gravity, and we may call it a preſſure, and meaſure it by grains weight. Every force that can bend a ſpring will move a body. This is a well known fact. Therefore it is next to certain, that it is this force which cauſes B to recede from A; nay, if we compare the motion of B with what *ſhould* reſult from the action of a force having this very intenſity, and varying in the ſame manner by a change of diſtance from A, taking in the diminution which the reſiſtance of the water muſt occaſion, we ſhall find the motions preciſely the ſame. All this can be diſcovered by DYNAMICS, n° 95, &c. Therefore we muſt conclude that this, and no other, is the cauſe of the receſs of B.

If, inſtead of placing B in contact with A, we place it at a diſtance from it, and puſh it toward A with an initial velocity, ſomewhat leſs than it would have acquired

quired in that place by its receſs from A, we ſhall find that it will approach A with a motion gradually retarded, till it ſtop at a ſmall diſtance from A; and will now recede from it again with an accelerated motion. In ſhort, we ſhall find that its whole motion to and from A is preciſely the ſame with what reſults from a ſimilar computation by n° 95 of DYNAMICS.

The whole of this phenomenon is conceived by every beholder, who has not imbibed ſome peculiar theory of a ſtream of impelling fluid, as the indication and effect of a repulſive force exerted by A on B, or of a quality of B, by which it recedes from A.

If now B be held faſt, and A be ſet at liberty, it is obſerved to be repelled by B, or to recede from B, in the ſame manner, and with the ſame force.

Thus, the two magnets appear to affect each other's motions, and are thought, and ſaid, by all to repel each other. The effect appears curious, but excites no farther thought in moſt minds: it is only the ſpeculatiſt that begins to ſuſpect that he has not conceived it properly.

Now, let us ſuppoſe that B is afloat on the ſurface of the water, and at reſt; and that A is puſhed towards it, by a ſingle ſtroke, cauſing it to move ſo moderately that it ſhall not ſtrike B, but have its motion deſtroyed by the repulſion before it reaches it; and let us farther ſuppoſe, that the initial velocity of A was exactly meaſured—the fact will be as follows. As ſoon as A comes within a certain diſtance of B, its motion begins to be affected; it gradually diminiſhes, and at length it ceaſes entirely, and A remains ever after perfectly ſtill. But it is alſo obſerved, that in the inſtant that A ſlackens its motion, B begins to move; that it gradually accelerates in its motion, and at laſt acquires the initial velocity of A, with which it proceeds, till the reſiſtance of the water brings it to reſt; perhaps at a conſiderable diſtance from A. This experiment is very amuſing, and the initial velocity of A may be increaſed in each ſucceeding trial, till at laſt it ſtrikes B. Even then the general appearance remains the ſame: A is brought to reſt and remains at reſt, neither reſiling nor advancing forward; and B moves off with the initial velocity of A. What we wiſh to be particularly noticed is, that as long as the initial velocity of A is leſs than a certain quantity (depending on the ſtrength of the magnets), the motion is communicated to B, or, to expreſs it more cautiouſly, motion is produced in B, without any thing happening that can get the name of impulſion with propriety. In the ordinary conceptions and language of mankind, impulſe always ſuppoſes actual contact; and impulſion is equivalent to a blow or a ſtroke. Both of theſe are indeed metaphorical terms, as well as impulſion. Perhaps the word "to hit," expreſſes this particular caſe more purely, and it is perhaps without any figure, and is the appropriate word. We do not ſpeak at preſent of the conception and language of philoſophers, but of perſons taking an unconcerned view of things, without any intention of ſpeculating farther about the matter.

Appearances perfectly ſimilar are obſerved in electrified bodies. If we hang two equal bunches of very light downy feathers by two equal linen threads, ſo as to hang cloſe by each other like pendulums without touching, and if, after having electrified them ſo that they repel each other to ſome diſtance, we draw one of them, which we ſhall call A, conſiderably aſide from the perpendicular, and then let it go to ſwing like a pendulum; we ſhall obſerve, that inſtead of accelerating till it reach the loweſt point of its vibration, its motion will be retarded; it will ſtop entirely when its thread is perpendicular, and will remain at reſt. In the mean time, the other bunch B will acquire motion, which will gradually increaſe till it equal the motion of A in its maximum ſtate; and with this it would proceed for ever, were it not riſing like a pendulum in the arch of a circle. The general fact is the ſame as in the caſe of the magnets. The moving body is brought to reſt, in which ſtate it continues, and the quieſcent body moves off with an ultimate velocity, equal to the initial velocity of the other; and all this happens without contact or impulſion, but is produced by the mutual repulſion of the electrified bodies.

If this general fact be compared with what happens in the colliſion of two billiard balls, it will be found perfectly ſimilar in every reſpect, but that of the contact and the impulſion, properly ſo called. The impelling ball is brought to reſt, and remains at reſt; and the impelled ball moves off with the velocity of the impelling ball.

This being the caſe, it is plain that we may derive ſome information from the motion of the magnets, that muſt greatly aſſiſt us in our conceptions of what paſſes in the rapid, if not inſtantaneous, production of motion in a billiard ball, by hitting it with another. In the caſe of the magnets, we perceive, and can diſcriminate, a progreſſive train of changes, which terminate in a final change, perfectly ſimilar to the change in the impulſion of the billiard ball. This will juſtify a very minute attention to, and ſtatement of, all the circumſtances.

23
Firſt caſe.
A moving toward B at reſt.

Let us attend to the proceſs of this operation, and the production of motion in the magnet originally at reſt, and the abolition of it in the one originally in motion; and let us reflect on what paſſes in our minds when we try to explain it to ourſelves. The trials mentioned at firſt, when one magnet was held faſt, ſhew us that each magnet repels or avoids the other, and that this action is found to be equal on both ſides, producing equal compreſſion of the ſpring employed for aſcertaining the intenſity of this repulſion when the diſtances are the ſame. This is the fact. It is no leſs a fact, that equal moving forces, ſuch as equal preſſures muſt be ſuppoſed to be, produce equal changes of motion in their own direction. Therefore, as ſoon as A comes to ſuch a diſtance from B that the mutual action takes place, both magnets are affected, and equally affected; that is, equal changes of motion are produced on each, but in oppoſite directions. The motion of A is diminiſhed, perhaps $\frac{1}{100}$th part in $\frac{1}{10}$th of a ſecond, and (let it be carefully remembered) while A paſſes over a certain ſpace, ſuppoſe the 10th of an inch. During this ſmall portion of time, B acquires as much motion as A loſes. This is not the motion loſt by A. This is inconceivable; for motion is not a thing, but a condition. But it is an *equal degree* of motion. B has paſſed over a ſmall ſpace during this time, perhaps the 50th part of an inch, with an almoſt imperceptible motion,

motion, that is gradually accelerated from nothing. Since A is moving faſter than B, it muſt ſtill gain upon it; and therefore the mutual repulſion will increaſe; and in the next 10th of a ſecond this force will take another and greater portion of A's original velocity from it, and will add a greater velocity to that already acquired by B. And thus, in every ſucceeding minute portion of time, the motion of A will be more and more diminiſhed, and that of B as much increaſed, by the equal, though continually increaſing, ſimultaneous repulſions acting in oppoſite directions. It is evident, that it is poſſible that the velocity of A may be ſo much diminiſhed, and that of B ſo much increaſed, that the remaining velocity of A ſhall be juſt equal to the acquired velocity of B. Till this happens, the diſtances of the magnets have been continually diminiſhing; for A has been moving faſter than B, and gaining on it. If the operation of the mutual repulſions could be ſtopped at this inſtant, both magnets would move forward for ever with equal velocities.

24 They acquire a common velocity x;

It is of particular importance to know what this common velocity is. This is determined by our previous knowledge, that the magnets repel or avoid each other with equal forces. Theſe forces may vary by a variation of diſtance; but the force acting on A is always equal and oppoſite to the force acting at the ſame time on B. This is the uncontroverted fact (the authority for which ſhall ſoon be conſidered). Theſe equal forces muſt therefore produce equal and oppoſite changes of motion. The motion acquired by B is equal to that loſt by A. But the magnets being ſuppoſed equal, and moving with equal velocities, they have equal quantities of motion. Therefore the motion acquired by B, or that loſt by A, is equal to what remains in A; that is, A has loſt half of its motion, and therefore half of its velocity; or the common velocity is half of the primitive velocity of A.

It was for the ſake of a ſomewhat eaſier diſcuſſion that we ſuppoſed the magnets to be of equal weights. But it is almoſt equally eaſy to aſcertain what this common velocity will be in any other proportion of the quantities of matter in A and B. It is a matter of unexcepted experience, that whatever be the weight or ſtrength of two magnets, their actions on each other are always equal. Therefore the ſimultaneous force muſt always produce equal changes of motion in the two bodies. But the change of motion is expreſſed by the product of the quantity of matter and the change of velocity. Therefore let A and B repreſent the quantities of matter in the magnets; and let a be the primitive velocity of A, and x the velocity which obtains when both are moving with one velocity. The velocity loſt by A is $a - x$. Therefore we muſt have $B x = A \times \overline{a - x}$, $= A a - A x$; and $A a = A x + B x$, $= \overline{A + B} \times x$, and $x = \frac{A a}{A + B}$. *The common velocity is therefore obtained by dividing the primitive quantity of motion by the ſum of the quantities of matter.*

25 Namely, $x = \frac{A \times a}{A + B}$

This may be conceived more compendiouſly in another way. Since B acquires as much motion as A loſes, the whole quantity of motion is the ſame as before: Therefore the common velocity muſt be had by dividing this quantity of motion by the whole quantity of matter. But we wiſhed to make the reader keep his attention fixed on the ſteps of procedure, and ſee the connection of each with the cauſes.

We ſhall find that this period of the whole proceſs, namely, the moment when both bodies have acquired a common velocity, and the preciſe magnitude of this velocity, are points of peculiar importance in the doctrine of impulſion; indeed they almoſt comprehend the whole of it.

26 But this does not continue, and the magnets ſeparate.

But this is a ſtate that cannot continue for a moment in the example before us. The repulſive or evaſive forces are ſtill acting on both magnets, and ſtill diminiſh the motion of A, and equally increaſe the motion of B. Therefore the velocity of A, in the very next moment, muſt be leſs than that of B; and B has, during this moment, gained on A, or has removed farther from it. This continues; A is ſtill retarded, and B is accelerated; and therefore gains more and more upon A, or ſeparates farther and farther from it. This muſt continue as long as the mutual repulſions are ſuppoſed to act. If we ſuppoſe that the *ſenſible* action of theſe forces is limited to ſome determinate diſtance, the mutual action will ceaſe when B has got to that diſtance before A. We may call it *the inactive diſtance*. After this, A and B will proceed with the velocities which they have at that inſtant. Let us inquire into theſe final velocities; and thus complete our acquaintance with the proceſs.

27 The common velocity is attained at the inſtant of neareſt approach.

We ſee (and it is important) that the magnets are in their ſtate of greateſt proximity at the inſtant of their moving with a common velocity, and that after this they gradually ſeparate, till they are again at their inactive diſtance. During this ſeparation they attain diſtances from each other equal to what they had during the period of their mutual approach. At theſe diſtances the repulſions are the ſame as before, and act in the ſame direction. Therefore, in each moment of ſeparation, and at each diſtance, A ſuſtains the ſame diminution, and B gets the ſame augmentation of its motion, as when they were at the ſame diſtance in the period of their mutual approach. The ſums total, therefore, of theſe equal augmentations and diminutions muſt be equal to the augmentation and diminution during the approach. Therefore the whole diminution of A's motion muſt be double of the diminution ſuſtained during the approach; and the whole augmentation of B's motion muſt, in like manner, be double of that acquired during the approach of A. Hence we eaſily ſee, that when the magnets are ſuppoſed equal, A muſt be brought to reſt; for in the period of approach it had loſt half of its velocity. It muſt now have loſt the whole. For ſimilar reaſons B muſt finally acquire the primitive velocity of A; for in the inſtant of greateſt proximity, it had acquired the half of it.

28 Repulſion is a cauſe adequate to the obſerved effect.

Thus we ſee that the equal mutual repulſions are preciſely adequate to the production of the changes of motion that are really obſerved; and muſt therefore be admitted as the immediate cauſes of theſe changes.

29 Effect when the magnets are unequal.

It is equally eaſy to aſcertain the final velocities when the magnets are of unequal ſizes; for the equality of their mutual repulſions is not affected by any inequality of their magnitudes. Their ſeparations, and the changes of motion during theſe ſeparations, will be the ſame with their approaches and the correſponding changes of motion; and the whole change on each will be double of the change ſuſtained at the inſtant of greateſt

greateſt proximity and common velocity. Hence we learn that the final velocity of B is $2x$, or $\frac{2Aa}{A+B}$; and the final velocity of A is $\frac{\overline{A-B}\times a}{A+B}$ For the primitive velocity of A being a, and the common velocity, in the inſtant of neareſt approach being $\frac{Aa}{A+B}$, the loſs of velocity is $a-\frac{Aa}{A+B}$, $=\frac{Aa+Ba-Aa}{A+B}$ $=\frac{Ba}{A+B}$. Therefore the final loſs of velocity is $\frac{2Ba}{A+B}$, and the remaining final velocity is $a-\frac{2Ba}{A+B}$, $=$ $\frac{Aa+Ba-2Ba}{A+B}$, $=\frac{\overline{A-B}\times a}{A+B}$.

30 II. Caſe. Both magnets in motion in one direction.

Let us, in the next place, ſee what will be the reſult when both of the magnets are in motion at the beginning of their mutual action. And, firſt, let both move in one direction. Let A, moving with the velocity a, overtake B, moving in the ſame direction with the velocity b, leſs than a. Moreover, let the velocities a and b be ſuch, that their differences $a-b$ is ſomewhat leſs than the ſum of the velocities α and β, which the mutual repulſions of the magnets would generate in them, if the magnets were placed in contact, and allowed to recede from each other till they get beyond their acting diſtance.

Theſe things being premiſed, let the magnets be ſet in motion in the ſame direction with the above-mentioned velocities a and b. The magnet A muſt gain on B, and at laſt come ſo near it, that the mutual repulſions begin to act on both. It is plain, that the motion of A will be diminiſhed, and that of B increaſed, by equal quantities, during every minute portion of the time of their mutual action. It is alſo evident, that the velocity of A may be ſo much diminiſhed, and that of B ſo much increaſed, that they ſhall be rendered equal. Alſo this will happen before the magnets touch one another; becauſe the original difference of their quantities of motion has been ſuppoſed leſs than the motion which the repulſive forces are able to generate or extinguiſh, by acting on them through the whole diſtance which gives occaſion to their action. Therefore the difference of the velocities is leſs than the ſum of the velocity α, which the mutual repulſion can take from A, and the velocity β, which it can give at the ſame time to B. The magnets will gradually approach, and the mutual repulſions, and conſequent diminution of A's, and augmentation of B's motion, will gradually increaſe, till the ſum of α and β is juſt equal to the difference of a and b; that is, till the bodies are moving with one velocity. If the mutual repulſions were annihilated at this inſtant, the bodies would move forward with this common velocity. What this is we determine with great facility, as we did in the former caſe: Becauſe the repulſions produce equal and oppoſite changes of motion in the magnets, as much is taken from $A\times a$ as is added to $B\times b$; and the ſum of $A\times a$, and $B\times b$, is equal to the ſum of $A\times x$ and $B\times x$, or $\overline{A+B}\times x=A\times a+B\times b$, and $x=\frac{Aa+Bb}{A+B}$. Therefore *the common velocity is had by dividing the ſum of the primitive quantities of motion by the ſum of the quantities of matter.*

31 Common velocity $=\frac{Aa+Bb}{A+B}$ but the magnets ſeparate, and the change is doubled in each.

But the repulſive forces continue to act as in the former caſe. The motion of A is ſtill more diminiſhed, and that of B augmented: Therefore the velocity of B muſt now exceed the velocity of A, and the magnets muſt ſeparate. Reaſoning in the ſame way as in the former caſe, it is evident that the mutual action does not ceaſe till the magnets have ſeparated to their inactive diſtance from each other, and that the whole change of motion in each is double of the change that it had ſuſtained when they were in their greateſt proximity, and moving with a common velocity. Theſe conſiderations enable us to aſcertain the final ſtate of each. The common velocity is $\frac{Aa+Ab}{A+B}$. Therefore the change made on the velocity of A, at the inſtant of greateſt proximity, is $a-\frac{Aa+Bb}{A+B}$, or $=$ $-\frac{B\times\overline{a-b}}{A+B}$, and the final velocity of A is $a-$ $\frac{2B\times\overline{a-b}}{A+B}$. In like manner, the change produced on the velocity of B is $=\frac{Aa+Bb}{A+B}-b$, or $=+$ $\frac{A\times\overline{a-b}}{A+B}$, and the final velocity of B is $b+$ $\frac{2A\times\overline{a-}}{A+B}$. We may alſo obtain the final velocity of each, by taking its initial velocity from twice the common velocity.

If, in this example of two magnets in motion, we ſuppoſe them of equal weight, we ſhall find that they will finally proceed with exchanged velocities. For when $A=B$, it is plain that $a-\frac{2B\times\overline{a-b}}{A+B}$ is $=$ $a-1\times\overline{a-b}$, $=a-a+b$, $=b$: and $b+$ $\frac{2A\times\overline{a-b}}{A+B}$ is $=b+1\times\overline{a-b}$, $=b+a-b$, $=a$. This caſe is eaſily ſubjected to experiment, and will be found fully confirmed, if we take into account the retardations occaſioned by the reſiſtance of the water to the motions.

31 Magnets moving in oppoſite directions.

Let us, in the next place, ſuppoſe the magnets to be moving in oppoſite directions with the velocities a and b; and (in order that the magnets may not ſtrike each other) let the ſum of a and b be leſs than the ſum of α and β, which the repulſions of the magnets would produce by repelling them from contact to their inactive diſtance.

As ſoon as the magnets arrive at their acting diſtance, their mutual and equal repulſions immediately begin to diminiſh both of their motions; and in any minute portion of the period of their approach, equal quantities of motion are taken from each. It is evident, that if the primitive quantities of motion have been equal; that is, if A and B have been moving with velocities reciprocally proportional to their quantities of matter, then, when the motion of one of them has been annihilated by their mutual repulſion, the motion of the other will be be deſtroyed at the ſame time, and both will be brought to reſt. Were the repulſions annihilated at this inſtant, they would remain at reſt. But becauſe thoſe forces continue their actions, the magnets will ſeparate again, regaining, at every diſtance, the velocity which they had, when at that diſtance, during their mutual approach; and when they have reached their inactive diſtance, they will have regained each its original momentum and velocity, but in the oppoſite direction. This needs no farther comment; but muſt be kept in mind, becauſe this caſe has a preciſe counterpart in the colliſion of ſolid bodies, meeting each other in oppoſite directions with equal momenta. But if the momentum of one exceed that of the other, thus, if $A \times a$ be greater than $B \times b$, then, when the magnet B is brought to reſt, A has ſtill a momentum remaining equal to $A\,a - B\,b$. Having therefore a certain velocity, while B has none, it muſt approach ſtill nearer to B, and a ſtill greater repulſion will be exerted on B than if A had alſo been brought to reſt, but ſtill repelling B. Since B is now acquiring motion in the direction oppoſite to its former motion, and A is ſtill loſing motion, a time muſt come when the motion of A is ſo much diminiſhed, and that of B ſo much augmented, that they are moving with a common velocity in the direction of A's primitive motion. The reaſoning employed in the foregoing examples ſhew us, that, in the preſent caſe alſo, this ſtate of common velocity is alſo the ſtate of the greateſt proximity, and that the magnets ſeparate again, till they attain their diſtance of inaction, and that the total change in each is double of what it was in their ſtate of greateſt proximity.

32 Common velocity $= \frac{A\,a - B\,b}{A + B}$ but the change is doubled by the ſubſequent ſeparation.

To find this common velocity, recollect, that when the momentum of B was extinguiſhed, that of A was ſtill $= A\,a - B\,b$. From what has been already ſaid on the other caſes, we know that when the common velocity obtains, the whole momenta are ſtill equal to $A\,a - B\,b$. Therefore the common velocity x muſt be $= \frac{A\,a - B\,b}{A + B}$.

The velocity loſt by A muſt therefore be $a - \frac{A\,a - B\,b}{A + B}, = \frac{B \times \overline{a+b}}{A + B}$, and the final velocity will be $a - \frac{2\,B \times \overline{a+b}}{A + B}$. The final motion of A will be in the ſame direction as at firſt, if a be greater than $\frac{2\,B\,\overline{a+b}}{A + B}$, otherwiſe it will be in the oppoſite direction.

In like manner, the change of velocity in B is $b + \frac{A\,a - B\,b}{A + B}$, becauſe the former velocity b is deſtroyed, and the new velocity is $\frac{A\,a - B\,b}{A + B}$ in the oppoſite direction. This is $= \frac{A \times \overline{a+b}}{A + B}$, and the final velocity of B is $= b - \frac{2\,A \times \overline{a+b}}{A + B}$.

33 The changes of motion in the magnets are ſimilar to thoſe in the colliſion of bodies.

Thus we have ſhewn, in the caſe of magnets acting on each other by repulſive forces, or actuated by forces equivalent to repulſive forces, how changes of motion are produced, which have a great reſemblance to thoſe which are ſeen in the colliſion of ſolid bodies. The motions which obtain in the inſtant of greateſt proximity are preciſely ſimilar to what *are obſerved* in the colliſion of unelaſtic bodies. Their common velocity after colliſion is always $= \frac{A\,a + B\,b}{A + B}$, or $= \frac{A\,a - B\,b}{A + B}$, according as the bodies were moving in the ſame or in oppoſite directions. The final motions of the magnets are alſo preciſely ſimilar to what *are obſerved* in the colliſion of perfectly elaſtic bodies. We took the inſtance of magnets, becauſe the object is familiar; but we can ſubſtitute, in imagination, an abſtract repulſive force in place of magnetiſm, and we can aſſign it any intenſity, and any law and limits of action we pleaſe. We can imagine it ſo powerful, that although its action be limited to a very ſmall, and even inſenſible diſtance, it ſhall always reduce the meeting bodies to a common velocity before they come into actual contact; and therefore without any real impulſion, as impulſion is commonly conceived.

There are ſome farther general obſervations that may be made on thoſe motions which are of importance.

34 Theſe changes are proportional to the relative motion,

1. We ſee that the changes of motion, and conſequently the actions, are dependent on the relative motions only, whatever the abſolute motions may be: For changes are always as $a - b$ when the bodies are moving in one direction, and as $a + b$ when they are moving in oppoſite directions. Now $a \pm b$ is the relative motion.

35 And reciprocally as the quantities of matter.

2. The change of velocity in each of the two bodies is inverſely as its quantity of matter, or is proportional to the quantity of matter in the other body. The changes in A and B are $\frac{B \times \overline{a \pm b}}{A + B}$ and $\frac{A \times \overline{a \pm b}}{A + B}$. The changing forces being equal on both ſides, produce equal changes in the quantities of motion; and therefore produce changes of velocity that are inverſely as the quantities of matter.

36 CONSERVATIO MOMENTORUM.

3. During the whole proceſs, the ſum of the momenta, or quantities of motion, remains the ſame, if the bodies are moving in one direction: if they are moving in oppoſite directions, it is the difference of momenta that remains the ſame; for in every inſtant of the proceſs equal changes of momentum are made in oppoſite directions. When the motions are in the ſame direction, as much is taken from the one as is added to the other; and therefore the *ſum* remains unchanged. When the motions are in oppoſite directions, equal quantities are taken from both; and therefore the *difference* remains unchanged. This is called the CONSERVATIO MOMENTORUM; and it is uſually enunciated by ſaying, that the quantity of motion, eſtimated in one direction, is not changed by the equal and oppoſite actions of the bodies. This is a particular caſe of a general law affirmed by Des Cartes, that the quantity of motion in the univerſe remains always the ſame when eſtimated in *any* one direction.

37 CONSERVATIO VIRIUM VIVARUM.

4. When the whole proceſs is completed, the ſum of the products made by multiplying each body by the ſquare of its final velocity, is equal to the ſum of the products made by multiplying each body into the ſquare of its initial velocity. For when the proceſs is completed, the two bodies are at the ſame diſtance from each other as when the mutual action began. There-

fore, during the proceſs, each body has paſſed over an equal ſpace, and in every ſimilar point it has been acted on by an equal force (although this force be different in different points of this ſpace). Therefore, in every inſtant, the ſimultaneous products of the quantity of matter by the momentary variation of the ſquare of the velocity are equal on both ſides; and therefore the products of the quantity of matter by the whole change of the ſquare of the velocity are alſo equal on both ſides. See Dynamics, *Suppl.* n° 95. and 110. where $v \dot{v} = \frac{\dot{f} s}{m}$; and therefore $m v \dot{v} = \int \dot{s}$, and $m \times V^2 - v^2$, or $n \times v^2 - V^2 = \int f \dot{s}$. Now, ſince theſe changes are in oppoſite directions, as much is added to one product as is taken from the other, and the ſum of the products of the quantities of matter by the ſquares of the final velocities, is equal to the ſum of the products of the ſame quantities of matter by the ſquares of the initial velocities.

Theſe two theorems are not principles, but general facts.

This is a particular caſe of the famous CONSERVATIO VIRIUM VIVARUM, claimed as a mighty diſcovery by the partizans of Leibnitz, and aſcribed to him; but he has no claim whatever to the diſcovery. It was communicated to the Royal Society of London in 1668 by Huyghens, as one of the general laws of impulſion, obtaining in what he calls *hard bodies*. Several of the Leibnitzian ſchool, indeed, extended it farther than Huyghens had done; ſome of them indeed very lately. The obſervation of this general law was ſoon applied to many excellent purpoſes in the ſolution of very intricate problems; becauſe it often ſaved the trouble of tracing the intermediate ſteps of a complicated proceſs. Aſſured that theſe products were invariable, the mathematician found it an eaſy matter to ſtate what conditions of the queſtion inſured this equality of products; and thus the problem was ſolved. In this manner Daniel Bernoulli gives moſt elegant ſolutions of ſome, otherwiſe almoſt intractable, problems in Hydraulics. For ſuch reaſons, as a mighty aid in mechanical inveſtigation, the diſcovery of Huyghens is extremely valuable. Its merit in this reſpect is perfectly ſimilar (though perhaps ſomewhat greater) to Des Cartes's obſervation of the *conſervatio momentorum.* It is alſo like the obſervation or diſcovery of Maupertuis, which he calls *the law of ſmalleſt action* (indeed it is the ſame under a different aſpect), or La Grange's *law of virtual velocities*, or D'Alembert's *law of equilibrium of action*;—all of theſe are general facts, laws by which the changes of motion are *obſerved* to proceed. But their authors have vaunted them as principles, as cauſes, from which to conclude effects; whereas they are really inductions from particular inſtances. We muſt alſo obſerve, that this law of *conſervatio virium vivarum* was not deduced either by Huyghens or any of the Leibnitzian ſchool, by reaſoning from more general principles. It was an expiſcation of ſameneſs in events, diverſified by other circumſtances. We do not recollect any author who has given what can be called a demonſtration of it, deducing it from principles or laws ſtill more general. We apprehend that the preſent caſe of its truth has been ſo demonſtrated by us. The *principle* is, that "a moving force is to be meaſured by the change of motion produced by it:" And the law to which this principle is applied is, that "the mutual repulſions of magnets are equal and oppoſite;" and the application is made by means of the "39th propoſition of the firſt book of Newton's *Principia.*" Our principle, which is the ſame with Sir Iſaac Newton's ſecond law of motion, is really an axiom of human thought. The propoſition is the conſequence logically drawn from this axiom; and the law of magnetiſm is an obſerved fact. We hope to ſhew, by and bye, that this propoſition, which is our n° 95. of Dynamics, is found to obtain in *every* inſtance that has been or can be given of the *conſervatio virium vivarum*, and that this *conſervatio* is only another way of expreſſing the propoſition. Having done this, we ſhall not think ourſelves chargeable with vanity when we ſay, that we have given the firſt demonſtration of this famous law. We cannot refuſe ourſelves ſome ſatisfaction at having done this; becauſe it has been ſo highly eſteemed, chiefly for the ſupport derived from it for the Leibnitzian meaſurement of the force of moving bodies by the *ſquare of the velocity* which it communicates; whereas it is the logical conſequence of the force being proportional to the *ſimple velocity.* We have only taken a weapon out of the hands of a plunderer, and reſtored it to its lawful owner, Sir Iſaac Newton. *Non ita certandi cupidus, quam propter amorem:* For we muſt ſay,

> *Tu pater et rerum inventor, tu patria nobis*
> *Suppeditas precepta, tuiſque ex, inclute, chartis*
> *Floriferis ut apes in ſaltibus omnia libant,*
> *Omnia nos itidem depaſcimur aurea dicta*
> *Aurea, perpetuâ ſemper digniſſima vitâ.*

We truſt that our reader will not think that this minute diſcuſſion of the mutual actions of magnets or other repelling bodies, in which we have engaged him, has been thrown away, ſince it has enabled us to apprehend clearly a caſe of two ſuch general laws as the *conſervatio momentorum*, and the *conſervatio virium vivarum.*

38 *Vis viva* loſt in the colliſion of unelaſtic bodies.

5. In the moment of greateſt vicinity and common velocity, there is a certain determinate loſs of the *vires vivæ*, or products of the matter by the ſquare of the velocity; and this loſs is proportional to the ſquare of the relative motion. The *vires vivæ*, at the commencement of the mutual action, are $= A a^2 + B b^2$ (I.) In the moment of greateſt proximity, the quantity of matter $A + B$ is moving with the common velocity $\frac{A a + B b}{A + B}$; therefore the *vires vivæ* are $= \overline{A + B} \times \frac{\overline{A a + B b}^2}{\overline{A + B}} = \frac{\overline{A a + B b}^2}{A + B}$, $=$

$$\frac{A^2 a^2 + B^2 b^2 + AB \times 2 a b}{A + B} \text{ (II.)}$$

$$\text{I.} \times \overline{A + B} = A^2 n^2 + B^2 b^2 + AB \times \overline{a^2 + b^2}.$$

$$\text{II.} \times \overline{A + B} = A^2 a^2 + B^2 b^2 + AB \times 2 a b.$$

$$\text{Difference} \quad - \quad - \quad - \quad AB \times \overline{a - b}^2.$$

Loſs of *vis viva* $= \frac{AB}{A + B} \times \overline{a - b}^2$, a quantity that is proportional to $\overline{a - b}^2$, the ſquare of the relative velocity $a - b$.

Had the bodies been moving in oppoſite directions, then (II.) $\times \overline{A + B}$ would have been $A^2 a^2 + B^2 b^2 - AB \times 2 a b$, and the difference from $\overline{A a^2 + B b^2} \times A + B$ would have been $= AB \times \overline{a + b}^2$, proportional to the ſquare of the relative velocity $a + b$.

Such

Phyſical cauſe of this loſs.

Such is the fact; and we ſhall find it of importance in the great debate about the force of moving bodies. Let us inquire into the phyſical or mechanical cauſe of it. In the moment of common velocity, the bodies are nearer to each other than they are at the beginning and at the end of their mutual action. Therefore (when they are moving in one direction) the body A, which follows, has been retarded through a ſpace which is greater than the ſpace along which the preceding body B has been accelerated. But, becauſe the ſimultaneous forces acting on the bodies along theſe unequal ſpaces are always equal, the area which meaſures the diminution of the ſquare of A's velocity (Dynamics, n° 95.) muſt exceed the area which expreſſes the augmentation of the ſquare of B's velocity, and there muſt be a loſs of *vires vivæ*. Now, we learned above, that the mutual action is the ſame when the relative velocity is the ſame; and therefore the approximation, which is the occaſion of this action, muſt be the ſame. And it is demonſtrated in Dynamics, n° 93. that the area, whoſe abſciſſa is the ſpace deſcribed, and ordinates the forces, expreſſes the ſquare of the generated or extinguiſhed velocity. This is evidently the relative velocity of the bodies, becauſe they are brought to a common velocity in the inſtant of greateſt proximity; that is, their relative velocity is deſtroyed.

39
The motion of the common centre of gravity is not changed by the mutual action.

6. During the whole proceſs, the common centre of poſition or gravity (A) is moving uniformly with the velocity $\frac{A\,a \pm B\,b}{A+B}$. For the motion of the centre of poſition is the average of the motion of every particle of matter in both bodies. $A\,a$ is the ſum of the motions of every particle of matter in A, and $B\,b$ is the ſum of the motions of every particle in B, before the mutual actions began. Therefore $A\,a + B\,b$ is the whole motions when the bodies are moving in the ſame direction with their different velocities. The number of particles is $A + B$: Therefore, if the whole motions be equally divided among all the particles, the velocity of each muſt be $\frac{A\,a + B\,b}{A+B}$. This is the average motion, or the motion of the centre of poſition, deduced from the notion we wiſh to impreſs of the character of this centre, as the index of the poſition and motion of any aſſemblage of matter. This velocity may be deduced more eaſily from its geometrical property. It is a point ſo ſituated between A and B, that its diſtance from each is reciprocally proportional to the quantities of matter in A and B, as is well known of the centre of gravity. It is equally plain, that when the bodies are moving in oppoſite directions, the average velocity x muſt be $= \frac{A\,a - B\,b}{A+B}$. Thus we ſee, that the motion of the centre of poſition, before the magnets have begun to act on each other, is the ſame with its motion when their mutual repulſion is the greateſt; namely, at the moment of their greateſt vicinity. It has continued the ſame during the whole proceſs: For we have already ſeen, that the ſum or difference of the momenta, or $A\,a \pm B\,b$, remained always the ſame; conſequently $\frac{A\,a \pm B\,b}{A+B}$, or x, the motion of the centre, remains always the ſame. Therefore the propoſition is demonſtrated. It is, indeed, a truth much more general than appears in the preſent inſtance. *If any number of bodies be moving with any velocities, and in any directions, the motion of the centre of poſition is not affected by their mutual, equal, and oppoſite, actions on each other.*

40
The motions, in relation to the centre, are reciprocally as the bodies.

7. During the whole motion, the motion of the bodies relative to each other, is to the motion of one of them, relative to the centre of poſition, as the ſum of the bodies is to the other body: For when they were moving with a common velocity, this velocity was the ſame with that of the centre; and they are then at reſt, relative to each other, and relative to the centre. And becauſe their diſtances from the centre are inverſely as the bodies, their changes of diſtance, that is, their motions relative to the centre, are in the ſame proportion: and the ſum of their motions relative to the centre is the ſame with their motions relative to each other. Therefore $A + B : A = a - b$: motion of B relative to the centre. Indeed we ſaw, that in their mutual action, the change of B's motion was $= \frac{A \times \overline{a - b}}{A+B}$, and the change of A's motion was $= \frac{B \times \overline{a - b}}{A+B}$.

41
The bodies ſeparate with the ſame relative velocity which they approached.

Hence we learn, that while the centre moves uniformly, the bodies approach it, and then recede from it, with velocities reciprocally proportional to their quantities of matter. This will be found a very uſeful corollary. We may alſo ſee that their final velocity of mutual receſs is equal to that of their firſt approach, or, their relative motions are the ſame in quantity after the action is over as before it began, but in oppoſite directions.

All theſe general facts, which are diſtinctly appreciable, and very perceivable, in this example of magnets, or electrified bodies, are equally appreciable in all caſes of mutual repulſions, however ſtrong theſe may be; and although the ſpace through which they are exerted ſhould be ſo ſmall as to elude obſervation, and though the whole proceſs ſhould be completed in an inſenſible moment of time.

42
An interpoſed ſpring has the ſame effect with the mutual repulſions.

It ſcarcely needs any comment to make it clear that the very ſame changes of motion muſt take place, if a ſolid body A ſhould come up to another ſolid body B, at reſt, or moving more ſlowly in the ſame direction, or moving in the oppoſite direction; provided that there be a ſpring interpoſed between them, which may hinder

---

(A) See the article Position in this *Supplement*; where it will be demonſtrated, that the centre of gravity (determined in the uſual manner) is the point by whoſe ſituation and motion we eſtimate with the greateſt propriety the ſituation and motion of the aſſemblage, of which it is the centre: it is therefore called the CENTRE OF POSITION. The reader is only deſired at preſent to recollect, that the centre of gravity, or poſition of two bodies, is ſituated in the line joining their centres; and that its diſtance from each is inverſely as their quantities of matter; and that the diſtance and motion of the centre is the medium or average of all the diſtances or motions.

A from ſtriking B; for, as ſoon as A touches the ſpring, it begins to preſs it againſt B, and, therefore, to compreſs the ſpring. It cannot carry the ſpring before it, without the ſpring's puſhing B before it. Preſſure on B is required for this purpoſe. This is ſupplied by that natural power which we call elaſticity, which is inherent in the ſpring, whether it be in motion or at reſt. It is not in *action*, but in *capacity*, *faculty*, *capability*, *power*, or by whatever name we may chooſe to expreſs the poſſeſſion. The occaſion required for its exertion is compreſſion. This is furniſhed by the motion of A; for A cannot advance without compreſſing it. This inherent force of the ſpring is *known* to act with perfect equality at both ends, in oppoſite directions. It exerts equal and oppoſite preſſures on A and on B; it diminiſhes the motion of A, and equally augments the motion of B (if both are moving that way). A is retarded, and B is accelerated; A is ſtill moving faſter than B; and therefore the compreſſion and the conſequent reaction of the ſpring increaſes, and ſtill more retards A and accelerates B. After ſome time, both bodies, with the ſpring compreſſed between them, are moving with equal velocities; the ſpring, however, is ſtrongly reacting on both, and muſt now cauſe them to ſeparate; ſtill retarding A, and accelerating B—They muſt ſeparate more and more, till the ſpring regain its quieſcent form, and its elaſtic reaction ceaſe entirely. During its reſtitution, its preſſures are the ſame as during its compreſſion, therefore, the whole change produced on each of the bodies muſt be double of what it was when the ſpring was in its ſtate of greateſt compreſſion, and the bodies were moving with a common velocity. In ſhort, the whole proceſs in this example muſt be preciſely ſimilar to that of the magnets in every circumſtance relating to the changes of motion in A and B. The common velocity muſt be $= \frac{A a \pm B b}{A + B}$. The final velocity of A muſt be $= a - \frac{2 B \overline{a \pm b}}{A + B}$, and that of B muſt be $= b + \frac{2 A \overline{a \pm b}}{A + B}$. The motion of the common centre muſt be unaffected by the action of the ſpring, and the motion of each body, relative to the centre, muſt be reciprocally as its quantity of matter, &c. &c.

43
The changes of motion are produced by the inherent forces which connect the particles.

We apprehend that this proceſs can ſcarcely be called impulſion; A has not ſtruck B. The changes of motion can ſcarcely be aſcribed to forces inherent in A or B, in conſequence of their being in motion. Any perſon, not already warped by a theory, will (we think) aſcribe them to a force inherent in the ſpring; inherent in it, whether at reſt or in motion, and only requiring a *continued* compreſſion as the proper opportunity for its continued exertion. This ſpring may be ſuppoſed to make a part of B, or of A, or of both; and then, indeed, the force may be ſaid to be inherent in either, or in both. But it is not the peculiar force inherent in motion, or in moving bodies *only*—it is the force of *elaſticity*, inherent in part of the body, but requiring a continued *compreſſion* for the production of a continued *repreſſion*. The effect of this reaction is modified by the very occaſion of the compreſſion. This may be the elaſticity of another ſpring. In this caſe it will only compreſs that ſpring.—It may be the advance of a body in motion; the reaction produces a retardation of that motion; it may be the obſtacle of a quieſcent body—it will give it motion; or, it may be the abſtruction by a body moving more ſlowly away than the ſpring is preſſed forward—it will accelerate that motion. Thus, in all theſe caſes, we cannot help diſtinguiſhing the immediate cauſe of theſe changes of motion from the ſuppoſed force of a moving body. Nay, the proceſs of motion is ſimilar, even when we ſuppoſe that the ſpring is not a thing external to the body, although attached to it; but that the whole body, or both bodies, are ſpringy, elaſtic, and therefore compreſſible. As ſoon as the bodies come into ſenſible contact, compreſſion *muſt* begin; for we may ſuppoſe the bodies to be two balls, which will therefore touch only in one point. The mutual preſſure, which is neceſſary in order to produce the retardation of A, and the acceleration of B, is exerted only on the foremoſt particle of A, and the hindmoſt particle B; but no atom of matter can be put in motion, or have its motion any way changed, unleſs it be acted on by an adequate force. The force urging any individual particle, muſt be preciſely competent to the production of the very change of motion which obtains in that particle. Except the two particles which come into contact in the colliſion, all the other particles are immediately actuated by the forces which connect them with each other; and the force acting on any one is generally compounded of many forces which connect that particle with thoſe adjoining. Therefore, when A overtakes B, the foremoſt particle of A is immediately retarded—the particles behind it would move forward, if their mutual connection were diſſolved in that inſtant; but, this remaining, they only approach nearer to the foremoſt ſtriking particles, and thus make a compreſſion, which gives occaſion for the inherent elaſticity to exert itſelf, and, by its reaction, retard the following particles. Thus each ſtratum (ſo to conceive it), continuing in motion, makes a compreſſion, which occaſions the elaſticity to react, and, by reacting, to retard the ſtratum immediately behind it. This happens in ſucceſſion: the compreſſion and elaſtic reaction begin in the anterior ſtratum, and take place in ſucceſſion backward, and the whole body gets into a ſtate of compreſſion. Things happen in the ſame manner in B, but in the contrary direction, the foremoſt ſtrata being the laſt which are compreſſed. All this is done in an inſtant (as we commonly, but inaccurately ſpeak), that is, in a very ſmall and inſenſible moment of time; but in this moment there is the ſame gradual compreſſion, increaſe of mutual action, greateſt compreſſion, common velocity, ſubſequent reſtitution, and final ſeparation, as in the caſe of bodies with a ſlender ſpring interpoſed, or even in the caſe of the mutually repelling magnets. In all the caſes, the changes of motion are produced by the elaſticity or the repulſion, and not by the transfuſion of the force of motion. The changing force is indeed inherent in the bodies, but not becauſe they are in motion; the uſe of the motion is to give occaſion, by continued compreſſion, for the continued operation of the inherent elaſticity. The whole proceſs may be very diſtinctly viewed, by making uſe of bodies of ſmall firmneſs, ſuch as foot-balls, or blown bladders. If blown bladders are uſed, each loaded with ſand, or ſomething that will require more force, and conſequently

44
Internal proceſs of change through the ſubſtance of each body.

conſequently more compreſſion to impel it forward; we ſhall obſerve the compreſſion of both to be very conſiderable, and that a very ſenſible time elapſes during the proceſs of colliſion. This may even be obſerved very diſtinctly in a foot-ball, which is always ſeen to reſt a little on the toe before it flies off by the ſtroke. When one foot-ball is ſtrongly driven againſt another, they plainly adhere together for ſome time, and then the ſtricken ball flies off.

If we return to the example of the two balls with the ſpring interpoſed, we may make ſome farther uſeful obſervations. When the ſpring is in its ſtate of greateſt compreſſion, and the balls are moving with a common velocity, we can ſuppoſe that the ſpring is arreſted in that ſituation by a catch. It is evident that the two bodies will now proceed in contact with this velocity, which we have ſhewn to be $= \frac{A\,a \pm B\,b}{A + B}$.

45
Nature of imperfect elaſticity.

Now, in the conſtitution of ſuch maſſes of tangible matter as we have the opportunity of ſubjecting to our experiments, we find a ſtate of aggregation which very much reſembles this. Some bodies are almoſt perfectly elaſtic, that is, when their ſhape is changed by external preſſure; and that preſſure is removed, they recover their former ſhape completely, and they recover it with great promptitude. Glaſs, ivory, hard ſteel, are of this kind. But moſt bodies either do not recover it completely, or they recover it very ſlowly—ſome hardly recover it at all. A rod of iron will, when conſiderably bent, not nearly recover its ſhape; a rod of lead ſtill leſs; and a rod of ſoft clay will hardly recover it in any degree. Theſe, however, are but gradations of one and the ſame quality: if the quieſcent form of a body is very little diſturbed, it will recover it again. Thus, a common ſoft iron wire of N° 6. and 12 inches long, if twiſted once round, will return completely to its original form, and will allow this to be repeated for ever; but if it be twiſted $1\frac{1}{2}$ turns, it will untwiſt only 1: and in this new form, it will twiſt and untwiſt one turn as often as we pleaſe. Even a rod of ſoft clay, $\frac{1}{10}$th of an inch in diameter, and 7 feet long, will bear one twiſt as often as we pleaſe; but if twiſted 4 times, will untwiſt itſelf only one turn, and will do this as often as we chooſe. In ſhort, it appears that the particles of bodies, uſually called unelaſtic, will admit a ſmall change of diſtance or ſituation, and will recover it again, exhibiting perfect elaſticity, in oppoſition to very ſmall forces; but if they are forced too far from this ſituation, they have no tendency to return to it completely, but find intermediate ſituations, in which they have the very ſame connections with the ſurrounding particles; and in this new ſituation, they can again exhibit the ſame perfect elaſticity, in oppoſition to very ſmall forces. Mr Coulomb conceives ſuch bodies to conſiſt of elaſtic particles: they manifeſt perfect elaſticity, ſo long as the forces employed to change their ſhape do not remove the particles from their preſent contacts; but if they are removed from theſe, they ſlide on to other ſituations, where they again exhibit the ſame appearances. To underſtand this fully, the reader may conſult the article Boscovich of this *Supplement*—The fact is ſufficient for our preſent purpoſe. Now, in this variable conſtitution, where the particles may take a thouſand different ſituations, and ſtill cohere, it is plain, that when a body has been dimpled by compreſſion, the particles have nothing to bring them back to their firſt ſituation when the compreſſing force is removed: the utmoſt elaſticity to be expected, is that which will not extend to one ſhift of ſituation; therefore, the reſtitution is altogether inſenſible. This is the caſe with all ſoft bodies, ſuch as clay—the ſame quality is manifeſted in all ductile bodies, ſuch as lead, ſoft iron and ſteel, ſoft copper, ſoft gold.

46
Effect of this colliſion.

Now let one of theſe bodies ſtrike another. The compreſſion, or the ſliding of the particles over each other, requires force, or mutual preſſure—This being accompanied by a reaction perfectly equal, muſt operate, during the compreſſion, preciſely as the equal repulſive forces did. It will take as much momentum from A as it gives to B; ſo that $A\,a \pm B\,b$ will remain invariably the ſame, and a common velocity will at laſt obtain, $= \frac{A\,a \pm B\,b}{A + B}$. The compreſſion can proceed no farther, and the two bodies muſt now proceed in contact with this velocity.

And thus we ſee, that in the caſe of compreſſible, but unelaſtic bodies, the changes of motion are produced by the coheſive forces inherent in the bodies; but not inherent in them becauſe they are in motion. We ſee clearly in this way, how the pendulum uſed by Robins and his followers gave a true meaſure of the velocity of the ball. All the while that it was penetrating into the pendulum, overcoming the coheſion as it went in, this coheſion was acting equally in both directions. While the fibre was breaking, it was pulling both ways; it was holding back the ball which was breaking it, and it was pulling forward the parts to which it ſtill adhered; and when it broke at laſt, it had produced equal effects on the ball and on the pendulum in oppoſite directions. By ſuch a proceſs, the pendulum was gradually accelerated, and acquired its utmoſt velocity when the ball had ceaſed to penetrate:. Therefore, this velocity muſt be $= \frac{A.a}{A + \text{pend}^{m}.}$

What ſhould we now expect to happen in the colliſion of bodies? Such bodies as exhibit perfect elaſticity, when examined by bending, or other fit trials, ſhould have their motions changed preciſely like the magnets, or bodies which repel or avoid each other at ſenſible diſtances. Bodies which exhibit no elaſticity whatever, ſhould continue in contact after colliſion. The common velocity in theſe ſhould be $\frac{A\,a \pm B\,b}{A + B}$. The perfectly elaſtic bodies ſhould ſuſtain changes of motion which are preciſely double of the changes ſuſtained by unelaſtic bodies, and ſhould ſeparate after colliſion with a relative velocity of receſs or ſeparation, preciſely equal to their relative velocity of mutual approach. And bodies poſſeſſing imperfect elaſticity, ſhould ſuſtain changes of motion which differ from the changes on unelaſtic bodies, preciſely in proportion to the degree of elaſticity which they are *known* to poſſeſs. And, laſtly, if the changes of motion which obtain in the colliſion of bodies, are preciſely thoſe which would reſult from the operation of thoſe inherent forces of elaſticity and coheſion, NO OTHER FORCE WHATEVER CONCURS IN THEIR PRODUCTION: For we know that thoſe forces *do operate* the colliſion; we ſee the compreſſion and reſtitution which are their effective cauſes, and their immediate effects. If any other force were ſuperadded, we ſhould ſee its effects alſo, and the motions would be different from what they are.

Now the fact is, that *we have never ſeen a body that is not, in ſome degree, compreſſible.* It has not pleaſed the Almighty Creator to make any ſuch here below. Aſſuredly He has not found ſuch to be of uſe for the purpoſes He had in view in this our ſublunary world. We know of no body that is perfectly unchangeable in its ſhape and dimenſions. It is therefore no loſs whatever to us, although we ſhould not be able to ſay *à priori* what their motions will be in colliſion. We cannot even fairly gueſs them, by reaſoning from what we obſerve in other bodies: For it is juſt as likely that their motions may reſemble thoſe of perfectly elaſtic bodies as thoſe of unelaſtic bodies; for we find that bodies of the moſt extreme hardneſs are generally highly elaſtic. Diamond, cryſtal, agate, quartz. and ſuch like, are the moſt elaſtic bodies we know. Philoſophers, however, rather think that the motions of perfectly hard bodies will reſemble thoſe of unelaſtic bodies; becauſe elaſticity ſuppoſes compreſſion. We do not pretend to ſay with confidence, what would be the motion of a ſingle atom of matter (which cannot admit of compreſſion) which is hit by another in motion. We ſee all the particles of terreſtrial matter connected with each other by certain modifications of the general force of coheſion, ſo as to produce various forms of aggregation; ſuch as aërial fluidity, liquid fluidity, rigidity, ſoftneſs, ductility, firmneſs or hardneſs; all of which are combined with more or leſs elaſticity. Theſe tangible forms reſult from certain poſitive properties of the material atoms of which the particles are compoſed; and, in all the caſes which come under our obſervation, theſe properties produce preſſures of one kind or another; all of which are moving forces. They are inherent in the particles and atoms: therefore when ſuch atoms are in motion, theſe forces are in a condition which affords occaſion for a *continuation* of this preſſure that is competent to the production of motion in another particle. But what would be the event of the meeting of atoms diveſted of ſuch forces, we profeſs not to know, or even to conceive.

47
The obſerved effects of colliſion are perfectly conformable to the propoſitions now eſtabliſhed.

The fact alſo is, that all the changes of motion, commonly called impulſions, *which have been obſerved*, are preciſely ſuch as have been deſcribed. Unelaſtic bodies proceed in contact with the velocity $\frac{A\,a \pm B\,b}{A + B}$. Perfectly elaſtic bodies ſeparate after colliſion, and each ſuſtains double of the change that is ſuſtained by an unelaſtic body. Bodies of imperfect elaſticity differ from the two ſimple caſes, preciſely in the proportion of the elaſticity diſcoverable by other trials. The mutual actions are obſerved to be in the proportion of their relative motions, whatever the real motions may he. For not only are the changes of progreſſive motion exactly in this proportion, but the compreſſions and changes of figure, which we conſider as the immediate occaſions of thoſe actions, are alſo obſerved to be in the ſame proportions, *in all caſes that we can obſerve and meaſure with accuracy.* All theſe things can be aſcertained with great preciſion by means of the colliſion of pendulous bodies in the way pointed out by Sir Chriſtopher Wren (a method attributed by the French to their countryman Mariotte, but really invented by Wren, and exhibited to the Royal Society of London the week after he communicated his theory of impulſion).

48
Extenſive proof of the univerſality of equal action and reaction.

We muſt alſo infer from theſe facts, that the actions of bodies on each other are mutual, equal, and oppoſite. This is really an inference from the phenomena, and not an original or firſt principle of reaſoning. The contrary is conceivable, and therefore not abſurd. In the ſame way that we can conceive a magnet repelling iron, without imagining that the iron repels the magnet, we may conceive a golden ball capable of impelling a leaden ball before it, without conceiving that the leaden ball will impel the golden ball. We do not find this eaſy indeed; becauſe the contrary is ſo familiar, that the one idea inſtantly brings the other along with it. We apprehend it to be impoſſible to demonſtrate, that a leaden ball will not ſtop as ſoon as it hits the golden ball, or *vice verſa*. But all our experience ſhews us, that the preſſures exerted in contact are mutual, equal, and oppoſite. The ſame thing is obſerved in the forces which connect the parts of bodies. A quantity of ſand or water balanced in a ſcale will remain in equilibrio in whatever way it is ſtirred about; its parts always exert the ſame preſſure on the ſcale: ſo does a body ſuſpended by a ſtring or reſting on the ſcale, by whatever points it is ſupported. This could not be if the particles did not exert mutual and equal forces; nor could the phenomena called impulſions be what they are, if the preſſures occaſioned between the particles by the compreſſions and dilatations were not mutual and equal. This law of action and reaction muſt be admitted as univerſal, though contingent, like gravity. Doubtleſs it reſults from the properties which it has pleaſed the great Artiſt to give to the matter of which He has formed this world. There is one way in which we can conceive, moſt diſtinctly, how this may be a univerſal property of matter. If we grant the reality of attractions and repulſions *e diſtanti*, and ſuppoſe that every primary atom of matter is preciſely ſimilar to every other atom in all its properties, and that this aſſemblage of properties conſtitutes it a material atom; it follows, that every atom exerts the ſame attractions and repulſions, or has the ſame uniting and evaſive tendencies, and then the law of action and equal reaction follows of courſe. This is ſurely the very notion that any perſon is diſpoſed to entertain of the matter. And if mechanical force and mobility are the qualities which diſtinguiſh what is material from mind or other immaterial ſubſtances, the law of equal and contrary reaction ſeems nearly allied to the claſs of firſt principles.

Of all the phenomena that indicate this perfect equality of action and reaction, the moſt ſuſceptible of accurate examination is the ſameneſs or equality of action when the relative motions are equal. Now there is no phenomenon more certain than this. In conſequence of the rotation of the earth round its axis, and its revolution round the ſun, it is plain that all our experiments and obſervations are on relative motions only. Now, we not only find that the actions of two bodies ſubjected

ted to experiment are equal when the relative motions are equal, but we find that all our meaſures of action on a ſingle body are proportional to the apparent motions which they produce. It requires preciſely the ſame force to impel a ball eaſtward, weſtward, ſouth, or north, at 12, or 3, or 6, or 9 o'clock: yet the real motions are immenſely different in all theſe caſes, and it is only the relative motions that have the proportions which we obſerve. Another very important point deducible from our experiments is, that the ſame *preſſure* produces the ſame change of motion, whatever may be the velocity. We know this by obſerving, that when the mutual dimpling or compreſſion is the ſame, the change of motion is the ſame, whatever be the hour of the day. This could not be if it required a greater preſſure to change the velocity 100000 into 100001, than to change the velocity 1 into the velocity 2. Yet this is one of Leibnitz's great metaphyſical arguments for proving that the force accumulated, and now inherent, in a moving body, is proportional to the ſquare of its velocity. We beg that this may be kept in remembrance.

It muſt be granted, that what we have already ſaid on the ſubject of impulſion may be called an *explanation;* for it deduces the phenomena from general and unqueſtionable principles, and from acknowledged laws of Nature. The only principle uſed is, that a moving force is indicated, characteriſed, and meaſured, by the motion which it produces. It is an acknowledged law of Nature, that preſſures are moving forces; alſo, that moving forces appear in caſes where we obſerve neither preſſures nor impulſions, and which we call repulſions or evaſive tendencies; that theſe are mutual and equal: and we have ſhewn, how a certain ſet of changes of motion reſult from them, and have ſtated diſtinctly the whole proceſs: we ſhewed, that theſe phenomena are ſimilar to thoſe of common impulſion; and we then ſhewed in what manner the motion of a body *gives occaſion* to the exertion of various moving forces, called *elaſticity*, *coheſion*, &c. and that this exertion muſt produce motions ſimilar to thoſe produced by repulſions *e diſtanti;* and, laſtly, we inferred, from the perfect ſameneſs of thoſe reſults with the actual phenomena of impulſion, that thoſe corpuſcular forces are the immediate and *only* cauſes of the changes called impulſions, and commonly aſcribed to a *peculiar* force inherent in a moving body.

49
Why does the philoſopher *attempt* to explain gravitation, &c. by impulſion?

From a collective view of the whole, we think it clear, that the opinion that impulſion is the ſole cauſe of motion is unwarranted. We ſee that the phenomena of impulſion are brought about by the *immediate* operation of preſſure; and we ſee numberleſs inſtances of preſſure, in which we cannot find the ſmalleſt trace of impulſion. It is therefore a moſt violent and unwarranted opinion, which aſcribes to repeated unperceived impulſions all thoſe ſolicitations to motion by which, or in conſequence of which, the motions of bodies are affected by diſtant bodies, or bear an evident relation to the ſituation and diſtance of other bodies; as in the examples of planetary deflection, terreſtrial gravitation, magnetical and electrical deflexions, and the like. There is nothing in the phenomenon of the preſſure of gravity that ſeems to make impulſion more neceſſary or more probable than in the preſſure of elaſticity, whether that of a ſpring or of an expanſive fluid. The admiſſion of an unperceived fluid to effect thoſe impulſions is quite unwarranted, and the explanation is therefore unphiloſophical, even although we ſhould perceive intuitively that an atom in motion will put another into motion by hitting it. We apprehend that this cannot be affirmed with any clear perception of its truth.

50
Impulſion is ſuppoſed to be better underſtood and more familiar.

On the whole, therefore, we muſt aſcribe that contented acquieſcence in the explanations of gravitation, and other attractions and repulſions, by means of impulſe (if the acquieſcence be not pretended), to the frequency and familiarity of impulſion, and perhaps to the perſonal ſhare and intereſt we have in this mode of producing motion. We know that it is always objected that nothing is explained, when we ſay that A repels B, or that B avoids A; but we muſt ſay in return, that nothing is explained, when we ſay that A impels B by hitting it, or that B flies away from the ſtroke. Why ſhould it not be allowed to uſe the term repelling power, when it is allowed to uſe the term impelling power, the force of impulſe, inertia? All theſe terms only expreſs phenomena. Does the word body expreſs any more?

51
It is not better underſtood.

The maxim, that a body cannot act *where* it is not, any more than *when* it is not, is a quaint and lively expreſſion, and therefore has conſiderable effect: It may be granted; for we apprehend that we underſtand ſo little about *when* and *where*, that we cannot demonſtrate the affirmative or negative in either caſe, and that they are on a par with reſpect to our knowledge of them. We can have no doubt, however, of the fact, that our mind can be affected by an external object that is merely recollected. And we apprehend, that we know nothing of the difference between body and mind but what we have learned by experience. Body, for any thing that we aſſuredly know to the contrary, may affect, or be affected by, a diſtant body, as well as mind may be. It is therefore worth while to pay ſome farther attention to the phenomena, in order to ſee whether this experience is ſo univerſal and unexpected as is believed. As Mr Cotes, and many of Newton's diſciples, are accuſed of explaining many phenomena by attraction and repulſion which their opponents affirm to be caſes of impulſion; it is not impoſſible but that ordinary obſervers, who have no preconceived theories, may imagine impulſions to obtain in caſes where a more accurate inſpection would convince them that no impulſion has happened.

52
Enquiry into the familiarity of impulſion. Inſtances of a foot-ball.

When we kick away a foot-ball, we conſider it as a ſort of ſolid continuous body; yet we know that it muſt be filled with compreſſed air. It may not be impoſſible to have it of its round ſhape without being ſo filled: but we know that, in this condition, it would not fly away from our foot by the ſtroke; we ſhould only force in the ſide which we kick, and the flaccid ſkin would lie at our feet. But when it is filled with ſtrongly compreſſed air, we can form to ourſelves a pretty diſtinct notion how it is made to move off. Our foot preſſes on a part of the ſkin: this compreſſes the air againſt the anterior part of the bag, and forces it away. If we reflect more ſeriouſly on the proceſs, we can ſtill conceive it clearly enough, by thinking on a row of aereal particles, reaching from the part ſtruck by the foot to the anterior part, each touching the other, and therefore forcing the anterior part forward. The air is conceived to conſiſt of a number of little ſpherules in contact, each of which is compreſſible; and we think the operation illuſtrated by ſuppoſing each to be like a little veſicle or bladder. This we believe to be the uſual way of conceiving the conſtitution of expanſive fluids: But this will not agree at all with the known properties of air; for it can be ſtrictly demonſtrated, that if ſuch a collection of elaſtic veſicles be compreſſed into the half of their ordinary bulk, every veſicle will be changed from a ſphere into a perfect cube, touching the adjoining cubes in every point of its ſix ſides, and ſtrongly preſſed againſt them. It can alſo be demonſtrated, that if a leaden cube of one inch be included in the box, and placed with its ſides parallel to the ſides of the box, and the compreſſion be then made, all the little cubic veſicles will acquire the ſame poſition. If the box be now turned upſide down, it can be demonſtrated that the weight of this leaden cube will not be ſufficient for overcoming the reſiſtance of the compreſſed cubes. This compreſſed maſs will not be fluid, but will require a very conſiderable force to preſs the leaden cube through it, juſt as we find ſuch a force neceſſary for moving a body through melted glaſs: the particles no longer ſlide on each other like uncompreſſed ſpherules; each will require about half of the compreſſing force, in order to overcome the friction, or obſtruction like friction, produced in ſliding along the ſurface of the contiguous cubes. But we know that air remains perfectly fluid, although vaſtly more compreſſed than this. This, therefore, cannot be like the conſtitution or form of air. Moreover, it is well known that air has been made ten times denſer than its ordinary ſtate, and is then perfectly fluid. It has alſo been made a hundred times rarer, and it ſtill remains perfectly fluid. In this ſtate its particles muſt be ten times farther removed from each other than in the former ſtate, of a thouſand times greater denſity. Yet we know that this rare air is compreſſed with a force equal to the weight of a ſtratum of mercury $\frac{1}{3}$d of an inch in thickneſs, and that if $\frac{1}{7}$d of this preſſure be removed, it will expand till it is 150 times rarer than common air; that is, there is ſome force which puſhes the particles ſtill farther from each other. This force evidently extends beyond the tenth particle of air that is made ten times denſer than common air. Therefore the elaſticity of air does not ariſe from the contact of particles, which are elaſtic like blown up bladders, but from ſome force which extends beyond the adjoining particles. There is no greater reaſon, therefore, for ſuppoſing, that the particles of air touch each other, than for ſuppoſing that the two magnets touch each other becauſe they repel. A row of magnets floating on quickſilver, and placed with their ſimilar poles fronting each other, and very near, will tend to ſeparate, and they require to be held in by a ſtop put at each end of the canal; and if one ſtop be gradually withdrawn the magnets will all ſeparate, and exhibit the general mechanical effects of a row of aerial particles ſeparating by the removal of preſſure. There ſeems, therefore, to be the ſame neceſſity for the operation of an intervening impelling fluid for producing this ſeparation or elaſticity of the aereal maſs, as for ſeparating the magnets.

Is very doubtful.

The reſult of theſe remarks ſeems to be, that the impulſion of a foot-ball is not brought about in the way that is commonly imagined, by the excitement of corporeal preſſure at the points of contact of the two foot balls. For we ſee it almoſt demonſtrated, that the progreſſive motion of the anterior part of one of the balls has been produced without contact, or, at leaſt, by the *intervention* of repulſions acting at a diſtance.—May not this obtain, even in the points in which we ſuppoſe the two balls actually to touch, in the act of impulſion?

53
Many caſes of doubtful contact.

But farther—Every perſon has obſerved the brilliant dew-drops lying on the leaves of plants. Every perſon acquainted with Newton's optical diſcoveries, muſt be convinced that the dew-drop is not in mathematical contact with the leaf; if it were, it could have no brilliancy. Moſt perſons have obſerved the rain drops of a ſummer ſhower fall on the ſurface of water, and roll about for a few ſeconds, exhibiting the greateſt brilliancy. They cannot, therefore, be in mathematical contact with the water. There muſt be a ſmall diſtance between them, and therefore ſome force which keeps them aſunder, and carries the weight, that is, counteracts the downward preſſure of the rain-drop. We know that ſome inſects with long legs can run about on the ſurface of water; and if we lift them carefully, and ſet them on glaſs, their feet do not wet it. Put a little ſpirit of wine into this water, and make it lukewarm, and the inſect inſtantly ſinks up to the belly, and cannot move about as before: Its feet will now wet a glaſs. A well-poliſhed ſteel needle, even of conſiderable ſize, if perfectly clean and dry, will float on water without being wetted: It is obſerved to make a conſiderable, depreſſion on the ſurface of the water, juſt as a heavy bar of iron would make when laid on a feather-bed—the needle diſplaces a quantity of water equal to itſelf in weight, yet does not touch it, for it is not wetted. If it be previouſly wetted, it will not diſplace any water, and will not float. There is ſomething, therefore, which keeps the water at a diſtance from the feet of the inſect, and from the needle, exerting a certain upward preſſure on them. The preſſure and the reaction are indeed very ſmall; but they would produce a very ſenſible motion if continued ſufficiently long in proper circumſtances. Here would be a production of motion, which moſt perſons would call an impulſion—yet there would be no ſtroke, no contact, and therefore no true impulſion.

We now beg the reader to attend minutely to Newton's famous experiment with the object glaſſes of long teleſcopes, which we have mentioned circumſtantially in the article OPTICS, *Encycl.* n° 63—68.

54
Very remarkable caſe of convex lenſes falſely ſeeming to touch.

When the upper glaſs is very thin and light, no colour appears at the point of contact: but by preſſing it down with ſufficient force, we ſhall have a black or unreflecting ſpot in the middle, ſurrounded by a ſilvery ring, and then by a ſeries of rings of various colours, according to the diſtance between the parts of the glaſſes where the colours appear. Newton has counted 50 of theſe rings. He ſhews, by a careful computation from the known figure of the glaſſes, that the differences between the diſtances which exhibit theſe colours are all preciſely equal, and that each is about $\frac{1}{8900}$ of an inch. Therefore, ſuppoſing that the glaſſes are in mathematical contact where the unreflecting ſpot appears, making one continuous maſs of glaſs, their diſtance at the outermoſt ring muſt not be leſs than $\frac{50}{9000}$ of an inch, or $\frac{1}{180}$ of an inch. Therefore, when

Impulſion.

when one glaſs carries the other, without any appearance of colour at the middle, we muſt conclude that there is a repulſion exerted between the neareſt parts, at a diſtance not leſs than $\frac{1}{180}$ of an inch, ſufficient for ſupporting the upper glaſs. It requires an increaſe of preſſure to produce the firſt appearance of colour; and when the preſſure is ſtill more increaſed, new colours appear in the middle, and the colour formerly there is now ſeen in a ſurrounding ring; theſe multiply continually, by new ones ſpreading from a central ſpot. A great preſſure at laſt produces the unreflecting ſpot in the centre, which, unlike to all the coloured ſpots which had emerged in ſucceſſion, is ſharply defined, and never round, but ragged, and it is immediately ſurrounded by a bright ſilvery reflection. The ſhape of this ſpot depends on the figure of the ſurfaces; for, on turning the upper lens a little round its axis, the inequalities of the edge of the ſpot turn, in ſome degree, with it. This ſeemingly trifling remark will be found important by the mechanician: A ſtill farther increaſe of preſſure enlarges the unreflecting ſpot, and the dimenſions of all the rings—When the preſſure is gradually withdrawn, the rings ſhrink in their dimenſions, the unreflecting ſpot diſappears firſt, and each ring in ſucceſſion contracts into a ſpot, and vaniſhes. Here we have, by the way, an explanation of the brilliancy of dew-drops: they come ſo near, perhaps, that the neareſt point reflects the ſilvery appearance—but they do not touch; the inſtant that they touch a wetted part, making one maſs of tranſparent matter, all brilliancy is gone.

55 They repel each other;

Here then are inconteſtible proofs of a force, be its origin what it may, which keeps the glaſſes aſunder, and even cauſes them to ſeparate; which manifeſts itſelf by withſtanding preſſure; and therefore is, itſelf, a preſſure, or equivalent to a preſſure—It varies in its intenſity by a change of diſtance; but we have not been able to aſcertain by what law. It muſt not be meaſured by the ſimple variation of the external preſſure; for ſince we ſee that, even before any colour appears in the centre, the weight of the upper lens is ſupported, we muſt conclude that the glaſſes are exerting at leaſt an equal force all around the circumference of the outermoſt ring. It is evident, that the computation of the whole force, exerted over all the coloured ſurface, muſt be difficult, even on the ſimpleſt hypotheſis concerning the law of repulſion: we can only ſay that it increaſes by a diminution of diſtance. It is very eaſy to compute the increaſe of external preſſure, which would ſuffice if the repelling force were equal at all diſtances; or if it varied according to any ſingle power of the diſtances. We have tried the inverſe ſimple, duplicate, and triplicate ratio; but the fact deviated widely from them all. The repulſion does not change nearly ſo much as in the ſimple inverſe ratio of the diſtances, if the glaſſes be ſuppoſed to touch in the whole ſurface of the unreflecting ſpot. But we found, that if we ſuppoſe them ſeparated, though at a diſtance equal to forty times the difference of diſtance at which the colours change, that is, $\frac{1}{121}$ of an inch, the preſſures employed in the experiment accord pretty well with a repulſion inverſely as the diſtance, but ſtill with a very conſiderable deviation in the great preſſures. In the courſe of a number of experiments with a favourite pair of lenſes, we broke the uppermoſt by too ſtrong a preſſure. We then cut out of it, with a lapidary's hollow drill, a piece of $\frac{1}{4}$ of an inch in diameter, and perfectly round, and we ſqueezed it on the other by a meaſured preſſure, till we produced a colourleſs ſpot of nearly $\frac{1}{8}$th of an inch in diameter, with a ſilvery margin. Computing from this, we thought ourſelves warranted to ſay, that not leſs than 800 pounds are neceſſary for producing a black ſpot of one inch ſquare!

56 And may impel without touching

Now, what is the conſequence of all this in the doctrine of impulſion? Surely this:—If a lump of this glaſs ſtrike another lump, and put it in motion, and if the mutual preſſure in the act of colliſion do not exceed 700 pounds on the ſquare inch, the motion has been produced without mathematical contact, and the production can no more be called impulſe than the motion of the magnet in our firſt experiment. The changes of motion have been the operation of moving forces, ſimilar to the force of magnetiſm; and if a ſtream of truly impelling fluid be neceſſary for producing the motion of the magnet, it is equally neceſſary for producing the motion of the piece of glaſs.

It may be ſaid here, that we cannot compare impulſe and preſſure. A ſlight blow will ſplit a diamond which could ſupport a houſe. A ſlight blow may therefore be enough for exciting all the preſſure neceſſary for producing mathematical contact. We muſt here appeal to what every man feels on this occaſion. We doubt exceedingly whether any perſon will think that, when one piece of glaſs gives another a gentle blow, and puts it into motion, with the velocity of a few inches per ſecond, a blow which he diſtinctly hears, there has been exerted a preſſure at all approaching to 800 pounds per ſquare inch.—We have ſuſpended a pair of lenſes, by an apparatus ſo ſteady and firm, that they could touch only at the centres of each ſurface; and, having placed ourſelves properly, we could ſee, with ſufficient diſtinctneſs, the momentary appearance of the coloured ſpot at the inſtant of colliſion. We ſaw this, with the fulleſt confidence that it was of no conſiderable breadth in a moderate ſtroke, and that it was very ſenſibly broader when the ſtroke was more violent. We did not truſt our own eye alone, but ſhewed it to perſons ignorant of philoſophy, and even to children, often without telling them what to look for, but aſking them what they ſaw. From all the information that we could gather, none of the preſſures came near to what muſt have been neceſſary for producing the black ſpot. This could not be miſtaken: for although the outer rings are but faint, there are five or ſix near the centre which are abundantly vivid for affecting the eye by the momentary flaſh. Beſides, the dimenſions of the lenſes, and the weight of the metal cells in which they were fixed, were ſuch as muſt have cauſed them to ſplit before the black ſpot could be produced in the centre.

And certainly do ſo, even in violent ſtrokes.

Theſe things being maturely conſidered, we imagine that few perſons will now doubt the juſtice of our aſſertion, that in all theſe examples, the motions have been produced without mathematical (or rather geometrical) contact.—And we imagine alſo, that few will refuſe granting that this is not peculiar to glaſs, but obtains alſo in the colliſion of other bodies. We have not thought of any method for putting this beyond doubt; but we have better reaſons than mere likelihood for being of this opinion. Every one acquainted with the

Newtonian diſcoveries in optics, knows that this curious appearance of the coloured rings is the conſequence of the action of tranſparent bodies on the rays of light, by which theſe are bent aſide from their rectilineal courſe, and that this deflection takes place at a diſtance from the diaphanous body; a diſtance which the ſagacity of the great philoſopher has enabled us to meaſure. Now, it is known that metals and other opaque bodies produce the very ſame deflections of the rays, bending them toward themſelves at one diſtance, and from them at other diſtances; in ſhort, attracting or repelling them as the diſtance varies. Nothing but prepoſſeſſion can hinder a perſon from aſcribing ſimilar effects to ſimilar cauſes, and, therefore, thinking it almoſt certain that this mutual repulſion is not peculiar to glaſs, but common to all ſolid bodies.

To all this we may ſurely add the celebrated experiment of Mr Huyghens; in which it is evident, that a ſmooth plate of metal attracts another, even although there be a ſilk fibre interpoſed between them. (See *Phil. Tranſ.* n° 86.) Is it not highly probable, that at a ſmaller diſtance the bodies repel each other? For we obſerve, that metals, as well as tranſparent bodies, attract the rays at one diſtance and repel them at another.

57 Impulſion is not ſo familiar as is believed.

Surely our readers will now grant, that the production of motion by impulſion, as diſtinguiſhed from the production by action *e diſtanti*, is not ſo familiar a phenomenon as was imagined, and that it may even be ſaid to be rare in compariſon: for the inſtances of moderate impulſes are numberleſs. The claim of this mode of explaining difficult phenomena by impulſion, has therefore loſt much of its force; and we ſee much leſs reaſon for calling in the aid of inviſible fluids, in order to *explain* the action of gravity, magnetiſm, and electricity.

58 Still greater doubts. Obſervations on a ſoap bubble.

But we have ſtill more important information from the optical diſcovery of Newton. Let the reader turn again to Optics, *Encycl.* n° 65, and read the account of the phenomena exhibited by the ſoap-bubble. The bubble is thinner and thinner as we approach the very uppermoſt point of it. It alſo exhibits numerous rings, which vary in their colour, in the ſame order as in the ſpace between the lenſes. Theſe rings come to view in the ſame manner. Firſt, a coloured ſpot appears in the ſummit of the bubble; this becomes a ring, and is ſucceeded by another ſpot, as the bubble grows thinner in that part, by the gradual ſubſiding of the watery film. At laſt a black ſpot appears at top, well defined, but of irregular ſhape, ſurrounded by a ſilvery ring. This ſpot, when viewed very narrowly, is obſerved to reflect a very minute portion of light, without *ſeparating* the differently colorific rays of which it conſiſts; but it *contains* them all, as may be proved by viewing it through a priſm. After ſome little time the bubble burſts.

Surely we muſt infer from this, that there is a certain thickneſs of the tranſparent plate which renders it unfit for the vivid reflection of light. Does it not legitimately follow from this, that the unreflecting ſpot between the lenſes ceaſes to entitle us to ſay, that they are in contact in that place? All that we can conclude from its appearance is, that the diſtance ſtill between the glaſſes is too ſmall to fit the place for the vivid reflexion of light. This concluſion is indiſputable. Were it refuſed, we are furniſhed with an inconteſtible proof by the ſame bountiful hand. Newton aſcribed the colours to the reflection of the plate of air between the glaſſes, and expected the ceſſation of them when the air is removed. His friend Mr Boyle had lately invented a commodious air pump. The trial was made, and young Newton found himſelf miſtaken; for the colours ſtill appeared, and he even thought them more brilliant. He then tried the effect of water, expecting that this would diminiſh their luſtre. So it did; and he found that the dimenſions of the rings were diminiſhed in the proportion of 4 to 3; namely, the proportion of the refractions of glaſs and water. By this time Newton had diſcovered the curious mechanical relation between bodies and the rays of light; and his mind was wholly abſorbed by the diſcovery, and by the revolution he was about to make in the mathematical doctrines of optics. Unfortunately for us, he did not, at that time, attend to the mighty influence which the diſcovery would have on the whole of mechanical philoſophy, and therefore occupied himſelf only with ſuch phenomena as ſuited his preſent purpoſe. A moſt important phenomenon paſſed unnoticed. In repeating Sir Iſaac Newton's experiments, we found that the diameters of the rings decreaſed in the proportion of 4 to 3 only in certain circumſtances. When the upper lenſe was preſſed on the other by a heavy metal ring, ſo as to produce three or four coloured rings, we found that when water got between them, ſometimes no colours whatever appeared; ſometimes there was a ring or two, and the diameters were diminiſhed in a much greater proportion than Newton had aſſigned. Well aſſured of the extreme nicety of all his proceedings, we were much puzzled with this diſcrepancy, and mentioned it to a moſt reſpectable and intelligent friend, the late Dr Reid of the univerſity of Glaſgow, a mathematician and naturaliſt of the firſt rank. He thought it not improbable that the glaſſes ſeparated from each other, lifting up the weight, by attracting the water into the interſtice, in the ſame manner that we obſerve wood to ſwell with moiſture. We immediately got an apparatus which compreſſed the glaſſes by means of four ſcrews; and now we ſaw Newton's proportion moſt ſtrictly obſerved. But in proſecuting the experiment, we found that the introduction of the water *always* effaced a very ſmall ſpot. This happened after precautions had been taken to prevent all ſeparation of the glaſſes. As the proportion of 4 to 3 has a relation to refractive power, although we have not been able to deduce it as a neceſſary conſequence, we nevertheleſs conſidered it as a ſufficient proof that the diſtances of the glaſſes *had not changed* by introducing the water between them. Therefore we think ourſelves well entitled to conclude, that the diſappearance of the black ſpot was not owing to a ſeparation of the glaſſes, which admits the water into the empty ſpace; and we affirm, that before the entry of the water, there was room for it in the place which reflected no light; that is, that although the glaſſes were preſſed together with a very great force, they were not in contact.

Remark.

It deſerves remark, that in endeavouring to produce the black ſpot, when water is between the glaſſes, we found great and unaccountable anomalies. Sometimes a moderate increaſe of preſſure produced it, and ſometimes we were not able to produce it by any preſſure.

Several lenſes were broken in the trial. We are led to think that the thickneſs which gives the ſilvery reflection is much greater than the 8900th part of an inch, and that it is not the ſame in all glaſſes. But we were interrupted in theſe experiments, and indeed in all active purſuits, by bad health, which has never permitted their renewal. The ſubject is of great importance to the curious mechanicians, and we earneſtly recommend it to their attention. There is ſomething very remarkable in the abrupt ſenſation of the coloured reflection. At a certain thickneſs *all* colours are reflected, without ſeparation, producing the whiteneſs of ſilver. The ſmalleſt diminution of it hinders the *vivid* reflection of *all* colours, and then there ſeems to ſucceed a thickneſs which equally reflects a ſmall proportion of *all* without ſeparation. The fineſt poliſh that can be given to glaſs in the tool of the artiſt, leaves irregularities which occaſion the irregular ragged figure of the ſpot. It is worth trying, whether ſmoothing the ſurfaces (both) by a ſoftening heat will remove this ruggedneſs. If it does, without deſtroying the ſharp termination, it will prove the abrupt paſſage from *eſſe* to *noneſſe*.

The laſt remark to be made on this important experiment in optics is, that the diſtance between the glaſſes which is unfit for vivid reflection, cannot be determined by means of the other meaſurable intervals. It may be equal to many of them taken together. The ſame muſt be granted with reſpect to the thickneſs of the black ſpot on the top of the ſoap bubble. We attempted to meaſure this thickneſs by letting a drop (of a known weight) of ſpirit of turpentine ſpread on the ſurface of water. As it ſlowly enlarged in ſurface, it decreaſed in thickneſs, and produced, in regular order, ſeveral of the more compounded colours of the Newtonian ſeries. But before it came to the 20th ring from the centre, it became very irregular and ſpotty.

59 Contact is not proved in colliſion.

The inference to be drawn from this combination of the two optical facts is remarkable and important. It is, that we have no authority for affirming that the changes of motion by the colliſion of bodies is brought about by abſolute contact in any inſtance whatever. The glaſſes are not in contact where there is vivid reflection; and we have no proof that they are in contact in the black ſpot, however great the compreſſion may be.

60 Therefore impulſion cannot explain gravitation;

It is hardly neceſſary now to ſay, that all attempts to explain gravitation, or magnetiſm, or electricity, or any ſuch apparent action at a diſtance by the impulſions of an unſeen fluid, are futile in the greateſt degree. Impulſion, by abſolute contact, is ſo far from being a familiar phenomenon, that it may juſtly be queſtioned whether we have ever obſerved a ſingle inſtance of it. The ſuppoſition of an inviſible impelling fluid is not more gratuitous than it is uſeleſs; becauſe we have no proof that a particle of this fluid does or can come into contact with the body which we ſuppoſe impelled by it, and therefore it can give no explanation of an action that is apparently *e diſtanti*.

61 But impulſion may be explained by continued preſſure.

The general inference from the whole ſeems to be, that, inſtead of explaining preſſure by impulſe, we muſt not only derive all impulſe from preſſure, but muſt alſo aſcribe all preſſure to action from a diſtance; that is, to properties of matter by which its particles are moved without geometrical contact.

This collection of facts conſpires, with many appearances of fluid and ſolid bodies, to prove that even the particles of ſolid, or ſenſibly continuous bodies, are not in contact, but are held in their reſpective ſituations by the balance of forces which we are accuſtomed to call attractions and repulſions. The fluidity of water under very ſtrong compreſſions (which have been known to compreſs it $\frac{1}{12}$th of its bulk), is as inconſiſtent with the ſuppoſition of contact as the fluidity of air is. The ſhrinking of a body in all its dimenſions by cold, nay, even the bending of any body, cannot be conceived without allowing that *ſome* of its ultimate unalterable atoms change their diſtances from each other. The phenomena of capillary attraction are alſo inexplicable, without admitting that particles act on others at a diſtance from them. The formation of water into drops, the coaleſcence of oil under water into ſpherical drops, or into circular ſpots when on the ſurface, ſhew the ſame thing, and are inexplicable by mere adheſion. In ſhort, all the appearances and mutual actions of tangible matter concur in ſhewing, that the atoms of matter are endowed with inherent forces, which cauſe them to approach or to avoid each other. The opinion of Boſcovich ſeems to be well founded; namely, that at all ſenſible diſtances, the atoms of matter tend toward each other with forces inverſely as the ſquares of the diſtances, and that, in the neareſt approach, they avoid each other with *inſuperable* force; and, in the intermediate diſtances, they approach or avoid each other with forces varying and alternating by every change of diſtance. See the article Boscovich, *Suppl.*

62 Phyſical contact explained.

From all that has been ſaid, we learn that phyſical or ſenſible contact differs from geometrical contact, in the ſame manner as phyſical ſolidity differs from that of the mathematician. Euclid ſpeaks of cones and cylinders ſtanding on the ſame baſe, and between the ſame parallels. Theſe are not material ſolids, one of which would preſs the other out of its place. Phyſical contact is indicated, immediately and directly, by our ſenſe of touch; that is, by exciting a preſſure on our organ of touch when it is brought ſufficiently near. It is alſo indicated by impulſion; which is the immediate effect of the preſſure occaſioned by a ſufficient approximation of the body impelling to the body impelled. The impulſion is the completion of the ſame proceſs that we deſcribed in the example of the magnets; but the extent of ſpace and of time in which it is completed is ſo ſmall that it eſcapes our obſervation, and we imagine it to be by contact and in an inſtant. We now ſee that it is ſimilar to all other operations of accelerating or retarding forces, and that no change of velocity is inſtantaneous; but as a body, in paſſing from one point of ſpace to another, paſſes through the intermediate ſpace; ſo, in changing from one velocity to another, it paſſes through all the intermediate degrees without the ſmalleſt *ſaltus*.

We thus avoid many abſurdities.

And in this way is the whole doctrine of impulſion brought within the pale of dynamics, without the admiſſion of any new principle of motion. It is merely the application of the general doctrines of dynamics to caſes where every accelerating or retarding force is oppoſed by another that is equal and contrary. We have found that the opinion, that there is inherent in a moving body a peculiar force, by which it perſeveres in motion, and puts another in motion by ſhifting into it, is as uſeleſs as it is inconſiſtent with our notions of motion and of moving forces. The impelled body is moved by the inſuperable repulſion exerted by all atoms of matter when brought ſufficiently near. The retardation of the impelling body does not ariſe from an *inertia*, or reſiſting ſluggiſhneſs of the body impelled, but becauſe this body alſo repels any thing that is brought ſufficiently near to it. We can have no doubt of the exiſtence of ſuch cauſes of motion. Springs, expanſive fluids, cohering fibres, exhibit ſuch active powers, without our being able to give them any other origin than the FIAT of the Almighty, or to comprehend, in any manner whatever, how they reſide in the material atom. But once we admit their exiſtence and agency, every thing elſe is deduced in the moſt ſimple manner imaginable, without involving us in any thing incomprehenſible, or having any conſequence that is inconſiſtent with the appearances. Whereas both of theſe obſtructions to knowledge come in our way, when we ſuppoſe any thing analogous to force inherent in a moving body ſolely becauſe it is in motion. It forces us to uſe the unmeaning language of force and motion paſſing out of one body into another; and to ſpeak of force and velocity as things capable of diviſion and actual ſeparation into parts. The force of inertia is one of the bitter fruits of this miſconception of things. It is amuſing to ſee how metaphyſicians of eminence, ſuch as D'Alembert, endeavour to make its operations tally with acknowledged principles. In his celebrated work on dynamics, the moſt elaborate of all his performances, he explains how a body, whoſe maſs is 1, moving with the velocity 2, muſt ſtop another body whoſe maſs is 2, moving with the velocity 1, in the following manner: He ſuppoſes the velocity 2 to conſiſt of two parts, and that, in the inſtant of colliſion, one of the parts deſtroys the motion of one half of the other body, and then the other part deſtroys the motion of the other half. Theſe are words; but in vain ſhall we attempt to accompany them by clear conceptions. His diſtinction between the force of inertia and what he calls the active forces of bodies, ſuch as the force of bodies which ſtrike each other in oppoſite directions, is equally unſuſceptible of clear conceptions. Active forces (ſays he) abſorb a part of the motion; but when inertia takes part of the motion from the ſtriking body, this motion paſſes wholly into the body that is ſtricken, none of it being abſorbed or really deſtroyed. He demonſtrates this by the equation $A \times \overline{a - x} = B \times \overline{x - b}$, which is a mere narration of facts, but no deduction from the nature of inertia, nor even any eſtabliſhment of that nature by philoſophical argument. And in attempting to give ſtill clearer notions (being ſenſible that ſome great obſcurity ſtill hangs about it), he ſays, "Inertia therefore, and properly ſpeaking, is the mean of communicating motion from one body to another. Every body reſiſts motion; and it is by reſiſting that it receives it; and it receives preciſely as much as it deſtroys in the body which acts on it." Surely almoſt every word of this ſentence is doing violence to the common uſe of language. What can be more incomprehenſible than that a body reſiſts motion only when it receives it? Should a man be thought to reſiſt being puſhed out of his place when he actually allows another to diſplace him, and not to reſiſt when he firmly keeps his place? All theſe difficulties and puzzling queſtions vaniſh when we give over ſpeaking of inertia as ſomething diſtinguiſhable from the active forces or cauſes of motion which we find in bodies, and diſtinguiſh by the names of elaſticity, coheſion, magnetiſm, electricity, weight, &c. and which philoſophers have claſſed under one name, accelerating or retarding force, according as its direction chances to be the ſame, or the oppoſite to that of the motion under conſideration. To ſuppoſe it a *peculiar* faculty by which a body maintains its condition of motion or reſt, is contrary to every conception that we can annex to the words faculty, power, force. It is frivolous in the extreme to ſay, that ſnow has the faculty of continuing white or cold; or that it reſiſts being melted becauſe it melts, or becauſe heat muſt be employed to melt it.

63
Strongeſt argument for inertia is the compoſition of force with a previous motion.

The only argument that we know for giving the name force to the perſeverance of matter in its ſtate of motion (or rather for aſcribing this perſeverance to the exertion of a peculiar faculty), which appears to deſerve any attention, is one that we do not recollect the expreſs employment of for this purpoſe, namely, the compoſition of a previous motion with the motion which a known force would produce in the body at reſt. We know that if a body be moving eaſtward at the rate of four feet per ſecond, and a force act on it which would impel it from a ſtate of reſt at the rate of three feet per ſecond to the ſouth, the body will move at the rate of five feet per ſecond in the direction E. 36° 52′ S. We know alſo, that if a force act on this body at reſt, ſo as to give it a motion eaſtward at the rate of four feet per ſecond, and if another force act on it at the ſame inſtant, ſo as to give it a motion to the ſouth at the rate of three feet per ſecond, the body will move at the rate of five feet per ſecond in the direction E. 36° 52′ S. In this inſtance, the body previouſly in motion ſeems to poſſeſs ſomething equivalent to what is allowed to be a moving force. Why therefore refuſe it the name? The anſwer is eaſy. The term force has been applied, by all parties, to whatever produces a *change* of motion, and is meaſured by the *change* which accompanies its exertion. There is ſome difference between the parties about the way of eſtimating this meaſure; but all agree in making, not the motion, but the change of motion, the baſis of the meaſurement. Now we ſhewed, at great length, in the article DYNAMICS, that the *change* of motion, in every caſe, is that motion which, when compounded with the former motion, conſtitutes the new motion. Did we take the new motion itſelf as the characteriſtic and meaſure of the changing force, it would be different in every different previous ſtate of the body, and would neither agree with our general notion of force, nor with the knowledge that we have of the actual preſſures and other moving forces that we know. The ſole reaſon why the previous motion is equivalent with a force is, that the only mark or knowledge that we have of a moving force is the motion which it is conceived to produce. The force is equivalent with the previous motion, becauſe we know nothing of it but that motion; and the name that we give it, only marks ſome external thing to which it has an obſerved relation. We call it magnetiſm or electricity, becauſe we obſerve that a magnet or an electrified body gives *occaſion* to its appearance. We never obſerve the reſiſtance of *inertia*, except in caſes where we know, from other circumſtances, that moving forces

Anſwered.

forces inherent in bodies are really brought into action. The inertia of the ball which has been moved by a ſtroke of another, is inferred from the diminution of that other's motion. But this is occaſioned preciſely in the ſame way as the diminution of the motion of the magnet A in the firſt example; an event which every unprepoſſeſſed perſon aſcribes to the repulſion of B in the oppoſite direction, and not to its inertia.

We truſt that our readers are not diſpleaſed with this detail of the procedure of Nature in the phenomena of impulſion. It has been prolix; becauſe we apprehend, that the too ſynoptical manner in which the laws of colliſion have always been delivered, leaves the mind in great obſcurity concerning the connection of the events. General facts have been taken for philoſophical principles and elementary truths; whereas they were deductions from the ſum total of our knowledge. They were very proper logical principles for a ſynthetical diſcuſſion; but their previous eſtabliſhment as general facts was neceſſary. We have eſtabliſhed the two moſt general facts from which the reſult of every colliſion may be deduced with the utmoſt eaſe. The firſt is, that in the inſtant of greateſt compreſſion, the common velocity is $= \frac{A\,a \pm B\,b}{A + B}$; and we have ſhewn that this is applicable to the colliſion of unelaſtic bodies. The ſecond is, that the change in perfectly elaſtic bodies is double of the change in unelaſtic bodies. The *conſervatio momentorum*, and the *conſervatio virium vivarum*, are alſo general facts; or rather they are the ſame mentioned with thoſe above, conſidered in another aſpect. They may all be uſed as the principles of a ſynthetic treatiſe of impulſion; and they have been ſo employed. Each has its own advantages.

64 Principle of ſmalleſt action.

Mr Maupertuis gives a treatiſe on the Communication of Motion, that is, of impulſion or colliſion, which has the appearance of being deduced from a new principle, which he calls the PRINCIPLE OF SMALLEST ACTION. He ſuppoſes that perfect Wiſdom will accompliſh every thing by the ſmalleſt expenditure of action; and he chanced to obſerve, in the equations employed in the common doctrine of impulſion, a quantity which is always a minimum. He chooſes to conſider this as the expreſſion of the action.

His principle or axiom, deduced from the perfect wiſdom of God, is thus expreſſed: "When any change happens in nature, the quantity of action neceſſary for it is the ſmalleſt poſſible." And then he adds,

"In mechanical changes, the quantity of action is the product of the quantity of matter in the body by the ſpace paſſed over, and by the velocity of the motion." This is evidently the meaſure adopted long before by Leibnitz (ſee *Phil. Tranſ.* vol. xliii. p. 423, &c.), and it is equivalent to $m\,v^2$; becauſe the ſpace multiplied by the velocity is as the ſquare of either. We refer to Dr Jurin's remarks on this paſſage for proof that this is by no means a juſt meaſure of action; and only obſerve here, that we can form no other notion of velocity than that of a certain ſpace deſcribed in a given time. The change produced is not the actual deſcription of a line, but the determination to that motion. It is in this reſpect alone that the condition of the body is changed; and therefore the product $m\,v$, and not $m\,s\,v$, is the proper meaſure of the action. On the authority of this maxim of divine conduct, Maupertuis inveſtigates the reſults which will make this quantity a minimum, and aſſerts that theſe *muſt* be the laws of colliſion. Luckily this inveſtigation is extremely ſimple, and very neat and perſpicuous; and it gives very eaſy ſolutions. For example, the unelaſtic body A, moving with the velocity a, overtakes the unelaſtic body B, moving with the velocity b. Both move after the colliſion with the velocity x. This velocity is required. To determine this, we muſt make $A \times \overline{a - x}|^2 + B \times \overline{x - b}|^2$ a minimum; or $A\,a^2 - 2\,A\,a\,x + A\,x^2 + B\,x^2 - 2\,B\,b\,x + B\,b^2$ is a minimum. Therefore $- 2\,A\,a\,\dot{x} + 2\,A\,x\,\dot{x} + 2\,B\,x\,\dot{x} - 2\,B\,b\,\dot{x} = 0$, or $2\,A\,a + 2\,B\,b = 2\,A\,x + 2\,B\,x$, and $x = \frac{A\,a + B\,b}{A + B}$; as we have already ſhewn it to be.

The amiable and worthy author grew more fond of his theory, when he ſaw what he imagined to be its influence extended to an immenſe variety of the operations of nature. Euler demonſtrated, that the quantity called *action* by Maupertuis was a minimum in the planetary motions, and indeed in all curvilineal motions in free ſpace. But all the while, this principle of leaſt action is a mere whim, and the formula which is ſo generally found a minimum has no perceptible connection with the quantity of action. In many caſes to which Maupertuis has applied it, the concluſions are in direct oppoſition to any notion that we can form of the economy of action. Nay, it is very diſputable whether it does not, on the contrary, expreſs the greateſt want of economy; namely, a minimum of effect from a given expenditure of power. In the caſe of impulſion, this minimum is the mathematical reſult of the equality and oppoſition of action and reaction. Maupertuis might have pleaſed his fancy by ſaying, that it became the infinite wiſdom of God to make every primary atom of matter alike; and this would have anſwered all his purpoſe.

65 Enquiry into the diſtribution of impulſe from the point that is ſtruck.

There ſtill remains to be conſidered a very material circumſtance in the doctrine of impulſion, which produces certain modifications of the motions that are of mighty practical importance. We have contented ourſelves with merely ſtating the moving force that is brought into action in the points of phyſical contact; but have not explained how this produces the progreſſive motion of every particle of the impelled body, and what motion it really does produce in the remote particles. A body, beſides the general progreſſive motion which it receives from the blow, is commonly obſerved to acquire alſo a motion of rotation, by which it whirls round an axis. It has not been ſhewn, that when a body has received an impulſe by a blow in a particular direction on one point, it will proceed in that direction, or in what direction it will proceed. Experience ſhews us, that this depends on circumſtances not yet conſidered. The billiard player knows, that by a ſtroke in one direction he can make his antagoniſt's ball move in a direction extremely different.

Theſe are queſtions of great intricacy and difficulty, and would employ volumes to treat them properly. We have already enlarged this article till we fear that we have exhauſted the reader's patience, and deviated from the proportion of room juſtly allowable to IMPULSION. We muſt therefore limit our attention to ſuch things only as ſeem elementary, and indiſpenſably neceſſary

ceſſary for a uſeful application of the doctrine of impulſion.

With reſpect to the *direction* of the motion produced by impulſion, the very example juſt now borrowed from billiard playing, ſhews that it is important, and by no means obvious. We are ſorry to ſay, that we have nothing to offer in ſolution of this queſtion that will be received by all as demonſtration. It is comprehended in the following propoſition, which we bring forward merely as a matter of fact.

66
Action of bodies by contact is perpendicular to the touching ſurface.

The direction of the ſtroke or preſſure exerted by two bodies in phyſical contact, is always perpendicular to the touching ſurfaces. Of this truth we have a very diſtinct and pretty example and proof by the billiard table. If two balls A and B (fig. 2.) are laid on the table in contact, and A is ſmartly ſtruck by a third ball C in any direction Cc, ſo that the line aA, which joins the point of contact a with the centre A, may make an obtuſe angle with the line AB, joining the centres of the two balls, the ball B will always fly off in the direction ABF. The preſſure on B, which produces the impulſion, is evidently exerted at the point b of contact, and the direction BF is perpendicular to the plane GbH, touching both balls in the point b. The primary ſtroke is at a, and acts in the direction aA, although C moved in the direction Cc. Had A been alone, it would have gone off in the direction aA produced. But the force acting in the direction aA is equivalent to the two forces ad and dA, of which dA preſſes the ball on B at b, and produces the motion. In like manner, another ball E, ſo laid that bBe is obtuſe, will fly off in the direction ED, which may even be oppoſite to Cc. Theſe are matters of fact; not indeed preciſely ſo, becauſe billiard balls are not perfectly elaſtic, reſtoring their figure with a promptitude equal to that of their compreſſion; and alſo becauſe there is a little friction, by which the point a of the ball A is dragged a little in the direction of C's motion. This may both give a twirl to A, and diminiſh its preſſure on B. The general reſult, however, is abundantly agreeable to the doctrines now delivered. But we wiſh to ſhew on what properties of tangible matter this depends; and although we dare not hope for implicit belief, we expect ſome credit in what we ſhall offer.

Demonſtration.

We have evident proof, that at a diſtance which is not unmeaſureable by its minuteneſs, and certainly far exceeds the 900th part of an inch, bodies repel each other with very great force. This diſtance alſo far exceeds the diſtance between the particles, if theſe are diſcrete. Let mn (fig. 3.) be the diſtance at which a particle repels another, and let P be a particle ſituated at a leſs diſtance than mn from the ſurface AC of a ſolid body. With a radius PA, equal to mn, deſcribe a ſegment of a ſphere ABC, and draw PB perpendicular to AC. It is plain that every particle of matter in the ſegment ABC repels the particle P, and that it is not affected by any more. Let D be any ſuch particle. It repels P in the direction DP. But there is another particle d ſimilarly ſituated on the other ſide of PB. This will repel P with equal force in the direction dP. Therefore the two particles D and d will produce a joint repulſion in the direction BP. The like may be ſaid of every particle and its correſponding one on the other ſide of PB. Therefore the joint repulſion of all the matter in the ſegment will have the direction BP. It is plain, that the radius of curvature of every ſenſible figure may be conſidered as immenſely great in compariſon of mn; and therefore the propoſition is manifeſt.

This is a propoſition of very great importance to the artiſt and the engineer, as well as to the philoſopher. In all the connections of engines and machines, the mutual action is regulated by this fact. The mutual preſſure at the contacts of the teeth of wheels and pinions depend ſo much on it, that it is eaſy to make them of ſuch a ſhape that they ſhall produce no force whatever that is of any ſervice; and it requires a ſkilled attention to their forms to obtain the ſervice we want. This will be conſidered with ſome care in the article MACHINE.

Having thus diſcovered the *direction* of the real impulſion, and that it may be very different from that of the force exerted, we proceed to conſider what will be the direction and velocity of the motion, and whether it will be accompanied with any rotation.

67
A ſtroke, whoſe action paſſes through the centre of a poſition of ſolid body, impels it without rotation.

Our readers are acquainted with the elementary mechanical property of the centre of gravity. If a body be ſupported at this point by a force acting vertically upwards, and equal to the united weight of every particle of matter in it, it will not only remain at reſt, but will have no tendency to incline to either ſide; that is, the upward force balances the weight of the whole body, and the mechanical momenta of all the heavy particles balance each other, like the weights in the ſcales of a ſteelyard. That this may be the caſe, we know that if the weight of every particle be multiplied into the horizontal lever by which it hangs (which is a line drawn from the particle perpendicular to a vertical plane paſſing through the centre of gravity), the ſum of all the products on one ſide muſt be equal to the ſum of all the products on the other ſide. Therefore, if we ſuppoſe the particles all equal, and repreſent each by unity, the ſums of all the perpendiculars themſelves muſt be equal. How is this balancing effected? Every particle tends downwards with a certain force. It muſt therefore be kept up by a force *preciſely* equal and oppoſite. This muſt be propagated to the particle by means of the connecting corpuſcular forces. The force propagated to any particle is equal and oppoſite to the force acting on that particle, which it balanced; and if not balanced, it would produce a motion equal and oppoſite to that produced by the other force. Gravity would cauſe every particle to deſcend equally; therefore the force which, by acting on one point, excites thoſe balancing forces on each particle, would cauſe them to move equally upwards. And ſince this is true in *any* attitude of the body, it follows, that a force acting in *any* direction through the centre of gravity, will cauſe all the particles to move in that direction equally; that is, without rotation.

Hence we learn, that when the direction of the ſtroke given to any body paſſes through the centre of gravity, the body will move in that direction without any rotation. If the quantity of matter, or number of equal particles in the body, be m, the moving power P will impreſs on each particle an accelerating force f, equal to the mth part of P. Therefore $f=\frac{P}{m}$, and $P=mf$. An accelerating force is eſtimated by the velocity v, which

which it generates by acting uniformly during ſome time t, or $v = f\,t$, and $\dot{f} = \frac{v}{t}$, and $P = m\,\frac{v}{t}$, and $v = \frac{P}{m}\,t$. The ſymbol t may be omitted, if we reckon every force by the velocity which it can produce in a ſecond. Thus may all forces be compared with gravity, by taking 32 feet for the meaſure of gravity. Then $m\,v$ will expreſs the number of pounds which give a preſſure equal to the force under conſideration. Thus if the force can generate the velocity 48 feet per ſecond in 100 pounds of matter, by acting on it uniformly during a ſecond, its preſſure is equal to the weight of 150 pounds.

This is *direct* IMPULSION.

When a body A, moving with the velocity a, overtakes or meets a body B, moving with the velocity b, and the line perpendicular to their touching ſurfaces paſſes through the centres of both in the direction of their motion, all the circumſtances of the colliſion are determined by the rules already laid down. This is called DIRECT IMPULSE; and it is this which admits the application of the ſimple doctrines of impulſion, deduced, as we have done it, from the action of accelerating forces. All that was ſaid of the changes of motion produced in the magnets obtain here without any farther modification.

We may juſt be allowed to take notice of a curious obſervation of Mr Huyghens on the colliſion of perfectly elaſtic bodies. Inſtead of impelling the elaſtic ball C by the ſtroke of the elaſtic ball A, we may cauſe A to ſtrike an intermediate ball B (alſo perfectly elaſtic), which is lying in contact with C. In many caſes, the ball B will not ſtir ſenſibly from its place, and C alone will fly off. Nay, if a long row of equal billiard balls lie in contact, and one of the extreme balls be hit by another ball in the direction of the row, only the remote ball of the row will fly off. All this is eaſily ſeen and underſtood, by conſidering them as bodies mutually repelling, and placed at the limits of their mutual action. Or even ſuppoſing them elaſtic balls, at a very ſmall diſtance from each other: The ball employed to ſtrike the firſt comes to reſt, and the ſtriken ball moves off with its velocity: It ſtrikes the ſecond ball of the row, and is brought to reſt: The ſecond ſtrikes the third, and is brought to reſt: And this goes on in ſucceſſion to the laſt, which is the only one that *can* fly off. The curious obſervation of Mr Huyghens is, that a greater velocity will be communicated by a large ball to a ſmall one, if we employ the intermedium of another ball of a ſize between the two; and that the velocity will be the greateſt poſſible when the intermediate ball is a mean proportional (geometrical) between the two. This is alſo eaſily deduced from the ſimilar attention to the action of the accelerating forces, or from the ſuppoſition of ſucceſſive impulſes. From this it alſo follows that a greater velocity will be produced by the intervention of two, three, or more, mean proportionals.

68
Oblique IMPULSION.

But the direction of the ſtroke may not be the ſame with that of the motion. This is called OBLIQUE IMPULSE. The caſes of oblique colliſions are extremely different, according to the directions of the motions; and the reſults are, in many of them, far from being obvious. But we have not room for a particular treatment of them. We ſhall therefore avail ourſelves of ſome of the general facts mentioned above, by means of which we may reduce all the varieties to ſome eaſy caſes. The moſt ſerviceable general facts are: 1. That the actions of bodies on each other depend on their relative motions; and, 2. That the motion of the common centre is not changed by the colliſion. Theſe enable us to reduce all to the caſe of a body in motion ſtriking another at reſt. We have only to determine their relative motion by the propoſition in DYNAMICS, n° 67. and then to ſuperadd the common motion, which changes the relative into the true motions. Thus if two bodies A and B (fig. 4.) meet in D, deſcribing the lines AD, BD, the colliſion is the ſame as if B had remained at reſt, and A had come againſt it with the motion AB. In the mean time, the common centre of poſition has deſcribed CD. If the bodies are unelaſtic, they remain united, and proceed in the line CD produced toward E, and their common velocity will be repreſented by DE, equal to CD, if AD and BD repreſented their initial velocities If the bodies are elaſtic, they ſeparate again, and they ſeparate from the common centre in the oppoſite direction, and with the ſame velocities with which they approached it. Therefore draw a E b parallel to ACB, and make E a, E b equal to CA and CB, and then D a and D b are the paths and velocities of the bodies. All this is abundantly plain, and is a neceſſary deduction from the general principle, that the motion of the centre is not affected by any equal and oppoſite forces which connect the bodies of a ſyſtem.

69
Often accompanied by rotation.

But this great ſimplicity is not ſufficient for aſcertaining the reſults of colliſion which occur in many of the moſt important caſes. It not only ſuppoſes that AD and ED are exactly proportional to the velocities of A and B, but alſo that they meet, ſo that the plane of mutual contact is perpendicular to the line AB, and that the ſtroke on each is directed to its centre. Theſe circumſtances will not always be combined, even in the caſe of ſpherical bodies. The conſequence will be, that although the motion of the centre remains the ſame, that of the bodies may ſometimes be different. We muſt therefore give a general propoſition, which will, with a little trouble, enable the reader to determine all the motions which can take place, whether progreſſive or rotative.

70
General theorem.

Let the body A (fig. 5.), moving with the velocity V, in the direction AD, ſtrike the body B at reſt. Let F be the point of mutual contact, and bFH a plane touching both bodies in F. Draw AFP perpendicular to this tangent plane, and through G, the centre of poſition of B, draw PGC perpendicular to FP, and GI parallel to FP. Let C, in the line PG, be the ſpontaneous centre of converſion (ROTATION, *Encycl.* n° 77. &c.), correſponding to the point of percuſſion F. Join CF. Let the direction cut the tangent plane in H, and PF in A; and let AH repreſent the velocity V.

The impulſe is made at the point F, in the direction AF or FP, and the centre of poſition of the body B will advance in the direction GI, parallel to FP, the direction of the effective impulſe. But becauſe this does not paſs through the centre G, the body will advance, and will alſo turn round an axis paſſing through G, perpendicular to the plane of the lines GP, PF, and the ſpontaneous axis of converſion will paſs through

71 Efficient velocity.

ſome point C of the line PG, and will alſo be perpendicular to the ſame plane. All this has been demonſtrated in the article Rotation, n° 94, &c. Complete the parallelogram AFHE. It is plain, that the motion AH is equivalent to AE and AF. By the motion AE, A only ſlides along the ſurface of B without preſſing it, or cauſing any tendency to motion in that direction, except perhaps a little ariſing from friction. It is by the motion AF alone that the impulſe is made. Therefore let v be $= \mathrm{V} \times \frac{\mathrm{AF}}{\mathrm{AH}}$; and then $\mathrm{A} \times v$ may be called the *efficient impulſe* of the body A in the preſent circumſtances, and v the *efficient velocity*. This will be diminiſhed by the colliſion. Let x be the unknown velocity remaining in A after the colliſion, or rather in the inſtant of the greateſt compreſſion and common motion of the touching points of A and B, eſtimated in the direction FP. The effective momentum loſt by A muſt therefore be $\mathrm{A} \times \overline{v - x}$: but the ſame muſt be gained by B, and its centre G muſt move in the direction GI, parallel to FP, with this momentum; and therefore with the velocity $\frac{\mathrm{A} \times \overline{v - x}}{\mathrm{B}}$. That this may be the caſe, the point of percuſſion F muſt yield with the velocity x, becauſe the bodies are in contact. But becauſe C is the ſpontaneous axis of converſion, every particle is *beginning* to deſcribe an arch of a circle round this axis. Therefore F is beginning to move in the direction Fg, perpendicular to the momentary radius vector CF. Let Fg be a very minute arch, deſcribed in a moment of time. Draw gf perpendicular to FP. Then Ff is the motion Fg reduced to the direction FP, and will expreſs the yielding of B in the direction of the impulſe, while G deſcribes a ſpace equal to $\frac{\mathrm{A} \times \overline{v - x}}{\mathrm{B}}$, and A deſcribes a ſpace x. Therefore Fg will expreſs x. Let Pp be the ſpace deſcribed in the ſame time that Fg is deſcribed. Draw pC, cutting GK in the point I. GI is the yielding of the body B to the impulſe, and muſt therefore be equal to $\frac{\mathrm{A} \times \overline{v - x}}{\mathrm{B}}$.

The triangles Ffg and CPF are ſimilar; for the angle CFP is the complement of Ffg to a right angle: It is alſo the complement of PCF to a right angle. Therefore Fg : Ff = FC : CP. But Fg : Pp = FC : CP; becauſe the little arches Fg, Pp have the ſame angle at C. Therefore Pp = Ff, = x. It is plain, that CG : CP = GI : Pp. Therefore CG : CP $= \frac{\mathrm{A} \times \overline{v - x}}{\mathrm{B}} : x$, and $x = \frac{\mathrm{A} \times \overline{v - x} \times \mathrm{CP}}{\mathrm{B} \times \mathrm{CG}}$, or $x = v \times \frac{\mathrm{A} \times \mathrm{CP}}{\mathrm{B} \times \mathrm{CG}} - x \times \frac{\mathrm{A} \times \mathrm{CP}}{\mathrm{B} \times \mathrm{CG}}$; wherefore $x \times \mathrm{B} \times \mathrm{CG} + x \times \mathrm{A} \times \mathrm{CP} = v \times \mathrm{A} \times \mathrm{CP}$, and $x \times \overline{\mathrm{B} \times \mathrm{CG} + \mathrm{A} \times \mathrm{CP}} = v \times \mathrm{A} \times \mathrm{CP}$, and $x = v \times \frac{\mathrm{A} \times \mathrm{CP}}{\mathrm{B} \times \mathrm{CG} + \mathrm{A} \times \mathrm{CP}}$, = the velocity remaining in A, eſtimated in the direction FP.

72 Unelaſtic bodies may ſeparate.

And u, the velocity with which G will advance, is $x \frac{\mathrm{CG}}{\mathrm{CP}}$; for CP : CG = P$p$: GI, = $x : u$. It is evident that A will change its direction by the colliſion: For in the inſtant of greateſt compreſſion, it was acted on by a force $= \mathrm{A} \times \overline{v - x}$ in the direction FA. This muſt be compounded with A×V, in the direction AH, in order to obtain the new motion of A; or it may be found by compounding x, which is retained by A, with FH, which has ſuffered no change by the colliſion. The bodies will therefore ſeparate, although they be unelaſtic: If they are elaſtic, we muſt double theſe changes on each. If B was alſo in motion before the colliſion, the motion of A muſt be reſolved into two, one of which is equal and parallel to the motion of B: the other muſt be employed as we have employed the motion AH.

Expreſſions ſtill more general may be obtained for x and u; namely, by taking the formulæ for the centres of converſion and percuſſion (Rotation, n° 96, 99.)

$$\mathrm{CG} = \frac{\int p r^2}{\mathrm{B} \times \mathrm{GP}}, \text{ and } \mathrm{CP} = \frac{\int p r^2 + \mathrm{B} \times \mathrm{CP}^2}{\mathrm{B} \times \mathrm{GP}},$$

where p ſtands for a particle of matter, and r for its diſtance from an axis paſſing through G perpendicularly to the plain of the lines GP and PF. In this way we obtain

$$x = v \frac{\mathrm{A} \cdot \int p r^2 + \mathrm{A} \cdot \mathrm{B} \cdot \mathrm{GP}^2}{\overline{\mathrm{A} + \mathrm{B}} \cdot \int p r^2 + \mathrm{A} \cdot \mathrm{B} \cdot \mathrm{GP}^2}$$

73 Change of progreſſive motion greateſt when the direction of the effective ſtroke paſſes thro' the centres.

It is plain from this propoſition, that the progreſſive motion of the body depends, not only on the momentum of the impelling body, but alſo on the place where the other is ſtruck: For even although the original momentum of A be the ſame, and the obliquity of the ſtroke, making v the ſame, and the body (and conſequently $\int p r^2$) alſo remain the ſame, we ſee that x and u depend on the ratio of CP to CG. Now C and P are always on oppoſite ſides of G: Conſequently, by removing the direction FP of the impulſion farther from G, we diminiſh CG and increaſe CP; and therefore increaſe the value of $x = v \frac{\mathrm{A} \cdot \mathrm{CP}}{\mathrm{B} \cdot \mathrm{CG} + \mathrm{A} \cdot \mathrm{CP}}$; and conſequently diminiſh the value of $\mathrm{A} \times v - x$, to which $\mathrm{B} \times u$ is equal. The greateſt momentum of B is produced when the direction of the impulſe paſſes through G, and no rotation is produced. Indeed we are led, by a ſort of common ſenſe, to expect this.

74 Importance of this theory to ſeamanſhip, &c.

This inveſtigation is by no means a piece of mere ſpeculative curioſity. It is the ſolution of the greateſt problem in practical mechanics. It is in this way that we muſt proceed in computing the actions of the wind and water on the ſails and hull of a ſhip. Were it not that many circumſtances concur in determining ſeveral of the preparatory ſteps, it is evident that the taſk muſt be almoſt impracticable. But the preſſure and its direction are generally determined by experiment, without the trouble of computation; and we are ſeldom ſolicitous about the ſubſequent motion of the wind or water.

75 Impulſion on bodies confined to particular paths.

There is another queſtion in impulſion which is of the firſt practical importance—namely, when the impulſe is exerted on the parts of a machine, where the body ſtruck is not at liberty to yield freely to the ſtroke, but muſt ſlide along ſome ſolid path, or turn round ſome axis, or take ſome other conſtrained motion. The operations of moſt engines depend on this. The operation of wedges, axes, and many cutting and piercing inſtruments, and the penetration of piles, impelled

GUILLOTINE PLATE XXIX.

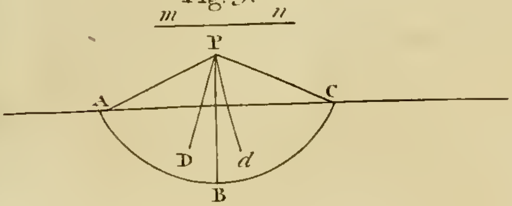

Fig. 5.

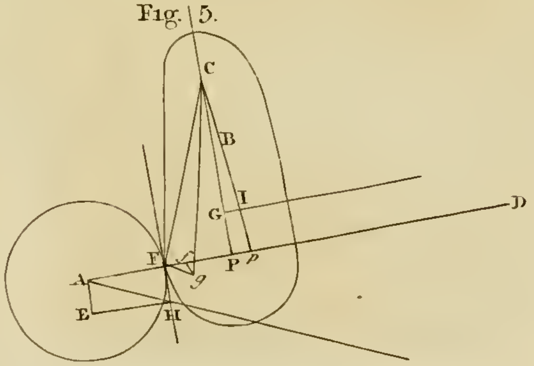

Fig. 4.

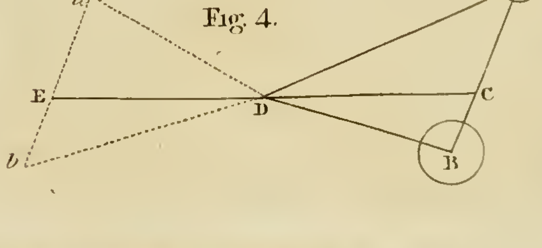

pelled by a rammer, are all aſcertained by the ſame doctrines. But the particular applications can ſcarcely be elucidated by any claſſification that occurs to us, the circumſtances of the caſe making ſuch great difference in the reſult, both in kind and degree. For example, in the ſimpleſt caſe that occurs, the driving of piles, the penetration of the pile depends, in the firſt place, on the momentum of the rammer. If the maſs of the pile be neglected, the penetration through a uniformly reſiſting ſubſtance will be as the ſquare of the velocity of the rammer (DYNAMICS, *Suppl.* n° 95.), and its abſolute quantity may be determined from a knowledge of the proportion of the weight of the rammer to the reſiſtance of the earth. But when we conſider that we have to put in motion the whole matter of the pile, we learn that a great diminution of the effect muſt take place. We ſtill can compute what this muſt be, becauſe we have the ſame momentum, with a velocity diminiſhed in a certain proportion of the ſum of the matter in the rammer and pile, to that in the rammer alone.—Another defalcation ariſes from friction, which continually increaſes as the pile goes deeper;—and a ſtill greater defalcation proceeds from the nature of the pile. If it is a piece of very dry ſtraight grained fir, it is very elaſtic, and acquires almoſt a double velocity from the ſtroke of a rammer of caſt iron. If it is moiſt and ſoft, eſpecially if it is oak, or other timber of an undulated fibre, it does not acquire ſo great velocity, and the penetration is very much diminiſhed. It is probable that a pile, headed with moiſt cork, could not be driven at all. The writer of this article found a remarkable effect of the elaſticity in the proceſs of boring limeſtone. When the boring bit was made entirely of ſteel, and tempered through its whole length to a hard ſpring temper, the workman bored three inches, in the ſame time that another bored two inches with a bit made of ſoft iron; and he would never uſe any but ſteel bits, if they could be hindered from chipping by the hammer (which muſt alſo be of tempered ſteel throughout). This has hitherto baffled many attempts. A pretty large round head, like a marlin ſpike, has ſucceeded beſt: but even this cracks after ſome days uſe. The improvement is richly worth attention; for the workman is delighted by feeling the hammer riſe in his hand after every ſtroke, and ſays that the work is not ſo hard by half. *N. B.* The ſtone cutters at Liſbon and Oporto uſe iron mallets.

76
Impulſion on machines.

The caſe of impulſion made on part of a machine moveable round an axis has been conſidered in the article ROTATION, *Encycl.* n° 72; where x is ſhewn to be $= v \times \frac{A \cdot CP^2}{\int p r^2 + A \cdot CP^2}$. But, in this formula, r denotes the diſtance of p from the point C, and not from G. $\int p r^2$ in this formula, is $B \cdot CG \cdot CP$; whereas, in the formula for a free body, where r is the diſtance of a particle from G, $\int p r^2$ is $= B \cdot CG \cdot GP$.

In the practical conſideration of this queſtion, the reader will do well to conſider the whole of that article with attention. Many circumſtances occur, which make a proper choice of the point of impulſe, and the direction of the tangent plane, of the greateſt conſequence to the good performance of the machine; and there is nothing in which the ſcientific knowledge of the engineer is of more eſſential ſervice to him. An engineer of great practice, and a ſagacious combining mind, collects his general obſervations, and ſtores them up as rules of future practice. But it is ſeldom that he poſſeſſes them with that diſtinctneſs and confidence that can enable him to communicate his knowledge to others, or even ſecure himſelf againſt all miſtakes; whereas a moderate acquaintance with theſe *elements* of real mechanics, may be applied with ſafety on all occaſions, becauſe arithmetical computations, when rightly made, afford the moſt certain of all reſults.

77
Great loſs of power by the yielding and bending of the materials.

There is a circumſtance which greatly affects the performance of machines which are actuated by impulſes, namely, the yielding and bending of the parts. When the moving power acts by repeated ſmall impulſions, it may ſometimes be entirely conſumed, without producing any effect whatever at the remote working point of the machine; and the engineer, who founds his conſtructions on the elementary theories to be had in moſt treatiſes of mechanics, will often be miſerably diſappointed. In the uſual theories, even as delivered by writers of eminence, it is aſſerted, that the ſmalleſt impulſe will ſtart the greateſt weight. But ſince impulſe is only a continued preſſure, and requires time for the tranſmiſſion of its effect through the parts of a yielding ſolid, it is plain that the motion of the impelling body may be extinguiſhed before it has produced compreſſion enough for exciting the forces which are to raiſe the remote parts of a heavy body from the ground. What blow with a hammer could ſtart a feather bed? Much oftener may we expect, that a blow, given to one arm of a long lever, will be conſumed in bending the whole of its length, ſo as to bring the remote end into action. Therefore great ſtiffneſs, and perfect elaſticity, both in the moving parts and in the points of ſupport, are neceſſary for tranſmitting the full, or even a conſiderable part, of the power of the impelling body. Perhaps not the half of the blow given by the wipers of a great forge or tilting mill to the ſhank of the hammer is tranſmitted in the *proper* inſtant of time to the hammer-head. The hammer, while it is toſſed up by the blow, is quivering as it flies. Should it reach the ſpring above it in the time of its downward vibration, it will not be returned with ſuch force as if it had hit the ſpring a moment before or after. A quarter of an inch will produce a great effect in ſuch caſes. It is found, that the minute impulſes given to the pallets of a clock or watch loſe much of their force by the imperfect elaſticity of the pendulum or balance. We muſt therefore make all the parts which tranſmit the blow to the regulating maſs of matter as continuous, hard, elaſtic, and ſtiff, as poſſible. The performance of ruby pallets is very ſenſibly weakened by putting oil on the face of them, eſpecially in the detached ſcapements, which act partly by impulſe. A wheel of hard tempered ſteel, working on a dry ruby pallet, excels all others. The intelligent engineer, ſeeing that, after all his care, much impulſion is unavoidably loſt, will avoid employing a firſt mover which acts in a ſubſultory manner, and will ſubſtitute one of continued preſſure when it is in his power. This is one chief cauſe of the great ſuperiority of overſhot water wheels above the underſhot.

We can now underſtand how it happens that Gallileo, Merſennus, and others, could compare the impulſe given

given by a falling body with the preſſure of a weight in the oppoſite ſcale of a balance, and can ſee the reaſon of the immenſe differences, yet accompanied by a ſort of regularity, in the reſults of the experiments. Galileo, Merſennus, and Riccioli, found them to be proofs that the forces of moving bodies are as their velocities; becauſe the heights from which the body fell were as the ſquares of the weights ſtarted from the ground. Graveſande found the ſame thing as long as he held the ſame opinion; but when he adopted the Leibnitzian meaſure, he found many faults in the apparátus employed in his former illuſtrations, and altered it, till he obtained reſults agreeable to his new creed. But any one who examines with attention all that paſſes in the bending of the apparatus, and takes into account the maſs of matter which muſt be diſplaced before the oppoſite arm riſes ſo far as to detach the ſpring which gives indication of the magnitude of the ſtroke, muſt ſee that the agreement is purely accidental, and may be procured for any theory we pleaſe (ſee *Graveſande's Nat. Phil.* tranſlated by Deſaguiliers, vol. i. p. 241. &c.) The propoſition, n° 95, DYNAMICS, ſuffices for explaining every thing that can happen in ſuch experiments. And it will ſhew us, that although the motion of impulſion is produced by preſſure alone, yet impulſe is incomparable with mere preſſure: It is not infinitely greater, but diſparate. A weight (which is a preſſure) bends a ſpring to a certain degree, and will derange to a certain degree the fibres of a body on which it preſſes, before it be balanced. The ſame weight, falling on this ſpring from the *ſmalleſt* height, will bend it farther, and may cruſh or ſhiver to pieces the body which would have carried it for ever. We ſhall make ſome further remarks on this ſubject, of great practical importance, under the word PERCUSSION.

78 Concluſion. THE method which we have purſued in conſidering the doctrines of impulſion, differs conſiderably from that which has generally been followed; but we truſt that it will not be found the leſs inſtructive. Although the reader ſhould not adopt our decided opinion, that we have no proof of pure impulſion ever being obſerved, and that all the phenomena which go by that name are really the effects of preſſures, analogous to gravity, he perceives that our opinion does not lead to any general laws of impulſion that are different from thoſe which are acknowledged by all. We differ only, by exhibiting the internal procedure by which they are *unqueſtionably* produced in a vaſt number of caſes, and which takes place in all that we have ſeen, in ſome degree. Our method has undoubtedly this advantage, that it requires no principle but one, namely, that accelerating forces are to be eſtimated by the acceleration which they produce. Even this may be conſidered, not as a principle, but merely as a definition—We get rid of all the obſcurity and perplexity that reſult from the introduction of inertia, conſidered as a power – a power of doing nothing; and we are freed from the unphiloſophical fiction (adopted by all the abettors of that doctrine, and even by many others) of conceiving the ſpace, in which motions are performed, and bodies act, to be carried along with the bodies in it.—This furniſhes, indeed, in ſome caſes, a familiar way of conceiving the thing, by ſuppoſing the experiments to be made in a ſhip under ſail, and by appealing to the fact, that all our experiments are made on the ſurface of a globe that is moving with a very great velocity. But it is an abſurdity in philoſophy, and, when minutely or argumentatively uſed, it does not free us from one complication of action; for, before we can make uſe of this ſubſtitution, we muſt demonſtrate, that the actions depend on the relative motions only: And this, when demonſtrated, *obliges* us to meaſure forces by the velocity which they produce.

As no part of mechanical philoſophy has been ſo much debated about as impulſion, it will ſurely be agreeable to our readers to have a notice of the different treatiſes which have been publiſhed on the ſubject:

Galilei Opera, T. I. 957. II. 479, &c.

Jo. Walliſii Tractatus de Percuſſione. Oxon. 1669.

Chr. Hugenius de Motu Corporum ex Percuſſione. Op. II. 73.

Traité de la Percuſſion des Corps, par Mariotte, Op. I. 1.

Hypotheſis Phyſica Nova, qua phenomenorum cauſæ ab unico quodam univerſali motu in noſtro globo ſuppoſito repetuntur. Auct. G. G. Leibnitzio. Moguntiæ 1671.—Leibn. Op. T. II. p. II. 3.
